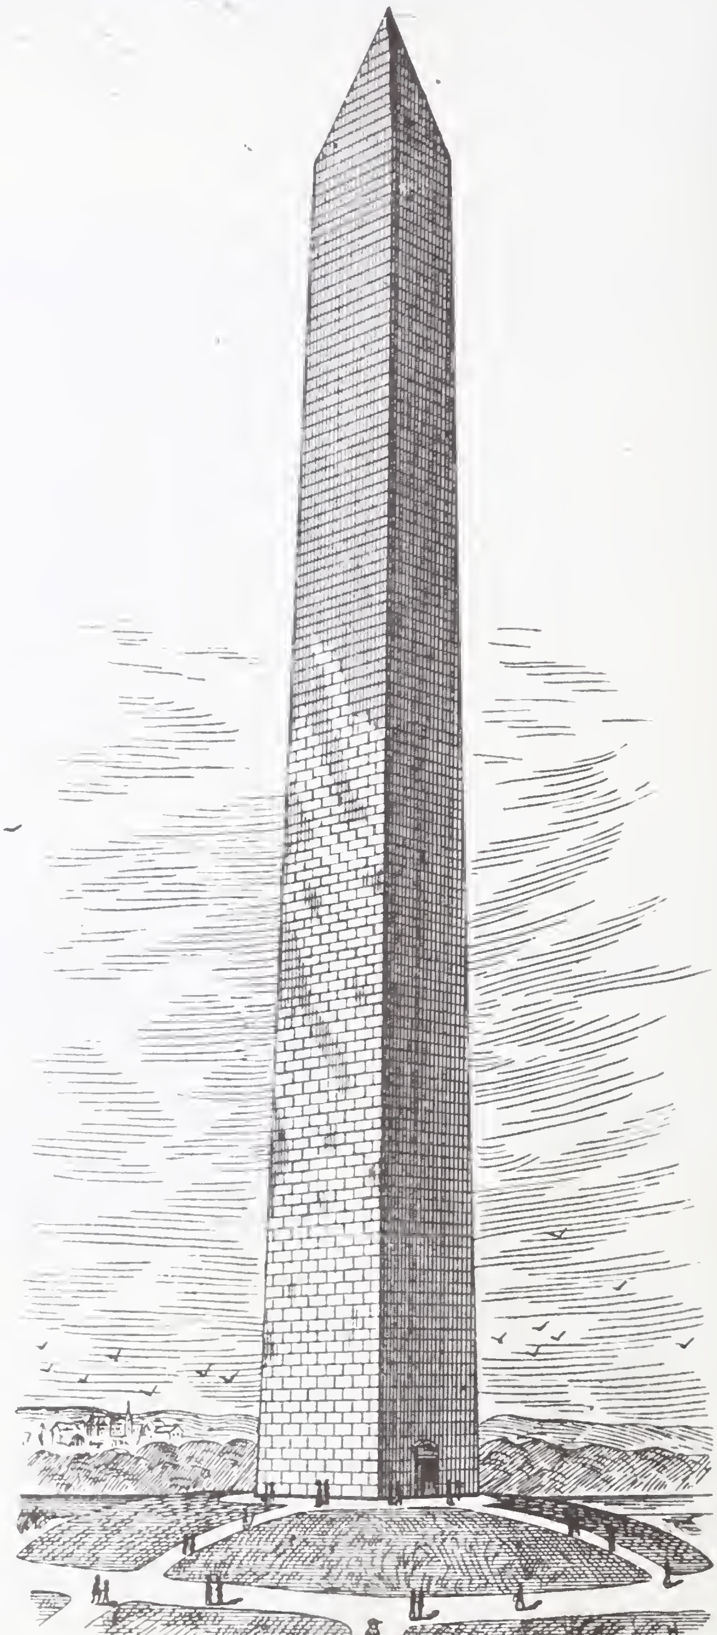
ACKNOWLEDGMENTS

A long list of those who have helped this book to life would be a sorry substitute for the thanks I owe them. Each cheerful donor knows the invaluable measure of his contribution, and what it did for the work. If ever an effort was joint, this is it. But the Inquisition is not dead, and I would not wish for them to be tarred for a heresy the responsibility for which is solely mine. But I can without scruple thank my publisher, and all those who so willingly labored there without prejudice, and I can thank the Librarian of Congress—without whom this book would not be—in the hope that he and his successors will reconstitute in this our New Atlantis a library wherein the ashes of Pergamum and Alexandria may, like our emblematic bird, live again, and from whose stacks no book shall evermore be burned or branded as heretical.



Washington National Monument

1. HISTORICAL BACKGROUND

The most stunning and prestigious monument in the capital of the United States is an enormous obelisk, named for the founder of the country, George Washington, a thirty-third-degree Mason. It is the tallest such monument in the world, 555 feet high, though not truly an obelisk, because it is not quarried from a single piece but put together from 36,000 separate blocks of granite faced with marble.

New York has a true obelisk, brought there from Egypt in 1880 at the substantial cost at that time of $100,000 to stand in Central Park near the Metropolitan Museum of Art. European capitals such as London, Paris, Rome, and Constantinople have their obelisks, also brought from Egypt, the apparent source of the fashion at least five thousand years ago, though where the Egyptians got the notion is a matter of conjecture.

In ancient Egypt there were a great many obelisks. The pharaoh Seti I, son of Ramses I and father of Ramses II, who reigned in the second half of the second millennium B.C., boasted that he alone fairly "filled Heliopolis with obelisks." This city of the sun, as it was called by the Greeks—the On of the Old Testament and the modern El Mataria, near Cairo—must have been an extraordinary sight standing on a rocky plateau in Lower Egypt, with its forest of slender gilded obelisks reflecting sunlight into the bright clear air of the wide Nile Delta.

Obelisks had already been raised at Memphis and Thebes by Thothmes III, named after Thoth, the Egyptian god of learning and science. Thothmes, whose reign is dated from the beginning of the sixteenth century B.C., is considered by many Egyptologists to have been the greatest pharaoh in the country's history. One of his more beautiful obelisks is now in New York. Another is in London. Thothmes brought the tallest standing obelisk in Egypt, 106 feet high, to Karnak, which already had at least thirteen such monoliths. It now stands in the square of Saint John Lateran in Rome. Thothmes's stepmother, Queen Hatshepsut, who was also his rival, raised four more (slightly smaller) obelisks in Karnak.

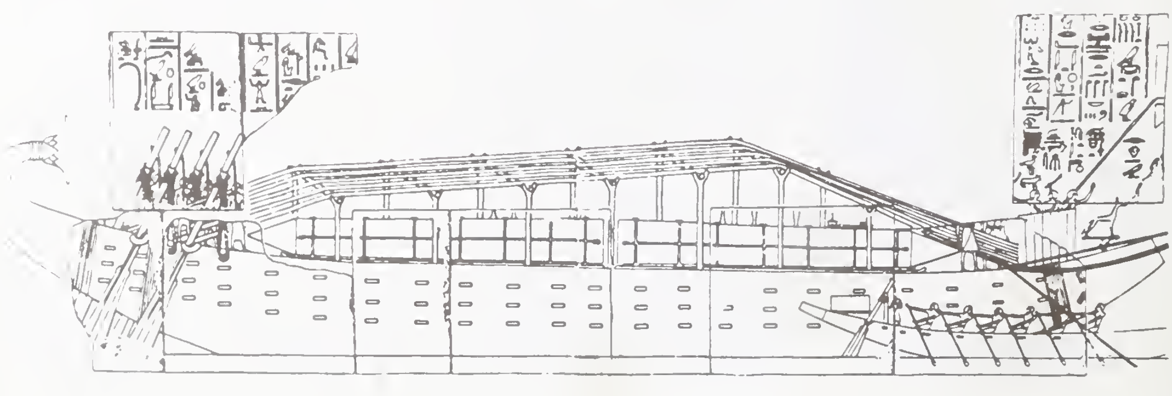
The next great name in Egyptian conquerors and obelisk raisers was Ramses II. This Nineteenth Dynasty king, who is said to have reigned for most of the thirteenth century B.C., is credited with having raised fourteen obelisks at

Obelisk reraised in Constantinople by the emperor Theodosius In A.D. 390. Originally more than 100 feet tall, it was reduced to half that size in transit from Egypt, where it had been originally raised in Karnak by Thothmes III.

Tanis alone; but his most renowned examples are the two he placed outside the Temple of Luxor in Thebes, one of which is now in Paris's Place de la Concorde.

The Roman historian Pliny the Elder, who died in the eruption of Vesuvius in A.D. 79, tells how Ramses, with the help of 100,000 workers, brought down to Heliopolis a great obelisk, all of 162 feet high. To prevent the workers from being careless with the dangerous machinery needed to raise such a monster, he had his son tied to the top of the obelisk. To save the one, workers must save the other—and thus their heads. Not that Ramses II ran much risk of losing an only heir: he is reputed to have fathered several dozen sons. The task was successfully accomplished; though what became of the obelisk, nobody knows.

Three of the most eminent historians of the ancient world, Herodotus, Diodorus Siculus, and Pliny, all tell the story of another pharaoh who raised two great obelisks at On. While crossing the Nile, this monarch is said to have been caught in a terrible storm, so menacing that the turbulent waters became a threat to his life. Outraged, the pharaoh is described as having seized a lance and hurled it into the seething river. The Nile, so the story goes, was offended, and struck the pharaoh blind. Nor could anyone cure him, though he tried a variety of doctors. Then an oracle informed the king of a remedy: he must bathe his eyes in the urine of a married woman who had slept *only* with her husband. With the help of his beautiful queen, the pharaoh daily bathed his eyes in the manner prescribed; but he still remained blind. In despair, he experimented with several more women until at last he found one who cured him. Those who had failed, he collected into a city called Zolla Rossa, and had them burned—women and city. The faithful lady with the successful remedy, he married. And so happy was this monarch, say the historians, that he raised all kinds of monuments in Egypt, including two huge obelisks, each reputedly 100 cubits



Two of Queen Hatshepsut's obelisks being floated down to Thebes from Aswan. Pliny tells how Ptolemy Philadelphus later brought Nectabis' obelisk to Alexandria. From the Nile he dug a canal to where the monolith lay. He then filled two flat-bottomed barges with granite blocks equalling twice the weight of the obelisk, and floated the barges under the needle. As the barges were unloaded they rose to accept the obelisk and float it away.

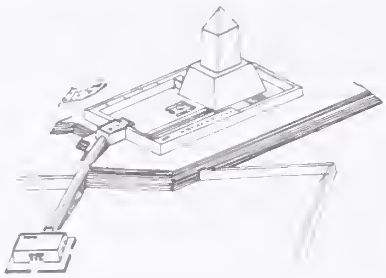
Dragging Constantine's obelisk to be raised in the Byzantine Hippodrome

high—which would be 165 feet—dedicated to the sanctuary of the sun. What happened to these, nobody knows; and if one had to rely on "classical" Greek and Roman authors to find out how such great obelisks were raised or what their real purpose may have been, one would be left ill informed.

There are other records—some more, some less plausible—of very ancient obelisks farther up the Nile, as far as Philae and Elephantine, by the first cataract, and even as far south as Soleb in Nubia. Available records of obelisks extend back to the Old Kingdom, with its first four dynasties, dated by Egyptologists to the third millenium B.C., whose pharaohs are credited with having built the Great Pyramids on the Giza plateau. But no obelisk of this era is known to exist. The records tell that Sahure, and other pharaohs of the Fifth Dynasty, built magnificent temples, such as the Temple of Neurine at Absia, adorned with obelisks, only parts of which survived. The earliest example of a complete needle appears to be that of King Senusret I of the Twelfth Dynasty, found at Heliopolis.

The obelisk of Teti, the earliest known true obelisk

Fragments of earlier obelisks, attributed to King Entef of the Eleventh Dynasty, date back to the end of the third millennium B.C. Though broken, their hieroglyphs have been well preserved, thanks to the protective coating of sand under which they were buried. Only no one yet knows what these particular hieroglyphs mean. Recent excavations show that these obelisks differ from later, more familiar ones, being shorter and squatter, and having taller masonry bases, sometimes as long as one-third of their shaft. According to Egyptologists, the longer bases were re-



Pharaohs of the Fifth Dynasty added to their pyramid complexes vast solar temples built around a huge benben. But these early needles, rather than true monoliths, were obeliscoid structures composed of separate blocks raised high on a truncated pyramid.

quired to raise these sacred "pryamidions," or *benben* as the Egyptians called them, nearer to the sun. In fact, there may have been other reasons, both occult and scientific.

Of the hundreds of obelisks that once stood in Egypt, only nine still stand; ten more lie broken, victims of infuriated conquerors, or of the religious fanaticism of competing cults. The rest are buried or have been carried away to foreign lands to dwell in dumb mimicry of Egyptian grandeur.

The first conquerer to remove an Egyptian obelisk was the Assyrian monarch Assurbanipal, better known by his Greek name of Sardanapalus, who ravaged Thebes in 664 B.C. and carried away two obelisks to his palace at Nineveh, presumably floating them down the Red Sea, across the Indian Ocean, up the Persian Gulf to the Tigris, and thence to Nineveh, some 1,600 miles away.

Sardanapalus in his harem

The next foreign conqueror, seeking to undo humiliation suffered at the hands of both Thothmes III and Ramses II, was the Persian leader Cambyses (or Kembathet), who defeated the Egyptian pharaoh Psametic III near Pelusium in a battle in which the Persians killed fifty thousand Egyptians. With the help of the battle fleet of the Phoenicians, who had also suffered repeatedly at the hands of pharaohs, the Persians swept the Egyptian navy from the seas, and made themselves masters of Egypt. Marching his army through the delta, Cambyses desolated the land with fire and sword till he came to the great city of On, which he took by storm and set on fire. In the holocaust that followed, the great Temple of the Sun was destroyed. Obelisks were dragged to the ground and mutilated, the

Constantine I, known as the Great (A.D. 280–337), bastard son of emperor Constantius I, became the first Christian emperor after defeating Maxentius at the gates of Rome.

most hated specimens being those that bore the inscriptions of the cruel deeds Thothmes III and Ramses II had performed against the Persians. Only when fire reached the base of one magnificent obelisk over 100 feet tall, did Cambyses, apparently out of admiration for its size (or so we are told by Pliny), relent and make his followers extinguish the flames.

Later conquerors of Egypt removed one or more obelisks as souvenirs. After the Macedonian generals of Alexander the Great had subdued Egypt and established a Ptolemaic line of Egyptianized Greek pharaohs, who ruled for three centuries, the Romans in 30 B.C. reduced the once proud kingdom to a province of Imperial Rome. It was their turn to loot Egypt of its obelisks. But first, in commemoration of their conquest, they built in Alexandria a great temple known as the Caesarium, or Palace of the Caesars. Started by Cleopatra after the birth of Cesarion, her son by Julius Caesar, the palace grew into the tallest and most impressive building in the city, surrounded by a sacred grove, embellished by porticoes, complete with library and works of art. As sentinels to guard its grand water-gate entrance, Julius Caesar's adoptive son Augustus, as Rome's first emperor, brought from Heliopolis, where they had stood for a millennium and a half, two great obelisks which came to be known as Cleopatra's needles. One is now in London, the other in New York.

Transporting and raising obelisks was no easy task, even for such expert engineers as the Romans. Although the records of Roman operations with obelisks are almost as incomplete as those of the Egyptians, Vitruvius, architect and military engineer to Augustus—claimed by modern Freemasons as one of their own—writes that the motive power for raising such enormous weights came from men working in a squirrel cage, thereby gaining a wheel-and-axle mechanical advantage. Vitruvius also describes a large two-legged shears for supporting tackle with which to raise an obelisk and set it on its base. But just how the job was really done remains a mystery.

Somehow, the Egyptians had developed a means of placing these huge blocks of granite directly onto a cubical pedestal which had to be absolutely level in order to have the apex of the obelisk truly vertical over its base—no easy task. The Romans, either because they could not match this expertise or because their obelisks had been injured at the base—by Persians or in transport—came up with a system of wedging astragals, or metal footings, to a column, between the base of the obelisk and the top of the pedestal. For this purpose the

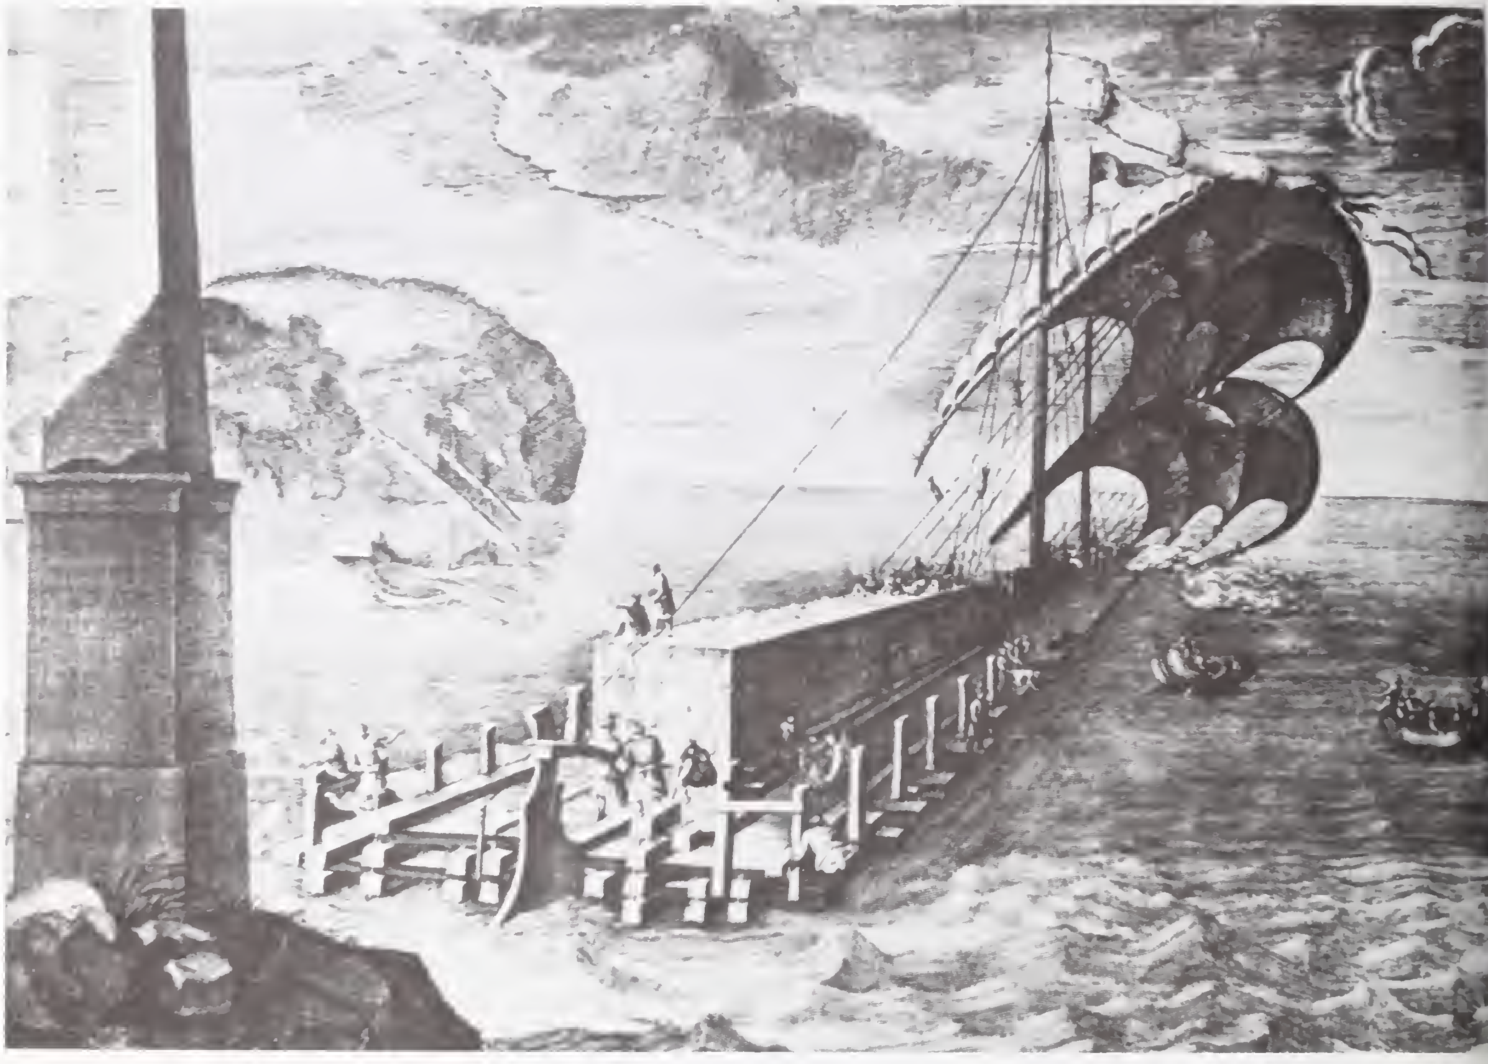
The standing obelisk at Heliopolis is the oldest known surviving needle in Egypt. Twenty meters high, it weighs 121 tons. From the inscription on it, Egyptologists have deduced it was raised on the jubilee of pharaoh Sesostris I in 1942 B.C. Heliopolis, with its Temple to the Sun, "its 13,000 priests chanting before a huge mirror of burnished gold, the sacred hawk in the golden cage, the pyramidal ben-ben, and the sacred calf Mnevis on its purple bed," was the greatest theological center in ancient Egypt. There the pyramid texts, the largest single collection of religious compositions yet recovered from early Egypt, were mostly composed by Heliopolitan priests. Of the ancient city, with its scores of obelisks, nothing remains but this lone example.

Reconstruction of an Egyptian temple with its standing obelisks

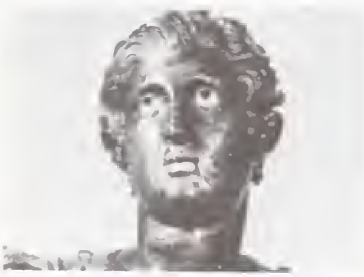
Romans cast bronze crabs, each about 16 inches in diameter, with shanks made to fit downward into the pedestal and upward into the shaft of the obelisk. As each monolith was settled onto its four crabs, hot lead was poured around dovetailed shanks so that future vandals could not so easily remove them—though they did, repeatedly. Crabs are said to have been chosen by the Romans as appropriate symbols to sustain obelisks dedicated to the Egyptian sun god because the Romans somehow considered the crab a symbol for their own sun god, Apollo.

Not content with moving two obelisks within Egypt, Augustus decided to transport another great needle all the way to Rome to be raised along the spine of the chariot-racing course of the oldest Roman circus, the Maximus, which had been laid out by Tarquin between the Palatine and Aventine hills. Augustus had no trouble choosing his obelisk. According to Pliny, the 75-foot porphyry needle he selected had been carved with hieroglyphs on order of the pharaoh whom Pliny calls Psemetnepserphreo and modern Egyptologists call Psammetikos, "during whose reign Pythagoras went to Egypt." This would have been in the sixth century B.C., though it is clear that the obelisk had been quarried many centuries earlier.

The main difficulty in transporting an obelisk consisted in being able to build a ship large enough to carry the enormous weight of 200 tons or more. To accommodate his obelisk, Augustus ordered a ship to be built at least 100 feet long. When the journey was successfully completed, the emperor exhibited the vessel in the naval yard of Pozzuoli, outside Naples, so that it could be admired by the people. After the obelisk was raised in the Circus



Painting in the Vatican of a Roman ship designed to bear an Egyptian obelisk to Rome. One such vessel could accommodate 1,200 passengers besides a cargo of niter, papyrus, and 400,000 bushels of wheat.



The emperor Gaius (A.D. 12-41), generally known as Caligula. A slave to his wild compulsions, he eventually went insane.

Maximus, Augustus decided he liked it so much he had another one brought from Egypt to be erected in the Campus Martius, or Field of Mars, where the Roman armies had once exercised, and where the censor G. Flaminius had built a circus in 220 B.C. This second obelisk was 9 feet shorter than the first but was covered with beautifully carved hieroglyphs, incomprehensible to the natives, though Pliny, with his intuitive ear for worthwhile lore, reported the glyphs to be "interpretations of natural phenomena according to the philosophy of the Egyptians."

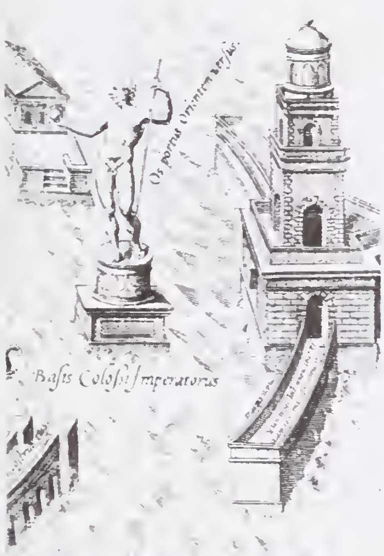
The next Roman emperor to bring an obelisk to Rome was Caligula, contemptuously described by the historian Suetonius as a singer, dancer, gladiator, and chariot driver—a job normally reserved for slaves—who brought an even taller one to adorn the Vatican Circus, which he built to entertain himself with chariot racing. To import his obelisk, along with the five enormous pieces of numidian

Roman chariot race around a central obelisk. These races date from the founding of Rome in the eighth century B.C. and were dedicated to the seasonal revitalizing of nature by the sun—symbolized by the central obelisk, pillar of life, and axis of the solar system. The racecourse was likened to the path of the planets around the ecliptic, with altars to each planet along the spine. Smaller obelisks marked the equinoctial and solstitial limits of the course. The charioteers bore different colors attributed to the various planets. Such festivals were worldwide. In Nineveh chariots with planetary colors raced around the city's crenellated walls; and in Yucatán the ballcourts similarly represent the concourse of planets wheeling around the vivifying sun in a narrow circuit of 7° north and south of the celestial equator.

granite designed to sustain it, Caligula constructed an even longer ship than Augustus's. The obelisk, taken from Heliopolis, had no inscriptions on its faces, and its ancient history could not be easily determined. It is believed to have been cut at Syene, the Arab Aswan, far up the Nile near the Tropic of Cancer, in the thirteenth century B.C. According to Pliny this may have been the obelisk set up by the pharaoh he calls Noncoreo, who raised it in gratitude for his restored eyesight. What is certain, says Pliny, is that nothing like the ship which bore it, with its three hundred oarsmen, had ever been seen before. To bolster the obelisk, and keep it from moving when the ship rolled, more than 1,000 tons of lentils in sacks were stuffed around its shaft. If the obelisk weighed 330 tons, as reported by Pliny, the base 174 tons, and the lentils 1,000 tons, the ship would have sailed with a minimum displacement of more than 1,500 tons, no small undertaking for those days.

Once the obelisk was safely at the mouth of the Tiber, Caligula ordered the ship tied up in Ostia harbor as a museum piece. In A.D. 40, just before Caligula was murdered, the obelisk was set in place in his Vatican Circus by means of a heavy framework of timber. Claudius, who succeeded Caligula, had the ship filled with the ubiquitous Roman mortar, *pozzulana*, and sunk to make a bigger harbor, with three docks "as tall as towers." During recent excavations for Rome's international airport at Fiumicino, the outlines of Caligula's ship were found, and it was seen to have been all of 240 feet long.

Nero, who succeeded Claudius, and, like Caligula, enjoyed driving a *quadriga,* or four-horse chariot, had the Vatican Circus protected by a wall all around so he could practice without being seen (or laughed at) by the people. Once he considered himself sufficiently proficient, he had the plebes called in to "raise their applause to the skies."



Towered docks at Rome's harbor, built by the emperor Claudius

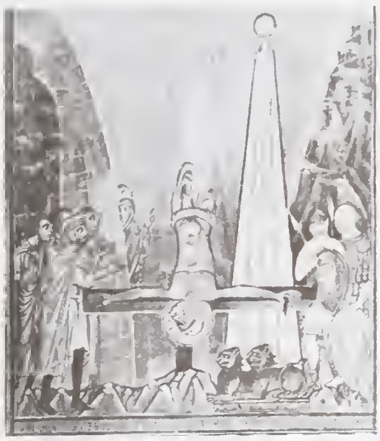
The obelisk as it was raised on the Pincian Hill, in 1820

When Nero put the blame on the early Christians for burning Rome—orders for which he had given—many of them were martyred in the Vatican Circus, among them Simon, called Peter, who is supposed to have met his death somewhere near the foot of the great obelisk.

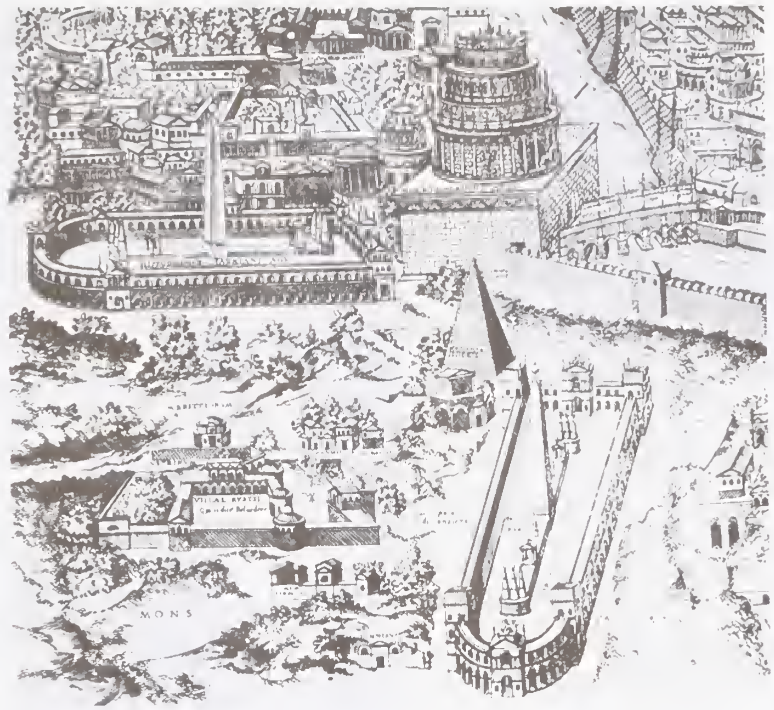
The emperor Hadrian, pained by the drowning in the Nile of his favorite boyfriend, the beautiful Antinoüs, decreed the building of a city on the banks of that river, to be called after him, and ordered an obelisk raised in Rome as a monument on which they said was writ in hieroglyphs the sad tale of the sacrifice made by this youth to serve his master. For many centuries no one knew quite where this obelisk had been raised. It was believed the self-castrated emperor Heliogabolus had taken it as a phallic ornament for his own small circus, but eventually it turned up near the present Basilica of Santa Croce in Gerusalemme in 1770 and was reraised in the Villa Borghese by Pious VII fifty years later.

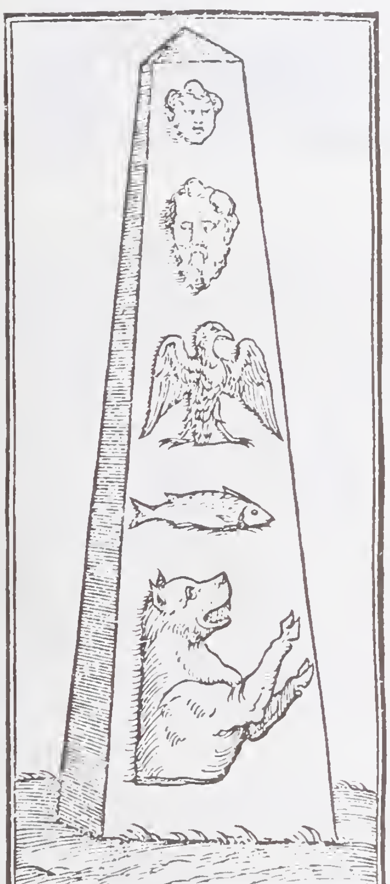
The only non-emperor in ancient Rome to have had an obelisk on his property was Julius Caesar's friend Caius

Giambattista Piranesi's etching of the Basilica of Santa Maria in Gerusalemme, where Hadrian's obelisk dedicated to Antinoüs was found. Its glyphs, honoring Hadrian, were carved in Rome, in imitation of Egyptian originals.



The supposed crucifixion of Saint Peter beside Caligula's obelisk in Nero's Vatican Circus, from a thirteenth-century fresco reproduced by Cesare d'Onofrio





Sallustius Crispus, who managed to accumulate such a fortune in Africa—without too much scruple—that he could afford to have a palace with baths, forum, tribune, and obelisk on a large estate that ran between the Quirinal Hill and the Pincio (and part of which is now the French Academy in the Villa Medici). Though this obelisk came from Egypt, its hieroglyphs were carved in Rome, copied from the obelisk of Augustus in the Circus Maximus. The work was so poorly done that some of the glyphs are backwards.

At the beginning of the fourth century A.D., when the Roman Empire began to split, and the emperor Constantine founded a new capital in Constantinople, he too had to have an obelisk. For "New Rome" on the Bosporus, he chose the tallest obelisk yet tackled by any Roman emperor, the great monolith which Thothmes III had brought from Syene to the Temple of Amon at Karnak before he died, and which his grandson Thothmes IV had raised some years later. Augustus had seen this colossus, and had thought of bringing it to Rome, but had not dared to do so because it was dedicated to Amon, of whom he stood in awe. Constantine, with fewer qualms, had the monolith dragged and floated to Alexandria in 330. But there it lay prostrate, as Constantine lay dying. In the ensuing insurrections, the Caesarium, with its extraordinary remnants of the great Library of Alexandria—wherein may have lain an explanation of the purpose of the great obelisks—also suffered its first destruction.

The Karnak obelisk of Queen Hatshepsut. "First of noble women," so named at the age of 13 after a mysterous ceremony, this queen is described as a sensuous, mystical creature who considered herself an incarnate goddess (born by theogamy) divinely ordained to rule Egypt. She was depicted wearing the traditional artificial beard of a pharaoh, and was referred to as "he." The daughter of Thothmes I, she married her half brother Thothmes II and ruled jointly with him. Her father, as third king of the Eighteenth Dynasty, was responsible for erecting the first pair of red granite obelisks at Thebes, each weighing close to 150 tons, for which he had a boat 180 feet long and 60 feet wide built to transport to Karnak. One of the obelisks still stands between the third and fourth pylons. Each face bears his name, but Ramses IV added his own, as did Ramses VI. Hatshepsut raised four other obelisks at Karnak, one of which still stands. Another lies broken beside it. On the occasion of her jubilee, she had another pair of obelisks quarried by the Aswan cataract and floated to Thebes, where they were raised in the Temple of Amon-Ra at Karnak. They were a hundred feet tall and weighed 232 tons, and their pyramidions were sheathed with electrum to reflect the sun. A text of thirty-two lines on the base describes the events. One of Hatshepsut's engineer-architects, Senenmut, is reputed to have controlled the clergy, as a state within the state, a secret society of architects and masons, devoted to the mother

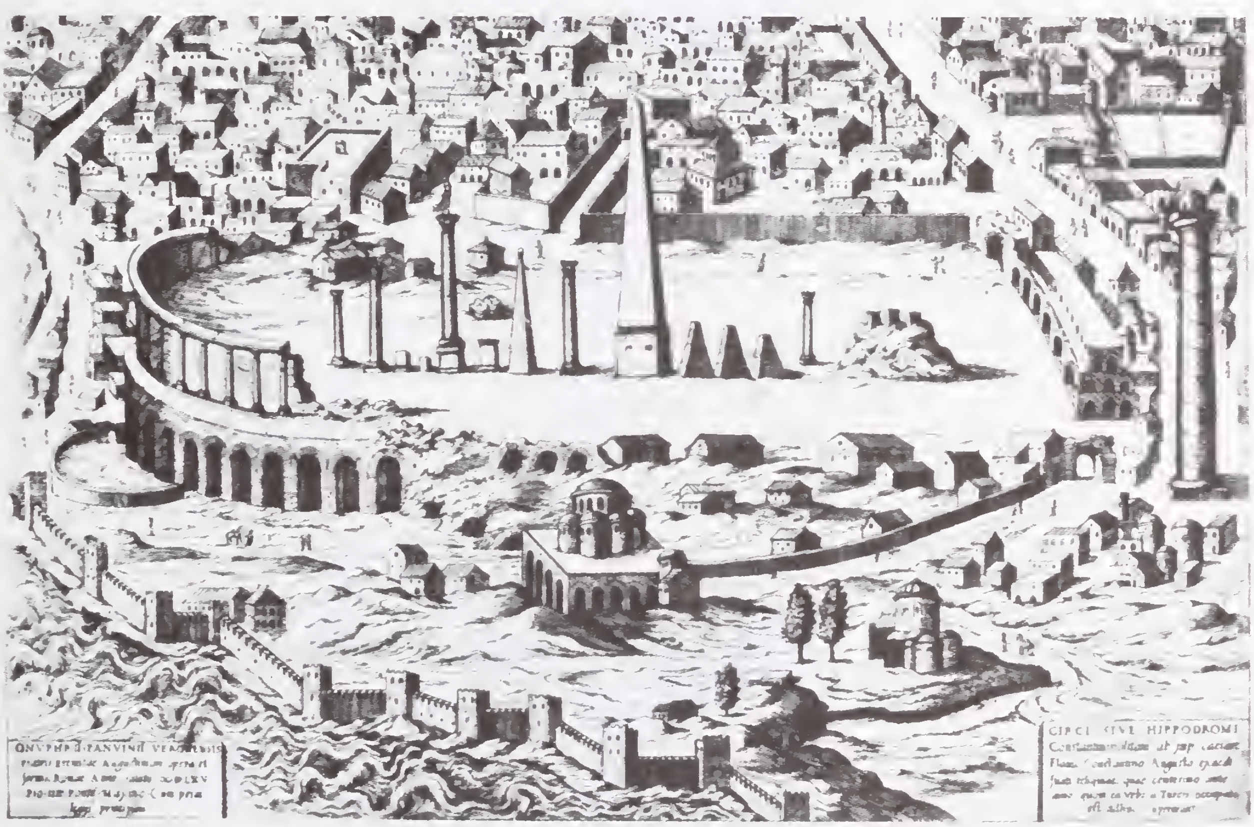
When Constantine's son and successor, Constantius, traveled to Old Rome, then governed by his brother Constans, he was so impressed by the grandeur of its monuments he decided to tie his own name to the eternal city by having the tallest of all known obelisks brought there from Alexandria. It took another enormous ship with three hundred oarsmen to ferry the red granite monolith, carved from the hills of Aswan, safely to the port of Ostia. From there it was floated up the Tiber on a huge raft as far as the Ostiense docks, where it was thrown into a side street, because the tyrant Magnentius had just slain Constantius's brother and occupied Rome.

Only when Magnentius conveniently committed suicide in Lyons in 353 was Constantius able to resume the job of dragging the obelisk along the present Aventine avenue to the center of the Circus Maximus. Ammianus Marcellinus, the Greek historian who wrote about Rome and was alive at the time, says that to raise it in the year 357 thousands of men were employed to pull on huge ropes, and that so many timbers were required the circus looked like a forest. He adds that as the needle finally stood erect, many more thousands of spectators were dumbfounded to see that it dwarfed the obelisk of Augustus, about 50 goddess, spread among the temples to survey "strict observance" of the rule. After her death, the images and names on Hatshepsut's monuments were removed. Her successor, Thothmes III, raised seven obelisks in Karnak and Heliopolis.

meters away, which had dominated the area for 367 years.

Meanwhile the inhabitants of Constantinople obtained another obelisk from Karnak, one believed to have been raised there by the pharaoh Menkherra-sonb. It too had been dragged to Alexandria on orders of Constantine, but had lain neglected since his death. Constantius's cousin, Julian, who succeeded him as emperor, got it moving again by urging the people of Alexandria to forward the old shaft to New Rome, in return for a colossal statue of himself. The ship which bore the obelisk from Alexandria was driven ashore in a storm near Athens, whence the shaft was at last brought to Constantinople by Theodosius I, who came to the throne twenty years after Julian.

Along with the fifteen authentic Egyptian obelisks which the Romans ferried across the inland sea to adorn their streets, forums, and circuses, they also raised a forest of imitations, many with hieroglyphs carved in the style of the Egyptian originals, which no one could any longer read or understand. Decay was at hand. Within a few centuries of the decline and fall of Rome came the decline and fall of its obelisks. With but one exception, all were knocked down and badly damaged by fire, especially around the bases, as if with the deliberate intent that they never be raised again.

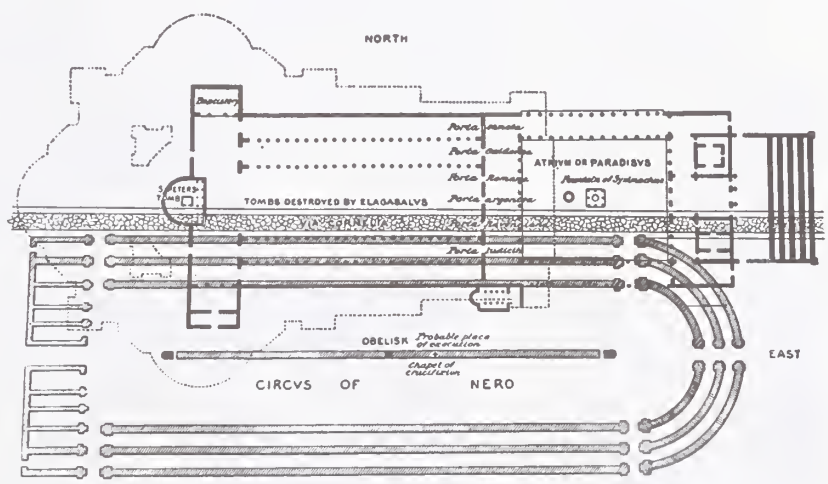


The circus at Constantinople, with its obelisks along the spine, where the ancient festivals gradually lost their meaning in the course of the decadent Byzantine millennium

For a long time this vandalizing was attributed to the various barbarous invaders who succeeded each other in waves. Later writers, beginning in the Renaissance, concluded that the obelisks had been disposed of not by barbarians, envious of such imposing monuments, but by bigoted Christians who hated or feared all that was pagan. Rodolfo Lanciani, the Italian-born historian and antiquarian, pointed out at the turn of the century that obelisks were not the only pagan monuments to be destroyed, desecrated, and broken up to make new buildings. In his *The Ruins and Excavations of Ancient Rome* he flatly absolves the barbarians: "We can discard the current opinion that attributes to barbarians the disappearance of Rome's monuments." According to Lanciani, whereas the scourge of invaders passed over the massive constructions of the Roman Republic and the Roman Empire, leaving what he calls hardly a trace of damage, the real harm was done by Christianized Romans of the Middle Ages and of the early Renaissance. "Can one," Lanciani asks, "really see the barbarians pulverizing the 65 kilometers of marble around the Circus Maximus?"

Ruins of ancient Rome with a fallen obelisk—and incomprehensible glyphs—depicted by Piranesi

The demolition and retrogression perpetrated by Christians lasted for a thousand years. As the great city slowly decayed, grass grew in the marketplaces and the forums; carefully laid stones were toppled, one after the other, till wolves roamed the empty spaces. Of the great obelisks, with one exception—that brought by Caligula—not a trace was left. They were buried, lost, forgotten. Even the sole standing example was up to its navel in refuse and dirt, its pedestal and bronze astragals completely buried. It still stood only because of the Christian basilica of Saint Peter, founded by Constantine, whose walls it almost touched. Any attempt to knock down the obelisk would have risked destroying this most holy of Christian churches, deliberately built on the spot in Caligula's Vatican Circus where Saint Peter was said to have been martyred.



Plan of Saint Peter's Basilica as it was built over the remains of Nero's circus beside Caligula's still-standing obelisk

If the Goths and Vandals had been interested in destroying obelisks, they would hardly have spared this example for that reason. More likely, the early pontiffs, exponents of an antipagan religion, wished to supplant once and for all these erect symbols of a pantheistic way of life and, as they did in the case of so many ancient pagan sites, turn this sole remaining obelisk into a Christianized place of worship, granting indulgences to pilgrims who would crawl about its base, praying to Saint Peter.

But such is the karmic wheel of life that it was to be the succeeding pontiffs in later rounds of history who would do their damnedest to raise again the old obelisks to their former grandeur, like so many phoenixes rising from their ashes to proclaim the very wisdom which the Church had wished to silence.

2. RESURRECTION OF THE OBELISKS

Ball atop Caligula's obelisk, close by the Vatican Basilica, said to contain the ashes of Julius Caesar. From a sixteenth-century print reproduced by Cesare d'Onofrio

An English prelate who traveled to Rome at the beginning of the fourteenth century, Master Gregorius, found the last obelisk still standing up against the walls of Saint Peter's Basilica, in a dark alley flanked by crumbling old houses. As its shaft was covered with dirt and weeds, well above the sign of any base, Master Gregorius had no way of telling the length of the obelisk, and conjectured it might be as long as 250 feet. More interested in the pagan antiquities of Rome than its Christian churches, Gregorius was captivated by the tradition that the bronze ball on top of the obelisk contained the ashes of Julius Caesar. In letters to his English parishioners, in which he cheerfully admitted that "he read much but understood little," Gregorius passed on the story that the obelisk had been raised on the exact spot where Caesar, on the way to the Capitol, had been accosted by an astrologer who warned him he would be killed on the ides of March.

The assassination of Julius Caesar

The antiquarian and historian Cesare d'Onofrio, in his *Gli Obelischi di Roma,* attributes the belief partly to the fact that the words *Julius* and *Caesar* appear four times in the Latin inscription below the obelisk, and partly to a misunderstood passage in Suetonius, "one of those cases of false etymology," says d'Onofrio, "so common among the learned when they try to explain away something they cannot understand." Suetonius, in his *Lives of the Caesars,* relates that right after the dictator's remains were

Nicholas V replaced the antipope Felix V, a duke of Savoy—not even a priest—elected when the Council of Basel in 1439 deposed Eugenius IV as a heretic.

With the end of the schism of the Church, Nicholas V reestablished Rome as the seat of the papacy, and to celebrate this triumph proclaimed a jubilee whose participants he milked to embellish Rome.

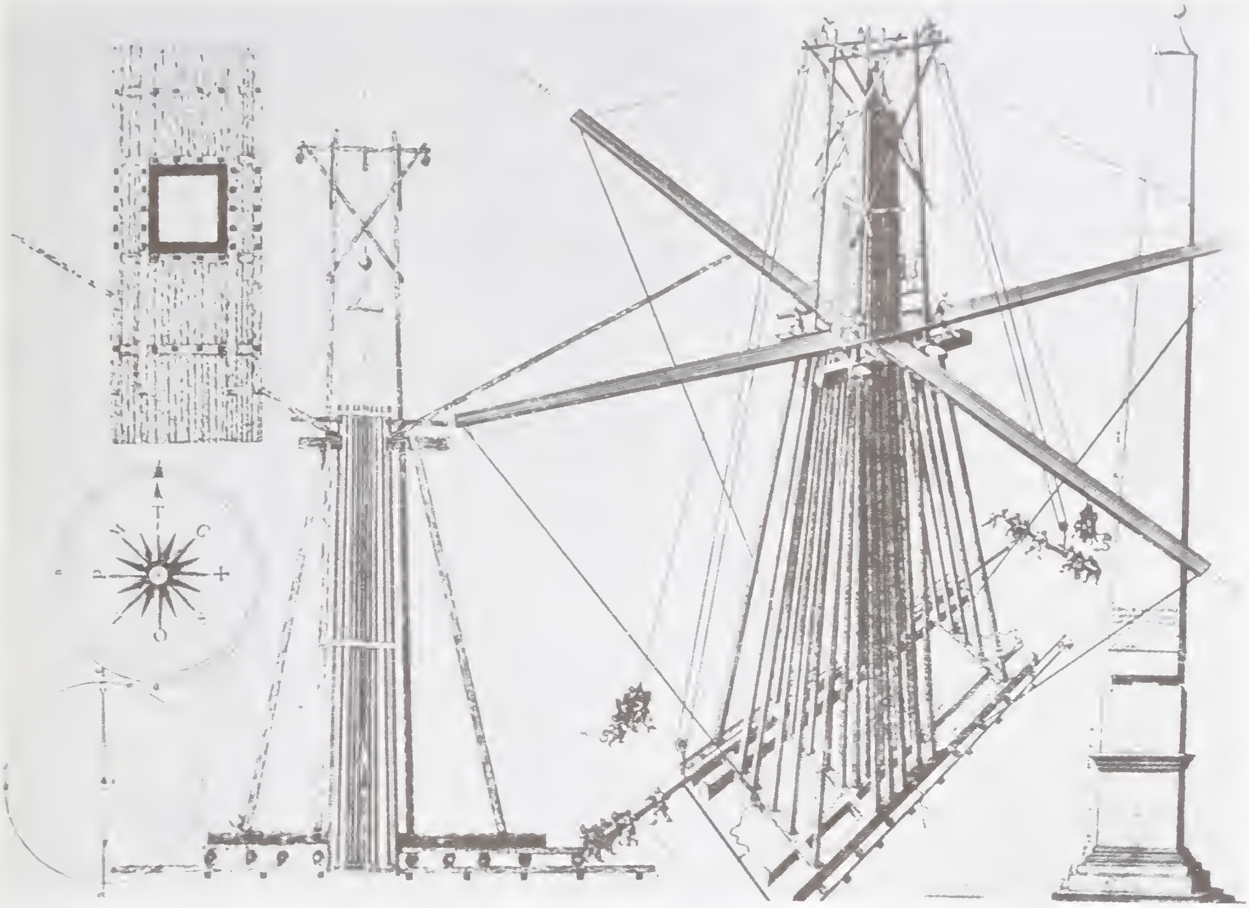
Antonio Sangallo

burned, the populace erected in the Forum a solid column of numidian stone, 20 feet high, dedicated to the Father of His Country.

The first serious attention paid to this last of the standing obelisks came in the Renaissance from Tommaso Parentucelli, Pope Nicholas V (1447-55), a humanist of considerable erudition, of whom his secretary—later Pope Pius II—reported that "what he does not know is outside the range of human knowledge." Part of Nicholas's grandiose scheme of rebuilding Rome into a stunning capital of Christendom was to have Caligula's Vatican obelisk moved from its dark hiding place to the center of Saint Peter's Square, there to be raised on four life-sized bronze statues of the Evangelists. By placing atop the obelisk a huge bronze Jesus with a golden cross in his hand, Nicholas declared, his wish was "to strengthen the weak faith of the people by the greatness of that which it sees." The night before the job was to be assigned to his favorite architect, a Bolognese engineer named Ridolfo Fioravante degli Alberti, better known by the nickname of "Aristotle," the old pope died, reputedly of a broken heart because Constantinople had fallen to the Turks.

Fifteen years later, when the Franciscan general Francesco della Rovere, who had spent his life as a mendicant friar, came to the papacy as Sixtus IV (1471-84), his secretary was to say of him "he was so exempt from avarice he could not endure the sight of money." Result: he depleted the papal treasury, waging war against the Florentines, the Venetians, and the Neapolitans, sending a battle fleet to its doom against the Turks, and spending a great deal of money beautifying Rome with such lavish constructions as the Sistine Chapel. Among his grander projects was a revival of the idea of moving Caligula's obelisk. But the project failed; this time because his architect, the same Aristotle whom Nicholas V had befriended, was caught minting his own coin and was locked up in Castel Sant'Angelo, from where he defected to Russia to build churches in the Kremlin.

A generation later, after Antonio da Sangallo had presented plans for a basilica of Saint Peter's in which Michelangelo was to become involved, Pope Paul III (Alessandro Farnese, 1534-49) became determined to have Caligula's obelisk raised in Saint Peter's Square. On several occasions he discussed the matter with Michelangelo, whom he knew had invented special equipment for raising heavy stones, but Michelangelo would not go along with the idea. When asked by friends why he, who was such an ingenious fellow, and had invented such good



Paul III, a great lover of luxury and a phenomenal nepotist, by means of which he alienated great fiefs of papal land to his bastard children. This pope introduced the Inquisition into Italy in 1542. He also approved the foundation of the Society of Jesus as an army to combat heresy. And it was he who established rigorous censorship and an index of forbidden books.

equipment, would not give the pope the pleasure of moving the obelisk, Michelangelo is reported to have replied: "What if it breaks?" More likely, Michelangelo disagreed with the motive behind the scheme—the raising of a mighty symbol to reinforce the suppression of heresy—and when commissioned by Paul III to paint the Last Judgment in the Sistine Chapel, made a point of painting a pope in hell.

It remained for a poor swineherd from the Adriatic coast near Ancona, another mendicant Franciscan friar, who came to the papal throne as Sixtus V (1585-90), to raise sufficient money to fell and reerect the obelisk. Born in poverty as Felice Peretti, the son of a chambermaid and a farmhand, this new pope turned out to be even more extravagant in his expenditures of public funds than had been Sixtus IV. But unlike his predecessor, Peretti managed rapidly to accumulate an enormous fortune through the imposition of heavy taxes and the sale of offices. Romans quipped that the only remaining commodity untaxed by Sixtus was the heat of the sun. In the short five years during which he was pope, Sixtus V got the reputation of having "built five bridges, watered five fountains, erected five obelisks, and left five millions in the treasury."

Sixtus V (1585–1590). Crafty and malignant, this new pope announced: "I come not to bring peace but the sword!" In all parts of the Papal States stakes were erected, on each of which stood the head of an "outlaw." With the sale of offices Sixtus refilled the papal coffers, raising the price for becoming treasurer from 15,000 to 50,000 scudi. He then placed a heavy burden on the poor by taxing such indispensable articles as firewood. With the vast wealth he accumulated in Castel Sant'Angelo, Sixtus created a battle fleet to fight the Ottomans and was the first to draft an army of his own people in the hope of seizing the Kingdom of Naples from Philip II of Spain. A compulsive "moralist," Sixtus ordered courtesans whipped naked for trafficking with married men, and was dissuaded by the governor of Rome from confining all the prostitutes in a ghetto only because there were too many. The ancient ruins of Rome Sixtus considered "festering sores" of an ugly pagan civilization riddled by superstition, to be obliterated; and the destruction of the Colosseum was only avoided by his sudden death, accredited by *vox populi* to a dose of poison administered by the Jesuits.

Domenico Fontana

Most of this was accomplished with the help of a Swiss-Italian architect from Lugano in the Ticino, Domenico Fontana, whom Peretti had hired when he was still Cardinal di Montalto, to construct for him several imposing edifices, including the mausoleum for Pope Nicholas IV. At that time, the incumbent pope, Gregory XIII, disapproving of such ostentatious shows of magnificence from a mere cardinal, had suspended Montalto's income. But Fontana, at his own expense, had kept right on architecting his patron's extravagant projects, a gesture which was to pay off handsomely two years later when Peretti became Pope. Not only was Fontana reimbursed from the papal treasury, he was given the job of completing the construction of the dome of Saint Peter's, which Michelangelo had left unfinished on his death twenty years earlier in 1564.

Three months later, he was given an even bigger task, one which would make his fame and fortune.

A tough reactionary, whom later historians were to dub "the Fascist Pope," Sixtus quickly cleaned up the papal states with a ferocious campaign against "outlaws and bandits," so as to be able to concentrate his efforts against all forms of heresy, of which Protestantism was the most rampant. More severed heads appeared on pikes outside the gates of Castel Sant'Angelo "than melons for sale in the market at Campo de' Fiori." Blasphemers had a hole burned in their tongues. Bandits had their guts ripped out and their quartered limbs hung on spikes. Death was meted out for adultery; and mothers who prostituted their daughters were condemned to the gibbet while the daughters were obliged to witness the execution. Pederasts were burned alive, as was a baker, for baking inferior bread. When several cardinals begged Sixtus to reprieve an innocent teen-ager, condemned for some peccadillo, the pope replied he would ennoble the boy's death by witnessing the execution.

While still a cardinal, Montalto had been inquisitor general for the extirpation of heresy in Venice, but he had been so high-handed in the conduct of his duties that he was forced to leave that island republic. So intransigent was he considered that on his election to the papacy one Roman wit seen leaving the city in a hurry explained he didn't believe Sixtus would even forgive Jesus His sins. With the excuse that he wished to "quench the detestable memories of idolatry" and "extirpate the idols exalted by pagans, such as pyramids, obelisks, and columns," Sixtus V decided to move Caligula's obelisk, and raise above it a Christian symbol to "enhance the spirit of the Counter-Reformation" and "exalt the mysteries of the Catholic religion."

On August 24, 1585, Sixtus V appointed a special commission to study the problem and to make a recommendation for the transport of the obelisk. Among those chosen were four cardinals, a bishop, a senator from Rome, and three conservators. But, as d'Onofrio notes, not a single technician was included. Having endowed the commission with sufficient funds and authority to ensure results, the pope specified that the learned gentlemen define the precise spot where the obelisk could be reerected, as a symbol of the conquest of Church over paganism and Protestantism. More important, they were to determine how such a fragile shaft of granite weighing 334 tons was to be dismantled, transported over a distance of almost 300 yards, and reerected without being broken.

Unanimously the commission invited anyone with a suggestion, no matter how farfetched, to step forward. Within less than a month, five hundred candidates presented themselves from all over Italy and from as far afield as Rhodes and Greece, including several engineers and a smattering of adventurous monks. Each came with his own suggestions and specially devised equipment. Most of the applicants brought plans, sketches, or models. The majority considered it essential that the obelisk be transported upright, believing it to be too difficult a task to lower and then raise it again. Others grandly proposed carrying both obelisk and base simultaneously in an upright position. Still others suggested carrying the obelisk at an angle of 45°. One architect, Francesco Masini, wanted to build a canal and float the obelisk to its new location.

Fontana, more conservative, brought a model in wood of a mechanism designed to handle the job, with ropes and pulleys all to scale, and a 2-foot obelisk made of lead. To the assembled congregation he demonstrated with words and motions how he could lower, transport, and reraise the full-scale obelisk without any problem. The commission appeared impressed by the plan, model, and presentation, as well as the fact that Fontana was the pope's protégé. Nevertheless, the commission hesitated to give such responsibility to a man of only forty-two. As a compromise, they appointed Fontana engineer-in-chief, placing over him, as supervisor, the seventy-four-year-old Florentine mannerist architect and sculptor, Bartolommeo Ammanati, who contributed nothing to the job, was ignored by Fontana, and is remembered mostly for having designed the Pitti Palace in Florence.

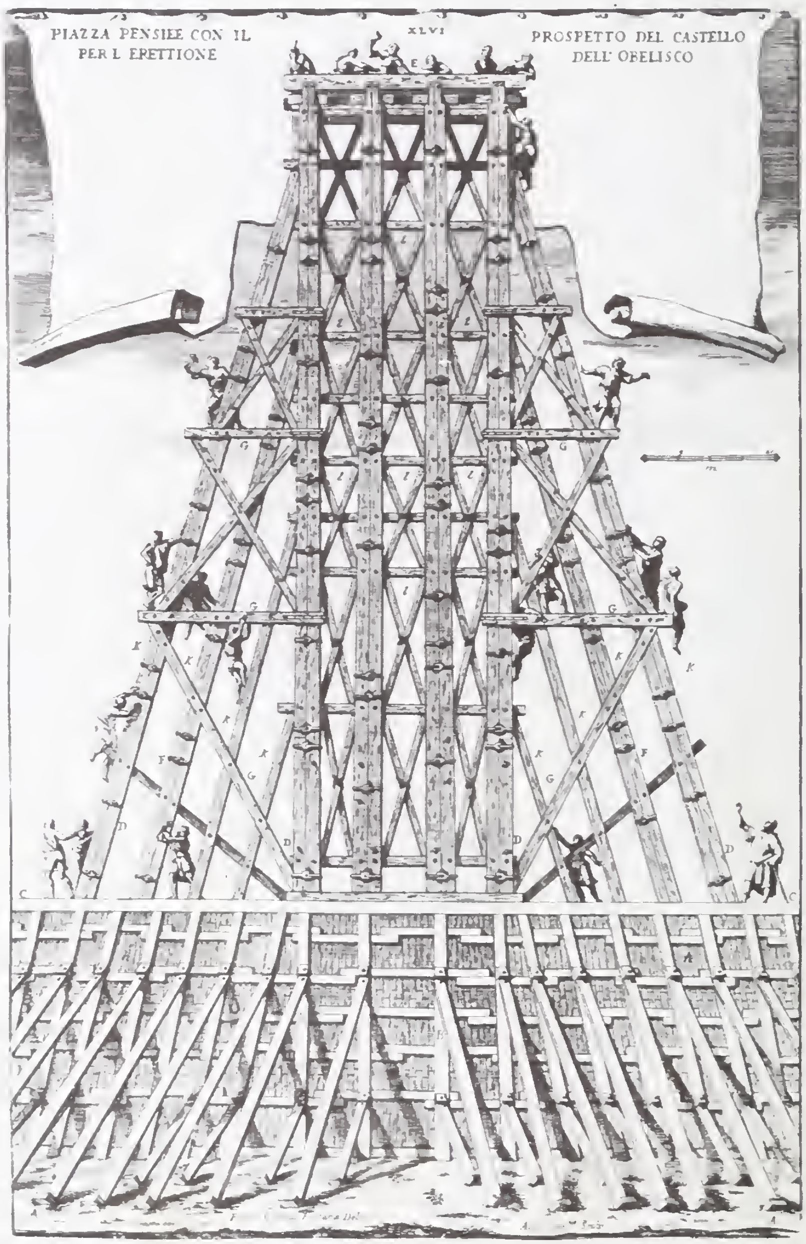
Sixtus V expressed his desires very precisely to Fontana: "Eradicate the memory of the superstitions of antiquity by raising the greatest footing ever for the Holy Cross."

On October 5, 1585, the pope, bypassing his own committee, ordered an edict of authority issued to Fontana for as long as it took to move the obelisk, granting him blanket license to impress men, draft animals, requisition timber, equipment, and subsistence of any sort, and even create a right of way in the city—which meant he could tear down any private house that got in his way. The decree also freed Fontana from the threat of litigation due to possible damage incurred in the operation. Everyone in the Holy See was given strict orders not to interfere in any way with the architect's actions or requirements. They were enjoined, on the contrary, to obey him, favor him, and help him.

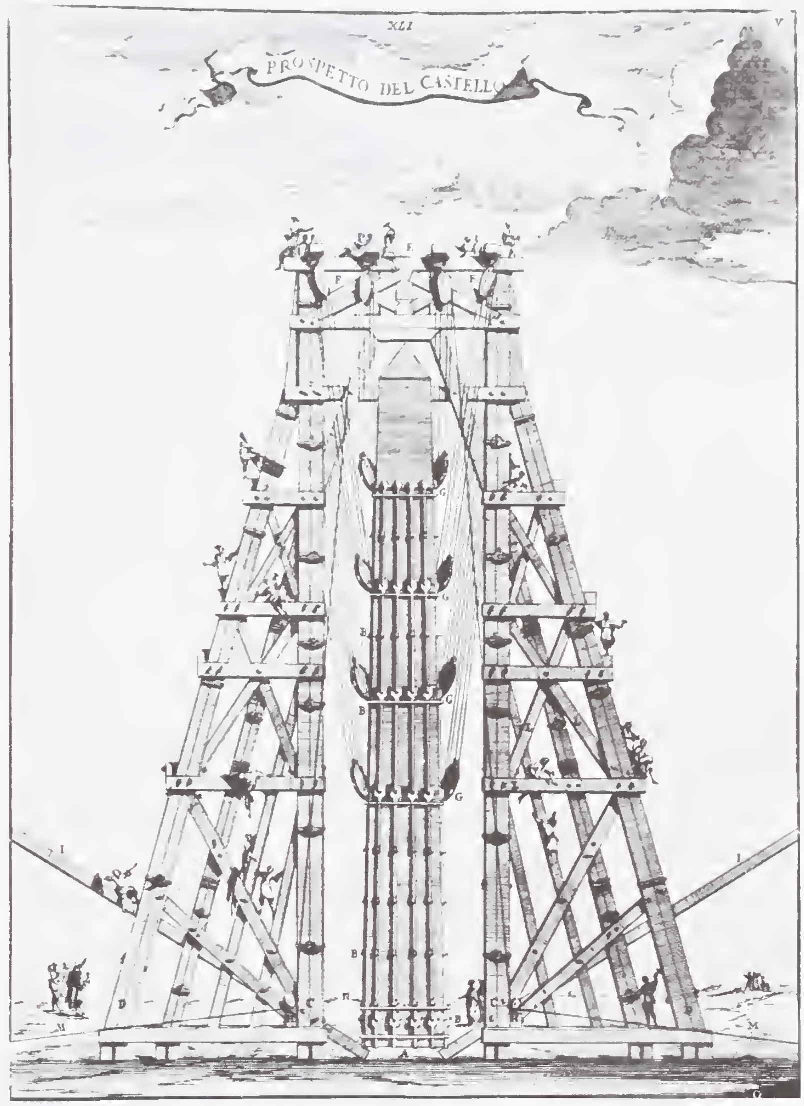
Various models were designed to move the Vatican obelisk. Fontana measured the height of the monolith as 83 feet on a base of 9 feet 2 inches, narrowing to a little less than 6 feet at the beginning of the 4-foot-high pyramidion. He estimated its weight to be 681,222 pounds. Forty capstans—truncated cones of timber around which the ropes were wound—would be needed to raise 90 percent of the obelisk's weight. Each rope had to be 3 inches in diameter, and 1,000 feet long. In determining the diameter and tensile strength of the rope, Fontana based his calculation on the premise that the steady pulling force of a horse would average 100 pounds. Two horses to a capstan with a nine-to-one ratio gave him a pull of 1,800 pounds per capstan. And when the ropes were passed through pulleys or blocks with a two-to-one ratio attached to four points of the obelisk's length, Fontana obtained an increase of motive power of 2×4×1,800, or 14,400 pounds per capstan. For the additional 10 percent lifting power, Fontana relied on the leverage of the long timbers by which the capstans would be turned.

Fontana's first problem was to create a solid base around the obelisk where the soil was soft and wet. For this he used pile drivers to pound oak beams 20 feet long and 9 inches in diameter deep into the ground, capping them with a layer of peeled, rot-resisting chestnut beams. On top of these he poured an aggregate of finely crushed basalt, flint, stone, and broken brick, mixed with a mortar of lime and clay, which set very hard. As a religious observance, appropriate to the occasion, votive bronze medals of the patron pope were laid in the concrete.

Fontana next had to create in real life the machine he had modeled for raising the obelisk. It meant building a *castello,* or huge scaffold of tall timber beams, high



Fontana tried to break one of the ropes with a pull of 50,000 pounds, but failed; so he concluded that this margin of safety would cover not only variations in the rope manufacture but also the peaks of tension imposed on any one capstan when other capstans might run slack. The blocks were made of wrought iron 5 feet long, with six metal sheaves, or grooved wheels, set in layers of three each. When the ropes were laid out on the ground, they passed over rollers to keep the thousands of feet from fouling.



enough above the obelisk to sustain the ropes and pulleys by means of which he planned to lift it, and strong enough to withstand a weight of almost 350 tons. Each sustaining member of this *castello* had to be built up of four columns of timber, 92 feet tall, each 11 feet square, bound together by iron hoops. To obtain the requisite 20-by-20-inch oak beams, 30 feet long, Fontana had to scour afield halfway to Naples. Each beam was then dragged to Rome from Campomorto, Santa Severa, or Terracina by teams of fourteen oxen. Iron bands and huge iron bolts with which to weld together the beams were obtained from ironsmiths in Ronciglione and Subiaco.

As soon as the *castello* was ready, Fontana had the obelisk protected by a double layer of reed matting over which was placed a layer of 2-inch planking, the whole held together by the great iron hoops. The long ropes were attached, leading to massive capstans, or wooden winches, like truncated cones, which could be revolved with levers to tighten the ropes. Realizing how vital the ropes were to success, Fontana personally occupied himself with their manufacture, going to the picturesque Umbrian town of Foligno near Assisi, where thousands of feet of rope were handwoven from endless strands of hemp.

All of these complex preparations took seven months of febrile work. By the end of April 1586, all was in order. Fontana set April 30 as the date for lowering the obelisk. A last preparatory task was the removal of the ancient metal ball still atop the obelisk, placed there fifteen centuries earlier by Romans in the belief it contained the ashes of Julius Caesar. When the ball was taken off, no ashes were found, and the myth was gently dispelled. Only no one bothered to ask what purpose the ball might have served.

On April 30, two hours before dawn, two masses were said in the small church of Santa Martinella, an annex of the Palazzo del Priorato, right off Saint Peter's Square. All around the great piazza, the access roads were blocked off with barricades and wooden palisades, making of it a closed *serraglio,* where a ban forbade anyone, on pain of death, from entering on the day the obelisk was to be moved, with the exception of those assigned to the job.

Crowding Saint Peter's Square

When all these hardy fellows had communed and made their prayers, they went into the *serraglio* just before break of day.

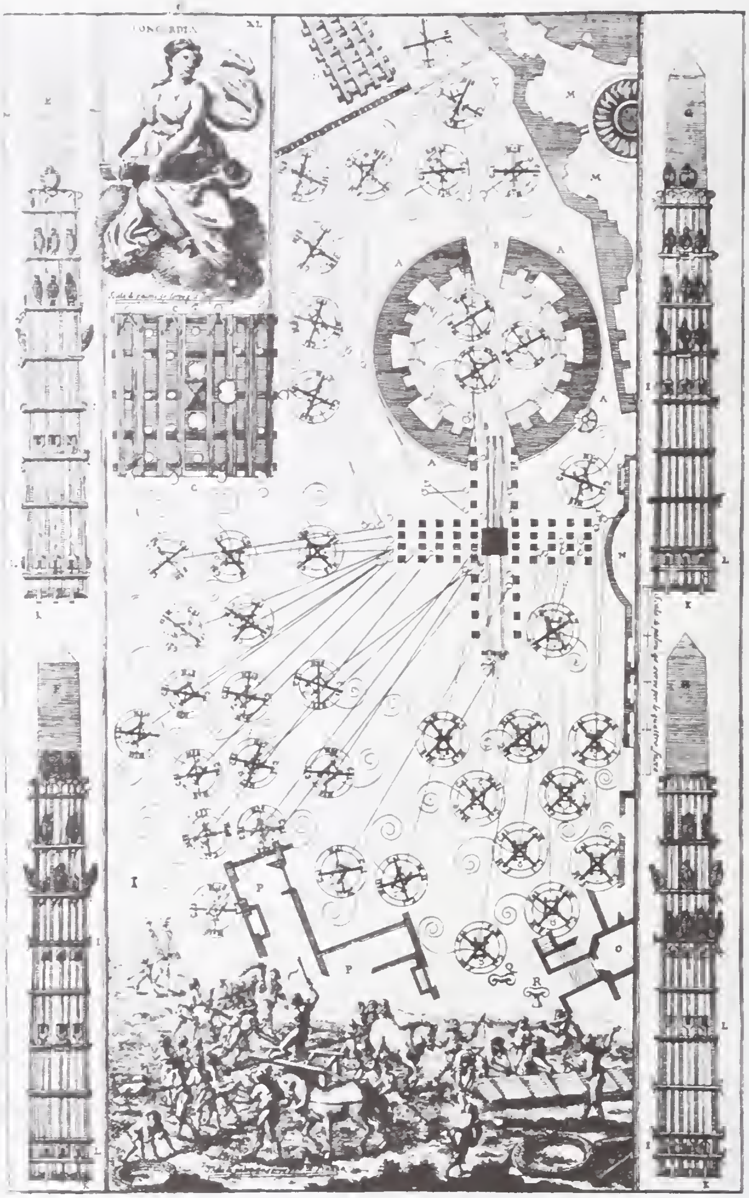
People were at the windows, on the balconies, and on the roofs of all the surrounding houses, even on the cornices of Saint Peter's Basilica, and on the drum of Michelangelo's still unfinished cupola. Among the spectators were the pope's sister, Camilla, the majority of the college of cardinals, and virtually all the religious and lay authorities of Rome, as well as many foreigners who had appeared from all over Italy and Europe to witness so extraordinary and marvelous a spectacle.

The city police, under the local sheriff, reinforced by Swiss Guards and a special detachment of cavalry, kept the swarming populace in order, administering summary punishment to anyone who misbehaved. No one was allowed to speak, spit, or make a noise of any sort during the course of the operations; and in anticipation of possible executions, a gibbet had been raised on the spot.

By each of the forty capstans, around which the great hawsers had been wound, stood two horses and twenty workers, all together seventy-six horses and eight hundred men, most of whom had their heads protected with metal helmets. The success of the enterprise depended on the uniform distribution of the great weight over the many ropes holding the obelisk, with no rope straining more than any other. To ensure that all the capstans turned synchronously, and to prevent some of the ropes from stretching harder than others, Fontana arranged for a trumpet to be blown every time he gave the order (from a high spot visible to all), and everyone was to make his wheel turn. The moment a bell was rung, this time from atop the *castello,* everyone was to stop. Two foremen were assigned to each capstan and twenty extra men were assigned to emergency calls; their task was to quickly bring rope, blocks, or replacement parts when failure threatened. Twenty more horses and drivers were placed in reserve, ready to move toward any point of need. Additional men with sledges and mauls clambered through the *castello* and around the obelisk, driving wedges to tighten the binding members and stiffen the system.

When all was ready, and Fontana had reminded those present that the work was being performed for the glory of God, everyone knelt and followed him in prayer. As soon as they had recited a *Pater Noster* and an *Ave Maria,* Fontana gave the signal for the trumpet to be blown. Nine

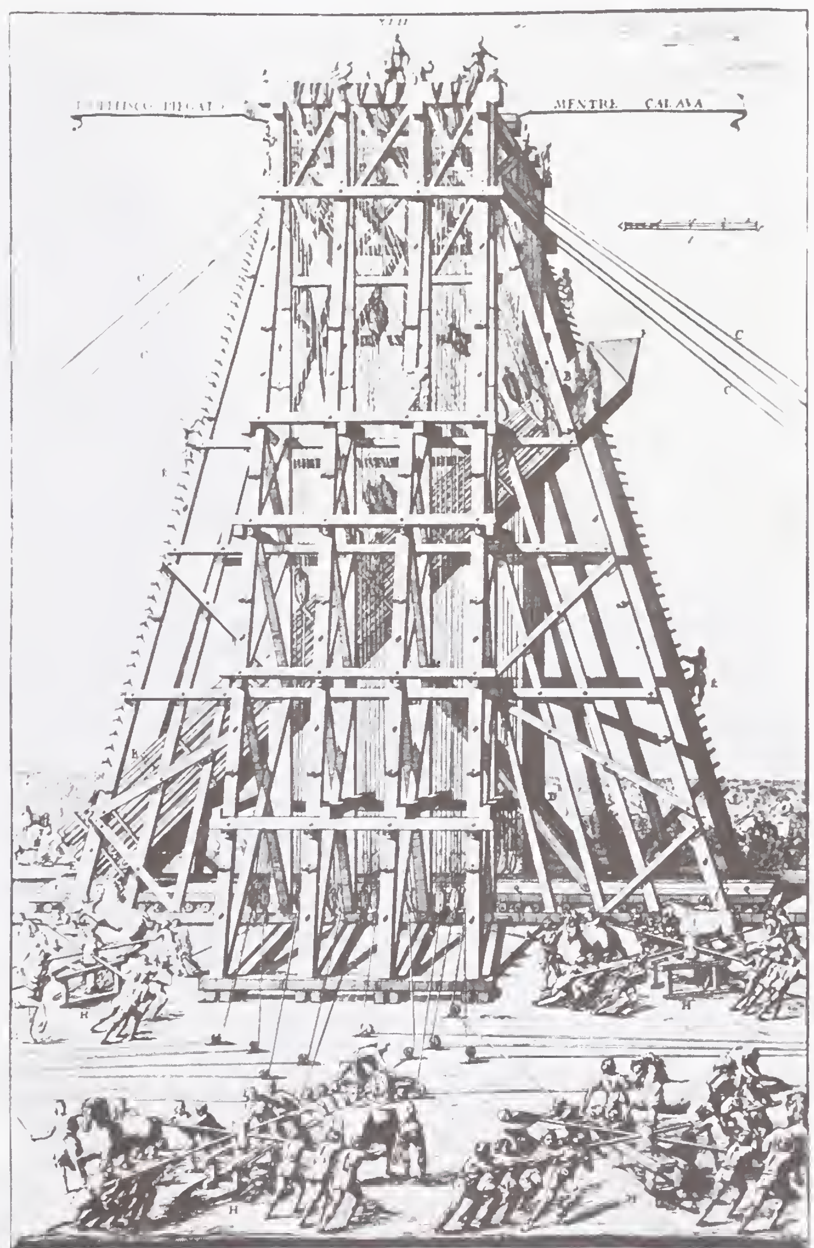
Aerial view of Saint Peter's Square



hundred and seven men and seventy-six horses pulled on the forty capstans. The ropes tightened to the breaking point. As Fontana described the scene, the earth appeared to tremble and the *castello* gave forth a terrible and agonizing screech. Those who had competed against Fontana in the competition now jeered at his plan, proclaiming that the ropes would fail because of unequal stress.

After the terrible creaking, when nothing seemed to have given way, and no man seemed to have suffered, Fontana gave the signal for the bell. Foremen ran to examine the equipment. It was noticed that one of the horizontal bands, closest to the top, had broken. All the other metal bands had also suffered, either having slid from their original positions or been twisted and nearly broken. Their radial component of tension had evidently been underestimated. But as all the rope bindings had held, Fontana decreed that the metal bands be replaced by ropes.

Repairs were made and power was once more exerted on the capstans to raise the obelisk. Up it went, millimeter by millimeter, till it had been lifted about a palm and the sun stood almost directly above it. Not wanting the work to be interrupted, Fontana had lunch brought to the workers on the spot in large baskets, the menu being bread, sausage, cheese, and smoked ham. All together two full barrels of wine were consumed. When work was

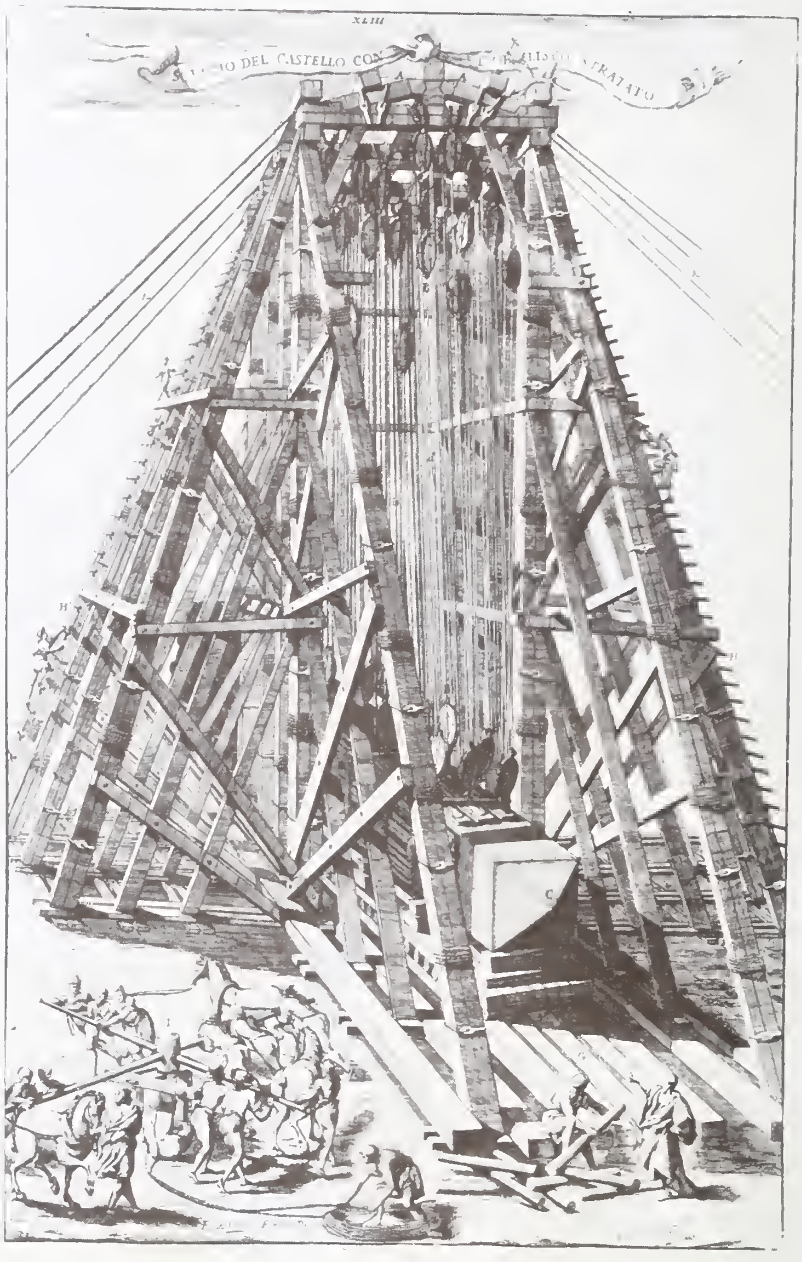


Lowering the obelisk

resumed, the obelisk was raised in further short increments until it reached a height of 2¾ palms, or 61 centimeters, above its base, the amount necessary to insert a dolly of beams on rollers. This was to facilitate lowering the obelisk from its vertical to a horizontal position.

By ten o'clock that evening, the obelisk rested upright on its dolly. The quitting signal was sounded. Success for this first part of the operation was celebrated by the firing of a signal gun, which was answered by a burst of artillery from the city's batteries, and by a great show of joy from the multitude.

The obelisk now had to be lowered from its vertical position and gently laid on a huge wooden cradle which

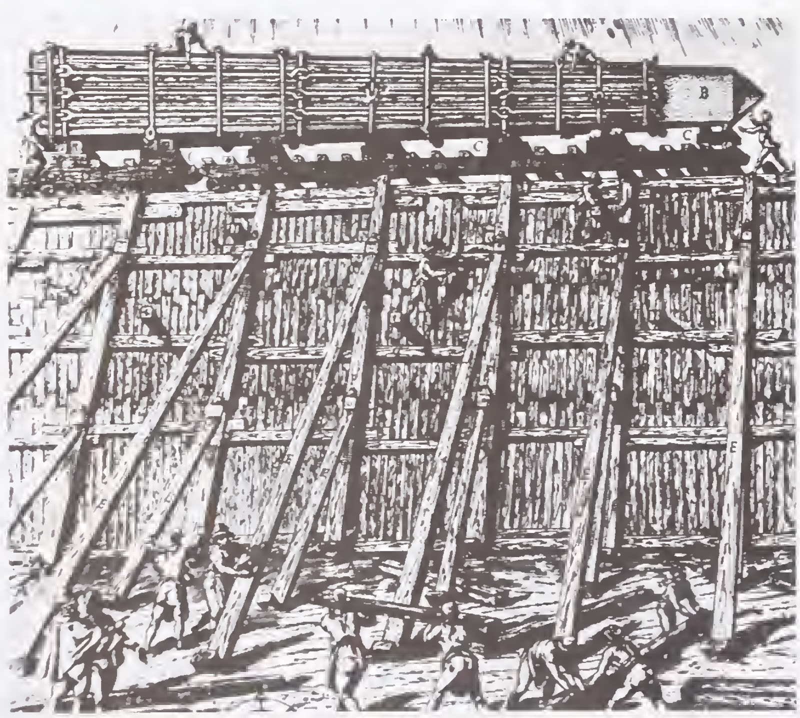


The obelisk safely on its cradle

was to move it on rollers to its new location. Room had to be made for its butt to swing out, so the shaft could be laid flat. This meant demolishing the walls of the sacristy of Saint Peter's Basilica, then rebuilding them. The great granite base also had to be unearthed and moved to its new position. And the four bronze crabs had to be removed to be replaced by recumbent bronze lions. Above all, the great *castello* had to be demolished and reassembled in its new location.

These operations took longer than expected. To dig out the pedestal, fifteen hundred years of accumulated earth and debris had to be removed from around the base. The solid bronze astragal crabs turned out to weigh 600 pounds apiece. Using hot lead the ancient Romans had so cunningly inserted them that masons could not pry them loose. Finally they had to chip them out. The main granite base was found to be a cube, 8½ feet on a side, weighing 55 tons. Beneath it, a rougher base weighed 63 tons. Farther down, as a footing, was a solid white marble slab. All of these, weighing a total of 140 tons, had to be raised and transported to the new site. When reassembled, they would reach a height of 27 feet.

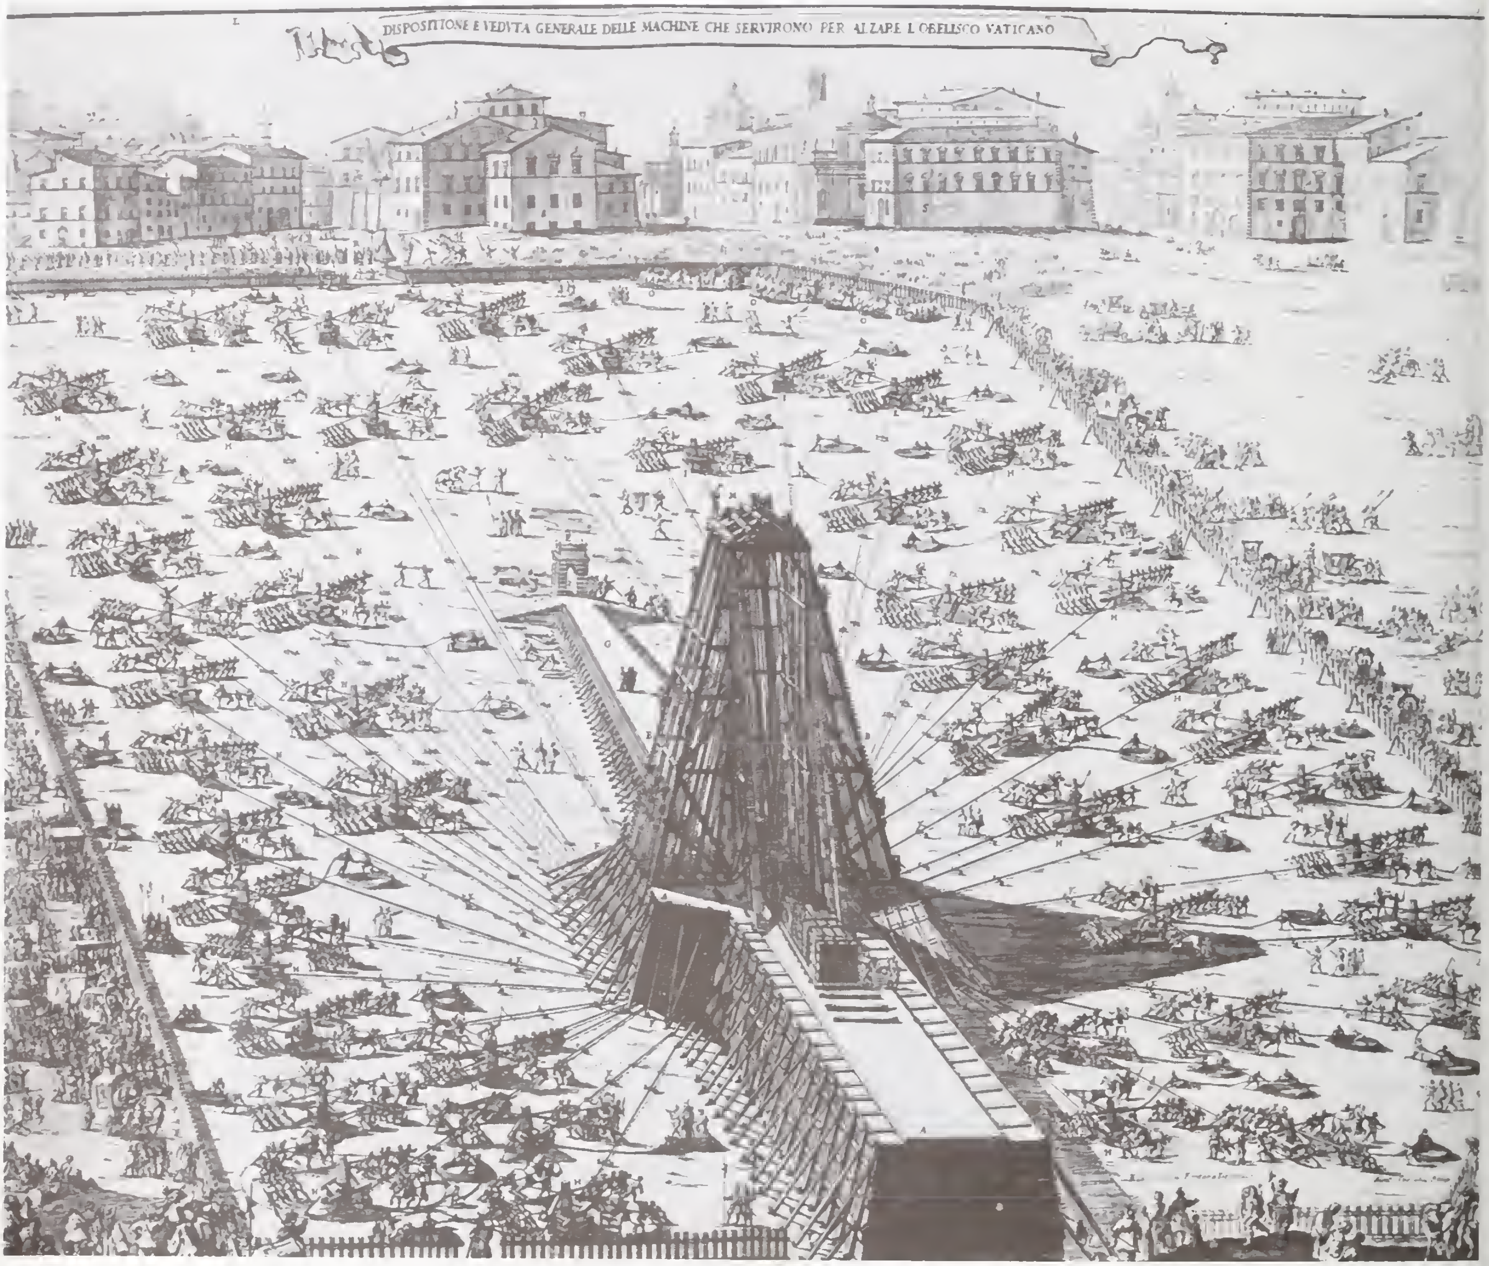
As the obelisk itself had to be dragged 115 canes (256.4 meters) to a spot 40 palms lower on the hill, and Fontana wished to avoid having to go almost 9 meters downhill with the obelisk and then having to raise it again that much, he had a great causeway built of earth dug from the Vatican Hill and held in place by a shored timber crib which maintained the level.



Fontana's causeway had to be 37 feet across at the top, widening at its terminus to provide room for repositioning the *castello* which was to swing the obelisk back to a vertical position.

By May 7 the obelisk was laid on its dolly, intact, without having caused harm to a single person. The pope was overjoyed, and the crowd accompanied Fontana to his home to the sound of drums and trumpets.

Preparations for resetting the obelisk dragged on through June and July. The *castello*'s timbers had to be moved one by one to the new site and carefully reerected on the broadened causeway. Despite the heat of summer, the work continued without pause. The pope declared he would not move to his summer residence until the obelisk was safely emplaced, which meant work had to continue all through August. But the heat became intolerable. Work



Fontana's rendition of the great square of Saint Peter's with his teams of 140 horses and 800 men ready to attempt to hoist the obelisk to its new position on the morning of September 10, 1586 was suspended so that the ropes would not catch fire. On August 30 the whole piazza was closed off with high palisades to prevent onlookers from seeing what was going on.

Sixtus hoped to be able to inaugurate the raised obelisk on September 14, the Feast of the Exaltation of the Cross. And to meet that deadline work was resumed. In order to superintend and to keep things on the go, the pope took his meals in rooms overlooking the piazza. On September 10, a Wednesday, everything appeared to be ready, despite a heat which still threatened the ropes. Again two masses were said before daybreak, this time in the Church of Santo Spirito, at the end of the piazza, toward the south. When the ceremony ended, each took up his allotted place. This time, because of the heavier strain in raising the obelisk, the number of horses had to be increased to 140. At dawn the forty capstans were ready and fully manned.

It was the crucial test. According to one source, the pope blessed Fontana and warned him to be most careful in what he was about to do that day, because he would have to pay for any error with his head. At the same time, says this source, Sixtus V, in his ambivalent love for Fontana, ordered that at all four gates of the borough horses be readied, so that if anything sinister should occur, Fontana would have a chance to escape the pope's ire. Other sources, less romantic, attribute to Fontana the preparation of the horses.

As the trumpet blew, 140 beasts and 800 men turned their capstans, tightening the ropes, and the obelisk slowly rose from its bed. By noon it had reached the critical halfway mark of 45°, at which point it was firmly trussed, and everyone broke for lunch. When work was resumed, the heat was tremendous and the tension on the ropes at its highest. The story goes that at one crucial point the strain became so great the ropes were again on the verge of catching fire. Despite the ban, on pain of death, of uttering a word, a boy is said to have shattered the silence of the great piazza with the cry of "Moisten the lines," which being done, the obelisk was saved from crashing down. The pope, so the story goes, instead of punishing the bold youth, rewarded him and his descendants in perpetuity, with the lucrative concession of bringing palms to the Palm Sunday festivities. The story, not substantiated by any contemporary sources or the research of Cesare d'Onofrio, is illustrated by a later fresco in the Vatican which depicts the boy being apprehended by papal guards.

Fresco in the Vatican showing the arrest of the boy for calling out, "Moisten the lines"

Most spectators, not to miss a single move, remained at their places throughout the day without even going home at mealtimes. Hawkers, selling food, made a fortune. By evening, as the French ambassador, the duke of Luxembourg, came to render his first obedience to the pope, he stopped to watch two separate heaves of the obelisk. At the end of fifty-two pulls and pauses, the obelisk was firmly vertical above its dolly.

The pope, on his way back from Pietro da Monte Cavallo to give a public consistory for the French ambassador, was advised that the obelisk was erect, and declared himself happy. It was September 14. Mortars were fired to inform Castel Sant'Angelo, from which many pieces of artillery resounded. Once more, the whole city rejoiced, running to Fontana's house with the usual noisy hosannahs.

Fireworks at Castel Sant'Angelo

On September 16 the dolly was removed, and the obelisk rested squarely on its base, held in place no longer by the astragal crabs of the ancient Romans but by four gilded lions of modern Rome. Created by the sculptor Prospero Bresciano, the lions were an architectural anomaly in that each lion had one head and two half-bodies, split down the middle like a hotdog bun so as to show a flank from any direction, of which d'Onofrio remarked, "I do not think there is any more monstrous invention around and about the streets of Rome." The allegorical significance of these lions, apart from the fact that they were the heraldic symbols on the Peretti coat of arms, was in demonstrating that just as the lions had been yoked by the weight of the obelisk, so the ferocity and arrogance of gentiles had been suppressed by true religion. Now all that was needed was to uncover the structure, embellish it with finishing touches, and bring the great square back to an even level.

By the twenty-seventh the obelisk stood in its pristine glory. The pope, admiring it from the windows of the Vatican Palace, ordered a procession to consecrate it with a golden cross and to purge it of its pagan past.

The first Friday after the erection, a bishop celebrated a most solemn Mass of the Holy Cross. When the procession reached the obelisk, the bishop blessed a great iron cross which was to be placed atop its pyramidion. With various exorcisms he proceeded to purge the obelisk, dousing it the while with holy water, and scratching crosses on its sides. The great iron cross was then hoisted by a rope, while a subdeacon climbed a ladder to hold the metal in place until it could be fastened to the top of the obelisk.

The obelisk standing before Saint Peter's Basilica, still bereft of Michelangelo's cupola, and of Bernini's colonnade

The event was celebrated by reading the poems of forty-five poets, including the Jesuit-educated Torquato Tasso, who, though he suffered from delusions of heresy, correctly noted that the Egyptians considered their obelisks symbols of the rays of the sun and named their pharaohs sons of the sun. Music followed the poets, and at the sound of trumpets the crowd all knelt. A public indulgence of fifteen years was conceded by His Holiness to all present, and to all who, passing the cross, should honor it. Artillery was fired from the battlements of Castel Sant'Angelo and the bishop cried out: "I exorcise you; creature of stone, in the name of omnipotent God, that you may become an exorcised stone worthy of supporting the Holy Cross, and be freed from any vestige of impurity or

The new alphabet of ornamental "Christian" letters designed by Sixtus's protégé, Luca Orfeo of Fanok, to adorn Christian monuments instead of the pagan inscriptions of ancient Rome

shred of paganism and from any assault of spiritual impurity."

But this was not enough for the pope. He considered the exorcism insufficient, and had the formula immortalized in large "Christian" letters (to differentiate them from pagan Roman letters) on the eastern and western sides of the base, just below the bodies of the four bronze lions.

Fontana's work had lasted exactly thirteen months, and had cost the Reverend Household 37,975 scudi, though Fontana in his bid for the competition had estimated only 16,000. To protect himself against this obvious eventuality, Fontana had all the while wisely maintained a regular public-relations office issuing bulletins and magnificent prints to illustrate the progress of the work, drawn mostly by Giovanni Guerra and etched by Natale Bonifacio, with ample captions by Fontana. They not only informed the world of the progress of the work, but were to form the basis for Fontana's own book on the subject, *Della trasportatione dell'obelisco vaticano,* printed in 1590, which left to posterity one of the most complete and handsome records, in format, type, and engraving, of what was considered by contemporary Europeans one of the greatest engineering feats ever performed. The pope was only too happy to pay Fontana in full.

On October 1, 1586, Sixtus V announced he had given his architect a chain of 80 gold scudi to support a gold medallion bearing the image of His Beatitude, along with a yearly pension of 2,000 scudi, of which 800 could be left to his heirs. Fontana was also made a citizen of Rome, a Knight of the Golden Spur, and a Palatine count with an escutcheon bearing a golden obelisk on an azure field. He received gratis all the lumber and equipment left over from the moving of the obelisk; and architectural commissions were thrust upon him. The pope, with a ghastly pun, had Fontana kneel as he dubbed him *"te nobelisco eternamente."*

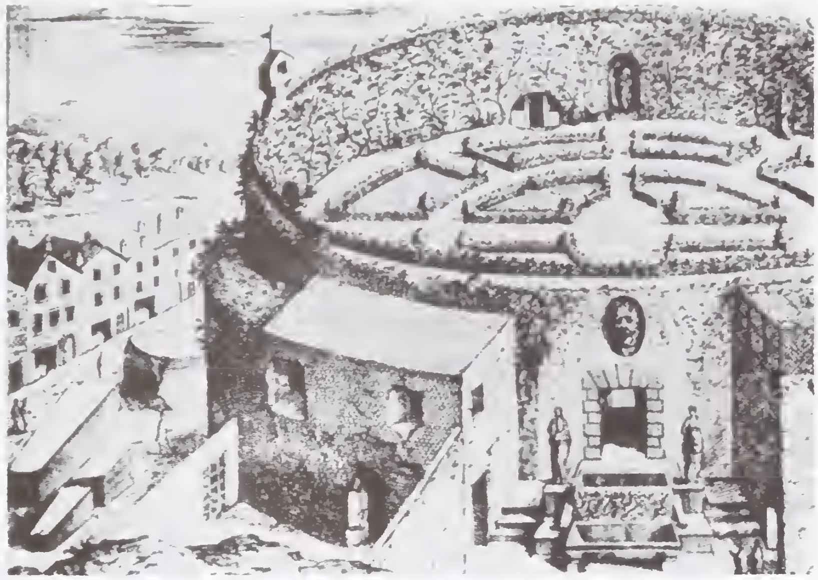
Scathingly, d'Onofrio remarks that Pope Sixtus V, hated by his people, managed to spend 80,000 scudi of their money in what amounted to a singular affirmation of his own personal power. By placing his name carved in beautiful letters on the base of the obelisk, says d'Onofrio, Sixtus V compared himself in greatness to the pharaohs who had first raised the obelisks and to the deified Roman emperors, such as Augustus, who had moved them to Rome. As d'Onofrio points out, not everyone in Rome was happy with the exploit, paid for by insufferable taxes wrung from the people. In a fierce lampoon of December 16, 1586, it was suggested that the

Fontana ennobled

architect transfer Saint Peter's *"guglia,"* or prick, to a more honorable and more decent place for such a tool: his own backside.

Unperturbed by such negative reactions, Sixtus V continued in the grip of his compulsion to erect great obelisks, starting a vogue which was to become the standard Freudian fantasy of a whole succession of Roman pontiffs up to the present. So ingrained is the Roman taste for anal and phallic jokes that as late as 1948, on the occasion of the Holy Year, or Anno Santo, when a great avenue of phoney obelisks was erected by Pius XII along the hideous via della Conciliazione (which

Augustus's mausoleum, built in the second decade B.C. on the confines of the Campus Martius, surrounded by sacred groves. Two obelisks, raised in the Alexandrine style, stood by the entrance until the fourth century A.D. One can be seen lying broken in the side street; the other is presumably buried.



runs straight from the Tiber to Saint Peter's Square, entirely destroying the former stunning shock of coming suddenly on Bernini's great colonnade), Romans were quick to dub the row of obelisks *supposte dell'Ano Santo,* suppositories for the Holy Anus.

As early as September 1586, while the scaffolding was being demolished in Saint Peter's Square, Sixtus summoned Fontana and ordered him to raise another obelisk. The only one left unburied in Rome lay in three fragments near Augustus's mausoleum, where it had been dug up during the reign of Leo X (1513–21). Fontana studied the possibility of putting the pieces of this relic together, but finally concurred with Leo's great military architects, Baldassare Peruzzi and Antonio da Sangallo, who had both declared it unsalvageable.

Instead, Fontana pursued the century-old rumor that a barber in the Campus Martius area, digging for a latrine in his tiny kitchen garden, had knocked against the base of an ancient obelisk, buried hard by the Church of San Lorenzo in Lucina. Almost a century earlier the antiquarians of Pope Julius II had viewed this relic and recognized it as a piece of one of the obelisks brought from Egypt by Augustus, and had urged the pope to re-erect it where it once stood in the Campus Martius. Julius II, occupied with his many wars, could not be persuaded, so the barber had reburied the obelisk. Now Fontana took picks and shovels to the site and began to dig, finding an obelisk that was broken into five pieces. In order for Sixtus V conveniently to observe these half-buried fragments, a wall was specially knocked down, but when the pope saw that the obelisk was in even worse condition than the one by Augustus's mausoleum and that several houses would

Luxurious summer villa of Sixtus V, known as Casa Peretti, on the Esquiline Hill, surrounded by its vast acreage of gardens

have to be destroyed in order to remove it, he decided to have the fragments reburied where they lay.

Yet Sixtus remained determined to have an obelisk to embellish the entrance to his private villa, recently completed by Fontana, on the Esquiline Hill near the Basilica of Santa Maria Maggiore. There, surrounded by vast gardens, his sister, Camilla, who had given up her job as washerwoman to take care of him, held sway over Sixtus's nieces and nephews, judiciously marrying them one by one into the nobility of Rome, where they produced for the Peretti family a succession of Roman princes both secular and churchly.

Sixtus's only alternative for an obelisk was to revive the possibility of putting together the three pieces of Augustus's other relic, which still lay near his mausoleum by the Church of San Rocco along the via Ripetta, a hazard to passersby and to traffic on its way to Piazza del Popolo. This time Fontana agreed; but perhaps because he doubted the outcome of the venture, he gave the delicate job of moving the fragments to his brother Marsilio, aided by his nephew, Carlo Moderno. To everyone's amazement the three pieces reached the piazza in front of Santa Maria Maggiore without mishap. There Fontana raised one above the other to hold firm on the spot where they still stand, a grand entrance to the gates of the papal villa, which, in the meantime, has given way to Mussolini's atrocious Terminus railway station.

Encouraged by this second success, and still prone to more erections, Sixtus summoned his historian, Monsignor Michele Mercati, to collect for him from the Vatican Library all the data he could find from classical authors on the subject of obelisks. Such a study might indicate where

The third obelisk of Sixtus V, raised at the back of the Basilica of Santa Maria Maggiore so as to face the entrance to his summer villa. To make way for the pedestal, Sixtus had several houses and old Roman ruins demolished. The inscription tries to link Augustus with the birth of Christ. The papal emblem and the cross atop the obelisk disguise the fact that its pyramidion had been destroyed sometime before it was buried. The etching is by Piranesi.

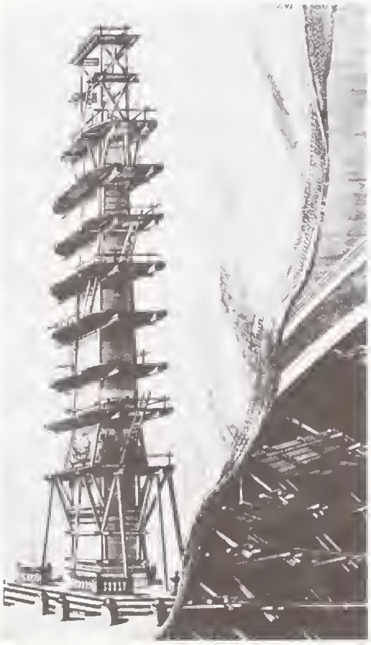
more obelisks lay buried in Rome. Mercati, who was later to put the fruit of this research to his own use in the first authoritative book on the subject of obelisks (*De gli obelischi di Roma,* 1589), came running to the pope, texts in hand, to inform him that there had once been two great obelisks in the Circus Maximus, the one raised by Augustus and another by Constantius. As no one, Mercati argued, could have lifted them, they must still be there, either whole or in pieces, somewhere under the vast expanse of vineyards and vegetable gardens of the friars of Santa Maria in Cosmedin, which now covered what had once been the great circus. This meant several acres would have to be probed. But no one knew exactly where to look, or how deep, and dowsing for needles was as yet an underdeveloped art. So the pope offered a prize to whoever could first locate a missing obelisk.

Spurred by the offer, an enterprising fellow named Matteo Bartalani da Castello fashioned for himself a 6-meter rod, with a sharp point for easier penetration and a ring handle for easier withdrawal, to probe the area. A few months later, in February 1587, while poking in a cabbage patch, Bartalani came across something hard at a depth of 5 meters. Digging a larger hole, he saw that he had struck the side of an obelisk, which turned out, after more digging, to be part of the great 106-foot-high obelisk brought to Rome by Constantius, the largest ever moved

across the sea, and which now lay broken in three large pieces.

Four days later, some thirty paces away, in the direction of the old Baths of Caracalla, Bartalani struck a second obelisk, smaller than the first. From the account of Diodorus Siculus, it was clear to Monsignor Mercati that the obelisk must be the one Augustus had brought from Heliopolis to raise in his circus.

Hole dug by Carlo Moderno in the Circus Maximus, overshadowed by the ancient Baths of Caracalla



For his efforts, Bartalani received from the pope the relatively enormous prize of 600 scudi, "a munificence," says Cesare d'Onofrio, "quite incomprehensible in Sixtus V, were it not for the fact that these labors had been performed by Bartalani under the aegis of his favorite, Fontana, who had obtained from the pope the new concession for his nephew Carlo Moderno of digging up the obelisks."

To bring to the surface the two monoliths from where they lay buried in the mud, more than 20 feet below the surface of the kitchen garden, was an enormous task, mostly because of the great amount of water that continually seeped through the ground from springs on the nearby Palatine Hill. Five hundred men were needed to work at the job, three hundred of whom were kept busy day and night drawing off water by various means. By May, both obelisks had been cleared of earth and laboriously raised to the surface under the guidance of Fontana's nephew.

Yet the hardest part was still to come. The three pieces of Constantius's obelisk had to be dragged to the spot where Sixtus V intended to raise them as a single obelisk in the square outside Saint John Lateran, a distance of over 3 kilometers, through narrow streets and up the

Constantius's Circus Maximus obelisks—reraised by Sixtus V in the Lateran Square before the new winter palace built for him by Fontana—had originally been raised in Karnak by Thothmes IV, in 1492 B.C. Spared by Cambyses, in 521 B.C. (when he tripped on his gown and pierced himself with his dagger), the needle, though reduced 3 feet by Fontana to 105 feet, is still the tallest monolithic obelisk standing in the world. Further to destroy pagan Rome, Sixtus ordered the perfectly preserved Arch of Janus demolished to build a base for the obelisk. Fortunately contemporary Roman conservationists raised such a protest, the arch still stands. The obelisk lying in the foreground belonged to Sallustius, and was eventually raised in the Pincio.

The Madonna del Popolo church, at the main entrance to Rome, was deliberately built to lay to rest the ghost of Nero, who was believed to haunt the area. After a cross was placed atop the exorcised obelisk, the spot was used as the starting point for horseracing up the Corso, and as an ideal setting for public executions.
The obelisk, originally quarried by Seti I, second pharaoh of the Ninth Dynasty, was raised by his son Ramses II in Heliopolis about 1300 B.C. Removed to Rome by Augustus it was set up along the spine of the Circus Maximus in 10 B.C. and overturned and buried in the Middle Ages. The original dedicatory inscription of Augustus was replaced on a new pedestal, along with the pious words of Sixtus V.

steep climb to the top of Monte Celio, which required the construction of a massive sloping roadway.

Working fast, Fontana was able to place the first piece on its base a year later, on July 5, 1588. By the twentieth, with the aid of the reconstructed and lengthened *castello* brought piece by piece from Saint Peter's Square, the second fragment had been securely placed above the first. By August 10, another great cross was raised above the pyramidion of the tallest obelisk in Rome. A fresh inscription specially carved into the base told obelisk-weary Romans of the apocryphal tradition that in that same piazza, a few feet from the raised obelisk, Constantine had been baptized the first Christian emperor of Rome.

Further to exalt the cross and demonstrate how "true religion had subjugated idolatry," Sixtus had Fontana drag the second obelisk, the one brought from Alexandria by Augustus, to the Piazza del Popolo, there to be raised, in

The message Sixtus V wished to convey *urbi et orbi* with the reerection of his obelisks was the ultimate triumph of the church militant against the demons of paganism. Each of his three obelisks in its new Christian surroundings became, in the words of Erik Iversen, "a monumental emblem on a gigantic scale, a sacred allegory and a subtle hieroglyphic enigma of the fashion of the period, to be expounded by the initiated and deciphered by the erudite."

The reraising of Sixtus's obelisks was considered an epoch-making technical achievement. It marked, says Iversen, the end of the Renaissance and the birth of the new orthodoxy of the baroque and the Counterreformation. Everywhere obelisks began to appear on cornices, pinnacles, roofs, buttresses, or as detached monuments in parks and squares. Yet these Catholic symbols were to be taken over almost *in toto* as the Freemasons' symbols of liberty.

the words of Mercati, "as the spoils of war won from paganism by triumphant religion." As the base of this obelisk was in very bad shape, almost 3 palms (76 centimeters) had to sliced away, leaving the obelisk only 23.9 meters long. Thus truncated to a mere 78 feet, Augustus's 235-ton obelisk was raised by Fontana and consecrated on March 25, 1589, with a gilded bronze cross above a star and some mountains to symbolize the reigning pontiff.

The advantage of placing Augustus's obelisk in the Piazza del Popolo was that it could be seen from the end of four of Rome's main streets: the Corso, the Babuino, and the Ripetta, as well as entering Rome from the Flaminias. The disadvantage to Romans in achieving these grand vistas was the destruction of whole neighborhoods of popular hostelries and wineshops. Also destroyed, to provide a new base for the obelisk, was one of the most beautiful of ancient Roman travertine buildings, the Septizodium of Septimus Severus.

Sixtus V—who considered it his duty to destroy as much of pagan Rome as possible—had his name and the date chiseled on one side of the base in bold "Christian" letters. On another side, Cardinal Antoniani, the papal secretary of state, placed a fatuously punning inscription which read as if it were the obelisk speaking: "More august and happier I rise before the sacred temple of her from whose virginal bosom [Santa Maria del Popolo] the sun of justice [Jesus] was born during the empire of Augustus."

ΘΕΟϹ

3. SYMBOLS OF HERESY

What might have given Sixtus a clue to the original purpose of his newly raised obelisk were the inscriptions on its four sides beautifully carved in hieroglyphs. But these were a mystery to one and all. What little was known about the enigmatic writing of the ancient Egyptians had been painstakingly gleaned from Greek and Roman authors, none of whom, as the Danish historian Erik Iversen puts it, "knew what they were writing about."

Diodorus, who traveled extensively in Egypt in the first century B.C., explained the hieroglyphs as "metaphysical and symbolic." He said that when the Egyptians drew a hawk they meant by it to signify anything that moved swiftly—a concept which they transferred to all swift things. For evil, said Diodorus, the Egyptians used as their symbol a crocodile.

How far the Sicilian was off the mark may be judged by recent discoveries that the crocodile was used by the Egyptians as a symbol for the benevolent dragon in the polar constellation of Draco (the plumed serpent of the Mexicans, and the celestial dragon of the Chinese), and it was also used to express the natatory power of the sun god Horus, who, as a crocodile, could traverse the waters of the deep from equinox to equinox, from Virgo in the fall to Pisces in the spring. Even more esoterically, the crocodile was the symbol of the initiate to the "mysteries" because it could see in the water even with its eyelids closed.

More sensible among the classical authors was Plutarch, the Greek biographer of the first century A.D., who said he was an initiate into the secret mysteries, and considered the hieroglyphs to be rebuslike pictorial expressions of divine ideas and sacred knowledge. The only treatises on hieroglyphs known to have existed were attributed to one of Plutarch's contemporaries, the Alexandrine scholar Chairemon, who was also a tutor to Nero. These had been lost, but fragments quoted from them describe nine hieroglyphs, one of which, a weeping figure, was largely understood to convey the concept of misfortune. Clearly, the classical visitors to Egypt had understood no more of the glyphs than modern tourists, although most of the Greeks and Romans, as Iversen, the most lucid modern scholar on the subject, cuttingly notes,

Hermes, known as Trismegistus, or thrice great (as philosopher, priest, and king), is the reputed author of innumerable books, and revealer to mankind of the science of medicine, chemistry, law, art, astrology, music, rhetoric, philosophy, geography, mathematics, anatomy, oratory, and—magic. He is also considered the author of Masonic initiatory rituals, for "nearly all the Masonic symbols are Hermetic in character." Forty-two of the most important of the scientific books attributed to Hermes are believed to have been destroyed in the burning of Alexandria; says Manly P. Hall, "the Romans—and later the Christians—realized that until these books were eliminated they could never bring the Egyptians into subjugation." Hermes' *The Pymander* contains an exposition of Hermetic cosmogony, and the secret sciences of the Egyptians regarding the unfoldment of the human soul, the key to which is the phrase "He who realizes that the body is the tomb of his soul, rises to immortality."

As the Egyptians likened humanity to a flock of sheep of whom the Supreme Being was the Shepherd, Hermes was depicted as the shepherd's dog. According to Manly P. Hall, the name Hermes is derived from "Herm," a form of Chiram, the personified universal life principle, generally represented by fire. The Greeks equated Hermes with the Egyptian god Thoth.
Hermes, regarded as the embodiment of the human mind, explained how mortal man came to his plight. The Father, the Supreme Mind, says Hermes, being Light and Life, fashioned a glorious universal Man in its own image, not an earthly man but a heavenly Man dwelling in the Light of God. But the Man beheld a shadow upon the earth and a likeness mirrored in the waters, which shadow and likeness were a reflection of Himself. The Man fell in love with His own shadow and desired to descend into it. Nature, beholding the descent, wrapped herself around the man she loved, and the two were mingled. For this reason earthly man is composite. Within him is the Sky Man, immortal and beautiful, without is Nature, mortal and destructible. Thus, suffering is the result of the Immortal Man's falling in love with His shadow and giving up Reality to dwell in the darkness of illusion. . . ."

"tried to cover their ignorance with the pompous cloak of a learned 'philosophical terminology.'"

By the time the Egyptians had become Christianized *en masse* in the second-century reign of the emperor Justinian, the hieroglyphs had been reduced to sinful pagan symbols, no longer to be read, discussed, or understood. Wherever possible they were to be disfigured or destroyed. With the burning of the great library of Alexandria a further quietus was laid on the subject which was to last a thousand years. Having burned the libraries and defaced the inscriptions, says Manly P. Hall, "Christians invented a ridiculous conglomeration of puerility which for several hundred years was palmed off upon a comparatively illiterate world under the name of Egyptology." And so it wasn't until the fifteenth century that any new light could be shed on the significance of the mysterious glyphs.

What the bright young minds of the Renaissance were to learn about their meaning was based largely on three manuscripts, fortuitously recovered, from late classical authors. One of these was found in 1414 in a monastery in Germany by the Florentine Poggio Bracciolini, later chancellor of the Florentine Republic. It consisted of the last eighteen books of the history of Rome written in the fourth century A.D. by Rome's last major historian, Ammianus Marcellinus. In Florence, the manuscript was given to Niccolò de Nicolli, then the greatest authority on classical bibliography, who had it copied and circulated in humanistic circles. Book seventeen contained a history of the obelisk of Constantius, and included a short general digression on obelisks and on Egyptian writing; there Ammianus said the Egyptians did not write with letters "as we do," but with signs expressing whole words or concepts. As an example he used the honeybee to represent a king, "for kings must exercise their rule with sweetness and also possess a sting."

Ammianus gave an extensive translation into Greek of the inscription on Augustus's Circus Maximus obelisk, which he said was quoted from the work of Hermapion, about whose person or work little or nothing was, or is, known, other than that he is presumed to have been a Hellenistic scholar living in Rome about the time of Augustus.

From Ammianus's manuscript the Florentines learned that the obelisk Augustus had raised in the Circus Maximus had once stood in Heliopolis, where it had been erected by the pharaoh Seti I, presumably about 1300 B.C.; also, that Seti had died before the inscription could be completed, a job carried on by his son Ramses II. As

Glyphs on Augustus's obelisk. In the Renaissance, says William R. Heckscher, obelisks were considered "the most powerful witnesses of a primordial religiosity and spirituality" and were accordingly interpreted as links between earth and heaven, "for if one looked at them from base to apex they would seem to suggest by their evanescence the transition from things terrestrial to incorporeal Divinity itself." To this Heckscher adds that, more importantly, if seen conversely, the obelisks, by their pyramidal shape, might be compared to the pencil of rays issuing from the center of the sun. Thus the "Egyptologists" of the Renaissance deduced from the classical authors of Greece and Rome that "through their obelisks the Egyptians imitated the rays of the sun whom they themselves worshipped."

to which of the enigmatic symbols represented what words or letters in Latin, Greek, or in any other language, the mystery remained, only slightly illuminated by a second document which surfaced five years later, in 1419.

This was a manuscript found on the Greek island of Andros by another Florentine traveler, Cristoforo Buondelmonte, who brought it back to Florence in 1422. Entitled *Hieroglyphica,* it purported to be a sixth-century A.D. translation into Greek of an original treatise on hieroglyphs written by one Horapollo of Nilopolis—an obvious pseudonym concocted from the gods Horus and Apollo—believed to have been an Egyptian scribe who had lived a couple of centuries earlier than the translator. Though the Greek was considered inferior, and the meaning of the glyphs had evidently already been lost by the time the original work was composed, it still constituted the only major treatise on hieroglyphs to have survived from classical times. As such, if only because of its uniqueness, it was, as Iversen points out, one of the first manuscripts to be set in print, in 1505, along with Aesop's fables, becoming for a while the canonical authority on all hieroglyphical questions.

The work is divided into two books, similar but possibly from different sources. Each of a total of 189 paragraphs deals with a separate hieroglyph, and its purported meaning.

To denote impudence, said Horapollo, the Egyptians represented a housefly, because "though perpetually driven away, it nevertheless returns." The ant, according to the *Hieroglyphica,* was the Egyptian glyph for knowledge, "For whatever a man may carefully conceal, this creature obtains a knowledge of." More discerning is his Egyptian glyph for discernment: a mouse. "When many different sorts of bread lie before him, the mouse selects the purest from among them, and eats it. Hence the baker's selection is guided by mice."

The number 16 was used by the Egyptians, according to Horapollo, to indicate voluptuousness, the explanation being that sixteen is the age "when men begin to hold commerce with women and to procreate children." Sexual intercourse was depicted by two 16s; and in Cory's English translation of the Greek, the explanation is discreetly left in Latin: *"Cum enim sedecim voluptatem esse disimus: congressus autem, duplici constet, maris ac foeminae, voluptate, proptera alia sedici adscribunt";* which simply means that as intercourse requires voluptuousness from both male and female, another 16 must be added. Some of the Horapollion aphorisms were drawn

Thoth, self-produced divine intelligence, at the creation, uttered the words which formed the material world, is depicted as a man with the head of an ibis. He was known as the "Scribe of the company of Gods," and was the author of the secret *Book of Thoth,* since lost, which was said to contain the arcana of the mysteries. Filled with hieroglyphics, the book was purported to give those acquainted with its use unlimited power over the spirits of the air and over subterranean divinities. From the older Egyptians, the Ptolomaic priests learned that Thoth bore the head of an ibis because the bird sleeping with its head beneath its wing assumes the shape of a heart—seat of life and true intelligence. The footstep or pace of the ibis was said to measure exactly 1 cubit a unit considered sacred and which, according to initiates, was given by Thoth, and appears mathematically in all the measures of the universe. The ibis's intestines were said to be exactly 96 cubits, or 144 feet, long.

from folklore. The beaver was to symbolize a man with self-inflicted injuries. "For the beaver," says Horapollo "tears out his own testicles, and casts them as spoil to his pursuer." Other bits of wisdom verge on magic, similiar to that of the Hawaiian Huna, who, according to Harvard's modern epigrapher, Barry Fell, may be descendants of the same Egyptians. To symbolize a woman who miscarries, notes Horapollo, the Egyptians depicted a mare kicking a wolf: "Not only by kicking a wolf does a mare miscarry, but it immediately miscarries if it should merely tread on the footstep of a wolf." Despite such farfetched homilies, there remain in the paragraphs of Horapollo strains of the perennial wisdom of the ancients, as is evident when he uses the grasshopper as a symbol for mystic man, a notion which survived through the Platonic philosopher Apuleius to Collodi in Pinocchio's talking cricket, who, in Horapollo's words, "does not utter sounds through his mouth, but chirping by means of his spine sings a sweet melody." And although only a dozen of the seven-score glyphs or symbols described by Horapollo turned out to be even closely related to their meaning in Egyptian, as deciphered by modern Egyptologists, publication of the book launched a vast quest into their secret meaning.

The best clue was to come from the most extraordinary of the three documents that surfaced in the fifteenth century, one which was to have a powerful revolutionary effect on political minds to this day, a Greek manuscript in seventeen books brought from Macedonia to Cosimo de' Medici. It was said to contain the secret wisdom of Thoth, the Egyptian sage whom the Greeks called Hermes Trismegistus, or the Thrice Great Hermes. Translated into Latin by Marsilio Ficino in 1471, it came to be known as the *Corpus Hermeticum,* a source for all the various and powerfully effective Hermetic philosophies that followed. According to Ficino, a quiet, scholarly philosopher with strong leanings toward paganism, Thoth, or Hermes, considered a contemporary or predecessor of Moses, had attained to gnosis, or the knowledge of God, by a sort of union with the godhead. Hermes was thus considered the first great teacher of the gnosis. After his death, he became a god, "as anyone who attains to gnosis becomes a god after death."

Man, according to Hermes, had taken on a mortal body merely to commune with nature, but at heart remained a spirit, a divine, creative, and immortal essence. Living beings did not die, but, being composite, dissolved the bond in order to reunite and re-form. Nothing dies; it only

Marsilio Ficino (1433–1499), Florentine philosopher patronized by Cosimo de' Medici, was the guiding spirit of Florence's Platonic Academy, which he wished to make into a spiritual community. He revived the Neoplatonic doctrine of a world-soul and identified demons with the Christian hierarchy of angels, "supercelestial" and "elemental," with souls and etheric bodies according to their status, of a like nature to human spirits. Ficino believed that the Egyptians with their magic could bring down spiritual entities into their statues of gods and maintain communication with them.

Giovanni Pico della Mirandola (1463–1494)

dissolves and transforms. The gnosis consisted in re-becoming a god.

To keep this explosive knowledge secret from those who might profane it, yet have it available to the initiate, it was, said Ficino, originally recorded in the Hermetic language of glyphs. As an explanation, he adduced that "the Egyptian priests, when they wished to signify divine things, did not use letters, but whole figures. . . ." This he followed with the Goethian notion that "God doubtless has a knowledge of things which is not complex discursive thought about its subject, but is, the simple steadfast form of it."

To Ficino the hieroglyphs were Platonic ideas about the universe and its spiritual realms, made visible, and through his translations into Latin of the works of Plato and of the Neoplatonist Plotinus, Ficino brought to the Renaissance an entirely new concept of Egypt as the source of the cosmic wisdom of both Plato and Pythagoras.

From Plotinus, the Florentines learned that the hieroglyphs were not images of the things they represented but Hermetic symbols devised by Hermes and endowed with qualities by means of which the symbols could recall to the initiate an insight into the very essence and substance of reality. Functioning not through rationalization, but by divine inspiration or illumination, they were to reveal the world of the soul, leading to an ultimate understanding of the true nature of the cosmos; this to be made possible by an immediate contact between the human intellect and divine ideas. Compared with the pedestrian tenets of Aristotle and Aquinas, these were flighty concepts. But because Plotinus was born in Egypt, and because Clement of Alexandria was also from Egypt, the men of the Renaissance were willing to go along with this interpretation of the hieroglyphs.

Convinced by such sensitive minds as that of Ficino's brilliant pupil, Giovanni Pico della Mirandola, who had mastered Hebrew, Chaldee, and Arabic as well as Latin and Greek, that profound religious doctrine was best expressed in enigmas, Renaissance scholars realized that the mysterious hieroglyphs which appeared on the obelisks could be explained as symbols by means of which it might be possible to express the innermost secrets of life, and open a window onto the world of magic. Magic, as practiced by the Renaissance magus, or master of esoteric wisdom, was designed to enable the "magus-man" to regain powers which were virtually godlike, there being, they believed, no latent force in heaven or on earth which could not be released by an initiate through proper inducements: a conceit, in the eyes of the Church, which bordered on heresy.

By blending the wisdom of the Jewish Cabala with the gnostic-Neoplatonist tradition to create the foundations of his higher magic, Pico found in meditative trances the technique for escaping from his body to explore higher realms of consciousness. And here came the rub. Both Ficino and Pico stressed the essentially sexual essence of their magic. Both provided justification for sexual magic as an ecstatic reconciliation of opposites in which a higher state could be attained.

An early forerunner of the political martyr Wilhelm Reich, Ficino regarded sexual desire as a current of energy responsible for the cohesion of the entire universe. To Florentine sensitives, erotic love could thus be a method of absorption into, or magical mastery of, the world of the divine. Ficino even went so far as to commend the pagan revels of Bacchus (or Pan) as a way of escaping from normal human limitations into an ecstasy in which the soul was miraculously transformed into the beloved god himself. To the churchmen of Rome, who officially condemned sex as satanic and evil, though they were personally clandestinely happy to indulge, this was heresy, to be dealt with by torture and the stake.

Because of the heretical nature of Pico's pronouncements, and especially because of his surprising thesis that no science gave a better confirmation of the divinity of Christ than "magia and the Kabbalah," he was arrested by the self-appointed vicar of Christ, Pope Innocent VIII (1484-92), a supposed celibate who openly subsidized a litter of bastards at the Church's expense (funded from the sale of indulgences to those guilty of killing innocent heretics) and who had launched his reign by issuing a bull ordering a holy war for the extermination of all witches and magicians. Only by making a public apology was Pico able to avoid being burned at the stake. Influenced by his friend, the reforming monk Girolamo Savonarola—who *was* burned, for constantly inveighing against the infamously corrupt rule of Innocent and accurately prophesying his imminent death—Pico, a tall, handsome young man, much loved by the ladies, chose to abandon the gay life of a Renaissance nobleman with his princely patrimony, to wander barefoot through the world preaching the simple Christianity of Jesus of Nazareth. Though somewhat vindicated by Innocent's successor, Alexander VI, Pico, to avoid further persecution, judiciously translated himself to another dimension at the early age of thirty-one, depriving the world of one of its brightest minds and its sweetest

When Savonarola raised his voice in the pulpit against the gangster methods and the gross corruption of the Church, prophesying a holocaust if the pope did not reform, he was offered a cardinal's hat to desist. When he replied, "No hat will I wear but that of a martyr reddened by my own blood," he was seized and obliged of his request. For forty days he was tortured to elicit a false confession, then hung on a cross with two of his accomplices and burned alive before a howling mob.

Cartoon deriding Alexander VI as venal and corrupt. A Spaniard by birth, known as the "infamous Roderic Borgia, greedy for gold and lustful for women," he owed his cardinal's hat to the nepotism of an uncle, Pope Calixtus III, and his papal crown to the vast sums of money he spent bribing other cardinals to obtain their vote. Once in office, Borgia lavished several fortunes on a score of illegitimate children provided by a variety of mistresses. His son Caesar, named archbishop of Valencia at 16, was made a cardinal at 18, along with his nephew Giovanni. Another son became duke of Gandia, owner of a vast personal fiefdom carved out of Church property. For himself, Borgia indulged in a life of extraordinary luxury, enlivened—as pornographically described in his secretary's memoirs—with dancing, stage plays, and sexual orgies. Only when the corpse of the duke of Gandia was washed up by the Tiber did Alexander shut himself up in Castel Sant'Angelo, overcome with grief, and promise to reform the Church. But this too proved an idle promise when suspicion of the murder fell on his son Caesar, then the most powerful cardinal in Rome. Alexander rewarded the suspect with the confiscated property of another noble, and allowed him to become a general to launch a series of military campaigns designed to refill the papal coffers. Cardinal Michaeli was cynically poisoned and his property seized. Any cardinal, nobleman, or official with money could be accused of an offense, imprisoned, tortured, and made to confess; murdered, he was deprived of his property. Anyone trying to oppose such action was seized by the pope's Spanish mercenaries and punished with death. When Alexander finally died at the age of 72, apparently by poison he intended for someone else, Caesar kept the news from the world long enough to seize the papal treasury. By the time the pope's death was announced, his body was so horribly decomposed it had to be quickly and forcibly stuffed into the first available coffin, too small for his rotting six-foot carcass.

souls. Ficino, determined to pursue the magical lore derived from the Egyptians, managed to avoid the stake only by taking holy orders.

What Pico had been guilty of was following two dangerously libertarian notions—as spelled out in Ficino's translation of Hermes's *The Pimander* and *The Asclepius*—which the Catholic Church, a political institution determined to defend by force its temporal power and financial benefits, could not tolerate. The first of the notions considered anathema by the Church, because it made superfluous the role of priest, bishop, or pope, consisted in the suggestion that "unless you make yourself equal to God, you cannot understand God; for like is not intelligible save to like. . . ." This was followed by the simple recipe for attaining to such a grand conceit: "make yourself grow to a greatness beyond measure; by a bound free yourself from the body; raise yourself above all time, become Eternity; then you will understand God." The divinity in question was, of course, neither the vindictive patriarch of Moses nor the caster-into-hellfire of the Roman Inquisitors, but the gnostic's wonderfully loving and all-pervasive One.

As the Church suspected that the revival of the Hermetic tradition—going back to the wisdom of the ancient Egyptian religion as symbolized by the great obelisks and their enigmatic hieroglyphs—posed a direct threat to its control, and that this "heretical" wisdom might be more truly a religion of love than their own debased and cruel version, popes and Inquisition began to exterminate on a grand scale followers of the gnosis wherever its proponents overtly displayed their beliefs.

As early as A.D. 321, when Constantine became the first Christian emperor, the Church of Rome set about suppressing all that was pagan, refusing to recognize the ancient mysteries. No longer teaching a universal religion, the Church pronounced the arts of ancient Egypt wicked and magical. Of these arts, hieroglyphic writing was considered the worst because it appeared to concentrate the secrets of them all.

At the Council of Nicea, presided over by Constantine—ostensibly to suppress the Arian heresy—the spiritual considerations of Christianity became once and for all subordinate to political control. Shortly after Constantine's death, to secure total temporal power, the Church produced what one historian has labeled perhaps the most shameless forgery in the history of false presences: the Donation of Constantine. "This document," says historian Michael Harrison, "purported to be the instrument by which the Emperor Constantine surrendered the imperial

Constantine defeating Maxentius at the Milvian Bridge

insignia of sovereignty over the Western Empire to the Pope of Rome"—applying to himself and his successors forever the emperor's title of Pontifex Maximus. "Appeal to this impudent forgery," says Harrison, "was made by Pope after Pope for centuries until, indeed, with the smashing of Rome's total power by the Reformation, the Donation of Constantine might be denounced for the swindle that men had long known it to be."

By the seventh century the Church had rewritten Catholic dogma to obliterate most of the original teachings of Jesus, substituting for the gentle Christian Gospels the narrow authoritarianism of Rome. Gone was the original Christian doctrine of reincarnation in favor of what has been called "a one-way trip to heaven or hell." This limited view, coupled with the Church's unwillingness to recognize the value of human sexuality, or the ancient pagan rites of fertility, was to have a deadly effect on man and nature, worsening as the centuries passed.

Then came the papal encyclical cynically laying perpetual sexual chastity on the priests of Rome. Unable to contract a valid marriage and thus beget legitimate heirs, priests and prelates could only will their property back to a Church which could only grow richer; that is, all with the exception of the cardinals and popes, who managed to create an enduring "black" aristocracy with the property they alienated from the Church to their "nephews." Being a rule and not an option, priestly chastity had the effect of unleashing on Christian women a pack of sex-starved clerics who could only satisfy their lust illicitly, with a sense of guilt to besmirch any tenderness or love, a shift from the world of eros to that of porno, and the sadistic persecution of happier, healthier mortals.

Blinding the archbishop of Ravenna

Piercing the eyes of an "heretical" bishop with a sharp iron

Using a hodgepodge of undigested mythology picked up from Egypt and the East, the Church set about scaring those who would not obey them (and pay them a 10-percent tax) with threats of eternal damnation in a fiery hell for sins or purported sins which only the Church could forgive, against payment of cash. Thanks to the sale of indulgences, crime without risk could be committed by payment in advance of the required sum: 7 pounds for perjury, 36 for incest, 1 ducat and 4 pounds for parricide, 11 ducats 6 pounds for poisoning a stranger.

But the system, further corrupted by simony, risked total collapse, and the Church, determined to survive, hit upon the only method it could envisage: the extermination of its enemies. For the dirty work, the pontiffs organized an SS Corps of investigating executioners: the Inquisition.

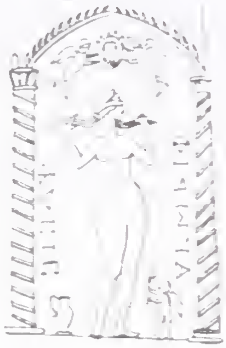
Anyone teaching a gospel closer to that of the ancient Egyptians—such as the Essene, the Therapeut, the gnostic, and the Manichee—was relentlessly persecuted, tortured, and painfully put to death.

Theodorus (642-649) started the vogue of dipping his pen into consecrated wine when signing the death warrants of heretics. The inhuman ordeal of torture by water was invented by Eugenius II (824-827). Gregory II (996-999) had the eyes of antipope John pierced and his nose and tongue cut out.

Among the first to be executed was Manes, originator of the Manichaean "heresy," which he had learned from the Egyptian philosopher and magician Terebinthus. Manes was crucified and flayed alive for having considered the philosophical system of the pagan sages superior to that of either Judaism or Christianity. The followers of Manes, known as the "Sons of the Widow" in memory of the widowed Isis and of the Osirian mysteries of Egypt, were accused of the crime of believing the spirit of God to be Light, radiant with the virtue of love, faith, fidelity, high-mindedness, wisdom, meekness, knowledge, understanding, mystery, and insight. Like the Essenes, the Manichaeans called themselves "Sons of the Light." Believing in metempsychosis and the ultimate salvation of all men, they held enlightened and purified love as the highest of human emotions, a love expressed through kindliness, friendliness, tolerance, and patience. In their opinion, only those who truly loved their fellow men and women and proved that affection through the defense of the rights of man were entitled to regard themselves as religious.

Gnostic sects, who found their primeval wisdom in the ancient mysteries of Egypt, and in the efficacy of numbers and hieroglyphs, were found guilty of searching for the

Gnostic symbols



At the end of World War II in the cave-riddled mountains of Jabal-al-Tarif in Upper Egypt, a discovery was made which threw light on the beliefs of the early Christian gnostics. Most of what had been known about them had come from their Catholic detractors who considered them heretics. In a cave, where they were hiding in the course of a blood feud, two Arabs (who had just murdered a rival, dismembered his body and eaten his heart) came upon a red earthen jar about a meter high. Inside were thirteen papyrus books bound in leather. Several were used to make fires, but in what remained scholars were to decipher fifty-two texts in Coptic dating from the early Christian era. They contained previously unknown gospels such as that of Thomas, of Philip, and of The Egyptians,

esoteric meaning in religion, and ritually massacred by the early followers of the Church. What the sexually tortured Fathers held against the gnostics was their love feasts, which the Fathers, without a glimmer of the philosophy entailed, characterized as grossly perverted orgies. Early Christian gnostics were accused of putting out the lamps in their churches at the end of evening services to indulge in indiscriminate sexual intercourse; also of practicing the Tantric ritual of offering human semen as a sacrament.

Even the Neoplatonic school of Alexandria was attacked; its beautiful and eloquent leader Hypatia, stripped naked by a mob of Catholic monks, was barbarously murdered with the complicity of Cyril, bishop of Alexandria. Yet from the Alexandrine school the ancient mysteries of the Egyptian gnostic-Christians were kept alive by the sect of Sufis, overtly Moslem, but with deeper philosophical roots. In Islam, Hermes became Idris, master of the Hermetic mystery, known only to the few. A Sufi heir to the mystery cults was Dhun-Nun, an Upper Nile Egyptian who derived his gnosis, or vision of unity, from a decipherment of hieroglyphs on the Egyptian temples. His ideal of an interreligious reconciliation was carried on by the sect of Ismaeli, who passed on to the Crusaders from the West, and especially to the Knights Templar, elements of Sufi esotericism and what came to be known as the Rosicrucian secrets.

Brought from the Levant to southern Europe, the Egyptian beliefs of gnostic, Manichee, and Sufi gave rise to the Bogomils, Cathars, Albigeois, Paulicians, Pataranes, Tisserands, and Waldensians. Secret assemblies of the Manichees and Cathars were dedicated to the liberation of human beings from the despotism and tyranny of the Roman Church, so that in the end all nations might dwell together in peace, governed by just laws and noble examples.

The Albigensians, with a stronghold in the south of France during the twelfth and thirteenth centuries, went even further. Heirs to a magical secret inherited from Egypt, known to gnostic and early Christian, they could help a soul painlessly across the threshold of death into what they termed "reunion with the Light." The Albigensian creed offered an escape from the endless wheel of reincarnation, an escape from the illusory prison of the body, with its seeming pleasures, and a "return within the compass of a single life into union with spirit." Here was an echo of the ancient Vedas, along with the message of the Buddha. Nirvana to the Albigensians was not an annihilation of consciousness but a participation in the evidently translations made about 400 A.D. of more ancient Greek manuscripts, possibly earlier than the Canonical Gospels attributed to Mark, Matthew, Luke and John. The content of the gospels, condemned by "orthodox" Catholics some time after Constantine, ranged from descriptions of the origin of the universe to myths, magic and instruction in mystical practice. One of the reasons for condemning these "Gnostic Gospels," as they came to be known, is given by Elaine Pagels in her book by that title. From the Apocalyse of Peter, she quotes the risen Christ as explaining to Peter that those "who name themselves bishop and also deacon, as if they had received their authority from God, are in reality waterless canals" and although they "do not understand mystery, boast that the mystery of truth belongs to them alone." The author of this little known gospel accuses the orthodox of setting up an "imitation Church" in place of the true Christian "brotherhood."

Another reason for condemning these early Christian texts may be found in the Gospel of Mary Magdalene, which hints at an erotic relationship between Jesus and his lovable follower; though, as Pagels is quick to point out, mystics have constantly chosen sexual metaphors to describe mystical experiences. But the most obvious reason for condemning these gospels—which some dedicated soul took the trouble to secrete in a cave some sixteen hundred years ago—was clearly political. Whoever could claim to *know* through inner vision could claim that his or her authority equalled or even surpassed that of Peter and his bloodthirsty successors. The gnosis, offering the initiate a direct access to divinity—of which priests and bishops might even be ignorant—also offered a theological justification for refusing to obey either bishop or priest. So the moment the Catholic Church obtained political and military power, the subversive gospels were everywhere destroyed and their proponents butchered.

universal consciousness—a state of love bordering on the divine.

In the Roman Church, the Albigensians saw an institution ridden with superstition, lacking in philosophical depth, corrupt and cruel; it seemed to them that Satan himself must have been responsible for setting up the Churches of Christendom as a means of destroying human souls. Like the Cathars, they renounced not Satan and his works and pomp, but "the harlot Church."

To the Albigeois enforced marriage by the Church was odious; he recognized no other sanction for the union of man and woman than mutual attraction. Some went so far as to proclaim the sacraments useless, suggesting that women ought to be communalized on account of the vanity of the pleasure obtained from them. Yet an advanced Cathar would not commit adultery, nor homicide, nor lie, nor swear an oath, nor pick and steal, nor do unto another that which he would not have wished done unto himself. He was to pardon wrongdoers, love his enemies, pray for them that calumniated him, offer the other cheek to the smiter, give up his mantle to him that took his tunic, and neither judge nor condemn.

Dante is reputed to have been a secret member of the Albigensian Church and to have officiated as a pastor in various European cities. He was also a member of a group called Fedeli d'Amore, or Faithful in Love; and Roberto Cesare Ambesi in his *I rosa croce* mentions a ciphered Rosicrucian wisdom hidden in the lines of the *Divine Comedy,* obtained mystically and by initiation, which, says Ambesi, transcends the limits of the times in which Dante lived.

The gnostics' radiant cult of the spirit, which took possession of men, a cult without vast buildings, elaborate decorations, pontifical hierarchy, or rich vestments, was seen by the popes as a serious threat to their materialistic church. Once it became clear that perhaps a third of all nominal Christians were secretly practicing an heretical religion, Christian persuasion was replaced by the rack, the gibbet, and the stake. Declaring that anyone who attempted to construe a personal view of God which conflicted with the dogma of the Church of Rome must be burned without pity, Pope Innocent III decided on a crusade "to exterminate the impious," accusing the Cathars of being "lascivious sects, who, overflowing with libertine ardor, are but slaves to the pleasures of the flesh."

To the cold nobility of northern France he offered as a lure the conquest of temperate and independent Provence,

Burning a victim of religious persecution

with its beautiful châteaus, its luscious vineyards, olives, and fig trees. German mercenaries were enlisted on the promise of looting the rich southern towns and of raping their lovely women, renowned as lighthearted, hot-blooded, and perversely sensuous.

And so was inflicted on the south of France one of the most ferocious massacres in history. Bands of northern brigands pillaged and plundered. In the Cathedral of Saint-Nazaire twelve thousand "heretics" were killed when the roof collapsed. Those who tried to flee were cut down and butchered. Thousands more were burned at the stake. At Toulouse, Bishop Foulque put to death ten thousand people accused of heresy. At Beziers the entire population of more than twenty thousand was slaughtered. At Citeau, when asked how to distinguish Catholics from Catharists, the abbé replied with his famed cynicism: "Kill them all; God will know his own."

Thus it fell to the Knights Templar to act as custodians of the esoteric tradition descended from the Egyptian and Chaldean sages. Anomalously acting as "military apostles of the religion of love," they dedicated themselves to the restoration of the Church as they believed it to have existed in the time of the apostles, setting up a bulwark against the abuses of the theocratic regime in Rome, with its cruel and despotic Inquisitors. From their Moslem peers in the Orient the Templars had learned to acknowledge Jesus as a great and holy prophet, one who had been taken to Egypt to be initiated into the highest degrees of occult science, recognized by the priests of Osiris as the long-promised incarnation of Horus, eventually to be consecrated Sovereign Pontiff of a Universal Religion.

Along with a reverence for the doctrines of alchemy, astrology, magic, and cabalistic talismans, the Templars

The torture and execution of Waldensian "heretics"

Grand Master of Templars

Templar uniforms and arms

appear to have brought to Europe from the East the secret teachings of the gnostics and the Sufis dealing with Tantric sex. According to the nineteenth-century German historian von Hammer-Purgstall the Templars secretly adopted a form of the rites of Gnosticism founded on phallic worship or reverence for the sexual principle in nature.

Formed in Palestine in 1118 by Hugues de Payen and Godefroy de Saint-Aumer, with seven other French knights, the Templars set up their order in the ruins of the Temple of Solomon; and the symbolic rebuilding of the temple was to become one of their spiritual goals: the temple of God being man. Digging in the foundations, they are said to have found a rare manuscript which traced for them the procedure employed by King Solomon in realizing the *Great Work,* the alchemical transmutation of the human soul back into light.

It was then that the Templars came into contact with the sect of the Johannite followers of Saint John the Apostle, whose secret objective was the restoration of the esoteric Egyptian tradition, to be achieved by the overthrow of the Bishops of Rome, in order to establish universal civil liberty, and thus reunite mankind under the one eternal religion of the world. This goal became the secret dream of the Templars: the formation of a civilization that would reconcile East and West, starting with a unique brotherhood of Christian and Moslem. But to achieve their goal they chose the same anomalous path as their opponents: they set about amassing great riches, becoming not only the greatest soldiers of the West, but its greatest bankers. They also became great builders of cathedrals, accomplished diplomatists, and the most reliable chamberlains at the courts of Europe.

Encounter between Christians and Saracens at Mt. Hattin in Palestine on July 4, 1187. Thirty thousand Moslems and Jews were massacred in Jerusalem by Christian crusaders. To stop this senseless slaughter, the Knights Templar found means of communicating with their Moslem brothers-in-arms as brothers in spirit.

Knights Templar entering their fortified temple in Paris, built in the thirteenth century opposite the Louvre

Then came disaster. King Philip the Fair of France developed a similar idea of making himself ruler of a vast Christian empire centered at Jerusalem. He also needed money. First he seized all the Jews in his kingdom and forced them to give up their fortunes by removing one of their eyes and threatening to remove the other. Then he so debased the value of the national currency he was obliged to take refuge from an angry populace in the Paris temple. There, among his protecting Templars, he coined the idea of seizing their riches.

On October 13, 1307, throughout France, some five thousand knights were arrested by officers of the king. Seized without warning, and kept in ignorance of their fellow knights, they were told that others had confessed and that their lives would be spared if they too confessed. But to what?

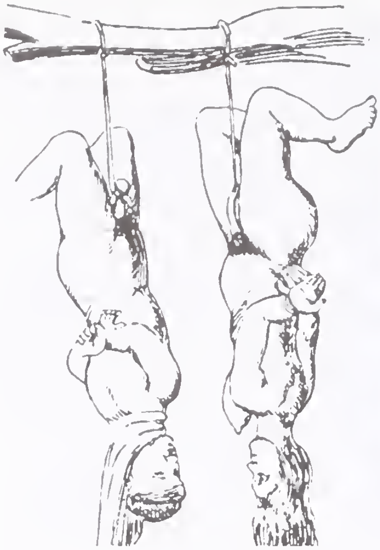
To have charged the Templars with planning an ecumenical world would have meant unveiling Philip's own scheme. So recourse was had to the easier charge of magic and heresy. Public indignation was aroused by further charges of sodomy and orgies with female demons. To these accusations were added denying Christ, spitting on the Cross, and worshiping the devil in the form of an idol called Baphomet.

Grand Master Jacques de Molay, with his bodyguard of sixty knights, was imprisoned in his own temple. Only a few hundred knights escaped. The rest were turned over for interrogation to Guillaume de Paris, Grand Inquisitor for France. Of the 140 Templars seized in Paris 36 soon died under torture; 54 more, in horrible torment, some being strung up by the testicles, confessed to whatever the Inquisitors asked, but repudiated their confessions as

Philip the Fair, king of France from 1285 to 1314

Baphomet, the Templar symbol of Gnostic rites based on phallic worship and the power of directed will. The androgynous figure with a goat's beard and cloven hooves is linked to the horned god of antiquity, the Goat of Mendes. The Tantric sexual symbolism of the figure is highlighted by the caduceus in place of the phallus. Modern exegesists see in the androgynous glyph the formula of sexual magic, symbolizing "the perfect fusion of Solar and Lunar energies in one organism."

The torture of de Molay



Templar strung up by the testicles

Clement V (Pope, 1305-1314)—Bertrand de Got, a Frenchman and former archbishop of Bordeaux—had the seat of the papacy transferred from Rome to Avignon by King Philippe le Bel. He is accused by historians of issuing "a series of bulls, perhaps the most disgraceful that ever proceeded from a vice-regent of God." Thirsting for the Templar riches, he let himself be bribed by the Knights of Saint John to share the loot. In what is described as "the most suggestive sale of indulgence on record," he offered Edward II of England full remission of his sins if he allowed reinstatement of the use of torture by the Inquisition. A month after the burning of de Molay, Clement died in agony from the loathsome disease of lupus.

soon as the torture was stopped. They were piled into wagons and carried to the fields near the convent of Saint-Antoine, where they were tortured to death by slow fire. All refused offers of pardon if they recanted, manifesting instead a constancy which, as a contemporary chronicler tells us, "placed their souls in great peril of damnation, for it led people to believe they were innocent."

Anyone who dared defend the knights was himself accused of heresy and condemned to death. When the pope, Clement V, tried to intervene on behalf of the imprisoned Templars, he was thwarted by Philip. Being a Frenchman who held court at Avignon, dependent on Philip for his freedom, the pope quickly gave in. And he too had his eye on the riches of the Templars.

De Molay, de Charney, de Peraud, and de Gonneville, the top officers of the Temple, were kept in jail for seven years, repeatedly tortured, until they confessed. Brought to trial and condemned to perpetual imprisonment, de Molay and de Charney, to everyone's amazement, arose and declared themselves guilty not of the crimes imputed to them, but of having basely betrayed the order to save their lives under torture.

On the same day, by sunset, two stakes had been erected on a small island near Notre Dame, the Island of Jews, opposite the king's gardens, piled around with burning charcoal to cause a slow death. When Grand Master de Molay saw the fire he stripped and slowly approached the patibulum, his body already so scarred that the skin of his back, belly, and thighs hung in shreds. It took all night and all day for him to die in a drawn-out, deliberate agony.

With the Temple suppressed in France, Philip seized what he could of its vast fortune. But the spirit of the

Templars was long to outlive him. In prison, de Molay is said to have secretly instituted four lodges of occult Masonry and to have designated a hiding place for much of the order's wealth. Some of the Templars who managed to escape from France took refuge in Scotland and England. In the latter the Temple survived in London's Inns of Court, keeping alive, underground, the ancient wisdom of Egypt passed on by Cathar, Manichee, gnostic, Sufi, Albigensian, and Free Mason.

With the suppression of the guilds on the Continent, the secret wisdom was no longer built into the stonework of the great cathedrals funded by the Templars. It was to survive instead in the veiled ritual of the lodge, and in the Hermetic language of the poet.

The same lawyer, de Nogaret, who prosecuted the Templars had previously seized and imprisoned Pope Boniface VIII, the shock of which so maddened the old pope he killed himself by beating his head against the walls of his room. Boniface had excommunicated Philip for contravening canon law by taxing French clergy to finance his war against England. After Boniface's death Philip, in order to have all his bulls annulled, especially *Unam sanctum* (which asserted the supremacy of the papacy over any temporal ruler), had his docile minion Clement V condemn Boniface posthumously for sodomy, murder, sorcery, and consulting with demons. Boniface was further accused by de Nogaret of murdering his predecessor, the weak-minded Pope Celestine V, by drilling a hole in the wall of his bedchamber and representing his voice as that of a messenger of God.

4. ELIZABETHAN WITS AND WIZARDS

What the Church most disliked about magic was the notion that individuals might commune directly with disembodied entities, especially to use them as intermediaries with higher or angelic realms. The priests of Rome wished to keep for themselves the sole right to deal with the beyond; and though they maintained they could invoke into their own churches a holy spirit, they considered anyone else who did anything similar worthy only of hell.

It was not that the Church did not believe in the existence of spirits that communed with mortals; the churchmen simply changed their nature from Greek δαενοης—immaterial beings or departed souls believed to hold a middle ground between man and the deities of the pagans—into Latin demons, characterized by the Church as evil and satanic.

On the authority of Aquinas, any commerce with such demons, though it might bring instant reward, was believed in the end to serve only the demons who were considered deceptive, and even if apparently good, actually only lying in wait to delude those who sought them.

Jan Wierus, one of the best known physicians of the sixteenth century, considered an originator of modern psychiatry, and famous in his time for an outspoken opposition to the persecution and torture of witches, even took a census in which he counted 7,405,926 demons, divided into 72 companies, under a captain or a prince, all commanded by *the* Evil One, a fiend, who, in the eyes of the Church, bore a relentless hatred for the human race. That these devils of an airy substance could penetrate human beings, "could take possession of a human spirit, and give rise to spectral images," Wierus had no doubt. So *all* magic, black or white, with the exception of that perpetrated by the Church in its own rites and incantations, became taboo.

This trend against magic had been growing in the Roman Church since the reign of Pope John XXII (1316–49), who issued a bull *Super Illius Specula* against the use of magic, and ordered all books on the subject turned in for burning. Accusing his opponents of heresy, sorcery and demon worship, he condemned those accused of magic, and especially those who claimed to commune with spirits, to be tortured and burned alive—a profitable

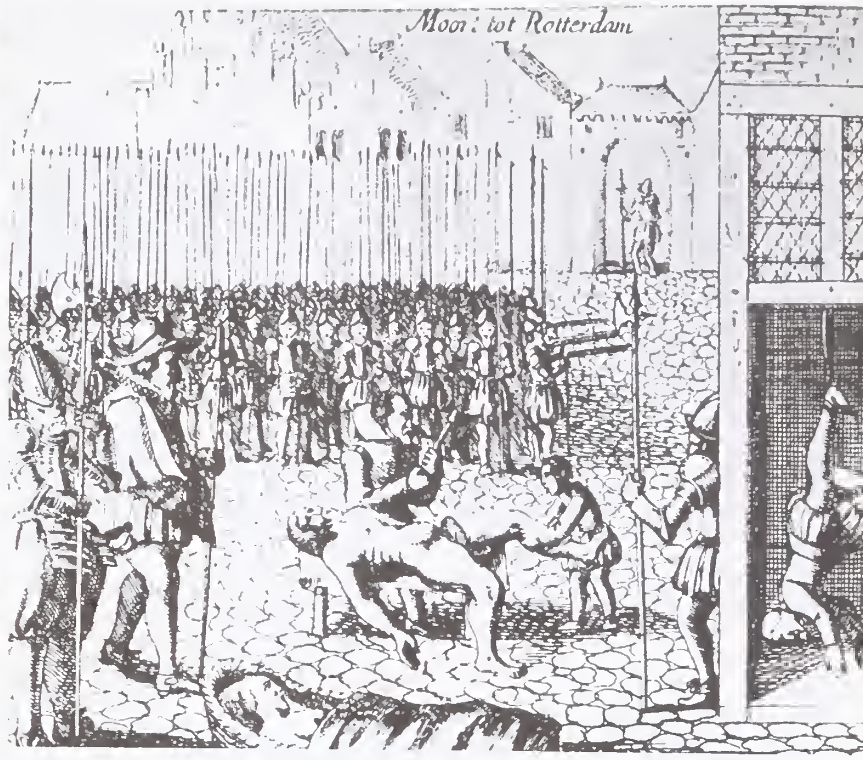
According to Saint Augustine, two realms have existed since the beginning of the world, the City of God (which includes the angels and good people) and the City of the Devil, in which he included not only demons, but the whole pagan world with its cult of demons. By magic, says Augustine, people try to compel the assistance of demons, but the demons in the end seduce people into worshiping them as gods. The magicians maintained, to the contrary, that only the pure in heart could practice the art of magic and that the demons were commanded through the power of God.

In a bull dated 1478, Sixtus IV allowed Ferdinand and Isabella of Spain "to appoint and depose Inquisitors and to possess themselves of the property of the condemned for the royal treasury." This Inquisition developed into a secret association of spies, fanatics, and informers determined to destroy freethinkers, philosophers, scholars, mystics, and anyone not crassly subservient to the "authority" of Rome. Under the system anyone could be accused by anyone, anonymously or otherwise, of suspicion of heresy. The mere accusation removed the victim from the jurisdiction of the state to that of a special ecclesiastical court. Once in the hands of the Inquisition, all friends and family had to cease association with the victim. Any "sympathy" displayed for a "heretic" was considered tantamount to heresy. There was no recourse to the civil law, no *habeas corpus*. All regular police officers, magistrates, and public officials, including governors and viceroys, were obliged to assist the Inquisition on pain of being considered sympathetic to the heretic. No one, no matter how high his station, was immune from persecution. Anyone was a heretic who spoke disrespectfully of church services, read or lent books condemned by the Inquisition, ate meat on fast days, missed mass, disapproved of anything done by the Inquisition, denied any assertion made by an Inquisitor, believed that the adherent of any other form of religion could be saved, or that the Church itself might someday be reformed and primitive Christianity restored.

process, as the property of the condemned was split between Church and Inquisition, a system of revenue legalized by Sixtus IV with a papal bull in 1478.

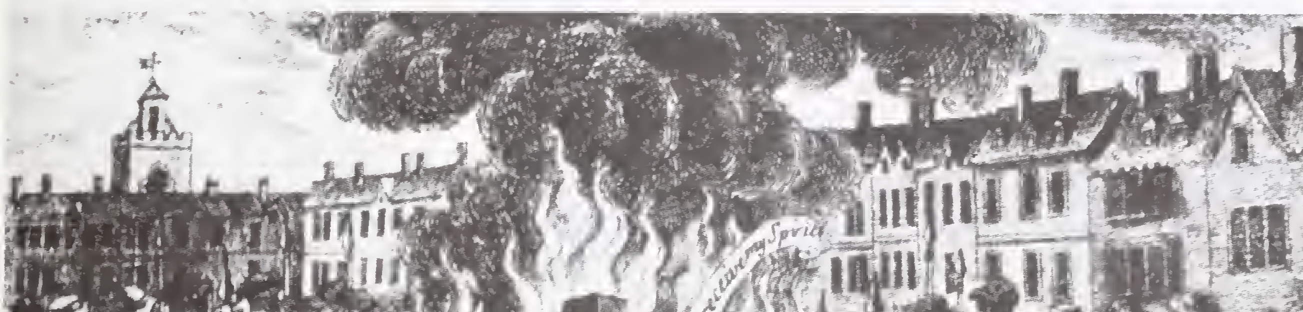
Throughout Europe the slaughter grew out of bounds. The entire population of the Netherlands was declared heretical and condemned to death by the Catholic Inquisition. Whole cities were denuded of men, the women systematically raped. Recalcitrants were buried alive, strangled, beheaded or had their breasts ripped off with red hot pincers. In Germany a hundred thousand perished; many more died in agony in Switzerland, France, and Italy; altogether more than a quarter of a million souls. Protestants were no better; Calvin and Luther, bigoted, intolerant, heartless, determined to crush what to them was "heresy" or "unorthodoxy," by the same means of physical terror employed by the Catholics. Protestant Dutchmen were crueler still in the revenge against Catholics and nonconformists.

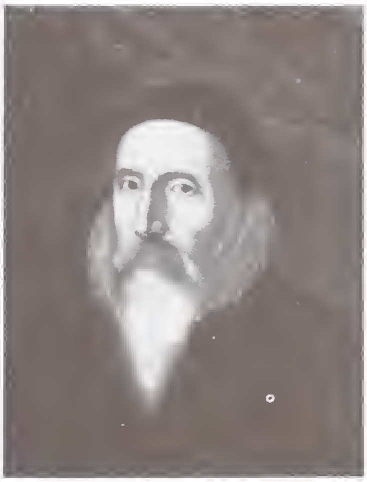
In England the butchery was not so widespread, but nonetheless fiendish. John Rogers, minister of the gospel in London, the first Protestant martyr in Catholic Mary Tudor's reign, was burned alive at the stake at Smithfield in February 1554 while his wife and nine children, one of them still at the breast, were obliged to watch. But the Spanish archbishop Caranza, who introduced the Inquisition to England, only managed to do away with three hundred victims before he was driven from the country. After Bloody Mary's death in 1558, Catholics suffered similar persecution. Dermid O'Hurley, Catholic archbishop of Cashel, was fastened to a tree, his boots filled with combustibles, and set on fire, a fire which was alternately



All over Europe Christians butchered one another in the cruelest ways in the name of God.

The burning of John Rogers





Dr. John Dee (1527-1608) was not only Elizabeth's occult adviser but acted as secret agent for the queen on frequent trips to Europe. Code-named 007, his adventures were even stranger than Bond's. A friend of Francis Bacon and Walter Raleigh, he was a member of the circle known as The School of Night, which met secretly at Raleigh's house in Dorset to discuss occult and scientific policy. A religious Hermeticist and practitioner of the religion of love and unity, Dee encouraged toleration to heal the breach in Christendom and establish a new Golden Age in which man could recover his intellectual capacity, his beauty, and his place beside God. Dee believed that through a mystical rapport with the world man could rediscover and regenerate the divine within. He was convinced that within man was an "astral" spirit, whose powers could be channeled to achieve more with science than did nature unaided. Aware, like Bruno, that all was ensouled, he believed man could do wonders with the effluvia from the stars, and that the main weapon of the magus was his own imagination. But Dee's theurgy, or invoking of spirits, got him in trouble with James I, who abhorred witchcraft, and once more he was nearly burned for sorcery.

quenched and relighted, prolonging his torture through four successive days.

But by this time the tune was changing at the court of Elizabeth. An Hermeticist follower of Pico and Ficino—very nearly burned for sorcery and treason by Mary Tudor when he cast her horoscope and that of her Catholic husband, Philip of Spain—was nevertheless convinced that Protestant and Catholic could yet be united through a return to the early Christian religion of universal love and to the more ancient Egyptian cult on which it was based. He was Dr. John Dee. Under Queen Elizabeth's protection, this venerable magus was able to propagate in England the Egyptian wisdom acquired in his prolonged and various travels in Europe, often as a secret agent of Elizabeth. Through his constant efforts, and his tutoring of the highborn nearest Elizabeth, Dee was to come close to fulfilling his dream of a united and spiritualized Christendom.

Avid for data on magic and how to perform it, Dee had gradually built up at his country house at Mortlake, 30 miles up the Thames from London, the greatest library in England, one far superior to those of either Oxford or Cambridge, with a special leaning toward the occult. On its shelves he accumulated all of Ficino's works, the greatest number of the manuscripts of Roger Bacon, the works of Paracelsus, Cardano, Agrippa, and as many of the other magicians whose treatises were available in manuscript or print. Still, he complained that no man and no book could give him the answers he required. To fill this void he "beseeched the giver of wisdom" to communicate to him what he sought through an angelic intermediary, as had been done with Abraham, and later with Ficino and Pico. Dee's plea was rewarded with the appearance of Edward Talbott, a strange sensitive who assumed the bogus name of Sir Edward Kelley, a scryer, or crystal-ball gazer, who could evoke what he called nonterrestrial entities in a black stone the size of a hat crown, specially polished and treated to catch the spectral forms of unearthly visitors.

As the operation is described by Dee, these forms would point to certain letters on various tablets and put together messages in what came to be called "Enochian," each message spelled backwards because "the words contained such potency that direct communication would have invoked forces disruptive of the whole work." Enochian, according to Dee, was a definite, though unknown, language, which he classified as "angelic." Through it, Dee developed nineteen calls, or keys, the first eighteen

With Kelly as his medium, Dee claimed he chiefly communicated with the archangels Michael, Gabriel, Raphael, and Uriel, who had instructed the Hebrew patriarch Enoch—hence Dee's use of that name for his angelic language. Enoch was said to have lived before the Flood, to have "walked with God," and been raised living into heaven after having engraved the primitive elements of religion and universal science on the two "columns of Enoch." The Book of Enoch purports to tell the story of the "sons of God" who came down from heaven to mate with the daughters of man—who then learned their secret magic. The civilizing force which the Hebrews personified in Enoch was the Trismegistus of the Egyptians, the Cadmus of the Greeks. Enoch-Hermes was said to have seen the living stones of Thebes rise up to the strains of Amphion's lyre.

By means of the "shew-stone" as a scrying instrument, Dee obtained his Enochian language from a number of charts divided into squares, each with a letter of the alphabet. Kelley would see visions of an angel pointing letter by letter as it spelled out a message.

The Enochian tablets consisted of 156 pyramids, each with over a hundred squares filled with letters, totalling 2401. Dee used one or more of these tables (as a rule 49 × 49), some full of letters, others only lettered on alternate squares. Kelley would gaze into the "shew-stone" and tell Dee the angel was pointing to a square, but not mention the letter.

being to summon various elements, the nineteenth enabling him to envisage thirty Aethyrs, or "spheres of the spirit world." So adept was Kelley at summoning spirits, he became scryer-in-residence at Mortlake at £50 a year, and the minutes of his seances, carefully noted by Dee over a period of eight years, cover several hundred pages now in the British Museum along with the original black "shew-stone."

One of the books produced by Dee on various scientific subjects, his *Steganographia,* gives details of the procedure required for summoning "angels who govern the various planets and various parts of the earth." Dee's magic was also designed to protect the soul during its upward journey through the various spirit realms toward the goal of Gnosis. And that is how Dee got in trouble with Pope Sixtus V, nearly at the cost of his life. In Prague, at the court of Rudolph II, Dee conjured spirits for a friend, Francesco Pucci, an Italian Catholic, also infused with the Hermetic ideals, who had abjured the Church. Apprised of the magical seances, the papal nuncio in Prague sent word to Sixtus, who immediately ordered Rudolph to have Dee and Kelley delivered to Rome for interrogation, an order which Rudolph would have been bound to enforce had not Dee, forewarned, wisely left Prague and taken refuge with Kelley in a castle at Tribau. Pucci, who had decided to return to the Church to explain his ecumenical, Hermetic views to the religious authorities in Rome, foolhardily traveled under the nuncio's safe-conduct, only to be seized, condemned, and promptly beheaded as a heretic.

Had Sixtus known of Dee and Kelley's next adventures in the realm of angelic or demonic forces, he would, doubtless, have been even more outraged. Kelley, suspicious that the manifesting spirits might—as the papal nuncio had insisted—be demons, and that he might be lured to his destruction, wished to desist. Dee, considering himself a pious man and a devoted Christian, was determined to continue obeying the messages from what he considered angelic voices.

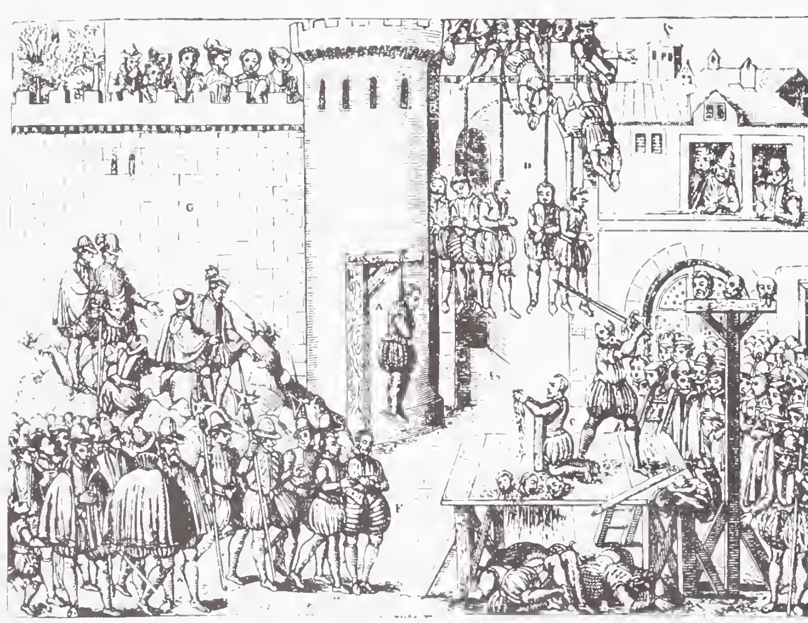
Queen Elizabeth of England had a double agent at the Vatican, appropriately known as le Chevalier Carré, and the perfidy of Sixtus V is exemplified by his having kept Elizabeth informed by le Carré of every detail of the organization of the great Spanish Armada for the invasion of England. At the same time Sixtus cunningly offered Philip II of Spain a million gold scudi to be paid as soon as he had successfully landed on the territory of "the bastard heretic" in England, hoping so to weaken Philip by a "Bay of Pigs" landing that Sixtus could, unopposed, seize from him a plum he longed for: the Kingdom of Naples.

The ensuing situation turned into a limited agape, or early Christian sharing, with overtones of experiments in Tantric sex, when—as reported in chronicles of the time—Kelley "cast a lustful eye on Dee's shapely vivacious young wife." Speaking through Kelley, a spirit named Mandini told both men "they had their wives in such sort that they should use them in common." When Dee asked Mandini if that meant spiritual or carnal copulation, the answer was "both." At dinner the decision was conveyed to the ladies. Surprised or not, they were evidently willing to comply; and for several months the quartet enjoyed a joint relationship until Kelley went back to Prague to be knighted in return for the promise of producing for the Bohemian sovereign alchemical gold by means of a red dust Dee had found in the grave of a bishop at Glastonbury Abbey.

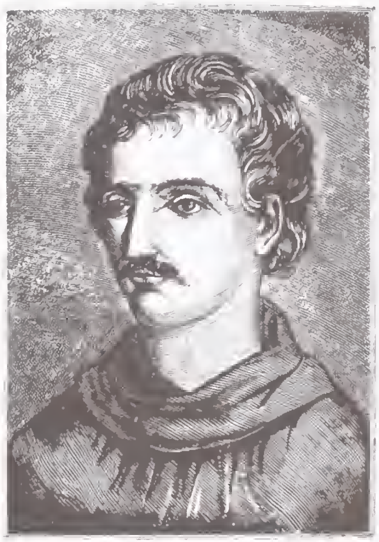
Back home at Mortlake, Dee found that a mob, accusing him of necromancy and of desecrating graves in order to have intercourse with spiritual essences, had ransacked and vandalized his great library, which caused him to compare the persecution he was suffering to the "raging slaunder of the Malicious Ignorant" endured by his young mentor Pico della Mirandola. But once more under Elizabeth's protection, Dee's house resumed its function as a meeting place for that distinguished cabal of English Hermeticists close to the Crown, such as Sir Francis Bacon, the Earl of Southampton, the Earl of Leicester and Sir Philip Sydney to whom Dee had been tutor. With great subtlety the group was using Shakespeare's plays as a means of political and religious pamphleteering for a return to the Hermetic values of Egypt, the secret wisdom of which they had been nurtured on by Dee, and by studying law in the old Temple, or the Inns of Court. As members of the Queen's Privy council, they too, if only to save their necks, wished to avoid the ghastly religious intolerance and religious warfare which was rending Europe.

To add his wisdom to this clandestine group of wits, there came from Italy perhaps the greatest philosopher of the sixteenth century, a fiery "heretic" who was to pay with his life for overtly challenging the Church of Rome whom he accused of having missed the secret message in the Egyptian glyphs adorning the obelisks and of having fallen from the path of the ancient wisdom.

Shortly before Sixtus V had come to the throne, Henry III of France, anxious for the hand of Elizabeth, had named as ambassador to the Court of Saint James's, Michel de Castelnau, marquis of Mauvissière, who, according to his peers, was a "remarkable and attractive man whose humanity transcended the religious cleavages of the times." Ten years earlier, Mauvissière had been sent by Henry's elder brother, Charles IX, equally interested in Elizabeth's hand, to try to pacify the outraged English queen after the ghastly Saint Bartholomew massacre, when a hundred thousand French Protestant men, women, and children had been cold-bloodedly ambushed and butchered by bigoted Catholics. This time, Mauvissière chose to take with him as a companion to the London of Shakespeare an Italian ex-monk, Giordano Bruno of Nola.



On the day of Saint Bartholomew, August 24, 1572, French Catholics ambushed and murdered all the French Protestants they could seize—men, women, and children—even ripping infants from the womb to prevent any survivors. As blood flowed in rivers and the streets were choked with corpses, the Catholic murderers went about the slaughter with white crosses on their hats and capes to be distinguished from their victims. In Rome the news was greeted with great feasts and gaieties.



Philosopher, poet, dramatist and intrepid supporter of intellectual freedom, Giordano Bruno obtained his doctorate in philosophy at Toulouse. With vast erudition, a vivid imagination, and originality of thought, Bruno lashed out with subtle irony and biting sarcasm against pedants in religion, science, philosophy or letters. In England, Sir Philip Sidney, who had studied jurisprudence at the University of Padua and was imbued with a love of Italian culture, may have financed the publication of Bruno's Italian works. Bruno dedicated to him his *Spaccio della bestia trionfante* and *De gli eroici furori.* Of Bruno's influence on contemporary drama, his biographer, Vincenzo Spampanato, points out that no less than ten of Molière's plots were influenced by Bruno's comedy, and he argues that half a dozen of Shakespeare's plays are strongly reminiscent of Bruno's work.

Bruno's reputation for dangerous views on matters spiritual had preceded him to England. Elizabeth's chief of intelligence, Sir Francis Walsingham, received a note from the British ambassador in Paris, Sir Henry Cobham, that "Dr. Jordano Bruno Nolano, a professor of philosophy, intendeth to pass into England whose religion I cannot commend." Indeed, in her *Bruno and the Hermetic Tradition,* Frances Yates—that remarkable historian of the Elizabethan age—suggests that the Italian was specifically brought to England on a secret political assignment of an obviously Hermetic or anti-Jesuit nature.

A small, thin man, with a meager dark beard, scornful of his attire—three buttons off his coat and hose pieced together from bits of his abandoned Dominican gown—Bruno seemed hardly presentable in society; yet this defrocked priest was to become such an intimate of the Hermetic conspiracy formed around the wits behind Shakespeare that he turned up in *Love's Labor's Lost* as the character Berowne. Charged with unorthodoxy for reading Erasmus in the toilet of his Dominican monastery in Naples, Bruno had escaped across the Alps to France to avoid being tried on a more serious count of heresy. What threatened to damn him was his conviction that a return to the Hermetic wisdom of the ancient Egyptians was the sole remedy against the fratricidal warfare ravaging Europe. An opinion identical with that of John Dee, who Peter J. French, in his biography of the old magus, suggests "was perhaps the only person in England who could have prepared the Sidney circle for that wild but brilliant ex-friar."

The England to which Bruno came was a haven for foreigners persecuted for their religious beliefs. Sensitive Elizabethans had been looking, since the guidance of Dee, to Renaissance Italy for the light of Hermeticism. Scores of distinguished Italians had taken refuge in London, including another ex-Dominican monk, Matteo Bandello, whose *Novelle* formed the basis of *Romeo and Juliet* and *Taming of the Shrew.* Bruno was quickly introduced by Mauvissière into the heart of the Shakespeare cabal, and was quickly patronized by Philip Sidney, by Walter Raleigh, who had been educated at Oxford with Sidney, and by Sidney's uncle, the queen's beloved Earl of Leicester, then chancellor of that stronghold of conservative Aristotelian study, Oxford University.

Bruno, who considered Aristotle *"stupidissimus omnium philosophorum,"* paralyzed his Oxonian audience with astonishment and indignation by expounding Hermetic conceits and by supporting what the ancient Egyptians

Nicolaus Copernicus (1473-1543), Polish astronomer, canon of the cathedral of Frauenburg, practiced medicine, giving his services free to the poor. His *De revolutionibus orbium coelestium,* dedicated to Paul III, described the sun as the center of a great system, with the earth as one of several planets revolving around it. But the first printed copy only reached him on his deathbed, saving him from the acrimonious debates of those who wished to refute a heliocentric system known to the Egyptians for several thousand years.

had known all along, Copernicus's proposition that the sun and not the earth was the center of the solar system, flatly contradicting Aristotle's notion of a finite universe constructed out of fixed geometric circles. Bruno insisted instead that the universe was infinite, that the sun was merely another star, and that stars were not fixed, but in reality suns, each with its own train of planets, cycling through the universe, "like great animals, animated by the divine life"—all of which had been standard to the ancient Egyptians, but denied and buried by the priests of the Catholic Church.

Following the Hermetic tradition, and the lead given by the magician Cornelius Agrippa, Bruno said he considered it unreasonable to suppose that the stars which give life and animation to all should themselves be without life and animation. Laying the Hermetic vision before his audience, the ex-monk allowed that he found it hard to believe any part of the universe could be without soul-life, without sensation, without organic structure. "From this infinite All, full of beauty and splendor, from the worlds which circle above us, to the sparkling dust of the stars beyond, the conclusion is drawn that there are an infinity of creatures, a vast multitude, which, each in its degree, mirrors forth the splendor, wisdom, and excellence of the divine beauty." Taking Copernicus's revalidation of the sun as the center of the solar system, Bruno used it to herald the dawn of a new age, the return of the Egyptian sun god Horus, and of the magical sun-worshiping religion of ancient Egypt, a true Aurora for philosophy after its burial in the dark ages of corrupted Christianity.

The Oxford academies received Bruno less than warmly. His lectures led to so much acrimony, he was forced to decamp in haste. For his part, the impression left on him by members of the university was that of a "pedantic pigheadedness fit to try the patience of Job." He accused the pedants of using empty words with which to mouth a sterile philosophy in language both trivial and superficial, without magical or incantatory power, instead of appealing to the magical hieroglyphic language of the Egyptians with its wisdom of the ages. As Bruno put it, by using the symbolic language of hieroglyphs, the Egyptians had managed to capture with marvelous skill the language of nature. "Later when letters of the kind we now use were invented by Thoth, or some other, it brought about a great rift both in memory and in the divine magical sciences." The most essential element in Bruno's outlook, says Fances Yates, was to find "these living 'voices,' signs, images, seals, to heal the rift in the means of communica-

In *Del'infinito universo et mondi* Bruno goes beyond Copernicus in his speculation about the nature of the universe, attacking the foundations of Aristotle's cosmology. And in *La cena de le ceneri* Bruno, expanding the Copernican theory, inveighs against contemporary English scholars, especially those at Oxford whose world he describes as "a constellation of the most pedantic, obstinate ignorance and presumption, mixed with a kind of rustic incivility, which would try the patience of Job." In his *Spaccio* Bruno reveals his strong attraction to Egyptian religion, condemning the hypocrisy of sixteenth-century princes who, with their sycophants, had created a "faithless, dissolute, irresponsible and indolent upper class." But for Queen Elizabeth, whom he visited frequently with Ambassador Castelnau, Bruno had great admiration because of her "judgement, wisdom, council and rule."

tion with divine nature which had been introduced by pedantry." In some trancelike experience, Bruno wished to unify through these "voices" the universe as reflected in the psyche "and thereby obtain the Magus' powers to live the life of the Egyptian priest in magical communion with nature."

And it is here that Frances Yates finds a link between Bruno and the Shakespeare texts where the English poet, rather than using the vacuous language of the pedants, searches for "significant" language with which, in Bruno's words, "to capture the voices of the gods." It warrants, she says, an entirely new approach to the relation between the two poets, both of whom subscribe to the same Hermetic philosophy championed by Dee.

In the works Bruno wrote in Italian during his stay in London, especially the *Cena delle ceneri* and the *Spaccio della bestia triumphante,* he preached a general reformation of the world based on a vision of nature achieved through Hermetic comtemplative exercises—a return to the magical metaphysical communion with other dimensions of consciousness, as practiced in Egypt. The basic theme of Bruno's *Spaccio* is the glorification of the magical religion of the ancient Egyptians, as described in Ficino's translation of the *Asclepius*. In his *De immenso,* Bruno attacked those who had destroyed this Egyptian religion, spreading instead cruelty, schism, evil customs, and contempt for the law. Like Ficino, Bruno picked up the gauntlet of the Renaissance magus in his stand for the dignity of man, for liberty, for toleration, for the right to say what he thought, irrespective of ideological censors.

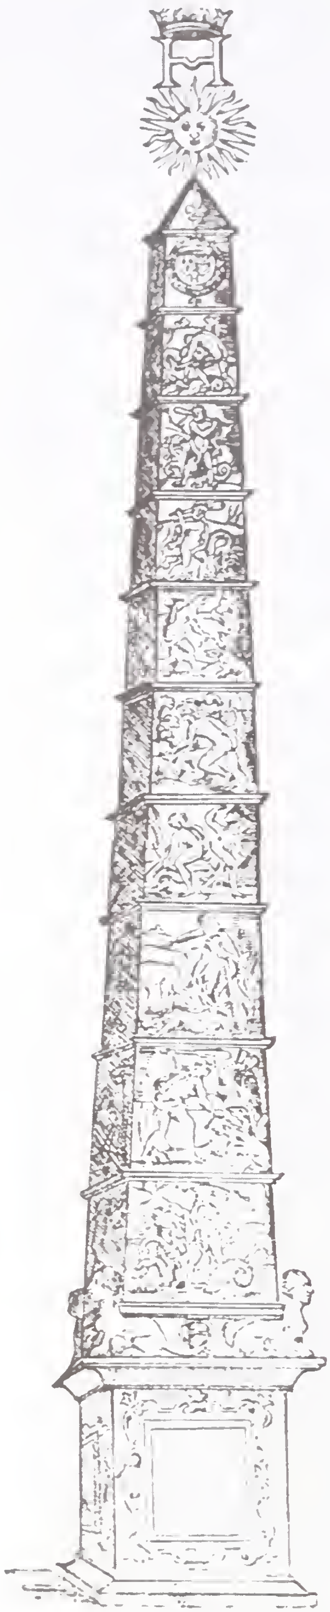
Bruno upheld the value of both "heroic" and "profane" love, as opposed to what the pedants had made of Christianity. For Bruno, all religious persecution, all war in the name of religion, broke the law of love. Varying the Renaissance theme of Platonic love treatises, Bruno opposed to profane love heroic love, or "frenzy" as he called it, pointing out that heroic love, as the Gnostics practiced it, had a divine object and led the soul in a gradual ascent from the sense world through intelligible objects toward the divinity.

As Yates sums it up, Bruno's fundamental ideal was a God-informed, God-governed universe, a universe embodying power, wisdom, and love, a universe essentially accessible to the human consciousness, partially now and progressively more so with the development of that consciousness. In a cabalistic sense, Bruno saw love as the living virtue in all things, one which the magician could intercept to lead him up from lower-level love to the supercelestial reality of divine love.

As for sexual love, far from condemning it, Bruno believed that man should make use of *all* his faculties. In an address to Philip Sidney he wrote: "It is not for me to oppose the sacred order of nature . . . God forbid that such a thought should ever enter my head . . . I never had a desire to become a eunuch. On the contrary I should be ashamed if I agreed to yield on that score were it only a hair to any man worth his salt in order to serve nature and God." Admitting that he had not managed to possess quite as many women as King Solomon, Bruno added that it had not been for lack of trying. And he did not believe in being tied down. "For I am certain that all the laces and tags that all present and future dealers in laces and tags have ever been able, or will be able, to plait or knot, even though they were aided by death itself, would not suffice for that purpose."

When Bruno left England, to resume his wanderings through Europe, he preached, as Yates notes, a kind of Egyptian Counterreformation, prophesying a return to Egyptianism in which the religious difficulties of the age would be dispelled. There would follow a moral reform with an emphasis on social good works and an ethic of social utility. Breaking with the Christianity of all the Churches, Bruno favored, as had the Gnostics, the Cathars, and the Albigeois, a purer religion which he considered the very essence of original Christianity.

The trouble, says Yates, is that by his rejection of orthodox Christianity and his enthusiastic adoption of Hermetic Egyptianisms, Bruno moved toward a form of



Obelisk raised for Henri IV on the occasion of his triumphant entry into Rouen in 1596.

magic which went beyond the mild "Christian" variety of Ficino, designed to reunite the soul with the deity. Bruno aspired to what she calls "a more medieval necromancy," one in which he wished to expand Ficino's magic into a full restoration of the magical religion of Hermes's *Asclepius,* a return, in Yates's eyes, to an old-style, frankly "demonic" conjuring. Hence the rub, as it had been for Ficino and Pico, and for Dee. The very heart of this magic (considered deadly dangerous by the Church) was not only the summoning into manifestation of spiritual entities, but the raising of consciousness to an ecstatic vision by means of sexual arousal, awakening the dormant serpent of fire. Somewhere Bruno appeared to have learned the secrets of Tantric sex.

In his *Opera Latine conscripta* he makes an attempt to outline a technique for controlling all emotions which is explicitly based on sexual attraction. And in *De vinculis in genere* he discusses "linking" through love or sexual attraction. As Yates cautiously remarks: "the problem can be put in terms of Eros." In the *Pimander,* in the Hermetic account of the creation of the magus man, this half-divine being came down to earth because he loved beautiful nature and was united to her in a passionate embrace.

But the world was not ready for Bruno's Egyptian Renaissance with its pagan love of nature—a nature in which man could find the image of a loving deity. Catholic and Protestant both turned on Bruno in disgust. In Wittenberg he was warned to leave town. From Marburg he was obliged to escape the malevolence of the rector of the university. In Helmstedt he was excommunicated from the Reformed Church. Frankfurt refused to let him lodge in the town, and the prior of the Carmelite convent, who did give him hospice, scathingly described him as "writing all day or walking up and down filled with fantastic meditations."

By this time Bruno had developed his life-long study of the art of memory into a technique for training the imagination into acting as the instrument for obtaining the magical power with which to communicate with "angels, demons, the effigies of stars, and the inner 'statues' of gods and goddesses in contact with celestial things." Here the hieroglyphs on the obelisks of Egypt took on a function as magical keys to another dimension. To Bruno the glyphs were symbols which, when imprinted on the memory through an imaginative effort, enabled man to recover knowledge of his true self, remember past lives, his spiritual essence, and become again one with the universe. But his opponents continued to dog him until in Zurich he received the invitation from an apparent support-

Henry IV (1553-1610), King of France and of Navarre, reared as a Protestant, only saved himself from the Massacre of Saint Bartholomew by announcing himself a Catholic. Returning to his faith he was excluded from succeeding Henry III, until he abjured his Protestantism and entered Paris in 1594. Excommunicated by Gregory XIV, he was assassinated by a Catholic fanatic, François Ravaillac.

Gregory XIII (Pope, 1572-85) joyfully receiving the severed head of Protestant leader Gaspard de Coligny, first victim of the Massacre of Saint Bartholomew, which Gregory celebrated in Rome with a festival of public thanksgiving

er, a young Venetian nobelman (Zuane, or Juan, or Giovanni Mocenigo), to visit Venice and there teach him the art of memory as well as any other magical tricks he might be able to impart, presumably Tantric and sexual.

Somewhat foolhardily Bruno agreed to return to Catholic Venice in 1591. Sixtus V, the city's old Inquisitor, had been dead a year, and the atmosphere appeared to have softened sufficiently for Francesco Patrizi's *Nova de universalis philosophia* to be published, containing a new edition of the Hermetica along with a dedication to the new pope, Gregory XIV (Nicolò Sfondrati, 1590-91), in which Patrizi urged the pontiff to have taught everywhere and especially in the schools of the Jesuits this peace-loving Hermetic religious philosophy. But Gregory, subservient to Philip II of Spain, was not that liberal, and replied by excommunicating the one sovereign in whom Bruno had put his faith as a potential Hermeticist, Henry IV of Navarre, who had projected a unified Christian Europe. Only Henry's eventual murder by an aspirant Jesuit was to put the quietus on another Nolan dream.

In Mocenigo's Venetian house, Bruno found his host's behavior peculiar. As impatient with ignorance as he was scornful of prejudice, Bruno argued with his pupil, and decided to return to Frankfurt, where his extraordinary work *De triplici minimo* had just been published, and where he wished to have more manuscripts put into print. Mocenigo, jealous that Bruno might impart his secret knowledge to others, threatened to have the ex-monk detained by the Holy Office—no idle threat, as Mocenigo had once been attached to the Venetian Inquisition.

That Mocenigo was looking for a way to trap his teacher is clear from the fact that he had collected from Bruno's works and conversations a mass of testimony bearing on his heretical beliefs, which he turned over to the Father Inquisitor of Venice. When Bruno continued to insist on leaving, Mocenigo had a band of toughs rouse him from sleep on May 23, 1592, and drag him to a Holy Office dungeon. Though he did not know it, for Bruno it was to be the end of freedom.

The Venetian procurator, Federico Contarini, explained to the doge that Bruno's crimes of heresy were most serious, "though he is otherwise one of the most excellent and rare talents that can be desired, and of exquisite doctrine and knowledge."

Brought before the Inquisition, Bruno made a confession of faith: "I presuppose an infinite universe, a work of infinite Divine Power, because I consider it unworthy of the Divine Power and Goodness to produce only this world when it could have created infinitely many worlds similar to our earth, which I understand along with Pythagoras, to be an orb similar to the moon, and the other planets and stars, inhabited worlds, the immesurable number of which, in infinite space, forms an endless universe." This statement alone, in direct contradiction to the concepts of Aristotle and Ptolemy, was considered by the officials of the Inquisition "altogether the most absurd of horrors" (*horrenda prosus absurdissima*), and was enough to condemn the prisoner as heretical.

Cardinal Santaseverina, the Supreme Inquisitor of Rome, who had declared the massacre of St. Bartholomew "a glorious day, exceedingly agreeable to Catholics," ordered Bruno conveyed to the Holy See to stand trial before the supreme tribunal of the Inquisition, accused formally of heresy and of having composed various books in which he praised the queen of England and other heretical persons. Convinced that if he could reach the font of authority at the Holy See, he would eventually not only be understood, but even honored, and his writings accepted, Bruno seems to have welcomed the transfer to Rome.

In February 1593 he passed through the dungeons of the Roman Inquisition, where he was visited by his judges, the lord cardinals who cross-examined the prisoner on his heresies and interrogated him concerning his necessities. As a result, he was provided with a cloak, a pillow, and a copy of the *Summa* of Saint Thomas Aquinas. With no pen or paper on which to compose his defense or make use of his talent for writing, Bruno was left to rot, his verbal

petitions unheeded. Four slow years went by before the prisoner was again visited by the cardinals, in 1597. After another cross-examination and probable torture, they told him he would have to relinquish "his vanities concerning diverse worlds." On January 14, 1599, eight heretical propositions were extracted from Bruno's works and read aloud to him in prison. He was given six days in which to recant. When faced with a decision, Bruno said simply: "I ought not to recant; therefore I will not."

He agreed, however, to accept the personal decision of the pope as to whether his system of thought was or was not heretical; but he insisted on being allowed to defend his views in writing. Pen and paper were provided. In his "Memorial to the Pope," Bruno claimed that his opinions had been unadroitly excerpted from context by ministers of the Holy Office, that he was prepared to give an account of all his writings and defend them against any

Clement VIII (Pope 1592-1605), renowned for his piety, declared that it was sinful to accept the smallest degree of venereal pleasure, and that anyone should be denounced to the Inquisition who maintained that kissing, touching, and embracing for the sake of sexual pleasure were not grievous sins. The sexual act had already been declared sinful in itself by Saint Augustine, as "the essence of original sin was the concupiscence which accompanied the act of generation." Priests were given explicit instructions on how to punish sexual infractions of all imaginable sorts. A raped girl could douche herself only during the first ten hours, or risk Hell. Once conception had taken place, she could do nothing. A man was not to masturbate even to produce sperm for a doctor; both would be commiting a deadly sin.

Francesco Romolo Bellarmino (1542-1621) entered the Society of Jesus in 1560 and was made a cardinal in 1599. As a consultant to the Holy Office (or Inquisition) he took a prominent part in the first examination of Galileo's "heretical" writings. A strong supporter of the Jesuits at the Vatican, Bellarmino came to be considered the greatest Roman Catholic controversialist of his day.

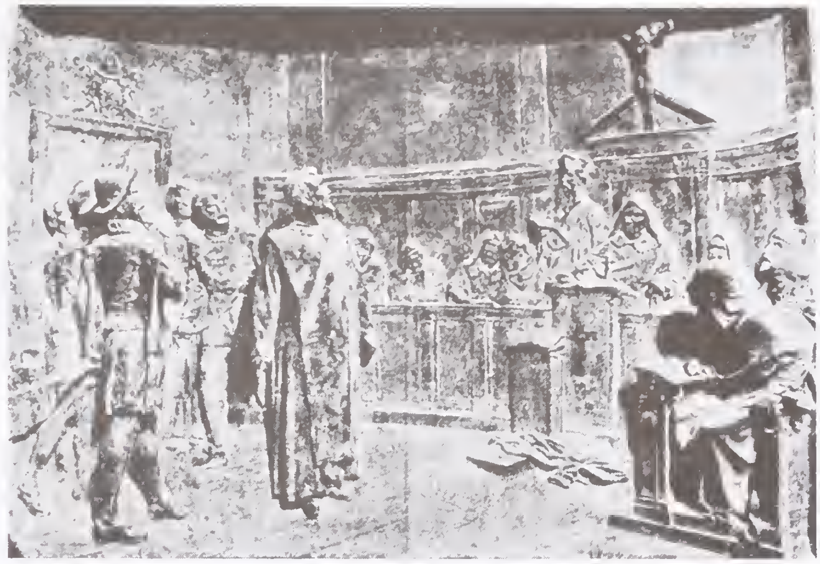
theologian. However, he would only abide by the opinion of the pope concerning things said or written by him, or by sacred canons if it should be proved there was anything in his writings or sayings contrary to them. Bruno further declared that if the Apostolic See and His Holiness definitely declared his eight propositions to be heretical, if His Holiness knew them to be so, or by the power of the Holy Spirit declared them to be so, then he was disposed to retract.

Along with the memorial went a long written defense of his position addressed to the new Pope, Clement VIII (Ippolito Aldobrandini, 1592-1605), who had succeeded Gregory XIV and had just ordered the beheading of Beatrice Cenci. But Clement, who has been described by the French author R. Gagey as "more audacious than Boniface VIII, more dominating than Sixtus V, and more perfidious than Alexander VI," was not even going to see Bruno's paper. On January 20, 1600, Bruno's "Memorial to the Pope" was opened by the Inquisition, but was apparently not passed on to the pontiff.

On February 4, Clement decreed before a full Congregation of Cardinals that if Bruno recognized his propositions as heretical, well and good; if not, he was to be condemned after forty days "to the treatment usual for impenitent and pertinacious persons." At his final trial, Bruno was pathetically certain that if only he could make his judges understand what he had to say, they would welcome his philosophy. In the great hall of the consistory with its baroque gilding and its damask hangings, Bruno knelt, pale, thin, while the judges remained obdurate and negative, especially Cardinal Bellarmine, who for twenty years embodied the Curia's opposition to science, and now did his best to secure a condemnation. After a short delay, the inquisitional notary pronounced sentence of death upon Bruno, ordering him turned over to the civil authorities for execution. Bruno heard the fatal words, unflinchingly, then rose and in a clear voice replied: "It may be that you fear more to deliver this judgement, than do I to hear it."

On February 8, the condemned man was subjected to the demeaning ritual of deconsecration of a former monk, and transferred from the ecclesiastical to the secular arm of the law with the cynical request that he be punished "as mercifully as possible and without shedding of blood"—the Church's sophistical formula for being burned alive at the stake. Locked in the Tor di Nona jail, near Sixtus's new bridge across the Tiber, Bruno awaited execution. As Rome at that time was full of Catholic

Bruno rebutting his judges in the Court of the Inquisition



pilgrims from all countries, the Inquisition prepared a monstrous spectacle for the occasion. Faggots were stacked around a stake in front of Pompey's theater in the Campo dei Fiori.

Early on the morning of February 17, Bruno was made to attend mass in the prison chapel and then fed a frugal breakfast of sweetmeats and wine from Ischia, so as not to faint on the way to the scaffold. At last the ghastly procession started from the prison of the Inquisition, as Bruno was led out through a jeering, leering crowd of Catholics come to see a "Lutheran" heretic meet his deserved doom. Accompanying the victim were the hooded Brothers of the Holy Sepulcher, chanting a lugubrious litany, and sardonically carrying green candles to symbolize the three theological virtues: the wick for faith; the wax for hope; the flame for charity.

Rome's Campo dei Fiori, or Field of Flowers, where Bruno met his death

Bruno given to the flames

With a firm step Bruno mounted the *patibolum,* consoling himself no doubt with his own gnostic dictum: "He who still fears for his life has not yet made himself one with the godhead." An eyewitness described the victim being bound to the stake, around which wood was piled. As the fires were lit, the "mystical poet, whose love encompassed the entire universe," turned his head from the proffered consolation of a crucifix and delivered his final words: "I die a martyr, willingly."

Bruno's body was burned and his ashes scattered to the winds so that not a trace be left on earth of any of his corporeal shell. But, judged from his own words, death to Bruno was only a slightly greater change than takes place every day in our bodies, in no way a diminution of life, but an exaltation of it: "We suffer a perpetual transmutation, whereby we receive a perpetual flow of fresh atoms, while those that we have received are leaving us." In his *Cabala del Cavallo Pegaseo* Bruno had openly accepted the reality of reincarnation, a tenet condemned by the Church since the Council of Nicea.

The Church, not satisfied with killing its victim, set about ruining his reputation, both as a thinker and as a man. All of Bruno's works were placed on the Index of forbidden reading; as many as possible were burned. For two hundred years Bruno's reputation for atheism, impiety, and misconduct was such that his writings were completely taboo, not only among Catholics, but even among Protestants. As late as 1830 they were forbidden to be shown in the public library of Dresden. Many were lost or remained unknown in archives of the Inquisition. Of those known to exist, no complete or reasonably accurate edition was published for more than two centuries. Yet the Hermetic tradition continued, and sensitive souls became aware of the magnitude of Bruno's contribution to philosophy. Through his intuition and vision he had anticipated a number of ideas which others in later centuries were to adopt and develop on the basis of more solid evidence.

The doctrine of evolution, the progressive development of nature, an idea unknown to classical philosophy, was first pronounced by Bruno, not vaguely or partially: he extended its laws to the inorganic as well as the organic world, maintaining that unbroken line of evolution from matter to man which only modern science later began to recognize.

In a number of ways Bruno's cosmology anticipated the conception of the universe as it was to be developed by modern physics and astronomy. In her recent thesis on Bruno, Dr. Ksenija Atanasijevic says: "Bruno's contribution to the development of subsequent philosophy and modern astronomy is beyond proper evaluation not only in terms of his conception of the infinity of the universe; with his comprehensively conceived and elaborately argued doctrine of the triple minimum he is also one of the leading forerunners of later monadology, atomism and the teachings about the discontinuity of space, time, motion, and geometrical bodies. . . . Bruno laid the firm foundations upon which was to rise, in the course of time, the magnificent edifice of new atomic science."

And she concludes: "By pointing out the complexity and non-uniformity of the ultimate parts of substance, Bruno revealed not only the unfailing correctness of his intuition but also the whole depth of his philosophical mind and thus became the illuminated precurser of later atomists and monadologists as well as the founder of geometrical finitism."

Philosophically, what Bruno died for was the belief that man could stand again "under the faithful guidance of the eye of the divine intelligence," and, with the powers within him, by the gnostic ascent, recover his knowledge of an infinite god in an infinite universe, a divinity, as Bruno reminded his audience, not far distant, but within us, its center everywhere, its circumference nowhere.

Holy Mountain of Initiation

5. SUB ROSA CRUCIS

With the death of Elizabeth of England in 1603, there was no monarch left to guarantee an original or outspoken thinker or follower of the Hermetic Egyptian wisdom preached by Bruno; so it went underground to be pursued *sub rosa*. Francis Bacon and John Dee ran into trouble with Elizabeth's successor James I, and in Bohemia, Rudolph II was forced by the Jesuit spearhead of the Counter Reformation to flee his ideal Hermetic court at Prague, leaving his library and laboratory to be sacked and destroyed. As Yates points out, the Egyptian philosophy, freely debated in the fifteenth century, struggling for supremacy in the sixteenth, was relegated, in the seventeenth, to the care of a minority of hidden initiates: the Rosicrucians.

Francis Bacon, Baron Verulam, and Viscount St. Albans (1561-1626?). Philosopher and statesman, lord chancellor of England, formulated and proclaimed the inductive method of modern science in opposition to the *a priori* method of scholasticism, the official philosophy of the Roman Catholic Church.

To perpetuate the Egyptian heritage as outlined by Ficino, Pico, Dee, and Bruno, there sprang up in the German states, or was revived there, a restricted society of conspirators announcing themselves to the world as the Brothers of the Rosy Cross. Pamphlets detailing their tenets appeared from secret presses, known as the *Fama Fraternitatis,* the *Confessio Fraternitas,* and *The Chemical Wedding of Christian Rosenkreutz.* Considering themselves good Christians, the brothers addressed the intelligentsia, warning against egotism and materialist covetousness, suggesting that it is man, not the Creator, who causes the bloodshed which ravages the world.

Johann Valentin Andreae

Some occultists would have it that Francis Bacon, as the reincarnation of Christian Rosenkreutz, reconstituted the fraternity in England whence he took it to Germany after a faked death, to reappear as Johann Valentin Andreae, presumed author of the three Rosicrucian manifestos. What actually happened has not been resolved historically. It is certain, though, that Bacon was involved with the brotherhood, which aimed to revive and spread throughout Europe and the world the wisdom of Hermes Trismegistus. Overtly in his *Advancement of Learning,* written shortly after Elizabeth's death, and in *Novum Organum* fifteen years later, Bacon professes the ideal of a reconstruction of science. In his "posthumous" *New Atlantis,* he sets forth the dream of an equally ideal religion and scientific society, and promises more, cryptically hinting on the title page that *"Tempora patet occulta veritas,"* or "with time, the hidden truth will out."

Christian Rosenkreutz, legendary founder of the Brotherhood of the Rosy Cross, is said to have traveled to Damascus, city of 300 mosques, to read the sacred books of the Sufis and acquire the wisdom of a mystic and cabalist. In Fez, with its 600 fountains, he went to learn magic from a school of astrologers, and how to communicate with elementals so as to govern the hidden forces of nature and open access to the realm of angels. Back in Germany with the mysterious book of *"M,"* he is reputed to have founded a brotherhood, originally inspired by Thothmes III, to give to European society the light and knowledge of the mysteries of Egypt, and so spread the doctrine of tolerance and the brotherhood of man. The Brothers' tenet that through love it was possible to be reabsorbed into the divine essence begat such virulent opposition it obliged the Brothers to go underground, communicating thereafter through allegory and cipher.

The *Chemical Wedding of Christian Rosenkreutz,* an Hermetic fantasy, suggested that real alchemy deals not with the transmutation of base metals into gold, but with regenerating the human soul. Its attribution to Johann Valentin Andreae is contested on the grounds that he would have been a mere boy at the time of its appearance; a more likely author is believed by occultists to be Francis Bacon.

The *Fama fraternitatis* recounts in allegory the rediscovery of an ancient philosophy, related to medicine and healing, the revelation of which would bring about a general reformation and advancement of learning leading man to an understanding of his true nobility and worth. In terms similar to those of Dee, Bruno, Ficino, and their antecedents, the Brothers of the Rosy Cross called upon the learned and the great of Europe to support them in a quest for a deeper understanding of nature, urging the world to desert the false philosophical teachings of Aristotle and the popes, and abandon the false medicine of Galen. The objective of the Brothers is de-

The Rosicrucian program was to reconcile Christianity with science, a program to be carried out by an elite of the wise, leading to a regeneration of religion and society. The intent was to revive what they considered to have been original Christianity, along with the healing talents of the therapeut and the Egyptian magical communion with spirits, plus the technique of the alchemist, in whose philosopher's stone they saw tne human heart, transmutable into a golden light. In nature, the Rosicrucian saw all around him the hieroglyphic symbols of divinity, crying out to be deciphered—the same nature, extolled by Bruno, in which he preached that all that there is to be known can be read.

But the Counter Reformation, spearheaded by the Jesuits, was in full swing. Reaction from Rome was violent: the Hapsburg-Jesuit alliance was on the point of achieving a universal victory of Catholicism over the Reformed Churches, loosing a fresh wave of persecution across Europe. As Catholics gained the upper hand, sorcerers and magicians were again burned by the thousand. Libraries of rare books and manuscripts were pillaged and given to the flames. It got so bad that the Rosicrucian Brothers issued a poster announcing they were leaving the fray to retire to Tibet. Whether they did or not, the Hermetic wisdom of Egypt disappeared from sight to find temporary succor with the strangest of foster mothers: the very organization devoted to its destruction: Ignatius Loyola's Society of Jesus.

Just as the French Jesuit François Garasse was accusing the Rosicrucians in 1623 of being wicked sorcerers, dangerous to religion and the state, "witch-like characters belonging to a diabolical secret society who should be broken on the wheel or hanged on the gallows," a twenty-year-old postulant Jesuit, Athanasius Kircher, unaccountably found himself holding the torch of Hermes. Asked to find a book in the library of the German Jesuit college in which he was a probationer, Kircher accidentally put his hand to Hans Georg Hörwarth von Hohenburg's *Thesaurus* with its illustrations of the hieroglyphs on the obelisks erected in Rome by Sixtus V. The magic of the obelisks had its instant effect. "My curiosity," said Kircher, "was aroused, and I began to speculate on the meaning of these mysterious glyphs."

But another flare-up of religious intolerance—the Thirty Years' War—cut short his speculations. As a Jesuit, Kircher found himself pursued by angry Protestants. Forced to flee Germany, he swam across the icy Rhine, nearly getting himself hanged by a Protestant patrol, but scribed as the liberation of humanity from ignorance, disease, and poverty. Their hope was to bring about a spiritual awakening of society, to extend human faculties beyond the physical plane into what would later be described as the "etheric, astral and spiritual worlds," reaching up to a transcendental plane of illumination.

Father Athanasius Kircher, S.J.

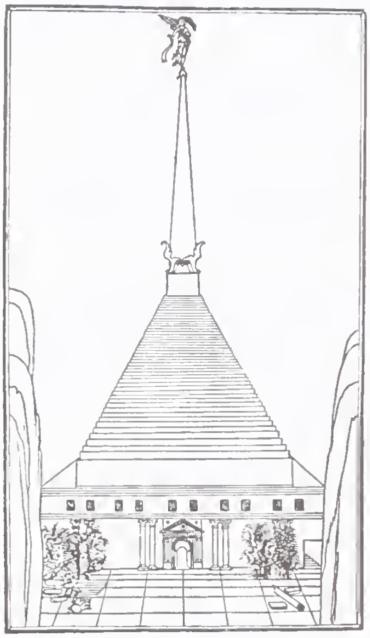
Nicholas Claude de Peiresc

eventually managing to find refuge in the papal city of Avignon, where he was able to continue his passion for obelisks and hieroglyphs by teaching mathematics and biblical languages in the local Jesuit college, cuckooing the wisdom of Hermes into the very organization designed to destroy it.

In those days, material on ancient Egypt was almost nonexistent; but fate propelled Kircher to a remarkable source in the nearby city of Aix-en-Provence, in the house of one of the most erudite and wealthy of antiquarian collectors, Nicholas Claude Fabri de Peiresc, a humanist and amateur scientist, a friend and correspondent of Galileo, who had found and brought back from his travels in Egypt a long roll of papyrus, discovered in a box at the foot of a mummy, whose hieroglyphs he hoped Kircher might help him decipher. Also in Peiresc's collection were several manuscripts never before seen in Europe, written in Coptic, the language of the Christian descendants of the Ptolemaic Egyptians, mostly biblical translations and lives of the saints. Spelled with an ordinary Greek alphabet—supplemented by seven special characters—the Coptic language had become virtually extinct since the Arab conquest of Egypt in the sixth century, except for its use in Upper Egypt in liturgical ceremonies. But Kircher was convinced that a study of this late-Egyptian language might give him a lead to the decipherment of the Egyptian hieroglyphs.

Kircher also found a rare manuscript attributed to the Arab author Rabbi Brachis Apenephius, which purported to give a method for interpreting the glyphs. But just as the young Jesuit was progressing in his study of Coptic, he

Cavalier Bernini



A Rosicrucian clue to Tantra, in which Poliphilo, in his dream of love, is led by a nymph to an agape, or orgy of love, and thence to witness an ancient rite dedicated to the phallic god Priapus, said to be the son of Hermes. Poliphilo also attends the nuptial rites of two ancient androgynous Roman deities, Vertunno and Pomona, indicating, according to Cesare Ambesi, the marriage of cosmic and telluric forces which, together, bring forth life on the planet, a mechanism admirably detailed by the modern Rosicrucian Rudolf Steiner. To Ambesi, Colonna's extraordinary poem links all the

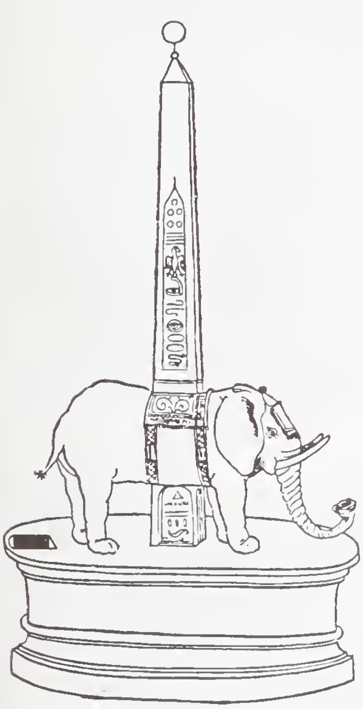
received orders from Rome to replace Johann Keppler as mathematician to the anti-Protestant Holy Roman Emperor Ferdinand II at the court of Vienna. It was an unwelcome assignment; it meant giving up his Egyptological studies. Fortunately for Kircher, Peiresc was on good enough terms with Urban VIII (Matteo Barberini), to have the pope countermand the order—which turned out to be welcome news also to the pope's nephew, Cardinal Francesco Barberini, who had just brought to his palace gardens an obelisk which had been found in the vineyard of certain Saccoccia brothers outside the Porta Maggiore in what had once been Heliogabalus's old circus. The cardinal was anxious to have Kircher come to Rome to see if he could fathom its hieroglyphs, and help him raise the 12-meter obelisk on a stone elephant as designed by his favorite baroque architect, Giovanni Lorenzo Bernini.

According to historian Cesare d'Onofrio, what may have suggested the idea of the elephant was nothing more hermetic than the recent arrival in Rome of a pachyderm for a sideshow to entertain curious Romans who had not seen such an animal since the king of Portugal had sent one as a present to Pope Leo X almost a century earlier. But New York's art historian William S. Heckscher in a fascinatingly erudite article on *Bernini's Elephant and Obelisk* in The Art Bulletin, of June 1973, thinks Bernini got the idea from a sketch which appeared in Francesco Colonna's *Hypnerotomachia Poliphili,* or *The Strife of Love on a Dreame,* originally published in Venice in 1499, translated into Elizabethan English in 1598, and into French in 1600. If so, both Bernini and Kircher were dealing with the subtlest of Rosicrucian symbolism. As analyzed by Alberto Cesare Ambesi in *I Rosa Croce,* Colonna's work "marks the true birth of the Rosy Cross, but in code," or what Italian philosopher Benedetto Croce calls "a language which intentionally suggests and underlines another more effective one." Like Dante's *Divine Comedy,* the tale starts with the hero lost in the woods. Asleep in a valley Poliphilo dreams of an elephant with an obelisk on his back and of another taller obelisk rising from a stepped pyramid, surmounted by a winged nymph. Into this obelisk Poliphilo is led by Cupid for initiation into the mysteries of love and life.

Bernini made several *bozzetti* for an obelisk atop an elephant, but for reasons that are unclear the project was dropped by the cardinal who set Kircher to transcribing the hieroglyphs from the broken pieces of obelisk lying in the garden of his palace in the hope that a translation might divulge their hidden meaning.

The obelisk in Palazzo Barberini

previous esoteric literature of the Middle Ages, including that of the Templars and Dante's *Faithful in Love,* to the future texts of the Rosicrucians, marking the true beginning of the fraternity. In the poem, Eros is the love force which moves the sun and the stars; and lovemaking between humans is associated with the power that makes for the growth of crystals, and the levitating force of trees toward the sun. The depicted obelisks represent access to superhuman states of consciousness, and the cornucopia held by the winged creature atop the obelisk is a symbol of the abundance that flows from the conquest of angelic states, leading to deeper esoteric levels of Sufi wisdom, the seven inner levels that must be conquered to become one with an occult sun.



Of assistance to Kircher in this puzzling assignment was a Roman patrician, Pietro della Valle, who had acquired in Egypt a unique manuscript in the form of a Coptic-Arabic dictionary. Kircher, with his knowledge of Arabic, soon found that Coptic differed decidedly from Hebrew, Chaldean, Syrian, Ethiopian, Armenian, and Samaritan, which further encouraged him to believe he was on the track of the enigmatic language of the ancient Egyptians.

At the Collegio Romano, a model university where the Jesuits trained their most talented scholars, Kircher was given the chair of mathematics, vacated by Father Christoforo Schein, who had been sent to Vienna in his stead. But it was a sad time for science: Lucilio Vanini, a brilliant young free-thinking teacher, who claimed that nature should be worshiped as the source of all things, was condemned for atheism. On his way to the scaffold to be burned he said: "Let us go joyfully to die, as becomes a philosopher." His tongue was forced from his mouth and severed by the executioner's knife. The ex-Dominican philosopher Tommaso Campanella, author of the splendid *City of the Sun,* with its ideal society, reflective of Bruno's admiration for the ancient Egyptians, had been kept in prison twenty-seven years, and frequently tortured—despite his having performed salutary magic for Urban VIII—and only escaped execution by pretending to be mad. Peiresc's friend Galileo had just been condemned by the Inquisition, and the Congregation of Cardinals in Rome, prodded by Bruno's nemesis Cardinal Bellarmine, prohibited the printing, reading, or possession of the works of Descartes. Even Jesuits were not immune from persecution, and Father Friederich von Spee was imprisoned for writing in his *Cantio criminalis* against the torture of witches, and only just escaped with his life.

Kircher, who was inclined to side with Galileo on the Copernican theory, took care to deny such an opinion, fearing the fate of Bruno, Vanini, and Campanella. Publicly he declared: "In case we seem to assert anything contrary to the decrees and instructions of the Holy Roman Church, we declare that we deny both the idea of the mobility of the earth, and of the inhabitants of the other heavenly globes." Hard to swallow, for an astronomer of his caliber.

To keep well out of trouble, Kircher plunged deeper into the study of Coptic. By 1636 he had produced his first book, *Prodromus Copticus sive Aegyptiacus,* in which he attempted an interpretation of hieroglyphs, which he explained as a symbolic system for expressing the theological teachings of the Egyptians. Publication of the book caused a stir among patrons of the arts wealthy enough to acquire it. Fascinated by Egyptian antiquities, Kircher's patrons knew little or nothing about Egypt other than from the fragments passed on to them in the Renaissance from Greek and Roman authors. Next, Kircher produced *Lingua Aegyptica restituta,* or *The Language of Egypt Restored,* which in no way delivered what it implied, though it contained della Valle's Coptic-Arabic dictionary, slightly updated.

From his reading of the classics and the Neoplatonists of the Renaissance, Kircher was convinced that the temples of ancient Egypt incorporated not only the cosmology of the ancients, but their system of physics. In 1639 he sent to Egypt a young man, Tito Livio Burattini, to measure the Great Pyramid of Cheops, inside and out, to see if he could find in its dimensions a figure for the circumference of the earth, as had been correctly suggested by the Milanese mathematician and astrologer Girolamo Cardano. Excitedly Kircher awaited Burattini's return with the careful measurements he had made as well as meticulous copies of many hieroglyphic texts taken from temples and obelisks. But Burattini was seized by bandits on his way back to Rome through the Balkans, and his invaluable manuscripts were scattered and destroyed. This left Kircher with nothing to go on but the few letters with data which Burattini had managed to send from Egypt.

Kircher's reconstruction of ancient alphabets, leading to his understanding of Coptic

For Kircher to do better, he needed more hieroglyphs, hence more obelisks. His opportunity came in 1644 with the death of Pope Urban VIII and the enthronement of Innocent X (Giambattista Pamfili). In a field along the old Appian Way, in what had once been the circus of the emperor Maxentius, four broken pieces of an obelisk

The Circus of Maxentius, with its broken obelisk, etched by du Perac in 1575
The fertility gods Ceres and Consus appeared at the end of Roman circuses, and recently excavated pre-Roman Etruscan tombs show chariots in a circus racing around conical obelisks.

surfaced from the area where they had been originally raised by the emperor Domitian late in the first century A.D. What better monument, Kircher reasoned, than to raise this obelisk in honor of Innocent X? The product of an old Umbrian family which had settled in Rome in the fifteenth century, the new pope was anxious to embellish the front of the house where he had been born and which his widowed sister-in-law and "confidante," Donna Olimpia Maidalchini, had begun refurbishing into a princely palace with the help of papal funds. Appropriately, it overlooked the oblong Piazza Navona, which had once been the stadium of Domitian, and earlier still, even more appropriately, one of the circuses attributed to the founders Rome, called by them *Agona,* site of the large *Ago,* or needle.

To Kircher's suggestion, the pope replied: "Father, we have decided to raise up this obelisk of no small bulk. It will be your task to work out the meaning of the inscriptions that are on it. We would like you, therefore, since you have been endowed by God with such gifts, to give yourself wholeheartedly to the task, doing all you can so that those who are amazed by the bulk of this great obelisk may come, through your endeavors, to understand the secret meaning of the inscriptions."

A committee was formed with Father Kircher as field director to excavate the obelisk from the ancient circus; but it was soon discovered that several pieces were missing from the fractured monolith, most of which appeared to be in the hands of local antiquarians. When it became known that the pope wanted the missing fragments restored, those who disliked or were jealous of Kircher decided to withhold the fragments to see if the Jesuit was canny enough to correctly fill in the vacant spaces with substitutes of his own creation.

The result, according to Kircher, was to vindicate his understanding of the subject. "Through the illumination God gave me, all unworthy though I was, I so formed the figures on the obelisk . . . that they fitted in perfectly with what was there already and in no way differed from those which were on the actual missing pieces. They were all amazed and could think of no explanation to my skill except that the Holy Spirit had given me the key to the inscriptions." Later "experts," less convinced, scoffed at Kircher for the folly of such presumption, though they could do no better.

Next came the problem of raising the obelisk. As no one had put one up since Fontana, models were requested from several leading architects, including Bernini's rival Francisco Borromini, who succeeded in obtaining the commission by submitting a pretty but banal sketch. Bernini, who had fallen out of grace with the Vatican since the death of his patron Urban VIII, was outraged, yet determined, with the help of his protector, Prince Niccolò Ludovisi, nephew of Pope Gregory XV, to steal the commission. As a stratagem, Bernini cast his model in solid silver and donated it as a bribe to the voraciously avid Donna Olimpia, with the proviso that it be placed in her house where her brother-in-law the pope would be bound to see it during one of his visits—regular enough to cause rumors of a more than brotherly attachment.

Arriving for lunch on the Feast of the Annunciation, after a hearty morning ride, Innocent was so struck by Bernini's model that he immediately gave him the commission with the quip: "To avoid a Bernini project, one must simply not see it."

Borromini's sketch for the Piazza Navona obelisk

The architect's grandiose project to erect a relatively short obelisk high above the piazza on a stunning baroque fountain was not cheap. Money for the job had to be raised through a special tax imposed on all the citizens of Rome, which hit the poorest, cutting down their bread. Bitterness was expressed in lampoons and pasquinades, the most savage of which were directed against the pope's sister-in-law, who was rightly suspected of being behind the scheme to glorify her brother's family. Much scurrilous play was made of her name, which lent itself to being fractioned into *olim pia,* Latin for "once virtuous," implying, as have several historians, a sexual relation with the pope. Every night as the great fragments of stone were left to rest along the streets of Rome on their slow way from the Via Appia to the Piazza Navona, there were cries of *"pane, pane, non fontane."* Anonymous hands attached to the obelisk placards, one of which played on words from the Bible: "If only these stones would turn to bread!"

But once the great phallus was raised, Romans consoled themselves with the gush of delicious *acqua vergine,* the best water in Rome, which issued from Bernini's fountain symbolizing the four great rivers of the world—the Ganges, the Amazon, the Danube, and the Nile, the last discreetly represented by a figure with its eyes covered because the river's source was unknown. Jokes were soon forthcoming about how the sculpted blackamoor representing the river Ganges was holding up his hand not in awe of the great obelisk, but for fear that the façade to Borromini's Church of Santa Teresa, which forms a backdrop to the fountain, was so badly built it would fall on his head.

That the obelisk had been raised with no significance other than to honor the Pamfili family, was clear to all. To resolve any doubts, an inscription was placed on the base spelling out the Pamfili emblems: "Above the noxious Egyptian monstrosities [the heiroglyphs] rests the innocent dove, wreathed in lilies of virtue, offering the olive branch of peace." The dove triumphant was to symbolize not the Holy Ghost but Innocent X Pamfili. Bernini, driving past his opus, is said to have drawn the curtains to his carriage with the remark: "How ashamed I am of such bad work."

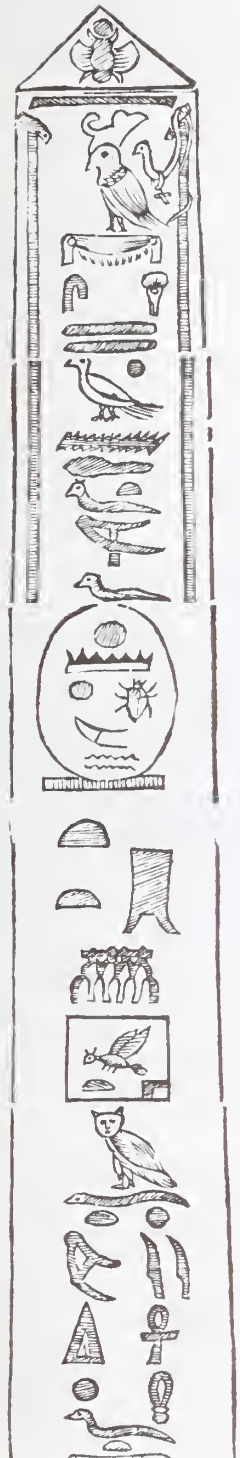
Dee's *Monas hieroglyphica,* which Frances Yates considers to be at the heart of the Rosicrucian mystery, deals with the mathematical properties of symbols—a subject as close to Kircher's heart as it had been to Dee's. Like Bruno, Dee pursued a philosophy of nature "which sought the divine meaning of the hieroglyphic characters written by God into the universe." And like Bacon, Dee presaged a scientific era in which man would compel nature to unleash forces to serve him to an extent undreamed of. Dee's notion that man could use numbers to achieve fantastic magical results is all too apparent in what passes for modern science, whose proponents, unlike Dee, do not appear to have been initiated into the secrets of alchemy and its great work of *spiritual* transformation.

Innocent X celebrated the raising of the obelisk by asking Kircher to publish an account of the entire proceedings, which gave Kircher the chance to put into print in some five hundred pages his attitude toward Egyptological problems in general, and hieroglyphs in particular. Entitled *Obeliscus Pamphilis,* and adorned with elaborate prints, only its second part treated of the obelisk in the Piazza Navona. The first part included an excursus on John Dee's *Monas* glyph, which Kircher connected with the Egyptian ankh, or symbol of life, and which he interpreted as a symbol of the ascendency of spirit over matter.

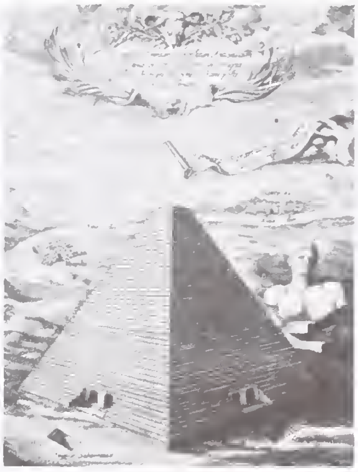
Delving into the arcane and the cabalistic, Kircher's fundamental thesis about the hieroglyphs was a reiteration of the Hermetic tradition: the glyphs were not an ordinary system of writing but "a sacred instrument bequeathed by the gods to the Egyptians . . . enabling them to express their wisdom and the secrets of esoteric knowledge in symbolic pictures the meaning of which was directly revealed to initiates by divine inspiration." For Kircher, each inscription had a quadruple sense: "literal, figurative, allegorical and analogical, to express the same thing." As Erik Iversen puts it: "With an absolute confidence in the authority of his sources, and in the firm conviction that all leading metaphysicians of antiquity, Pythagoras and Plato as well as Plotinus and Iamblichus, had been directly influenced by Egyptian theology, Kircher had no doubt that his studies of their works combined with his knowledge of the Cabbala and the Hermetica, had given him a complete insight into what he considered Egyptian philosophy and thought."

With this as a premise, all that Kircher needed was to identify each hieroglyph with the basic Neoplatonic concept applied to it. The notion was genial. But despite his enormous erudition, his enthusiasm, and his almost superhuman industry, the results were inconclusive. Fortunately for Kircher, although at the time there was no one sufficiently equipped to confirm his argument, there was also no one equipped to refute it.



Kircher's translation of the glyphs on this Minervan obelisk deals with a supreme twofold spirit—the great Hemphta—whose generative powers infuse stars and sun to bring forth the bounties of life. In what sounds like a Tantric allusion, he calls the Left Hand of Nature "the Fount of Hecate."

Kircher next produced his *Oedipus Aegypticus,* a formidable work of almost two thousand pages, with numerous engravings, which appeared in four volumes between 1652 and 1654. New type had to be cast for the oriental languages he quoted, and for the Ethiopian, Chinese and Egyptian glyphs he reproduced. Expert printers and engravers had to be hired, which could only be done with the lavish patronage of the Holy Roman Emperor, the scholarly composer of music, raised by the Jesuits, Ferdinand III. In Iversen's words, Kircher, "as a modern Oedipus attempted to solve the riddle of the Egyptian Sphinx."



The Great Pyramid of Cheops as reconstructed by Kircher from Burattini's measurements

In the body of his *Oedipus,* Kircher came close to doing just that, defining a symbol as "the significant sign of a hidden mystery, whose nature is to lead one's mind through meditation on certain similarities to the comprehension of something much different from the thing presented to external senses, the nature of which can be said to be transcendent or hidden, as obscured by a veil." As an example he noted that the Egyptian scarab did not symbolize the actual sun but "the secret and mysterious operations of that body which foster growth and generation." In the body of his *Oedipus,* Kircher clarifies and explains the more important of his ideas relating to Egyptian language and antiquities, to their mathematics, mechanics, medicine, chemistry, theology, and magic. But the last part is largely a rehash of his earlier notions on hieroglyphs, the result of twenty years' study during which he consulted some three hundred ancient authors, including all the favorites of the Hermeticists.

Kircher said he regarded the Hebrews after Moses as betrayers of the Egyptian wisdom, perverting the Egyptian fertility cult into what he called crude phallic worship, and he objected to Islam because it promised a heaven of sex-fulfillment. Somewhat incongruously he also attacked the occult sciences of magic, alchemy, dowsing, divination by dreams, theurgy, and chiromancy, leading Joscelyn Godwin, in *Kircher, A Renaissance Man and the Quest for Lost Knowledge,* to wonder "whether his protestations are just a blind, enabling him to expound dangerous doctrines with impunity." Certain it is that in so doing, Kircher kept the ancient wisdom bubbling in an otherwise stagnant sludge of orthodoxy.

In his *Oedipus,* the obelisks of Rome are illustrated with glyphs that do not always resemble their originals all that closely. On the basis of Burattini's surviving tracings, Kircher was nevertheless able to add better reproductions from the two obelisks still standing in Alexandria and Heliopolis.

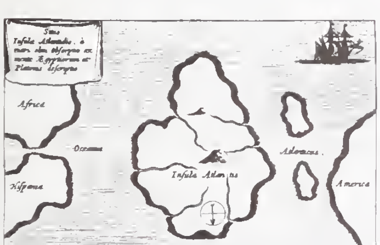
Kircher's method of decipherment was an identification of each glyph with its metaphysical idea. ‡ he identified with "generation"; ‡ with "force"; ‡ with "infernal"; ‡ with "supernal" or "celestial"; ‡ with "emanating from above." None, alas, was to be supported in the light of orthodox Egyptological deciphering. Yet intuitively Kircher sensed that though some of the glyphs represented ordinary material objects, they could also be used alphabetically as letters. The sign ‡ he correctly identified as "water," and went further, correctly, to suggest the phonetic value of *m,* with a reference to the Coptic word for water: *mu*. As Iversen writes: "It is Kircher's incontestable merit as the first to have determined the phonetic value of an Egyptian hieroglyph. Yet he remained more interested in the possible symbolism of the glyphs and the esoteric knowledge they might transmit."

In the *Oedipus,* Kircher follows Pico in comparing the glyphs of the Cabala with those of the Hermetica, and though he agrees with Ficino and Bruno about the magical power of the Egyptian cross, or ankh, he condemns cabalistic magic. Yet, in the end, he makes his Hermetic point by including Hermes's hymn from the *Pimander,* adding a hieroglyph enjoining silence and secrecy concerning these sublime doctrines—the colophon employed by the Brothers of the Rosy Cross!

The two human figures represent man surveying and measuring the planet, which is suspended by a chain to the hand of God. Sun and moon affect the twelve varying zephyrs of the cartographer's wind rose, clearly indicating Kircher's understanding of the Copernican notion of the earth spinning in the void around the sun, an earth whose circumference he correctly believed the Egyptians to have measured and incorporated into the Great Pyramid on the Ghiza plateau.

The year after the last volume of *Oedipus* appeared, the pompous and austere Innocent X died, to be succeeded by Alexander VII (Fabio Chigi), at last a philosopher and poet, who yet favored the Jesuits in general and Kircher in particular. A patron of the humanities, who had devoted his resources as cardinal to the promotion of art and science, the new pope was to embellish Saint Peter's basilica with Bernini's stunning baroque colonnade, and to offer Kircher a decade of undisturbed study in his favorite subjects, which were becoming more catholic—in the original sense of the word. Refreshingly, the new pontiff was an extraordinary anomaly: an Hermetic scholar who took a personal interest in Kircher's hieroglyphical studies, contributing generously to the publication of Kircher's many more works, and so, indirectly, to keeping alive the wisdom of Ficino, Pico, and their Thrice Great Master.

By climbing down the maw of erupting Vesuvius, and by exploring the famous "cave of the dog," whose volcanic fumes of carbon dioxide hovering along the ground would kill that animal, but leave a man unaffected, Kircher got involved in the mysteries of the world beneath the soil, which led to perhaps his most famous work, *Mundus subterraneus*. Fascinated with astronomy (on which subject he produced his *Iter extaticum*), Kircher was a firm believer in the influence of heavenly bodies on earthly happenings and phenomena. A student of Paracelsus, he mirrored the Swiss master's notions of a panspermia, or universal seed of all things, "a certain material spirit, or something made from the most subtle heavenly aura or from portions of the elements, a certain spiritous sulphurous-saline-mercurial vapor, the universal seed of things."



Kircher's Atlantis

Of the existence of Plato's Atlantis, Kircher had no doubt, placing it as a large island in the middle of the

Atlantic, about where the Azores now lie. On the art of consonance and dissonance Kircher wrote ten books in which are treated the whole doctrine and philosophy of sound, especially as applicable to philosophy, mathematics, physics, mechanics, medicine, politics, metaphysics, and theology. He gave numerous accounts of the curative powers of music, such as a melody to cure the bite of the tarantula and a tune to calm the frenzy of the mentally disturbed.

Frontispiece of *Ars magna lucis,* showing the light of the sun (depicted as Apollo) shining onto earth reflected by the moon (Diana), all emanating from *IHVH* surrounded by angels

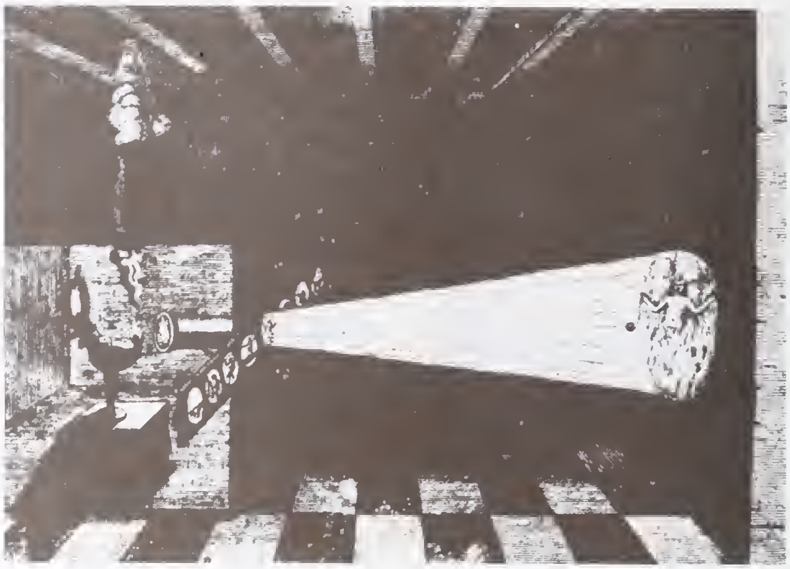


Illustration of a magic lantern as described by Kircher in his *Ars magna lucis*

In his *Ars magna lucis et umbrae,* a thousand-page analysis of the phenomena of light and shadow, Kircher included methods for designing and constructing sundials. He even built a great pyramidal sundial, and designed an *horologium catholicum,* or universal clock, ostensibly to mark the different time of day in the various Jesuit colleges scattered around the globe, but more specifically to help establish longitude. The idea was a development of Galileo's suggestion that the moment of some astronomical event, such as an eclipse of one of Jupiter's moons, could be predicted with the help of tables in some standard time related to a fixed degree of longitude, and that a person in some other part of the world, observing the same event in terms of local time, could readily calculate the longitude of the place from which the observation was being made. Kircher even devised a sort of calculating machine which he claimed provided practical results to various mathematical and scientific problems.

When he was shown the remains of the obelisk found in a cellar in the area of the old Campus Martius, Kircher suggested to Alexander VII that it be raised on the spot

That obelisks were involved with magnetic phenomena in the solar system was prophetically illustrated by Kircher in this sketch showing a large magnet in the central obelisk (symbolic of the sun) variously affecting magnets in the different-sized globes surrounding it.

where Augustus had used it as a great gnomon, or sundial. In his report to the pontiff, Kircher further suggested that the Vatican obelisk, which had been reraised by Fontana for Sixtus V, be similarly used as a sundial by the insertion of markers in the pavement of Saint Peter's Square. Both projects were more than Alexander VII, in a frail state of health, could face; but just before the death of the pope, Kircher found a way to repay his beloved patron by organizing for him an Hermetic monument in the form of a small but extraordinary obelisk raised by his old friend Bernini.

Some Dominican friars digging a new wall around their garden in the convent of Santa Maria Sopra Minerva, the ancient Roman dromos of Isis, had struck a pink granite obelisk buried about 15 palms beneath the surface. Alexander immediately appointed Kircher to head a committee to supervise the excavation of what turned out to be a short (5.5-meter) obelisk with remarkably well preserved hieroglyphs carved on all four of its sides.

Kircher's homage to the Hermeticist Pope Alexander VII

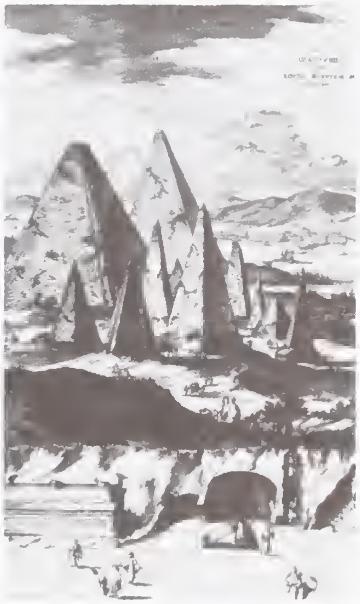
Kircher's reconstruction of the ancient Roman Iseum

Ironically, this monument to Isis (the Pallade Egizia of the Romans), erected on the site later dedicated to the pagan goddess of wisdom, Minerva (upon whom the Christians superimposed their Virgin Mary), was quickly seized by the Dominican fathers as their rightful property. They wished, they said, to raise it in the square before their church, on a base of six hillocks (symbols of the incumbent Chigi pope) surrounded by four dogs with torches in their mouths, a play on the words *domini cani,* or "hounds of the Lord," to indicate the bird-dog qualities of their order in ferreting out heresy. Alexander VII reluctantly gave in to the Dominicans' desire to have the trophy placed before their church, but vetoed their self-serving design, assigning Kirchner to see that this thoroughly Egyptian relic was more sensitively raised according to the old and clearly Hermetic design of the cavalier Bernini: that of an elephant with the obelisk on its back.

Just before the pope died, Kircher was further able to repay his beloved patron by underlining the Hermetic thought chiseled onto the base of the obelisk: "Oh you who here see transported by an elephant, the strongest of animals, the hieroglyphs of the wise Egyptians, heed this monument: to sustain solid wisdom, a robust mind is needed." All through the Middle Ages the elephant had been considered a wise and intelligent animal. In the works of Horapollo it was the glyph for a strong man in search of what is beneficial and essential. It was plain that the monument was specifically designed for Alexander VII, whose mind, despite his physical frailness, was considered strong enough to handle the Hermetic wisdom of Egypt. But the satirist Segardi, taking the symbolism one step further, used the fact that the elephant's rear end is turned toward the monastery of the Dominicans to compose the epigram *"Vertit terga elephas vertague proboscide clamat Kyriaci Frates Heid Vos Habeo"* or, in short, "Dominicans, you may kiss my arse!"

The Minervan obelisk facing away from the Dominican monastery

The Society of Jesus, founded in 1541 by Ignatius Loyola, adept, through the device of the spiritual retreat at conjuring visions to convince susceptible heretics to return to the Church, was to carry the standard of the Counter-Reformation. In a virtual state of war, Jesuits served as the military light horse of the church under the absolute orders of a general known as the "black pope," who was elected for life. Individual Jesuits were bound by a vow of personal obedience to both the "black" and "white" popes, ready to follow orders anywhere at any time, "manageable as a stick in his hand . . . unaffected as a corpse." A sacrifice of intellect to total obedience was considered "pleasing to God." Aware that the cause of the Reformation was the "ignorance, neglect and vicious lives of so many priests, especially in the higher ranks," Jesuits devoted their efforts to better education; and for three centuries were the best schoolmasters in Europe. By 1620 there were 20,000 Jesuits traveling to the ends of the earth, often suffering cruel martyrdom, dragging with them to death thousands of Christian converts. In Japan, when the Christianized women of the Shogun refused to perform in his harem, 250 churches were burned and 200,000 converts killed. Cardinal Bellarmine argued that since all authority derives from God, any Christian price forfeits his right to authority if his government contravenes the wishes of the Church. Subjects have no obligation to such a prince, and can take steps to remove him. The argument led to accusations of assassination against the Jesuits, including that of Henry IV. A spurious document, *Monita Secreta Societas Jesu,* purported to give secret instructions for acquiring power over princes and rich widows, and how to poison. Accused of becoming "the apostles of the rich and influential," Jesuits soon incurred universal hostility, especially from other members of the Church. In the course of the next century, the works of 27 Jesuits, including Bellarmine, were ordered burned by the common hangman. Another decree declared that Jesuit doctrines "contained the errors of Arius, Nestorius, Calvin, Luther, Wycliffe and Pelagius; that they were blasphemous, outrageous, and insulting to the Blessed Virgin and the saints; destructive to the divinity of Christ; favorable to Epicureans and Deists; encouraged murder and patricide, usury, vengeance and cruelty; threatened the safety of princes, and were in contradiction to the decisions of the Church, to the divine will, to peace and good order." The good fathers were accused of pederasty. In France, they gained the enmity of Madame de Pompadour by refusing her absolution while she remained the king's mistress, so she got Louis XV to expel them from France, and requested the pope to suppress the society. From Portugal they were expelled for purported complicity in the attempted assassination of King Joseph I. Clement XIII, in his eighty-second year, is said to have died of shock when requested by France, Portugal and Spain to dissolve the society. In a brief, *Dominus ac Redemptor,* in which he referred to the suppression of the Templars, Cardinal Ganganelli as Clement XIV declared the Society of Jesus extinguished, abolished, and abrogated forever, with all its houses, colleges, schools and hospitals. Its general, Lorenzo Ricci, was thrown into Castel Sant' Angelo where he died two years later. Many of the 22,000 disbanded Jesuits took refuge in Prussia and Russia where they were used by Frederick II and Catherine II as teachers for pupils whom they considered illiterate bores.



From the frontispiece of his *Sphinx mystagoga* it was clear that Kircher believe the wisdom of the world to have come from Egypt and to have been incorporated in its tombs, pyramids, and obelisks.

Times grew rougher for supporters of the Hermetic tradition. In England, Jesuits took advantage of the civil disorders which broke out after the death of Cromwell to intrude themselves among the Rosicrucians to pervert the order and cause its apparent disappearance. No longer protected by Alexander VII, Kircher gave up his jobs at the Collegio Romano, determined quietly to devote the rest of his life to archaeology and the solution of the riddle of the obelisks and their mysterious glyphs.

In an epoch when it was the fashion to search for unicorns and mermaids, and the Rosicrucian Elias Ashmole was organizing his antiquarian's museum at Oxford, one of Kircher's main interests became his own museum of rarities and oddities which he had collected to go along with his Egyptological curios. To these he added geological specimens, preserved birds, skeletons, mechanical models, as well as his own inventions, which included a variety of musical instruments, alchemical glassware, and microscopes. From all over the world Jesuits sent him donations such as rhinoceros horns, gold embroidered vests, girdles studded with rubies, idols, icons, and strange drugs. Soon he had an exhibition hall in the Collegio Romano 300 feet long with side galleries of curios such as the skeleton of a bird with three legs, and a monstrous 10-ounce stone removed from the bladder of his comrade Father Leo Sanctius. But the principal attraction remained his central exhibit of a range of Egyptian obelisks.

As Kircher's early work had dealt with the crucial but still mysterious force of magnetism, his last book describes his experiments with a microscope which could "amplify a fly into an elephant and a flea into a camel." In vinegar and milk he found innumerable "worms," which led him, well ahead of his time, to guess that the plague, of which no one knew the cause, might be propagated by tiny living organisms.

In November 1680, almost on the same day as his old friend Bernini, Kircher died in his seventy-ninth year, to be derided, ridiculed, and even questioned in his honesty. Ever since, he has been the whipping boy of Egyptology, though as Iversen says, "His devotion, his untiring enthusiasm, and his positive contributions have been disregarded by the science he sacrificed his life to further and to serve . . . an easy prey to egyptologists who have sacrificed his reputation for a witticism, mostly without having opened his books." A fair criticism, as the volumes are hard to come by, even in the very best libraries, and their thousands of Latin pages are still judiciously untranslated into any vernacular.

As Maristang notes, Kircher's life work, in its scope, went far beyond the limits of Egyptology, representing one of the last efforts to combine the totality of human knowledge in religion, philosophy, history, and science into a theological system, a universal cosmology based on the concepts and ideas of a Neoplatonized Christianity. Iversen, in sum, wonders if Kircher's conceptions of Egyptian religion and mythology, though undoubtedly fantastic and unhistorical, "are very much further from the truth than the sterile and lifeless waxworks to which the more sober, unmetaphysical methods of modern egyptology have reduced the Egyptian pantheon." From a humanistic as well as an intellectual point of view, he adds, "egyptology may very well be proud of having Kircher as its founder." Yet three hundred years were to pass before this remarkable scholar was given the credit he justly deserved for keeping alive the torch handed down to him from ancient Egypt.

Nothing, says Kircher, on the frontispiece of his *Ars magna sciendi,* is more beautiful than to know all.

Summoning a spirit

6. EGYPTIAN RITES OF MASONRY

Pius VI was lampooned for his vanity. When he added an eagle and a *fleur-de-lis* to his escutcheon of "two winds," the people of Rome suggested he restore the eagle to the empire and the lilies to the king of France, keeping for himself the "winds." Historian Jean François de Bourgoing said of him: "his prodigality and his taste for brilliant but expensive enterprises rendered him more odious than many princes who were really wicked." When an enormously expensive sacristy was added to Saint Peter's (at a cost to the people of 200,000 crowns) Pius added a plaque which read "What the public voice demanded, Pius VI completed." To which some Roman added: "You lie. The public was never consulted. Only your vanity."

The century which followed Kircher's, the so-called Age of Enlightenment, was to see a reversal in the fortunes of the religious contestants, bringing into play the destruction of the Society of Jesus and a flourishing of the Hermetic tradition in the ranks of all manner of Freemasonic orders, including their more secret organizers—the Rosicrucians and the Illuminati.

Two revolutions, one in America and one in France, ended the dogma of the divine rule of kings in favor of republican governments with the political and religious freedoms propagandized by Freemasons and eventually protected by the Bill of Rights. But despite the banishment of the Jesuits from most European countries, the popes, especially Pius VI, who was to reign longer than any previous pontiff, fought back. Opening his pontificate with an encyclical which forbade individual freedom of conscience, Pius VI, by the intransigence of his stand against political progress in France—which he was able to enforce by threatening with excommunication a weak and believing Louis XVI—became responsible, though perhaps unwittingly, for the abortion of an orderly evolution to constitutional government, bringing on instead a grossly radical revolution in which almost every value was drowned in the blood of the Terror.

The year before the American Declaration of Independence, the elevation to the seat of Saint Peter of Giovanni Braschi was greeted by the poor of Rome with foreboding and caustic pasquinades—those satirical notes clandestinely attached by wits to two mutilated statues known as Pasquino and Marforio, whose salty dialogue constituted an outlet for the pent-up misery of citizens. Ominously, Romans pointed out that any ruler with a six in his title had always brought disaster to the city. *"Semper sub sextis perdita Roma fuit,"* they lamented, thinking of Shakespeare's villainous and bloody Tarquinus Sextus, who deprived the city's poor of their arms and set them to slave work building great monuments, and of Urban VI, an intractable nepotist responsible for executing several cardinals and initiating the Great Schism which divided the Western Church for forty years, and of that unforgettable Spaniard, Alexander VI, the Borgia tyrant.

Nor were the poor of Rome happy with a pope who seemed determined not only to wage a war on "bad" books, but to revive the ostentatious splendor of the reign of Lorenzo the Magnificent's son, Leo X, at their expense, by diminishing their ration of bread—especially when he chose to rub salt in the wound by having engraved on the monuments he raised with their slave labor MUNIFICENTIA PII VI P.M., a practice which gave rise to such satires as the insertion of a reduced loaf of bread, engraved with the same papal inscription, into the hands of Pasquino.

Surrender at Yorktown

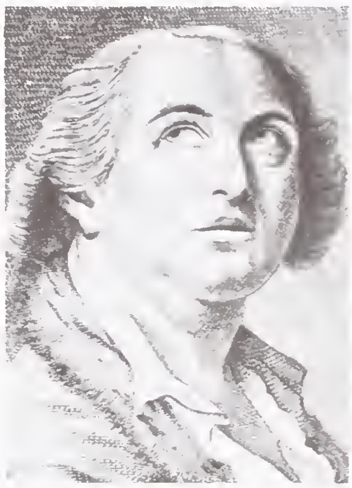
In the fall of 1781, as Freemason George Washington defeated Freemason Charles Cornwallis at Yorktown, and Freemason Frederich Baron von Steuben received the Englishman's sword, in Rome, lowlier masons, digging foundations for a small house by the hospital of San Rocco, struck the point of an obelisk. Further probing revealed two more pieces, plus the base, which had been broken in two. It was the same relic, the soutaned observers realized, which had been disinterred two centuries earlier in 1549, on the land of Monsignor Francesco Soderini, and quickly reburied because Pope Paul III had died before anything could be done about it.

To Pius VI the hospital of San Rocco, which specialized in caring for unwed mothers and illegitimate children, now raised a cry for compensation to remedy the damage caused by digging around their buildings. The new pope, though as profligate a nepotist as any of his predecessors—his nephew Romualdo Onesti, speculating on property sequestered from Jews soon made such a fortune he was able to acquire title to the dukedom of Nemi and have himself named both prince of the empire and grandee of Spain—continued to refuse the hospital any compensation until someone suggested raising the required 1,200 scudi to indemnify the monks through the sale of lottery tickets to the poor.

With that problem so economically settled, Pius ordered his papal architect, Giovanni Antinori, to repair the broken pieces of the San Rocco obelisk, no matter what the cost, and have it raised on the Quirinal Hill opposite his great palace, already expansively decorated by Fontana and Borromini, which served him, because of its finer air, as a summer residence. The obelisk was to stand in the Square of the Horsemen, so known because of two enormous Roman equestrian statues placed there by Pius V in the mistaken notion they represented Castor and Pollux, mythological twin sons of Leda by Zeus.

Classical horses in the Quirinal Square before the raising of the obelisk brought from Augustus's mausoleum

How much Pius wished to raise the obelisk as yet another antipagan symbol against the wave of revolutionary ideas spreading through America and Europe, and how much he merely wished to beautify Rome, remains moot. But the times were electric with the reforming ideas of Mason, Rosicrucian, and Illuminatus. The execution of victims for supposed offenses against the Church and its tenets, though diminished, had not ceased. In the Pas-de-Calais town of Abbeville, two young Frenchmen had just been sentenced to have their tongues torn out by the roots with pincers and their severed right hands nailed to the door of the church, before being burned to death by slow fire, simply because a wooden cross on a country bridge had been found whittled away with a knife—a crime of which the boys had been accused. One of them, named d'Etallode, succeeded in fleeing. The other, La Barre, was duly executed on July 1, 1776, in the manner prescribed, thus becoming one of five million such victims estimated by Victor Hugo to have succumbed to the Churches, apart from those killed in religious wars.



Alessandro Cagliostro

It was then, just as the American Continental Congress was meeting in Philadelphia to announce the Declaration of Independence, that there appeared on the European scene a new and extraordinary young man, determined to raise even higher than Pius's obelisk the torch of freedom by reviving the Egyptian tradition of Bruno. At the very time La Barre's body was being consumed by the flames, and the last Englishwoman to be burned alive was given to the flames in Horsham, a medium-sized man of thirty, with dark curly hair and large magnetic eyes, arrived in London in the company of a stunningly beautiful wife of twenty-one. The newcomer, elegantly but soberly attired, handsomely coiffed, with a sword at his side, cut a noble figure, followed by a retinue of servants, who addressed him as Count Cagliostro.

Serafina Cagliostro

In Whitcombe Street, Leicester Fields, where the couple took rooms, black smoke was seen to pour from the chimneys as the mysterious stranger practiced the art of alchemy over ovens and retorts, surrounded by books on the Cabala, the tables of Pythagoras, the calculations of Agrippa, and the computations of the abbé Trithenius, whose astrological magic was considered not only a form of telepathy, but a means of acquiring universal knowledge "of everything that is happening in the world." With these interests, it was only natural that Cagliostro should gravitate toward the Order of Freemasons which considered itself the repository of alchemical secrets going back to the Temple of Solomon.

Masonic procession in eighteenth-century London. The Esperance Lodge 369 is said to have been frequented mainly by French and Italian residents in London, and to have been attached to the Continental Masonic Order of Strict Observance, supposedly a continuation of the Knights Templar.

On April 17, 1777, at the King's Tavern on Gerard Street, in Soho, Alexander Count Cagliostro was initiated into the Lodge of Esperance 369, with the grade of Master Mason, accorded him because of his membership in the Knights of Saint John of Jerusalem, a sovereign order recognized by the Scottish Observance, formed in the 1750s by a baron von Hund, which claimed to possess secret documents of the Knights Templar dating back to the fourteenth century, and which operated under the orders of mysterious Unknown Superiors with the object of regenerating Freemasonry in an aristocratic sense.

Ever since 1646, when Elias Ashmole had been the first gentleman "accepted" into the order of Masonry, the operative guilds had taken in more and more mystics and occultists with no relation to the actual building trade. By the beginning of the eighteenth century, these "accepted" Masons, mostly aristocrats, humanists, and rationalists, outnumbered the "operatives," who withdrew to form their own trade unions. The last Grand Master of the actual builders had been Christopher Wren, obliged to leave his post in 1702 because of his religious opinions. The new "accepted" Masons, though they considered themselves the perpetuators of the ancient mysteries of Egypt, with its higher science and deeper understanding of the secrets of nature, passed down to Gnostic, Neoplatonist, and Templar, were yet a living order, tolerant of all religions, with the fundamental tenet that "there is only one Supreme Being; He is all, the one and only."

The reason for the papal anathema, according to Freemasons, was their assertion that every man is himself the living, slain, and rearisen Christ in his own person. To which a twentieth-century 33° Mason has appended: "Well may Catholic and freemason alike stand appalled at the stupendous blasphemy which is implied, as they ignorantly think, not knowing themselves of the stuff and substance of the Supreme Self, each for himself alike no less than Very God of Very God."

Politically, it was the Mason's prime desire to spread knowledge, confident that once understanding and tolerance gained an ascendancy in men's minds, they would condemn and reject narrowly enslaving dogma. Believing that only in free debate, without censorship, could society develop, Masons aimed at the establishment of complete freedom of worship, freedom of speech and association, freedom of the press, and freedom from arbitrary arrest and imprisonment without trial. They wanted every man to have the right to choose his type of employment and place of residence—entailing the abolition of the serfdom still binding in Europe—and envisaged an eventual government controlled by public opinion, subject to a representative parliament. They believed that humanity, if it so desired, could attain to a social order, such as that of the ancient Egyptians, reflecting the order of the cosmos.

But the Church thought otherwise. When the Encyclopedists, a group of Masons in France, tried to bring out a translation of Chambers Encyclopedia edited by Denis Diderot, with the collaboration of Voltaire, Rousseau, Montesquieu, d'Holbach, and d'Alembert, it was banned by the Church, placed on the Index of forbidden books, and copies were burned wherever possible. Clement XII issued a bull forbidding Catholics, on pain of excommunication and the threat of hellfire, from joining or supporting Freemasons, because they allowed persons of all religions into their order, were "depraved and perverted," and for "other just and reasonable motives known to Us," which, not being specified, were presumed to be sexual.

In London, introduced into society by his brother Masons, Cagliostro was appreciated not only as an alchemist, but as a natural healer and producer of marvelous elixirs and rejuvenating pomades, sought after by the ladies, who were much attracted to this man of mystery. But because neither Cagliostro nor his wife could speak English well they were obliged to rely on a Portuguese housekeeper to interpret for them. This woman soon introduced into the household friends and relations who complained so pitifully of poverty, they induced Cagliostro to use his clairvoyant powers to foretell for them one set of winning numbers in the national lottery. When Cagliostro refused to continue this unconventional form of welfare, from which the beneficiaries had earned several hundred pounds, they organized a plot to denounce their benefactor to the police for theft in order to gain entry to his house with a warrant and seize the notebook in which he kept his secret computations for foretelling the outcome of the lottery.

Cagliostro with the upcoming numbers in the royal lottery

Unjustly arrested, Cagliostro was kept four months in the King's Bench jail before the beneficiaries, common London swindlers, could be brought to justice; at which point, lest one of them be hanged for theft, Cagliostro chose to withdraw charges. But the charm had gone out of residence in England. Admitting he too was perhaps unjust in attributing to the whole nation the faults of a few individuals, he nevertheless "determined to leave a place in which I found neither laws, justice nor hospitality."

The Comte de Saint-Germain—a transparent pseudonym for "holy brother"—moves in the twilight between history and legend, using many names: Baron Gualdi, Comte de Gabalis, Lord Welldone, Count Orloff. Biographer Marie-Remonde Delorme believes him to have been Prince Leopold Racoczy, one of three sons of Francis II of Transylvania, born in 1696. Paul Chacornac, another biographer, thinks him more likely to have been the son of Queen Marie-Anne de Neubourg, who had been married without issue to Charles II of Spain but had a child by her lover John Thomas de Cabrera, Duke of Rioseco, Grand Admiral of Castille, exiled with the arrival of the Bourbons. Marie-Anne's de Medici uncle appears to have fostered the exiled child in Florence. In Paris, where Saint-Germain appeared in 1744 he looked about fifty, but Madame de Gergi, daughter of the French Ambassador to Venice, remembered seeing him there in 1710, when he looked no older than forty-five. Like Cagliostro, he was said to have discovered the elixir or life. His rejuvenating pomades were much in demand by the ladies. Described as aristocratic, with large dark eyes, powerful but full of tenderness and humor, he was elegant but soberly dressed, displaying a wealth of diamonds said to have been alchemically produced. An accomplished musician, he played and composed with equal ease, and was renowned for a stock of tales he told in almost every European language. He could write a love letter with his left hand while composing a poem with the other, or compose the same text with both hands so alike they appeared identical when superimposed. He could tame bees and charm snakes. After falling into a cataleptic sleep for hours or days, he would descibe having visited the remotest corners of the planet, or even the stars. He described his past lives, including that of Menkh-Kheperseneb, son of Hatshepsut, recounting historical events as if eyewitnessed. He was as great an alchemist as

On the Continent, the Cagliostros traveled to the Hague, Brussels, Liege, Nüremberg, Leipzig, and Sarrebourg, everywhere welcomed from one Masonic lodge to the next. In Prussia they were cordially received by King Frederick II, a Mason, who, influenced by his close adviser, the comte de Saint-Germain, had become not only tolerant of all forms of religion, but intolerant of the use of torture, which was banned from his kingdom. And it was from meeting Saint-Germain that Cagliostro appears to have discovered his real mission in life: to act as a catalyst to bring Masonry—which, on the Continent, seemed to be divided into divergent strains, some no more than a vain pursuit of high-sounding titles and exotic costuming—back to the esoteric principles of ancient Egypt with a purified and regenerated ritual. For this, Cagliostro decided to organize an Egyptian rite, no longer merely speculative, but "transcendental, at once Christian, yet reviving the early rites of initiation into the Osirian myths of death and resurrection, of communion with the dead."

The grandiose goal was "to restore to man the powers which had been his in Eden before the fall, before having been obliged to struggle by the sweat of his brow"—a state in which Catholic dogma appeared to wish him kept forever. Man, said Cagliostro, following the Hermetic tradition, was fundamentally of an archangelic nature, a demigod, with power to command spiritual beings and to reign on earth. But to do so, to become once more the happy intermediary between the divine and its counterparts in nature, man must first reacquire his love and understanding of nature.

From various books on magic, but chiefly from an Egyptian papyrus discovered in the Upper Nile Valley, Cagliostro developed a rite designed to regenerate Masonry by regenerating each individual Mason.

In a castle in Holstein placed at Saint-Germain's disposal by Prince Charles of Hesse, Cagliostro and his wife were initiated into the Order of the Knights Templar. Jean Pierre de Luchet has described the scene as taking place in the fantastic setting of candle-lit dungeon with Saint-Germain seated on a golden throne; but as Luchet's object was to denigrate Masonry by concocting spurious "memoires" of Cagliostro, and as he could hardly have attended in person, the description is doubtful.

But it was from this point on that Cagliostro began to display his colors as a Rosicrucian adept, claiming to be not only capable of transmuting baser metals into gold, but of transmuting his "non-self" into his "real self"—the object of the Great Work of "spiritual alchemy."

chemist, and a series of impressive laboratories were placed at his disposal by the aristocracy and royalty of Europe. Without means of support, he was free with money, generous to those in need, arousing the suspicion he had access to the hidden assets of the Rosicrucians, perhaps the remnants of the Templar's treasure. A personal counselor to kings and princes, Saint-Germain served as intermediary between prime ministers in England, France, Austria, Prussia, and Russia. In London in 1745, he was confined to the Tower in the company of Emmanuel Swedenborg and the Marshal of France de Belle Isle, *habeas corpus* having been suspended by the landing in Scotland of the Jacobite son of James III. Known as a member of the Jacobite pro-Catholic Scottish Rite Masonry, to which the majority belonged who had gone into exile with James II, Saint-Germain's predicament was increased by the discovery on his person of a letter of thanks from the Pretender. This led to the presumption of his being on a spying mission for Louis XV, who had mounted a fleet to help the Pretender. When the aspirant James IV was defeated at Culloden, Saint-Germain was allowed to leave England, presumably thanks to his connections in the British aristocracy and his high standing in Masonic circles. From 1746 to 1758, Saint-Germain disappeared from Europe, and, according to biographer Pierre Laermier, was in the Far East with Hindu gurus to develop a deeper understanding of reincarnation, hypnosis, pharmacology, clairvoyance, levitation, telekinesis, and the secret practice of the Tantric arts already familiar to his brothers of the Rosy Cross. Back in Paris in 1758, with his old friend Marshal de Belle Isle as Minister of War, Saint-Germain was befriended by Madame de Pompadour and frequently invited to dine with Louis XV, who spoke of him as a person of illustrious birth. In her diaries she relates how he fascinated the king with his ability to eliminate flaws from gems, ren-

Exactly how much Cagliostro learned from Saint-Germain is difficult from the record to establish, but it was after seeing him that the younger man began to formulate his new Egyptian Rite of Masonry based on the ancient Hermetic wisdom as well as on the later Alexandrine Rites of Memphis.

In Berlin, Cagliostro appears to have read the *Crata Repoa,* published in Germany in 1770, a book giving details of initiation into the ancient mysteries of the priests of Egypt. A French translation had been edited by Freemason Anton Bailleul in 1778, and that same year the Abbé Rodin, a member of the Parisian Lodge of the Nine Sisters, published a description of the initiatory mysteries of ancient Egypt in his *Researches on Ancient and Modern Initiation.*

Manly P. Hall, in his *Freemasonry and the Ancient Egyptians,* has reprinted an English version of the *Crata Repoa* made at the end of the nineteenth century by a high Mason of the Rite of Memphis, Dr. John Yarker, and Hall claims that a comparison "leaves no doubt that they are from a common source and are maintained by a common inspiration."

The *Crata Repoa* is a reconstruction of the rituals of initiation into the ancient mysteries put together from hints and allusions contained in the writings of such classical authors as Porphyry, Herodotus, Iamblichus, Apuleius, Cicero, Plutarch, Eusebius, Arnobius, Diodorus Siculus, Tertullian, Heliodorus, Lucian Rufinus, and others. From these fragments insight can be gained into the degrees of initiation undergone between neophyte and adept. According to Hall, a high Mason in his own right, the third degree of the *Crata Repoa* corresponds closely to the third degree of the Blue Lodge of Modern Freemasonry.

Crata Repoa initiatory scene from Manly P. Hall's *Freemasonry and the Ancient Egyptians*

dering them more valuable, or to conjure visions of the future, frightening the king with a vision of his grandson, Louis XVI, decapitated. The object of such seances, according to Saint-Germain, was to convince the monarch that reform was essential not only in the Church but in his government if he wished to avoid revolution, urging him to move toward a constitutional monarchy such as in England, and a federated Christian Europe for which peace between France and England was the key. By 1760, Louis agreed to send Saint-Germain to England on a secret mission to negotiate with George III an end to the Seven Years War, which was ruining France. The mission was aborted because of an encounter in the Hague with the adventurer Casanova. Casanova informed French Foreign Minister de Choiseul, who was against the scheme. Forewarned of imminent arrest, Saint-Germain moved quickly to asylum with his friend Frederick II of Prussia, and from there to Russia to help Catherine II seize the throne from her impotent husband Paul III, by summoning—as one historian tells the story—the ghost of Peter the Great to give her instructions how to act. After many adventures, Saint-Germain found in the Duchy of Schleswig-Holstein the ideal prince to help him develop his Rosicrucian projects—

As reconstructed in the *Crata Repoa,* the ancient rite began with circumcision as a permanent sign of belonging, followed by several months' imprisonment in a subterranean vault where the neophyte underwent a severe fast to symbolize that in this life the body is the sepulcher of the soul and can only be released from the serfdom of darkness through the light of initiation. Bound and hoodwinked, to symbolize the limitations of the mortal state, the neophyte was shown that the evils which petrify him when blindfolded lose their power once his eyes are uncovered. Binding the eyes was also a symbol for the necessity of binding the physical senses if the superphysical world is to be perceived.

In the first grade of the ancient Egyptian rite, the neophyte was shown a ladder to climb as the symbol of metempsychosis, his foot placed on the lowest rung to indicate that the ladder of the mysteries extends from the mundane sphere to the empyrian of the wise, and that each disciple as he ascends the grades must become teacher to those directly below him in attainment. The ladder likewise symbolized seven psychic centers of the human body, a ladder to be climbed by mastery of the secrets of yoga. In the first degree, according to Hall, the robes and garments were designed to represent the changes in the auric colors of the disciple resulting from his newly directed spiritual purpose, the conical hat being a symbol of aspiration toward the light, while an apron was a sign of purification. Robed in purity, the disciple was groomed to become "a guardian at the gates of truth," and given the secret password *Amoun,* meaning, says Hall, to be discreet.

How much of this ritual Cagliostro was able to apply to his adepts presumably depended on their desire for advancement, but mostly Cagliostro appears to have used his talents as a thaumaturge and magus to attract followers to at least embark on the way.

According to Cagliostro there had been three important Egyptian practices performed in the Holy of Holies of the Great Pyramid: the convocation of disembodied entities, either of "gods" or of spirits of the dead; divination through a child medium; and, finally, some form of spiritual and physical regeneration.

From the various esoteric doctrines practiced in the temples along the Valley of Nile, Cagliostro took the idea of reestablishing "an intimacy with the ancient 'gods' of Egypt and of enticing their participation into the life of Man." In this he was following the lead, spelled out in Hermes's *Asclepius,* of Ficino, Paracelsus, Agrippa, Dee, Charles of Hesse, son-in-law of the King of Denmark and Grandson of George II of England, who became the magus' truest friend and admirer. A student of alchemy and the magic of evoking spirits, Charles of Hesse was convinced of the existence on the planet of illuminated men, who had penetrated the secret teachings of the ancient Egyptians, Brothers of the Rosy Cross, who received precise, clear revelations from superior beings. Hesse, who was reputed to have mastered the method of intercourse with ghosts and supernatural beings that would appear at his call, was also able to describe his own past lives, which he said included one as King Josias of the Old Testament, another as Joseph of Arimathea, and most recently as the Protestant preacher Zwingli.

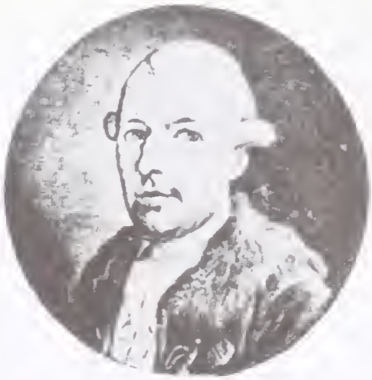
Baroque representation of the archangel Michael

Bacon, and Saint-Germain; and Cagliostro appears to have learned from the Rosicrucian manual *Enchiridon,* the actual steps by which adepts could be put in touch with "angels and the spirits of the dead."

In Leipzig, at the Lodge of Minerva of the Three Palms, Cagliostro learned from Dom Permety, a Benedictine alchemist who had developed a *Hermetic Rite of Perfection,* to convoke "the entities that revolve in heaven." Permety was later made a member of the Academy of Berlin by Frederick the Great, then curator of his Royal Library; eventually he formed the lodge of Illuminés of Avignon.

On the basis of these various techniques, and what he claimed to have learned in his travels in Egypt, Cagliostro fashioned his rite for summoning angels: it amounted to hypnotizing a child, usually a young girl whom he called a dove, or a boy whom he called a *pupille,* to scry in a crystal bowl, illumined by candles, wherein the child could see visions and make prophecies. The officiating magus could then tell people about their own past, including their past lives, with the hoped-for effect of waking them up to the fact that they were indeed immortal spirits, occupying different bodies, and that they were on the planet with some goal to achieve. By communicating with what he claimed to be disembodied entities, and even sometimes by succeeding in materializing some sort of visible form for those present, Cagliostro was better able to convince the participants in his rituals of the Hermetic tenets that the material world they lived in was but one level of reality, interconnected with other more rarefied dimensions, leading up through a spirit world to the divine, where, eventually, all was One.

Several of those who joined the rite brought their own children to act as mediums. In Wittau, Count von Howen brought his son, who turned out to be an expert, going into trance and immediately seeing visions, among which he described the archangel Michael, leader of the planetary spirits, as a shadowy figure robed in white, followed by other archangelic entities such as Anael, Raphael, Zodiachel, Uriel, Anachiel, and Zachariel, appearing in various guises. More instantly convincing were descriptions given to individuals of their own immediate family lives, often amazingly correct. Cagliostro also made more general prophecies. In November 1780 he declared that the empress Maria Theresa of Austria had died. Five days later, the news was confirmed. He then prophesied that the empress's daughter, Marie Antoinette, would give birth without trouble to a healthy dauphin, which she did a few weeks later.



When the chair of Canon Law at the University of Ingelstadt in the Catholic stronghold of the Southern German monarchy of Bavaria became vacant in 1774, after being held for ninety years by the Jesuits (the order was dissolved by Pope Clement XIV), the Curator of the University, Baron Johann Adam Ickstatt, a liberal member of the Privy Council of the Elector who had begun to liberalize the University, appointed to the chair his twenty-six-year-old godson, Adam Weishaupt. Adam's father, also a professor at the University, had died when the boy had been only seven, leaving him to the Baron's care. Brilliant, and well trained by the Jesuits in the conspiratorial methods of access to power, young Weishaupt decided to organize a body of conspirators, determined to free the world from the Jesuitical rule of Rome and help humanity back to the pristine Christian faith of the hermetic martyrs. He is reputed to have been initiated by a German merchant named Kölmer, who had spent many years in Egypt, into a secret doctrine based on Manichaeism. Mayday of 1776, Weishaupt founded his own sect of the *Very Perfectibles*—better known as Illuminati—with five original members, self-described as reformist libertarians, partisans of absolute equality. It was Weishaupt's contention that all that was needed to recover man's original nature was "to create the good society," a goal, he maintained, which demanded only that "men should understand the weight of prejudice and error encumbering them." Universal happiness, complete and rapid, could be achieved, he declaimed, by dis-

In Ingolstadt, Cagliostro is believed to have met Adam Weishaupt, professor of philosophy and canon law at the university, who, in 1776, had founded the sect of Illuminati. Calling themselves heirs to the Knights Templar, they declared their interest in using celestial intervention as achieved by Cagliostro for the furtherance of a program of worldwide religious reform, but one more radical than Cagliostro's, "committed to avenging the death of the Templar's Grand Master Molay by reducing to dust the triple crown of the popes and disposing of the last of the Capet Kings."

Cagliostro obliged, and described in prophetic detail the decapitation of Louis XVI, an event hardly to be envisaged at that time as anything but improbable.

posing of hierarchy, rank, and riches. "Princes and nations," said Weishaupt, "will disappear without violence from the earth; the human race will become one family; the world will be the abode of reasonable men. Mortality alone will bring about this change imperceptibily." Unable in Catholic Bavaria to achieve this utopian goal by direct means, Weishaupt determined to work from within an existing organization: the Masonic order. In 1777, just a year after Cagliostro had joined a lodge of the same Strict Observance, Weishaupt was initiated in Munich into the lodge of *Theodore of Good Counsel.* Within two years he was in control of the lodge. Further to expand membership in his Illuminati, Weishaupt recruited a youthful but effective Masonic organizer, Adolf Francis, Baron Knigge. By 1779, there were 54 members of the Illuminati, mostly young noblemen and clergymen, established in four Bavarian cities. Thereafter, with the help of a Masonic bookseller, Johann Bode, the order branched out through Southern Germany and Austria, and down into France and Northern Italy. Intellectuals, such as Goethe, Schiller, Mozart, and Herder were attracted. Bode even managed to recruit Saint Germain's friend and protector Prince Charles of Hesse, then director in Germany of the Strict Observance Ritual, though he soon withdrew, influenced apparently by Frederick Wilhelm, heir to the throne of Prussia. By the end of the 1780's, "no one could be sure how many Masons shared the Illuminati views." Already Bavarian Jesuits were preparing a massive counterattack. As with Luther, they first attacked Weishaupt on his personal life, accusing him of having fathered an illegitimate child and of having tried to perform an abortion for his sister-in-law while awaiting dispensation to marry her. Thanks to a bolt of

On the physical level, what the aspirant initiate found appealing in the Egyptian rite was a means, probably learned from Saint-Germain, of regenerating the body every fifty years. As described by Cagliostro, the method, starting with the full moon of May, required forty days of the strictest dieting and consumption of elixirs designed to eliminate all toxins from the body. At the end of the ordeal, in a climax of convulsive fever, the body was to shed hair and teeth, which with all the other cells of the body, were to regenerate and last another fifty years.

For the postulant to recover knowledge of his own immortality, Cagliostro developed a spiritual retreat of forty days leading to initiation and enlightenment.

For spiritual regeneration, the psychic objective involved the search within the male for his female counterpart, and for females the male, so that, mated, they could "flower, through the miracle of love, and give birth to a whole new self on a higher plane."

For women, Cagliostro founded the Egyptian Lodge of Adoption, with Serafina as Grand Mistress. Robed in a white-and-gold gown embroidered with the words *Virtue, Wisdom, Union,* she officiated with the symbol of will in her hand: the sword. On her apron of white leather, trimmed with blue roses, symbols of regeneration, were the words *Love* and *Charity.*

lightning which struck the house of one Illuminatus, the police seized a cache of incriminating papers. The Elector issued an edict outlawing all secret societies in the provinces. Another edict of March 2, 1785, specifically condemned Freemasons and Illuminati, offering rewards for those who would reveal what they knew of the organization. Numerous documents seized in a police raid provided the government with what were considered sensational revelations, showing prescriptions for inducing abortions, for making secret inks, and indications that the order claimed the power of life and death over its members. The Illuminati were accused by the Jesuits of seeking ingredients for abortions to be "free to debauch women, or indulge in all manner of licentiousness." Dismissed from his post at the University, Weishaupt fled to a neighboring province. The order went underground; but the Jesuits continue to pursue it to this day.

As a place to settle, Cagliostro chose the Rhineland city of Strasbourg. There he arrived with a special rose powder which he said enabled him to soften hard marbles, and with formulas he claimed allowed him to transmute metals and precious stones; he also brought elixirs for health and long life. He is described as entering the city in a coach covered with magical symbols, preceded by six servants riding black horses. As news spread that the great miracle healer had taken a house in town, rich and poor flocked to his door, on crutches, on stretchers, in every state of disease. In all of these Cagliostro took a benevolent interest, soothing, restoring confidence, healing. The record is abundant, precise, and incontrovertible. Hundreds of cures were attested to by official statements and reports, including those of several physicians and priests.

But when asked how he performed his miraculous cures without orthodox training, Cagliostro replied that a spiritual healer had no need for what passed as "medical science," that his was a more ancient therapeutic art he had learned in the East. Through his gift of clairvoyance, he said, he could analyze the mind as well as the body of his patients, urging them to purify their souls. The power to heal, he insisted, came not from him, but from the

patient; it was largely a question of finding the equilibrium of the forces that flowed from the greater cosmos through the smaller cosmos of the human body, an equilibrium which could sometimes be reestablished, as he had learned from Egyptian and Chinese medicine, with no more than a single word or a gesture.

He extolled the sublimity of nature and the limitless possibilities for spiritually regenerated man in a state of "pre-Adamic" grace. "He who is illumined by the light of Nature," he quoted Paracelsus, "will succeed in penetrating the whole structure of man, and will find the right remedy." Like a good Rosicrucian, Cagliostro not only refused to accept money for his cures, but was constantly distributing largesse to those of his patients who were too poor to feed themselves or take care of their needs in order to get well. And though the source of Cagliostro's money remains a mystery—unless he somehow had access to the remaining treasury of the Templars—he was never in any financial trouble involving the law.

Cardinal de Rohan

News of Cagliostro's fabulous cures reached the ears of the bishop of Strasbourg, Louis René Édouard, Cardinal de Rohan, Prince of the Empire, Landgrave of Alsace, Headmaster of the Sorbonne, Grand Almoner of France, a descendant of the ancient kings of Brittany. As scion of one of the most important families of France, he held vast lands, and resided at his sumptuous Château de Saverne, where he was attended by fourteen butlers and twenty-five valets. The cardinal, who, like Cagliostro, cherished a passion for alchemy, sent word that he was eager to meet the magus. "If the cardinal is ill," replied Cagliostro, "let him come to me and I will cure him. If he is in good health he has no need for me, nor I for him."

The rebuff, instead of infuriating or insulting the cardinal, aroused his curiosity. In his luxurious coach, he drove off to visit Cagliostro on the excuse that he wished to be cured of his asthma. Cagliostro obliged, explaining that he saw no conflict between holy religion and celestial magic, the latter being sanctified by the Bible under the laws of Saint John. "Magic," said Cagliostro, "is an art due to divine goodness, dedicated to the fullfilment of the divine will." Rohan invited Cagliostro to stay at his château, where he put a laboratory at the magus's disposal and where the cardinal attested to seeing Cagliostro produce before his eyes not only gold, but diamonds. "In my place, in my presence," said the cardinal, "he has made five or six thousand pounds worth of gold."

When the cardinal's elder brother, Charles de Rohan, prince of Soubise, became seriously ill in Paris, Cagliostro

Mesmer's baquet

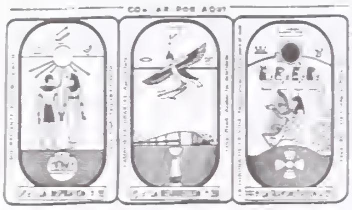
agreed to travel with the cardinal by coach to the capital to effect a cure. It was the summer of 1781, just when Pius VI and Antinori were preparing to raise the obelisk in front of the Quirinal. In Paris, Cagliostro found the prince of Soubise wasting away as the result of an attack of scarlet fever. In three days the magus had the old man on his feet, and in two weeks he was back at court, where Louis XVI was so impressed he ordered special protection extended to Cagliostro.

Letters of recommendation from Louis's minister for foreign affairs, count de Vergennes, from the keeper of the Royal See, the marquis de Miromesnil, and from the minister of war, Marshal de Ségur, charged the authorities in Strasbourg in the king's name to extend every consideration to Cagliostro. But the fact that the magus performed his cures without charge, and often on patients whom the orthodox medical profession declared to be incurable, roused the enmity of the organized doctors of Strasbourg. What most irritated the faculty members of the university was his overtly authoritarian manner in matters of curing. The physicians of Strasbourg, outraged at Cagliostro, did to him what their compeers in Vienna were then doing to Franz Anton Mesmer for the very same reason: they launched a monstrous campaign of calumny, including public posters, anonymously labeling Cagliostro a quack and a charlatan, so poisoning the atmosphere that he decided to leave.

In Lyons, center of Illuminism, and of interest in the occult, lived numerous followers of the clairvoyant philosopher who explored the spirit world in vision—Emanuel Swedenborg. There were also the followers of the so-called "unknown philosopher," Claude de St. Martin, and of Martinez de Pasqually's Elus Cohens who had returned to the Gnostic concept of the universe as a living divine organism in which man could rise through the cabalistic spheres to his true and divine self. Received with great enthusiasm by the Masons of Lyons, Cagliostro believed he had found the true setting for building a Central Masonic Lodge devoted to his Egyptian Rite. The Lyonnais were happy to contribute to the creation of a *Lodge of Triumphant Wisdom* of which Cagliostro would be Grand Cophte. Started in 1784, the splendid temple was ready in 1785, complete with huge pillars of Jakin and Boaz, red and white, as in the Temple of Solomon, symbols of the two forces which, in equilibrium, sustain the universe, represented in the temple by a great vault decorated in the image of the infinite. As in Egypt, the walls were carved with hieroglyphs, and there were statues of Isis, Anubis, and Apis, the sacred Egyptian bull.

Anubis, jackal-headed "god of the dead," is called "guardian of the secret of transformation and leads the deceased toward a state of bliss or to grievous trials." According to myth, Anubis was the son of Nephthys, who had tricked her brother Osiris into having intercourse with her. Abandoned by Nephthys, Anubis was raised by Isis. He helped find and embalm the body of murdered Osiris, through whose kingdom he then guided the dead.

From all sides, says Cagliostro's biographer François Ribadeau Dumas, adherents flocked to Cagliostro's Egyptian rite, "drawn by the beauty of its sentiments, the loftiness of its ideals, its central rule of love." In the lodge, the neophyte was to be put through the grades of initiation, applying himself to the problems of living in the world while remaining pure to spiritual law.



De Gébelin suggested that the Tarot cards were leaves of a sacred book which had descended from ancient Egypt, representing symbols of philosophical and metaphysical importance. Tarot was understood to mean the innermost nature of something, its principle, or the law of its being, one which could act as the key to ultimate reality.

In the second grade more symbolic hazards were applied, and the neophyte was taught to withstand bodily terror by being covered with snakes. Removal of the snakes meant liberation from the illusions of this world. By breath control the neophyte was to learn to master the serpent power within his own body. Instructed in the secrets of geometry, he was to measure the universe by the rule of living. As a symbol of the fall of the human race from the Golden Age of Saturn he was given the caduceus of Toth and told it was an emblem of the movement of the sun around the ecliptic.

In the third degree of the *Crata Repoa,* which Hall corresponds to the third degree of the Blue Lodge, the neophyte descended into the abode of the dead where lay in effigy the murdered Osiris, slain by Set, the animal nature in man, the mummy bonds emblems of the hampering agencies of ignorance, superstition, and fear. Here the sword of karma was placed against the neophyte's throat to remind him that if he broke the law, he would destroy only himself, that the law of society represents the law of the universe.

Hall believes that in this ritual the neophyte was actually knocked out by a blow on the head to experience seeming death in order to learn that he could exist outside his body. Alternatively he was given a drug from a goblet made from a human skull to lead him to the world of spirit.

As Kenneth Grant points out in his *The Magical Revival,* the Egyptians distilled the juice of the sycamore, the sacred fig tree, because it was noticed that mortals who drank it "were transformed into immortal spirits, able to penetrate the spirit world and hold commerce with disembodied spirits and other subtle entities." The liquor was then mythified as nectar, ambrosia, or the drink of the gods. In India the juice of the *peepul* was said to "place men on an equal footing with the gods, enabling them to see into the past and into the future, to transcend space and time, to know the secrets hidden in the regions of the universe."

After this stage came the greater mysteries in which the initiate was shown the "elemental potentates, archangels, angels and tutelary spirits and the various orders of the upper world," to demonstrate, as Yarker puts it, "the great perfection to which the Egyptians had reduced the science of theology."

In the next grade the initiate was taught the secrets of alchemy, or how to direct the power of fire to decompose substances and combine others, in order to acquire metaphysical knowledge and superphysical powers by means of which to transmute the evil in human nature into perfect "gold" or "light."

In the sixth, or penultimate, grade, the initiate was shown that the "gods" of the Egyptians were "the principles of life and the workings of universal law . . . vast beings rooted in eternal principles sustaining the universe by their emanations." Here the initiate was shown the bodies of the dishonored dead who had betrayed the secrets of the Society indicative of the occult truth that the spiritual powers of the universe cannot be perverted without fearful compensation, and that broken vows will destroy the body and unseat the reason. In the seventh grade, say Yarker and Hall, all the great mysteries were explained.

But Cagliostro could not tarry with his adepts in Lyons. He was summoned to Paris by his friend Cardinal Rohan, who, anxious to return to royal favor, and hopeful of becoming the king's first minister, pleaded with Cagliostro to use his wonder-working powers to help him regain the favor of Marie Antoinette. The queen had been displeased with Rohan ever since he had returned from being French Ambassador to the Viennese court of her mother, the Empress Maria Theresa, who disliked the cardinal for his lavish style of living and his penchant for pretty young ladies.

Grand Master Court de Gebelin

Cagliostro and Serafina arrived in Paris in January of 1785 as guests of the Cardinal, and were put up in his sumptuous palace, the Hotel de Strasbourg. But Cagliostro, seeking privacy, soon moved to a smaller house of his own not far away in the rue Saint Claude, now the Boulevard Beaumarchais.

French Masons were quick to welcome Cagliostro, inviting him to join the Lodge of the Nine Sisters, that "most mystical and esoteric of the French Lodges," also described as "a university of world political philosophy," grand-mastered by Benjamin Franklin, then the main link between the secret societies of Europe and America, to whom Cagliostro is reported to have prophesied that a New Atlantis would be rising in America. Among the other distinguished members of the Nine Sisters were Voltaire, Helvetius, and Thomas Jefferson. Another brother was Franz Anton Mesmer. And one of Mesmer's patients, who attested to having been cured by him, was a former Grand Master, Antoine Court de Gébelin, France's leading orientalist, first to identify the pack of Tarot cards as a reservoir of ancient Egyptian wisdom, the secret teachings of the Egyptian priests, who, he asserted, had thus disguised their arcane knowledge, their symbolic depic-

The duc de Chartres, shortly to inherit his father's title of Duc d'Orléans, was one of the richest men in France, but popular in Paris because of his gifts to the poor. Known as a liberal, with aspirations to becoming a constitutional monarch, he is described by contemporaries as "possessing the charming manners of a *grand seigneur,* never rude or cruel, full of gentle consideration for all about him, though selfish in his pursuit of pleasure." Accused during the Revolution of aspiring to replace Louis XVI, he adopted the title of Citoyen Egalité and was elected deputy from Paris to the Convention. When faced by the terrorists' guillotine, he was accused of arguing that he was not truly of noble extraction, but the son of a coachman who had been his mother's lover. Shocked by such behavior, surviving Masons are said to have celebrated his defection with a ritual degradation and breaking of his sword.

tions of the structure of the universe, received from Hermes Trismegistus so that it might survive through the ordeal of Christianity after the collapse of the pagan world.

Asked by a committee from the leading Masonic lodges of Paris to interrogate Cagliostro on ancient Egyptian philosophy, de Gébelin was struck by Cagliostro's amazing replies, as were all those present, who admitted they had met their master in such matters. Urged by fellow Masons to open an Egyptian-rite lodge in Paris, Cagliostro installed himself as Grand Cophte of the Temple of Isis in the rue de la Sourdière. There he admitted women to "the mysteries of the pyramids," attracting such high-ranking ladies as the queen's favorite, Madame de Lamballe, who was initiated at the vernal equinox of 1785. Cagliostro then formed a supreme council with the duc de Montmorency as Grand Protector, Jean-Benjamin de Laborde, farmer-general of France as Grand Inspector, and Beaudard de Saint-James, wealthy treasurer general of the French navy as Grand Chancellor. His Royal Highness the duc de Chartres, Grand Master of French Masonry, attended an Egyptian-rite ceremony, declared his confidence in Cagliostro, and announced his official recognition of the rite. Another *grand seigneur* with equally liberal tendencies, fresh from aiding the Americans in forming a republic, also joined Cagliostro's Egyptian rite and proclaimed his absolute confidence in the powers of its Grand Cophte; Marie Joseph Paul Ives Roch Gilbert Motier, Marquis de Lafayette.

The Duc de Richelieu, under an assumed name, and wearing a disguise, came to consult Cagliostro and was shown a past life as Ruggieri before Catherine de Médicis. And just as clearly as he described the past lives of the duke, Cagliostro declared he could see the rot behind the apparent splendor of Louis's police state, which was causing misery and degradation among the masses. But although Cagliostro called for greater social justice for the poor, the sick, and the underprivileged, his political principles were oriented more toward "regenerating the Christ in man," as a means of achieving a peaceful transition to a constitutional monarchy. In the more liberal forces of Masonry, and especially among the followers of his own rite—whom he confidently estimated to amount to a million souls—Cagliostro saw a determined desire to search for a better system of life, without recourse to bloody revolution.

In France, where the papal bulls against Masonry had never been promulgated, twenty-six Masonic lodges were presided over by priests, and members of the clergy of all ranks constantly frequented Masonic rituals. Catholic lodges had been founded in Paris under the protection of the marquises de Girardin and de Bouillé, both royalists and friends of Saint-Germain, whose goal was to "establish communication between God and man by means of intermediary beings." Soon so many priests were attending the Egyptian ceremonies, declaring themselves highly satisfied with the rite, that Cagliostro, whose dream was to effect a union of his Egyptian science of magic with the fundamental beliefs of Christianity, was moved to hope his order might at last be recognized by the pope, as had been the order of the Knights of Saint John.

Cardinal de Rohan promised Cagliostro his support and appealed to the archbishop of Bourges, to whom Cagliostro explained his rite. A favorable report was apparently sent to Rome, and the dossier seems to have been presented to Pius VI under promising auspices.

Pius was just then admiring from the windows of his summer palace on the Quirinal the San Rocco obelisk at last being raised by his architect Antinori between the two great horses placed in the square by Sixtus V. The delay of four years in handling the needle had been caused by Antinori's failure to find a way to turn the great rampant beasts so the pope would not have to face their rear ends. Prodded by Pius, Antinori at last found a way; and the operation, in the end, required no more than ten minutes per horse.

But the Romans did not think much of the monument, nor of the expense it had entailed, and some wit changed the inscription on the base of the equestrian statues—which had been mistakenly attributed to the Greek sculptor Phidias—from OPUS PHIDIAE to OPUS PERPHIDIAE PII SEX II. And the obdurate and purblind reaction of Pius to Cagliostro's ecumenical suggestions was to dash the magus's hopes for a peaceful solution to the revolutionary fervor in France. Instead, an unexpected Parisian scandal was to pit the pope's dutiful acolyte Louis XVI against the forces of Freemasonry and accelerate the French Revolution.

7. PIOUS TERROR

Jeanne de la Motte managed to live at Versailles by boasting royal blood as a descendant of an illegitimate scion of the Valois family who had committed forgery under Louis XIII. Her husband, a gentleman soldier in the gendarmerie, was a rake and a gambler.

The day Calgiostro arrived in Paris, Cardinal de Rohan, in his haste to get back into the good graces of Marie Antoinette, had fallen for the ploy of a scheming female, Jeanne de Saint-Remy de Valois, who called herself Countess de la Motte. The impoverished descendant of a bastard son of Henry II, the woman used a tenuous position at court to convince Rohan she had access to the queen whose favors she could obtain for the cardinal, if, with his large fortune, he would guarantee a financial transaction. The queen, said de la Motte, wanted a fabulously expensive diamond necklace which the king, considering the economic condition of the country, thought impolitic to buy for her. But if the cardinal would merely act as guarantor to the bankers who owned the necklace, the queen could acquire it immediately and pay for it in installments from her private funds. In return she would grant the cardinal her "favor," and even meet him clandestinely in the park of Versailles.

None of this had the cardinal told Cagliostro, though the latter had repeatedly warned him to beware of de la Motte as an unreliable fraud. The cardinal, already infatuated by the schemer's sexual attractions, was even more delighted by the prospect of becoming a lover of the reputedly sensuous queen. But the scheme went wrong; and when Louis XVI was informed of his wife's involvement, the la Motte woman, in a desperate attempt to save herself, tried to shift the blame onto Cagliostro whom she accused of being the Cardinal's own *eminence grise*. By chance, or good fortune, one of the financial backers of the jewelry firm which had delivered the necklace was Monsieur Beaudard de Saint-James, Grand Chancellor of Cagliostro's Egyptian-rite lodge. Promptly he informed Cagliostro of the charges brought against him by the countess, who accused him of having purloined the necklace and selling the stones in England—which was just what she had done, with the complicity of her husband, a disreputable minor guard's officer.

Foolishly, Louis XVI ordered an investigation by parliament, and by *lettre de cachet* had Cardinal Rohan arrested just as he was about to celebrate mass on the Feast of the Assumption in the royal Chapel. Into the lurid dungeons of the Bastille the unhappy cardinal was followed by Cagliostro and Serafina, all placed incommunicado.

As the months wore by, without news of his wife, or of the outside world, Cagliostro kept himself sane by writing his memoirs. Outraged at the horrible injustice of a system which allowed a king by simple *lettre de cachet* to imprison in the Bastille anyone he chose, for as long as he chose, even for a lifetime, without access to a lawyer, to be tortured at the pleasure of his jailers, Cagliostro prophesied the brutal death of the Bastille's governor, the Marquis de Launay, and the transformation of the fortress into a Temple of Freedom, property of the people of France.

Brought to trial before a parliamentary court, and asked who he was, where he was from, what he did, and by what right, Cagliostro replied: "I do in God's name all the good I can. It is a right that requires neither a name, nor a country, neither proofs, nor caution. . . . Am I not a free man? Judge me by my habits, by my actions. Tell me if they are good, tell me if you have seen any that are more effective. Then do not occupy yourselves with my nationality, my rank, or my religion."

When, on the witness stand, Madame de la Motte accused Cagliostro of all sorts of crimes, saying she "only regretted not living in those blessed times when a charge of sorcery would have led Cagliostro to the stake," Cagliostro calmly replied that he forgave her, and

Jeanne de la Motte conspiring with Marie-Nicole Leguay, alias Baroness d'Oliva, who bore a remarkable resemblance to Marie Antoinette, as they arrange a meeting with Cardinal Rohan. The girl agreed to impersonate the queen at night in the rose garden of Versailles to induce Rohan to act as security for the diamond necklace. She gave him a rose and a note signed "Antoinette de France," hopeful harbingers of a sexual assignation.

Jeanne de la Motte being branded on the shoulder by the hangman with red-hot V for *voleuse,* or thief, before being exposed naked to the crowd in front of the Conciergerie with a rope around her neck. She later died in London from a fall from the window of her lodgings. The jewels she stole from the necklace, small and very blue, were bought by John Frederick Sackville, third duke of Dorset, ambassador to the court of Louis XVI, and are in the possession of the family at Knole in Kent.

that he assumed her calumnies must be inspired more by the desire to clear herself than of actual hatred against him. The parliamentary court, after due deliberation, found Madame de la Motte to be the guilty party, condemning her to be publicly whipped, naked, by the executioner, and to be branded with a hot iron on both shoulders, forfeiting all her properties. Cagliostro, Serafina, and Rohan were found guiltless and released. But the governor of the Bastille, fearing a daylight demonstration in favor of Cagliostro by the people of Paris, only let the Cagliostros out close to midnight. But a tumultuous crowd of almost ten thousand Parisians who considered Cagliostro a hero against whom the king had been arbitrary and unjust, was there to greet them and carry them on their shoulders to their house, acclaiming Cagliostro for his liberalism, his powers as a healer, his generosity to the poor, and his innocence as a victim of the hated Austrian, Marie Antoinette, whom the Parisians believed to have been guiltily involved in the affair of the necklace.

As for the queen, incensed by the release of Cagliostro, she forced the vacillating Louis to order him out of Paris in twenty-four hours and out of the country in twenty-one days. As the Cagliostros' ship sailed from Boulogne, an estimated five thousand French well-wishers waved farewell to the man they considered the greatest living benefactor of mankind.

From London, Cagliostro addressed a letter to the people of France in which he attacked Louis XVI's absolutist regime, prophesying the advent of a new constitutional monarchy in which *lettres de cachet* would be abolished, and predicting that stone by stone the Bastille would be demolished till the people of Paris could dance on its site.

Romantic cliché of the demolition of the hated Bastille

In his memoirs, written in the Bastille, Cagliostro described a childhood in Medina, under the name of Acharat, where he was tutored by an elderly Greek occultist, Althotas, confidential adviser to Grand Master Pinto, who took him to live in the palace of the Grand Mufti Salahyn, high priest of the Moslem religion. There, said Cagliostro, he was taught botany and medicinal physics while being exposed to the wisdom of Islam, eventually traveling to Mecca to be initiated into Chaldean magic and the wisdom of the Assyrian sect of the Old Man of the Mountain—the Hashishin. A further pilgrimage, similar to that of the legendary Rosenkreutz, took him to Egypt to be initiated into the secrets of the Great Pyramid, and be told of the great underground halls where the ancient priests protected a precious store of human knowledge. In Fez, said Cagliostro, while in a trance, he was further initiated into the contents of the Rosicrucian secret books of *T* and *M*.

The widespread publication of this letter in France aroused Louis and Marie Antoinette to further vengeance. Ambassadors and agents of the king were ordered to make life, wherever the Cagliostros might try to enjoy it, impossible.

Grounds for such an action were to be fabricated with the expertise of a professional blackmailer and libelist, Theveneau de Morande, a police informant who for some years had spied on the French community in London, and who lived on a yearly pension of 4,000 francs blackmailed out of Louis XV's mistress, Madame du Barry, by threatening to divulge details of her private life as a prostitute, which, in the end, he did anyway. Morande, as the editor in London of a scandal sheet called *Courrier de L'Europe*, was hired to launch a scurrilous campaign of defamation against Cagliostro and his wife. In a series of articles paid for by Louis, he set to libeling Cagliostro as a charlatan, an imposter, and a petty crook, using for ammunition the evidence fabricated by Madame de la Motte, ordered destroyed by parliament, a surviving copy of which was

Marie Jeanne Bécu, countess du Barry, known as "la sultana," the all-powerful courtesan mistress of Louis XV for whom the diamond necklace was originally designed, before the king suddenly died. In her ghosted memoires she tells how Cardinal Rohan brought Cagliostro to her house to show her her future in a "metallic glass and ebony frame, ornamented with a variety of magical characters," warning her she might not like what she saw. When du Barry looked she fainted—presumably at the sight of her own head rolling from the guillotine on December 7, 1793.

furnished to Morande by Louis's minister of state, Baron de Breteuil. Morande also managed to collect stories from those of Cagliostro's former servants who had stolen from him, or betrayed his confidence, and were now happy to defame him for money. Added to this anecdotal padding were attacks from one of the most dangerous of all sources: those women, such as Baroness von der Ecke, whose favors Cagliostro had declined.

Cunningly, Morande hit upon an assured method for defaming Cagliostro: he attributed to his victim the crimes of a pimp and petty crook, the Sicilian Giuseppe Balsamo, who was known to have been repeatedly arrested for minor crimes and for selling the favors of his pretty wife, Lorenza, to prospective victims. For Morande, it was nothing to charge that Cagliostro and Balsamo were one and the same. For Cagliostro, there was nothing to be done but deny the allegation, which he vehemently did: "It is not I who under the name of Giuseppe Balsamo was driven ignominiously from Paris in 1772. And, it is not my wife, who under the name of Lorenza Feliciani was imprisoned. No police register, no testimony, no investigation by the Bastille authorities, no notice of information, no proof at all has been able to establish that I am Balsamo. I deny that I am Balsamo."

But the libel spread, and as each lurid article, concocted in the best style of red-herring journalism, followed the other, the appetite of readers grew with what it fed on. Using false and anonymous letters to the police, Morande was able to print details so circumstantially lascivious that the public began to wonder if indeed it might not have been duped, if Cagliostro, at least in his early life, might have been the crook Balsamo. As Morande's *Courrier* went the rounds of Europe, Catherine the Great of Russia, turned by her Jesuit friends against Masons, used Morande's material to lampoon all of Masonry through Cagliostro in a series of plays which drew ridicule on the magus as a charlatan and mountebank. Even Goethe, a brother Mason, fell for the *canard*. In disguise he traveled to Palermo to investigate the identity of Balsamo by interviewing his family, and though Goethe obtained not a shred of evidence to support the contention that Cagliostro was Balsamo, he decided to protect his own flank by waffling.

All over Europe, such is the nature of man, people too closely associated with Cagliostro thought it best to dump their former hero. Some of the charges were wild: such as

Gillray's caricature of Cagliostro at a convivial gathering of the Lodge of Antiquity in London in November 1786, where, instead of the sympathy he expected from fellow Freemasons, the magus was ridiculed by one called Mash, an optician, who gave a burlesque imitation of the Grand Cophte of Egyptian Masonry as a quack doctor vending a spurious balsam to cure every malady. Cagliostro was so mortified he withdrew, and left the country.

those of the comte de Mirabeau—never averse to changing coats—who voiced the opinion in a pamphlet that Cagliostro had all along been an emissary of the Jesuits "hatching secret plots in Protestant countries."

In London, whereas the Lodge of Antiquity of the Scottish rite had honored Cagliostro with a magnificent reception on his arrival in November 1786, Masonic friends began to avoid him for fear of being tarred by Morande, especially when his journal accused the membership of the London lodge which had initiated Cagliostro of being composed of "valets and barbers." The atmosphere necessary for Cagliostro to create a lodge of his Egyptian rite in London no longer existed. To avoid trouble with Louis's agents, Cagliostro left for the Continent, alone and incognito.

In Switzerland he was greeted and cared for by staunch Masonic friends, but the atmosphere was no better suited for a prolonged residence. From Switzerland, where Serafina had joined him, the Cagliostros traveled to Turin; but the king of Sardinia, on instructions from Paris, ordered the refugees out of town within twenty-four hours. At Rovereto, in the Austrian Tyrol, where Dante had sought refuge in exile from Florence, Cagliostro was welcomed by old and trusted Masons, who helped him open a lodge of the Egyptian rite by the shores of the Adige. There he set about curing the sick, as usual, gratis, until the doctors, priests, and magistrates joined to force him out of town.

Friends advised him to try Trent, where the bishop, Monsignor Pier Vigilio Thun, an Austrian prince, was much taken with alchemy and occultism. The bishop welcomed Cagliostro and even accepted the possibility that his rite might be accepted by the Church, if only Cagliostro could, as he had done for him, lay out its content to Pius VI, directly, person to person. To facilitate matters, the bishop addressed a letter to the Vatican secretary of state, Cardinal Boncompagni, asking for a safe-conduct for Cagliostro to travel in the Papal States. The cardinal answered that "Cagliostro, being under no prohibition in the Pontifical States, has no need for the safeconduct you request."

Further to aid Cagliostro in his venture, the bishop of Trent addressed letters of recommendation for him to cardinals Boncompagni, Zelada, Colonna, and Albini. After a great banquet in the bishop's palace, on May 17, 1789, just as Mirabeau in Paris was challenging the will of Louis XVI in the States General, precipitating events toward a break with the monarchy, the Cagliostros set off by carriage for Rome to obtain from Pius VI approval for his

When asked to be more specific about his nationality, Cagliostro replied: "All countries are dear to me. All men are my brothers. I am a wanderer. On my way I do what good I can; but I do not tarry. As I pass I leave a little light, a little warmth, a little of myself until all shall be spent at the end of my career, when the rose will flower on the cross. I am Cagliostro. Need I say more? If only you realized that you are, as you are, the sons of God, if you were not so vain, you would have already understood." Asked to explain the secret of his nature, he replied without pomp or vanity: "I am of no time and no place. As a spiritual being I exist eternally, and if I immerse myself in my thoughts going back over the years, if I project myself towards a way of life quite far from that which you may perceive, I can become whomsoever I please. Participating consciously in the absolute being, I best regulate my actions with that which surrounds me. My name is that of my function; and I choose it, as I choose my function, because I am free. My country is the one in which I momentarily pause. Date it yesterday, or tomorrow, if it suits you, and that illusory pride of a grandeur that may never be yours. I am he who is."

Architect Antinori showing Pius VI the newly raised fifty-foot obelisk believed to have been part of Sallustius's circus dedicated to the festival of the goddess Flora. It was now adorned with a spherical star containing a piece of wood reputed to have come from the Most Holy Cross of the Crucifixion, with relics of saints Paul, Andrew, Gregory the Great,

Egyptian rite of Masonry, a move intended to reunite Christian and Mason in the Hermetic dream of a new and progressive order.

And so the trap was set.

Arriving in Rome at the end of May, Cagliostro and Serafina, who was happy to return to her native city and visit her aging parents, were just in time, as they put up at the small hotel della Scalinata on the Spanish Steps, to witness the inauguration of another obelisk raised by Antinori for Pius VI at the top of the steps, facing the Church of the Trinità dei Monti. Placed so that a person standing at the exit of the pope's summer palace could admire from a single spot the perspective of three separate obelisks at the end of the via Quattro Fontane, the via Sistina, and the via XX Settembre, the new monument was clearly an adornment to Rome. But its symbolic function was the more apparent in the face of political trouble in France. Like its predecessors, this obelisk was being raised as an overt symbol of the Church's determination to squash the Hermetic tradition from Egypt manifesting as it was in France through efforts of French Masons, 477 of whom were members of the States General.

Pius's plot was Jesuitical in the extreme. On the pope's direct orders, Cagliostro, from the minute he arrived in Rome, had been placed under surveillance by agents of the Inquisition, not only in the hope that they might ferret

and Pius V. Broken pieces of the obelisk had lain opposite the Lateran Palace ever since Pope Clement XII had stolen them from the garden of the duke of Sora (where they had surfaced among the flowerbeds in 1734), on the excuse that *all* the antiquities in Rome belonged to the Reverend Household. Then came the French connection. In 1765 France's minister of finance tried to buy the needle for 25,000 francs to place in front of Nôtre Dame de Paris. And on the grounds that the entire Pincian Hill had belonged to the kings of France since Charles VIII, the Minimi Friars of the Trinità, afraid the work would undermine their church, appealed to the French ambassador, Cardinal de Bernis, to have the project stopped. Pius VI remained obdurate; the needle went up just as Cagliostro arrived in town, in time to hear the complaints of the populace, who joked about its shortness. Goethe, also in Rome, described a hat at carnival made of a tiny red obelisk atop an enormous white pedestal.

Cardinal François Joachim de Bernis, French ambassador to the Vatican, whose poetry had so pleased Madame de Pompadour he was named minister of foreign affairs under Louis XV. The marquis de Sade, in *Justine,* renders one of the most pornographic poems in the French language, attributing its authorship to the cardinal.

from their secret hideouts the Masons of Rome, but in the hope that Cagliostro might be used as a scapegoat for discrediting Masonry throughout the world. A pirated copy of de la Motte's memoirs, including the false letters she had fabricated as having passed between Rohan to Marie Antoinette, had been delivered to Pius, along with the libelous articles produced by Morande.

Unaware of the trap, and secure in the protection of his letter from the secretary of state, Cagliostro first drew up a petition to Pius, laying before him the regulations and constitution of his Egyptian rite. He then called on the Vatican and left his credentials, declaring that the rise of Masonry in the heart of Catholic countries could not fail to deserve the benevolence of the Vicar of Christ, especially as the ritual had as its preamble: "Love and worship the Lord God with all your heart, cherish and serve your neighbor by doing all the good to him of which you are capable, let your conscience be your guide in all your actions."

Masonic circles in Rome, mostly in the aristocracy, and among foreign diplomats, welcomed Cagliostro, especially at Villa Malta, near Porta Pinciana, the Roman residence of the Knights of Saint John of Jerusalem, a great many of whom were initiate Masons, as was their Roman Master, the Bailly de Loras. There Cagliostro organized Masonic séances, and initiated members of Roman society into his Egyptian rite. In Malta House he was safe, since its grounds were covered by diplomatic immunity. There he performed one séance in the presence of the French ambassador, Cardinal de Bernis, and several members of Rome's nobility, which was later described by an eyewitness, the abbot Lucantonio Benedetti, as taking place in a large hall adorned with Egyptian, Assyrian, and Chinese idols.

When a young female medium described seeing a crowd surging toward Versailles, demanding the overthrow of the king, the French ambassador became much perturbed. And even more so shortly thereafter, when he heard that the revolution had actually started in France, that the scene described by the young medium had actually taken place in real life, conveyed by some occult means. On July 14, as Cagliostro had predicted, the people of Paris seized the Bastille, and slaughtered his old jailer, the Marquis de Launay.

On August 4, ecclesiastical privileges were overthrown in France, there were riots in churches, convents were sacked and burned; the clergy made plans for a civil constitution, separating themselves from Rome. A decree

Caricature of Louis XVI, overwhelmed by the gross burden of both the nobility and the clergy of France

was issued by the National Assembly declaring that all men have a right to think as they choose in matters of religion, and express their opinions on the subject, that man is accountable for his actions, not his beliefs, which are his own business. Man, said the decree, is bound to obey only laws to which he has consented.

In reaction, Pius VI issued a contract to Antinori to raise a third obelisk, in Piazza Montecitorio, before the papal Palace of Justice—ironically the seat of Italy's future parliament, and took immediate security measures to prevent the entrance into the Papal States of potential subversives. Watch was redoubled against a possible uprising among an estimated five thousand armed Masons within the Papal States, who were believed to be only waiting for a signal to rise up with the help of more groups in such Masonic strongholds as Bologna and Ancona. In Rome it was suspected by the Inquisition that Cagliostro had come as a secret agent or commissar of Weishaupt's radical Illuminati to perform just such an action.

Meanwhile, urged by Roman Masons to organize a lodge of his Egyptian rite, Cagliostro chose to do so almost within the shadow of Antinori's Trinità dei Monti obelisk, in the studios of a French painter, a fellow of the adjacent French Academy, Augustin Louis Belle, in whose quarters Masons had been secretly meeting for more than two years. One room, known as the room of "reflection," was draped in black, with a small table holding a skull. A larger room, known as the "Temple," adorned with the usual two columns and various emblems of Masonry, held a throne for the Master.

There, Cagliostro initiated a Capucin monk, a professor of theology in Paris, Father François Joseph Roulier, who said he was attracted to Christian occultism and the symbolism of the Masons, and whom Cagliostro believed might be useful in Rome in furthering acceptance of his rite by the Vatican, or, in the words of Ribadeau Dumas, "uniting the Children of Hiram with the sons of St. Peter." Far from being of help, the Capucin is believed by several historians to have been an agent of the Inquisition. The first documentary piece of evidence against Cagliostro, produced after the Capucin became his secretary, was a letter addressed by Cagliostro to the French States General, over which Cardinal Rohan was then presiding, in which he asked to be allowed to return to live in France; it was passed straight into the hands of the Inquisition. The letter, evidence enough of revolutionary leanings, prompted the Inquisition's first move, which was to put pressure on the family of Serafina, obliging her father, by who knows what sinister methods, to sign a complaint against Cagliostro for practicing Masonry—a crime forbidden by law in the Papal States.

Immediately Cagliostro was warned by a fellow Mason, Giuseppe Ferretti, that trouble was at hand. Other Masons secreted their incriminating emblems and went into hiding. Cagliostro, confident of his own good faith, and of his letter from the secretary of state, did nothing to protect himself, other than send out an appeal to other Masons in Rome to come to his rescue in case he was taken prisoner. What Cagliostro did not know was that Cardinal Boncompagni was no longer secretary of state, having just been opportunely replaced by Cardinal Zelada.

Cardinal Francisco Zelada, Vatican secretary of state, a Spanish Jesuit, who spent many years in charge of the secret Vatican archives

On December 3, 1789, Pius VI turned over his dossier on Cagliostro to the supreme tribunal of the Holy Office. The assessor requested the arrest of Cagliostro. On Sunday, December 27, though it was the Feast of Saint John, and a holy day, on which one did not arrest, the pope, for fear that Cagliostro might flee the trap, granted the special request. Monsignor Rinuccini, governor of Rome, ordered Cagliostro seized, and Belle's studio searched.

About 10:00 P.M. a squad of papal grenadiers broke into

Cagliostro's lodgings and carted him off to Castel Sant'-Angelo. Serafina was taken to a convent. All of Cagliostro's papers and correspondence, all of his Masonic impedimenta, were seized; no effort had been made by him to hide any of this material, sufficient to incriminate any man as a Mason. Hardly the precaution of a Weishaupt agent of subversion.

Some prominent Masons were arrested in the city, including the duke of San Demetrio. The marquis Vivaldi managed to disappear in time, and his wife, dressed as a man, fled to Venice. Loras, master of the Knights of Saint John, escaped to Malta. Yet, from the documents found in Cagliostro's house, and from the contents of Belle's "Temple," the Inquisition was able to reconstruct only the secret Masonic ceremonial, and the dress of the officers, but not the inner meaning of the ritual, the mystery of which had to be revealed from initiate to initiate, as Cagliostro had hoped to do in person to Pope Pius VI.

For fear that someone might attempt to liberate Cagliostro, the guard was doubled at Castel Sant'Angelo. No one without a special pass was permitted within. So serious was the threat considered that Carnival festivities were canceled in Rome lest Masons take advantage of fireworks to pull some trick.

From his dungeon Cagliostro was brought before a group of top Inquisitors, including Cardinal Zelada and Cardinal Antonelli, head of the Church's Propaganda Office. The governor of Rome was present, as was the state treasurer, Monsignor Giovanni Barberi, acting as Inquisitorial secretary. Hardly the talent required to interrogate the petty crook Balsamo, whom the Inquisition, using Morande's Jesuitical device, now claimed to have in their hands. Forty-three times, over a period of almost a year,

Interrogation by the Inquisition at the end of the eighteenth century

Grilled by the Inquisition

Cagliostro was grilled by various Inquisitors. No record is available of what transpired at his so-called trial, carried on in absolute secrecy. All documents relating to it have disappeared or been suppressed.

It is even difficult to reconstruct what happened to Cagliostro during his imprisonment in Castel Sant'Angelo, or the degree to which he was tortured. It was rumored he had been strangled so that Balsamo could be put on trial in his place to show that the law was dealing not with a personage of importance, but with a mean delinquent. Though how popes, cardinals, archbishops, ministers, and the crowned heads of Europe, could, for twenty years, have had social intercourse with a creature so mean and so villainous as Balsamo was painted, was never explained; nor was the fact that everywhere Cagliostro had been in Europe he was idolized by those he met and cured and by them was considered to be a great and enlightened benefactor of humanity.

All that came out of the trial was the judgment, passed by the tribunal of the Holy Office on March 21, 1791. A week later, in chains, his head veiled in black, in the presence of Pius VI, the prisoner was forced to kneel and hear his sentence. Giuseppe Balsamo was condemned to the penalty established by Clement XII and Benedict XIV against heretics, dogmatizers, heresiarchs, masters of superstitious magic: death by burning.

Pius, with the excuse that he wished to allow the prisoner more time to repent—but clearly not wishing to create another martyr by blood—piously commuted the sentence to perpetual imprisonment in a fortress, without hope of pardon. Posted on the streets of Rome, between the holy figures of Saint Peter and Saint Paul, the decree stood for all to read and take warning that to be a Mason in the Eternal City was a capital crime, one the Church intended to proscribe forever. Using the occasion as pretext for a general denigration of Masons, Pius issued an apostolic edict confirming and reinforcing previous pontifical edicts against Masonry, invoking the severest corporal punishment of death against anyone practicing the rituals, especially those of the Egyptian rite.

The same day, there appeared for sale on the streets of Rome a pamphlet printed by the Pope's Reverend Household anonymously written, which purported to be a compendium of the life and deeds of G. Balsamo known as Count Cagliostro. Its author was the Inquisitorial secretary, Giovanni Barberi, not a Jesuit as most historians aver, but a lay monsignor, who chose this method—one of the grossest injustices— to defame and vilify a prisoner with no means whatsoever of defense.

What Cagliostro may or may not have said under torture is moot; the top secret dossier of the minutes of his trial has not been made available from the Vatican archives. Barberi's compendium is the sole known source for Cagliostro's supposed revelation of a secret meeting with the heads of Weishaupt's Illuminati during which he is said to have received large sums of money to spread their propaganda and "illuminize French Masonry." To this charge the French translator of the compendium arbitrarily added a preface associating Cagliostro with "the gloomy follies of the German Illuminati," accusing the German sect of "surrounding thrones, blindfolding sovereigns in error and keeping from them men of talent and vision," a charge repeated to this day by right-wing propagandists. The hero of Barberi's compendium is described as "short, dark-skinned, plump, surly-eyed, speaking a Sicilian dialect mixed with an ultramontane vernacular, without cognition, science, void of any resource that might make it beloved. . . ."

This of the Cagliostro who had constantly frequented the highest society and the greatest minds in Europe, described by those who knew him as "intelligent, sympathetic, gay, temperate, active, at ease with princes and all the great, whom he considered he could help but from whom he required nothing in return," and, by Maurice

Among Cagliostro's effects confiscated by the Inquisition was a seal consisting of a serpent pierced by an arrow and holding an apple in its mouth. This serpent has been interpreted as the green dragon of Hermetic philosophy, or the Hebrew letter *Aleph*, symbolizing equilibrated unity. Another source has interpreted it as a sigil of the three celebrated emblems carried in the Greek mysteries: the phallus *I;* the egg, *O;* and the serpent, Φ—the first being the emblem of the sun, the second of the female, the third of the destroyer and reformer, eternally renewing itself.

Magre, in his *Return of the Magi,* as having had "a broader view of events and human nature than any other man in history." It is easy to understand, says Magre, why his followers called him the "Divine Cagliostro." "A marvelous spirit had descended into him."

Is this the same person of whom Barberi asks: "How could such a man have had access to gracious women whom he managed to deviate from the path of virtue?" To which he replies: "The women he was able to conquer were all so old and so ugly they could find no other mate than Balsamo." The magus's famous cures, says the compendium, were all the result of pure chance, or not cures at all. His Egyptian elixir "was nothing but cheap wine with some aromas capable only of exciting the vertigo of sensuality." Balsamo-Cagliostro was labeled a thief, a pimp, a counterfeiter, a syphilitic, a criminal wanted by the police of several countries.

No mention whatsoever was made in the compendium of the role of Cardinal Rohan, nor of his description of Cagliostro as "the most extraordinary man, the most sublime, whose knowledge is equalled in the world only by his goodness."

Yet this libel by Barberi is what became the prime source for future historians. Thomas Carlyle, in a vicious attack on Cagliostro, whom he never met, admitted having based his entire work on Barberi's compendium.

W. R. H. Trowbridge, another major biographer of Cagliostro, sums up the case: no proof was, or ever has been, brought forth in support of the libels. Not a word of testimony was heard in support of the list of crimes of which Cagliostro was accused. No witness in court or elsewhere ever identified Cagliostro as Balsamo. The family of neither was summoned to Rome to give evidence. No proof was formulated.

Dr. Marc Haven (whose real name was Emanuel Lalande), a member of the cabalistic order of the Holy Cross, in his earlier biography of Cagliostro, calls the magus "a human being as sublime in love as in wisdom," and concludes: "No one every proved Balsamo and Cagliostro were the same person." As Henry d'Almeras puts it in his *Cagliostro and Freemasonry in the Eighteenth Century:* "From his whole life they were able to substantiate only one single crime, that he had been a Free Mason, a crime which the pontifical bulls punished with death."

By striking down a petty Balsamo, the Church hoped to discredit all of Masonry as a phony font of religious tolerance, of liberty, equality, and fraternity, a slogan attributed to Cagliostro, as terrifying to established institutions as it was appealing to their victims. Now every last Mason in Europe who had known or frequented Cagliostro would be made to feel the shame of having been deluded by a quack and a charlatan, a pimp and a snake-oil peddler. Masonry and its officials would be made the laughingstock of Europe for having fallen for such "garbage" as Cagliostro had conveyed in his "spurious" Egyptian rite. All liberal ideas would be as discredited as the Masonic leaders who had supported them.

Further to demean Cagliostro, he was forced, barefoot, in penitent's garb, with a candle in his hand, to walk between two lines of monks from Castel Sant'Angelo to Santa Maria Sopra Minerva, the ancient temple of Isis, where he was obliged to kneel before the altar and abjure his errors. In the same piazza, in the shadow of the obelisk raised by Kircher in memory of one Hermetic pope, Cagliostro's manuscript on Egyptian Masonry, declared "seditious, heretical, blasphemous, and tending to destroy the Christian religion," was given to the flames by the hand of the public executioner. With it were burned all of Cagliostro's Masonic emblems. Lost to the world, as the crowd clapped and shouted, were his *The Ritual Rules of Egyptian Masonry, Concerning the Beatific Vision, Concerning the Evocation of Higher Spirits, Physical and Moral Regeneration, The Art of Prolonging Life, The Art of Making Gold, The Divine Cabala,* and *Astrological Calculus*. Masons tried to defend Cagliostro's position, but the reaction was ruthless, and their pamphlets were bought up and destroyed by Church and police.

Of the homages paid to Cagliostro shortly after his condemnation, perhaps the most tender and lasting came from his fellow Mason Wolfgang Amadeus Mozart. In *The Magic Flute,* first produced in Vienna on September 30, 1791, Mozart portrayed the Grand Cophte of the Egyptian rite as Sarastro, the high priest of Isis and Osiris, central figure of the opera, venerated by his followers.

From Rome, Cagliostro was taken in chains by forced night marches to the fortified bastion of San Leo, atop a peak in the Montefeltro Mountains near San Marino, the most feared prison in Italy, whose inmates were known to have been driven mad in a matter of weeks. The marches across the Apennines took place in the dark for fear that someone might recognize the prisoner and make an attempt to free him. At San Leo, Cagliostro was placed in a dungeon which had served as a water cistern, deep underground, and when it was rumored that a group of French Masons might be preparing to land around the fortress from balloons, the jailers, warned by Cardinal

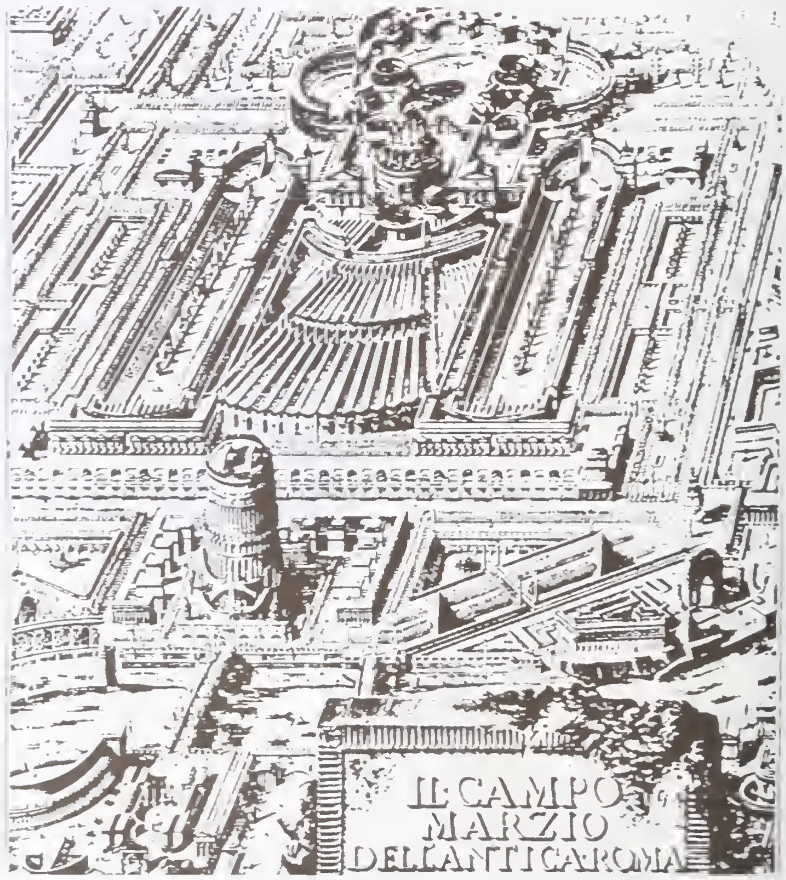
The reputedly impregnable Castle of San Leo, where Cagliostro was immured

Zelada that they would pay with their heads for Cagliostro's escape, walled the prisoner up alive, leaving only a small hole through which to spy on him, pass him his gruel, and torment him with the same question posed to Christ on the Cross: "If you are really the Son of God, why don't you call on your angels to set you free?"

Still hoping for a pardon from Pius, that he might seek refuge in revolutionary France, Cagliostro had a message sent to the pope warning him that a girl dressed as a page would try to stab him, that eventually he would lose his temporal powers and be taken a prisoner from Italy. The girl was apprehended; but it did nothing for Cagliostro, other than validate his clairvoyant powers. Pius was too busy unveiling his last obelisk in the Piazza Montecitorio before a great throng in the presence of Mesdames

The obelisk raised by Pius VI on Montecitorio—opposite the papal court of justice and future seat of Italy's Parliament—was his most important venture, if only because at last some attention was paid to the original point and purpose of such monuments. First raised in Heliopolis by Psamometitos II of the Saite dynasty, the obelisk is described by Pliny the Elder as having been brought from Alexandria to Rome by Augustus in 10 B.C. and set in a marble pavement in the Campus Martius marked out with bronze stripes and decorated with mosaics representing wind roses and the constellations of the zodiac; its purpose was to serve as a great gnomon, or sundial. The pavement, says

Pliny, was laid out for an appropriate distance so that the shadow of the obelisk at noon on the shortest day of the year exactly coincided with its height. Bronze rods let into the pavement measured the shadow day by day, as it gradually became shorter and lengthened again. According to Pliny the device had been engineered by the mathematician Novius Facundus, though others attributed it to Manlius. Unfortunately, Pliny was not explicit enough to make it clear whether the monument served only as a *solarium,* to indicate the length of the meridian shadow, or also as an *horologium,* to indicate the hours of the day. In any case, something went wrong with the device, for Pliny reports that after thirty years its astronomical indications no longer corresponded. This he attributed to a change in the path of the sun, or to some other heavenly change, or because the earth had shifted its axis, or because of earthquakes which could have tilted the needle. Pliny even considered that the foundations could have been affected by inundations of the Tiber, though he discounted this explanation, "as the obelisk's foundations are as deep as it is tall." The needle was reported still standing in the eighth century A.D., and Iversen believes it to have been knocked down by the Norman Duke Robert Guiscard who put Rome to



the sack in 1084 while freeing the tyrranical pope Gregory VII from imprisonment in Castel Sant'Angelo. It disappeared again until discovered by a barber in his cellar, where Fontana took Sixtus V to see it in 1587, though they buried it again as too burned and damaged to raise. In 1666 Kircher suggested to Alexander VII it would be easy to dig up the broken pieces, but his patron died too soon. A few years later, Cornelius Meijer, a Dutch inventor living in Rome, suggested raising the obelisk to serve as a solar gnomon, adding that because of the narrow vertical slit in the bronze ball atop the needle it might be used not only to note the passage of the sun's rays but also for sighting the north star and thus counting off the hours of the night. But Innocent XI was too weak for the job, which was left to Benedict XIV who jovially agreed to inspect the needle through a wall dug through the cellar of the Lottery. To extricate the five broken pieces without destroying the economically essential Lottery, the pope had recourse to an extraordinary old man called Niccoló Zabablia, a very rough fellow, who could neither read not write, and could barely express himself in words, but was renowned for the invention of simple machines to move great weights in restricted areas. Between May and August 1748, Zabablia brought out the five pieces and lay them in the filthy courtyard of the Palace of the Lotto. Benedict came in a carriage to admire, but as no architect dared raise the fragments they lay in a courtyard until Pius VI dragooned Antinori into accepting the challenge. Six days before the storming of the bastille he had it raised as a symbol against revolution. When the obelisk had first been discovered, Romans digging wine cellars and latrines had found beautifully wrought bronze constellations and a sundial clock with seven gilded degrees. This led to a dispute between what d'Onofrio calls the *eruditi* and the *matematici* as to whether the obelisk could function as a clock for Romans or merely as a rough gnomon to observe the sun's shadow from solstice to solstice. Pius's papal treasurer, Cardinal Ruffo, convinced that it could do both, hired a quarryman to carve out a series of marks in the cobbles of the piazza to indicate the hours of the day by means of the shaddow cast by the ball atop the obelisk, as well as along a meridian to mark the solstices. An immediate cry was raised by Rome's professors who argued against the "vain design" of having an obelisk serve as a sundial. d'Onofrio quotes two illustrious opponents. One, Giacomo Pessuti, ridiculed the idea of an *horologium* "for reasons . . . obvious to anyone with the slightest tincture of optics or astronomy." Obelisks, he argued, had naturally fallen into disuse as gnomons because of "the advent of wheeled clocks." He also claimed that heavy traffic of pedestrians and carriages would render the venture useless. Another opponent, the abbot Giuseppe Calandrelli, noted ironically "that the project would make the papal states ridiculous, as if they were without an elementary knowledge of astronomy, reduced to establishing noon with the use of a gnomon." He compared the situation to "a poor lay Capucin who, in his miserable kitchen garden, has to stick a nail in the wall to indicate to his bretheren when it is noon." But Ruffo had his way, and onto the base went an inscription in Latin: "Royally raised as a pyramid marking the time on its dial, long in a dunghill it rested, broken, disdained, and forgotten. Now to new splendour and dignity called by Pius VI, proudly it counts with its shadow each of his glorious hours."

de France, Adélaïde and Victoire, the two maiden great-aunts of Louis XVI, living daughters of Louis XV, who had managed to escape to Rome from the Revolution. As an overt display of the antirevolutionary feelings rife at the papal court, the ceremony was, like the puffed-cheek Aeoli of the papal arms which adorned the obelisk's pyramidion, whistling in the wind. Two weeks later Antinori was dead. Shortly thereafter the Mesdames de France died miserably in Trieste; as for the pope, he was burned in effigy in Paris, a foretaste of what was in store for him.

In San Leo, unable to take his rejuvenating elixir, Cagliostro realized he was doomed, and made his last prophetic announcement: "I will be the last victim of the Inquisition; for when I come to eternity I will pray so hard there will come a new order upon this earth."

It was June 8, 1795.

On August 23, according to the prison record, Cagliostro suffered an apoplectic stroke. A Capucin monk, Cristoforo Cicerchia, ran to his side, imploring him to make peace with the Church: "You still have a few moments in which to buy yourself a good place in heaven," he pleaded. But Cagliostro refused. He would neither repent nor confess. On August 26, as recorded in the parish register, Cagliostro expired. As a heretic, his body was ordered by the local bishop to be buried in unhallowed ground with no religious rite.

The daughter of one of the jailers reported, some years later, that in his cell Cagliostro had painted a full-length portrait of himself using a brush made from the hairs of his beard and color from the rust on the cell bars; it showed Cagliostro dressed in pontifical robes pointing to the image of a Masonic temple on his bared chest; beneath his feet were the emblems of the Catholic Church.

An eyewitness described four men bearing his body on an old broken door. At the bottom of the hill, sweating because of the August heat, the bearers deposited their load by a well to have a drink in a nearby wineshop. Sufficiently inebriated, they dug a hole on the promontory, into which they placed a brick as a pillow for the corpse's head. Its features covered by an old used handkerchief were buried in earth.

Two years later, on December 8, 1797, as Napoleon returned to Paris to capitalize on his Italian victories, the castle of San Leo surrendered to General G. E. Dambrowski of the Polish Legion of Napoleon's Cisalpine Republic, and its inmates were released, so the story goes, to dig up Cagliostro's grave and use his skull to swill wine as a toast to their liberation. Ironically, the

French troops entering Rome from the Flaminia to congregate in Piazza del Popolo around the obelisk of Augustus, reerected by Sixtus V

presence of the French troops in the Papal States was precipitated by the murder in the streets of Rome of the French agent Hugo de Basseville by a group of conspirators headed by Cagliostro's inquisitors Giovanni Barberi and the Cardinals Zelada and Albini.

When General Duphot of the French embassy, who was engaged to Joseph Bonaparte's sister, was also murdered, Napoleon's General Louis Alescanshe Berthier, later Prince of Wagrom, captured Rome, set himself up in Pius's Quirinal Palace, and declared the Papal States a republic. Barberi was condemned to death for this second overt act of murder, done presumably on orders from, or with the consent of, the pope. Particular severity was exercised against Barberi, says historian Jean François de Bourgoing, because he was "deservedly hated on account of the influence he acquired, and of the persecutions by which he had harassed all the inhabitants of Rome—whether natives or foreigners." According to Bourgoing, Barberi's exceptional actions arose from his prejudices and his ignorance, "Being exclusively versed in criminal jurisprudence, he was unacquainted either with political affairs or with mankind." But whereas Barberi managed to escape and hide out in what was then the inaccessible wilderness of Monte Argentario, beyond the lagoon of Orbetello, Pius VI, in his eighties, his legs

Pius VI taken prisoner by Napoleon's troops in Rome. In one day the pontiff's nephews, Cardinal Braschi and the duke of Nemi, sank from opulence to beggary.

paralyzed and unable to flee, was forced to cede to France the papal lands of Avignon, Ferrara, and Romagna. Taken prisoner, first to Siena, then to Florence, then to Turin, and eventually to Grenoble, Pius VI was never again to see the Rome he had adorned, nor the obelisks with which he had adorned it.

What remained of Pius's fame was an enormous folio volume of nearly seven hundred pages, *De origine et usu obeliscorum,* commissioned by him from the Danish scholar Jorgen Zoëga, who had settled in Italy in 1783, which came off the presses as Napoleon's troops invaded Rome. The volume, greeted as the most comprehensive and dispassionate survey of Egyptology that had yet appeared, contained in the first two chapters the accumulated material from classical authors on which what was known of Egypt was based. There followed an archaeological and historical description of all the known obelisks in Europe and Egypt, taken mostly from Mercati, Bandini, and Kircher, to which Zoëga added an excursus on pyramids.

Jorgen Zoëga at work on his obelisk book

Though Zoëga declared his purpose to be the collection and exhumation of all the evidence from authors ancient and modern which had any bearing at all on the obelisks of Egypt, he found the data to be "absurd," thus missing the whole point of what he was studying. He did show, by detailed measurements, that most of those proposed by his predecessors were not even consistent and he did attack the problem of the hieroglyphs. The volume contains the most extensive and carefully reproduced collection of original hieroglyphical inscriptions published till then. What is more he stressed the distinction between the hieroglyphic script and the large-scale drawings which often accompanied them, showing that the direction of hieroglyphic writing was indicated by the figures facing the start of each line.

In his attempt to classify the number of separate glyphs, Zoëga reached a total of 270 on the obelisks themselves, and 958 including all the inscriptions in European museums. From this he deduced that the total was not nearly large enough for an entirely ideographic script in which each word of the language has its own separate sign. This led him to suggest that certain figures of animals, birds, or plants used in the hieroglyphs might represent letters that could be read as sounds. This suggestion constituted the first ideational breakthrough in the decipherment of hieroglyphs; it also contributed the first modern European usage of the words *phonetic signs,* or *notae phoneticae.*

On the negative side, Zoëga concluded that there were no esoteric or symbolic secrets whatsoever involved in the shape of the great obelisks: that their slender pyramidal shape arose solely from considerations of aptness, beauty, and durability, "so that there was no mystery about it." A mystery there was: but he had missed it, as had Pius. And all the time the evidence had been within their grasp.

As General André Massena's troops went through the liberated Castel Sant'Angelo, they discovered an anonymous manuscript which had been seized in Cagliostro's lodgings on the day of his arrest. Entitled *La Très Sainte Trisophonie,* or *The Most Holy Threefold Wisdom,* it was a beautifully handwritten work with a score of colored illustrations and many glyphs. That it survived the fires of the Inquisition is due, most probably, to the apparently totally innocuous allegorical language in which it is written.

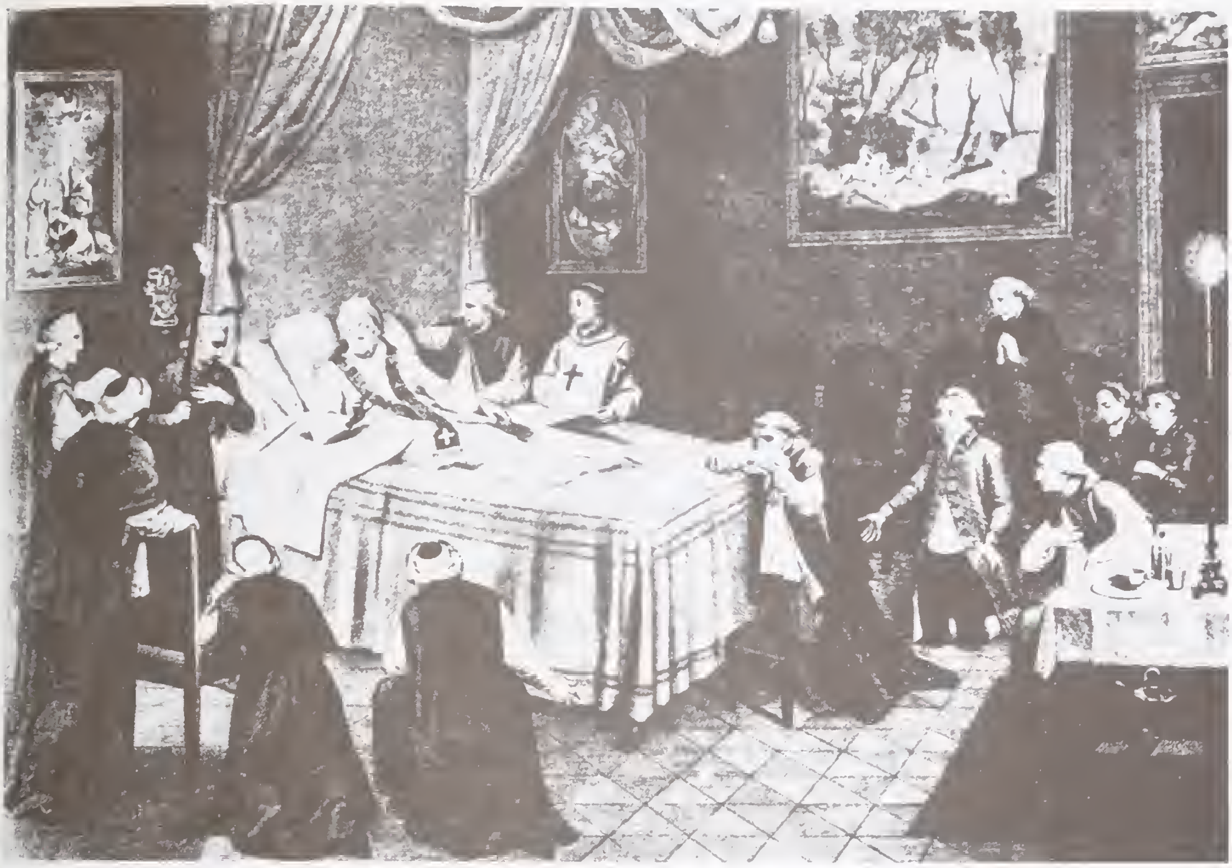
Grillot de Givry, who first commented on the discovery in his *Musée des Sorciers,* just over a hundred years later, interpreted the text as cabalized alchemy, presumably from the pen of Saint-Germain, one of the sole remaining documents attributable to this timeless sage of the eighteenth century.

Manly P. Hall's reprint of the only remaining text of this rarest of occult works

Illustration in *La très sainte trisonophie* of a couple scrying. Theodore Bersterman, in his treatise on crystal-gazing published in 1924, says: "Scrying is a method of bringing into the consciousness of the scryer by means of a speculum (or mirroring surface) through one or more of his senses the content of his subconscious, or rendering him more susceptible to the reception of telepathically transmitted concepts, and of bringing into operation a latent and unknown faculty of perception."

But it was not until the middle of the twentieth century, when the Californian philosopher Manly P. Hall reproduced the book in its entirety from the original and only example, now in the library of Troyes, adding copious notes and a prefatory text, that it was shown to be "in every respect an authentic ritual of the Society of the Rosicrucians, possibly the actual record of Saint-Germain's own acceptance into the mystical brotherhood of which he finally became the Grand Master." The early sections, says Hall, seem to derive their inspiration directly from the neo-Egyptian ritual called the rite of Memphis.

That Pius and his cohorts missed the mystery, unable to decipher the Hermetic meaning behind the overtly blameless story, is explained by Edward C. Getsinger, an authority on deciphering ancient texts, who found that the volume contained the most ingenious codes and methods of concealment he had ever encountered; "a perfect example of how symbolism is used to intimate truths too dangerous to reveal."



Pius VI on his deathbed in captivity

It is clearly, says Hall, a threefold enigma. "From its symbolism, it seems that one of the keys is alchemy, or soul-chemistry; another Essenian Cabbalism; the third Alexandrian Hermetism, the mysticism of the later Egyptians." Those who wish to consult Manly Hall's notes may come as close as it is possible in an overt document to learn the truths for which Cagliostro laid down his life, truths which were only to reappear in the next century with the discovery of the Egyptian so-called *Book of the Dead*.

But none of this was for Pius. By the time he was taken from Rome, Saint-Germain had vanished from the scene. And, in condemning Cagliostro, the poor pontiff had managed to bury the one clairvoyant who might have given him a clue to the mysterious meaning of the obelisks and their glyphs, just as, in patronizing Zoëga, he had managed to bury in a tome of pluperfectly pedantic Latin, the whole subject of obelisk and glyph.

And there it lay, requiescent, but not in peace. Sadly, Zoëga admitted his failure: "When Egypt is better known to scholars, and when the numerous ancient remains still to be seen there have been accurately explored and published, it will perhaps be possible to understand the meaning of the Egyptian monuments."

8. NAPOLEON REDISCOVERS EGYPT

Jean Jacques Champollion (Figeac)

Jean François Champollion (le Jeune)

Frontispiece of the *Description de l'Égypte* with Napoleon's imperial *N*

As Pope Pius VI lay on his deathbed in August 1799, a young French professor of history at the university of Genoble, Champollion-Figeac, had been pulling strings to get himself named to a group of savants being selected by the twenty-nine-year-old General Bonaparte to accompany him on his conquest of Egypt.

Jean Jacques Champollion had already added to his surname the appellation of his native town of Figeac in order to distinguish himself from his eight-year-old brother, Jean-François, for whom he anticipated a great future, and whose limelight he did not wish in any way to shade. Convinced that the boy had a truly remarkable mind and deep devotion to scholarship—at four he had learned to read and write by comparing a written missal with the prayers he had learned by heart—the elder Champollion had taken the youngster into his home to give him special tutoring in advanced studies. To repay his elder brother's courtesy in calling himself Figeac, the younger Champollion added to his own name that of Le Jeune, or Junior. But because of his olive complexion, curly black hair, and slightly slanted eyes with yellow irises, which gave him an oriental appearance, his sister-in-law called him Sagir, the Arabic word for "junior," a nickname which stuck to him for life.

Despite strong recommendation, Champollion-Figeac was not selected to go to Egypt. But the Paris Directorate was only too happy to be rid of Napoleon, whom they considered an irritating and formidable rival. His overt object was to cut off Britain's route to India. A stronger motivation was his driving search for fame. "I must seek it in the East; all great fame comes from that quarter." In the footsteps of Alexander the Great, Napoleon wished to conquer the world, but first he had to conquer the East, overthrow the Turks, seize Constantinople, take Europe in the rear, paving the way for the fall of India, China, and the world.

The idea was not original. It had already been envisaged by Sixtus V in 1587 when he outlined the scheme to the Venetian ambassador, Giovanni Gritti, in his lamentably vernacular Italian: "A little money, a little money, Mr. Ambassador, and I could send an army into Egypt. Seven-

General Napoleon Bonaparte

Obelisk raised at Rouen in honor of Napoleon's victories in the Italian Campaign

ty or eighty galleons, well armed, would do the trick. I could seize and fortify Alexandria and be master of Egypt. It would buy off the inhabitants and make them into Christians, perhaps even with the help of Arabs who are against the Turks." Sixtus even had the genial notion of cutting a canal to Suez, but was afraid the difference in water level in the Red Sea might cause a dangerous flood in the delta.

An occupation of Egypt by the French had also been envisaged by another student of hieroglyphs, the German philosopher and mathematician Gottfried Wilhelm von Leibnitz, discoverer of differential and integral calculus, who had suggested the idea to Louis XIV. Leibnitz (who had been offered custodianship of the Vatican Library but had turned it down because he would have had to join the Catholic Church), like Zoëga, did not agree with Kircher's belief that the hieroglyphs contained esoteric wisdom. He considered the inscriptions on the obelisks to be merely "historical texts commemorating events and victories."

Napoleon, as a freethinker, was more sanguine about cracking the riddle, which his Masonic friends in Paris convinced him was essential to a proper understanding of political history. To do the job, he had deliberately collected some 150 scientists and artists, many of them Masons, recruited from the Académie des Inscriptions, including scholars of the highest distinction, such as Gaspard Monge, Étienne Geoffroy Saint-Hilaire, Edmé François Jomard, Claude Louis Berthollet, and Jean Baptiste Joseph Fourier. That obelisks were on Napoleon's mind is evident from the story that his wife Josephine, also a Freemason, came to see him off at Toulon, and asked him, as she kissed him good-bye, to bring her back one from Thebes, even if it were only a small one.

On May 19, 1798, Napoleon's armada sailed with thirteen ships of the line, fourteen frigates, seventy-two corvettes, and nearly four hundred transports carrying forty thousand troops. In his cabin, Napoleon carried with him the Bible, the Koran, the Vedas, a book on ancient mythology, Montesquieu's *Spirit of the Laws*, translations of Thucidides, Plutarch, Tacitus, Livy, and several books on such military commanders as Turenne, Condé, Luxembourg, and Marlborough. For lighter reading, he took along Cook's *Voyages* and forty English novels.

His archrival, Horatio Nelson, somewhere at sea in the Mediterranean, was cruising with his squadron in the hope of intercepting and destroying the French armada. But the two great fleets, each commanded by a Freemason, silently passed in the night, narrowly missing an encounter.

Six weeks later—after stopping in Malta to loot the treasure of its Knights—the French squadron reached Alexandria on July 1. Napoleon's troops quickly seized the town, once a sophisticated metropolis of half a million souls, with 4,000 public baths and 400 theaters, which had been reduced under the Ottoman Turks to no more than a village of four thousand souls. A miserable march through the desert took the expedition to the Giza plateau. There, at the great Battle of the Pyramids, Napoleon defeated sixty thousand Mameluke warriors by letting their intrepid horsemen shatter their silk-and-gold-laden bodies against the firepower of his classic infantry squares.

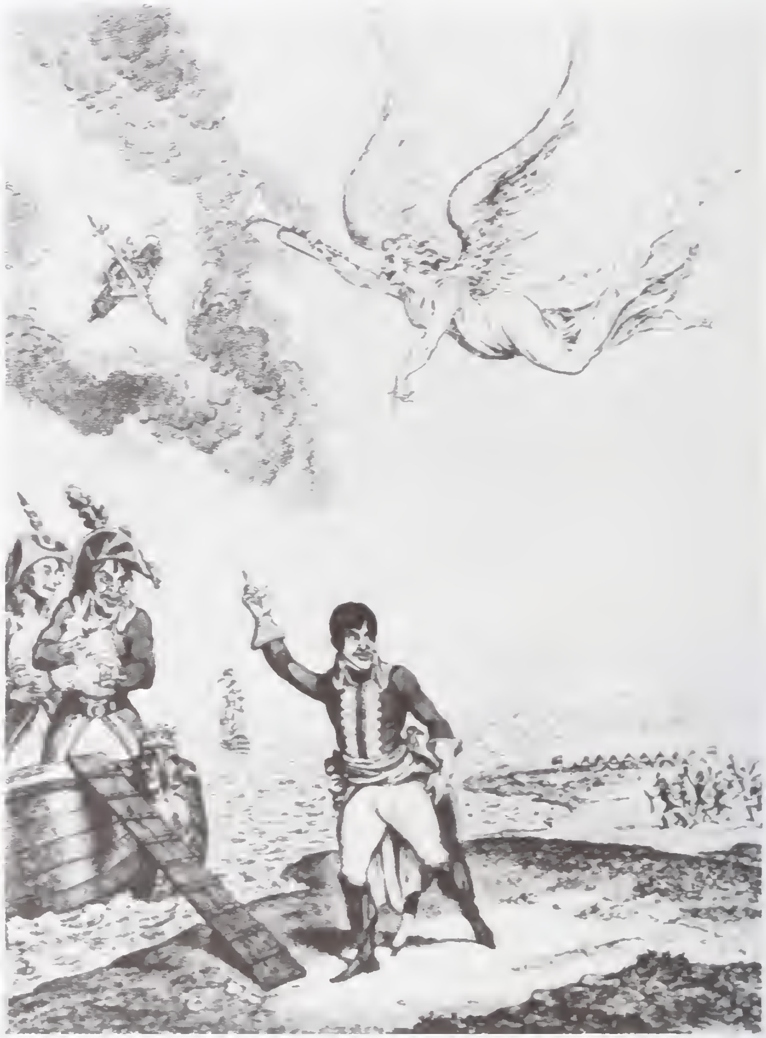
In three weeks, Bonaparte's generals chased the remnants of the Mamelukes up the Nile as far as the Aswan cataract. With the entire country subdued, Napoleon declared Egypt a French protectorate. Promising to treat local citizens with restraint and respect, he set up in Cairo a government which included prominent Egyptians. It was then safe for his savants to be let loose to loot the country of its ancient treasures as they unearthed temples, dug into pyramids, and measured obelisks for transfer to Paris. Soon they had collected antiquities from all over the country, housing them in a special collection in Cairo. Thus came to light a slab of black basalt found by a detachment of French soldiers working on fortifications near the village of Rashid or Rosetta. From this discovery it looked at last as if the key to the unravelment of the secrets of Egypt was at hand. The stone was covered with inscriptions in three distinct scripts: one hieroglyphic, one mysterious, one clearly Greek.

But the French had counted without Albion. A short distance from Rosetta, in the Bay of Aboukir, Nelson caught the French fleet by surprise. As brilliant at sea as Napoleon was on land, the young admiral trapped the French between two fires and sank all but one of their ships of the line, leaving the French army stranded in Egypt in the midst of a population rapidly growing hostile.

Nelson wounded during the Battle of the Nile

From this victorious Battle of the Nile there mushroomed a coalition of British, Turks, and Arabs, determined to expel the French from Egypt. When an uprising in Cairo caused the death of several hundred French soldiers, Bonaparte retaliated by shooting and beheading the insurgents, rolling their heads in the squares. En route to attack the pasha of Acre, who had raised an army, Napoleon captured Jaffa, but unable to feed or guard three thousand prisoners, he had them shot to a man, wiping out the male population of the city, an act of cruelty so heinous it put marrow into the defenders of Acre. Thus this last stronghold of the Templars, which had fallen to the Moslems in 1290, now cost Napoleon an empire. When the town would not surrender, blocking the would-be world conqueror's way to the East, Napoleon bitterly remarked: *"J'ai manqué ma fortune à Saint Jean d'Acre,"* and began his first retreat.

To save his reputation at home, this general of the French stole secretly from his troops, sailing on the sole frigate that had survived the British attack. Once more slipping past Nelson's fleet, Napoleon reached Corsica well before the news of his defeats, to be greeted as a hero, a welcome which paved his way to the coup of 18 Brumaire and his being named consul of France, then first consul.

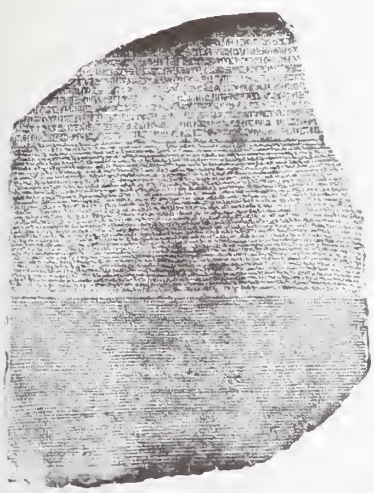


Cartoon lampooning Napoleon's clandestine flight from Egypt

Meanwhile, the British general Sir Ralph Abercromby had landed an army at Aboukir Bay, 14 miles northeast of Alexandria, and attacked Napoleon's abandoned forces.

General Abercromby dueling with French dragoons

So stalwart was the conduct of the foot soldiers of the Twenty-eighth Gloucestershire Regiment, heavily engaged by the French *par devant et par derrière,* that they gained the unique distinction thereafter of wearing their badges both at the front and back of their headdress. Even Sir Ralph distinguished himself by engaging in personal combat with some French dragoons, until the French, facing capitulation, fired a few volleys and quit. From one of these last volleys a spent ball struck Abercromby in the head. Succumbing in the moment of victory, he left to his number two, General Hely Hutchinson, the honor of receiving the surrender of the French. Gallantly, the Englishman gave the debris of Napoleon's army free passage back to France.



The Rosetta Stone, described in the *Courrier d'Égypte* as of very fine-grained black granite, found by Pierre François Xavier Bouchard, an officer in the French engineers, at Fort Jullien, Rosetta

But all the antiquities collected by the French, including the Rosetta Stone, were claimed by the British as spoils of war. Hearing the terms, the savants rose in rebellion and refused to part with their trophies. Saint-Hilaire did not mince his words: "You are taking from us our collections, our drawings, our copies of hieroglyphs; but who will give you the key to all that? . . . Without us this material is a dead language that neither you nor your scientists can understand. . . . Sooner than permit this iniquitous and vandalous spoilation we will destroy our property, we will scatter it amid the Libyan sands and throw it into the sea. We shall burn our riches ourselves. If it is celebrity you are aiming for, very well, you can count on the long memory of history: you too will have burnt a library in Alexandria." General Hutchinson, a man of vision, was sufficiently impressed to allow the French to keep their collection. But he insisted on retaining the Rosetta Stone. Lost to France, it went to reside in the British Museum, where no one, as Saint-Hilaire had warned, could make head or tail of its glyphs.

In a Grenoble bookstore, the younger Champollion, then nine years old, came across a copy of the *Courrier de* *l'Égypte* with a description of the discovery of the Rosetta Stone. Spurred by the suggestion that a decipherment of the hieroglyphs might eventually open up the whole of Egyptian history, he plunged into the study of Latin and Greek so as to be able to read for references to Egypt in the classics. It was to take him several months.

By this time the senate in Paris had proclaimed Napoleon emperor of the French. Abandoning for the moment his dream of conquest in the East, he decided instead to concentrate on reorganizing his empire at home. One of his first moves was to establish the University of France, which he linked administratively to all the regional universities and to all the public *lycées*. As a result, Champolloion-Figeac, a good Bonapartist, managed to obtain for his younger brother a scholarship to the Grenoble *lycée*. Fourteen years old, Champollion-le-Jeune was not tall but had a firm, slender body full of strength. According to his major biographer, Hermine Hartleben, the boy's handsome features, fine-boned and full of magnetism, caught people's attention; and when he talked on matters he liked, such as Egyptian history, he seemed to vibrate with an intense desire to be understood. Adults, startled by his self-assured manner and the ease with which he conversed, were drawn to him and indulged him.

Grenoble was then a university town of twenty-five thousand inhabitants, standing on the left bank of the river Isère in a lovely fertile plain with hills and mountains that swept up steeply toward the distant peak of Mont Blanc. The seat of the bishopric, with fortifications dating back to the Roman emperor Diocletian, its people were nonetheless independent *dauphinois,* strongly democratic, intellectual, boasting of many learned societies.

PTLOMÊS
(Ptolemy)

When a new prefect was appointed to the district by Napoleon, it turned out to be Jean Baptiste Joseph Fourier, the engineer-historian who had been to Egypt with Napoleon and served as secretary to the French Institute in Cairo. In Grenoble, when Fourier was asked to become a member of the learned Académie Delphinate, its secretary, Champollion-Figeac, asked if he could introduce his younger brother. Amazed at how much the boy already knew about Egypt, Fourier showed him the small museum of Egyptian antiquities he had collected, including stelae, amphorae, statues, stone tablets, and fragments of papyri covered with hieroglyphs. Most exciting to young Champollion was a rough parchment copy of the three texts of the Rosetta Stone. When told that no one could either read or understand the glyphs, the boy replied firmly: "Then I will."

From the Greek text, which he could readily translate, Champollion saw that the stone carried a decree issued in Memphis in 196 B.C. by an assembly of Egyptian priests in honor of King Ptolemy V Epiphanes, to commemorate his benefactions to the indigenous priesthood. More interesting was a colophon which decreed that the stone be engraved in three different characters: hieroglyphs, native letters, and Greek. From this it seemed clear that the stone carried three versions of the same text. Unfortunately, the top and both sides of the Rosetta tablet had been broken away, so that only half of the hieroglyphs were left, not one line of which was complete.

Fourier explained that so far the best efforts at deciphering the tablet had been achieved by working on the nonhieroglyphic text, the so-called demotic script, to see if any relation, letter to letter, could be found between it and the Greek text. Sylvestre de Sacy, Europe's leading orientalist, had tried his hand at the problem by picking out the proper names which appeared in the Greek text and then searching for the equivalent letters in the demotic. In this way he had managed to locate the names of Alexander and Ptolemy.

A Swedish diplomat, John David Akerblad, widely traveled in Egypt, to whom de Sacy had lent a prepublication copy of the inscription, had identified Arsinoë, Verenice, and Aetos, establishing that such words as *Greek, Egyptian, temple, love,* and *abundance* were written with the same alphabet, of which he identified twenty-nine letters. Fourier explained to the boy that the demotic words deciphered by Akerblad were almost identical with Coptic words for the same concepts, which seemed to vindicate Father Kircher's notion that ancient Coptic had been the language of Egypt.

Thanks to Fourier, Champollion was now able to obtain rare material that would otherwise have been impossible for him to consult, including the works of Kircher. Promptly the boy launched into a study of Coptic, and produced a map of Egypt following the Coptic names, disregarding the Greek and Roman ones, which he considered suspect. He also began to study Arabic, Chaldean, Syriac, Ethiopian, Sanskrit, Send, Pehlevi, Parsee, and Persian, hoping to find other clues to the langauge in which the hieroglyphs might have been written. He even launched into Old Chinese, because some authorities maintained the ancient Egyptians had come from China to settle on the Nile.

By the time he was seventeen, Champollion had made his first table of the succession of Egyptian pharaohs, based on data culled from the Old Testament, and from ancient works in Greek, Latin, Arabic, and Coptic. Shortly thereafter, he was invited, despite the opposition and hostility of several members of the faculty, because of his youth and his intolerance of ignorance and prejudice, to read a paper to the faculty of Grenoble University. Trembling slightly, agitated by some inner emotion, the slim, dark-skinned youth stood erect before the gathering of professors, then announced that he proposed to regale them with an encyclopedic view of ancient Egypt in all its aspects. As the young scholar spoke, brushing a hand through his dark curly hair, the audience became enthralled. Never had they heard anything like it. There were gasps of amazement as he mentioned rare sources he had consulted, ancient Coptic scripts, Hebrew and Arabic sources, sources which represented hundreds of hours of concentrated reading in many ancient languages, mostly from obscure books that the professors had not even heard of. He described the country as if he had lived there, creating the illusion he had stepped out of ancient Egypt into the nineteenth century. As one historian put it, he had so thoroughly absorbed the ancient Egyptian culture, he gave the uncanny feeling to those in his presence that he was an ancient Egyptian reincarnated.

When Champollion finished, there was a hush, followed by a buzz of excitement. His conviction and sincerity had carried all before him. The president of his lyceum jumped up and embraced him. Professor Renauldon told him he could immediately join the faculty of the university. Unanimously he was accepted as a corresponding member of the Academy of Grenoble. From humble student he found himself a highly regarded teacher, but not for long. Such precocity could only engender jealousy. To escape it, and the antagonistic atmosphere of academia, Champollion wanted more than anything to be allowed to go to Paris to pursue his study of the Rosetta Stone and its hieroglyphs, admitting to his brother that he had the weird feeling he had been present in Memphis in 196 B.C. when the stone had been raised.

Napoleon's victory at Austerlitz

It was 1808. Napoleon had defeated the Austrians at Austerlitz, and by taking Berlin replaced what was left of the Holy Roman Empire with a French-controlled Confederation of the Rhine. In Paris, he set up a court as precise and rigid in its etiquette as that of the *ancien régime,* rivaling the splendor of Louis XIV, though it could be said for the empire that it did not restore the feudalism, privileges, and exactness of the Bourbons.

In Paris, Champollion became a student of Sylvestre de Sacy, the head of the Académie des Inscriptions, who had finally managed to obtain a plaster cast of the Rosetta Stone. Champollion was soon lost in the dusty archives of the Paris libraries, only coming out to wander into another institute or museum, searching constantly for anything to do with ancient Egyptian or with Coptic. In the Bibliothèque Nationale, he found and annotated Kircher's *Lingua Aegyptiaca restituta* and was able to work on the Coptic manuscripts stolen by the revolutionaries from the Vatican.

In the Louvre Museum, Louis XVI's former palace, which had been opened to the public in 1793, he could admire the works of art accumulated by a series of French monarchs, or more recently looted by Napoleon from the churches, galleries, and museums of Italy, the Netherlands, and Germany. There, Baron Dominique Vivant Denon, named by Napoleon director of the museum, had formed the Egyptian collection from the enormous quantity

Silvestre de Sacy, head of the Academy of Inscriptions, founded to supply Louis XIV (the Sun King) with "learned ornamentations for his pleasure."

of antiquities brought back by Napoleon's savants, to which he continued to add.

Convinced that Coptic was to Egyptian what modern Italian is to Latin, Champollion tried to find someone in Paris who could teach him to speak the language. There was no one, other than a Coptic priest who said mass at the church of Saint Roch, by the rue de Rivoli; from him he was able to learn something of the pronunciation of contemporary Coptic, but little more. For practice, Champollion spoke Coptic to himself whenever he was alone, which was most of the time.

With no money other than what his brother sent him from his own small earnings, the young man found a room next to the Louvre, cheap, shabby, with an iron bed, rickety sofa, and two chairs. It was damp and cold. His meals consisted of bread, cheese, and onion, with an occasional bowl of stew, eaten rapidly and sparingly. His coat was threadbare, and his shoes were stuffed with paper. The gray dampness which hung over Paris induced a cough with spasms which developed into a severe pain in the chest.

In 1809, when Napoleon began drafting recruits for military service in his new campaigns, the young Champollion only just managed to be exempted through the intervention of Fourier and de Sacy. But his money ran out, and his landlady, catching him speaking to himself in Coptic, threw him out as a lunatic, leaving him no choice but to go home without having solved the riddle of the glyphs.

In Grenoble, his brother managed to get him the post of assistant to the octogenarian professor of history at the university, but a jealous group of professors soon banded against him, determined to force the young savant from the faculty. They could not tolerate his pointing out the errors in their instruction. "I do not like to compromise with truth," he insisted, "it is shameful to play politics with education." Believing that teachers had to be intellectually free and immune from pressure, Champollion began to write satirical sketches attacking both the royalists and the Bonapartists, which endeared him to neither.

By this time Napoleon had divorced his childless Josephine to marry the archduchess Maria Luisa of Austria, thus allying France with Austro-Hungary. As the ersatz Holy Roman Emperor he decided to emulate his predecessor caesars and pontiffs, and in a decree issued from Schoenbrün, ordered the erection of an obelisk made of Cherbourg granite in memory of the campaigns of Iena and the Vistula, bearing the inscription "From the Emperor Napoleon to the People of France."

Napoleon, whose Arch of Triumph stands at the top of the Champs-Élysée, planned an even bolder and grander monument to outdo the glory of Thebes and Rome—a 180-foot obelisk to replace the statue of Henri IV on the Pont Neuf near where de Molay was burned. This colossal needle was to be formed of six superimposed granite monoliths, the lowest of which was to weigh a million pounds. The sculptured faces were to cover more than 10 million square feet (or about 24 acres). Calculations were made and plans drawn by Charles Le Père, who had accompanied Napoleon to Egypt, where he had been responsible for *mis*-measuring the Great Pyramid of Cheops. No more than the foundations were laid for Napoleon's needle before the plans collapsed along with the empire.

Louis XVIII caricatured as interested mostly in the problems of his mistresses

Ten projects were submitted, in one of which two elephants on either side of an Egyptian colonnade rendered homage to the "new Alexander." But the jury chose a more sober design by the architect Jean François Chalguin. The foundations were laid, but Napoleon, retreating from Moscow, was badly defeated at Leipzig. Pursued by his enemies into France, the depressed dreamer was forced to abdicate on April 11, 1814, and go into exile to Elba. The obelisk was stillborn.

As the Bourbons reclaimed the French throne upon which to seat a fat, lazy, and inept Louis Xavier Stanislas, comte de Provence, brother of Louis XVI, as Louis XVIII, Champollion buried himself in his work. That year he published his *Egypt Under the Pharaohs* in two volumes; it was dismissed as fanciful. Stung by the critics, Champollion realized the only way to prove his point would be to decipher the hieroglyphs and show a truer history and chronology of Egypt.

Then came the "hundred days," not only to reprieve Napoleon, but by chance to bring Champollion and the emperor together. Tired of his island prison, the ex-emperor slipped past his guards on Elba and landed unopposed at Antibes in the south of France. "I shall reach Paris without firing a shot," he predicted. To avoid the royalist towns of Provence, he headed toward Savoy and republican Grenoble, where an old friend was in command. Just before Grenoble, a body of royalist troops barred his way. Stepping forward, Napoleon threw open his coat to reveal his well-worn uniform and the ribbon of the Legion of Honor. "Soldiers, if any among you wishes

Napoleon's return from Elba

to kill his Emperor, here I am!" An officer gave the order to fire, but the soldiers refused, crying *"Viva l'Empereur!"* Crowding around him, they tore off their white Bourbon cockades.

In Grenoble, Napoleon put up at the Auberge des Trois Dauphins and asked for a competent man with a clear mind and lucid style to translate his verbal instructions into written orders. The mayor suggested Champollion-Figeac, then head of the faculty of letters at the university.

The elder Champollion, who had now legally changed his name to Figeac, arrived at Napoleon's quarters in the inn with his younger brother, whom the emperor began to cross-examine about Egypt, becoming so impressed that he kept the youth in his small room while a crowd fidgeted anxiously outside.

Napoleon in Grenoble. Leaning against the still-barred gates, he is said to have taken a pinch of snuff and then tapped with his silver snuff box until the gates were opened by a welcoming crowd.

The next day, to pursue the conversation, Napoleon sought out Champollion in his quarters at the university library to tell him he admired the courage with which he imposed his views: "I would never have taken Toulon in 1793 if I had not done the same," said the emperor. "I was just your age." Champollion talked to Napoleon in Coptic, which enthralled the emperor, who agreed it was the key to understanding ancient Egyptian, and said he intended to restore Coptic as the national language of Egypt. He promised to have Champollion's dictionary printed at government expense as soon as he got to Paris. "I will do it by decree," said Napoleon, "just as I ordered the publication of Ptolemy's *Almagest* translated by de Sacy, and the great Chinese dictionary which had been languishing for a hundred years."

Wanting to know more about Egypt for his future plans, which involved a great irrigation project to make the country bloom, Napoleon spent several hours with Champollion, pumping him on every facet of the subject. When Napoleon set off to reconquer Paris, he took with him Figeac as an aide, leaving young Champollion to edit the Bonapartist newspaper started by his brother, the *Journal de Isère,* the first number of which described Napoleon's triumphant march from Elba toward Paris, emphasizing the democratic ideals of liberty on which the new regime was to be founded, rather than the former imperial pomp.

299. Serment de Ney — Serrement de nez

Cartoon playing on the French word *nez* (pronounced "ney") for "nose."

By the time Napoleon reached Lyons, he was addressing everyone as "citizen" and promising a liberal constitution. Republican sympathizers disillusioned with the Bourbons who had shown themselves incapable of ruling, and had deliberately broken every stipulated agreement made with Napoleon at the time of his abdication, flocked to his tricolor banner with shouts of *"Vive l'empereur!"* Even Napoleon's old marshal, Michel Ney, Prince of Moskowou, who had suggested to the Bourbons bringing Napoleon back to Paris in a cage, took one look at the approaching tricolor and came over to the emperor's side, quickly imitated by his troops. Louis XVIII, hearing of the triumphant reception given the returning hero, slipped quietly out of Paris.

Napoleon welcomed back to his old quarters in Paris

At the Tuileries, officers and soldiers seized the emperor and carried him up to his old apartment on the second floor. Figeac, who was with Napoleon all the way to Paris, now became a member of several committees charged with projects of reform.

But the "hundred days" were soon over; the combined reactionary forces of Europe proved too strong. Figeac was with Lucien Bonaparte at the Palais Royale on the evening of June 20, 1815, when they received the news of Napoleon's defeat at Waterloo by a combination of English, Dutch, Belgian, and Hanoverian troops under the command of the duke of Wellington. Louis XVIII slipped back into the Tuileries just as quietly, this time protected by Scottish muskets. Everywhere in France, royalists were forcibly put back into power by foreign bayonets. In republican Grenoble, which held out against the royalists, raising barricades, Champollion rushed about to hide the rarest volumes and manuscripts of the library from a vicious royalist artillery bombardment.

As Napoleon abdicated at Fontainebleau, Austrian soldiers were installed in Grenoble. Champollion's paper was taken over by antirevolutionists who cried for Napoleon's accomplices to be shot. Blood flowed. Thousands, including Marshal Ney, were executed. Champollion got away with a mere dismissal from the university, and exile to his native town of Figeac. The Bourbons were back, having, as Talleyrand remarked, "learned nothing, and forgotten nothing."

Frontispiece of the *Description de l'Égypte* with the bust of Louis XVIII replacing the imperial *N* of Napoleon.

When Napoleon seized power as emperor he initiated the reestablishment of orthodox Catholicism in France, with Pius VII as pope, but kept him a virtual prisoner at Fontainebleau. When the new pontiff requested the suppression of Masonry, Napoleon decided instead to make use of it. The Grand Orient and the Grande Lodge were united, and the emperior's brothers, first Joseph, then Lucien, were named Grand Master of the joint body. Dignitaries of the new empire quickly followed suit. But it was a chastened Masonry, deprived of its Illuminist tendencies, anxious to integrate itself in the new structure of patronage. With the defeat of Napoleon, Pius VII was restored to the Papal States, so relieved, they say, that he levitated during the celebration of Mass. Masonry was once more forbidden. The Inquisition was revived along with the index of forbidden books. The church threw its support to absolute monarchs, while parliaments and democracies were termed "atheistic," and the Jesuits again sought to make every sovereign the vassal of Rome.

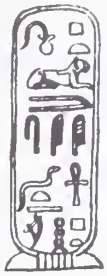
Cameo of Thomas Young

The Inquisition, abolished by Napoleon's brother Jérôme as King of Westphalia, was reestablished by Pius VII. In Paris, Figeac obtained the protection of the Masonic group which, under the leadership of Edme François Jomard, was allowed to continue to edit and bring out the remaining folio volumes of the *Description de l'Égypte* minus the imperial "N" which had decorated the earlier volumes.

To keep alive, young Champollion managed to give private lessons, slipping up to Paris on holidays to consult the copious and magnificent illustrations in the huge volumes of the *Description,* which were causing a sensation in Europe among those who could afford to read them, and were strong enough to lift them.

In Grenoble the new prefect was the baron d'Haussez, a former revolutionary from the Vendée who had rallied to the empire and then reverted to the royalists with the return of Louis XVIII. More royalist than the king, he now hated liberals, and especially Champollion, whom he accused of conspiring against the safety of the state. A cold, unpleasant man, who kept a guard at every window, he showed Champollion copies of his Bonapartist letters to Figeac intercepted by Fouché, the chief of police, who had survived every regime from the Terror to the Reaction. Unable to work in Grenoble, Champollion sought refuge with his brother in Paris. There, in a top-floor attic on the rue Mazarine, he survived the stagnation of the Bourbonic restoration by devoting himself entirely to cracking the secret of the hieroglyphs, working mostly with material provided by his brother, who had been collaborating with André Dacier, the permanent secretary of the Academy of Inscriptions, where thousands of reproductions of glyphs had been accumulated.

A competing researcher in England, Thomas Young, a physician by profession and a physicist by inclination, had found a direct relation between hieratic and demotic, and published his results in 1818. By noticing a collection of characters that occurred thirty times in the demotic script of the Rosetta Stone and comparing them with where their equivalent appeared in the Greek text, Young concluded that they stood for the word *king,* yet he could not tell which letter stood for which hieroglyph. Nevertheless the system enabled him to establish the correct significance of such words as *Osiris, immortal, victory, year,* and *likewise*. But he had no idea of how to read the individual letters, most of which he got wrong or transposed. He did correctly guess that a cartouche was a convention indicating a royal name; but otherwise, with the hieroglyphs, he



PTOLMÊS
(Ptolemy)

KLEOPATRA
(Cleopatra)

The island of Philae (now submerged by the Aswan Dam) lay about 5 miles south, or upriver, of Aswan, beyond the first cataract and before the second. The obelisk found by Bankes was 20 feet long and weighed 6 tons. It was inscribed with the names of Ptolemy IX (184(?)-116 B.C.) and his sister-wife Cleopatra. Bankes later found the lower half of its matching pair, which he had removed to England.

made no further headway, considering, as did everyone else at the time, that they were purely ideogramic—that is, standing for words or ideas, not sounds.

Champollion had at first thought likewise. But when he counted the number of words in the Greek text of the Rosetta Stone and the number of signs in the hieroglyphic text, he found there were three times too many of the glyphs; this led him to conclude that they *must* represent sounds, not words. By transcribing the Greek name *Ptolemaios* letter by letter from demotic to hieratic and then to cursive hieroglyphic, Champollion was finally able to find virtually the same hieroglyph in the Rosetta Stone. This meant that the proper names of Greeks, such as *Ptolemy* and *Cleopatra,* must be written phonetically, letter by letter, in all the hieroglyphs. Unfortunately, there was no *Cleopatra* in the Greek text of the Rosetta Stone; but in a text known as the Casati papyrus, he found the demotic form for this last of the Ptolemaic queens. What he needed now was another Rosetta Stone. And in 1891 he got it in the form of an obelisk.

Some years earlier, a French traveler, Frédéric Caillard,

had found an obelisk on the island of Philae above Aswan, between the Nile's first and second cataracts, smaller than most, only 22 feet long, but which weighed about 6 tons. Unable to move it, Caillard bequeathed it to the French consul, Bernardino Drovetti. But Drovetti's competitor in the racket of ravaging Egypt for treasures to sell to wealthy antiquarians, the British consul Henry Salt, also got wind of the find and hijacked it. With a wealthy young English antiquarian, William Bankes, an adventurous friend of Byron's, Salt arrived on the scene and arranged with the gigantic Italian explorer and adventurer Giovanni Battista Belzoni, to have the obelisk floated down the Nile so it could be shipped to Bankes's estate in England.

Giovanni Battista Belzoni

Belzoni's men had built a rough stone causeway from the bank but the weight of the obelisk sank the stones into the mud of the Nile until only the tip was visible above the swirling waters. In despair Belzoni had divers lay heavier stones underwater until the obelisk could be gently levered back onto land. With heavy ropes tied upstream a boat bearing the obelisk was delicately manuevered through the steepest part of the cataract until it shot out into clear water to be safely navigated downstream to Aswan and Alexandria for shipment to England as a successful coup for the British.

Henry Salt, British consul general in Egypt, considered himself an artist and a litterateur but spent his career selling antiquities for profit, though his first collection netted him a paltry £2,000 from the British Museum. Only after his death did his second collection fetch £7,000 at Sotheby's. With Belzoni, Salt quarreled over who should get credit for their joint discoveries, and in the end he declared: "I have but one wish: never to have my name coupled with his." Salt died having received neither a pension nor the recognition as a scholar he so assiduously longed for.

While Bankes continued up the Nile with an elderly Prussian nobleman, Baron Sack, Belzoni immediately ran into difficulties and nearly lost the obelisk when it got loose and slipped into the Nile, requiring enormous exertion and some sharp engineering to recover. Next he had to float it down the cataracts, a job so dangerous the boat captain buried his head rather than watch. Finally, he had to overcome Drovetti, who did everything in his power to recover the obelisk, including making threats to Belzoni's life. At one point Drovetti even tried to convince a native sharif that the obelisk was his property because the hieroglyphs on it said it had belonged to his family!

The French consul Bernardino Drovetti (seen here with his gang of trusties) was a Piedmontese born in Barbaria who accompanied Napoleon to Egypt as a colonel. Like his great rival Salt, he had difficulty selling his Egyptian loot to Catholic Charles X because it was feared it would show the Egyptian civilization to be older than the 4004 B.C. accepted by theological dogma. Eventually he disposed of it with the Berlin Museum and with the king of Sardinia for the monarch's Turin collection. After 27 years on the Nile, Drovetti ended his days in an asylum for the mad.

The Philae obelisk, which W. J. Bankes financed Salt to steal from Drovetti, as it stands in Kingston Lacy House in Dorset.

In the end Belzoni got the trophy safely to Cairo, where it was shipped to England, to be set up on Bankes's Dorset estate, Kingston Hall, in the presence of Arthur, duke of Wellington. On the base of the obelisk was an inscription in Greek in honor of Ptolemy Euergetes II and of Cleopatra, his wife. Of the two hieroglyphic cartouches, Ptolemy's was immediately recognizable. It was hoped that the other would bear the name of Cleopatra. In 1821 a lithograph was made of both the Greek and the hieroglyphic texts, a copy of which reached Champollion in January 1822. Immediately he recognized the second cartouche as that of Cleopatra, spelled nearly as in the transcript of the demotic name, only more fully. It confirmed for Champollion the value of the letters *polt,* which appear in both *Ptolemy* and *Cleopatra*.

Altogether this gave him fourteen recognized alphabetical signs among the hieroglyphs; but what puzzled Champollion, as it had puzzled Young, was that different signs appeared to express the same sounds, a fact for which neither expert could account. Some signs, like the egg at the end of the Cleopatra cartouche, Champollion realized from other research was simply a designation of the feminine. But he was now convinced that he was on the right track to decipher the lot, and that nothing could stop him. Locked up in what he called his "arsenal" attic studio, he began to apply the system to all the available texts on obelisks. A cartouche from a Karnak obelisk reproduced in the *Description de l'Égypte* quickly gave

ALKSANTRS
(Alexander)

him ALKSDR, for Alexander. The Barberini obelisk, which had first brought Kircher to Rome, gave him HADRIAN, and SABINA his wife. Furthermore, as the general inscription on the obelisk contained a repeated group of eight letters, obviously a proper name, and since Hadrian's favorite was the youth Antinoüs, Champollion deciphered the name as ANTEINS, proving the stone to have been carved in his memory.

Kircher's next obelisk, the Pamphilian, raised by Bernini in Piazza Novona, referred to VESPASIAN and his son TITUS. Other obelisks of the Roman period carved with hieroglyphs gave Champollion the names of LUCILIUS, SEXTUS, AFRICANUS, TIBERIUS, DOMITIAN, NIRVA, and such titles as CAESAR and AUTOKRATOR. It was now clear that late Egyptians had used phonetic glyphs to spell out foreign names and titles. If only there had been some Egyptian names of pharaohs in the Bible, Champollion mused, he could see if the principle also applied to native pharaohs; but there were none.

Like a caged beast, Champollion paced his arsenal, begging everyone to send him more texts. Then it happened. In September 1822 he received copies of some inscriptions from a French architect, Huyot, who had copied them from the famous rock temple of Abu Simbel between the first and the second cataracts. One of the

Temple of Ramses II at Abu Simbel

texts contained a cartouche with a royal name written with the picture of the sun, which Champollion recognized as the glyph for Ra, followed by an unknown sign, , like an *m*, and two . Champollion then found another cartouche with the same and glyphs preceded by the glyph for an ibis, which he knew to be the representation of the god Thoth. Thus he had the names of two pharaohs: Thoth () and Ra (), obviously Thothmes and Ramses.

It was a breakthrough. Unmistakably the ancient Egyptians used phonetic glyphs to spell out not only foreign names, but also Egyptian names. Could it be that all of the hieroglyphs were phonetic? It was a step Champollion dared not yet take, though he sensed that success was at hand.

In a fever of excitement, he rushed to the institute, where he threw the papers onto his brother's desk, pronouncing the now famous statement: *"Je tiens l'affaire!"* I've got it! Then his legs buckled and he fell into a coma which lasted three days.

When Champollion recovered, he was able to transcribe the names of a score of ancient Egyptian gods and pharaohs. From the next text given in Greek by Hermapion for the Piazza del Popolo obelisk, brought to Rome by Augustus, and raised by Sixtus V, Champollion deciphered the title *Whom Amon loves,* and established that the Egyptians gave their pharaohs a name and a title in two cartouches joined by the phrase *Child of the Sun*.

Soon he had read fifteen more glyphs of pharaohs going back as far as the eighteenth dynasty. From the Campus Martius obelisk raised by Antinori for Pius VI he got PSMTK for the pharaoh known to the Greeks as PSAMMETICHOS. He also discovered that proper names were followed or preceded by signs indicating a species, such as god or man.

He now had the alphabetical equivalent of twenty-four Egyptian glyphs. But knowing the letters of a language does not mean one can read the language. His only hope was the Coptic connection. Had Coptic not existed, Champollion would have seen no way to reconstruct any of the language other than its personal names and places. But if he could find a group of hieroglyphs that coincided with an ordinary word in Coptic, the meaning of which he knew, he might have a start on the language of ancient Egypt.

Before launching into this strange new world, he decided to announce his limited breakthrough to the Académie des Inscriptions, which he did in a letter, since famous, addressed to its permanent secretary, Dacier. On September 22, 1822, under the great cupola of the institute, Champollion gave the substance of his discovery to twenty-five academicians. Each was issued a leaflet with the names of the pharaohs Champollion had deciphered, along with their equivalents in Greek and Coptic, dramatically bringing home to his audience the fact that they were witnessing the beginnings of true Egyptology, a means of opening up the ancient civilization of Egypt.

De Sacy was quick to appreciate and approve Champollion's thesis. But neither Young nor Jomard, both jealous of Champollion, would accept his system of decipherment; they refused to attribute importance to his discovery. In England and Germany, Champollion's translations were rejected out of hand, though few of those who voiced their criticism bothered to test his method on other inscriptions. Only the brothers Humboldt, in Germany, gave Champollion credit for one of the great discoveries of mankind. Finally, Salt, who had helped with the seizure of the Bankes obelisk, admitted that Champollion's system had enabled him to decipher several words.

PRECIS

SYSTEME HIÉROGLYPHIQUE

RECHERCHES

By this time Champollion was analyzing and translating not only phrases but small inscriptions and whole sentences, proving that the system he had discovered was applicable to the entire body of Egyptian glyphs. These results he wrote up in his *Précis du système hieroglyphique,* dedicated to Louis XVIII, in which he showed in more than four hundred quarto pages with forty-six plates that the hieroglyphs were both phonetic and ideographic, that some could be read phonetically as letters, others as ideograms—in other words, that some could be used to indicate the object represented, such as a man, or bird, and at other times stand for the alphabetic value of the initial consonant of that Egyptian word. The précis has been called "one of the most important and original works of modern scholarship."

A short while later, a distinguished, well-dressed man called at 28 rue Mazarine and asked to see Champollion. When his sister-in-law asked whom she should announce, she was told: the duke of Blacas, first gentleman-in-waiting to Louis XVIII. Blacas said he had come on behalf of the king to present Champollion with a gold snuff box with his initials in diamonds and the inscription: "From King Louis XVIII to Monsieur Champollion, on the occasion of his discovery of the hieroglyphic alphabet." The king ordered Champollion's précis printed at state expense, and encouraged him to create an Egyptian grammar and a dictionary of hieroglyphs.

With this success Champollion was able to marry and have a daughter, Zoraide, who was born on March 1, 1824. A few weeks later he was received in private audience by Louis XVIII, who asked him to travel to Turin to consult and reorganize three hundred cases of Egyptian antiquities, including two hundred papyri with hieroglyphs and assorted stelae looted in Egypt by the French consul Drovetti and bought by the king of Sardinia for his Turin museum. Champollion was to copy the inscriptions so as to create a more correct version of Egyptian history, and at the same time negotiate in Leghorn for the acquisition for Louis XVIII of the valuable Egyptian antiquities "collected" by Henry Salt.

In September, Louis XVIII died and was succeeded by his reactionary younger brother, the count d'Artois, who came to the throne as Charles X, to set up what Wellington called "a government by priests, through priests, for priests." Luckily, the new king, though violently antirepublican, confirmed Champollion's commission to travel to Italy. In Turin, Champollion made a sensational discovery: the work of Clement of Alexandria, who had

Charles X, brother of Louis XVI, and chief of the ultra-royalist reactionaries at court, passed his youth "in scandalous dissipation" incurring a debt of 56 million francs. Claiming to reign by divine right he threw power into the hands of the extremist Jesuits and declared, "I would rather hew wood than be a king under the conditions of the king of England."

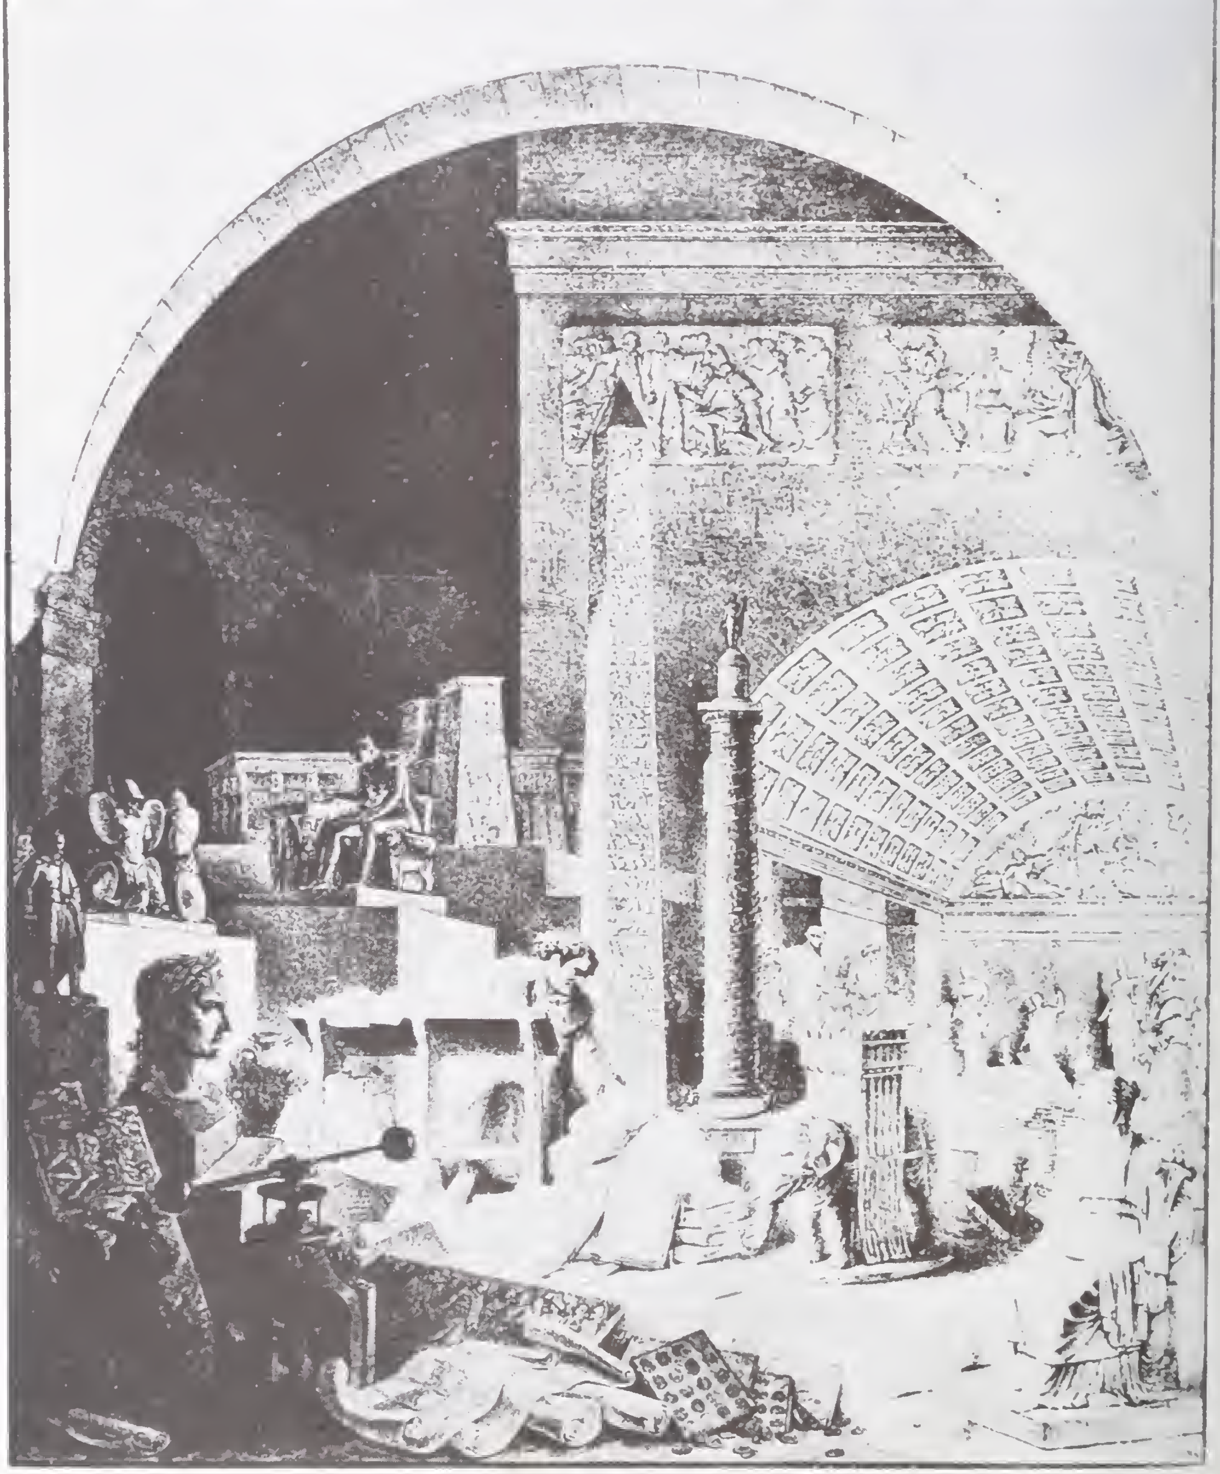
lived about A.D. 200, an expert on "heretics," who may have been an initiate into the "mysteries," and who, by his knowledge of the ancient Egyptians convinced Champollion that all of what passed for Egyptian history would have to be rewritten. He also found the only then known example of a great Egyptian literary work, transmitted directly from the time of the pharaohs: 165 chapters written in pure hieroglyphics. Eventually published as *The Book of the Dead,* it proved to be one of the most vital documents ever discovered in Egypt, and enabled Champollion to begin to tear away the veil from that country's past.

Champollion worked hard at transcribing the glyphs, but his notes for a book were stolen by a fellow researcher, Salvolini, and did not surface till long after Champollion's death. From Piedmont, Champollion went to Rome to study the hieroglyphs on the obelisks there and to make a catalogue of the Egyptian antiquities in the Vatican. Received by Pope Leo XII, he was told that with his discovery, he had done a great service to religion—though not to which.

Back in France, Champollion was awarded the Legion of Honor; he was also named curator of a special Egyptian collection at the Louvre which Charles X wished to form with the cases of antiquities bought from the king of Sardinia. On November 4, 1827, the collection was inaugurated in the presence of Charles X, and opened to the public on Christmas Day. To decorate the entrance of his new museum, the King decided to have an obelisk transported from Alexandria, where Champollion was to travel in order to check out the obelisks there, then mount an expedition to copy and bring back correct drawings of as many Egyptian antiquities as possible.

The young Sagir's dreams had at last come true.

Called *The Book of the Dead* by early Egyptologists, these ancient texts dealing with the awakening of the soul at death are more aptly called *The Book of Coming into Light.*



9. CHAMPOLLION PARTS THE VEIL OF ISIS

On July 31, 1828, Champollion sailed from Toulon on the frigate *l'Egle* with seven young French artists and one medical doctor, Pariset. At Civitavecchia they were joined by a group of five Italians sent by the duke of Tuscany under twenty-eight-year-old Ippolito Rosellini, an Egyptologist and professor of languages at Pisa. The Italians were to help Champollion transcribe inscriptions and make drawings of temples and monuments. As the group approached Alexandria, their ship was caught in a storm and several of the adventurers, fearing *l'Egle* would sink, put messages in bottles and tossed them overboard. Then the sea calmed, and early on the morning of August 18, they spotted the landmarks of Alexandria: Pompey's Pillar, and close by, the standing silhouette of Cleopatra's Needle. Champollion jumped ashore and kissed the soil of Egypt.

His first endeavor was to copy the inscriptions from the second of the obelisks raised by Augustus in front of the Caesarium which had fallen beside its still standing neighbor, Cleopatra's needles, and required excavation from the sand. From its inscriptions, Champollion concluded that both it and its companion had once stood before the Temple of Thothmes in Heliopolis. But why the obelisks had stood in pairs, he could not fathom.

Drovetti, who had done all he could to prevent Champollion from coming to Egypt because he was afraid the visitors might constitute a danger to his various looting schemes, now refused to take responsibility for their expedition. Nonetheless, he was obliged by orders from Paris to take them to see the khedive or viceroy of Egypt, Mohammed Ali.

When the British left Egypt in 1803, such chaos had followed, with rampant plundering and assassinations, that the religious leaders in Alexandria had appealed to Mohammed Ali, commander of the Turkish troops in Egypt, to restore law and order. A reliably cruel and unscrupulous tyrant from the hills of Albania, he did just that, seizing the opportunity to establish a certain independence from his Ottoman masters. By treacherously murdering the entire corps of the Sultan's Mameluke beys, he turned the Ottoman province of Egypt into what amounted to his own independent state, one in which foreigners could vie to

Denon, in the Louvre, among the treasures looted by the French in Egypt

Mohammed Ali, a converted Christian orphan from Macedonia, wished to bring Western technology to Egypt, harness the Nile for agriculture, and introduce industrial manufactures into Egypt. He was in no way interested in ancient temples except to use their beautifully hewn blocks to build factories that would never go into production. His prime addiction was to the pleasures of his harem of five hundred lovely women—two hundred in Alexandria, three hundred in Cairo.

On the eastern point of Phoros stood the great lighthouse, first of the Seven Wonders of the World, reputedly as high as the Washington Monument. Begun by the first Ptolemy, it was completed by the second. Originally an island, the point was later joined to the mainland by a half-mile mole called the *hepastadion,* six stadia long. At the head of the mole stood the Temple of Hephaestus, and behind the emporium the great Caesarium with its two guardian obelisks.

invest, and where their consuls as virtual ambassadors could collaborate with the autonomous viceroy in looting the country.

On August 24, in the very hottest days of summer, Consul Drovetti came with horse and carriage to fetch Champollion and the captain of *l'Egle* to meet Mohammed Ali. The rest of the party followed on donkeys. To Champollion the sumptuousness of the pasha's palace, on the peninsula of Pharos where the great Alexandrine lighthouse had stood, came as a shock because of its stunning contrast with the poverty of the people in the streets.

Mohammed Ali, then 60 years old, with a long white beard, received the Frenchmen in one of the cool rooms of the palace, seated between two windows, dressed in a simple robe. Of medium height and cheerful countenance, his eyes full of vivacity, the Pasha smoked a long pipe decorated with diamonds as he asked Champollion about the sort of voyage they planned. Champollion replied that all his life he had dreamed of visiting this most beautiful of countries, and that to read the hieroglyphs and rediscover the ancient history of Egypt, he wished to go as far up the Nile as the second cataract, studying the ancient sites along the way.

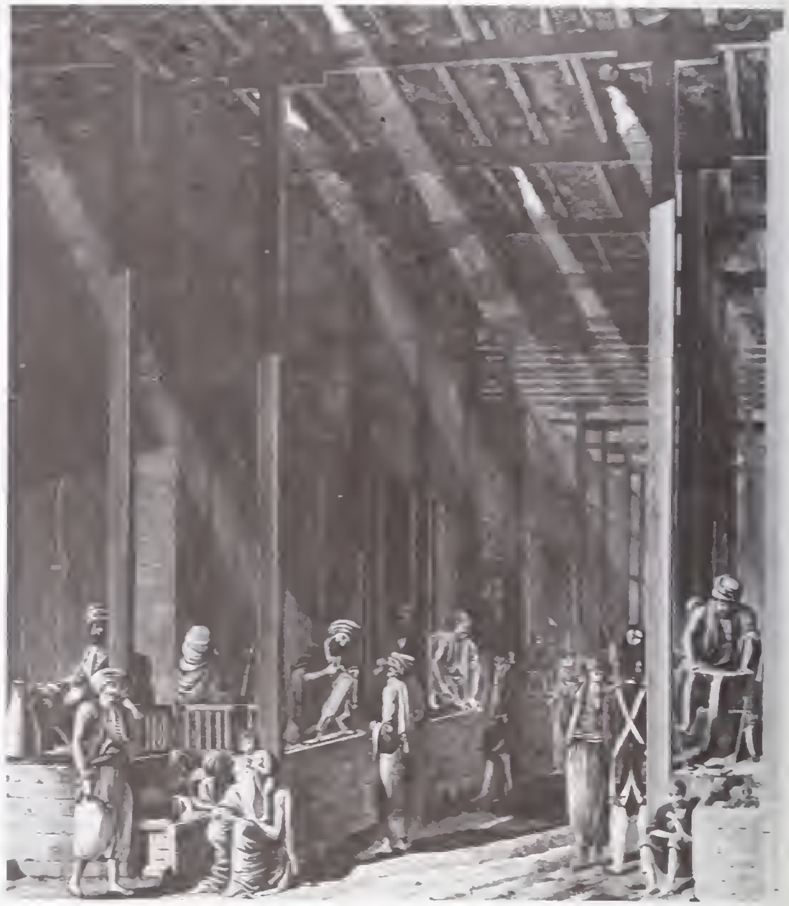
Mohammed Ali stroked his beard and offered them coffee. To show that he was privy to what was going on, he remarked that everyone seemed to be trying to prevent the voyage. "They don't want you to see too many antiquities too close," he said with a wry smile. "But don't worry, I'll give you a *firman* [a passport], and two of my personal body guards." All he asked in return was a translation of the inscriptions on the Alexandrine obelisks, which Champollion, working all through the night, delivered the following morning.

Palace of the khedive

Typical Nile boat

Thanks to the pasha's support, Champollion was able to bypass Drovetti and rent the largest and best equipped boat on the Nile, the *Isis*. As they set sail, Champollion felt he was reliving the dreams of his youth. "Everywhere I go," he wrote in his diary, "and everywhere I look, everything I touch is like renewing acquaintance with things I have known and loved all my life." Between Alexandria and Cairo he followed the map drawn by the editors of the *Description de l'Égypte,* carefully correcting the names of the towns which the members of Napoleon's expedition, in their ignorance of either the Egyptian or the Coptic language, had misnamed or misplaced.

In Cairo, as he wandered through the twisted streets, stopping from bazaar to bazaar, Champollion found himself back in the world of *A Thousand and One Nights*. He had grown a long handlebar moustache, and shaved his head, which he covered with an enormous brightly colored turban. At his side hung a large scimitar. With his dark skin and extraordinary command of the language, he passed easily for an Arab. Eyeing his companions, dressed in native pantaloons and bright brocade, with the yellow pointed boots much favored by rich Turks and Egyptians, Champollion said with satisfaction: "I am a completely new person! I don't feel tired as I did in Paris." Much taken with the beauty of the native females, he describes in detail the erotic dances of the ubiquitous *aalmas,* or dancing girls, but gives no details of his own amorous adventures.



Cairo bazaar

In October the group prepared to travel up the Nile aboard the *Isis*. At Memphis, where, according to the Rosetta Stone, King Ptolemy V Epiphanes had been deified, Champollion correctly classified architecture of different epochs by a mere glance at the ruins. As the group roamed about, sketching and measuring, or copying inscriptions, the natives who followed them laughed at these people "who could read stones."

Sakkara, with its ancient stepped pyramid, they found largely destroyed, plundered for building material for the pasha's palaces at El Difdjar. Everywhere they went, they saw that agents of antiquities dealers such as Salt and Drovetti had ruined the sites, rendering them impossible to study. Tombs had been devastated, pillaged, and refilied. Fragments of mummies had been scattered so profusely they made what Champollion called "a plain of mummies."

At Antinoe, rebuilt by Hadrian for his boyfriend, they found nothing left of the beautiful monuments described and drawn by the members of the Commission de l'Égypte: the inhabitants had destroyed and burned the limestone blocks to extract the lime. Little was left standing other than the indestructible granite columns.

Since the Renaissance, Egyptian graves had been systematically robbed to provide Italian cardinals with private collections. By the time Richard Pococke, a British traveler, visited Egypt in 1737, he complained, "They are every day destroying these fine morsels of Egyptian Antiquity; and I saw some of the pillars being hewn into millstones." Champollion saw that thousands of movable objects were being exported by collectors, dealers, tourists, and unscrupulous consular agents such as Salt and Drovetti, subjecting Egypt to an orgy of destruction. Not only amulets, scarabs, papyri and whole mummies were being taken, but entire rooms, freizes, and tombs were stripped and shipped.

Still, Champollion was able to buy a heavy granite head of Ramses II for one piastre, and make the owner drag it himself to the boat.

At the end of October they arrived at Esna, where they wanted to visit the temple on the west side of the river, greatly admired by the Commission de l'Égypte. Too late. Twelve days before their arrival, the temple had been pulled down by the pasha to strengthen a quay on the river. Luckily the temple of Esna has been spared as a

Temple of Esne

storehouse for government cotton; but Champollion found its decadent Ptolemeic sculpture quite detestable.

At Armant he described the temple, and copied many of its reliefs—which was lucky, for it was later in the century destroyed by the viceroy Said for stones to construct a sugar factory. Denderah they encountered by moonlight.

At Denderah they found six rooms within the thickness of the walls, and six more underground, access to which was very difficult as the passages were full of bats and there was little air. The walls and the colossal columns were covered with scenes in relief, including a great zodiac painted in two bands along the ceiling of the portico. The famous ceiling zodiac had already been blasted out with dynamite in a cops-and-robbers duel between Salt and Drovetti, and shortly thereafter a quarter of the temple was quarried away for a saltpeter factory.

Without native guards, but well provided with arms, they set off through the night, singing arias from the latest operas as they marched to find the temple, most likely from Rossini's *Semiramide* which had premiered a few years earlier.

When the temple loomed before them, bathed in soft moonlight, they saw that it was the best-preserved structure they had yet encountered. To enter its vast halls they lit torches, which revealed hundreds, even thousands, of inscriptions, from which Champollion deduced that the temple was not dedicated to Isis, as everyone maintained, but to Hathor, whom he identified with Venus or Aphrodite, the goddess of mirth and love. Champollion saw that two pharaohs of the New Kingdom, Thothmes III and Ramses II, had added to the original construction, as had succeeding monarchs down to the Ptolemites, followed by the Romans, the last deducible from the carved names of Augustus and Antonius.

At El Kab they went ashore to see the temple, but found it, too, had disappeared, destroyed by Mohammed Ali, as were the two temples of Amenophis III and Thothmes II, of which nothing was left but the drawing done by the commission. In November the party reached Karnak at Thebes, where they visited the Temple of Seti I, the

These seated colossi on the plain of Gournah, across from Luxor, were identified by Greeks with Memnon, a mythical king of Ethiopia, known as "Son of the Dawn." The statues were renowned for giving off harplike sounds at dawn (apparently caused by expansion of the stones in the morning sun); but the Persian troops of Cambyses, curious to know what made the giants howl, broke up the stones. They were further damaged by an earthquake in Roman times. Egyptologists saw in the statues representations of Amenophis III (or Menephtah), son and successor to Ramses II, which had once stood before his mortuary temple, already destroyed in Augustus's time. Champollion found their bases covered by 15 feet of accumulated dirt. Later measurements showed that the bases were linked by cubit and proportion to the king's chamber in the Pyramid of Cheops.

Memnon Colossi, and the Ramesseum; but Champollion, seeing that "it would take a lifetime to copy all the glyphs," decided to spend more time on his return.

Further up the Nile, at Edfu, he found an immense and magnificent temple also dedicated to Hathor and to her mate, Har-Hat, the personification of celestial science and light, whose son Hawsont-Tho Champollion considered the equivalent of Eros, or "love," in the Greek myths. Sculptured representations of the three divinities, with qualifications and titles, threw a new light for him on the Egyptians' theogonic system, or genealogy of gods. At Abydos, Champollion found dynastic sites mixed in whith those of the Greco-Roman period, all badly ravaged by vandals. Sliding almost naked on his belly to enter the buried interior passages of temples, he nearly stifled, but obtained some extraordinary drawings. Found lying in a dead faint in one of the tombs, he joked on reviving that he "needed complete silence in order to hear the voices of his ancestors." On the walls of an ancient tomb he found more than a hundred different kinds of birds carefully depicted, and more than a dozen different dogs, several not native to Egypt.

The Temple of Edfu with its two immense pylons half-buried in the sand, rebuilt in the Ptolemaic era at the end of the first millennium B.C. Champollion deciphered glyphs on its walls dating back to the third millenium B.C.

At the first cataract, the group had to abandon the *Isis* and proceed to the second cataract in three small barques lent them by the commander of the province of Esne. Champollion was excited to see Philae, the lovely island where the Bankes obelisk had been discovered. From the river it appeared unspoiled, with temples and colonnades overgrown with fragrant tropical plants, shaded by tall palm trees. But they soon found that Christians, with hammer and chisel, and in the name of God, had ruthlessly obliterated inscriptions and friezes on the porticos of the Temple of Isis, lopping off heads, hands, feet, and phalli.

In Nubia, in the Temple of Kalabschi, Champollion got a better insight into the basic religion of the ancient Egyptians. He saw that Amon-Ra, their supreme and primordial being, was not only his own father, but husband to his mother, the goddess Mouth—that is, the feminine portion contained within himself, at the same time male and female—and that all the other Egyptian gods were merely forms of these two principal constituents. Most important, Champollion found that no matter how far back he went into Egyptian history, the people had been highly civilized, possessing hieroglyphs, mathematics, music, and an understanding of embalming. There seemed to be no beginning. Only under the Ptolemites had they become decadent. By this time Champollion had the long black beard of a Capucin monk, and had assumed the dress of a desert Arab, eating pilaf with his fingers, smoking three pipes a day, and keeping healthy by drinking nothing but Nile

water, possibly on the advice of his predecessor up the river, that intrepid seventeenth-century traveler responsible with Francis Bacon for organizing a New Atlantis in Virginia, George Sandys, who recommended Nile water "for it procureth liberal urine, cureth the dolour of the reins, and is most sovereign against the windy melancholy arising from the shorter ribs, which so saddeth the mind of the diseased."

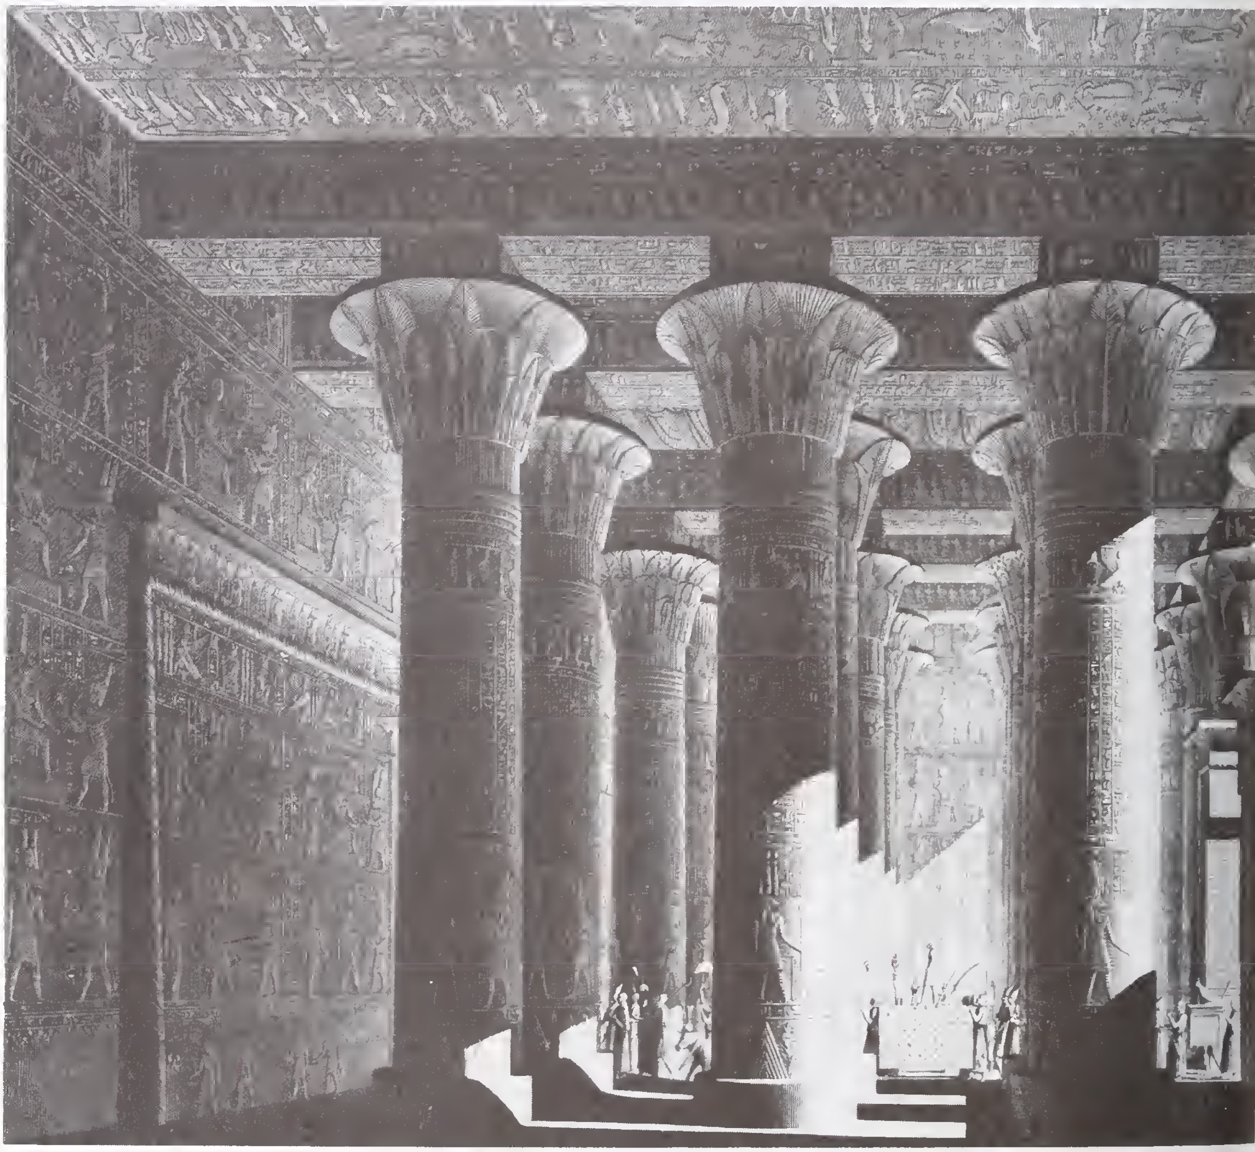
Nubia, for Champollion, grew desolate, with crocodiles asleep on the sandbars, and unexpectedly cold at night.

Reading the stones

Crossing the Tropic of Cancer in January 1829, Champollion complained that he almost froze. So they turned back, also because Drovetti had held up their mail and the money due Champollion.

Slowly coming back down the Nile, the party stopped and made careful drawings and notes of hieroglyphs on all the temples they could find, "hoping to bring back all of Egypt in our portfolios." This time they stayed seven months in Thebes, which Champollion described as the most magnificent work produced by the hand of man, the grandest and the most marvelous. No nation on earth, he concluded, either ancient or modern, had ever conceived architecture so noble, and on such a scale. "The Egyptians of old," he said to Rosellini, "thought like men a hundred feet tall. We in Europe are but Lilliputians."

Hypostyle temple of Esne



In Thebes, Champollion learned that a British engineer in Alexandria was studying the means of removing to England the recumbent obelisk which Mohammed Ali had now donated to the British. To Drovetti he wrote that he was delighted the Englishman wished to waste his country's money on removing such an inferior obelisk. Instead he recommended that if France were to put up an obelisk in Paris, it should be a Theban one. To his brother in Paris he described in detail just how the obelisks could be felled and dragged to the river, and told him that the natives could be hired for a few sous and the sharifs easily bribed, especially one—"who had the soul of a Frenchman." Champollion pleaded with his brother to convince the French government to increase the budget for the extra cost of transporting one or even both Theban obelisks. "It would not be amiss to put before the eyes of the nation such a monument, so as to disgust it with the knickknacks [*colifichets*] and gewgaws [*fanfreluches*] which we call public monuments, veritable boudoir trinkets, perfectly suited to our great men, and worthy of architects who are but meticulous imitators of all the poverty of the Bas Empire."

In Cairo, Champollion was amiably received by Mohammed Ali at a palace luncheon, where they met the pasha's adopted son, Ibrahim, a pockmarked man of forty, who suddenly fell to the floor stricken by an attack of apoplexy. Mohammed Ali, thinking his son had died, allowed his eyes to fill with tears. But Dr. Pariset rushed to Ibrahim's side, and the pasha was amazed to see his son revive. Thereafter he treated both Frenchmen with extraordinary regard, and would talk to them for hours, saying: "One of you has restored the life of my son, the other has restored the glory of my country."

Before bidding them farewell, the pasha asked Champollion to write for him a short history of ancient Egypt from all of the new inscriptions he had copied, and this

Champollion did, pleading in return that the pasha forbid further destruction of Egypt's ancient monuments and prohibit the export of its valuable antiquities, requests which the pasha eventually incorporated into a decree. Not that Champollion let the decree affect his own immediate export of all that he and his group had collected.

Back in Alexandria in September, Champollion became friendly with a young naval lieutenant, Raimond Jean Baptiste de Verninac Saint-Maur, commander of the corvette *Astrolabe,* which was to take the party and all its loot back to France in November. Finding in Verninac a fellow Bonapartist, Champollion plotted with him the means of bringing back to France one of the Theban obelisks, which they hoped to have raised in memory of Napoleon's conquest of Egypt.

On December 6, 1829, after a year and almost four months in Egypt, Champollion sailed from Alexandria on the *Astrolabe,* with an enormous collection of notes and sketches, plus two thousand pages of hieroglyphic inscriptions, entirely transcribed by hand. He also had notes on all the monuments still standing along the Nile from the Pyramids to the second cataract, reproduced with great fidelity. Fifteen hundred drawings, many colored *in situ,* had corrected virtually everything published in the *Description de l'Égypte,* whose sketches, though esthetic, turned out to have been lamentably inexact, some of the inscriptions, in Champollion's opinion, having evidently been invented by a doubting or lazy draftsman who could not believe that the hieroglyphs would ever be deciphered.

Champollion arrived in Toulon just before Christmas, to find the port in great turmoil, preparing for an expedition against the Barbary pirates of Algiers, to which his new friend Lieutenant Verninac was promptly assigned.

In Paris, Champollion found his brother at a new address, by the Bibliothèque Royale (now Nationale), to which he had been appointed curator. As a present, the young Champollion had brought him a small piece of crocodile meat, too far gone to be eaten. Figeac had duly passed on all of Champollion's recommendations about bringing back the Luxor obelisks, and the minister of the navy had been quick to support the notion, going so far as to suggest the commissioning of a special vessel to do the job; but, being the same Baron d'Haussez who had gotten Champollion into trouble as a Bonapartist in 1815, the minister intended to see that Champollion was cut out of the picture and take for himself all the glory of the project, a feat he managed to accomplish so successfully that in the two volumes of d'Haussez's memoirs, Champollion is not even named.

With Drovetti (who also hated Champollion), d'Haussez organized a committee which obtained from Charles X the order to bring back to France not only the two Theban obelisks standing before the Temple of Luxor but also Cleopatra's Needle and its recumbent partner in Alexandria. To negotiate with Mohammed Ali the cession to France of the Luxor obelisks, d'Haussez decided to send a special envoy to Alexandria. As a suitable ambassador, because of his taste in art and letters, and because he had traveled widely in the Near East, d'Haussez selected the king's commissioner to the Théâtre Français, Baron Isidore Taylor, who had been aide-de-camp to General d'Orsay during the Spanish campaign against Wellington. To advise on the engineering problems of removing the obelisks, Taylor was to take with him a French naval engineer, Lefebure de Serisy, who had recently served as Mohammed Ali's adviser in reconstructing the Egyptian fleet, destroyed two years earlier in the Battle of Navarino when British, French, and Russian squadrons had defeated the Turks and established the independence of Greece.

In May 1830, Taylor and Serisy sailed from Toulon with an initial purse of $20,000 for expenses, plus various presents to entice the Egyptian viceroy. Among these, for propaganda purposes, was a richly bound folio edition of the twenty-volume *Description de l'Égypte*. There were also some socially prized items such as Sèvres porcelains, cut glass, and table crystal, as well as items considered suitable to an oriental potentate, such as arms, helmets, and breastplates. On the recommendation of Consul Drovetti, some artificial pieces of anatomy were included for the school of medicine in Cairo.

Arriving in Alexandria, Taylor found that Mohammed Ali was still in his winter palace in Cairo. He was received instead by Ibrahim, who gave the baron a stunning piece of bad news. The French had been so tardy in removing Cleopatra's Needle that it had been given away, after much soliciting, to the British consul, Mr. Barker. Upset, and in receipt of urgent requests for his return to Paris from the intendant of the king's household, who complained that his absence was prejudicing the success of the Théâtre Français, Taylor nevertheless decided to try to salvage the situation by awaiting the arrival of Mohammed Ali.

After lingering another month in Cairo, the pasha at last

Karnak, slightly north of Luxor, consisted of a group of temples occupying about 150 acres, its walls covered with intaglios of the god Amon and scenes of pharaonic splendor. It was the national shrine of Egypt for more than two thousand years. The great obelisk in the foreground was raised by Thothmes I. Other, smaller obelisks were raised by Hatshepsut and Ramses II.

turned up, sufficiently mollified by the French diplomat's manner and by his lovely presents to reverse his decision, reconfirming to Charles X of France the gift of Cleopatra's Needle. As a bonus he added both the Luxor obelisks. Mr. Barker was to be assuaged with what the pasha considered an equitable solution: an offer to the British of quite another prize, the great obelisk of Queen Hatshepsut still standing in the Temple of Karnak—the pasha being convinced that the British could never remove it.

Taylor wrote at once to Paris that the Alexandrian and Luxor obelisks were now the property of Charles X. But by July, events in France had taken a turn. News reached Alexandria of a three-day revolution in Paris which had forced the reactionary Charles X, King of France, to abdicate in favor of the bourgeois Louis Philippe, King of the French, helped into power by a conspiracy of Masons. Mohammed Ali changed his mind and refused to allow the embarkation of Cleopatra's Needle onto the ship *Dromadaire,* specially sent out by d'Haussez. Mr. Barker, seizing the advantage, quickly conceived a plan to remove the obelisk to England, placing several of the pasha's agents in his pay.

Taylor did his best to convince Mohammed Ali that nothing was fundamentally changed in France by the revolution, that the gift had not been to the person of the king, but to the nation, to the people of France. Mohammed Ali pondered, and finally changed his mind, reconfirming the gift to the government of Louis Philippe "in gratitude to France for numerous tokens of favor and friendship," but mostly in the hope of obtaining naval equipment for his infant Egyptian navy.

By this time Taylor had learned that there was no hope of getting heavy timbers from Caramanie in Cyprus needed to load the Alexandrine obelisk, so he decided to return to France to speed up the building of a special vessel to fetch the Luxor obelisks before there were any more changes of mind. In Paris, Taylor found that d'Haussez had fled to England, accused with several of his colleagues of being responsible for the reactionary ordinances which had brought about the revolution of July. His successor at the naval ministry, Gèneral Horace Sébastiani, had, however, been on a mission to Egypt under the consulate, and saw no reason to change the arrangements for the obelisks made by d'Haussez. Only there was no ship in the French navy capable of sailing 1,800 leagues across the Mediterranean, 200 leagues up the shallow Nile to Thebes, then back again loaded with a single 250-ton obelisk, let alone one capable of facing the contrary winds of the Atlantic's Bay of Biscay before being towed past the low and narrow bridges of the Seine all the way to Paris.

Such a ship would have to be specially designed and built, breaking all the rules of naval architecture. In order to hold an 80-foot obelisk, the ship would have to be at least 100 feet long. To sail the Atlantic it would have to be well keeled. To sail up the Seine it could be no wider than 25 feet. To cross the sandbanks at the mouth of the

Nile it would have to be as flat-keeled as possible, yet sturdy enough to be beached on the banks of the Nile and receive a load of 250 tons. For such an extraordinary craft it was decided to lay five separate keels specially reinforced with extra strutting to spread the weight of the obelisk evenly over its bottom.

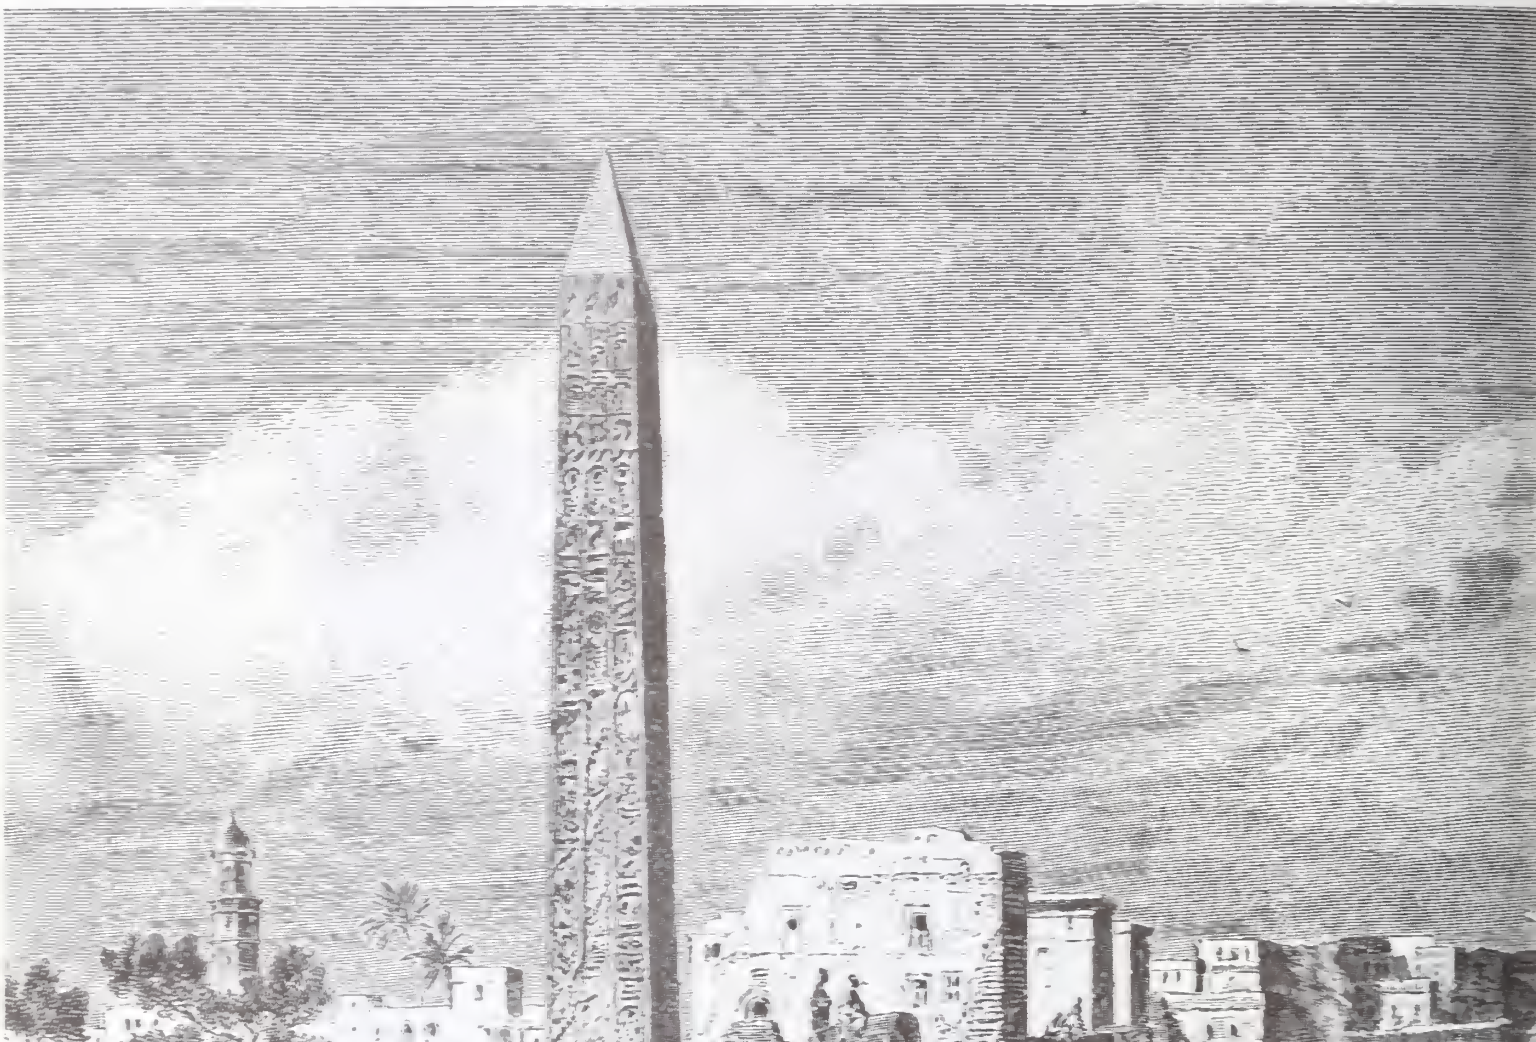
As a name for this novel ship, the one which Champollion had originally suggested, the unnovel *Luxor*, remained. And now that d'Haussez was gone he was also able to suggest as captain Lieutenant Verninac Saint-Maur, who had just distinguished himself in the French operations against Algiers by bringing back in the *Astrolabe* 10 million French francs in gold looted from the Casbah.

No sooner had Verninac deposited the gold in the French treasury than he heard of his appointment as captain of the *Luxor*. Verninac took over his new command with some doubts as to its seaworthiness, and immediately lightened its load by ordering a reduction of most of its armament. As a second-in-command, Verninac selected another young naval officer, Lieutenant M. de Joannis. Three more officers were to command a crew of 136 sailors, along with two naval surgeons, Dr. Angelin and Dr. Pons.

To handle the actual operations of felling the obelisks, the maritime prefect of Toulon recommended a diminutive naval engineer with the appropriate name of Lebas. Monsieur Jean Baptiste Apollinaire Lebas's orders were to fell the right-hand obelisk facing the palace at Luxor, as selected by Champollion, and embark it on the ship. During the felling and embarkation, Lebas was to be in sole command; otherwise command rested with Verninac. To help Lebas with his job, he was allowed to select from the Toulon base a master carpenter with assistants, smiths, caulkers, jointers, stone cutters, and several first-rate boatswains.

While Verninac loaded the ship with a year's worth of supplies, including pistols, sabers, rifles, and ammunition, Lebas loaded equipment necessary to lower the obelisk, including several 50-foot beams almost 2 feet in diameter, forty 16-inch boards of the same length, and 4 inches thick, 1,200 meters of rope as thick as a man's arm, 400 meters as thick as a man's leg, several heavy capstans, block and tackle, pulleys, and a forge. Lebas was empowered to hire as many men ashore as he needed for the job, payments for whom would be provided by the new French consul in Alexandria, M. Mimaut, who had replaced Champollion's enemy Drovetti.

On April 13, 1831, fully loaded, the *Luxor* sailed from Toulon with a favorable breeze, carrying a band of adventurers who hoped to duplicate an engineering feat which had not been accomplished since the time of the Romans—the removal to Europe of one of the great Egyptian obelisks. As the extraordinary vessel passed the boom, all the ships of the French navy lined up in Toulon harbor sounded general quarters. Toulonnais massed on the quays waved handkerchiefs; mothers, sisters, and sweethearts dabbed their eyes.



10. BOURGEOIS ADVENTURERS

With the wind either abeam or astern, the *Luxor* breezed along at a comfortable 8 knots, but it was soon clear to Captain Verninac that she was not a seaworthy craft. When the wind shifted to the east, obliging him to sail close-hauled, the keels would not hold, and the *Luxor* progressed sideways like a crab. Hit by a storm, the ship was unmanageable. As the storm died, Verninac realized that for the return trip with the obelisk aboard, he would have to have one of the navy's newfangled steamships tow him to Toulon.

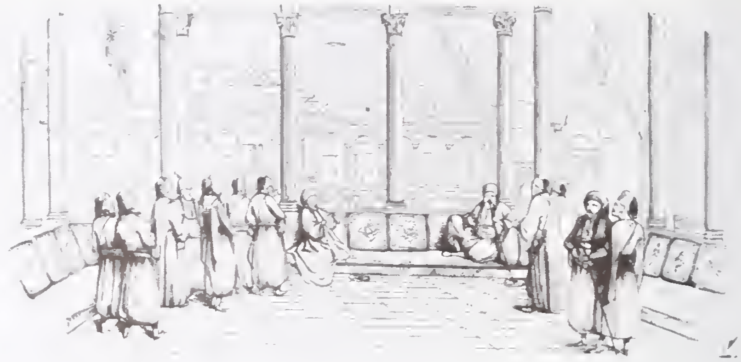
On May 3, at dawn, the sandy dunes of Africa appeared against the blue sky above Pointe d'Aboukir, reminding the crew nostalgically of both Bonaparte's victory on land and of Admiral Brueis's disastrous defeat in the bay. At 10:00 A.M., the ancient landmarks of Alexandria—for both sailor and bedouin—Pompey's Pillar and Cleopatra's Needle, appeared on the horizon, and the *Luxor* anchored in Alexandria harbor opposite the sparkling white palace of

Pompey's Pillar

the viceroy of Egypt, Mohammed Ali Pasha, and Captain Verninac went ashore to call on the khedive's son Ibrahim, whose prime preoccupation at that time was the instant recruitment of an army with which to attack his Ottoman masters, who had insulted his father.

When Mohammed Ali and his suite arrived at the palace, Verninac, Lebas, and Angelin, all in full French naval uniform with huge epaulettes and fore-and-aft hats, were received by His Highness in the large hall with arched porticoes and thick Turkish carpets. Raising himself on his cushions, pipe in hand, Mohammed Ali asked for the engineer Lebas, as if he were so small he could not see him. Laughing at his own joke, the pasha then honored Lebas by asking him to sit beside him and tell

Alexandria, founded by Alexander the Great in 332 B.C., became one of the great cities of the East, with half a million inhabitants, second only to Imperial Rome. When the Arabs conquered it in A.D. 640 they found 4,000 palaces, 4,000 baths and 400 theaters. It contained two of the greatest libraries in history, the Serapeum and the Soter each with 400,000 volumes; the former was destroyed by Christians, and latter in 641 by the Caliph Omar, who is recorded as having said: "If those books contain the same doctrine as the Koran they are of no use, since the Koran contains all the necessary truths. If they contain controversy, they should be destroyed." So the parchments were given to the public baths to be burned as fuel for six months.



him all about the problems of the obelisk. Captivated by the pasha's deep probing eyes, Lebas, as he later recounted in his report on the operation, listened carefully to "His Highness' refined, perspicacious, and profound ideas."

Mohammed Ali, as he had done for Champollion, graciously accorded the expedition a *firman* for free circulation in all his states, plus the protection of two janissaries to see that his *firman* was obeyed. He ordered that everything possible be done to facilitate the enterprise, even producing for the French, as dragoman, or guide, an ex-Frenchman who had stayed in Egypt after Napoleon and had adopted the oriental name of Youssouf Kachef, an exotic fellow who spoke excellent Arabic, and knew most of the sheikhs up the Nile.

Alexandria, at the extreme western edge of the Nile Delta, was not on an actual estuary of the Nile. The main mouth of the great river emptied into the Mediterranean just north of the town of Rosetta. Navigation on this estuary was only possible for the *Luxor* at floodtime, which would come toward the end of June, a month or more away; and even so, shifting sandbanks blocked the mouth, which became most dangerous when whipped by sudden winds. The *Luxor*'s third mate, Midshipman Juarez, sent ahead to the mouth of the Nile to sound out the depth of the sandbars, returned with a competent pilot.

At dawn on June 11, Lebas set off with a flotilla of small flat-bottomed barques called *dgermes,* loaded with the heavy equipment from the *Luxor,* heading across Aboukir Bay for the westernmost mouth of the Nile, about 12 leagues east of Alexandria. As the water at the mouth of the Nile was 6 feet deep over the sandbars, and the *Luxor* drew 8½ feet, Verninac had been obliged to lighten the ship to the utmost, and as it could no longer sail on the open sea on its own without ballast it had to be towed by a French thirty-cannon brig, the *d'Assas,* which opportunely appeared in Alexandria harbor.

Lebas, in his *dgerme,* noticed the sea was taking on a yellowish tint. From the frown on the pilot's face, he concluded they were approaching the mouth of the Nile. Small mounds of sand appeared on the surface of the water, forming sinuous passages of unequal depth, wide enough for the small boat to negotiate, but difficult for the *Luxor.* To guide the *Luxor* through the treacherous sandbars Verninac had found a single-toothed Arab pilot who had spent a lifetime negotiating what the Turks called the *boghaz,* or narrow maritime passages. At daybreak on the seventeenth, the *Luxor,* cast adrift from the *d'Assas,* headed for the *boghaz.* Small boats lined each side of the narrow frothy passage, which continued to shift under the impact of waves, current, and a stiff breeze. On the way through, Verninac caught sight of the wreck of a ship which had missed the passage and been battered against the banks. Moments later, a heavy shock signaled that all five keels had struck bottom. If the *Luxor* could not surmount the bank, she risked being caught by the sands and held for the rest of the year, putting a quietus on the whole expedition.

Heavy waves raised and lowered the ship. Sails strained in the quickening breeze. With a groaning lurch, the ship was carried across the barrier into what Verninac described as "the tranquil waters of the most beautiful of rivers." The Arabs shouted hurrahs. Cannons from the Turkish forts guarding each side of the mouth fired a welcome. Unable to respond with salvos, because they had dismantled all their guns, Verninac flew pennants and made up for his apparent rudeness by a donation of Bordeaux and Champagne to the local Turkish garrison.

There was a brilliant sun. The sky was alive with swallows and terns. Broad-beaked pelicans circled overhead as the ship slid slowly past an island which had not been there when Napoleon had charted the area thirty years before. Along the banks of the river, date palms framed a delightful panorama where the Rosetta Stone had been discovered. On the gently flowing Nile, the *Luxor* was a novelty. Natives ran from their cottonfields and rice paddies to stand at the river's edge and admire the mountainous ship. Children left their sheep and buffalos unherded to stare in wonder at what they called a floating mosque.

Three hours later the *Luxor* anchored off the actual town of Rosetta, surrounded by a cool green landscape. It was explained to the Frenchmen that many of the town's lovely houses were uninhabited since the newly dredged Mahmudi Canal, shorter and safer, had siphoned off traffic directly from the Nile to Alexandria, leaving Rosetta commercially high and dry. While the *Luxor* waited for the waters of the Nile to rise sufficiently for it to proceed upstream, Verninac and his crew were able to enjoy Rosetta and its surrounding wonderland of orange groves, banana plantations, and cool shady gardens lined by avenues of sycamores.

The town of Rosetta on the east Nile

But Lebas could not linger. He had to reach Thebes in time to dig a berth for the ship on the riverbank, as close to the obelisk as possible, so that the *Luxor* could be floated over it at floodtime and be left in a level drydock when the waters eventually withdrew.

There were four types of boats on the Nile: the *dgermes,* with large lateen sails, svelte enough to scoot up the river in any season; *agabas,* heavy flatbottomed barges, drawing very little water, used for towing supplies when the waters were at their lowest; the *masch,* known as the store-ship of the Nile, a craft of 400 to 500 tons, used to sail only during the inundation of the river; and *canges,* narrow boats, light and elegant, with the fine lines of a yacht.

Midshipman Juarez and surgeon Pons, with ten sailors and a detail of sixteen carpenters, smithies, and stone cutters, were to go ahead to Cairo, 40 leagues up the river in a mixed flotilla of native boats loaded with equipment.

Lebas, Juarez, and Pons boarded a light *cange,* which could travel speedily either by sail or by scull, and installed themselves on the stern, where a small superstructure had been divided into two rooms—a messroom and sleeping quarters.

On July 19 the whole flotilla abandoned the *Luxor* off Rosetta and set sail for Cairo. As Lebas put it, "All was new to us, the countryside, the trees, plants, costumes, and the language of the Arabs." Avidly taking stock of the varied products, many of them unknown in France, the Frenchmen let their eyes wander happily over the passing delta. The banks were bordered with flowering hedgerows, forests of date palms, and fragrant mimosa. Beyond the fertile fields, a wasteland of desert stretched to the horizon.

Here and there the Frenchmen spotted land, once fertile, which had fallen into the most depressing poverty. Nearby villages lay in ruins, replaced by hovels of sun-dried mud, roofed over with palm fronds. They noted that despite the fertility of the delta, the Arab population appeared to be miserable and half-starved, lining the riverbanks to implore assistance, displaying their naked half-starved children. Everywhere the Arab men were covered with rags, prematurely aged by ill-treatment and privation. The only social institution appeared to Lebas to be the caprice of the Turk, who could have any Arab lashed on any pretext with a *courbache,* or heavy whip of hippopotamus hide.

On the roof of every house or hut Lebas was surprised to see a pigeon coop, from which at dawn myriad of pigeons would fly out, darkening the sky, and return at noon to rest through the heat of the day. No one seemed to shoot or eat these birds; they were raised solely for their excrement, a powerful fertilizer for field and garden.

At Abou Mandour they passed a famous mosque where female pilgrims came to perpetuate their bondage by obtaining fertility from the waters of a reportedly magic fountain. Every evening Lebas and his colleagues would go ashore to study the manners and customs of the people, whom they were surprised to find essentially gay, despite the ever-present threat of the *courbache*. The curious natives stared at the Frenchmen's clothes and asked many questions.

By day Lebas would flit from bank to bank of the Nile in his light *cange,* trying to keep the Arabs, with their heavier *agabas,* constantly on the move. Like a cabby with a tourist, the river captains, or *reis,* of the *agabas,* would take the longest time, dallying wherever possible to increase their salaries, running onto sandbanks they could easily have avoided. At one point there was a near disaster when one of the grounded *agabas* sprung a leak and threatened to wet and ruin the heavy cordage needed for lowering the obelisk. Luckily the French sailors saved the day by using their leather hats, or *bousingots,* to bail the leaking craft long enough to remove the cordage.

Eleven days after leaving Rosetta, Lebas reached Cairo and complained to the Turkish governor about the malingering of river *reis*. The Turks forthwith produced the *courbache,* and it was all Lebas could do to insist that he wanted efficiency, not punishment. With a shrug the Turks assigned to him four janissaries, whose job was to keep the river captains on the mark.

Cairo from the river

They also visited the nearby plain of Memphis, where Menes, the reputed founder of the First Dynasty, is said to have changed the course of the Nile. There also his great capital city had once stood, described for the Frenchmen by Herodotus and Strabo; but the Frenchmen found only rubbled ruins among the date palms. In the evening they walked to where their *cange* was moored in sight of the earliest known pyramid, the Stepped Pyramid of Saqqarah, said to have been built for King Soser of the Third Dynasty by Imhotep, the most renowned of architects in ancient Egypt.

At Cairo, the lower-river pilots were replaced by upper-river pilots. These were of a different race, called Barbarin, the inhabitants of lower Nubia, darker-skinned, more supple in their movements, with a grace which Lebas found almost pretentious. Their faces were more like those sculptured on the monuments of ancient Egypt, their voices softer and fluted, ending in sharp notes as they spoke a dialect quite different from the Arabic of the delta.

Before starting upriver, Lebas and his companions left Cairo for a short visit to the pyramids of Giza.

The pyramids of Ghiza seen from the Nile

Everything that Lebas saw of ancient Egypt was a pleasure to him. He found his eye lighting agreeably upon the forests of columns in the temples because their number and size were harmoniously designed for the heavy roof they were intended to bear. The plans of the buildings he found simple and precise, and therefore easy to comprehend. Egyptian paintings, reliefs, and sculpture he found charming and extraordinarily descriptive, the figures admirably expressing the passions and pains which animated them. So deeply was he affected by what he saw, he found it difficult to tear himself away from the hypnotic lure of the amazing ruins.

Sailing up the Nile is favored in July by the northwest or northeast winds, which predominate throughout the period of inundation. With the wind abeam or astern the sails could easily overcome the current, except where the river looped so widely that the wind came head-on. There the Arab sailors would jump ashore and pull the *cange* with heavy lines, cadencing their footsteps with a song. As they moved further south, on either side of the Nile the plains began to be bordered with limestone mountains from whose flanks the stones of the Great Pyramids had been quarried. Here the progress of the boat was slow enough for Lebas and his colleagues to take short excursions into the Arabian hills, where the ancient monuments attracted them, temples they knew from Denon's beautiful etchings and from those of the *Description de l'Égypte.*

Lebas found the heat of Upper Egypt stifling and nearly insupportable for a European. The Frenchmen constantly quenched their thirst with water from the Nile and took advantage of every cooling breeze caught between the riverbanks, which at some points rose to high peaks where the river cut between the Libyan and Arabian chains. Sailing in the evening, refreshed by the northwest breeze, was pleasantest. As the Nile below the cataracts is bereft of rocks, there was little danger of nocturnal mishaps. Stars, barely visible in Europe, sparkled brightly in a deep blue sky, while the Arab sailors, bunched around the mainmast, chanted nostalgic songs.

The cange's great lateen sails, like butterfly wings on its antennae masts, heeled the barque through the swift current, churning up a frothy wake. On the riverbank the shadows of sycamore and palm tree slid past with a mysterious calming effect. The only sinister note was occasioned by mournful wails that would drift across the water from some darkened village.

They passed Atfyr, Beni-Sonef, Sbou Girgeh. Lebas would have liked to linger over the sights, but the threat of not reaching Thebes in time to berth the *Luxor* before the Nile receded from the apex of its inundation pressed him on. It was not till Siout, the capital of Upper Egypt, where he was required to deliver a letter to the governor, that Lebas stayed ashore a whole day.

North of Abou Fedda, Lebas learned from the pilot that they were in for trouble. Here the Arabian chain rises straight from the east bank to a height of 100 meters. Forced through a narrow passage, the Nile boiled along with enormous force, and the wind swirled and hit the *cange* from every direction. To overcome the hazard, the Arab master resorted to some magic, jabbing his knife into the mast, throwing a handful of salt into a hastily built fire, praying to the Prophet. He then tore off the head of a chicken and sprinkled its blood on the masts, anchors, and doors, attaching a few sticky feathers here and there, all the time appealing to the divinity of the river. Mixing a concoction of oil, tea, alcohol, and salt, he poured it on the turbulent waters of the Nile.

The *cange,* struggling with all its sails against a current of 4 or 5 knots, had barely covered a third of the way through the Abou Fedda passage when it was hit by a stronger squall. A bolt of lightning cracked the mainmast.

It was the forerunner of a tornado. The wind shifted around the compass, buffeting the frail barque forward and backward. Sailing on its forestay, but mostly blown along like a straw, with its keel scraping bottom, the *cange* was in constant danger of being crushed against the sheer side of the cliff. The ordeal lasted more than two hours; then the wind calmed and the skipper managed to pull the craft through to safety. Three hours later they were at Manfalout.

The wind was now favorable and propelled the *cange* so fast that in five days they were in sight of a superb forest of doums that preceded the ruins of Denderah. Lebas would have liked to visit the Temple of Hathor, from which the already famous but still undeciphered zodiac looted by Drovetti had been brought to Paris at great expense, but again he was afraid to tarry. Instead, he obtained permission from the local Turkish governor to return later and cut a hundred doums as lumber for felling the obelisk at Luxor. "For a little money," said the indifferent Turk, "the natives will bring you a whole forest."

The great Gamouleh bend in the Nile was handled by the Arabs with ropes. As they came around it the vestiges of the ancient city of Thebes appeared, lit by the last rays of the sun. To starboard stood the ruins of Gourna; beyond

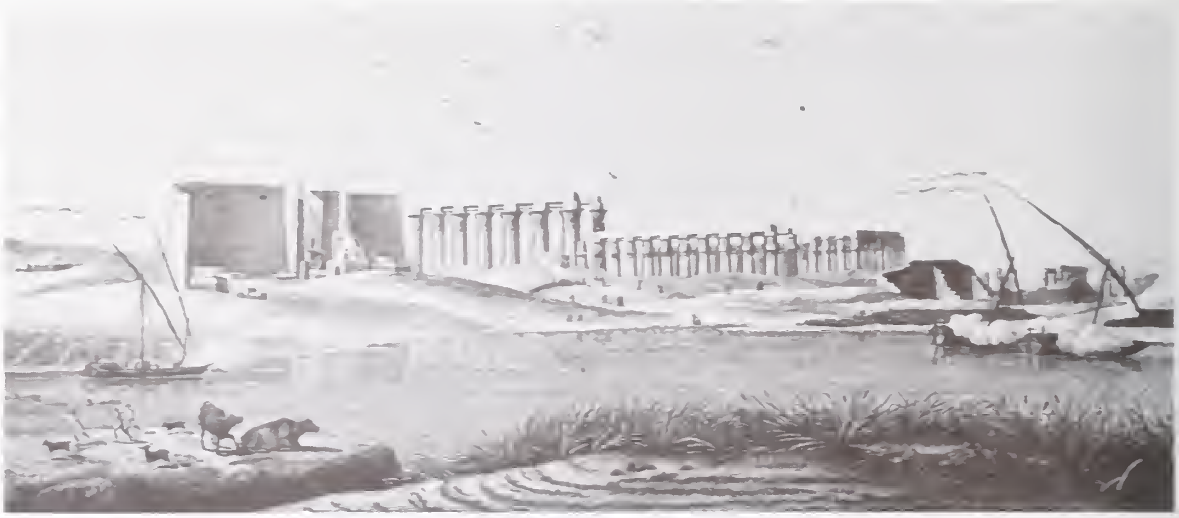
Gerald Massey explains the magic involved in mummification. As the embalmer rolled up the mummy in its bandages, he would, by the rhythm of his gestures and the formulas he chanted, fix the "shadow," or *shout*, of the deceased into the body, for fear it would wander about as a demon or unleashed passionate force. Embalmed and drugged and tranquilized by incense and music, it would not waken unless grave robbers (or Egyptologists) freed it from the shackles of its bonds. If so it would take off in search of human fluids to keep itself alive. A freed shadow, says Massey, could obsess a person to death, or take over the fetus of a pregnant woman. Destroying the mummy would no longer help. A special chant was needed to destroy the name.

Across the Nile from Luxor, beyond the Valley of the Dead, with its line of funerary temples, lies an arid, savage mountain chain riddled with deep passages and vaults—tombs for the pharaohs, where their mummies lay in richly ornamented sarcophagi in exquisitely decorated rooms filled with the treasures of Egypt. All around, more tombs for queens, princes, viziers, generals, priests, and important personages were dug into hill and valley above the floodline of the waters of the Nile.

them, against the distant Lybian chain, the temples of Medinet-About and the sinister Valley of the Tombs of the Kings. To port rose the columns of Karnak, with its immense pylons, dominated by the giant obelisk of Hatshepsut, higher than the ones at either Alexandria or Heliopolis. A mile or so up the river, still to port, stood the colonnade of the Palace of Luxor, its two pink granite obelisks, russet in the sunset, barely visible as they guarded the immense gateway.

Musing at the ruins of Thebes, Lebas was struck with wonder at the thought of a city of a hundred gates, with colossi, monoliths, and colonnaded palaces, all of which he had heard described by Champollion. But his prime preoccupation was to reach the obelisk he was to fell. He could just see it, in the twilight to the right of the great entrance to the Ramesseum at Luxor.

One by one the *agabas* drew up at Luxor on the eastern bank of the river by a sandy beach which climbed gently toward the village, a conglomeration of mud huts nestling among the ruins of the great palace of Ramses II.



Arrival at Thebes

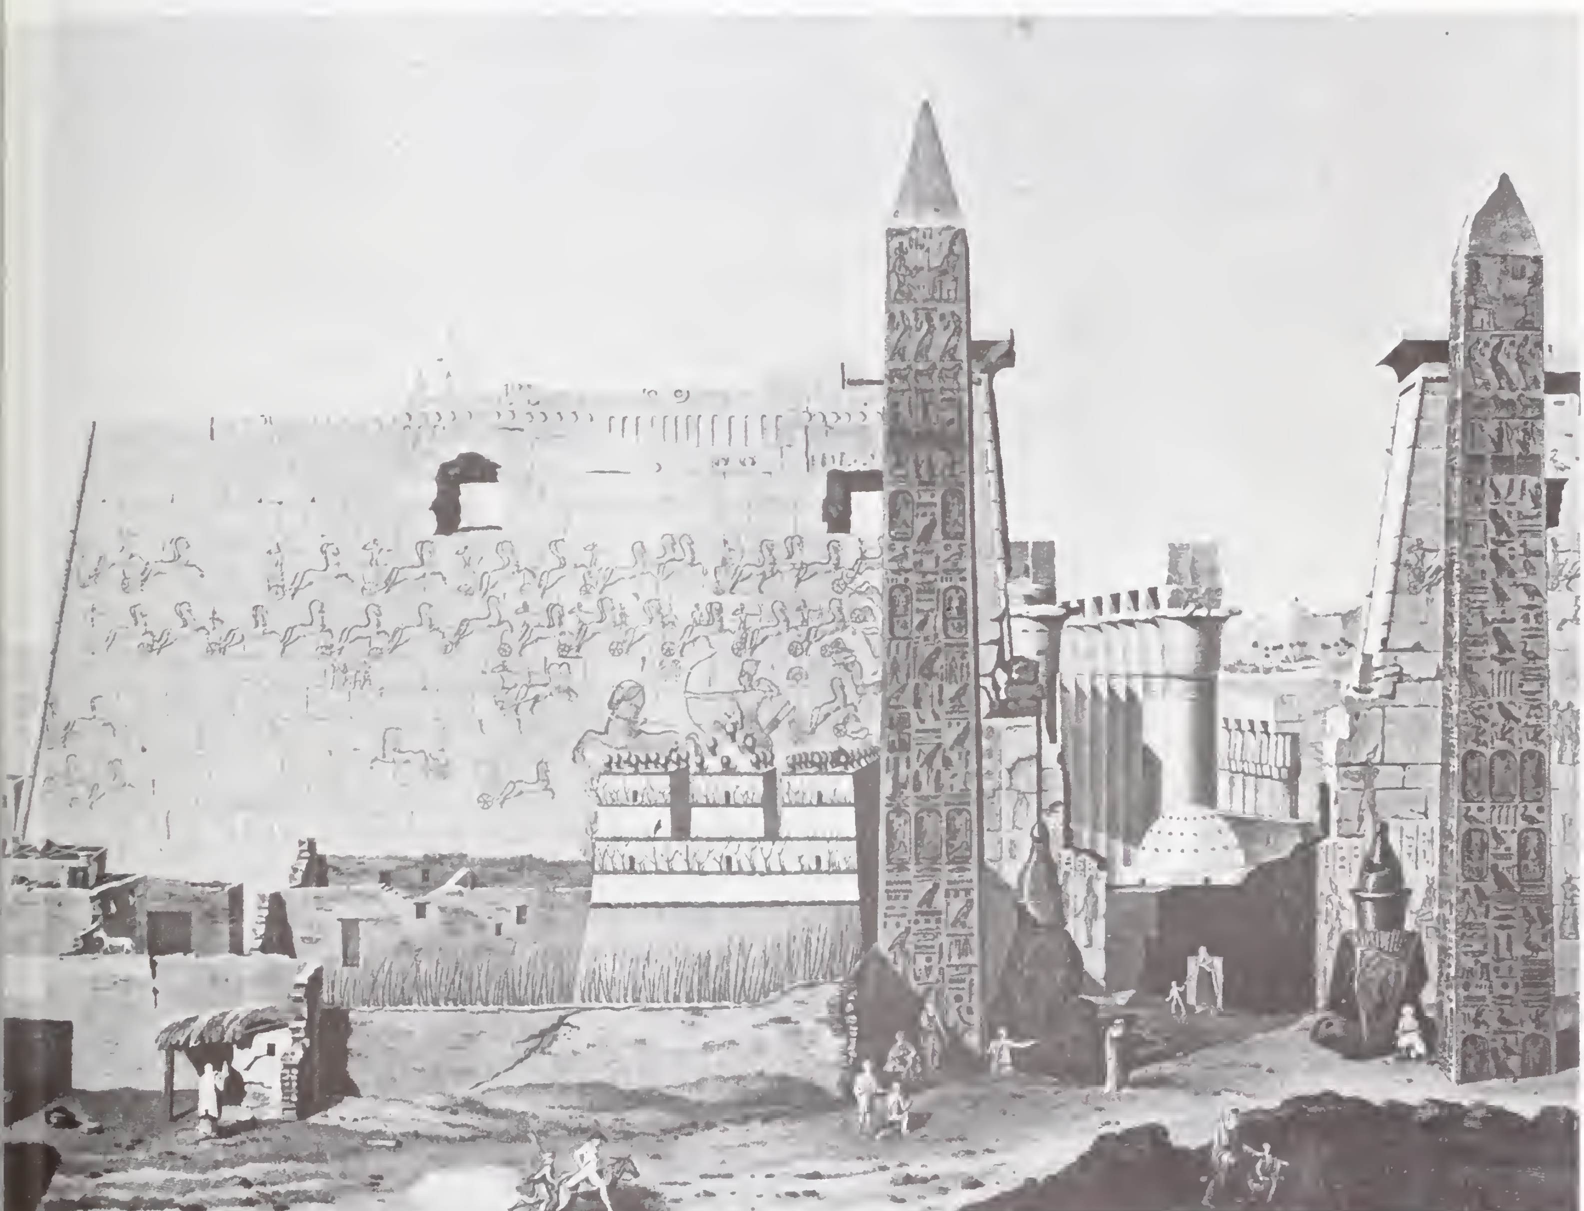
The inhabitants, attracted by the appearance of barques flying the French *tricolor,* and the possibility of *bakshish,* lined up along the bank, covered in rags, hands out, bemoaning their misery. As Lebas's *cange* dropped its anchor, he jumped ashore, followed by the French sailors, who clambered across the sand, disappearing among the mud huts to get a closer look at the one great pink granite obelisk which was the object of their journey. The natives would not believe the French had come to remove the obelisk. They considered such an idea so fanciful it had to be a ruse to disguise some ulterior motive. They believed the foreigners to be making a reconnaissance of the area before returning to take over as conquerors. "Do you not know," they explained, "that these needles were set up with a special mastic hardened by the sun which it is impossible to pull apart without cutting up the stone?" Where, they inquired, was the man big enough to perform such a prodigious feat? When they saw the engineer Lebas, they burst into friendly peals of laughter, laced with cries of "Allah! Allah!"

Lebas and his sailors crowded round the base of the obelisk, which stood in a mass of rubbled stone, its shaft deeply buried in the sand, touching it tenderly and making estimates of its height and weight. The master stone cutter they had brought from Toulon, an Italian named Mazacqui, gently tapped the eastern face, listening carefully to the resounding surface, then cried out in a mixture of Italian and French: *"Moussu, la pietra, elle est felée, mais je ne crois pas qu'elle soit routta; lou son est sano, on pourra l'enlever pourvu qu'elle tombe piano, piano"* which translates as "Sir, the stone has a lesion, but I don't think it is cracked through. It sounds quite whole. We will be able to take it, providing we lower it slowly, slowly."

Lebas was dumbfounded; there had been no mention of a fissure in any of the works he had read on Luxor. He was also worried that he might be accused of having cracked the obelisk in the process of felling it. In a sort of stupor he returned to his *cange*. The next day, more cheerful after a good rest, Lebas set to work with some hired *fellahin*. Clearing away sand and debris they traced the fissure all the way to the base, twelve feet below the surface. But Mazacqui had correctly deduced from the sound that the fissure was not deep enough to cause trouble. It appeared to be as old as the obelisk.

What did provide an obstacle were the one-story huts the natives had built so close to the obelisk they would be destroyed by its felling.

Object of the quest



Native huts nestling in the great palace of Sesostris, or Ramses II

Lebas concluded that clearing a way to fell the obelisk would mean destroying thirty of the native huts, which would have to be valued for expropriation. For this purpose, and to cope with the oriental custom of *bakshish,* Verninac had been provided with 40,000 francs, and Lebas with 20,000. But Lebas found to his surprise that for once the sight of gold had no effect upon the Arab owners, who could not be induced to give up their homes.

The dragoman Kachef then explained to Lebas that the Arabs were merely waiting for nightfall so as to be able to remove from their houses the goods they had harvested and secreted from the Turkish overlords. The next day, negotiations were resumed before an expropriation committee consisting of Lebas, the local Turkish governor, or nazir, and the local judge, or cadi, plus the headman of the village, who wore a green turban to indicate a doubtful descent from the prophet Mohammed. Ibrahim, the local interpreter, a tall, lean figure with a huge protuberance of a nose, heatedly waved his arms and kicked his legs, alternating threats with persuasion, and making a thousand grimaces. The Arab families pressed hard around the committee table, the men's faces pouring with sweat, the women, veiled, displaying their emotional distress through darting black eyes, uttering sharp guttural cries.

This brouhaha reached a paroxysm and died suddenly—at which point the interpreter told the stupefied Lebas: "We are in agreement. His Excellency the nazir

Luxor natives in the ruins of Ramses' palace, whose columns are half submerged in a millennial accumulation of dirt.

invites the committee to dinner." The indemnity amounted to 4,000 francs. Each hovel owner came personally to kiss the hand of Lebas and thank him for his munificence.

At the nazir's table, Lebas, dressed in his grand naval uniform, did not feel too comfortable, squatting before a common dish, feeding with his fingers, dipping his bread into the communal sauce, and tearing the meat with his teeth. Each dish was on the table only a few moments before it was whipped away. In all, Lebas counted thirty-five dishes, including two whole muttons, which the brin-bachi, or town major, carved up, handing Lebas as the choicest morsel, the liver, dripping like a sponge.

The meats were followed by sweets, creams, fruits, and rice cakes, all washed down with water from the Nile. To Lebas's distress, there was no wine or liquor, only Turkish coffee. After the ritual rinsing of hands, he was offered the first smoke from a hookah with an amber mouthpiece, which was passed from mouth to mouth. When Lebas expressed his surprise to Kachef over the sudden happy ending of the expropriation ceremony, he was informed with a smile that the whole performance had been a *mise-en-scène* by Ibrahim to merit a proportionate reward. All he had needed to say was: "The government wants your house. The *courbache* is at hand!" Still smiling, Kachef told Lebas of Ibrahim's first words upon the Frenchman's arrival at Thebes: "Well, friend, how much do you think this gentleman is worth?"

11. MUDDLING ON THE NILE

From what the Arabs said, and from signs left along the riverbank, Lebas could distinguish the limits of the previous year's flooding of the Nile, which had reached just 400 meters from the base of the obelisk he wished to remove. His problem was to dig a berth deep enough not only to house the *Luxor* when it arrived, but to float it again with its extra load of 250 tons at the peak of the river's coming flood.

Lebas's announcement that he would pay a daily wage, instead of merely administering the lash, brought hundreds of ready hands. But the French overseers soon found the Arabs capable of digging a simple hole, not a trench, which required the use of rules and lines; so they had to instruct them at every moment just where to dig and where to level.

Four hundred *fellahin,* dressed in cotton trousers, and equipped with spades, raised a great cloud of burning dust that hid them from the village. While the men dug, the women and children hauled dirt in wicker baskets, boys and girls in two long lines, all equally naked. They would help each other load a basket on the head, then set off all together chanting to the cadence of what Lebas called an extremely obscene song. "Such customs," he remarked in his puritanical manner, "which in Europe are repugnant to our mores, should not astonish in a country where it is the custom to call each part of the body and its function by its proper name."

At certain times of the day the heat was so intense that the young carriers, whose soles were not yet hardened, would upturn their baskets and put them on their feet while the Arab overseers, wielding palm fronds, shouted *"Yalla volet, Yalla benti!"*—Come on boys, come on girls! Drenched in sweat and covered in dust, the workers were constantly quenching their thirst from special urns of Nile water placed at regular intervals. At the drumbeat signal that ended the day's work, men, women, and children would rush to soak in the Nile, oblivious of the menace of crocodiles, then come and squat in circles of forty or fifty on the beach where Lebas would make the round to pay them their daily wage of 15 centimes. In five days the natives dug Lebas a channel 50 meters long, 12 meters

Five leagues from Thebes, at Maximianopolis, with the wind head on, and no means of hauling the anchor, the *Luxor* was obliged to stop, but the local nazir, or vice-governor, a thin-faced beardless man with a large aquiline nose, ordered his janissaries to impress the inhabitants of four local villages. From a cloud of dust appeared 400 naked men, dark-skinned, goateed, and with leather feet, reluctantly ready to do the pulling. Beaten by the janissaries, they started at a slow cadence. Inch by inch the *Luxor* moved forward to the sound of a monotonous chant in praise of the "Sultan of Fire," or Napoleon Bonaparte, who, according to the song, had "led his Western men safely to the shores of the Nile to destroy the Mameluke oppressors who dissolved before him like the mists of the Nile before the morning sun!" Under the lash, it took the gangs ten hours to move the *Luxor* 3 leagues around the Gamouleh bend. Starved, worn out from fatigue, some thirty fellahs fell by the way. But by dawn the *Luxor* could once more hoist its sails. For their efforts the surviving fellahs each received 35 centimes, a liberality which filled them with such joy they crowded round to kiss the hands of their Gallic benefactors.

wide, and 1.5 meters deep, perfectly suited as a berth for the *Luxor*.

The Nile was rising fast, its waters changing from deep green to russet, undermining the crumbling banks. By July 7 it had risen sufficiently for the *Luxor* to leave Rosetta and set sail upstream. Three weeks later, after a trip that included sailing before favorable winds, being towed by four hundred naked men, and many exotic sights for Verninac and the crew, the *Luxor* was able to anchor offshore in sight of the obelisk, loudly acclaimed by the populace, who were most amazed to see such a monumental ship being maneuvered by no more than the thin shrill sound of a whistle, without word or other signal being given.

On August 16 the *Luxor* slipped into the end of its berth, carried forward little by little by the waters of the Nile until it could be lashed into its resting place, pointing directly at the obelisk. A month later, on September 16, the retiring waters left the *Luxor* firmly grounded in its sandy berth. Two more banks of sand were built up along the ship's flanks to be watered daily so as to keep the hull from cracking in the heat. Further to protect the hull, several rows of reed matting were raised on palm beams all around the sides. The ship's masts were lowered, and

Matted against the 120° sun

The Memnonium of Thebes

all its gear was housed in a room of the great palace of Sesostris—better known as Ramses II.

Lebas had installed his engineers in the great hall of the south palace of Emenophis Memnon. Verninac now set up quarters for his crew in the two main galleries of the south portico—"where the pharaohs had once dispensed justice and the priests preached mystic lessons"—stringing hammocks between the ancient hieroglyph-encrusted columns. Sailors' lockers at the foot of each hammock gave the appearance of a regular naval barracks. In the adjoining rooms the Frenchmen created a storehouse for supplies, a bakery with an oven, a carpenter and joiner's shop, an arsenal with a powder room, a forge for the smithies, and a stable for the horse which milled the grain for their daily bread. To accommodate doctors Angelin and Pons, a hospital was built with thirty beds in a long airy hall lighted by twelve windows.

The officers were quartered on the roof of the palace, where they were given the three-room residence of the brinbachi, who was evacuated on orders from the nazir. On this rooftop, between the south wall and the northern extremity of the vestibule, Lebas arranged for a small room, 15 feet square, to be built for each officer out of Nile brick. All gave onto a broad terrace overlooking the neighboring countryside with its rolling plain, dotted with

View from the French compound

French officers' quarters

To make a solid roof atop its ancient pillars, Lebas had several palm trees ripped into joists with which he replaced the missing architraves. Filling the empty space with palm fronds, he had them covered with a mixture of Nile mud and chopped straw, which was quickly baked by the sun into a useable floor. Though a good rain might have washed it away, there was little likelihood of a downpour in the serene blue skies of Egypt.

mimosa and dates, which ran up to the foothills of the Arabian chain.

On this platform were also built a reception room, a mess hall and a common room, or divan, all neatly whitewashed and furnished with the officers' effects from the *Luxor*.

The quarters, which could easily be reached from a ramp of sand banked against the palace walls by the desert wind, were comfortable enough, says Verninac, except for the heat, which normally stood about 100° in the shade, and except for the scorpions which kept crawling out of cracks in the wall, and the vipers that rested in the ceiling, and the great gecko lizards which ran wild along the walls.

The actual village of *Luxor* had been built within the millenial crumbling walls of the two great palaces, on a ridge 700 meters long by 350 wide, 3 meters above the level of the plain, on foundations dating back at least thirty-four centuries and most likely more. The gateway between the two great obelisks led into the heart of the village where a garrison of five Turks ruled a population of eight hundred Arabs. Everywhere the mudbrick huts of the modern inhabitants were nestled in among the ancient columns, walls, pylons, and obelisks, like an incrustation of bird's nests. Where the propylaeum had stood, a mosque with a low minaret rose up for the muezzin to summon the faithful to prayers. Streets in which the windblown sand accumulated in uneven piles wound tortuously between the Arab houses, one-story affairs of sun-baked adobe brick, mainly clustered around the north end of the place of Sesostris, each surmounted by a pigeon coop with cut branches for the pigeons to roost on protected from the midday sun. Camels knelt in the dust, donkeys slept on their feet; everywhere were flies. Dogs, almost wild, the descendants of an ancient Egyptian species with long fur, pointed noses, broken ears, and narrow hips, barked almost incessantly.

The road from Luxor to Karnak, once lined with 1,500 sphinxes

One main road—possibly the ancient avenue which had once linked the quarters of Thebes to the eastern bank of the Nile—led through the town to a colonnade composed of fourteen gigantic columns, each 45 feet high with a lotus capitol. From there the avenue had led between two rows of fifteen hundred sphinxes, half-woman half-lion, almost 2 miles to the palace of Karnak. A few tamarisk trees with filiform leaves relieved the monotony of the sand.

Each sailor was assigned a plot to till, and in a few days the area around the palaces took on the aspect of a French hamlet, sailors preparing gardens and building private huts in which to spend leisure hours.

French gardens at Luxor

The flooding of the Nile had brought the countryside to life, turning dust to soil. Everywhere hedgerows sprouted with sweet-scented flowers. From France, the men had brought a variety of seeds and grains, and the land was of such vitality that stringbeans bore leaf within a few days and were edible within the month. Tomatoes, basil, sweet-peas, grew almost before their eyes. For meat the Frenchmen were provided by ambulant butchers who would slaughter their cows on the spot, spread the entrails on the ground to attract the flies, then cut off pieces to sell to the passerby. From the Nile, Coptic fishermen brought fish. Of the forty-odd species in the river only three were considered edible—the finni, the voult, and the ketcher. Turtles also flourished in the Nile, about a meter long, but were not considered by the French good enough for the table.

Auctioning fish in the market

The sailors would have liked to swim in the Nile, but on the very first day, an Arab who had gone down to fill a jar begun to scream, and before their eyes was dragged under by a 20-foot crocodile, leaving a large bloodstain on the surface. Eventually the Frenchmen discovered that the crocodile was not so dangerous, and would normally run when approached. But they kept their distance, learning to locate the reptile by a strong musty smell recognizable at 15 feet. The French were more startled by a large variety of amphibious lizard called *tupinambis,* which grew to a length of 4 feet; but they were pleased to find them good to eat.

What these hot-blooded Mediterranean Frenchmen did for women during their stay at Luxor is not spelled out in the memoirs of the chroniclers. But Lebas says they were

Bedouin market

much attracted by the women of Egypt with their lips painted dark blue, walking proudly and elegantly, their light garments barely veiling stunning forms, pure and fresh, which "conjured into delicious reality that which art and imagination alone could conceive as perfect."

And in his veiled Victorian manner, Lebas makes no bones about the availability of the Egyptian women, despite their premium on virginity, pointing out that on marriage, although the mother ritually ripped her daughter's maidenhead in the presence of a few relatives who then carried the bloodied linen through the streets to hang in the window of the house of the bride-to-be, such a custom "left leeway for a certain chicanery on the part of the mother of the bride." While an Egyptian girl could be condemned to death for losing her virginity to a European, her head being cut off and her body thrown into the Nile if she were caught *in flagrante,* the culprit, says Lebas, could still save the girl if he had himself circumcised on the spot and espoused the faith. "That being as it may," adds Lebas, "any other form of complaisance is perfectly tolerated and entrains no particular danger."

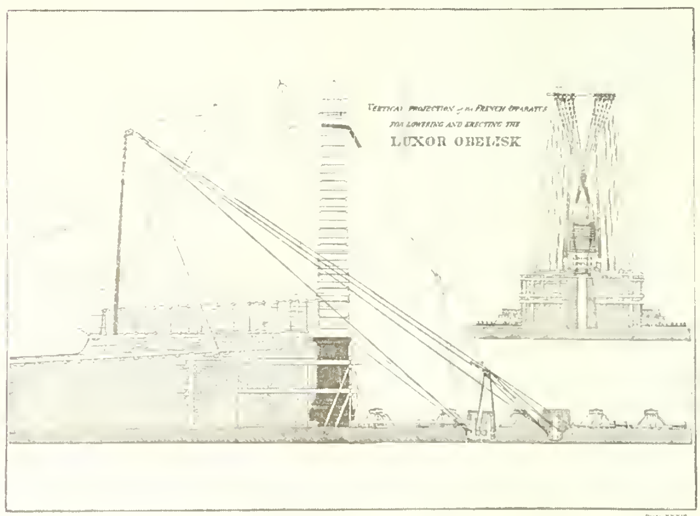
By the end of September, while the natives finished digging a 400-meter causeway along which to drag the obelisk to the bow of the sand-berthed *Luxor,* Lebas was ready to fell the western monolith. When its base had been cleared of sand and rubble, the men found a pedestal of granite which had become friable from the effect of mineral salts below the surface. The base was formed of three blocks of granite atop a single slab, the south side of which was carved into four cynocephalous or dog-headed baboons, each bearing on its breast a legend to the glory of Sesostris.

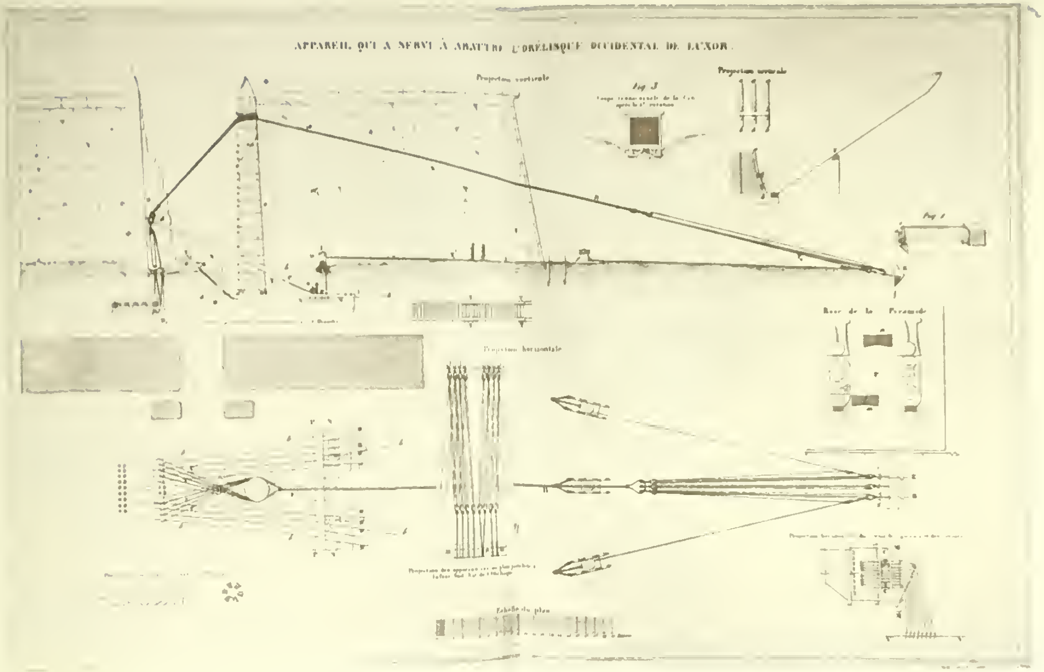
Dancing girls

Causeway along which the obelisk was dragged to the *Luxor* for embarkation

As the base was about even with the *Luxor*'s berth, it would have meant removing an extra 45,000 cubic meters of dirt to make a horizontal causeway. It would also have meant knocking down more intervening houses, and running the risk of unearthing some ancient ruins that would have been difficult if not impossible to move. Lebas decided it would be better to attempt to twist the obelisk on its base and bring it down to rest on the higher embankment of sand and rubble which had accumulated round it. He could then dig a more shallowly inclined slipway down to the river, along which it would be easier, with the help of gravity, to drag the monolith.

Lebas' method for delicately lowering the obelisk, so as not to break it





Equipment for lowering Ramses' needle

The main problem in lowering the obelisk was to do so—in the words of the mason Mazacqui— *"piano, piano."* Lebas believed the reason so many obelisks had been smashed, especially in Rome, was because they had been felled with ropes tied only around the top, and with no counterpull to slow the descent.

On August 1 three long ladders were raised one above the other along the south face of the obelisk. At a signal from Verninac, the tricolor was unfurled from the pyramidion, and the Frenchmen saluted with shouts of "Now it belongs to France! Soon to be in Paris!" Lebas, more circumspect, was reminded of La Fontaine's "one should never sell the bearskin till one has it on the floor."

The whole job of lowering the obelisk had to be done with no more sophisticated equipment than the winches, block and tackle, and the hoisting gear brought from France. The carpenters built a wooden scaffolding and then a wooden casing to protect the obelisk, economizing as best they could on the hard-to-come-by lumber. No matter what method was used to fell the monolith, its sharp edges had to be protected by boards that could not be less than 16 centimeters thick, nailed together with crosspieces and doubly bound with iron bands and screw bolts. To protect the edge of the base, on which the obelisk was to pivot and rotate, a special oak beam was hollowed to fit.

To rip auxiliary beams of date palm, and to cut through the rocklike beams of oak which the French had brought from Toulon, Lebas organized special teams of Arabs who soon became proficient at cutting either straight or curved lines as requested by the master carpenter. Such ripping in such a climate was too arduous for Europeans. In a short time the Arab children had learned the names of all the French tools, and could fetch them in an instant, saving the Frenchmen much time, which was badly needed, as a race was on to accomplish the work before the oncome of the *khamsin*, a wind from the south which lasted fifty days, making life unbearable with tempests and tornados of sand.

Then came the bad news. Some boatmen coming up the river told of cholera ravaging Alexandria and Cairo. Soon the river was filled with the *canges* of Europeans fleeing upstream, closely pursued by the plague. The French consul informed Lebas he had lost a son. Fifteen of Verninac's men caught the plague, but no one abandoned his post. Work on the obelisk proceeded as usual, and Angelin and Pons took such good care of the French victims that none succumbed.

Not so the Arab workmen. Of the village's eight hundred inhabitants, more than one hundred died, at the rate of about ten a day. The workers would suddenly keel over in the middle of their work, or would be stricken just as they were being paid their salaries. This caused an almost constant wailing from the habitations of the Arabs, where women bared their breasts, covered themselves with ashes, rolled their dark eyes, and addressed pitiful entreaties to the defunct.

Ibrahim Pacha, son of Mohammed Ali, terrified by cholera, came up the river in his red-sailed *cange,* standing alone in the bow, speaking to no man, fixing his own food, and daily washing his only change of linen in the water of the Nile. He had panicked and abandoned his army outside Cairo. At the First Cataract, he placed guards on either bank and forbade anyone to pass. This caused a backflow of refugees, many of whom docked their boats at Luxor and camped out on the beaches, spreading the plague.

A few days later, Ibrahim, shamed by an insulting message from his father, slunk back down the river to Cairo to lead his army into battle against his Ottoman masters. When the refugees saw him go, they too followed suit.

On October 1 the sun rose with a lovely tint of autumn. The obelisk was entirely sheathed in lumber, the trestles holding the block and tackle were raised and abutted. The scaffolding was removed and the tricolor once more unfurled from the top of the flower-wreathed trestle. A heavy cable was attached to the pyramidion, leading to several blocks and tackle, and half a dozen winches. Men pushing on the winches were to tilt the obelisk forward far enough to shift its center of gravity so that it would wheel and then fall by itself. To steady this movement and control the fall of the monolith, Lebas arranged for a trestle of huge poles 40 feet long to act as a fulcrum over which cordage could pull the obelisk in the direction opposite its fall. This cordage was anchored round the solid base of the second obelisk. To keep the bank from crumbling and falling as the obelisk came to rest on it, a brick wall had been built up, capped with a cylindrical pole of oak.

One hundred and ninety Arabs manned the winches. Eight men controlled the braking rope, great anxiety showing on their faces as the moment of trial arrived. The French commanders were armed with naval whistles. The villagers—Turks, Arabs, Egyptians and Copts, men, women and children, all those not engaged on the ropes, including the very old men with green turbans—were in attendance at the historic scene. So was the hawk-nosed nazir of Thebes. Sir James Gardiner Wilkinson, described by the French as an antiquary, draftsman, and geographer, turned up with three English travelers and a Greek named Triandafilon, who lived in a nearby cave. Sunlight illumined the silent faces of the colossi of Memnon, which, before they were vandalized, had resounded harmoniously to the touch of sunrays.

Verninac gave the order. The winches turned. The tackle stretched through the blocks. Tension increased as the windlasses oscillated on their axes. Unfortunately, instead of rolling, the oak cylinder at the base ripped like cloth. The wooden casing of the obelisk began to creak and crack. Heavy vibration caused the hoisting shears to tremble. The obelisk's head leaned slightly toward the river, traversing an arc of 8°, then came to a stop. All was still.

The officer in charge of the winches issued a warning that under the heavy strain the anchor points of the blocks were slipping forward in the sand. The relieving tackle was excessively taut. He suggested moving faster so as to take the obelisk past its vertical center of gravity, and shift the strain from the winches to the

braking cables and the trestle. Slowly the center of gravity swung past the vertical, and the obelisk began to fall of its own weight. It was now a question of whether the braking mechanism would hold as planned. It depended on the thrust being equally distributed. For this, Lebas had made a movable cylinder with eight necks for the ropes. Though apparently useless, it proved itself essential in this crucial descent until the obelisk lay safely on the sand in one piece.

Lebas then had the carpenters make use of the demolished scaffolding to build a 21-meter cradle in three movable parts on which the obelisk could be slid toward the river. As the rear section was freed it would be shifted to the front. But the quality of the lumber was such that the cradles could not be made as solid as required, and there were not enough pieces left over to repair a section if it were damaged. The master carpenter reported that every particle of wood had been used. If anything should break, he would be unable to repair it.

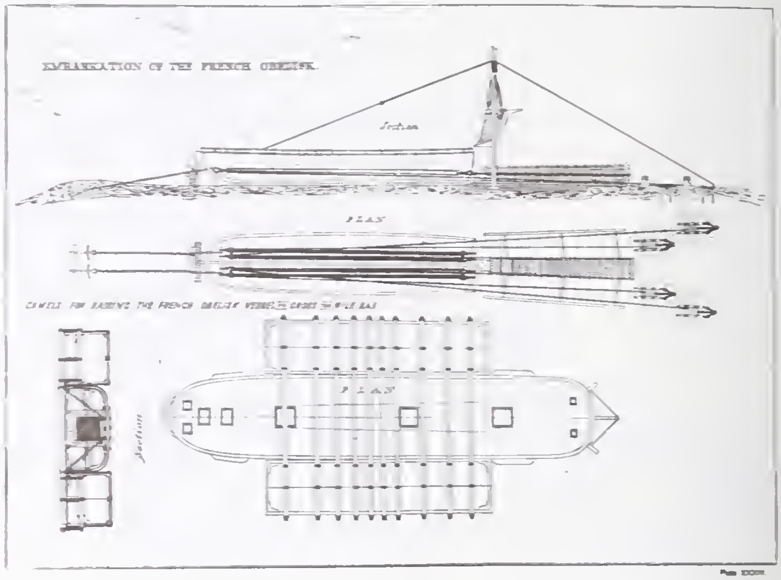
On November 16 Lebas got 160 Arabs to man the winches. The pulleys whined under the tension. Frenchmen incited the Arabs with hurrahs, but the obelisk would not budge. Two of the heavy tackles parted, causing irreparable loss. Lebas was puzzled. The effort exerted was twice what was necessary to move the obelisk, but because the cradle was completely buried in the sand, he could not spot the trouble.

It took two days to clear the cradle and see that a snapped oak pole directly beneath the obelisk had been driven 45 centimeters into the brick wall, causing an insurmountable obstacle. Lebas noted that under the heat and pressure of the strain, the soil at some points had been virtually turned to rock, too hot to handle. As for the pole, it had sheared into annular sheets like a telescope.

Ten jacks beneath the obelisk finally raised it into proper sliding position; and this time, when full pressure was exerted, the obelisk moved forward a few centimeters. Thereafter it was a matter of time and sweat—almost a month of painful hauling, averaging fifteen hours a day, while the Arabs pushed on the winches singing the ancient chant of the galley slave: *"Where is my homeland? When will we see it? When will we return to the home of our fathers?"*

All along the way the obelisk had to be controlled with sturdy props on either side to keep it from rolling off its cradle. By December 18 the pyramidion had reached the berth of the *Luxor.* To fit the monolith into the ship, the whole bow had to be cut through with a great saw, 3 meters behind the bowsprit, in a great vertical slice. As one Frenchman put it: "The ship was deflowered to receive the great phallus." The severed segment of bow was then hoisted aloft by several hoists. To slide the obelisk into the ship without crushing the hull, a ramp of packed dirt on a foundation of heavy stones was built right up to the raw cut. To drag the obelisk within the hull precisely to where its center of gravity would coincide with that of the ship, two cables had to be passed through holes in the stern and anchored in the sand some

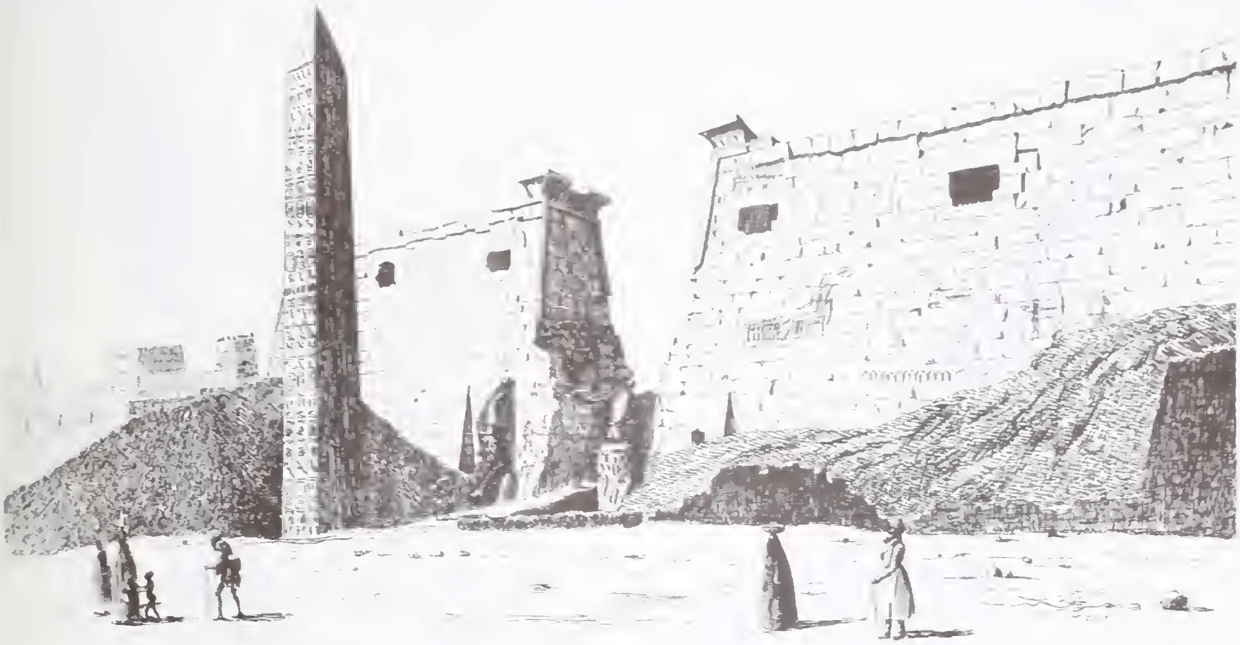
Lebas' pulley system for launching the *Luxor*



distance away, symmetrically placed on either side of the main longitudinal axis. A brick wall raised these cables to prevent any ripping of the ship's stern—also to protect the hull in case the tackle were to snap under the pull of forty-eight men.

On the morning of December 19, Lebas ordered the winches in motion. In less than two hours the obelisk was safely aboard. It had taken four and a half months of excruciating work, sleepless nights, worry, and anxiety. All together, they had moved 90,000 cubic meters of sand, cut through a sizable hillock of debris, demolished thirty houses, cared for and fed 140 Frenchmen in a country with few resources, in the desert, in the midst of a cholera plague, all the while working in clouds of burning, choking dust, with the temperature mostly above the 100° mark. It was hard, says Lebas, to describe the joy of the assembled sailors and workmen.

The next day, when the bow of the ship was refastened, the mark of the saw was virtually imperceptible. The governor, thinking it would take the French at least two weeks to place the obelisk aboard the *Luxor,* had not turned up on the nineteenth. Now neither Turk nor Arab could understand what had happened. They kept looking at the ship and the place where the obelisk had lain, and could not believe their eyes till they had touched the obelisk inside the ship. Even so, they attributed the translation to the work of *afreets,* or *jinns.* On his arrival, the governor, amazed at the performance, announced that Mohammed Ali would pay for all the expenses of lowering and embarking the obelisk, forthwith reimbursing Lebas with 25,000 francs.



The solitary obelisk which still stands guard at the gates of Luxor

But the work had taken just a few days too long. The Nile, pulling back into its channel, was leaving the *Luxor* with its heavy load high on the drying sand. There was no longer any hope of leaving before the next inundation, sometime during July 1832. It was a heavy blow. It meant the Frenchmen would not see their families for another whole year; and it meant another twelve months of living in makeshift quarters in the palaces of Luxor.

Resigning themselves to the situation, the men set about securing the obelisk within the hold of the ship; struts and crosspieces had to be fashioned, which would take the carpenters some time, working with nothing but the detritus of lumber still available. As their work aboard the *Luxor* needed no supervision, Lebas decided to take a trip up the Nile to visit the temples and ruins of ancient Egypt, at least as far as the first cataract, where Napoleon's army had come to a halt after scattering the remnant of the Mameluke forces, and where all the great obelisks had originally been quarried. He was determined to see for himself the greatest of them all, which lay half-quarried near Aswan, and discover why this particular spot had been the source of so many obelisks.

12. GALLIC COCKCROW

On January 9, 1832, Lebas embarked with his servant—"a good looking young man of seventeen with a lovely figure"—aboard a *cange* crewed by five Arabs. Casting off, they intoned a favorite chant: *"Habouzale, habouzelphi."* A favorable breeze, filling their lateen sails, glided them past an island rich in vegetation situated opposite the sanctuary of the temple.

The next day at 2:00 P.M. they reached the Temple of Esne, 15 leagues upstream from Thebes, by a small town on the banks of the Nile built into the ruins of the ancient city of Latopolis. Remnants of the old port and docks were still visible, and Lebas admired the great colonnade, which the natives used as storage space for firewood. The local mamour, or prefect, gave Lebas a letter to the nazir of Syene, assuring him that "with this, they will take you up the cataract faster than the water rushes down." What had made the mamour so complacent was a sudden infatuation with Lebas's young servant, an infatuation which engendered from Lebas the caustic remark that in the Ottoman Empire any young man could rise the faster by lying down.

The next day Lebas visited Edfu, whose gigantic temple dominated like a citadel the small town built on the slope of the hill. While anchored by a sandbank at two in the morning there was a cry of *"Arame! arame!,"* or thief, thief! His servant, afraid, says Lebas, of falling into the hands of bedouins and "suffering what might be justly considered a degrading ordeal, or repetition of the favors extended to him by the Turkish mamour," beat against the

After the evening meal, while the cabin boy fed the fire, there was always a routine of song and dance initiated by a saucy tale from some sailor, followed by a graver tale from the *reis,* usually about money and the sultan. To the sound of two hollow reeds and the vibrations from a skin glued to an earthern funnel held beneath the arm and beaten with both hands, the sailors would abandon themselves to raucous and lascivious dancing. Lacking females, the sailors' entertainment tended toward the homosexual. A sailor, his sole garment a long shirt, would make progressively more indecent movements to an applauding audience.

door until Lebas appeared with a gun. On both knees the pilot also implored Lebas to fire his gun to scare away the thieves who were known to come from underwater, their naked bodies heavily greased, to swim away with whatever they could seize, including other pretty bodies. Lebas fired in all directions, and returned to his slumbers, only to discover in the morning that the pilot had taken advantage of the fracas to seduce his servant. To dissuade the pilot from further advances, Lebas threatened to have him given two hundred strokes of the *courbache* as soon as they reached Aswan.

At Djebel Selseleh they passed large quarries dug into a hillside. Between there and Aswan they came across the temple of Loum Ombou with its grand façade consecrated to the crocodile, its vast edifice partly demolished by the river, which had undermined the foundations. As they approached Aswan, the bed of the river, which had been muddy, became studded with dangerous black protuberances of granite, highly polished by the flow of water, which, according to the Arabs, had been hurled down from the mountains by the gods who wished to close the channel.

Moored in Aswan harbor they found a *cange* flying the Turkish flag, aboard which were Mohammed Ali's doctor, Monsieur Botta, the French consul general, Monsieur Mimaut, and a desert Arab of some renown, called Baraka, meaning Providence. After a daily fare of eggs, rice, fish, and dates prepared in a hundred ways by his servant, Lebas was relieved to be invited to dinner on the Turkish *cange*, where he was feasted with choice viands and game.

Aswan (so-called by the Arabs) was the ancient Egyptian town of Sun-t ("allowing the entrance"), called Syene by the Greeks. Just below the first cataract, it formed the border between Egypt and Nubia and was an important geodetic and astronomical site. Opposite Aswan lies the island of Elephantine, the largest rock formed by the first cataract. Close to the Tropic of Cancer, it is the only location in Egypt from which an accurate observation can be made at the solstice to establish the circumference of the earth. Lebas found that Elephantine had been stripped of the lovely temple depicted in the *Description de l'Égypte*.

Lebas found the Lybian hills around Aswan to be the source of a fine-textured, rose-colored granite, normally free from seams and flaws, known as syenite, consisting of quartz, feldspar, and hornblende, from which all the great obelisks of Egypt appeared to have been quarried.

A ten-minute ride into the hilly hinterland brought Lebas to the area from which all the great obelisks were said to have been quarried. There, on a flat surface, he found the outline of an enormous obelisk half carved out of solid red granite, apparently abandoned after three faces had been shaped because of an unexpected fissure. It was difficult for Lebas, because of the effect of foreshortening, and because parts of the obelisk were buried by windblown sand, to estimate the length of the monolith, but he figured it to be one third again as long as the largest obelisk at Karnak, and to weigh three times as much, or a thousand tons. This, he concluded, would have required at least 12,000 men to slide along a greased runway as he had done with the much smaller obelisk at Luxor.

Six-inch holes drilled into the granite at eighteen-inch intervals around the recumbent stone indicated to Lebas that plugs of soft palmwood could have been introduced into them. Soaked with water, these would have frozen in the cold nights of that latitude, causing the plugs to expand and split the granite. To flatten the top, he surmised that fires could have been lit which would have made the granite crumble. The sides of the obelisk appeared to have been worked to a finish by pounding with six-inch dolerite balls which abounded naturally in the surrounding hills. The underside of big stone was pierced by a number of tunnels which led Lebas to surmise they had served for the insinuation of timbers to act as a sledge with which to move it once the entire underface had been cut away.

The largest known obelisk, half quarried from a vein of Syene granite

All of which caused Lebas to marvel at the brilliance and endurance of the ancient Egyptian engineers. Considering the trouble it had cost him to move his obelisk he could not imagine how they had managed to quarry, move, ship and raise one four times its weight without even the winches and tackle available to him.

As a final exploration on the Upper Nile he decided to study the great temple of Abusimbel, to see how the Egyptians could have carved it out of a solid mountain as described by Belzoni and recently visited by Champollion.

Classical authors gave the region an eerie reputation by reporting that the inhabitants for miles around were all as deaf as the cataract stones because of the terrible roar of the waterfall.

Back on the river, teams of camels were employed to drag the *cange* up the cataract, past the date-burdened island of Elephantine, where the ancient Egyptians had an

astronomical observatory, and a nilometer to measure the flooding of the river. Dark Nubians, excellent swimmers, skipped from rock to rock, attaching lines as brakes to prevent the *cange* from being swept away by the swift flow of current and crushed against the rocks. Overhead, swarms of black crows circled to inspect the maneuver while sand swallows darted to and fro.

Twelve leagues above the second cataract, in a wasteland of sterile mountains devoid of all vegetation, Lebas sought out the two cyclopean temples of Abusimbel, carved deep into the vertical side of the mountain, one with its entrance flanked by 60-foot standing colossi, the other, bigger still, with eight identical colossi of Ramses, seated on either side of the entrance.

From Abusimbel Lebas decided to turn back to Luxor, traveling more leisurely, taking sidetrips after duck, snipe, hare, partridge, and doves. The river itself abounded with an extraordinary variety of birds: eagles, falcons, storks, plovers, ibis, and the percnotaire, a huge beast with lovely plumage.

Lebas was most fascinated by the idiosyncrasies of three peculiar birds. One, which he called the scissor bird, because of the scissor shape of its beak, would cut its fish into morsels before swallowing them, then regurgitate the bones in a round white ball. Another odd bird, the *Sharadrius niloticus,* a sky-blue bird with black bands, called a *cak* by the Arabs, would spend its day cleaning the teeth and gullet of the sleeping crocodiles, whose open mouths were a lure for swarming insects. Lebas was also intrigued by the sacksack, a black-and-white bird, with a gray back, which acted as the sentinel of the Nile, screaming at the sight of anything unusual, and alerting birds and animals for miles around of the possibility of danger.

Back at Luxor, Lebas found that his fellow Frenchmen had spent their time tending their gardens. The acacia trees planted barely a year earlier were now 15 feet tall and as thick as a man's arm. A fig tree the size of a thumb, planted at the door of a garden, was 12 centimeters thick and covered with fruit. Some, like Joannis and Verninac, had gone on hunting trips into the interior, or on voyages of exploration up the Nile. All together, during Lebas's absence, ten Frenchmen had died from one cause or another, mostly dysentery. One sailor, failing to follow Angelin's strict rationing orders, had got into the larder and consumed 2 pounds of raw rice. Within forty-eight hours his stomach had exploded.

The year's stay had turned the rest of the Frenchman into shadowy figures. Fifty were laid up in the hospital, mostly with dysentery; and even Angelin had sickened. To relieve twenty of the sickest, Verninac ordered them sent ahead by boat to Alexandria. Though their cases weren't serious, the doctor recommended a different regime and the more European climate of the delta. All were anxious to get back to France for fear they could not survive much longer in the climate. As the Nile approached flood time, there were just enough healthy men to recommission the *Luxor* and see to clearing the sand around it. When this was done the planks were found to be tight enough to hold water, whereas the deck, which had been exposed to the sun, had cracks they could see through.

To receive the waters of the Nile around the keels, a large hole was dug. Each year the Nile announced its flooding by tiny oscillations, which took place at the latitude of Thebes sometime in late May, and a gradual change in color caused by rains in the Abyssinian highlands. At first the water would lose its transparency, taking on a greenish tint. Gradually the green would grow deeper until it could be seen in a scooped-up handful. According to the Arabs, the deeper the green, the bigger the inundation. Eventually the water turned brick-red.

That year the Nile was slow in flooding; its telltale oscillations only became evident during the first few days in June. Everyone became agitated, rushing to the river's edge to look and examine. Small twigs were placed in the ground from which to note the smallest change in level. News bulletins of the rise were posted on the door to the mosque. Faces lit up with excitement. Arab women celebrated by singing religious chants up and down the river's edge.

As late as July 30 the water continued to rise rapidly and evenly, without causing any damage. Many of the Frenchmen spent their nights by the river to watch the markers being swept away. They would even feel for them in the dark. By August 5 the water of the Nile had turned deep red, and the *Luxor* was an island. It needed only thirty more centimeters to float. Everyone believed it would float the next day, or, at the very least, the day after. On August 6 the river began to subside, and continued to fall back until August 12. The French were stunned. It meant the prospect of spending another whole year in the Theban heat. Anxiously they consulted Arabs for opinions. The imam, or priest, said the Nile was just catching its breath, and would rise again. He suggested a donation of two muttons to the mosque, to propitiate Allah.

Among the harbingers of the flooding of the Nile were beetles that rolled up their seed into a small ball of dung which they buried by the riverbank for safety against the coming flood. Nile beetles figured in the constellation of the Crab, the point along the Zodiac at which the inundation began, known as the month of Mesore.

According to Lebas, the Arabs consumed very little, especially by comparison with their Turkish overlords. He figured the yearly cost of feeding and clothing an Arab would not exceed 15 francs, his daily fare being based on three small loaves of millet bread, or *doura*, augmented, depending on the waters of the Nile, by some cucumbers, watermelons, chicory, dates, onions, or their favorite, lentils. All of the good land of Egypt, and all its produce, belonged outright to the Pasha. Only the land closest to the channel of their river, the last to be uncovered in April and May, was considered common, because of the short time it remained unflooded. Here the fellahin were allowed to sow at will their quick-growing products by the simple process of making a hole with a stick and covering the seed with the foot. Often they would have to wade into the rising water to gather late sproutings. When the waters of

On August 13 the water rose again. Verninac fixed a line to the stern of the *Luxor*, had an anchor carried out into the middle of the Nile, and attempted to winch the ship free. For three days the French pulled, but the *Luxor* would not budge. On the eighteenth, with a supreme effort, they managed to move the *Luxor* a few feet. The water rose again, a hair, and by evening the ship was once more afloat on the Nile. The greatest problem now was to get it safely down the river.

Worried about sailing the flooding waters with the heavily loaded *Luxor* facing treacherous currents and unforeseeable hazards, Verninac had ordered from Toulon two *peniches*, or pinnances—small two-masted vessels rigged like schooners, which could be propelled by oars. Though announced by a courier, they had failed to arrive, and Verninac was afraid to wait any longer lest he fail to arrive at the mouth of the delta while the water was still high enough to float him across the sandbars.

During the night, the inhabitants of Luxor and Karnak crowded the riverbank to be ready to bid the *Luxor* farewell when it hauled its anchor in the morning. At 11:00 A.M. the breeze freshened and the *Luxor* set its sails. Two

the Nile subsided in November, the first crop planted was always broad beans. On the next land uncovered in December, wheat, barley, peas, and lentils were planted. In February the fresh beans were harvested, in March the poppy seeds, in April the lentils, in May the peas. During the season of the pointed peas the natives would economize on their *doura* by walking through the fields avidly eating the peas directly from the pod. In April, when the trees were in flower, the natives would fertilize the females by hanging well-developed male fronds from the female branches. Wheat and barley were harvested in May and June. In July and August, on land not yet covered by the rising waters, corn was planted, to be harvested in October and November. But legally all of this was the property of the pashas. With the natural resources of the Nile, Lebas was convinced that in a short time modern Egyptians could be brought to a much higher standard of living in which the arts and sciences could once more flourish. Were the land distributed to the native farmers, he believed, it would bring Mohammed Ali a hundredfold in revenues. As things stood, the pasha only managed to collect a tiny portion of what the natives could be induced to cultivate, the rest being hidden or stolen by the middlemen.

janissaries came running up with a present from the nazir for Dr. Angelin: a pet hyena. It was a pathetic cortege. As the *Luxor* had been preparing to sail, and the janissaries had been unable to catch the creature, and the nazir had not been specific as to how this should be done or whether the gift was to be dead or alive, the janissaries had stoned the hyena to death and now ceremoniously brought along the carcass, already in a state of putrefaction, as a farewell gift for Angelin, who had loved the nazir's living pet.

Slowly the *Luxor* moved downstream. The crowds ran along the bank, waving; some swam out to cling to the ship's side; others followed in small boats. The French were amazed by this demonstration of affection, especially as they had seen the same Arabs totally impassive under the *courbache* of the Turks.

With the wind head-on, as it prevailed during the period of inundation, Verninac figured he could zigzag downstream from bank to bank by presenting alternate flanks to the wind. But he soon found the rudder would not respond sufficiently to keep the ship in control. The *peniches* arrived, but were 3 meters too short for the job. When Verninac tried them, they caused the *Luxor* to run up hard against the bank, luckily without damage. To solve his problem, Verninac decided to emulate the system of the ancient Egyptians as described by Herodotus. According to the Greek historian, the Nile boats of his day sailed downstream by means of a sieve of heather reinforced with rushes lashed to the bow; this caused the rapid current to propel the boat forward. A heavy rock dragged along the bottom served as a brake to help maneuver from side to side.

Turkish nazir wielding the courbache

Verninac threw a heavy anchor over the stern to use as a brake. Thereafter he was able to make his way downstream irrespective of wind or current. Unfortunately, on the thirty-first, the anchor stuck and there was no way to raise it. The ship was about to go under when the pulley snapped, its fragments being hurled to a great distance, luckily without killing anyone aboard. The next day the tiller struck ground. With the ship immobilized, the Nile waters, on the opposite side from the current, heaped a sandbank straight up against its flank; by midnight the *Luxor* was almost submerged. Luckily a sudden gust, filling the sails, dragged the ship off the embankment.

The famous Gamouleh elbow gave them plenty of trouble. At one point, they found themselves with full sails whirled completely about, moving at full speed backward down the current. Date palms whizzed past at such a speed that if the *Luxor* had hit the bank, it would have been crushed to kindling. Luckily the river began to bend in the opposite direction, and the *Luxor* was able to wheel in time.

With another anchor, Verninac managed to control the boat safely to Cairo. There they took a break from their ordeal long enough to enjoy a festival known as the dalmees, a local saturnalia, where, as voyeurs, they could enjoy the dance of the bee, in which an Arab woman pretending to have a bee in her galabia removed all her clothes in a series of wild dances. But Verninac could not dally. It had taken him as long to come down the Nile as it had to go up. He was worried about reaching the mouth in time to cross the sandbars. Any time in the past two weeks he could have crossed with ease; but September, with its great flights of pelicans, had come and gone.

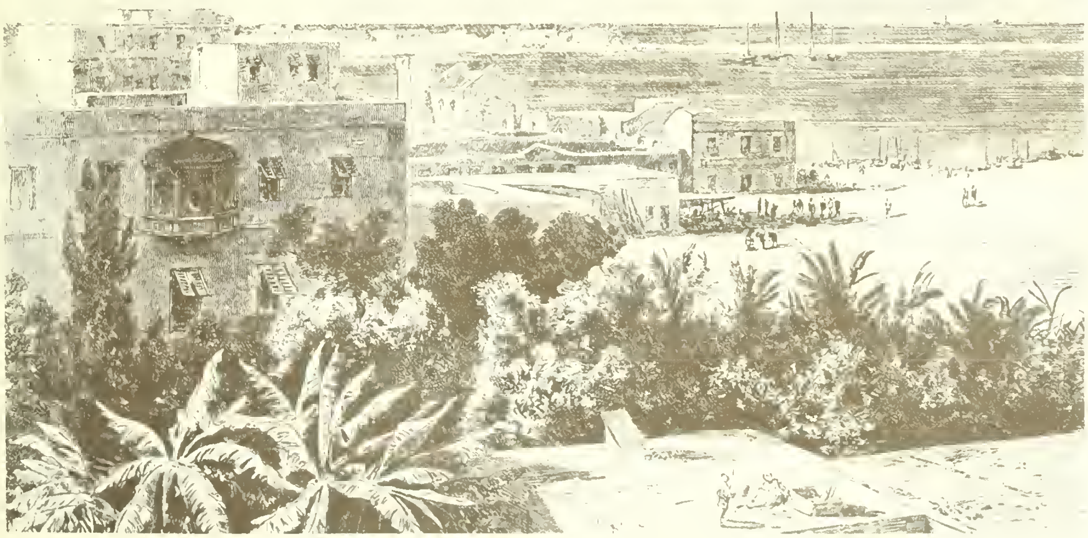
On October 1 the *Luxor* arrived at Rosetta to find the water at the sandbars 20 centimeters too low to pass. Lebas thought of raising the ship by means of two large flanking pontoons, but it was too heavily laden to withstand the strain. On the off chance that a sudden change in the wind might cause a break in the sandbars, they anchored by the mouth of the river.

It was not an uncomfortable wait; the more European climate with its autumn air revivified the crew. But weeks dragged into December and its dangerous storms. It became unwise to linger. Back at Rosetta, Verninac demasted and decommissioned the *Luxor,* storing its gear on dry land, and began to look for winter quarters for officers and men. Rosetta had its compensations. There were still plenty of bananas, oranges, and grapes. The men could pass their days at the Turkish baths, smoking pipes, or drinking coffee. The crew, says Joannis, "soon managed to create such pleasantly domestic situations they were enabled to forget the postponement of their return to France," till an unexpected event changed their plans. An Anatolian ship loaded with oranges, struck by a gust of wind, crashed into the sandbanks and sank, causing a breach of 2.5 meters in the bank, where there had been nothing but sand. The pilot who had witnessed the crash rushed back to Rosetta to inform Verninac that the breach was wide enough and deep enough for the *Luxor* to pass through.

In thirty-six hours the ship was recommissioned and reached the sandbar on January 1, 1833. By noon the weather was perfect, the wind favorably astern. Beyond the sandbank, riding at anchor, was the steamship *Sphinx*, sent from Toulon to tow the *Luxor* back to France. Inch by inch the *Luxor* moved through the breach, followed by the *peniches* holding anchors in case of trouble. A freshening breeze and sudden rough seas caused the *Luxor*'s keel to ground on the sandy bottom. As darkness fell, the ship was once more immobilized. Everyone aboard was in a state. The pilot clutched at his beard, crying "Allah! Allah!" Hardtack and wine were distributed. An anchor was rowed forward and attached to a winch. By 10:00 P.M. the slight Mediterranean tide reached its peak; with a lurch, and a great hurrah, the *Luxor* slipped over the final barrier into the salty sea.

Raising its *huinier*, the *Luxor* went to anchor by the *Sphinx* which, the next day, towed it safely to Alexandria harbor. There the *Luxor* was flooded with visitors. Ball

Alexandria harbor



after ball was given in honor of the Frenchmen, while Verninac waited for suitable weather to sail. Winter in the eastern Mediterranean can be rough and foul. Several times the departure of the French was delayed by storms and heavy winds. Apart from the lovely Pointe des Figures, and Mohammed Ali's palace, they found the French Quarter, with its wide avenues and squares, the only pleasant part of the city. There the local merchants and consuls opened their houses to the men. Lebas was again received by Mohammed Ali, who expressed great satisfaction at the successful removal of the obelisk, and was only macabre in his curiosity to know how much weight the obelisk would lose under water, if the ship should sink. When Lebas thanked Mohammed Ali for his generous help in securing to France the Luxor obelisk, the khedive replied: "I have done nothing for France that France has not done for me. If I give her the relic of an old civilization, it is in exchange for the new civilization of which she has spread the seeds in the Orient. Let the obelisk be a tie between our two countries."

Finally the *Luxor* set off from Alexandria, on April 1, towed by the *Sphinx* at a speed of 4 knots. On the night of April 2 a breeze from the west turned into a violent storm. By noon of the third the *Luxor* was dwarfed by enormous waves. The *Sphinx* was making no headway, and to avoid wasting coal, it let itself drift toward Rhodes. As a result, the *Luxor* began to roll so heavily the seas were washing over the gunwales, threatening to loosen the obelisk and sink the ship before the horrified observers aboard the *Sphinx*. To salvage the situation, Verninac spread all his sails. This inhibited the heavy rolling, but risked demasting the ship. Finally the winds subsided. By the sixth, both vessels were able to anchor in the harbor

The *Sphinx* with *Luxor* in tow

of Rhodes, which the French found depressingly Turkish, with no sign of the ancient Knights of Saint John, or the famed Colossus.

About 6 leagues away, at Marmara, on the Caramanian coast, they found a pleasant cove called La Bonbonnière. There they spent some time having their clothes washed and hunting in the mountains, where there was much game and a landscape with windmills run by pretty falls of water. Next they went to Milos in search of coal. Finding none, they went on to Navarino and Zante, still with no luck. At Corfu the British high commissioner, Lord Nugent, obliged them with supplies from the British naval base. Both the British and the Corfiotes were most cordial in their welcome, sumptuously feasting the French. Crowds came aboard the *Luxor* to admire the obelisk and compliment the officers and crew.

Leaving Corfu, the *Sphinx* and the *Luxor* bucked another storm all the way to Cape Spartivento. On May 4 the wispy outline of Etna appeared to the west, and they slipped unharmed between Scylla and Charybdis. The Liparis were shrouded in fog, but Stromboli lit up the night sky with eruptions every ten minutes. In honor of Homer's Strombolian god of the winds, Verninac uncorked the last of the Champagne. It helped them double Cap Corse and drop anchor in Toulon harbor on the tenth of May, 1833, just two years and twenty-seven days after they had left.

For fear of the Egyptian plague, the Toulonnais refused to let the crew ashore, obliging them to submit to the excruciating ordeal of a month's quarantine within sight of their homes and loved ones. Only Lebas was allowed to go ahead to Paris to prepare a berth for the *Luxor* on the city's embankment.

On June 22 the *Luxor* sailed for Gibraltar on the first leg of its journey around Iberia. Across the bay, in Algeciras, they stopped to obtain permission from the authorities to put in at any Spanish port in case of trouble or bad weather. As it was the anniversary of the birth of Fernando VII's queen, Maria Cristina, the festivities were brought aboard. Crowds of dignitaries came to examine the obelisk; in the stateroom converted for the occasion into a ballroom, everyone danced the fandango and the bolero.

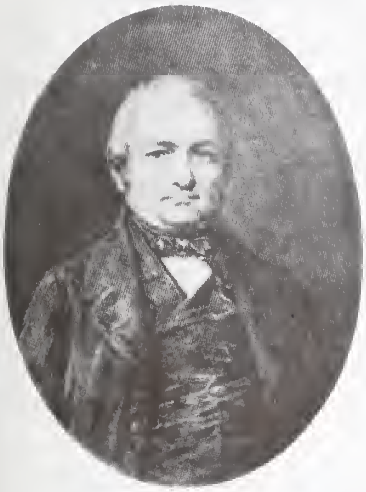
Approaching Cape Saint Vincent, the southernmost tip of Portugal, in a strong west wind, the convoy was obliged to lay off Lagos, on the Portuguese coast, where the crew of the *Luxor* witnessed the extraordinary spectacle of two warring battle fleets tied side by side. The corvettes, brigs, frigates, and schooners of Don Pedro, contender for the Portuguese throne, had just captured the superior forces of his rival, Don Miguel, despite the latter's ships of the line. On August 11 the *Luxor* caught sight of the coast of England and headed east for the military port of Cherbourg, just in time: the hurricane season had begun to ravage the channel ports, whose coasts were littered with wrecks and corpses.

At Cherbourg, Verninac received orders from the maritime prefect to await the arrival of King Louis Philippe, who was traveling with his family in western France. The king, accompanied by his wife and all the young princes, came aboard to decorate Angelin and Joannis with the Legion of Honor, and to inform Verninac of his promotion to *capitaine de corvette*. After listening to a description of the felling of the obelisk and being introduced to the ship's officers, Their Majesties were taken aboard the *Sphinx* for a naval review with lots of gun-firing and cries of *"Vive le roi!"*

The *Luxor* now had to be towed up the Seine to Paris. On September 12 the *Sphinx* took her as far as Cap de la Heve, at the estuary of the Seine, where there were more dangerous sandbanks to negotiate as far inland as Quilleboeuf, the actual mouth of the Seine. At La Heve the *Sphinx* was replaced by the river tug *Heva* for the trip to Rouen, where the *Luxor* would have to wait, tied to the Quai d'Arcourt, for the first autumn rains to raise the waters of the Seine sufficiently for the ship to be towed the rest of the way to Paris. But the rains were late; not till the middle of December did the river rise enough to move the *Luxor*.

Lebas rejoined the ship and ordered her lightened of all unnecessary equipment, including her masts, so as to pass under the twenty-two bridges between Rouen and Paris. Midday on December 14 the *Luxor,* which now resembled a flat *peniche,* negotiated the Pont de l'Arche and began its slow ascent up the Seine, drawn by eight pairs of horses. At points where the current was particularly strong, as many as thirty-two horses had to be engaged.

When the ships docked near the Bridge of Meulan, the water of the Seine was so high the *Luxor* could no longer pass under the arch nearest the towpath, and the local authorities, worried about damaging their precious bridge, made a lot of trouble before they would allow the more complicated maneuver of towing the ship through the central arch. When the *Luxor* reached the Bridge of Saint-Cloud, on the outskirts of Paris, at midnight of December 22, the bridgemaster refused to let it through, despite a written order handed him by Verninac. The water was rising so fast the ship risked being blocked below the bridge for several months. After an hour's harangue the bridgemaster finally relented, and the *Luxor,* just in time to avoid being caught, was winched through in the early hours of the morning.



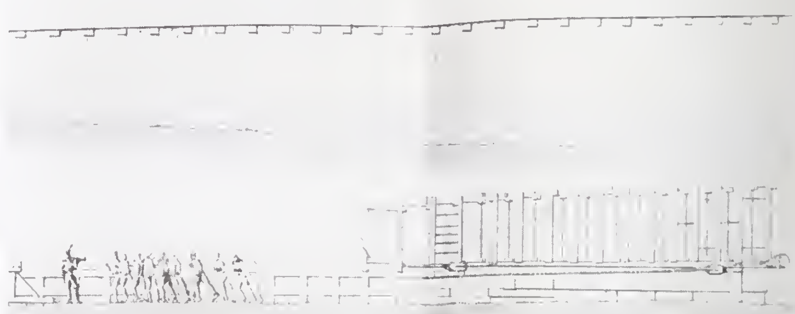
Louis Adolphe Thiers (1797–1827), historian and statesman from Marseilles, author of a history of the French Revolution, was one of the Freemasons involved in the enthronement of Louis Philippe in 1830. He became prime minister in 1836, and president of the republic in 1871.

In a thin misty rain a Parisian crowd had gathered along the Quai d'Orsay and on the Pont de la Concorde to see King Louis Philippe ride past on his way to open the 1834 joint session of the chamber of peers and of deputies at the Palais Bourbon. As the *Luxor* hove through the mist drawn by its teams of horses, word quickly spread that the obelisk from Luxor had arrived in Paris; but the crowd was disappointed to look down on the dirty, mastless ship with its tired crew in workaday waxed slickers. It had now passed from the jurisdiction of the minister of marine to that of the minister of commerce and public works, in the person of another diminutive Frenchman, described by Lebas as one who accorded to the arts and sciences "an enlightened protection," but who was to become better known as "the greatest little man of French history," the first president of the Third Republic: Louis Adolphe Thiers, a professed Freemason.

To beach the *Luxor,* with its five keels, and to avoid the risk of breaking either its stem or its cargo, Lebas had prepared another solid berth on ground near the Pont de la Concorde, just high enough to be left dry as soon as the waters of the Seine retreated from their peak.

The authorities could not make up their minds whether the obelisk should be placed at the Rondpoint des Champs-Élysées, in the courtyard of the Louvre, as a sentinel before the Madeleine, or in the Place de la Concorde as a symbol of a reunited France. Under various authorities of the Restoration, the center of the great square had been successively occupied by various monuments, the last of which was an equestrian statue apotheosizing Louis XVI on the spot where he had lost his head.

On December 24, King Louis Philippe announced he would visit the *Luxor,* which was rapidly spruced up for the occasion. Among the dignitaries assigned to greet the king was Geoffroy Saint-Hilaire, member of Napoleon's Institut d'Égypte and president of the Academy of Sciences. Arriving in his ceremonial palm-fronded uniform, complete with bogus épée, the old gent slipped on the narrow gangplank and plunged into the icy waters of the Seine, whence he was retrieved by two sailors and taken to Angelin's quarters, where his lobster-red body was toweled back to normal. The king, arriving by launch from the river-side, climbed aboard without mishap, and having inspected the obelisk in the ship's hold, gave Verninac 2,000 francs to be distributed to the crew.



Coupe de l'appareil de débarquement suivant l'axe du Bâtiment.

To drag the obelisk up the embankment, Lebas impressed a company of artillerymen. To house the obelisk, pending the decision whether or not to place it in the Place de la Concorde, Lebas hired a pavilion. Once more the bow of the ship was sawed off. As at Luxor, a wooden cradle was built to slide the obelisk on a wooden track. Two hundred and forty artillerymen pushing on winches managed to drag the obelisk safely out of the ship, and, the next day, up the ramp. Thereafter, the obelisk lay for eighteen months in the pavilion, while a suitable pedestal was being devised. It took till August 1835 to find the right granite, in a town with the odd name of Later-il-Dut, on the coast of Brittany, for a pedestal which weighed 236½ tons—more than the obelisk itself. The *Sphinx* was sent to retrieve the finished pedestal and did not arrive back in Paris until April 1836. Three hundred artillerymen manned winches as the obelisk was dragged to the very spot where Louis XVI and Marie Antoinette had been decapitated barely forty years earlier, there to be raised with a trestle similar to the one which had felled it in Luxor. Inch-by-inch the monolith advanced across the square, eased by the old Egyptian method of pouring boiling grease onto the runners. But three more months were to pass by before the raising equipment was in position, and most observers began to wonder if the obelisk could actually be erected.

On October 24, 1836, all was ready. Ten winches, each of which could lift 15,000 kilograms, were to lift the obelisk's 125,000 kilograms past the crucial point of equilibrium. By eleven-thirty 350 artillerymen stood in an elliptical enclosure, ready to man the winches at an order to be sounded by a trumpet. It was a dangerous operation. Were a single order to be misinterpreted, the obelisk could come crashing down to kill or maim hundreds of workers and onlookers. The idea of clearing the Place de la Concorde of all spectators had been considered, but was discarded as unpopular. By noon more than 150,000 Parisians had gathered as close as they could get to the action.

At the sound of the trumpet the winches began to turn, the hoisting gear tightened, tension built up, and the trestle straightened almost imperceptibly. The master carpenter called out, "The obelisk has moved!" At noon the clarion sounded. Winches began to turn to the cadenced march of the artillerymen. The point of the pyramidion left its berth and began to describe a slow arc upward. But, as the foot of the obelisk described a similar arc in the opposite direction, its sharp edge dug into its wooden base, causing the juices to squirt from the lumber under pressure.

No harm came of it, and by the time the king and queen and members of the royal family appeared on the specially decorated balcony of the naval ministry, the obelisk had reached an angle of 38°, almost the point of utmost strain before the center of gravity could shift. There was the sudden cracking sound of splitting timber, and Lebas

The Paris authorities, hoping to use the occasion to show the populace the great advances of modern engineering over that of the ancients, had decided to use the raising of the obelisk to publicize a newly developed steam engine, virtually unknown to the public—"a mysterious and formidable creation which could terrify with its noise like thunder." By demonstrating to the public that a single man at the controls could lift the whole of Sesostris' monolith, the authorities hoped to impress upon the populace how well those at the helm of the ship of state were in command of science, or, as they put it: "man's most glorious conquest over nature."

Fortunately a banal defect in the equipment voided the experiment, which was to have proved that "nature, working for man, would be the sole serf of the future."

shouted for an immediate stoppage. The tension on the braces was such that they resounded to the touch like the strings of a violin. Bolts began to buckle. Obelisk, trestle, and base all risked being hurled by the strain in the direction of the Madeleine. The workers, though in imminent danger of being crushed, did not budge. To overcome the danger point, Lebas ordered accelerated pulling.

Minute by strained minute the obelisk rose, until at last it was upright, suspended a few inches above its base. All seemed in order when Lebas realized that in the excitement he had omitted to give the order to have the retaining chains loosed from the pyramidion. Two sailors quickly climbed the obelisk to cast them off before any damage could ensue.

Now the problem was to let the obelisk down onto its base gently enough not to crack it. To accomplish this delicate maneuver, winches were ordered to make three turns, two turns, one turn, then half a turn. Thus, five years from the day it had been felled where it had stood for four millennia, the obelisk once more rested upright on a solid base. There was wild applause as carpenters climbed the scaffolding to raise the tricolor above the pyramidion.

Louis Philippe uncovered his head to salute the same colors which had been raised thirty-five years earlier by

The obelisk in the Place de la Concorde, with Napoleon's Arch of Triumph at the end of the Champs Élysées

Napoleon's savants over the ruins of Thebes. Lebas crossed the square to join the king, who had summoned him for congratulations and to invite him to dinner that night at the Tuileries. As a reward for raising the obelisk, Lebas was named engineer first-class, curator of the marine museum, and member of the counsel of admiralty.

From the Château of the Tuileries that night, Lebas could see the pyramidion of the obelisk, which his carpenters had specially illuminated. After dinner the king gave Lebas 3,000 francs to distribute to the workers who had raised the obelisk. Everyone appeared to be astounded that Lebas had managed to place the obelisk within 2 centimeters of where it had been meant to go, overlooking the fact that, originally, ancient engineers had erected it squarely on a base exactly as they had intended.

Local chroniclers, remarking that the obelisk would probably survive the splendor of Paris at least as long as it had survived the splendor of Thebes, praised its beauty, grandeur, solemnity, durability, simplicity, proportion, polish, harmony, and even its phallic qualities. But no one mentioned or seemed to have any idea as to what might have been the original purpose of the obelisks of Luxor.

The one person who might have cracked the riddle for them, Jean François Champollion, recently elected a member of the Académie des Inscriptions and named by Louis Philippe to an archaeological chair specially created for him at the Collège de France, had just finished his *Grammaire Égyptienne*—which he considered "my visiting card to posterity"—when he was struck by apoplexy and confined to bed. In January 1832, just as Lebas had been embarking to travel up the Nile to Aswan, Champollion had become too sick to lecture and was obliged to retire to Figeac. There the doctors diagnosed his strange disease as something brought back from Egypt which manifested itself in the form of bronchitis, gout, galloping tuberculosis, and partial paralysis. A career, which was about to flower brilliantly, was struck in the bud. On March 4 of that year Champollion was dead.

With this first real giant of Egyptology out of the way, a small but energetic clique of envious and malicious enemies began to poison his memory by continued efforts to minimize and ridicule his findings, questioning, as they had with Kircher, his honesty and integrity. "It is sad," remarks Erik Iversen, "that every scientific achievement must submit to the disgraceful ordeal and mock trial of envy, ignorance and stupidity, painful and often fatal to the victim, even if truth prevails."

For the next several decades after his death, Champollion's claim to having deciphered the hieroglyphs was hotly disputed. The English refused to accept the evi-

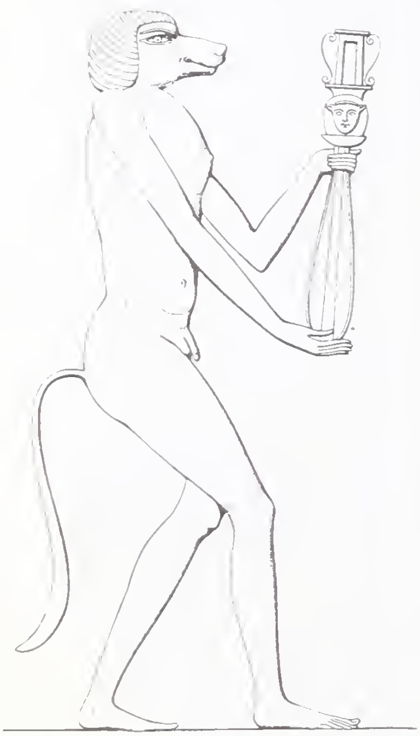
PISA



dence; the Germans rejected his method. It was left to Ippolito Rosellini to publish in ten volumes, over a period of eight years, the results of their expedition to Egypt. Not till 1866 was Champollion properly vindicated, when what amounted to another Rosetta Stone was found by the German Egyptologist Karl Richard Lepsius in the delta ruins of Tanis, inscribed in hieroglyphics, demotic script and Greek. The stone bore a decree in honor of Ptolemy III and Berenice II, his queen, inscribed in 239 B.C. in the ancient Egyptian seaport of Canopus on the western mouth of the Nile. With this newly discovered text, Lepsius was able to corroborate Champollion's dictionary of hieroglyphs and prove the accuracy of his grammar.

Sixty-four years after Champollion's death, Sir Peter le Page Renoulf at last addressed the Royal Society in London to pay homage to the brilliance of Jean François Champollion le Jeune as the true founder of modern Egyptology. Egyptologists were able to forge ahead with translations of glyphs to reveal laws, rituals, literature, customs, and manners of the ancient Egyptians. From these efforts a picture emerged of a people who had carried art and science to a height which modern man had only begun to match. At last Pico, Dee, Bruno, Cagliostro might come into their own.

To drive home to the world the importance of this revival of Egyptian wisdom, a group of British Freemasons decided to erect a symbol to it in London by bringing back from Alexandria the obelisk donated by Mohammed Ali which the French had negligently left in place.

13. VICTORIAN VANITY

Napoleon's troops had already fastened a cable around Cleopatra's upright needle in Alexandria and were on the point of felling it to bring back to France in commemoration of their 1798 victories in Egypt when they were rudely interrupted by General Sir Ralph Abercromby's Twenty-eighth Gloucestershires, who forced the French to abandon the attempt. Victory gave the British the idea of bringing back to England the obelisk to celebrate the defeat of Napoleon. But instead of the upright needle, which seemed tricky to lower without breaking, Major General the earl of Cavan, in command of the small force of Britishers left to garrison Alexandria, decided it would be easier to ship to London the prostrate monolith beside it. Cavan sought permission from the local Turkish authorities to remove the fallen needle, and schemed with his military engineer, Major Alexander Bryce, on how to embark the trophy.

To finance this operation, the British troops were "graciously" invited by their officers to "voluntarily" subscribe a certain number of days' pay to "meet the expenses of an undertaking in which their feelings were deeply interested." Officers and men—so goes the official report—"vied with each other in offering their contribution to the furtherance of an object so gratifying to their national and professional pride." Seven thousand pounds were collected to build a jetty from which to load the obelisk into the stern of a captured French frigate, *El Corso,* where it would lie on a bed of timbers.

Work was begun, and "pay issued to the working parties from the funds they themselves had contributed"; but after the soldiers and sailors, aided by a gang of Arabs, had expended a week of heavy labor they only managed to move the obelisk 6 inches. Then a gale washed away the jetty, and in London the British commanders of the army and navy ordered the project canceled, the official reason given to avoid displeasing the Ottoman sultan to whom the obelisk technically belonged, but unofficially for reasons of state. *El Corso* was disposed of; what was left of the money was returned to the troops.

Not to be totally frustrated, Cavan had a tablet inscribed to the memory of Britain's exploits against the French in Egypt. Afraid the Turks would destroy it as soon as the British left, he had it buried beneath the base of the prostrate obelisk, where no one could possibly see it. In the words of the official account: "They found the pedestal to Cleopatra's Needle and having heeled it to starboard they made a cavity to receive the tablet and replaced the heavy stone."

Once the last of the British had left Alexandria in 1803, the monolith was allowed to disappear again beneath the sand, there to be forgotten until Mohammed Ali, as the new khedive of Egypt, realized he might use the trophy as bait to obtain from the British enough corvettes to develop a navy and so defend himself against his former master at the Ottoman Porte. Renewing his offer to donate the prostrate obelisk to Britain, Mohammed Ali even volunteered to pay for it to be loaded onto a ship. But the admiralty, who did not wish to see the upstart viceroy develop even a weak Egyptian fleet along their route to India, allowed the offer to dangle.

Not so the generals who had served in Egypt in 1801, and who were still hankering and agitating for their prize. But as the years stretched into decades without their being able to change the admiralty's mind, they finally presented a memorandum to Queen Victoria's consort, Prince Albert, to see what he could do. Dutifully, the prince addressed a letter, signed "Albert," to the queen's minister, Lord John Russel, in which he supported the notion of having "this universally renowned work of art brought to London." But even his royal efforts were of no avail against the admirals.

Cartoon lampooning the khedive for walking off with Cleopatra's Needle

Only when it was rumored that Mohammed Ali was flirting with the French in the hope of improving his navy, and had offered them *both* obelisks in Alexandria, was a new ruckus raised in Parliament. But when the French unaccountably refrained from taking the obelisk, it too died down. What was needed by the military survivors of the Egyptian campaign to get their obelisk was more propaganda, and it came in the form of two reports, neither too subtle. A London magazine carried the story of a Briton having been seen sitting astride the prostrate obelisk, knocking off chunks of the inscribed stone with a hammer as mementos for himself and his fellow tourists. When the writer of the article had expostulated with his fellow Briton, reminding him that the relic belonged to the British nation, the vandal was quoted as replying: "I know. And as a member of the British nation I mean to have my share." That the story was apocryphal is evidenced from the fact that the obelisk was still buried deep in the Alexandrine sands of the delta. Some smart propagandist was pulling at Albion's heartstring.

The second story, with a French villain, induced even greater Bullish choler. It was reported that the Greek owner of the land on which Britain's obelisk lay had hired a French engineer to dynamite the monolith into pieces small enough to be used for building material.

That did it. General Sir James Edward Alexander, a ranking Freemason and great-nephew of Sir Alexander Bryce, who, as Major Bryce, had originally helped Lord Cavan try to remove the obelisk in 1801, went into action. It was March 1875. "I determined," wrote Alexander, "to endeavour to save the national disgrace of the loss and destruction of the trophy, and resolved to do my utmost to have it transported to London to grace the metropolis with a monument similar to those at Rome, Paris and Constantinople."

Alexander found the khedive, Ismail, who had been educated in Paris, a pleasant-looking man, in good condition, wearing the usual red fez, dark surcoat, and white vest, but no sign of rank, a mode he had adopted since the opening of the Suez Canal six years earlier, when he had begun to claim rank as a European sovereign. But his administration was so expensive and his aides so corrupt he was soon obliged to sell to Britain his shares in the canal, which signaled the beginning of his downfall.

Alexander's first move was to go to Egypt and confirm permission from Mohammed Ali's grandson, the reigning khedive, or viceroy, Ismail Pasha, to remove the obelisk. From the British government Alexander received partial assistance in that Lord Derby, then foreign secretary, gave him a semidiplomatic status by instructing the British agent in Egypt, General Stanton, to introduce him to Ismail Pasha. In Cairo, General Alexander put up at Shepherd's Hotel, full pension, for 16 shillings a day. Among the guests were Lord Grey, whom Alexander described as keeping up the British sporting reputation abroad. He had just spent eighteen thousand cartridges on pelicans, ducks, quail, and one on a crocodile.

Alexander's audience with the khedive took place on March 25, in the Palace of Abdin, guarded inside and out by a reconstituted body of Mamelukes, in crimson and gold. For the occasion, Alexander wore a general officer's undress uniform with a sword and a sash. In French, the khedive said to Alexander: "This obelisk was presented to the British nation by my ancestor Mohammed Ali Pasha, for services rendered to Egypt. It belongs to Britain. I give it up freely. How is it to be removed?"

Alexander explained, as best he could, and accepted the gift with good grace, knowing that the khedive was being generous because he wished to sell to Great Britain his shares in the Suez Canal to help defray part of the 100-million-pound debt he had run up with a swarm of foreign concession-hunters, who had helped him to loot the country. Taking his leave, Alexander returned to Alexandria, where he asked his dragoman, Mustapha Ali, to show him the obelisk.

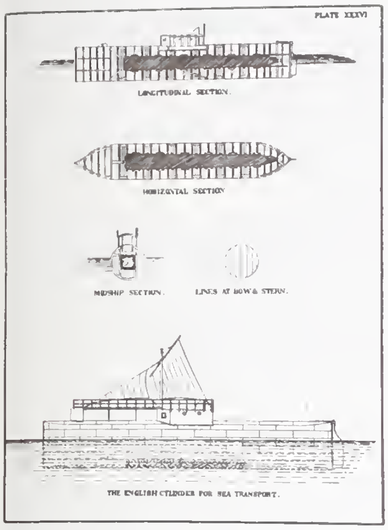
"There," said the dragoman.

"Where?" said Alexander. "I see nothing."

Mustapha gave orders to an Arab standing nearby, and when a large amount of sand had been cleared away, a portion of the obelisk came into view. It lay near the seawall, which was wasted by the water of the Mediterranean. For some distance out, the sea was very shallow and choked with the remains of ancient buildings, broken columns, and other debris from centuries past. So encumbered was it that an ordinary vessel capable of carrying a 200-ton load could not possibly come close to shore, especially a shore that was frequently exposed to gales.

Several people came forward with suggestions to Alexander as to how he could move the obelisk.

First, the obelisk had to be completely uncovered, so as to examine its condition and accurately estimate its weight. A working party of Arabs was engaged, and Dixon was able to establish that the obelisk was 68½ feet long, with a base 7½ feet wide. From this data he estimated the obelisk had a volume of 2,517 cubic feet and a weight of 186⅓ tons.



Dixon's plan for transporting the obelisk to England

Alexander settled instead on the advice of a civil engineer from the North England Iron Company to whom he had been introduced by an officer of the Porte, Chamberlain Bey. The engineer, Waynman Dixon, also a high-ranking Mason, explained to Alexander that he and his brother John has been interested in the obelisk for some years and had worked out a careful scheme for getting it back to England.

Having had a good look at the obelisk, Dixon was convinced that the only method of getting it into the sea, and back to England, was to encase it in an iron cylinder which could be rolled down the slopes till it floated. If the cylinder were built in properly watertight segments and given a keel, it could be towed by a regular steamship—all the way to England. Such segments, said Dixon, could easily be built in a British naval yard, and shipped out to Egypt. Only, who was to pay for the job?

In a letter to a friend and fellow Mason in England, Dr. William James Erasmus Wilson, Alexander had already referred to "Cleopatra's Needle." Wilson, a doctor in his middle sixties, who had piled up a fortune as Britain's leading dermatologist, augmented by shrewd investments in gas- and oil-company shares, offered to meet and discuss the matter with Waynman Dixon. An indefatigable traveler in the Near East, particularly interested in Egyptian antiquities, Wilson was renowned as a generous benefactor of charities, having bequeathed no less than £200,000 to the Royal College of Surgeons.

When Wilson found out that Dixon was also a high-ranking Mason "all formality and ceremony were at once banished." Dixon told Wilson he could encase the monolith in boiler plates, steady the cylinder with bilge plates, ballast it, fix on a rudder, a cabin, and a spar deck, then tow the whole thing to England for about £7,000. Would Dixon, Wilson asked, undertake safely to set up the obelisk in London on the banks of the Thames for £10,000—"no cure, no pay"?

"Willingly," replied Dixon; and Wilson's only further stipulation was that Dixon converse with another Freemason, civil engineer H. P. Stephenson. They met in a solicitor's office in Bedford Row and agreed upon a contract.

But by this time, back in Alexandria, Alexander had found himself stymied. The obelisk had been entirely surrounded by a tall palisade, put up by the owner of the land on which the obelisk lay, a Greek named Giovanni Demetrios, who had been complaining to the khedive for a score of years to get the obelisk removed from his property as it was a hazard to its development. Now the

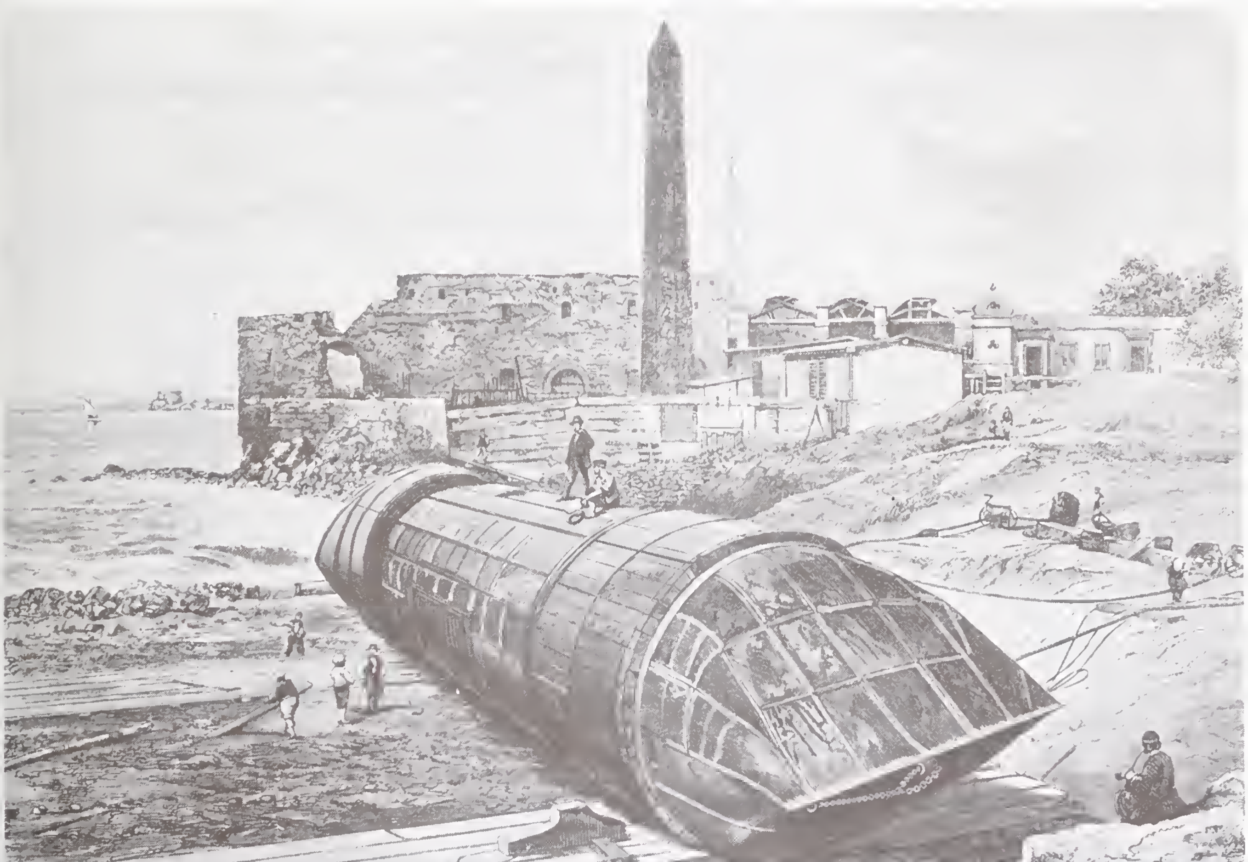
Greek complained that by giving away the obelisk without consulting him, the khedive had wounded his feelings, adding that the khedive had no right to allow strangers to trespass on his private property. Demetrios refused to allow anything to be done unless he received a heavy indemnity for the removal of the obelisk.

To resolve the situation, Alexander called on Demetrios with a lady friend—a Mrs. Gisborne—in the hope, he said, that female influence might affect the old Greek. Alexander found him living in a handsome residence in a beautiful garden, a man of culture, with his personal physician in attendance, Dr. Neroutsas Bey, "a very intelligent antiquary." After much coffee-taking and palavering, Demetrios gave in, explaining that as a Greek, who was thankful to Great Britain for what she had done to help liberate his country, and as a connoisseur and collector of antiques in his own right, he had no desire but to help. There was only one condition: that he be considered the donor of the monument. Alexander readily agreed, and a deed of gift was drawn up which showed that both Demetrios and the khedive had made a present to Britain of the obelisk.

It was now only a question of receiving the iron cylinder segments from England and of assembling them about the obelisk. To superintend the job, Waynman Dixon had commissioned an old salt, Captain Maximilian Carter, who had served twenty-two years with the Peninsular and Orient Line. He was to inspect the segments of the vessel being constructed at the Thomas Iron Works Company under the instructions of a naval architect.

Meanwhile, Dixon recruited another gang of Arabs to remove all the sand from about the obelisk. With hydraulic jacks capable of lifting 100 tons, he had them raise the shaft onto a solid bed of long pine beams and railway sleepers, uncovering in the process several skulls and

human arms and legs, which he promised to the British Museum. When Captain Carter arrived in Alexandria, he was pleased to find the obelisk lying parallel to the sea, but concluded he would have a hard time rolling the completed cylinder into the water because of the hundreds of building stones lying about the shore front and extending far into the sea; many of them were relics of old Roman pavement, others, more ancient, were covered with Egyptian hieroglyphics. Divers were hired to remove enough of these enormous blocks of stone—some of which weighed more than 20 tons—so as to make a path for the obelisk through the shallow water to where it could be floated in a depth of about 10 feet. But some of the blocks were so large they had to be blasted with dynamite, as did some buildings further out to sea whose huge walls appeared to be the foundations of an enormous Roman bath.



Cleopatra's Needle encased in its iron cylinder, 9.8.1877

When the cylinder was finally wrapped around the obelisk in ten watertight compartments, it looked like an enormous boiler, 93 feet long and 15 feet in diameter. Dixon figured that if the center of gravity of the obelisk inside the cylinder was kept 10 inches below the main axis of the cylinder, it would—once it was a vessel—

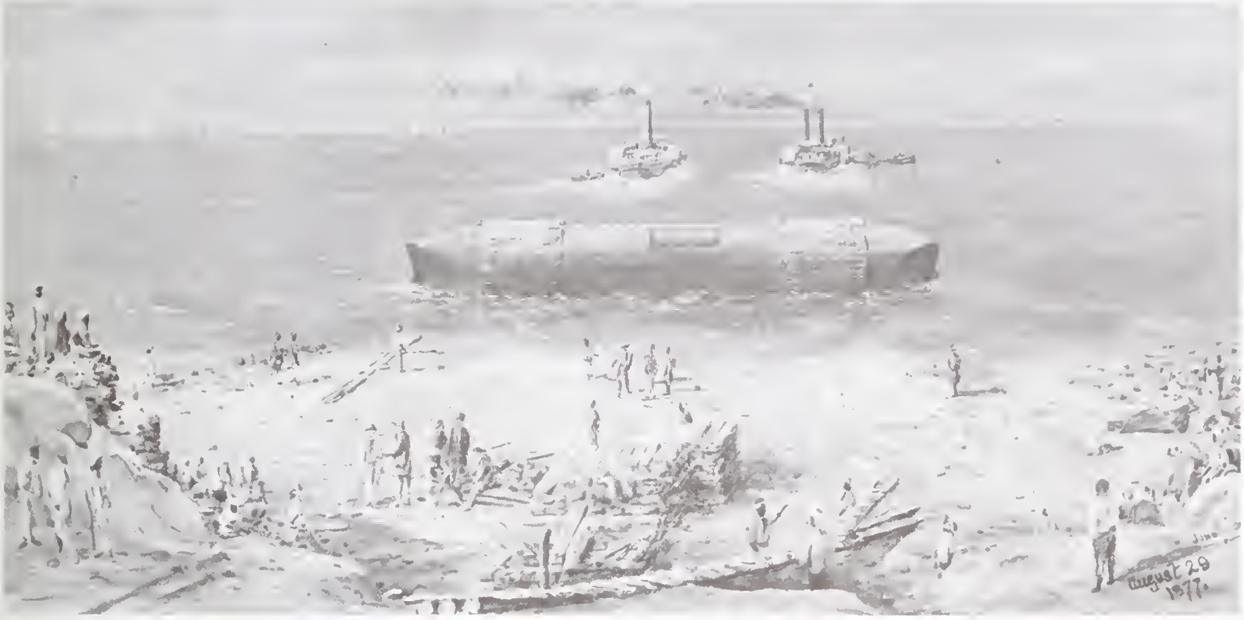
remain in a state of equilibrium in the sea, no matter which way it was rolled by wind or wave. To protect the outer surface of the cylinder while it was being rolled into the sea, timber rings 9 inches thick and 18 inches deep were strapped around it, near the ends, making huge wheels on which the vessel could roll. To start it rolling, hawsers were passed nine times round the vessel and taken to winches on board heavy lighters moored some distance out. Other hawsers were fastened on land to check any undesired movement.

On the day set for the launching, August 28, 1877, a terrible fog shrouded the scene, but it soon cleared, and several thousand spectators turned up from the mixed population of Alexandria to view the operations in what developed into a heat wave of 90° in the shade. A select group of visitors, protected by parasols, included Princess Said, sister of the khedive, and the British consul general, Mr. Vivian.

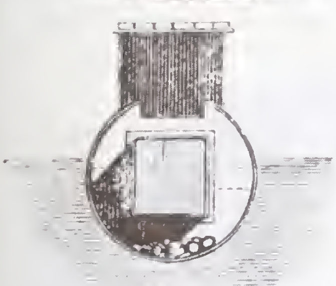
At the appointed signal, the winches began to pull, hawsers strained, and the cylinder slowly turned, its movement hardly perceptible. By noon it had made one full revolution, covering a distance of 50 feet. Then the anchors began to drag out to sea, and the ropes had to be shifted to tugboats which steamed away at full power, just managing to keep the cylinder rolling. By 5:30 P.M., the cylinder had reached the water's edge and by seven it was in 3 feet of water; there it was left for the night.

Soon after daylight on the twenty-ninth, tugs began to

Floating the cylinder



The cylinder being towed to the Alexandria docks



With the use of heavy jacks, the obelisk was placed 4 inches below this axis and forced into place with heavy timber struts. The other 6 inches were gained by loading 12 tons of iron rails into the vessel's bottom as ballast. Further to steady the craft, its fore and aft compartments were completely filled with concrete.

tow again, and by noon the cylinder should have floated. But it didn't. It was half full of water, and there was no way to get inside because the manholes had rotated to its underbelly. Arab divers were summoned, but could not figure out what had happened. When a hole was cut in the surface, above water, and a double suction pump set to work, it had no effect on the level of the water within the cylinder. A deepsea diver in proper suit found that a large stone, hidden in the sand, had penetrated the bottom of the cylinder. Water had mysteriously flooded all the compartments. It was then discovered that in the excitement of the event, everyone had forgotten to close the bulkhead manholes.

To remove the half-ton stone took several days. The cylinder had to be rolled so that its 18-inch hole could be riveted from above water. Two more days and the cylinder floated. Safely towed 9 miles to a great floating dock belonging to the Egyptian government, it was to be fitted with 40-foot bilge keels riveted to the bottom, plus a cabin, a bridge, and a rudder. As soon as the latter was hung from the stern, the vessel was ready for the open sea.

For a crew to man the cylinder under his command, Carter had hired five Maltese sailors and a Maltese carpenter, who agreed to make the run to England for £20. A boatswain insisted on fifty. To tow the cylinder, Dixon had obtained the *Olga,* a steamship belonging to William Johnson and Company of Liverpool, for £900, half to be paid in advance and the remainder on safe arrival, with the obelisk, in Falmouth.

On September 19 a party was held aboard the cylinder, attended by "a hundred and fifty ladies and gentlemen" who watched as the daughter of the British admiral MacKillop Pasha christened the cylinder *Cleopatra* with a bottle of Champagne broken against the stern. On September 21, 1877, despite remonstrances from the Maltese crew that it was bad luck to set off on a Friday, Captain Carter, who had worked himself into a state of exhaustion to get the *Cleopatra* shipshape, agreed to sail. Dixon, traveling on the *Olga,* was anxious to get the obelisk to London and avoid having to wait for fair weather in the spring. Slowly the *Olga* steamed out of Alexandria harbor, with the *Cleopatra* in tow.

The odd-shaped vessel showed herself to be staunch and buoyant, but not easy to steer. She yawed wildly, and in an undulating sea pitched severely, causing great and uneven tension on the 700-foot wire towline. Even at a moderate speed the *Cleopatra* would sink her bow, obliging the *Olga* to go dead slow.

Captain Carter spent all of the first night on deck. The next night the heat was so oppressive his men could not sleep below. Stretching themselves on the narrow deck, wherever they could find room, they tried to snatch fitful half-hours of sleep. Then the breeze freshened, and the *Cleopatra* began to plunge, making sixteen to seventeen dives a minute, completely submerging her bow, which required the crew to hold on with both hands as the sea swept over the entire vessel.

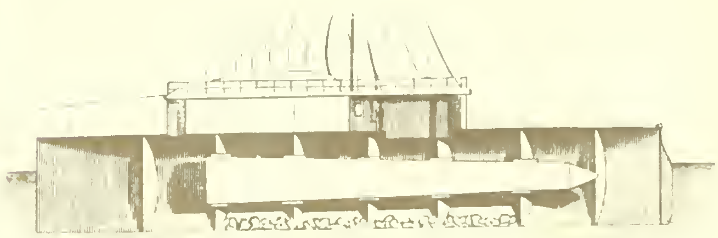
The boatswain got sick from an inflamed liver, and the crew asked to put into Malta. Lest they all bolt, the captain refused. Instead, he gave them each a glass of grog and opened a bottle of Champagne for himself and

The *Cleopatra* towed by the *Olga*

The captain in his cabin

Taking care of the boatswain

the invalid boatswain. One man short, Captain Carter had to stand watches, assist in the cooking, and even trim the lamps at night. He no longer took off his clothes except to wash them and put them on again. Every six hours he took pains to examine the compartments below deck to see that all was secure. To reach the obelisk, he had to wriggle down a small hole in the floor of the saloon, crawl through the manholes in the various divisions, and examine each diaphragm. When the candle he held in his mouth as he crawled beneath the obelisk began to burn his nose, he had to drop it, obliging him to grope his way back for a full half-hour before he could reach the open air. It was not, said Carter, using a Britisher's understatement, "drawingroom work." At first he had difficulty squeezing through the narrow manholes. Later he joked that the regular but simple diet enabled him to slip through "like a halfstarved rat."



Longitudinal section of the cylinder with ballast and bulkheads

Near the island of Galita, the ship ran into much thunder and lightning. A ball of fire danced on the masthead, and there were wild screams from the *Cleopatra*'s crew of "the devil! the devil!" Carter explained it was nothing but Saint Elmo's light, not unusual in the Mediterranean in stormy air full of electricity.

On October 2, the *Olga* signaled she had to put into Algiers for coal. There the ship's crew got so drunk they assaulted their chief officer, tearing out one side of his whiskers. At Gibraltar, when Dixon went ashore and engaged two more sailors, he was warned by naval men that October was a singularly bad month to head across the Bay of Biscay, especially with such a tricky cargo. There was also a report from America warning that a hurricane was expected to cross the Atlantic in mid-October. But Dixon was determined not to have to leave the *Cleopatra* in Gibraltar for the winter. So they sailed on as planned.

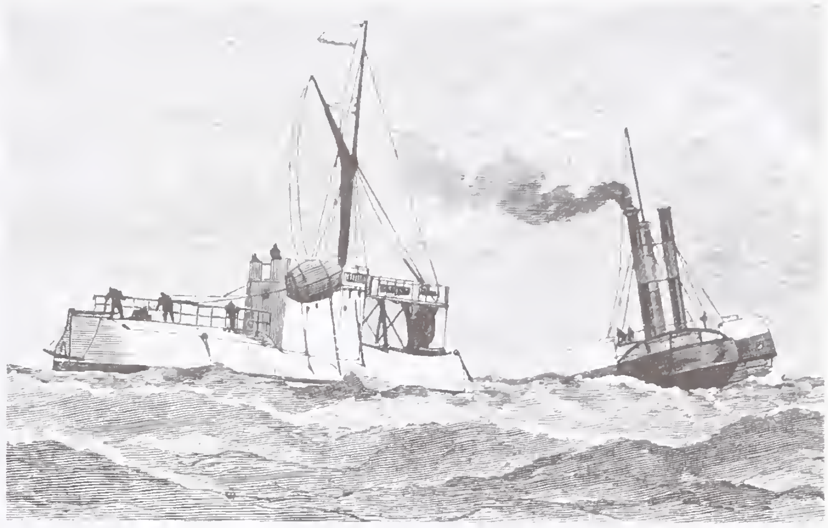
On October 10, at 2:30 A.M., the two vessels spotted the light off Cape Saint Vincent. At six thirty they rounded the cape itself. From the west-northwest a long Atlantic swell

Rough going in the Bay of Biscay

set in, over which, according to Carter, "the *Cleopatra* rode like a duck." As they passed the mouth of the river Tagus, steamers came out to have a look at the strange craft. On Saturday, October 13, at 5:00 P.M., Carter reported seeing Cape Finisterre, the westernmost point of northern Spain. There was a light southerly wind; but he also noticed unmistakable signs of an approaching storm.

On the fourteenth, Captain Booth of the *Olga* noted in his logbook that at latitude 44°55′ north and longitude 7°52′ west, off the northernmost tip of Spain, the wind freshened, increasing with squalls and fast-rising seas. But with the *Olga*'s engines going dead slow, the *Cleopatra* was doing all right. Nevertheless, to steady the *Cleopatra* against the rising waves, a sea anchor was prepared in the form of a conical canvas bag 6 feet long by 15 feet in circumference, its mouth kept open with crosspieces. When thrown overboard at the end of 40 or 50 fathoms of rope, it would help keep the vessel's head to the wind.

By noon a furious squall came up from the south-southwest, accompanied by hail and rain. The wind increased till it was blowing a heavy gale. So long as the vessel was before the wind, Carter felt he had no cause for anxiety, although the whole of the after part of the vessel was frequently immersed, the sea occasionally rolling over the cabin. All afternoon the barometer contin-



ued to fall, while the wind began to veer to the west. As the sea became more quarterly, it broke heavily against the deckhouse, and Carter had serious fears of the whole superstructure being swept away.

By 5:00 P.M. he made up his mind to heave to, and lie with his head into the wind to ride out the storm on his sea anchor. Captain Booth on the *Olga* acknowledged his signal and replied, "Greater risk to tow line if heave-to!" Nevertheless, he set a mainstay sail and just before sundown proceeded with what Carter called "consummate skill and judgement" to bring his ship well round to the wind. Only just too late. The *Cleopatra*'s broadside was struck by a tremendous sea which overwhelmed her, hurling her over on her starboard beam, where she remained with a heavy list. The timberwork securing the iron rails employed as ballast had given way. Shifting about, the rails caused the vessel to lay over at an angle of more than 45°.

Carter, who had already been wrecked three times before, and had been on an Indian ocean liner when it caught fire, did not panic. Instead, he opened the manhole door in the saloon floor and went down with his crew into the hold to try to right the ballast. The gale was now at its height. Though the seas were breaking completely over the *Cleopatra,* she was only making water at the upper bolt-holes. With the hull half full of water and 12 tons of railway iron sloshing around, the job wasn't easy. After an hour's work, the crew finally got the ballast shifted sufficiently to right the vessel. Then a huge wave struck the starboard side and the ballast shifted again, causing the ship to list to port at an even worse angle than before.

Slowing her engines almost to a stop, the *Olga* came as close as practicable, distinguishing signals of distress

from the *Cleopatra.* At this point the gale began to slacken. Toward 9:30 P.M., Captain Booth decided to risk lowering a boat, and called for volunteers. The second mate, William Askin, a young man of twenty-six, immediately volunteered, along with five seamen, all from Liverpool.

Captain Booth stopped the engines and got a lifeboat safely clear of the ship and into the water. In the dark, Booth could just distinguish the lifeboat as it approached Carter's vessel. A line thrown from the *Cleopatra* was caught by Askin and one of his mates, but they were unable to hold onto it. As the rope slipped through their hands, the boat drifted past the *Cleopatra*'s leeward side into the dark night.

On the *Olga,* Captain Booth waited for the reappearance of his lifeboat, which he assumed to be on the far side of Carter's vessel. When it hadn't arrived by eleven, Booth maneuvered as close as he could to the *Cleopatra,* and hailed her, to ask about the boat. He could make nothing of the answers, except that the men were in serious distress. The *Cleopatra* was listing very heavily to port, and he noticed that they had cut away her mast.

Booth's only recourse was to launch a "messenger buoy" to sweep the *Cleopatra* with a line in the hope that its crew might grapple it and haul it aboard. The wind was moderating slightly; but a heavy sea was still running, causing the *Olga* to pitch and roll so heavily she was shipping much water, and the attempt failed.

As there were no volunteers to man another lifeboat, Booth concluded he had no other choice but to keep as

Captain Carter's sketch of the problems encountered in the heavy sea

close as he could to the *Cleopatra* and wait for daylight. All night Carter and his crew continued in their efforts to right the ballast. As often as they did so, the merciless sea threw it back. When day dawned, the gale had moderated considerably; though the sea was still running high. As the *Olga* approached, it found the *Cleopatra* settled heavily on her port beam, its crew still alive and in full force. Of the lifeboat, not a sign.

Booth slipped another cask overboard as a buoy, but again it failed to reach the *Cleopatra*. Edging closer, he managed, after several ineffectual attempts, to throw a line aboard the crippled vessel by means of which a 5-inch hawser was hauled in to keep her in position. Standing to leeward, Booth lowered a boat which managed to reach the *Cleopatra* and take Captain Carter and his Maltese crew safely aboard.

Booth then cut loose from the vessel, leaving her on her beam end, expecting her to sink at any moment. At full speed he proceeded in search of the missing lifeboat. With lookouts aloft he steered westward and soon passed a boat hook and then a messenger buoy, but saw no sign of the lifeboat. By ten thirty, there being nothing in sight from aloft, Booth bore up and ran down to leeward, passing the *Cleopatra*'s severed mast, but saw nothing of her hull, or of the lifeboat.

At noon, hopes of finding either the boat or the *Cleopatra* began to fade. Booth concluded that the lifeboat had been swamped and the crew lost. The *Cleopatra*, with her precious needle, must have gone to the bottom. Heading for Falmouth, he prepared a signal to the effect that six men had perished in a lifeboat, and the *Cleopatra* and her cargo had been lost in a heavy gale in the Bay of Biscay.

In London, where the press and the public had been following the moves of the *Cleopatra* from dispatch to

London reports the abandonment of Cleopatra's Needle in the Bay of Biscay dispatch, arguing as to where the trophy should be placed, the news was stunning. Everyone was suddenly glum and silent. Only Dixon refused to believe the *Cleopatra* was lost. He insisted that the vessel had been left with eight watertight compartments and only a small amount of water in her hold, leaking from the bolt-holes on her top. The huge stone, according to Carter, had been perfectly secure when the ship was abandoned. All the seams were tight, and all of the manholes fastened. The worst that could happen, said Dixon, was that the 12 tons of rail ballast could roll from side to side, listing the vessel alternately from port to starboard, but with the fore and aft compartments filled with cement, Dixon maintained, the vessel could not capsize.

Furthermore, he pointed out that the 200 fathoms of steel cable hanging from her bows would act as a sea anchor, keeping her head to the wind, and that if she were to run into shallow water, the cable would act as a regular anchor. Convinced the *Cleopatra* was still afloat, Dixon appealed to the first lord of the admiralty to dispatch a steamer in search of her, pointing out that she was a serious hazard in the track of passing vessels, especially as she had no lights.

On October 15, the *Fitzmaurice,* a small iron screw steamer of 297 tons, bound from Middlesbourcugh to Valencia, Spain, with a cargo of pig iron, encountered heavy winds in the Bay of Biscay and was forced to lie to until the seas calmed sufficiently for her to resume her course. Off the northern coast of Spain, some 90 miles north of the port of Ferrol, and 15 miles northeast of Corunna, the *Fitzmaurice* sighted a strange object in the sea. As the *Fitzmaurice*'s captain Evans reported the event, at about 5:00 P.M. he spotted what appeared to be the bottom of a ship on the lee beam. Putting the helm hard up, he bore down upon the object and just at dusk realized it was the *Cleopatra,* about which all Britain was agog.

As there was too much sea to board her, he waited, with great difficulty, on account of the rough weather, till dawn of the following day, when he was able to fasten two 9-inch hawsers to the vessel. Two hours later the strain of the heavy sea caused both lines to part. The captain launched another boat and screwed more hawsers to her, setting off at a very slow pace through the heavy sea.

The next morning such a heavy gale blew from the southeast that the ropes parted again, and the captain was only able to refasten them with the greatest difficulty. Limping along, the *Fitzmaurice* finally managed to tow the *Cleopatra* into the pretty little port town of Ferrol, one of the best harbors in Europe. As soon as he was able to inspect the way in which the obelisk had been packed, Evans saw that it was still in perfect shape, but concluded that whoever had arranged the ballast had been a soldier, not a sailor. When the news reached London of the safe discovery of both *Cleopatra* and obelisk, there was general rejoicing, except for the fate of the six missing sailors. From Balmoral, Dixon received a message that Queen Victoria had suggested inscribing the names of the six drowned men on the pedestal to the needle.

At Falmouth, another message, undelivered, awaited the drowned second mate, William Askin, to inform him that his wife had given birth to their first child. A fund was immediately set up for the widows and dependents of the drowned sailors. Dixon put up the first £250, and the owners of the *Olga,* who had thought highly of Askin, and had placed him first in turn for promotion in their service, undertook to organize the fund.

Meanwhile, John Dixon, Waynman's brother, set off with Captain Carter for Glasgow to sort out the salvage costs with the owner of the *Fitzmaurice,* a Mr. Burrell. They did their best to induce the Scot to be moderate in his charges, on patriotic grounds, explaining that it had been a great honor for him, in the eyes of the nation, to have been owner of the vessel which had picked up the *Cleopatra* and towed it to Ferrol. They suggested he be content with that honor, providing the crew was paid a moderate sum for their trouble. Burrell claimed £5,000 in cash. When Dixon offered him £600, the "hard-headed Scotchman" could not be moved.

In Liverpool, Carter went to retrieve from Captain Evans his sextant and other instruments, as well as his log book. His portmanteau had been broken open and thrown overboard with all his private papers, and about £20. His clothes were gone. So were several antique coins and rings. The *Fitzmaurice*'s mate was wearing his shirtstuds. Yet Captain Evans declined to relax the lien on the *Cleopatra,* or on the obelisk, until the claim for salvage was met in full.

Taking the case to an admiralty court, Dixon was able to obtain a reduction in the salvage price from £5,000 to £2,000. As soon as the sum was paid, Captain Carter was able to proceed to Ferrol on a Spanish steamship with a fresh crew from Liverpool to refit the *Cleopatra* with 2 tons of nuts, bolts, chains, and varied ironwork.

At Ferrol, which was well provided with dry docks and warehouses, Carter was able to fit out the *Cleopatra* with a new mast, sails, steering yoke, and tiller. Water and

The *Cleopatra* leaves Ferrol in tow of the steam-tug *Anglia*

provisions were taken aboard on January 1, 1878. To tow the vessel to England, a 270-ton, 140-horsepower iron tug, the *Anglia,* arrived from Liverpool with a well-known artist aboard from the *Illustrated London News,* who was commissioned to make sketches of the *Cleopatra* and her obelisk for an avid British public, more anxious than ever for the arrival of the trophy. Dixon was worried that the *Anglia* would have to weather another 350 miles across the Bay of Biscay; but he had received a good meteorological forecast from the *New York Herald,* and he estimated that there would be a long moon starting January 19.

The *Cleopatra* resumed her journey on the fifteenth, moving at 5 knots on a tow line of 120 fathoms. Again the ships ran into a gale, which sent huge waves breaking over both vessels, tossing them badly.

"Shall we bear up and turn back?" signaled the captain of the *Anglia*.

"Not if I were in your place," answered Carter. "Better proceed at half speed."

One more boisterous night with heavy rain, and on January 21 *Anglia* and *Cleopatra* pulled into Gravesend in the mouth of the Thames to a chorus of cheers from a crowd on land, and a telegram from Queen Victoria congratulating Dixon on the safe arrival of the needle. *Anglia* and *Cleopatra* responded by dipping their ensigns.

At London's East India docks, the dockmaster, sensing the patriotic air in the wind, generously allowed the *Cleopatra* to dock free of all the usual charges.

But now that the obelisk was safely in the British capital, the great dispute was renewed as to where it should be placed. The earl of Harrowby maintained that

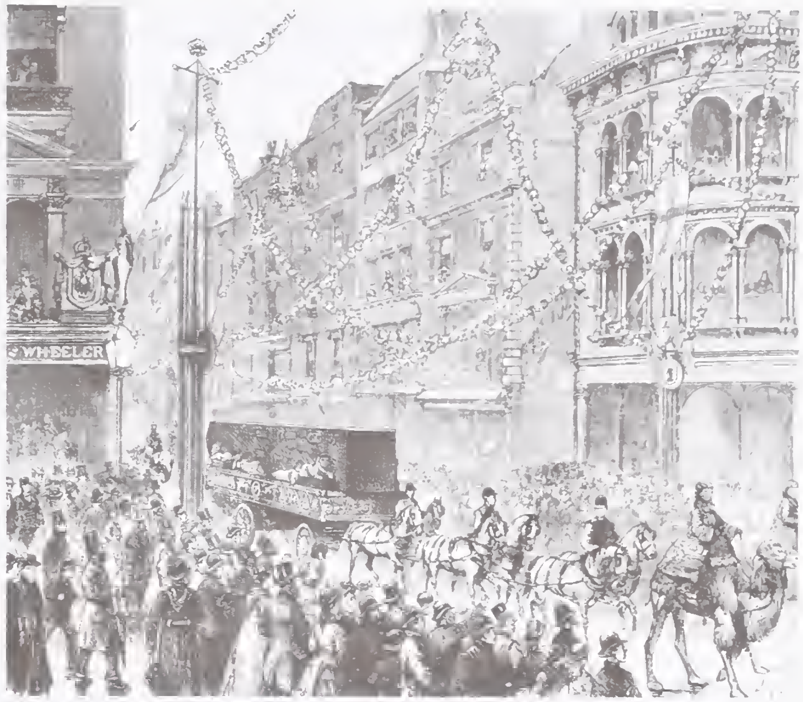
The *Cleopatra* at Gravesend, in the mouth of the Thames, as drawn by the artist aboard the *Anglia*

the choice of the site should be determined by what he called "moral fitness." His idea of a morally fit place was Parliament Square, where the trophy could recall its associations with the victories of Nelson and Abercromby in "surroundings which remind us of the most venerated memories of national history."

"In any other position," said the earl, "it would be a mere tall stone, a mere monolith, only remarkable for its dimensions, and for imperfectly seen configurations upon its surface, but having no significance, telling no story, awakening no associations. . . ."

Imaginative illustration of the obelisk already raised in Parliament Square.

Even more imaginative scene of the obelisk being paraded through the streets of London



The needle by moonlight

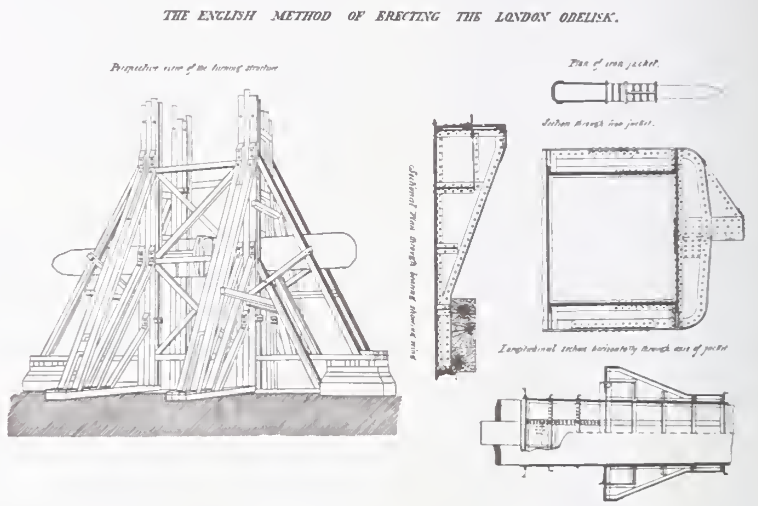
In *The Times,* "A Peer in Reply" thought otherwise, saying that Harrowby had failed to see the moral fitness of placing this relic of tyrannical pharaohs in a spot "hallowed by centuries old associations with the development of our parliamentary institutions and Christian religion." The anonymous peer summed up his argument: "it would be the violation, not the fulfillment of all moral fitness."

Still others wished to place the trophy in front of the British Museum, where it could be closer to other Egyptian antiquities, but the spot was ruled too dark and too small and it was feared that underground utilities would be endangered. At last it was decided to raise the monument on the Adelphi steps of the Victoria embankment, where the obelisk could be admired from a distance (especially by the crowds coming over Waterloo Bridge), where it could have a small park around it, and where, because of its proximity to the river, it would not crush in transit, with its 186 tons, any of the gas or sewer lines of London. Yet even the embankment was objected to by a fellow of the Royal Institute of British Architects, John Holden, who raised the question of possible dangers to the needle from the pressure of the wind, suggesting it might be blown over. John Dixon, with a heavy sigh, pointed out that, from his calculations, whereas less than 30 pounds of pressure per square foot could send a man flying, level Charing Cross station, or sweep a passenger train from the rails, 130 pounds of wind pressure would not upset the obelisk.

"No obelisk," said Dixon, "has ever been overturned by the wind."

As an ornamental base of the obelisk, it was arranged that an architect and an engineer with the Gilbert and Sullivan names of Vulliamy and Bazalgette provide four bronze sphinxes. These colossi, 19 feet long, 9 high, and 6 wide, were to be copies of an authentic Egyptian sphinx set up in the garden of the duke of Northumberland's castle whose sphinx was thought to be of the same period as the obelisk because of a Thothmes III cartouche on its base. Vulliamy and Bazalgette also filled with solid concrete two arches in the embankment that had been used as reservoirs for water with which to flush the steps, thus providing the obelisk with a solid base 4 yards thick and with an area of 1,500 square yards, the lot resting on a tenacious stratum of London clay.

To raise the obelisk onto these sphinxes, four immense uprights had to be fashioned out of six heavy balks of timber, 60 feet high and a foot square. They were to be braced together by tie beams, and supported in their vertical positions by struts thrown out on all sides.



Dixon's method of raising the obelisk on the embankment

The obelisk was fitted with an iron sheathing, 20 feet long, forged in four pieces, so as to be raised 40 feet on a pair of iron girders which fitted into the grooves of a great wooden framework, there to be allowed to swing on its axis from a horizontal to a vertical position.

While the "battle of the sites" was still in progress, the *Cleopatra* lay in the East India docks, with a few plates removed so that the public could catch a glimpse of the great butterfly dormant in its cocoon. General Alexander, who had worked so hard to bring the needle to England, naturally rushed to see it, taking with him a popular military figure, Colonel Lennox Prendergast, whose fame derived from having been with the Scots Greys, in the celebrated charge of the heavy dragoons at Balaclava.

While waiting for the completion of the pedestal, it was decided to moor the *Cleopatra* off the steps of Saint

The *Cleopatra* at Westminster in the shadow of Big Ben

Thomas Hospital, opposite the Houses of Parliament. Shortly before noon on Saturday, January 26, 1878, the *Cleopatra* left the East India docks wearing a holiday dress of bunting, to be towed by one tug, and steadied by two others, up the Thames on a sluggish tide. Salutes were fired from the wharves as the cortege passed, and cheers rang out from the bridges. Watermen made a profit from towing passengers round the *Cleopatra* at threepence a head; and, as no one had a clue as to why the obelisk had originally been raised in Egypt, let alone the meaning of the hieroglyphs, hawkers did a brisk trade in penny histories, published by W. Sutton, 91 Saint John Street, W. Smithfield, which purported to be "A complete history of the romantic life and tragic death of the Beautiful Egyptian Queen Cleopatra, and all about her needle, 3,000 years old, and the events that led to its arrival in England, complete with an interpretation of its curious hieroglyphic inscriptions."

To explain the hieroglyphs, the pamphlets quoted the incomprehensible translations of Dr. Birch of the British Museum, who amused and amazed with such passages as: "Horus, the powerful bull, beloved of the Sun! the King of the south and north, Menkheper-Ra, his father Tum has

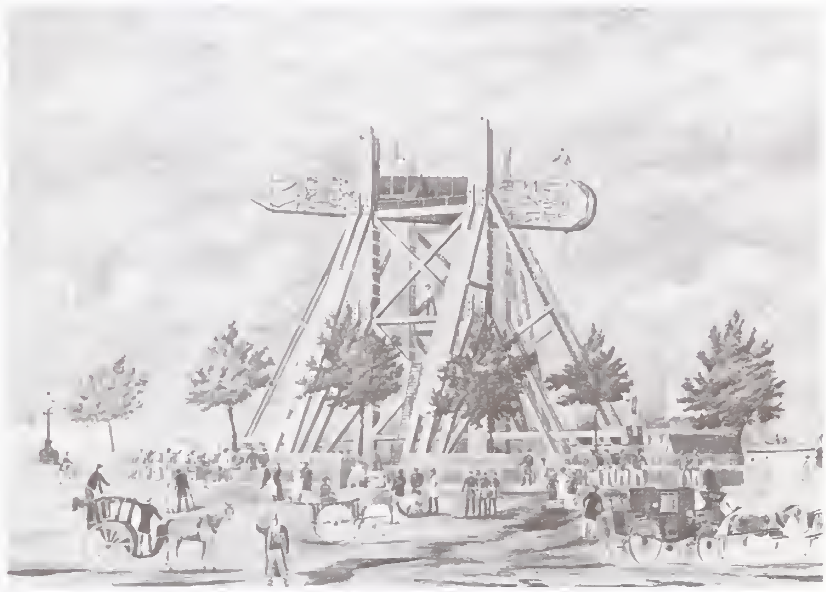
set his name up to him in the palace attached to Heliopolis giving him the seat of Seb, the dignity of Khepera, the son of the Sun Thothmess III, true ruler, beloved of the Benu of An, ever living." The penny histories further pointed out that whereas the inscriptions on three sides had been deciphered, those on the fourth side had not, and "therefore any representations to the contrary in other accounts are spurious."

Four months later, on May 30, the *Cleopatra* left her moorings off Saint Thomas Hospital for her last cruise—almost running into a string of coal barges. Luckily, Captain Carter, who stuck with the vessel to the last, managed to avoid a collision. At high tide, the *Cleopatra* was floated between two pairs of graduated posts, 65 feet apart, to her final resting place, where she was promptly put up for sale. When no one felt inclined to buy such a relic, even as a souvenir, she was ordered dismantled and stripped. Curious onlookers watched her slow disintegration, and the striptease revelation of her phallic cargo. Most visitors were only allowed by card or appointment, among them such notables as the prince and princess of Wales (later Edward VII and Queen Alexandra), Benjamin Disraeli, Earl of Beaconsfield, and Dr. Erasmus Wilson, who was later to pick up the check for the whole party—in return for a knighthood.

Dismantling the cylinder

When the carcass of the *Cleopatra* had been stripped clean, the obelisk was raised by hydraulic jacks and slid onto the embankment by screw traverses until its center of gravity came to rest over the proposed site. So delicately was the obelisk balanced that Dixon was able to make its apex describe an arc of several inches with nothing but the pressure of his own weight.

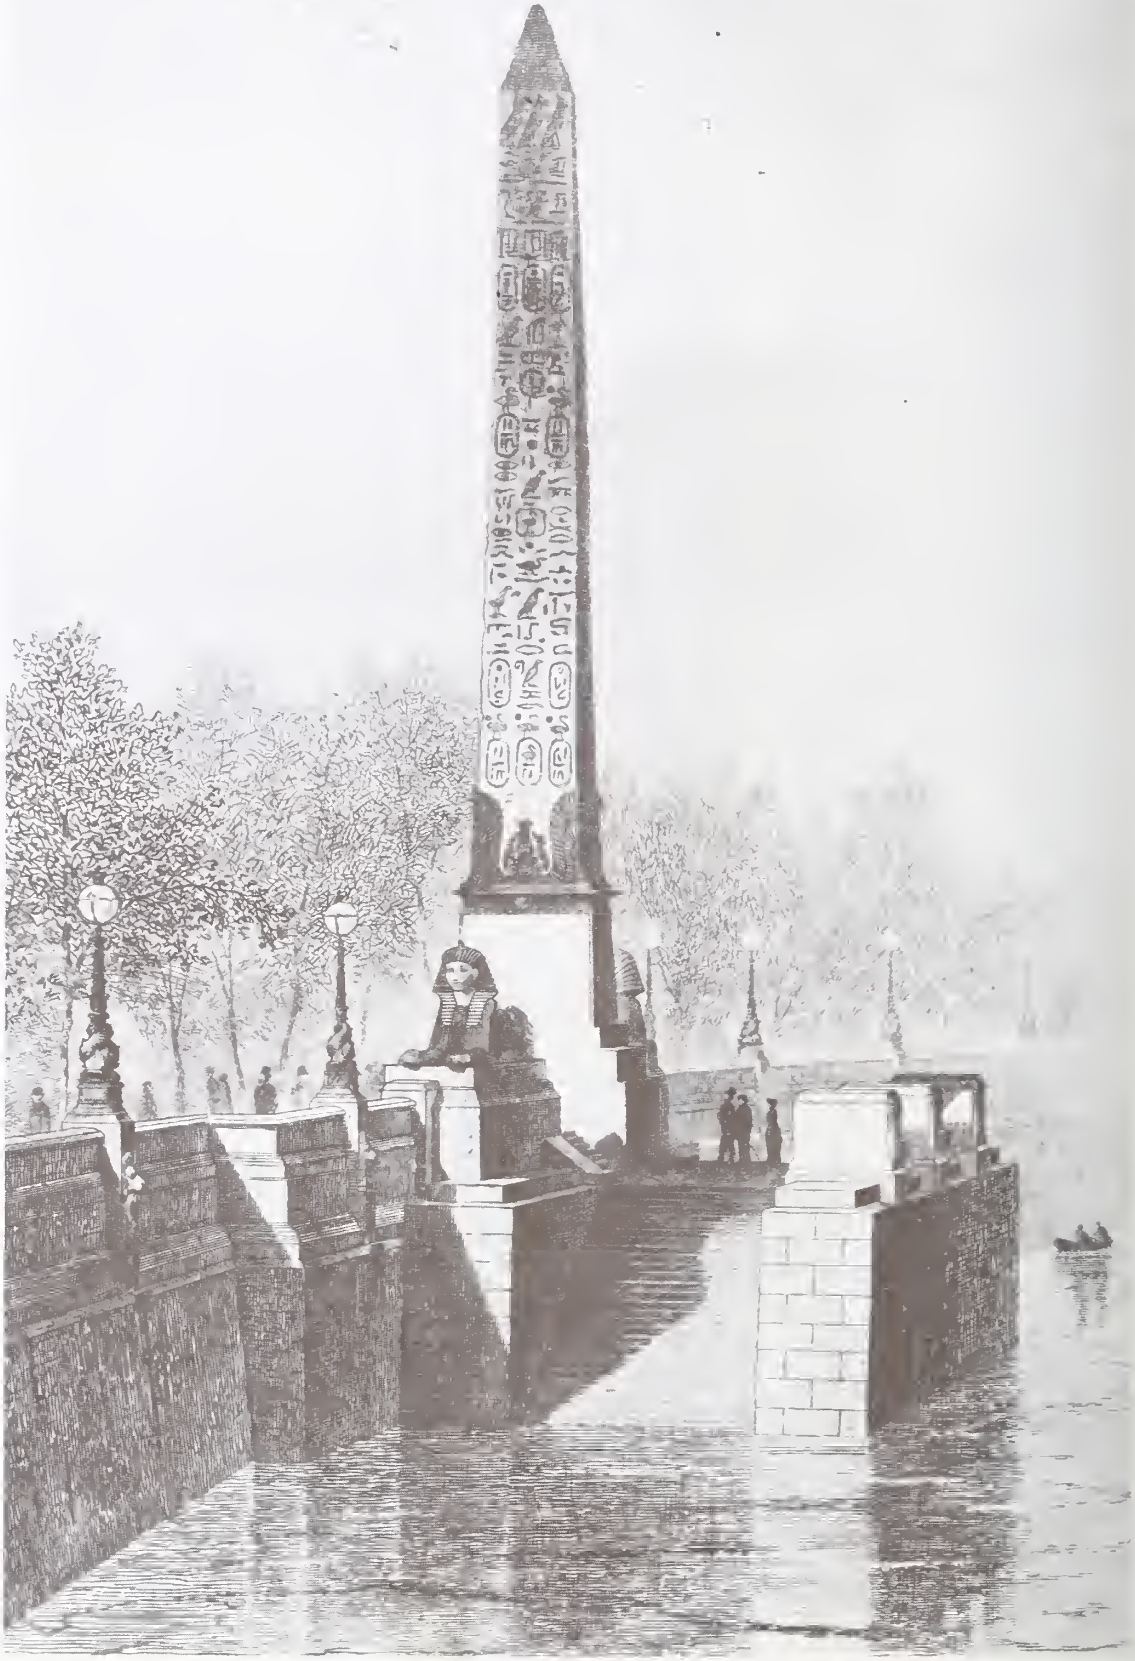


The needle about to be erected. In the pedestal were placed a collection of curious objects considered important to the Victorian world: 1878 photographs of twelve beautiful Englishwomen, a box of hairpins and other articles of feminine adornment, a box of cigars, several tobacco pipes, and an Alexandrian feeding bottle. To this were added a set of toys, a shilling razor by Mappin, a Tangye hydraulic jack, specimens of wire ropes and cables used to raise the obelisk, and a complete set of British coins plus one rupee. Along with samples a standard foot and pint went a portrait of Queen Victoria, a map of London, several current newspapers, and copies of the Bible in various languages. Finally there was inserted verse sixteen of chapter three of the Gospel of Saint John, translated into 215 languages, Francis Bacon's version of which is: "For God so loved the world, that he gave his only begotten Son, that whosoever believeth in Him should not perish, but have everlasting life."

On September 13, an hour before the obelisk was to officially swing on its pedestal, a heavy downpour scattered the gathering crowds. But the sun returned at 3:00 P.M., and from behind a line of constables barricading the embankment, thousands watched as the great rose granite obelisk of Thothmes III, controlled by ropes and chains, swung slowly to an angle of 45°, then 60°, then firmly came to rest on its new London base just as Big Ben chimed three thirty.

The crowd burst into cheers, which reechoed from the roads, the river terraces, and the bridges. A Union Jack was run up on the flagstaff overtopping the pyramidion on the north side, and a Turkish flag was raised on the south, in honor of the khedive, who was to be disposed of by the British within the year and sent into exile on the Bosporus for not having paid his debts. There were more cheers for the queen and for Waynman Dixon.

The penny pamphleteers, awed by the hoary antiquity of the monument, pointed out that it might have been seen by Abraham when he went down into Egypt, that Joseph, who married the daughter of Potiphar, a high priest of On, may have witnessed its first erection; that Moses, brought up by the priests of On, may have brushed against it daily.



Others pointed out that the obelisk had been standing in Egypt when Troy had not yet fallen, when Homer was not yet born, when Solomon's Temple was not yet built, and that it was still standing when Rome had risen, conquered the world, and passed into history.

An American naval officer and fellow Freemason of Waynman Dixon's, by name Henry Honeyman Gorringe, whose hope was to raise Cleopatra's still standing sister needle in New York, and who was to have a great deal more to say about obelisks, summed up the London by-standers' satisfaction that afternoon with his lapidary: "The time-worn shaft will remain erect for many years to come."

But the penny historians had the last word when they augured that the needle would look down "upon all the present and future stupendous creations of human genius, until the advent of the yet unborn but surely approaching time when IT and the land whereon it stands and the ancient life-teeming, wealth-laden Thames shall sink out of sight, and the British Empire be no more."

14. MANHATTAN'S MASONIC MONUMENT

William H. Vanderbilt

The obelisk of Thothmes III as it stands on Greywacke Knoll. First raised in Heliopolis in the sixteenth century B.C., as one of a pair, with Cleopatra's Needle, it stood at the east entrance to the Temple of the Sun, its orientation deducible from the glyphs on its face. Most likely knocked down by Cambyses when he destroyed the temple in the sixth century B.C., it was raised by the Romans in Alexandria, where it stood through the burning of the Caesareum in A.D. 366 and the sack of the city by the Saracens in A.D. 640. The English traveler Paul Lucas who visited Alexandria in 1714 found the lower portion of the shaft buried to a depth of 12 feet.

The first suggestion that an obelisk be removed from Egypt to the United States appears to have been made by Ismail Pasha, at the time of the opening of the Suez Canal in 1869. He made the offer to William Henry Hulbert, editor of the *New York World,* and a leading American Mason, who was in Cairo for the festivities. In September 1877, when the prostrate obelisk at Alexandria was being removed by Dixon, Hulbert was informed by an English friend, Louis Sterne, then in New York, that because of the good relations Dixon had developed in Egypt, he could definitely secure, as a gift to the United States, the standing obelisk in Alexandria. He would also undertake to remove it to New York if someone could be found to defray the cost, which Dixon estimated at £15,000.

Hulbert discussed the offer with fellow Masons Judge Ashbel Green, and Chauncey M. Depew, then proposed to William H. Vanderbilt, the railroad tycoon, reputed to be the richest man in the world, and also a Mason, that he provide the funding. When Vanderbilt agreed, Hulbert spoke with the secretary of state, William M. Evarts, who instructed the consul general in Cairo, E. E. Farman, to take up the matter formally with the khedive, using "all proper means at his disposal."

On March 4, 1878, Farman reported to Evarts that the khedive made no special objection to the transport of the obelisk to New York, but warned that it would be best not to make too much noise about its removal. There was evidently considerable local opposition to the idea, especially among the foreign residents of Egypt. Hulbert informed Dixon that the upright needle had been given to the United States and that Vanderbilt had agreed to pay the £15,000 needed to move it. But Dixon, who had just been obliged by a higher admiralty court to pay the full £5,000 salvage for the *Cleopatra,* was so out of pocket he complained that he would have to raise the ante to £20,000 to deliver the obelisk to New York. Hulbert rejected this increase, without even consulting Vanderbilt, and began to solicit tenders for the job, immediately snaring Lieutenant Commander Henry Honeyman Gorringe, USN, who read the announcement in the *New York World* of June 17, 1879, and promptly offered his services.

Henry Honeyman Gorringe

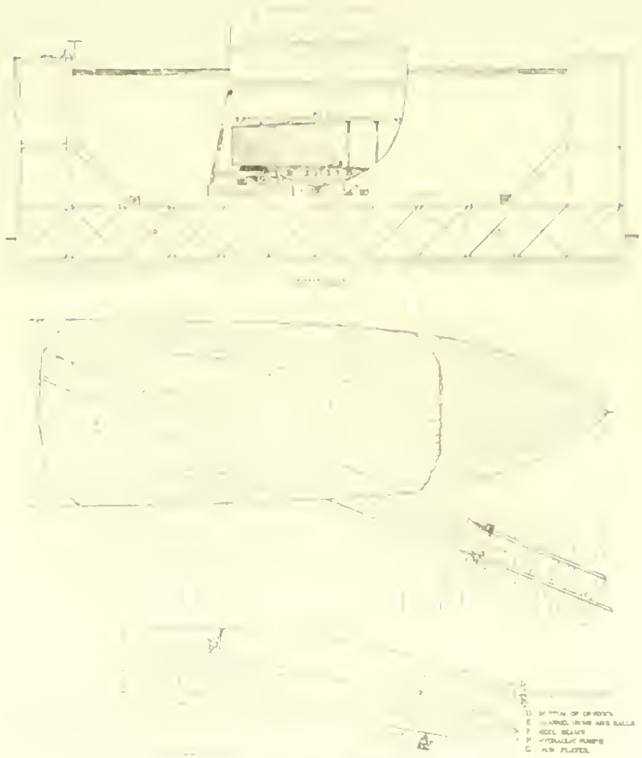
Thirty-eight years old, Gorringe had been employed in the United States Hydrographic Service, where he had recently been commissioned with a fellow naval officer, Lieutenant Seaton Schroeder, to cruise through the Mediterranean on a navy paddlewheeler, the *Gettysburg*. During a stay in Alexandria in 1878 the two officers had several times inspected the standing obelisk and conceived a vague plan of conveying the monument to America if the chance ever presented itself. Gorringe even studied the method used by Lebas to remove the Luxor obelisk, and the method used by Dixon for Cleopatra's Needle, deciding that both plans were unsuited to the transport of the standing obelisk to New York.

Hulbert and Vanderbilt were sufficiently impressed by Gorringe's plan to present to him an outline of Vanderbilt's terms. If Gorringe would undertake to bring over the obelisk and raise it on whatever site might be approved by the New York commissioner of parks, furnishing the underground foundations at his own expense, Vanderbilt would pay him $75,000 upon completion of the work; but he would assume no liability whatsoever until the obelisk was securely in place. Within two days, Gorringe accepted the proposition and its conditions.

At the request of Secretary Evarts, Gorringe and Schroeder were granted a leave of absence from the navy. Evarts also sent a dispatch to the United States vice-consul in Cairo, N. D. Comanos, asking that all proper official and personal aid be rendered to Gorringe so as to accredit him to the government of the khedive as the officer authorized to receive the obelisk on behalf of the City of New York. Gorringe's only remaining problem was to raise the money necessary to carry out the venture, an endeavor which led him straight into what he termed "almost insurmountable difficulties." At length, a fellow Freemason, and friend of long standing, Louis F. White of New York, offered him sufficient funds to start his operations.

Though neither of the vessels transporting the Paris and the London obelisks had been motored, Gorringe figured the ship that would carry the New York obelisk had to be constructed with her own motive power and be large enough to care for herself under all conditions of weather. But he abandoned the idea when he found that construction of such a vessel around the obelisk would cost the whole amount promised him by Vanderbilt. The alternative was to embark the obelisk on an ordinary ship. Here again, there was no precedent for the loading into a steamship such an enormous weight. The largest and heaviest masses yet placed intact in a steamship's hold

Gorringe's sketch indicating how to place an obelisk within the hold of a ship



had been some 100-ton guns made in England for shipment to Italy. As the obelisk could not be carried on deck without specially strengthening the vessel, at great expense, the only place for it was in the hold below the waterline. How to get the obelisk into the hold was the problem.

Gorringe's plan called for embarking the monument into the steel hull of a steamer through an aperture made in the bow, as Lebas had done at Luxor. But when he and Schroeder searched for a suitable American vessel, they could find none.

On August 24, 1879, Gorringe and Schroeder sailed for England on the *Arizona*, reaching Liverpool eleven days later. There they spent two weeks searching for a suitable English steamer to charter; again, none was available. The rates quoted for a charter were equivalent to the cost of purchase. So the naval officers decided to go ahead to Alexandria and prepare the obelisk in the hope of finding a suitable ship when and if the time came to load it.

From England they traveled through France and Italy to Trieste, still part of the Austro-Hungarian Empire, with the intention of buying timber for felling the needle. There they were told they could purchase timber just as cheaply in Alexandria, whither they sailed from Venice on the S.S. *Ceylon*.

Arriving in Alexandria on October 16, they found a great agitation had been started among the foreign residents to prevent the removal of the obelisk. A howl had gone up when the news leaked out that some Americans proposed to remove the needle. Violently abusive articles appeared in the press; meetings were held and petitions to the khedive were circulated for signature. Threats of personal violence were made, openly and by letter, against anyone who would attempt to start work on the removal of the obelisk.

Egypt was no longer the country it had been under Mohammed Ali or under his son Said Mohammed, or even under his grandson Ismail Pasha, who had been forced three months earlier to abdicate and retire to exile in a palace on the Bosporus, where he remained a state prisoner of the sultan; because of his wildly extravagant expenditures and the debts he could not repay, the Great Powers had seized the opportunity to intervene in Egypt and establish a joint Anglo-French control commission.

As Alfred Milner puts it in his *England in Egypt*, trying to take some of the blame off Ismail: a series of unfortunate conditions had been necessary for Ismail's personality to become "as pernicious to his country" as it did. "It needed," says the historian, "a nation of submissive slaves, not only bereft of any vestige of liberal institutions, but devoid of the slightest spark of the spirit of liberty. It needed a bureaucracy which it would have been hard to equal for its combination of cowardice and corruption. It needed a whole gang of swindlers—mostly European—by whom Ismail was surrounded."

Gorringe was amazed by all the clamor over an obelisk which, until his arrival, nobody had bothered about in the least, even to the extent of preventing its defacement and the accumulation of offal around it. Two men had been allowed to make a business of breaking off pieces from the sharp edges of the shaft and from the edges of the intaglioed hieroglyphs to sell to relic hunters. It would not have been impossible, said Gorringe, for anything to have been more neglected and less appreciated by the residents of Alexandria and the tourists who passed through the city en route to the Nile, than was the Alexandrian obelisk. "The disagreeable odors and clamors for backsheesh hastened the departure of strangers," said Gorringe, "and they rarely devoted more than a few seconds to its examination."

As soon as the two American naval officers had established themselves in apartments in Alexandria, near the site of the obelisk, they set off for Cairo accompanied by vice-consul Comanos to obtain an audience with the new khedive, Tewfik Pasha, Ismail's son by a simple *fellah* woman. Tewfik received Gorringe and Schroeder very cordially and inquired about their plans for transporting the obelisk, cautiously expressing the hope that it would not be taken down unless they were sure of being able to remove it. To speed up such an operation, he gave them an order to the governor of Alexandria, requesting him to formally deliver to them the obelisk on condition they be charged with all expenses incurred in its removal.

Unlike his brothers, Tewfik Pasha, had not been educated in Europe, and was so displeased with the news of his succession to the viceregency of Egypt he beat up the servant who brought him the message.

Gorringe took the first train back to Alexandria and presented the order to Governor Sulficar Pasha. Within three days a formal transfer of ownership was accomplished. To the protests and petitions from the European consuls and other resident foreigners to prevent the transfer, the khedive and his ministers replied: "Too late. Cleopatra's Needle is in the possession of the United States Officer sent to receive it."

The foreign residents now attempted to physically prevent Gorringe from removing the obelisk. When a force of laborers started clearing away the ground around the base of the obelisk on October 27, an individual arrived and ordered the work stopped. He claimed to Gorringe to be the owner of the ground on which the obelisk stood, and said that if work continued, he would apply to the Italian consul, whose janissaries would be sent to forcibly eject the Americans and their employees from the premises.

Gorringe immediately fetched the American vice-consul, and together they called on the Italian consul, who informed Gorringe that any Italian subject occupying a property which belonged to him had the right to the Italian consul's protection, if necessary by the armed force of the Ottoman sultan's janissaries. The owner, explained the Italian consul, had been given authority by Mohammed Ali to build a bathing establishment by the seashore near the obelisk, but his property had been destroyed by the sea during a gale. Claiming compensation from the Egyptian government, the Italian had commandeered the land around the obelisk and built on it a shanty as insurance against losing his case.

Gorringe discovered that the claim had indeed been pending since the international courts had been organized in Egypt for the trial of cases between foreigners and the Egyptian government, and between individuals of different nationalities. But so absurd was the claim, it had never been placed on the docket, and was only kept current at the insistence of the Italian consul. To remedy the situation, Gorringe notified the Italian consul general that he would institute a suit for £15,000 against anyone who attempted to interfere with his work of removing the obelisk, and limited the time to four o'clock that afternoon for an amicable acceptance of his proposition to rent the ground.

There were some surprised Italians, but their consul shortly thereafter informed the American consular agents that the Italian claimant had accepted Gorringe's offer to lease the land, and proposed the appointment of arbitrators to fix a suitable sum. Before nightfall the lease was effected.

On the morning of October 29, a hundred Arabs, varying from ten to seventy years of age, began work, divided into three gangs. The middle-aged dug and filled baskets; the old lifted them to the backs of the young; these carried them to the shore and emptied them into the surf. This hivelike activity continued for a week until 1,730 cubic yards had been removed. The pedestal and steps to the obelisk had been cleared, and enough space created in which to construct a caisson to transport the obelisk to the port for embarkation.

Demolishing the foundations under the obelisk, without blasting, was difficult, as the cement had set to an unexpected degree. But as soon as it was broken up, the pedestal steps were moved out from under the obelisk. To raise the pedestal clear of the steps, steel wedges were driven under it until there was room enough for the end of a bent steel bar to be inserted. Hydraulic pumps acting on the upper part of this bar raised the pedestal clear of the steps and held it suspended until channel irons and cannonballs could be placed beneath it to move it with greater ease.

When Gorringe found the bottom of the lower step below the pedestal to be nearly at mean sea level, he felt certain that the foundation could not have sunk so nearly uniformly, and that a subsidence of the ground of about 17 feet must have occurred since the obelisk had been erected nineteen hundred years earlier. The sea had gradually approached the site of the obelisk, and the constant washings of the surf had begun to affect the foundation. For some fifteen years the obelisk had been inclining gradually toward the sea, leading Gorringe to the conclusion that in a few years it would have fallen, doubtless breaking.

At some point in its history, all four edges of the base of the obelisk had been broken away, and four bronze crabs, shaped like sea crabs, had been inserted at the corners, the better to support it. Only two crabs remained; the others had long since been stolen by thieves who inserted stone blocks in their place.

While the excavations were still in progress, another attempt was made to prevent removal of the obelisk. A creditor of the Egyptian government applied through the international court to seize the obelisk and keep possession of it until his claim was paid. Gorringe realized that the entire proceeding was simply aimed at stopping his work, getting the obelisk under the jurisdiction of the court, and keeping the case pending until his attempt to remove it had been abandoned. So he raised the American flag atop the obelisk and, in his words, "prepared the means of defending it in a manner that carried conviction." When the court was advised that the American was taking no notice of the writ, and intended to use resistance against anyone who tried to take possession of the obelisk, it withheld the writ.

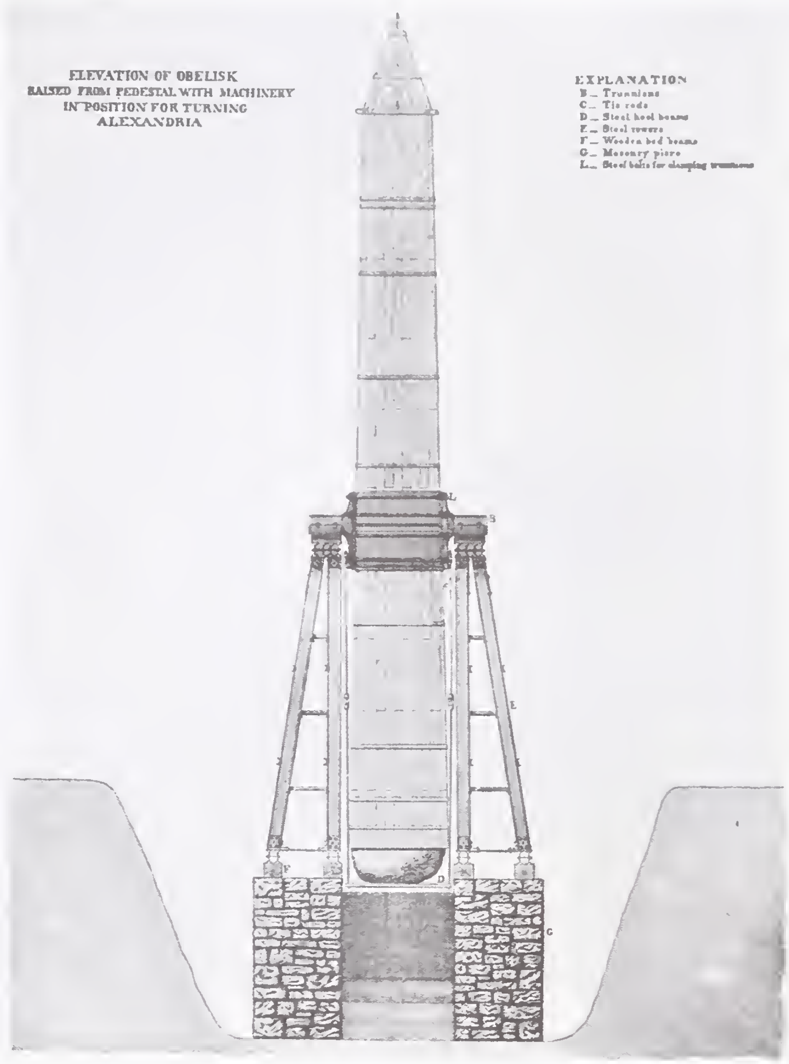
No sooner had this affair quieted, when some of the consuls general in Cairo, at the instigation of resident European archaeologists, again attempted to have the work suspended, so that the matter could be referred to their various governments, arguing that by the terms of a convention entered into by several powers, the Egyptian government had agreed to prevent the exportation of any object of antiquity. Gorringe met the threat by pointing out that no attention had been paid to this convention when the English had removed their obelisk, and that the consuls and archaeologists themselves were constantly shipping articles to Europe. To clinch his argument, he showed that the Ottoman *firman* which gave legal assistance to the Egyptian government stipulated that Egypt should not make treaties with foreign powers, and that therefore the convention was without legal basis. But fearing that pressure might be put on the khedive or his ministers, Gorringe negotiated through a prominent and powerful pasha in Constantinople, whom he had befriended, to ensure prompt confirmation of the gift of the obelisk from the Ottoman Porte, if such a *démarche* became necessary.

More determined that ever, Gorringe now set his men to work day and night, to get the obelisk off its pedestal. The material and machinery for removing the obelisk had been shipped from New York via Liverpool and arrived on November 11. But there was no truck in Alexandria suitable to transport the great trunnions, or truncated arms, like those of a cannon, on which the obelisk was to be turned from a vertical to a horizontal position. Placed on the only vast truck available, the heavy trunnions were hauled to the site by a gang of Arabs on the Christian sabbath—when there was less traffic on the narrow streets of Alexandria—for which effort an American missionary roundly abused Gorringe and his Arab workers from a borrowed pulpit, denouncing the holiday removal of the obelisk as the work of the devil. As Gorringe described the situation, the Arab Mohammedans spent their sabbath, or Friday, in a rational manner, sleeping during

Machinery and trunnions designed by Gorringe for raising and turning the obelisk

the morning, attending services at the mosque at noon, and devoting their afternoons to social intercourse and amusement. The Christians, almost to a man, said Gorringe, "would devote the thirty-six hours from Saturday evening to Monday morning drinking, gambling, fighting, and other excesses, and return to work drunk, sleepy and bruised."

Before the obelisk could be turned, timber had to be provided onto which it could be lowered. As the Egyptian prime minister, Riaz Pasha, had ordered the governor of Alexandria to offer Gorringe the same assistance in removing the obelisk as had been offered the British, Gorringe was convinced he was to have the use of the timbers which had been left by the British, still in a government warehouse. But the officer in charge, a European, was against the removal, and managed to evade the order. The only alternative was to buy some soft planking at the exorbitant price of $4,300.



The obelisk raised sufficiently to remove the bronze crabs securing it to the base

On December 2, the turning structure was placed in position. Three days later the obelisk was lifted clear of the pedestal, and the heavy bronze crabs removed. Rumors had been circulating that a demonstration by the foreign residents was to take place when the obelisk was turned horizontal in the presence of the governor of Alexandria. But Gorringe had found a friend, and fellow Mason, in Rear Admiral Aslambekoff, of the Russian Imperial Navy, who, from aboard his flagship, the *Qminim,* in the port of Alexandria, promptly landed a large force of unarmed but trained seamen to form a cordon around the obelisk.

On December 6, the day set for the turning, large crowds of Greeks, Italians, and other Europeans gathered in the vicinity, becoming noisy and unruly when they were prevented by the Russians from entering the cordoned-off enclosure. The moment the obelisk began to move there was absolute stillness; the only sound came from the

rendering of the ropes around the posts and an occasional creak of the structure as the point of the obelisk slowly described an arc. All seemed in order when a very loud crack occurred, followed by an even sharper snap. One of the tackles had parted. Gorringe gave the order to slack the other tackle, to retard the motion but not arrest it. Instead of slackening his line, the man attending the fall "lost his wits," held fast, and the second tackle snapped.

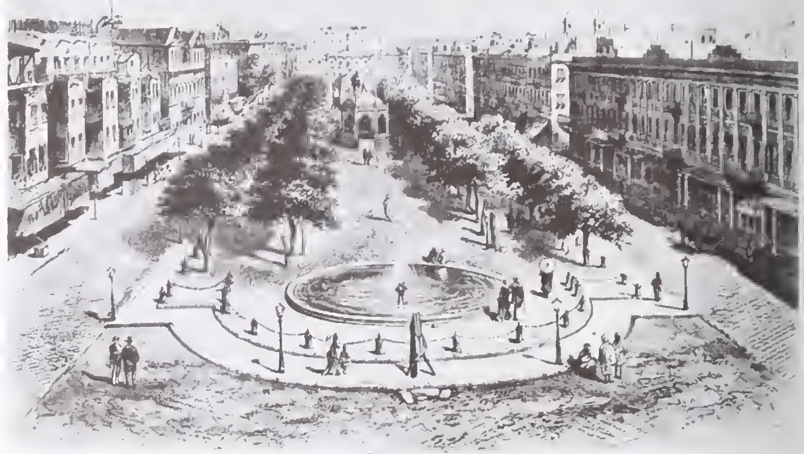
The obelisk, moving slowly at first, gathered speed. There was intense excitement. The Arabs and Greeks around the base began to flee. An ear-splitting sound reechoed, and the obelisk heavily struck the stack of timbers, splintering three courses of balks, and rebounded twice, finally coming to rest in an almost horizontal position. By some miracle the needle was intact. The Alexandrian crowd, giving vent to what Gorringe called its first manifestation of friendliness, raised a loud cheer.

Shattered timbers break the fall and preserve the needle.

The man attending the first tackle explained that having looked up to see what had caused the noise, he had involuntarily checked the passage of the rope through his hands. This brought the whole strain onto his tackle, causing it to break. The man on the second tackle, unaware of the accident until he saw his companion flee precipitously from the obelisk, excusably, said Gorringe, lost his self-control, and down went the obelisk.

As soon as the weight had been transferred to the stacks of lumber the towers and trunnions were removed, and demolition of the piers gradually began in order to lower the obelisk 43 feet to ground level, at the rate of 3 feet a day. An iron truss cradle which moved on cannon balls had been specially designed and made in the United States to transport the monolith overland to the port of embarkation. This distance was less than a mile, and the route was over comparatively unfrequented streets, except for a short stretch across what had once been the ancient causeway connecting Eunostos island with the mainland, now the most important part of the city.

The foreign merchants were determined not to allow the obelisk to be moved through the city, using the excuse that it might crush the sewers. Gorringe's guarantees of repairing all damage were of no avail. Nor could the

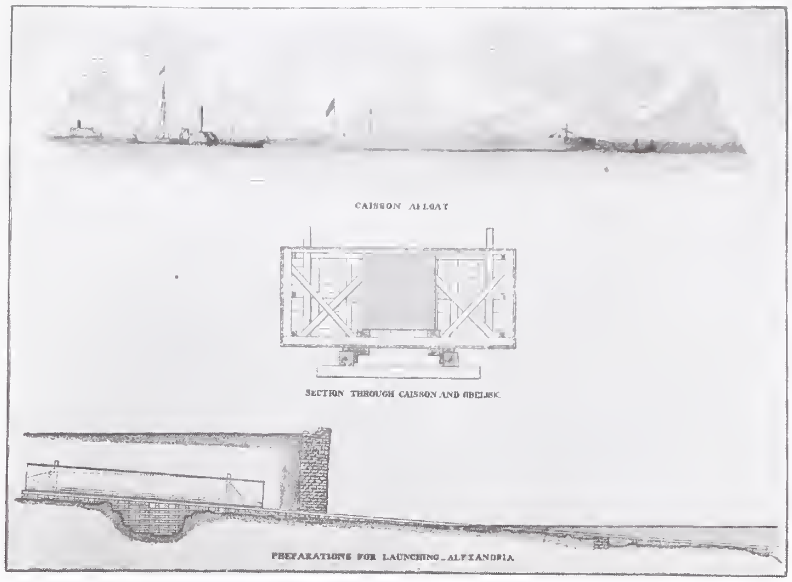


The streets of Alexandria

Egyptian government intervene and overrule the foreigners. In return for keeping the streets paved and clean, the government had transferred control of the streets to the foreign merchants.

The alternative method, sea transport in a wooden caisson—covering a distance of 10 miles—was expensive and very dangerous. The transportation cradle, which had cost $5,100, became a dead loss and had to be thrown away. The cost of constructing the caisson was another $2,200. But preparations for launching a caisson over a shallow bank still encumbered with heavy blocks of marble and granite was even more expensive. Despite the passage cleared by Dixon, the submerged foundations of the famous palaces of Alexandria were still directly in the way. These obstructions could only be removed by divers, a difficult task along an open coast, with the surf breaking two-thirds of the time.

Diving operations, whenever the sea would permit, continued until March 1880, during which time the divers had to be paid whether at work or not. A single day of heavy surf often destroyed the work of diving operations of a whole week. A pier with derricks had to be constructed to lift out the blocks. The estimated weight of material removed, ranging from 3 to 7 tons apiece, was 170 tons. The difference in cost to Gorringe, owing to the refusal of the foreign merchants to allow the obelisk to move overland, was close to $21,000. A wooden caisson 83 feet long, 11 feet deep, 22 feet wide at one end, and 30 feet at the other, was built around the obelisk in order to float it to a dry dock. Inch by inch the caisson was pushed forward till it finally floated. Armed with two keels and two



Much lubricant was used on the ways to facilitate the caisson sliding into the sea, and every precaution was taken against fouling the sliding surfaces, but after the caisson had slid rapidly for 20 feet, it abruptly stopped. As with the *Cleopatra,* a towline was run out to a tug, and two anchors were planted offshore with cables leading to the caisson; but the combined force of the tug and threefold purchases on the cables did not move it an inch, even when a pressure of 100 tons was exerted. The cause was found to be a foreign body, washed in by a heavy sea, which had stripped the sliding ways.

The wind turned to a gale, and the waves threatened to break the caisson and the obelisk within it. To save the situation, water was let into the caisson. When the seas subsided, water was pumped out and the obelisk, still intact, was floated to Alexandria.

keelsons, the caisson was successfully towed to the port of Alexandria.

Meanwhile, Gorringe had been negotiating for the purchase of an English or Italian steamer, when his attention was attracted by an old tramp, the *Dessoug,* chiefly, as he put it, because of "the fullness of her form and particularly of her low line." Lying dismantled in the Alexandria arsenal, she had been built in England in 1864 and employed in the Egyptian postal service between Alexandria, Smyrna, and Constantinople, until extravagance and corruption in the service had caused her withdrawal. Careful measurements showed that there was just enough room under her lower-deck beams to take into her fore compartment the full length of the obelisk. Though her hull was perfect, her hold, said Gorringe, was filthy, for she had been neglected "to a degree that cannot be imagined." To refit her and repair her, which was to be Schroeder's job, a large expenditure was necessary, which made it essential she be purchased at a low price. To accomplish this, Gorringe decided not to make an offer at once, but to treat the matter with apparent indifference.

Leisurely he commenced negotiations via the assistant postmaster general. After several informal conferences, an offer of £5,000 sterling was made to the postmaster general, who affected, said Gorringe, to regard such an offer as a joke, suggesting that the matter of price be treated seriously; other negotiations, he added, were pending for the purchase of the *Dessoug*. This simply meant that a firm of shipbrokers, who had been trying to charter or sell Gorringe a vessel, when informed of his negotiations for the *Dessoug,* had made an offer to the

Egyptian government in the hope of being bought off by the American. A member of the firm even offered to withdraw if he was paid a commission of 10 percent on the purchase money.

To bring matters quickly to a head, Gorringe informed the postal ministry in Cairo that his own offer would be withdrawn at noon the next day, unless formally accepted before then. Quickly, the Egyptian government accepted the offer of the shipbrokers, but demanded an immediate guarantee of payment. The brokers, who had no use for the vessel except to sell it to Gorringe, offered it to him for £6,000, but were informed that he would not purchase her from them under any circumstances.

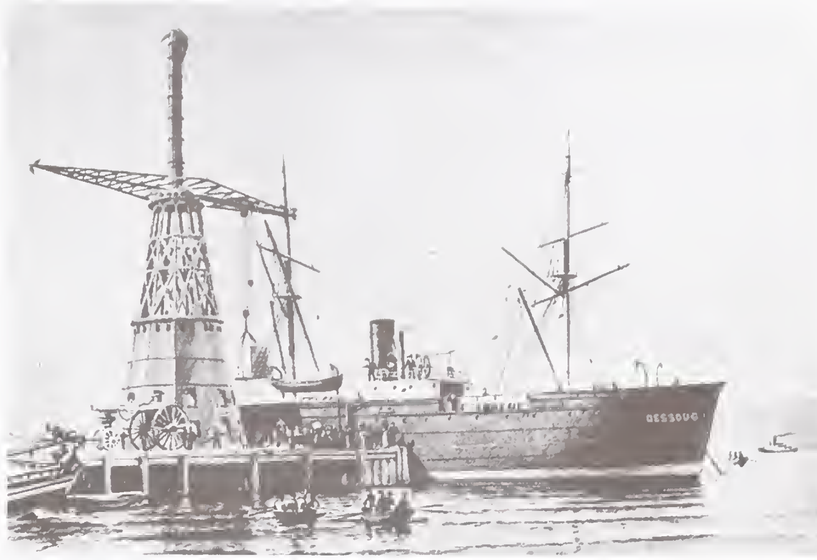
When the brokers could not give the required guarantee, and the time allowed had elapsed, Gorringe was notified by the government that he could have the vessel for £5,100. The money was paid, and the transfer effected on December 3, in the strictest secrecy. This was because another government vessel, laid up in the same arsenal, had been seized, along with the money paid for her, on a warrant issued by the court on behalf of someone who had a claim against the Egyptian government, so that transfer could not be effected from the government to the purchaser.

Legal transfer to Gorringe was quickly effected in the office of the director of postal services, whose representative then went straight aboard the *Dessoug* with Gorringe to haul down the Egyptian flag and raise the United States ensigns on mastheads and peaks in the presence of the amazed Arabs in charge of the vessel. When ordered to gather their personal belongings and leave, the Arabs made no protest, but insisted first on delivering what Gorringe called "formal and fervent prayers."

This was lucky; for Gorringe discovered that a seizure of the *Dessoug* had only failed because of his quick and secret action. A notice in Arabic, Greek, Italian, French, and English was posted on each gangway, prohibiting anyone from coming aboard, at the peril of his life, without permission. "As there was no one to whom I could call for protection," Gorringe wrote, "I was bound to protect my property myself, with all the means in my power." Several boats approached the gangways, but seeing the signs and the welcome Gorringe had prepared for them, no one attempted to board.

One condition of the purchase was that Gorringe be allowed to use the government's floating dock for embarking the obelisk as soon as it was felled. Orders from Prime Minister Riaz Pasha, acting for the nervous khedive, were specific, but when the obelisk and the *Dessoug* were

The *Dessoug* as Gorringe found her



ready to be mated, the Egyptian official who had control of the dock refused to comply, ordering several small river steamers to be hauled into the dry dock instead of the *Dessoug.* Before Gorringe could appeal to Cairo, the official had the dock pumped out and the plates torn off the bottom of the steamers; that way they could no longer be floated, no matter what the ministry ordered. When Gorringe realized that the riverboats could just as easily, and much more cheaply, have been hauled out on shore than into an expensive dry dock, he knew the official had been acting deliberately. He attributed the maneuver to the widespread belief in Alexandria that the obelisk could not be embarked in the manner he proposed, and felt that this had caused the official to speak of the embarkation as if it would entirely destroy the dock, or occupy it to the exclusion of all other business for a long period.

Nearly five weeks passed before the dock was disengaged, but Gorringe did manage to get the caisson slipped in earlier by having the level of dock water altered, which did not affect the small steamers "beyond washing out their filthy holds and destroying some of the vermin for which they are justly celebrated." Even so, the official refused to follow direct orders from Cairo and only let Gorringe enter the caisson on condition that he allow another big ship to dock before the *Dessoug.* To this Gorringe was obliged to agree because the caisson was leaking so badly there was danger of its being sunk by accident or design. As soon as it was in the dock, Gorringe had the caisson demolished, not so much to advance the work of embarkation but to ensure that the obelisk could not be removed from the dock other than aboard the *Dessoug.*

On May 10, 1880, the *Dessoug* entered dry dock. A foreman shipwright was brought from Glasgow expressly to superintend the opening and closing of the hole. Three gangs of thirty Arab boilermakers went to work day and night without intermission. Seven thousand rivets, sixteen frames, and thirty plates had to be removed from the starboard bow to make a hole large enough to admit the obelisk at an angle of 21° to the axis of the keel, the greatest angle at which it could be embarked without having to turn it twice during embarkation.

The caisson had been placed in the dock in just the right position for the shaft of the obelisk to be slid into the *Dessoug* as soon as her hole was readied. Gangs of carpenters were engaged in the difficult job of packing timber under the forward run of the hull, and under the track of the obelisk, to prevent straining the frames. The bed of the track was laid continuously from where the obelisk lay, through the aperture, and into the hold. The

Inserting the obelisk

obelisk was then rolled in on cannon balls. To ensure uniform pressure on the balls, soft wood was packed in between the iron channel and the stone.

It took ten days for these nuptial preparations, and eight hours to consummate the insertion of the obelisk. Almost as soon as the pyramidion had disappeared within the cavity, the last frame was up and riveted again. Inside the hold, a force of the best shipwrights that could be hired in Alexandria shored and stowed the obelisk against the serious danger of its shifting at sea. To obviate the risk of being broken by the inner working of the ship, the obelisk was placed on a bed of Adriatic white pine, very spongy and soft, while 10 feet at the extremities was left without support. When this was done, Gorringe felt that the vessel could be laid on her beam-ends without causing the obelisk to break adrift.

On June 1, three weeks from the day the vessel had entered dry dock, she was floated out with the obelisk within her. It was then necessary to ballast the vessel and load the pedestal and base. The largest of the base steps weighed 7 tons, the smallest nearly a ton. The pedestal itself weighed nearly 50 tons, and had to be placed in the after hatchway, on a special iron frame, to distribute the weight; but the most powerful crane on the quay could only lift 30 tons.

Gorringe decided on a wild gamble. He would try to lift the pedestal with the additional and simultaneous help of an available floating derrick that could lift 25 tons. Slowly the pedestal was raised 30 feet in the air; but just as it was being swung over the hull of the steamer, a sharp sound was heard, and the pedestal began to oscillate. Were the pedestal to fall, it would destroy the vessel, which Gorringe ordered instantly moved. The steel wire with which the pedestal was slung had stranded; only two of the seven strands remained intact. A chain cable was quickly substituted, and the pedestal safely stowed away.

At last, the *Dessoug* could sail; but the nationality of the vessel remained a delicate question to settle. Under the laws of the United States, she could not be registered as an American vessel. Sailing under the Egyptian flag would have involved serious risks. The British or another European flag, according to Gorringe, would have been even more objectionable, especially in terms of the evasion of laws relating to ownership. Finally Gorringe concluded there was no course available but open defiance of the law, which he felt the circumstance warranted. To make the voyage to New York, he determined to sail without registry of nationality, thereby taking the risk of having his

The 50-ton pedestal about to break loose over the stern of the *Dessoug*

steamer seized by any vessel at war, or by the authorities of any port at which he might be obliged to touch. Gibraltar was the only port he intended to call at for coal, and there he had a personal acquaintance with the chief military and naval authorities, whom he felt confident would not examine the ship's papers too closely. Further to lighten the risk, he made arrangements for taking on coal from lighters on the eastern side of the Gibraltar peninsula.

Providing a crew and securing a reasonable rate of insurance for the voyage had been the cause of endless trouble and negotiation from the day the vessel was purchased. By insisting that he would pay no more than a 2-percent premium, or make the voyage without insurance, Gorringe finally got the agents to lower the premium from 25 percent to 5 percent, and finally to 2 percent.

For a crew he was obliged to send to Trieste, and for officers, to England. The second and third officers turned out to be confirmed drunkards. One had to be dismissed to prevent him from killing himself, as he twice fell from the second deck to the hold, and twice overboard while drunk.

The quartermaster, according to Gorringe, would have done credit to a pirate ship. Only the engineer was useful, but hard-drinking. Before the ship was even ready to sail, forty-eight men deserted, convinced that the obelisk would sink at the first touch of weather. As the ship had no nationality, deserters could not be arrested; and without the means of enforcing discipline, the only available method, as Gorringe put it, "was the summary one." To get a full crew, Gorringe sent a power of attorney to a ship's agent in Trieste, stipulating that the next lot arrive in Alexandria only the day the vessel was ready for sea, so they could not back out. With this ruse, Gorringe managed to keep all but three men aboard; but of the lot only four could speak or understand English.

Back from Cairo, where he had rushed to make his personal farewell to the khedive and thank him for having resisted the pressure of foreigners to revoke his father's great gift to the City of New York, Gorringe took command of his unusual charge. On Sunday, June 12, moorings cast, the *Dessoug* steamed slowly out of Alexandria harbor amid a general dipping of colors and the sound of steam whistles and the cheers of the other ships' crews. But could she, Gorringe wondered, cross the Atlantic? Or even the Mediterranean as far as Gibraltar?

At Gibraltar, instead of being seized as a prize, the ship was visited by the governor, Lord Napier of Magdala, and Lady Napier, accompanied by the staff of Government House. Taking on coal and fixing two leaking boilers delayed departure three days, but at midnight on June 25 the *Dessoug* steamed out into the Atlantic. The weather was rough, but all went well till they passed the Azores. Fifteen hundred miles out of New York there was a terrible noise from the engine room and the engines came to an abrupt standstill. The after crankshaft, which had a flaw, had broken in two.

Fortunately Gorringe had had the foresight to place aboard a spare section, obtained at great difficulty as part of the articles of purchase. With all the men available working day and night, the brasses were bored and the shaft reconnected in six days, during which the *Dessoug,* progressing on its sails, covered a little less than 100 miles. To add to this ordeal, the weather turned foul and a waterspout formed to windward, moving directly toward the ship. With too little wind to maneuver, and being without cannons to fire into the spout and break it up, Gorringe realized they were in for a heavy dowsing. All the hatches and skylights were quickly covered, and the bulwark ports opened in the hope of excluding as much water as possible from below. There was a suspenseful five minutes, then the spout changed its course, passing 50 yards to starboard. Had it burst on the *Dessoug*'s deck with its 50-foot column of water, it could have seriously endangered both ship and cargo.

On July 13 the vessel ran into another heavy gale, with high seas that almost completely arrested its progress. Two huge waves did considerable damage to boards and skylights; but a close watch was kept on the obelisk and its fastenings, and no movement was detected.

Steaming ahead as hard as the boilers would allow, the *Dessoug* stood off Fire Island on July 19, where, by a prearranged signal, her position was reported to New York. At 2:00 A.M. on July 20, she anchored off Staten Island, at the quarantine station, and after having been granted pratique, or permission to communicate with shore, moved up the Hudson to moor off Twenty-third Street.

There now occurred, on a smaller scale, the same "battle of the sites" which had taken place in London. Before leaving New York, Gorringe had consulted with William Hulbert and F. E. Church as to William Vanderbilt's preference for a location. All had expressed a preference for the area of Central Park near the Metropolitan Museum, rather than the other favored sites, which were the circle at the intersection of Fifth Avenue and Fifty-ninth Street, and the southwest entrance to the park, the chief objection to these sites being the fear that the monument would be lost among the tall buildings surrounding it. On July 27 it was decided that the obelisk would be erected on the top of Graywacke Knoll, in the park by the Metropolitan Museum, one of the highest points on Manhattan, in the midst of pretty drives and walks. To avoid further needless discussion, strict secrecy was maintained about the choice.

Gorringe would have liked to land the obelisk from the East River, within easier reach of the knoll, but the strong tidal currents and the short intervals of slack water made this impossible. The best landing he could find for the obelisk was at the foot of Ninety-first Street and the North River; but first he had to land the pedestal, and as it was impossible to move it by truck over the roadway of this street, the *Dessoug* was first moored along the wharf at the foot of Fifty-first Street, where a derrick was able to land the pedestal with a speed strongly in contrast with its embarkation at Alexandria.

This was the largest and heaviest stone on record (with the exception of the obelisk itself) ever to have been

moved on wheels through the City of New York. Thirty-two horses in sixteen pairs were attached to the truck for hauling; the first forward impetus was given by hydraulic pumps applied to the tires of the rear wheels, and as soon as the truck was in motion, the horses were started and kept going at a slow trot. But the weight was too great; the wheels sank into the pavements. When this occurred, the slings which bound the pedestal were slackened until the truck was released and timbers could be slid on the pavement beneath the wheels.

The route to be followed was along Fifty-first Street to Fifth Avenue and up to the East Eighty-second Street entrance to the park. From there to the site, the pedestal was successfully moved on greased skids, just as it had been originally in Egypt. But there it came to a rest. No action had been taken by the Department of Parks to prepare the knoll for the foundation. Four laborers from the department had merely removed the young trees to clear away the surface. A few days later their work was even suspended without apparent reason. Gorringe complained that it was the invariable custom for the department to prepare foundations for the reception of monuments and statuary contributed by individuals for the adornment of the city, and that in this case the custom was being violated.

Anxious to get the foundation prepared before winter, Gorringe decided to go ahead on his own and sought from the department almost daily the requisite authority to proceed with the work at his own expense. This was withheld for several weeks, and only granted under onerous conditions that involved a large increase in the cost of the work. Political and religious bias had evidently been behind this attempt at sabotaging what was seen to be an enterprise designed to enhance Masonic prestige in the city. But the delay could not be extended indefinitely, and by the beginning of October the earth was removed from the top of the knoll, the surface of the granite leveled and the cavities filled in with cement. Over this a thin layer of concrete was laid and the foundation replaced, so that it stood exactly as it had in Alexandria, each piece in the same relative position to the others, and to the points of the compass.

There only remained the 7-ton syenite base which was reserved for the Masonic ceremonies, this being the last piece to be placed before the 50-ton pedestal was moved into position. The Most Worshipful Jesse B. Anthony, Grand Master of Masons in the state of New York, was invited to lay the "corner-stone," and, after consultation with the commissioner of parks, fixed October 9 as the date.

On that morning nearly nine thousand Freemasons paraded past an estimated thirty thousand New Yorkers lining the sidewalks between Fifteenth Street and Eighty-second Street. Each commanderie of Masons was headed by a band. At the entrance to the park, the crowd grew more dense, and in the park itself it was so great that policemen were unable to keep spectators out of the spaces reserved for the ceremonies. The column of Masons, having marched to the base of the pedestal, opened ranks three deep and faced in.

The line extended all the way to Sixtieth Street, where the Grand Master and the Grand Lodge officers left their carriages and marched through the line to the platform on the Graywacke Knoll, followed by the Masters and Wardens of the lodges. The ranks were closed, and the commanderies were massed on the west side and the lodges on the north and east sides, while the south side was crowded with spectators, some occupying as a vantage point the great pedestal at the foot of the knoll.

When order had been obtained, the Grand Master addressed the brethren: "This monument in its associations brings forcibly before us that period of which at present we know so little and of which the researches of the scholar, the calculation of the astronomer, the study of the rocks by geologist, and the skill of the engineer, are each year adding to our information and startling us with wonderful results. This trophy comes from that land the history of which was long lost in the mist and obscurities of ancient fable and tradition,—a land of wonderful creations of human power and genius, that has been, and long will continue to be, a place of interest and curiosity to the learned."

Looking up into the gray autumn sky, the Grand Master continued: "The Egyptians were the first to have observed

Jesse B. Anthony, Most Worshipful Grand Master of Masons of the State of New York, laying the cornerstone of the future monument

the course of the planets, observations which led them to regulate the year from the course of the sun." He then suggested that the great pyramids which were believed to have been constructed as tombs might also have been designed for astronomical purposes. He attributed to the ancient Egyptian priesthood, twenty-five hundred years before Christ, knowledge of the precession of the equinoxes and the ability to predict with certainty the position of stars over periods of thousands of years.

As the Masonic marshals kept order in the crowd, the Grand Master continued: "Egypt itself is a book of history,—one of God's great monumental records, on the face of which He has written with His own hand many of the strange events of the past. It was the birthplace of literature, the cradle of science and art, the garden and garner of the world. The people of those days excelled in many respects the advanced growth of the present century. Could we but know that which time will yet unveil, we should be astonished at the revelation and ashamed of our littleness."

Pausing to survey the multitude, he asked: "Should we not take a broader ground and look to the principles which antedate the time assumed for the origin of Masonry as at present constituted? There can be no question but that in the secret societies of Egypt are to be found some elements now embraced in the principles or symbolism of Masonry of the present. . . ." Then with full Masonic rites the Grand Master laid the cornerstone.

All that now remained was to disembark and raise the obelisk. Ever since Gorringe had docked in New York, he had been occupied with the problem of getting the obelisk ashore. Unfortunately the owners of the docks had also discovered this fact. On opening negotiations with their representative, it became evident to Gorringe that as the dock owners had the right to fix whatever price they pleased and make their own conditions for the use of their property, they were going to dictate their own terms without regard to the customary charges. In fact, they fixed a price far in excess of that charged for other steamers, and made Gorringe give security for any injury to their property that might result from disembarking such a load.

Gorringe offered the owners the same rates paid by other steamers, and proposed the appointment of a commission of experts to watch the operation of disembarking the obelisk and decide what amount of damages, if any, should be paid them resulting therefrom. The dock owners answered that unless he accepted their terms and conditions *at once,* they would not agree to take the *Dessoug* into the dock at any fixed rate, according to turn, but would leave the disembarkation of the obelisk till some time when there was no immediate demand for the facilities. Without replying, Gorringe left the office, determined to devise some other plan for disembarking the obelisk.

At first he thought of taking the *Dessoug* to Philadelphia or Baltimore, disembarking the obelisk in the spacious dry dock in either of those cities, and bringing it to New York on floats by canal. But negotiations with the dry-dock owners and their representatives developed the same feeling as in New York about extra charges. Besides, Gorringe realized there would have been no end to obstacles in connection with the Customs authorities and navigation laws. The *Dessoug* had neither register nor nationality, and could not legally leave the port of New York.

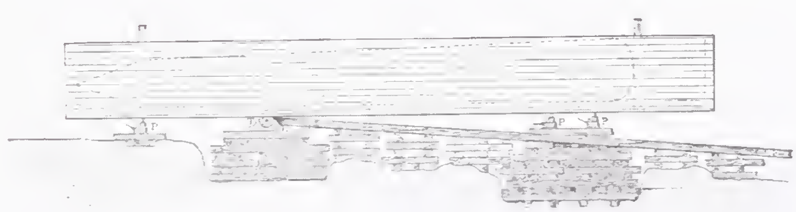
Gorringe next planned the construction of a marine railway at the foot of Ninety-sixth Street, where the obelisk could be landed directly onto Manhattan island.

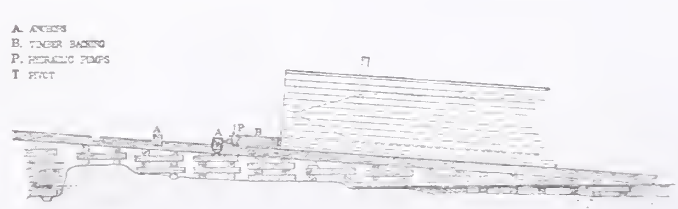
But this was found to be impracticable because of the Hudson River Railway, which skirted the shore, and because of the abrupt decrease in the water's depth close to the riverbank. The Dock Department insisted that the structure be removed entirely and the piles pulled out after the disembarkation of the obelisk, which would have cost almost as much as building it.

Having almost despaired of being able to accomplish his object without yielding to the demands of the dock company, Gorringe reached a solution which he summed up in one word: *tide.* He determined to make the rising tide lift the obelisk onto any available marine railway, and the falling tide land it. There would thus be no lack of power, and no need of a dry dock.

Before communicating his plans to anyone, Gorringe visited incognito all the marine railways on the shores of New York bay, and fixed on a new one at Staten Island as the best adapted to his purpose. The proprietor had no knowledge of his plans until the terms of an agreement had been entered into for the occupation of his ship. When everything was satisfactorily arranged, only the *Dessoug*'s bow was hauled out of water on August 21 on the east shore of Staten Island while iron shipwrights worked at opening a hole in it.

News that the obelisk was to be disembarked on the morning of September 16 brought to Staten Island a crowd of spectators who occupied every available spot from which to view the work. The weather being favorable, pontoons were pumped out at low water and adjusted to their proper position under the obelisk. The rising tide caused them to gradually raise the cross-timbers clear of





Front and side elevation of the pontoon for floating the obelisk ashore the capping on the piles until the weight of the obelisk had been transferred from the stage. At high water, 4:00 P.M., they were hauled out of the ship into the bay, bearing the obelisk on their decks.

At the foot of Ninety-sixth Street, a landing stage had been prepared for the obelisk, identical in principle to the one at Staten Island. The steamer *Manhattan,* belonging to the Dock Department of the city, was in readiness to tow the pontoons from Staten Island. The steamer *Rescue* of the Coast Wrecking Company stood in attendance to escort it. The time of high water at the foot of Ninety-sixth Street was about two hours later than at Staten Island. The distance was 12 miles. At 4:55 P.M. the *Manhattan* started ahead with the pontoons in tow. As she proceeded up the bay, tugs and steamers diverged from their course to greet the strange object with vigorous and prolonged blasts of their steam whistles. The obelisk reached the landing stage at Ninety-sixth Street at 7:15 P.M. The evening was very dark, and it was difficult to adjust the pontoons between the rows of piles. After one or two failures, owing to the swiftly running tide, the job was finally accomplished. As soon as the pontoons were in position their valves were opened to admit water, and in a few minutes the obelisk had been landed on Manhattan.

The next hurdle was the Hudson River Railway tracks skirting the riverbank, which carried passenger trains at frequent intervals, the longest time between trains being only an hour and a half at noon. To have blocked the road for more than two or three hours would have involved serious loss and much inconvenience to travelers. Orders were given by the railway officials to stop all trains at

Disembarking the obelisk from the *Dessoug*

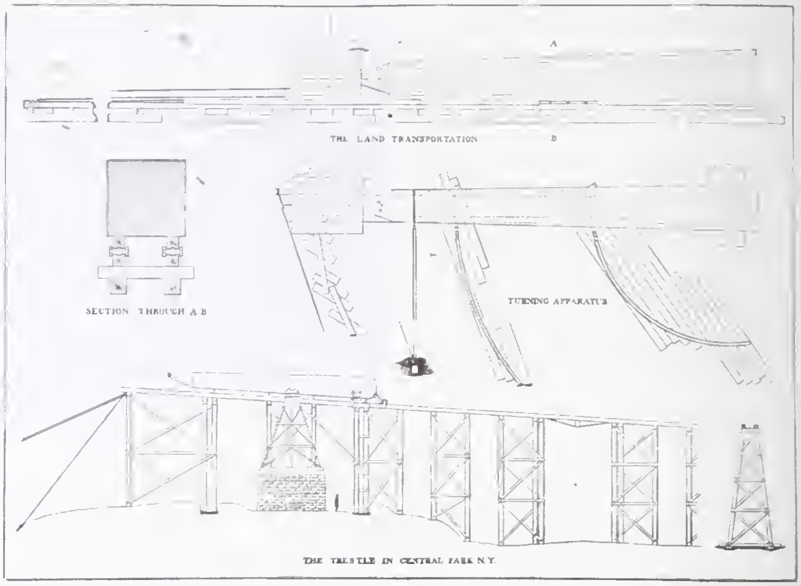
Crossing the Hudson River Railroad

11:00 A.M. Immediately after the passage of the last train, a temporary bridge was thrown across the track and in one hour and twenty minutes the obelisk was resting on the roadway of Ninety-sixth Street. One freight train had been delayed twenty-five minutes. The regular passenger trains were not delayed at all.

Gorringe first tried rolling the obelisk on cannon balls in iron channels, but the channels crushed under the weight, and he could find no economic way to reinforce them. So he reverted to the ordinary cradle, rollers, and track of a marine railway. The traction to be overcome averaged 38 tons—that is, the strain on the purchase was equal to a lift of 38 tons before inertia and friction could be overcome. To keep the cradle from slipping back in case the rope or anything connected with the pulling purchase should give way, men were stationed in the rear of the obelisk with large iron wedges, held close against the rollers. The least retrograde movement could be caught by the points of the wedges, and the weight of the large end of the obelisk would then act as a brake.

Rainy weather, difficulty in finding suitable men, and other varied factors delayed the work, and the obelisk did not reach West Boulevard until October 27. A heavy fall of snow on December 28, followed by intense cold, delayed the operation of hauling the obelisk into its trestle. It wasn't till January 5, 1881, that the center of gravity was placed directly over the axis of the pedestal and foundation, and the tedious land journey was completed. In the end it had taken 112 days to travel the 10,905 feet to the knoll in Central Park, at the rate of about 97 feet a day.

On January 15 the obelisk was lowered from the trestle by hydraulic pumps until its entire weight rested on trunnions in the turning structure. When tested, the obelisk turned easily in either direction. As the bottom of the obelisk was imperfect from injuries received in ancient



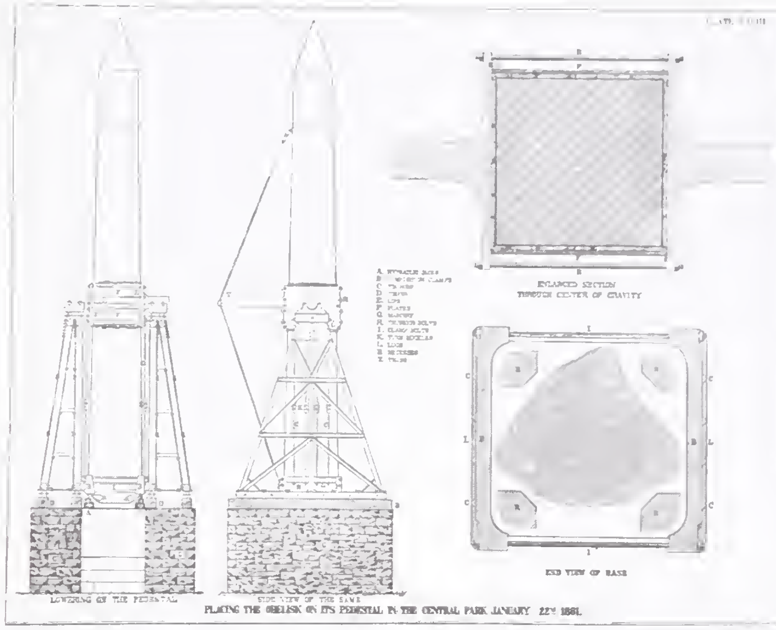
Gorringe's plan for land transportation

Trestle crossing the main drive in Central Park

times, and not more than two-thirds of its area would come in contact with the pedestal, Gorringe decided to give it maximum stability by supporting its corners with four bronze crabs exactly like the ones used by the Romans. These were cast at Gorringe's own expense from plaster models of the originals by a sculptor, Theodor Baur, who endeavored to make them as nearly as possible the same as the crabs cast by the Romans nineteen centuries earlier, and they averaged 922 pounds each. More than merely ornamental, they gave the obelisk an added bearing surface on the pedestal so that it would require a severe earthquake to budge it.

On January 22, long before the hour fixed for turning the obelisk, spectators occupied every available space in the park and its vicinity from which a good view could be obtained. In spite of the piercing cold wind and thick bed of snow that lay on the ground, Gorringe noted that ladies formed at least half of the estimated ten thousand per-

Machinery for placing the obelisk on its base on February 22, 1881



sons who came to witness the erection. A cordon of park keepers encircled the immediate vicinity of the site, and with difficulty kept the crowd from encroaching within the space reserved for workmen. A platform had been raised on the north side of this space to accommodate distinguished persons and officials, guarded by a battalion of sailors and marines from the Brooklyn Navy Yard, who arrived at the park a little before noon, headed by the Marine band.

Five thousand cards had been issued as a souvenir of the event, bearing on one side a picture of the obelisk as it had stood in Alexandria, and on the other an announcement that it would be placed on its pedestal in Central Park at noon. The mayor, the aldermen, and other officers of the city, many of the civil and judicial officers of the state, many civil, judicial, army, and navy officers of the United States, nearly all of the foreign consuls residing in New York, a large delegation of the members of the Grand Lodge, almost all the members of the Anglo-Saxon Lodge in a body, and a large number of distinguished citizens and professional men, accompanied by their wives and families, crowded onto the platform. A few minutes before noon the Honorable William M. Evarts, secretary of state, the Honorable Nathan Goff, Jr., secretary of the navy, and Mr. William Henry Hulbert, editor of the *New York World,* drove up to the foot of Graywacke Knoll, and took positions reserved for them on the platform.

As Fontana had instructed the workmen in Saint Peter's Square, the men now handling the raising tackle and those handling the withholding tackle had been told, respectively, to haul and slack away only when Gorringe held up his hand, and for as long as it was held up, and to stop as soon as he lowered it.

After a moment's conversation with Evarts, the signal was given, and 220 tons of obelisk slowly turned, while the spectators preserved a silence that was almost unnatural. When the obelisk reached an angle of 45°, Gorringe gave the signal to stop so that it could be photographed. This broke the spell, and when the obelisk resumed its motion, a loud cheer went up which was prolonged until the shaft stood erect, and the Marine band played national airs while the sailors presented arms. Only five minutes after the first signal was given, the obelisk was vertical on its pedestal. Congratulations followed, and the spectators dispersed.

Turning the obelisk

A number of lead boxes of different shapes and sizes had been prepared to fit into available spaces enclosed by the steps to the base, and into these were placed articles contributed by the various government departments in Washington and by individuals who considered them suitable relics of nineteenth-century civilization in America, such as the *Congressional Directory* for 1880. The Treasury Department sent a full set of medals of U.S. presidents, plus a full set of silver and minor coinage for the year 1880. The Department of the Interior contributed such enlightening items as the *Report of the Commission of Education* for 1877. The War Department sent along the weather record for July, as well as the general orders announcing the death of General Myer. The Navy Department outdid itself with silver medals commemorating its victories in the War of 1812, and a model of an improved anchor.

Gorringe tried to secure a complete system of the newly invented Bell telephone, but failed. When he asked a representative of the American Bible Society to contribute editions of the New Testament, or any part of it, in all the ancient and modern languages and dialects into which it had been translated and published, he was referred to a bookstore where he could buy them. He did; and they were carefully deposited in a lead case, where he hoped "they would be preserved for an indefinite period." To fill vacant spaces in the boxes, a variety of books were inserted, such as *Webster's Unabridged Dictionary,* the works of William Shakespeare, a New York City directory, a map of the city, the *Nautical Almanac, Hayden's Dictionary of Dates,* Wilkinson's *Egypt,* an *Encyclopedia of Mechanics and Engineering,* and a *Compendium of Electricity and Magnetism,* unaware that the ancient Egyptians might have already encoded such secrets in the dimensions of the obelisk.

Fifteen months had elapsed from the day the work of removal had begun in Alexandria. During that time the obelisk had traveled 5,380 miles by water, and 11,520 feet by land; it had been lowered 39 feet, and lifted 230. The expenses, much exceeding the original estimate, ultimately amounted to $102,576. But Gorringe was relieved that his work had been completed with no accident or incident to spoil its success.

The ceremony of formally presenting the obelisk to New York City was fixed for February 22, and the use of the grand hall of the Metropolitan Museum nearby was tendered by the trustees. From noon on, not a train on either of the elevated tracks, nor a car on the several street railways, went uptown that wasn't loaded with passengers. By 2:00 P.M. an estimated twenty thousand people were in Central Park between Graywacke Knoll and the museum, filling all the adjacent walks and drives.

At 2:10 the doors leading to the museum were opened and the holders of tickets were admitted by a platoon of park police specially pressed into service. Gorringe compared it to the crush of a favorite opera night ten times intensified. The mayor, W. R. Grace, was there to receive the gift to the city, seated next to Secretary Evarts, Gorringe, and the president of Columbia University, F.A.P. Barnard. Dr. Crosby, a Protestant minister, began the ceremonies with a prayer somewhat different in tone from that of the Masonic dedication:

"Almighty God, our Heavenly Father, Who hast given to us a goodly heritage in this land of liberty and peace, and hast afforded us opportunity and means for growth in wisdom and knowledge, we desire to lift up our hearts to Thee with Humble and grateful acknowledgment of Thy mercies and to ask for Thy continued favor. We thank Thee for the prosperity of our beloved city, for its health and thrift, for its wealth and enterprise, and for its institutions of charity and education. We thank Thee for the centers of refined culture Thou hast enabled our citizens to establish by which to elevate and enlighten the public mind, and now this day we do give Thee our hearty thanks that Thou hast permitted the enterprise which connects us with an extreme antiquity to be brought to a successful termination; and we pray Thee, most gracious Lord, that those who have been especially instrumental in forwarding this work may be rewarded by seeing its utility, both as an ornament and a teacher among us, adorning the city, while it contrasts our light and privileges with the darkness and tyranny of the older time. We beseech Thee, Almighty God, to accept our petition for Jesus' sake. Amen."

A hymn, which had been adapted to the music of Martin Luther's "Ein' Feste Burg," rang out with greater fidelity to the object of the ceremony:

Great God, to Whom since time began
The world has prayed and striven;
Maker of stars, and earth, and man—
To Thee our praise is given!
Here, by this ancient Sign
Of Thine own Light Divine,
We lift to Thee our eyes,
Thou Dweller of the skies—
Hear us, O God in Heaven!

15. E PLURIBUS UNUM

Masonic lodges were introduced into the American colonies at the time they were being proscribed by Clement XII in 1738. By the beginning of the Revolutionary period, there were lodges in each of the thirteen colonies, including seven Provincial Grand Lodges.

Whether or not the idea for a union of the colonies originated among colonial Freemasons, it was certainly achieved through their leadership. Boston Masons organized the Tea Party at the Green Dragon Tavern, described by Daniel Webster as "the Headquarters of the Revolution" and by the British as "a nest of sedition." Paul Revere was a Master Mason, as was every general officer in the Revolutionary army, starting with Jospeh Warren, Grand Master of the Massachusetts Grand Lodge, the first to die at Bunker Hill. Two thousand more Masons were among officers of all grades, including Catholics and a score of the Jewish faith, such as Colonel Isaac Frank, aide-de-camp to George Washington, and Major Benjamin Nones, on General Lafayette's staff.

Of the fifty-six signers of the Declaration of Independence, some fifty were Masons, as was its prime author, Thomas Jefferson. The same was true of the Constitutional Convention.

In colonial times Freemasonry had been the only institution in which leaders of the different colonies could meet on common ground—Protestant, Catholic, or Jew. Local government differed too widely, from the town-meeting system of Puritan New England to the vestry system of the Southern colonies. In the Lodges men of the most diverse religious and political views, rich and poor, could come together in a spirit of mutual harmony and confidence. Founded on the broad universal principles of the brotherhood of man, the immortality of the soul, and the existence in the universe of a Supreme Architect, the lodge became a sanctuary in which any man, from general to private, could meet on an equal plane—something the princes of the world found hard to tolerate.

As Americans began to rebel against the injustice of George III's government, the lodges became divided into "modern" and "ancient," the former patronized by royal governors and British civil military officers, mostly sympathetic to the Crown; the "ancient," composed primarily of merchants, mechanics, and laborers, was intensely demo-

Drafting the Declaration of Independence

George Washington as a Master Mason

cratic, in favor of independence. With the progress of the war, independent American lodges superseded those of English, Irish, and Scottish jurisdiction.

In Virginia, when the members of Alexandria Lodge No. 22 declared themselves independent of any foreign jurisdiction, they named George Washington as First Master of the Lodge. Washington, at the age of twenty, had been entered on November 4, 1752, as an apprentice Mason in the lodge at Market House in Fredericksburg and nine months later, in his twenty-first year, was raised to the degree of Master. In the midst of hostilities, in 1780, when the idea was suggested at the Grand Lodge of Pennsylvania of creating a Grand Master of all the Grand Lodges formed or to be formed in the United States, George Washington was unanimously elected to fill the post. But the commander in chief, too busy with the war, was obliged to decline.

At last, when peace came, it was the Grand Master of New York's Grand Lodge, Robert Livingston, who administered to Washington his oath of office as first president of the United States. When the cornerstone of the nation's new Capitol was laid on September 18, 1793, the ceremony was performed in concert with the Grand Lodge of

Masons from Lodge 22 parading in Alexandria, Virginia

Maryland and with several lodges under the jurisdiction of Washington's Lodge 22, with the new president clothing himself for the occasion in a Masonic apron and other insignia of the brotherhood.

At George Washington's burial on his estate at Mount Vernon, 20 miles south of the District of Columbia, six of the pallbearers and three of the officiating clergymen were brother Masons from Alexandria Lodge 22. And "the mystic funeral rites of masonry" were performed by the new Grand Master of the Lodge, as, one by one, Washington's Masonic brethren cast upon his bier the ritual sprig of acacia, Osirian symbol of the resurrection of the spirit. On the coffin with two crossed swords was placed the Masonic apron specially made for Washington by the Marquise de Lafayette. So it is not surprising that the idea to raise to Washington's memory the greatest Masonic monument in the world, an obelisk of marble to tower majestically 600 feet above the waters of the Potomac, visible from his home in Mount Vernon, should have been conceived in the minds of America's Freemasons.

Within hours of Washington's death, his fellow Mason, Representative John Marshall of Virginia, later the country's first chief justice, rose in the House and moved that a monument be raised to the man "first in war, first in peace, and first in the hearts of his countrymen." Promptly in both Houses a bill was passed to raise $200,000. But no money was appropriated; and for a quarter of a century no step was taken to implement the resolution. Instead, the infant nation, founded on the tenets of the great liberating movement of northern Europe, which aspired to

Obelisk marking Washington's tomb in Mount Vernon, Virginia

religious liberty and the right of every man to worship God according to the dictates of his conscience, found itself swept by tides of religious intolerance almost as deadly as those of the sixteenth century, and the waves of controversy ebbed and flowed around the building of the monument.

The trouble all started in England in 1797, when a reactionary French Jesuit named Augustin Barruel fled to London from the September massacres of the French Revolution and brought out a five-volume opus, *Memoirs pour servir à l'histoire du Jacobinism,* in which he placed the blame for the bloodbath of the Terror squarely on Freemasons, singling out Saint-Germain, Cagliostro, and Weishaupt as the major Masonic villains. Tracing the slogan of "Liberty and Equality" back to the early Templars, Barruel declared that the secret of Masonry *did* consist in those two words, but that "in the higher degrees the twofold principle of liberty and equality is unequivocally explained not only by *war against kings and thrones,* but by *war against Christ and his altars.*"

POUR

A

L'HISTOIRE

A LONDRES

To Barruel, the Jacobins had instituted the Terror as members of a vast plot to overthrow society and religion, the worst villains being Weishaupt's Illuminati, cuckooed into Freemasonry. In his early volumes, Barruel claimed that a formal and systematic conspiracy against all religion had been formed and zealously prosecuted by the encyclopedists Voltaire, d'Alembert, and Diderot, assisted by Frederick II of Prussia. In his third volume Barruel attached the "wickedest anti-Christian conspirators: devoted to atheism, universal anarchy and the destruction of property, boring from within to undermine every government, wishing for the nations of the earth to be directed from their nocturnal clubs." Imagine, wrote Barruel, "thousands of lodge rooms converted into nests of human vipers, men possessing warped intellects with one uncontrollable impulse surging through their arteries—destruction! destruction! destruction!—and you will be getting down to the true cause of the holocaust which drenched the French nation in human blood."

Barruel charged that not only the lower orders of Masonry were duped by Weishaupt, but also those of Weishaupt's own Illuminati, for whom he had provided another top-secret level of direction known as the Aeopagus, a withdrawn circle of directors of the whole order, who alone knew its secret aims. To Barruel, such revolutionary leaders as La Rochefoucauld, Lafayette, and the duc d'Orléans, had become Illuminati agents and dupes of the more extreme radicals such as Danton, provocateurs who sparked the Illuminati-directed rebellion. Barruel further charged that the entire French Masonic establishment had been converted to Weishaupt's revolutionary ideas, its lodges turned into secret committees which planned bloodshed. "Masonic units, dotted by the thousands all over the map of Europe, were thus transformed into places of anarchy, devoted to creating mob violence."

In his fourth and fifth volumes, Barruel went into the minutiae of how the holocaust had been carefully plotted in a secret meeting between Saint-Germain and Cagliostro, who had organized "six hundred thousand masons into a conspiracy with the duc d'Orléans as the chief villain, ambitious to possess the throne of France." Barruel attributed to Saint-Germain, Cagliostro, and Weishaupt the deliberate steering of the Revolution into the Terror. "The power to govern France was vested in the *Comité de Salut Public* composed of three hundred men, all leaders in the Illuminated Order." And, according to Barruel, these same Illuminati had spread to America and infiltrated American Masonry.

Jefferson, after reading one volume of Barruel's *memoirs,* called it "the ravings of a Bedlamite." Historian Vernon Stauffer, more politely dismisses the connection between Illuminati and the French Revolution as "suffering from the fatal defect of lack of historical proof." And John Morris Roberts, in his recent *The Mythology of Secret Societies,* sums up the conclusions of more rational historians: "It is difficult to grasp, let alone understand, the success—and enduring success—of this farrago of nonsense." Not only, says Roberts, does Barruel "mistranscribe and misreport," he is "careless about ideological and doctrinal distinctions. He wrote nonsense about Swedenborg and the Martinists, and he cribs, uncritically, stories which weaken his case in the eyes of anyone who has some acquaintance with the world of which he is writing." And yet, Roberts concludes, almost audibly sighing: "Few objective scholars have dictated the shape of their subject for so long as this unbalanced and indiscriminate priest."

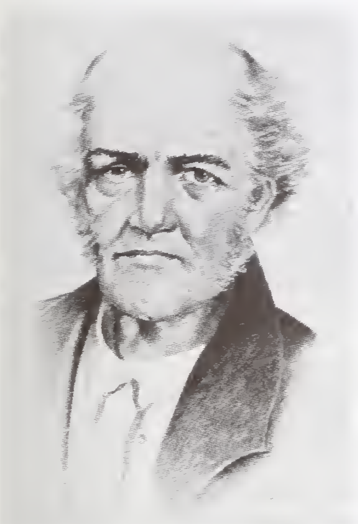
Hardly was Barruel's book off the presses in England when a Scottish Freemason, John Robinson, professor of natural philosophy at the University of Edinburgh, with the excuse that he was anxious to disculpate English Masonry from having been involved in the French Revolution, brought out a sequel echoing Barruel's "data" in *Proofs of Conspiracy Against All the Religions and Governments of Europe, Carried on in the Secret Meetings of Free Masons, Illuminati and Reading Societies*. The book was a quick best seller; with the result that as further editions were brought out in Edinburgh, Dublin, and New York, a wave of anti-Masonic and anti-Illuminist feeling spread across America, carefully enflamed by Barruel's brother Jesuits. Even Washington was accused of having been an Illuminatus, and was obliged publicly to play down his Masonic connections.

President George Washington in the Alexandria Masonic lodge

When, in 1799, a German minister, G. W. Snyder, sent Washington a copy of Robinson's book with the warning that the Illuminati were preparing to "overthrow all government and religion," asking the ex-president to prevent the plan from "corrupting the Bretheren of the English Lodges over which you preside," Washington replied that he had heard "much of the nefarious and dangerous plan and doctrines of the Illuminati, but never saw the book until you were pleased to send it to me." Subtly, Washington added that he wished to "correct an error you have run into, of my presiding over the English Lodges in this country. The fact is, I preside over none, nor have I been in one, more than once or twice, within the last thirty years—I believe notwithstanding, that none of the Lodges in this country are contaminated with the principles ascribed to the society of the Illuminati." All of which was palpably true, though perhaps somewhat sophistical, as the lodges to which Washington belonged after 1776 were not English, but American.

In another letter, written a month later, Washington further corrected Snyder's misunderstanding. "It was not my intention to doubt that the doctrines of the Illuminati, and principles of Jacobinism, had not spread in the United States. On the contrary, no one is more fully satisfied of this fact than I am. The idea that I meant to convey was that I did not believe that the Lodges of Freemasons in *this* country had, as societies, endeavoured to propagate the diabolical tenets of the first, or pernicious principles of the latter, (if they are susceptible of separation). That *individuals of them* may have done it, or that the founder, or instrument employed to found the Democratic societies in the United States, may have had these objects—and actually, in my view, had a separation of the people from their government, is too evident to be questioned.'' And although the next four presidents of the United States were all Masons, an organized surge of anti-Masonic feeling swept the country, threatening the institutions of Masonry and testing the fidelity of its members. To be seen wearing a Masonic emblem meant risking social ostracism.

In these circumstances, the prospect of erecting a Masonic monument to Washington grew dimmer. On January 15, 1824, Representative James Buchanan (later president) proposed that something be done about the 1799 resolution. His proposal was tabled. And even when John Quincy Adams, the first non-Masonic president, reminded the members of Congress of the resolution in December 1825, no action whatsoever was taken.



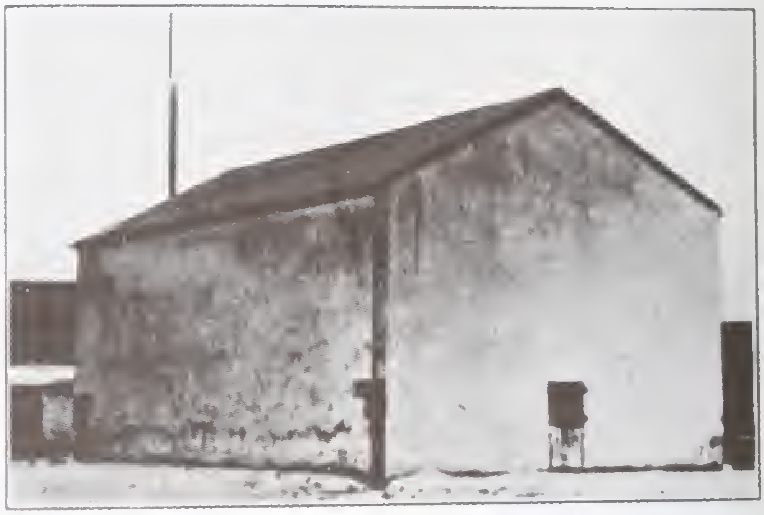
William Morgan

In the country the anti-Masonic movement had increased as there came into being the first third party in American politics, the Anti-Masonic party, which grew rapidly as a result of the hysteria generated by the disappearance in 1826 of a brick mason named William Morgan, little known other than for his penchant for the bottle, and for a dubious past as a Mason. In May 1825 Morgan had been mistakenly exalted to the degree of Royal Arch Mason in Batavia, New York, on the basis of his oath that he had received the earlier necessary degrees in Canada, where the Masonic ritual was somewhat different. But Morgan's drinking habits and his financial looseness aroused suspicion, and when it was established that he had not been initiated into the lower degrees, he was dropped from the order. In revenge, Morgan decided to publish a book containing the ritual secrets of Freemasonry, for which he obtained a contract from a printer of the *Batavia Republican Advocate,* also a former Mason who had failed to advance in his lodge in Albany, and ever since had cherished a grudge against the brotherhood.

As Morgan set to work on his book, keeping the local barrooms advised of his progress, feeling began to run high among Masons that a stop should be put to what they considered Morgan's treachery. News of the intended publication finally roused Masons in New York State to take action, though most counseled that if the book were greeted with silence it might become stillborn.

John Whitney, an ardent New York Mason, incensed by Morgan's behavior, went to Governor De Witt Clinton, Grand Master of New York Masons, but was advised to purchase Morgan's manuscript, for which $1,000 would be made available, and warned to do nothing that might conflict with the law.

On September 11, 1826, Morgan was arrested on a warrant sworn out by a tavern keeper in Canandaigua, New York, and charged with theft. Acquitted, he was re-arrested for a debt of $2.68 and jailed for his inability to pay. On September 12, Morgan was released on payment of the sum by a third party, who, with several companions, drove Morgan away in a coach. Morgan was later traced to Fort Niagara, where he had been confined in an unused military depot. Thereafter he disappeared completely. As



Depressing military depot where Morgan was held captive

a *cause célèbre* for anti-Masonic propaganda, the disappearance was a true bonanza. A great cry was raised, and his abductors were accused of being Masonic murderers, fulfilling their secret oath to dispose of traitors in the most gruesome way. According to formal allegations of the Anti-Masonic party, the ritual manner of inflicting death on traitors among Masons was "cutting the throat and tearing out the tongue, tearing out the heart, severing, quartering and disemboweling the body, and burning the ashes—tearing the breast open, and throwing the heart on a dunghill to rot—smiting the skull off, and exposing the brains to the sun—pulling down the house of the offender, and hanging him on one of the timbers—striking the head off, and placing it on a lofty spire—tearing out the eyes, chopping off the hands, quartering the body, and throwing it among the rubbish of the Temple."

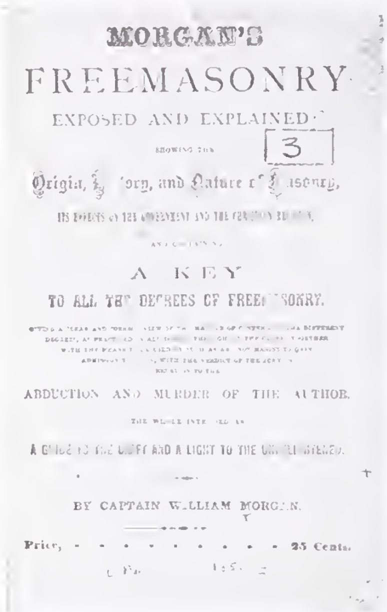
To calm a population outraged by this further "farrago of nonsense," Governor Clinton issued three successive proclamations urging all good citizens to cooperate with the authorities in helping to find Morgan and punish his abductors. A $2,000 reward was offered for information leading to his recovery and for bringing to justice his assailants. A free pardon was offered to anyone involved who would uncover the offenders.

The discovery that certain Masons had arranged for the change of horses and drivers for the 125-mile drive from Canandaigua to Fort Niagara, brought jail sentences to those involved. And every possible effort was made to prove as murderers these Masons; only lack of a body made it impossible. When a man's corpse was washed ashore on the beach of Oak Orchard Harbor, New York, about 40 miles below Fort Niagara, Morgan's widow, though she admitted the clothes were not those of her husband, expressed belief that the body might be his. But whereas Morgan had been bald, with a smooth face and the peculiarity of long white hairs in his ears and nostrils, this body had a heavy beard and a full head of hair.

To remedy the discrepancy, a leading member of the Anti-Masonic party, Thurlow Weed, editor of a Rochester paper, present at the inquest, was accused of having had the corpse shaved and hairs plucked from his forehead to thrust into its ears and nostrils. Result: a verdict that the body was Morgan's. Publicity about the verdict, as it brought on another wave of anti-Masonic outrage in the country, also brought to Oak Orchard Harbor the widow of a man, Timothy Munroe, who had fallen from a boat and drowned. So minutely did the widow describe the clothing worn by her husband and so accurately did the details tally with marks she said were identifiable on his body, that another inquest was ordered and the verdict reversed. The corpse was declared to be that of Munroe.

Of Morgan, nothing more was heard, and though stories continued to be circulated that a group of Masons had drawn lots to dump him in the river with a weight around his neck, Masons stuck to the story that Morgan had been taken across the river to Canada, where Canadian Masons near Hamilton, Ontario had given him $500 to make himself scarce—after which he had disappeared without a trace.

Not that the disappearance of Morgan did anything to halt publication of what was purported to be his book, put together by Miller, his contractual publisher, from manuscripts in the possession of his widow. To arouse sympathy and to publicize the book, Miller even appears to have set fire to his printshop, for which he was then indicted.



MORGAN'S
FREEMASONRY
EXPOSED AND EXPLAINED:
3
A KEY
ABDUCTION AND MURDER OF THE AUTHOR.
BY CAPTAIN WILLIAM MORGAN.
Price, 25 Cents.

The book, quickly pirated, sold by the hundreds of thousands of copies, adding fuel to the anti-Masonic blaze.

That one such disappearance could bring down the wrath of a whole country on the Brotherhood of Masons, whereas the Church could historically be held responsible for several million agonized deaths under torture and execution, seemed to Masons unaccountably unequitable, especially as no other "ritual murder" could be attributed to American Masons, who pointed out that by their own code of ethics, they, above all, were bound to obey the law of the land, "with respect for God, country and their fellow men."

Clearly, the Morgan incident had only been a spark, like Marie Antoinette's affair of the diamond necklace, which lighted a well-prepared pyre designed to destroy the fraternity. Social, racial, religious, and political forces had been working beneath the surface to capitalize on the frenzy of the anti-Masonic movement.

Conventions of anti-Masons convened throughout the country, to sweep anti-Masonic candidates into office. Again the principal ammunition at these conventions were the works of Barruel and Robinson, freely excerpted and produced as the sacrosanct evidence of history. Illuminism, said Ethan Smith, chairman of the Committee on the Connection between French Illuminism and the higher degrees of Free Masonry, at the 1832 anti-Masonic Republican convention in Massachussets, was designed to bind the world with invisible hands, and had been infiltrated into America well before 1786. "Both Robinson and Barruel," said Smith, "testify to the fact. Barruel mentions a lodge of this order in Portsmouth, Virginia, and two lodges as having descended from it. Illuminism exists in this country; and the impious mockery of the sacramental supper, described by Robinson is acted here." Smith then quoted from Christoph Girtanner's book on the French revolution: "active members of the propagandists in 1791 numbered fifty thousand, with funds of thirty millions of livres. They are extended over the face of the world, having for their object the promotion of revolutions, and the doctrines of Atheism. And it is a maxim in their code that it is better to defer their attempts fifty years, than to fail of success through too much precipitation."

Smith also quoted from a printed sermon of a Reverend Dr. Morse, who assured the public of an official communication from the Illuminated lodge Wisdom, of Portsmouth, Virginia, to the Illuminated lodge Union. "The letter," said Smith, "was intercepted. In it were the names of their officers, and the number of their adepts; being then 100, mostly French. In this letter, it appeared that there were thousands of such Lodges of Illuminism in the world; and many in the western world." Smith came to the point of all the fuss: he produced the same charge which had been leveled against Pico, Ficino, Dee, and Cagliostro: Illuminism had been most secretly planted by the side of Speculative Masonry to indulge in *gross infidelity and licentiousness*. Here, at last, was the note needed to enflame a "Christian" opposition.

The churches joined in the general attack, barring Masons from their pulpits as "irreligious." Ministers preached the "satanic nature of the Masonic lodge" and called it incompatible with the Christian faith. Baptists were told to dissolve their ties with Masonry or risk having "the Hand of Christian Fellowship" withdrawn from them. Other denominations announced they would support no Mason for any office in either town, country, or state. Masons were stricken from jury rolls; hostile crowds formed to prevent Masonic meetings; and individuals were so persecuted that in many cases they were driven to emigrate. In the early 1830s, of 227 lodges in New York State, only 41 remained. New York's membership dwindled from 20,000 at the time of the Morgan incident to a mere 3,000. All the lodges in Vermont surrendered their charters, and it was the same in all the other states of the Union. As one historian sums up the carnage: The Temple of Masonry was shattered, the brotherhood scattered.

Many politicians campaigned on an anti-Masonic platform and rose to eminence, such as Millard Fillmore, who worked his way up to the White House, and William H. Seward, governor of New York and a United States senator, who narrowly failed to occupy the White House, but was to become Lincoln's secretary of state. There was a slight respite when Andrew Jackson, Grand Master of Masons in Tennessee, was elected president for a second term; and then gradually the halls of Masonry once more began to throng with candidates who, after the lesson of Morgan, were more warily chosen from among those whose "pure lives and characters would make them an ornament to the order." As the lodges multiplied, Grand Master James Willard was able to announce that thanks to the constancy of members, Freemasonry was once more held in respect and honor in the country, as was the memory of its founder, George Washington.

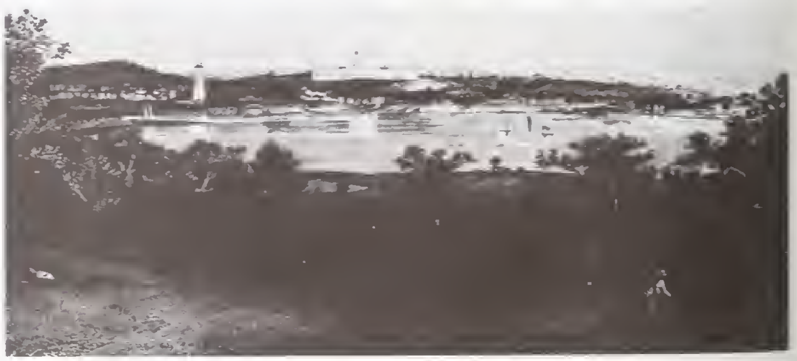
In Washington, D.C., what was described as "a number of patriotic citizens" assembled to revive the plan for erecting a national monument, asking for voluntary contributions from all the people, rich and poor, in the amount of

Washington, D.C. in the 1830s, showing Navy Yard and Capitol

$1 each. That this group, which called itself the Washington National Monument Society, was fundamentally Masonic is evidenced by its first president, Washington's brother Mason, Chief Justice John Marshall.

Ads were placed by the society to elicit designs from American artists for a monument "harmoniously to blend durability, simplicity and grandeur" at an estimated cost of $1 million. As to form, there was no limitation, but, as might be expected, a committee selected the design of Freemason Robert Mills for a 600-foot obelisk surrounded at its base by an olympian rotunda.

By 1847 the society had collected and gained from judicious investments a total of $87,000, and seemed on its way to success. A liberalizing trend in the country echoed a similar trend in Europe, especially with the election to the papacy in 1846 of Giovanni Maria Mastai-Ferretti. As Pius IX, the new pope auspiciously inaugurated his reign with a political amnesty and several badly needed reforms in the judicial and financial systems of the Papal States, proverbially the worst run in Europe, cutting down ecclesiastical graft. Censorship was mitigated and,



Peaceful capital of the United States at a time of revolutionary ferment in Europe.

Architect Robert Mills's design for a grandiose Washington monument, with an expensive circular colonnaded building (250 feet in diameter and 100 feet high) from which a 70-foot-wide obelisk was to rise 600 feet above the city. The columns were to stand 45 feet high, 12 feet in diameter, surmounted by an entablature 20 feet high, the lot crowned by a massive balustrade.

in March 1848, wonder of wonders, the pontiff promulgated a constitution with a parliament consisting of two chambers, to which many Italian Masons were elected.

In this happy atmosphere the United States Congress passed a resolution authorizing the Washington National Monument Society to erect the obelisk designed by Robert Mills, granting them, as a suitable site to build on, a 30-acre lot overlooking the Potomac south of the White House. There beautiful marble from the Symington Beaver Dam quarries in Baltimore County could easily be brought by water or by rail. The estimated cost of construction was $55,200 for the obelisk and $1,122,000 for the entire job, which Congress agreed to provide.

Mills was authorized to contract for the required material and to have a rail line laid right up to the base of the monument. And so thoroughly had the atmosphere changed that the laying of the cornerstone—a 24,500-

pound block of Maryland marble donated by Freemason Thomas Symington—could be performed with a suitable Masonic ceremony scheduled for July 4, 1848.

Stands were built around the site to make a vast sloping amphitheater of seats. Near the Fourteenth Street Bridge (then called Long Bridge), a triumphal arch was decorated with the same live eagle, now forty years old, which had hailed the arrival of Freemason Lafayette when he had visited the capital twenty years earlier. A parade of carriages led by President James Knox Polk was followed by the Masonic fraternity, headed by their Grand Marshal, J. B. Thomas; and the ceremonies were opened with a prayer led by the Grand Chaplain of the Grand Masonic Lodge of Maryland.

It was a lovely day. Recent rain had laid the dust and turned the sod a fresh green. Bells tolled solemnly as close to twenty thousand people crowded around for the ceremony, fares having been reduced by rail and stagecoach lines into the city.

Among the spectators were past and future presidents Martin van Buren and Millard Fillmore, as well as Mrs. Alexander Hamilton, Mrs. John Quincy Adams, and a delegation of Indians with whom George Washington had originally signed treaties of peace. Benjamin B. French, Grand Master of the Grand Lodge of Free and Accepted Masons of the District of Columbia, deposited articles in a cavity beneath the stone using the same gavel and wearing the same Masonic apron and sash worn by George Washington when he laid the cornerstone of the Capitol in 1793.

Having applied the square, level, and plumb to see that the stone was "well laid, true and trusty," the Grand Master placed on the stone the ancient Masonic elements

Masonic ceremony laying the cornerstone with the same silver trowel used by Washington to start the capital in 1793 of consecration: corn for plenty, wine for joy, oil for health. He then turned to his brother Mason, Robert Mills, and presented him with the square, level, and plumb, the working tools he was to use in the erection of this monument, saying: "You, as a Freemason, know to what they morally allude: the plumb admonishes us to walk upright in our several stations before God and man, the square to square our actions with the square of virtue, remembering that we are traveling upon the level of time to that 'undiscover'd country from whose bourne no traveller returns.'"

The Honorable Robert C. Winthrop, Speaker of the House, then delivered an address which reflected the encouraging political mood of the times, alluding to the rash of liberating revolutions of 1848 as the "mighty movements which have recently taken place on the continent of Europe, where events which would have given character to an age have been crowded within the changes of a moon." In these changes, said Winthrop, "we see the influence of our own institutions . . . we behold in them the results of our own example. We recognize them as the spontaneous germination and growth of seeds which have been wafted over the ocean, for half a century past, from our own original Liberty tree."

Handsome, but epileptic, Pius IX managed by his Jesuitically enflamed "ultramontanism" to concentrate all ecclesiastical power in the person of the Roman pontiff. By 1870 the Vatican Council had squashed all the independent power of the bishops, who lost their autonomous standing and became mere papal delegates. Pius then proclaimed the dogma of the infallibility of popes and the much-disputed notion of the immaculate conception of the Virgin (to whom he wished to raise an obelisk but instead erected a great pillar opposite the Office of the Propagation of the Faith).

That the occasion was intentionally and intensely Masonic was unmistakable from Winthrop's words: "Everywhere the people are heard calling their rulers to account and holding them to a just reponsibility. Everywhere the cry is raised for the elective franchise, the trial by jury, the freedom of the press, written constitutions, representative systems, republican forms." And in an unusual tribute to Pius IX, Winthrop continued: "In some cases, most fortunately, the rulers themselves have not escaped some reasonable symptoms of the pervading fervor for freedom, and have nobly anticipated the demands of their subjects. To the sovereign pontiff of the Roman States in particular belongs the honor of having led the way in the great movement of the day, and no American will withhold from him a cordial tribute of respect and admiration for whatever he has done or designed for the regeneration of Italy. Glorious indeed on the page of history will be the name of Pius IX if the rise of another Rome shall be traced to his wise and liberal policy."

But this was not to be. In November of that same year Pius fled from the republic of Rome to the Kingdom of Naples, and there, completely reversing his liberal policy, threw himself into the arms of the Jesuits, calling on France and Austria to help him back into power. Rein-

Column raised by Pius IX in honor of the Virgin Mary

stated in Rome with foreign bayonets in April 1850, Pius inaugurated as violent an antiliberal reaction as had occurred after the defeat of Napoleon in 1815 and one which was to swing the political pendulum to the farthest opposite extreme. Absolute autocracy was restored in the Papal States, and anyone could be thrown into Castel Sant'Angelo without a trial.

By 1851 Pius showed the absolutist direction he was taking by proclaiming Roman Catholicism as the sole religion of the Spanish people, to the exclusion of all other creeds, a principle which was then applied to Latin America with the hope of doing likewise in North America. By 1854 Pius, well on his way to announcing his stunning dogma of the infallibility of popes—an idea strongly disputed by a great many Catholic bishops—defied the whole trend of liberal thought by branding as false the basic beliefs of democracy and liberalism. Reinforcing his predecessors' bans against Masonry, Pius attacked public education, free libraries, and the right of men and women to choose their own religion, claiming for the Catholic Church control of all culture, all science, and all systems of education, declaring: "The pontiff neither can nor ought to be reconciled with progress, liberalism and modern civilization."

Arguing that the Son of God had established one religion and imposed on all men the obligation of embracing it, Pius branded all Protestants and Jews as heretics, doomed to damnation, there being no salvation outside the Roman Church. Catholics were forbidden to read certain books or to discuss their religion without approval of a priest, who, in turn, could be reprimanded and punished for proposing mercy for heretics. Catholics were to be held to the dogma that hellfire was real, and that the unfortunate non-Catholic damned would never lose consciousness of their torment throughout all eternity.

Unashamed, the pontiff declared himself to be Father of Princes and Kings, Ruler of the World, Viceroy of the Lord Jesus Christ, claiming for himself absolute political power and declaring it to be the duty of all states to carry out orders from Rome, that only the Roman Church could decide whether a law was "good" or "bad" and that obedience to a law unpleasing to the pontiff was not binding on the citizens of any state.

Summed up, these clearly expressed political principles of the Roman Catholic Church, to which was applied the epithet *ultramontanism,* appeared formidable to American Masons. According to Pius IX's famous *Syllabus Errorum,* the ultimate source of law and government in the United

States lay not in the people but in the "will of God as interpreted and expressed by the Pope." The primary and ultimate functions of the government of the United States were to carry out the principles of the Roman Church as promulgated by the pope. Freedom of speech and the press were to be permitted only to the extent they did not interfere with the principles and activities of the Roman Church. Public funds were to be used to support the Catholic Church and its schools. Most alarming, Catholics who were citizens of the United States owed a primary political allegiance to the Roman Catholic pontiff who could lawfully use force to overthrow their government. Catholics were not to approve a policy of separation of Church and State, and states had no right to legislate in matters such as marriages, only to be recognized by the Church, which forbade contraception and abortion even if required to save a mother. A leading Jesuit writer in the United States classed with prostitutes those American wives who used contraception, and called them "daughters of joy," maintaining that birth control resulted in sin which was no more than mutual masturbation.

All of which, not unnaturally, was unpalatable to American democrats, especially when the Catholic clergy insisted that the laws of Rome superseded the laws of the republic, and that Catholics were duty-bound to force all people into the pattern laid down by the Church. What made the system intolerable to its opponents was the fact that Catholics in America had no say whatsoever in the choice of their own priests, bishops, or cardinals, all of whom were appointed from Rome to perpetuate the system of management and control, bishops being deliberately selected for their subservience to the Vatican. The country began to be flooded with Catholic immigrants—as many as 300,000 a year, mostly poor, illiterate, and superstitious—Irishmen fleeing the potato famine, or Germans escaping crop failures and political persecution, all under the control of foreign priests. American Protestants found themselves faced with an army officered by disciplined bishops under a single omnipotent commander in chief whose chiefs of staff were the Jesuit generals. Whereas at the time of the founding of the republic there had been perhaps 1 percent of Catholics in the colonies, now there were as many as 10 percent who could effectively influence elections in which Yankees could even find themselves reduced to minorities. As the established Protestants saw their longtime position of privilege being eroded, religious intolerance flared up to a degree almost comparable with the horrors of the Counter-Reformation.

The country was flooded with salacious literature accusing priests of seducing their pretty penitents.

Protestant ministers rose in their pulpits to denounce Catholics as un-American because they were obliged to take orders from an autocratic, antidemocratic foreign power. These ministers, believing in human sinfulness and predestined damnation, became, in the words of historian Carleton Beals, "a band of neck-swollen, hate-mongering tub thumpers." In the streets scores of Protestant antipapist magazines began to appear, and masses of anti-Catholic literature were put out by Protestant Bible societies. As sex was the easiest and most obvious peg on which to hang an inflamed propaganda, religious presses gave free reign to stories of secret orgies in nunneries, the rape of young girls by priests, the killing of bastard babies, with headlines such as "Six Thousand Babies' Heads Found in a Nunnery Fishpond." Most popular were the "confessions" of escaped nuns who described being forced into carnal intercourse with priests. *Awful Disclosures* by Maria Monk, the joint effort of "a disordered whore and unprincipled religious demagogue," sold 300,000 copies before the Civil War.

When a Catholic priest in Carbean, New York, outraged at the distribution of Protestant Bibles to his parishioners, angrily burned several copies publicly, the whole country reacted. Nor did it help when Bishop Hughes of New York defended the act, saying: "To destroy a spurious corrupt copy of the Bible was justified and praiseworthy." Described by pro-Catholic Carleton Beals as "pretty much a Torquemada deprived of rack and screw and hot irons," Bishop Hughes gave an outrageous sermon in Saint Patrick's Cathedral, boasting that the pagan and Protestant nations were crumbling before the force of Rome.

"The true Church," thundered the bishop, "would convert all Pagan nations, even England, with her proud Parliament. . . . Everybody should know that we have for our mission to convert the world—including all inhabitants of the United States—the people of the cities, and the people of the country, the officers of the Navy and the Marines, commanders of the Army, the legislatures, the Senate, the Cabinet, the President and all."

To counter the bishop, his opponents made use of a firebrand named Allessandro Gavazzi, a former priest and teacher turned revolutionist who had fled from Italy to the United States under the auspices of The American and Christian Foreign Church Union, a scandal-making organization formed to fight the "Corrupting Catholic Church." Gavazzi wanted nothing but to annihilate the papacy, and swore to devote his life to "stripping the Roman harlot of her barb." Although a renegade, he wore a long monk's robe embroidered with a blazing cross. Six feet tall, with an "almost savage physical energy," he caused riots wherever he went.

Protestants turned against Catholics as they had against Baptists, Methodists, Shakers, and Quakers, using the same methods of "torture, whippings, brandings, arson and murder, looting and raping in the name of the democracy they claimed to support." Everywhere "native" American parties began to mushroom, waving the Stars and Stripes, and raising up mobs to burn Catholic convents, churches, houses; to assault nuns and murder Irish and other European immigrants. As the nation became torn with bitter sectionalism and seething social unrest, there was repeated rioting, in Boston, New York, Philadelphia,

Opening battle between the Bowery Boys (Know-Nothings) and the Dead Rabbits (Tammanies) from Beals's *Brass-Knuckle Crusade*

A contemporary print illustrating the Astor Theatre riot of 1849

Baltimore, Providence, Hartford, New Orleans, Saint Louis, Cincinnati, Louisville, and San Francisco.

According to Herbert Asbury in his *The Gangs of New York,* at least thirty thousand men in the city were active members of gangs, and not only men but women fought in the streets. "One notorious female," says Carleton Beals in *Brass-Knuckle Crusade,* his description of early fascism in America, "carried a tomahawk, knife, and gun and wore boots cleated with broken glass. Another sheathed her nails in steel and filed her teeth to needle point. *Hell Cat Maggie,* they called her." Tammany Hall's "Sons of Saint Tamina," started, as Beals says, "by hatchetman Aaron Burr who first made secret gangsterism into a political system," found themselves pitted against Protestant bully clubs who sought to control the polling booths with sticks, knives, and guns.

That the times were rough is evidenced by miscreants in New Jersey being branded on the cheek and given public floggings. A girl convicted of petty theft was sentenced to 210 lashes on her bare back. Joseph Smith, founder of the Mormons, taken by a mob from an Illinois jail, was murdered, as was his brother. Abolitionists were dragged through the streets at the end of ropes and frequently killed. Southern states imposed the death penalty for preaching to "blacks" or teaching them to read and write. And, although Washington, in his will, had emancipated his slaves and left a trust fund for their education and for the schooling of their children, the Bible Society refused to send Bibles to slaves.

As the whole country, aroused by the fervor of prejudice, prepared to square off for the bloodiest civil war in history, there came into being a secret society known as the Supreme Order of the Star-Spangled Banner. To avoid the Constitutional guarantee of religious freedom, its members pledged to vote only for non-Catholics selected by their secret upper tier caucuses, swearing never to betray the society's secrets, under pain of expulsion and implied penalty of death, and to deny affiliation by replying to the curious with the simple phrase: "I know nothing." Multiplying like rabbits, they soon numbered five million members, with new ones enrolled at the rate of five thousand a week. By 1855 they were a power in the land, controlling Maryland, Delaware, Kentucky, New Jersey, Pennsylvania, California, all but one of the New England states, and nearly every state in the South. Millard Fillmore became president standing on the Know-Nothing platform, and U. S. Grant rose to fame in the same way. But the proudest "claim" of the Know-Nothings was that George Washington had been the first of their party, citing his apocryphal words at Valley Forge: "Tonight let none but native-born Americans stand guard."

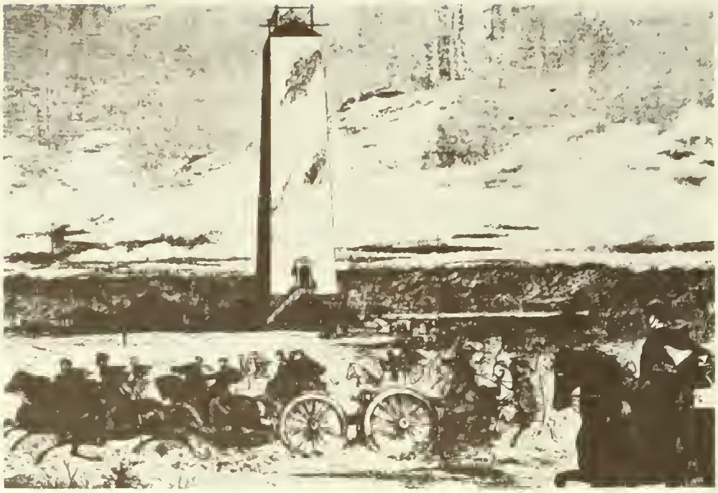
Unwittingly they were to do their assumed hero a gross disservice. By this time the Washington Monument had reached a height of 170 feet at a cost of $230,000. But the Washington National Monument Society, complaining that the turmoil of the times had dried up subscriptions, appealed for money to the various states. Alabama replied that it could give no money, but offered to contribute a stone of the requisite dimension—4 feet by 2 feet, by 1½ feet. Other states followed suit, including municipalities and associations, as did foreign governments such as Switzerland, Turkey, Greece, China, Japan, and the Vatican—from which Pius IX sent a block of marble, ironically taken from the Pagan Temple of Concord in Rome.

But even these contributions were nowhere near sufficient to do the job, and the society's board of managers appealed to Congress to take whatever action it deemed proper. A select committee recommended a subscription of $200,000, the exact sum originally voted in 1799, but never provided. It too was to be canceled, by the occurrence of an extraordinary event.

On March 6, 1855, between 1:00 and 2:00 A.M., a group of men rushed out of the darkness round the foot of the monument and seized the night watchman, whom they locked up in his shack, so as to break into a shed where the pope's stone was boxed. With skids, bars, and blocks they rolled the stone out to a scow in the nearby canal basin, then ferried it out into the Potomac almost to Long Bridge, and dumped it.

The men, nine members of the Know-Nothing party, had drawn lots for the job, announcing that the marble block represented "a designing, crafty, subtle scheme of the

Union artillery, horse-drawn past the abandoned monument as the country prepared for war



far-reaching power that was grasping after the whole world to sway its iron scepter with bloodstained hands over the millions of its inhabitants." The same night a group of about 750 members of the Know-Nothings, many of whom had surreptitiously joined the Washington National Monument Society, called a meeting and voted their own officers into control of the society, defenestrating the others. On the morrow Know-Nothings announced they were in possession of the Washington Monument. Congress's reaction was speedy. They tabled the recommended appropriation, effectively killing it.

The disappearance of the pope's stone angered "a large body of citizens" and also discouraged further contributions; so all construction ceased. Two weeks later Robert Mills died, and with him went what appeared to have been the last ray of hope for continuing the monument. During the next three years, as the battle continued between the old members of the monument society and the new Know-Nothings, only 13 courses, or 26 feet of masonry were laid, consisting mostly of rubble rejected by the master mason. By 1858, unable to raise any money—in 1855 they only managed to collect $51.66—the Know-Nothings finally surrendered all their records to the original society with the entire treasury of $285. As a national party the Know-Nothings were through.

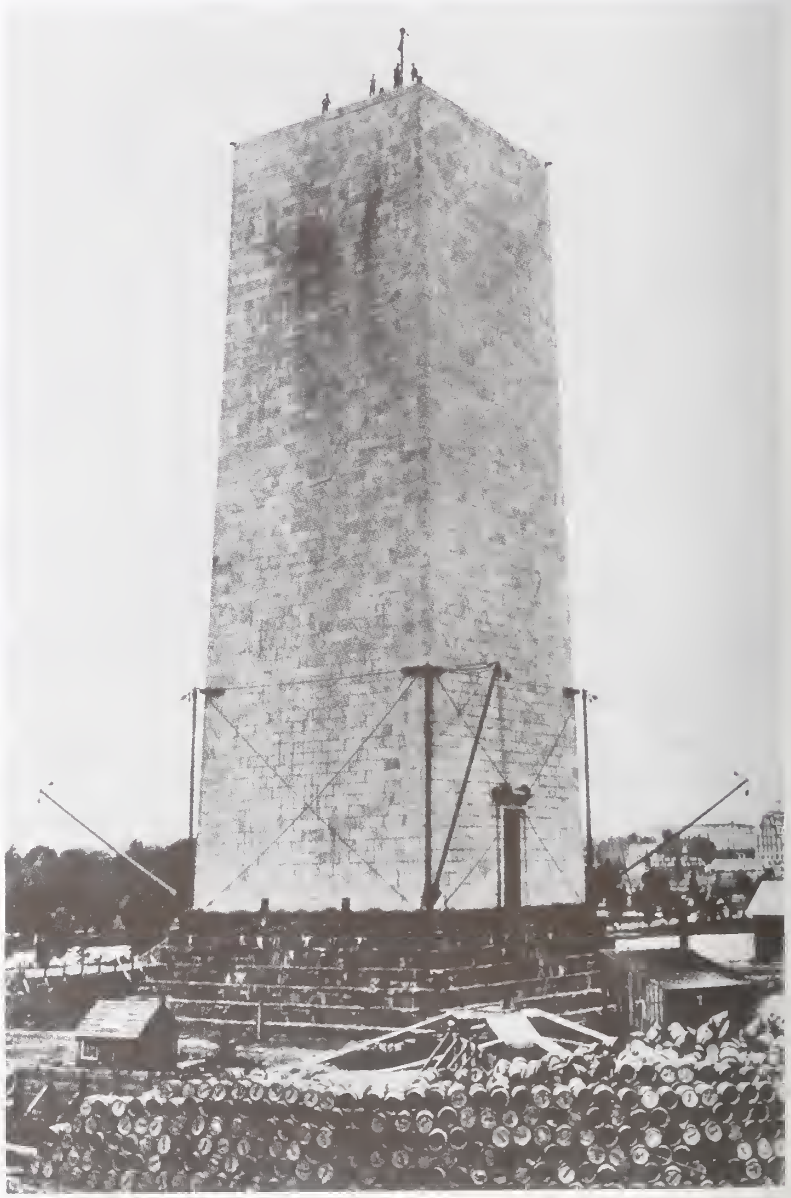
In February 1859, to prevent any recurrence of such events, Congress incorporated the Washington Monument Society with President James Buchanan presiding *ex officio*. But the Civil War was looming, and in all of 1860 the society was only able to collect $88.52, 48 cents of which came from Washington's native Virginia, and 15 cents from Mississippi. With the outbreak of war, the

Cattle grazing around the monument to supply Union troops

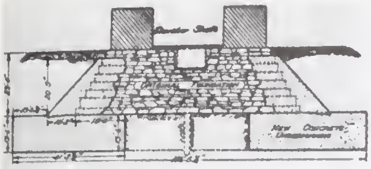
monument stood 176 feet high, less than a third of its prospected height. In the words of Mark Twain, it "looked like a hollow oversized chimney." All construction was halted during the war while the grounds on which it stood were used to graze cattle for the Union commissary.

Following the war these swamplike grounds came to be known as Murderer's Row—"the hangout of escapees, deserters, and other flotsam of the war"; and it wasn't until ten years later, with the approach of the first centennial of independence, that Congress once more went into action. But there was now a real question as to whether to try to continue the building or simply tear it down and write off the quarter of a million dollars already spent. The problem lay in the foundations—81 feet square and 25 feet deep, solid masonry—which was now considered too weak a base onto which to raise the projected 600-foot obelisk. It was feared the structure would sink into the swampy terrain or be blown over by the wind. In the House, there were complaints about asking the people of the United States for money to "finish this unsightly and unstable shaft upon this unsafe foundation . . . this ill-shapen badly put together structure of mixed blocks." It was said that "storms, the uncertain foundation, the swaying to and fro of such a column will sooner or later bring it to earth."

The ignorance of some of the politicians was exemplified by Representative Samuel S. Cox of New York, who pompously declared: "If you raise this obelisk which



Monument's surroundings as a dumping ground and storehouse



Engineers' plan to remove 70 percent of the old foundation and insert a new concrete pad capable of supporting an 82,000-ton shaft

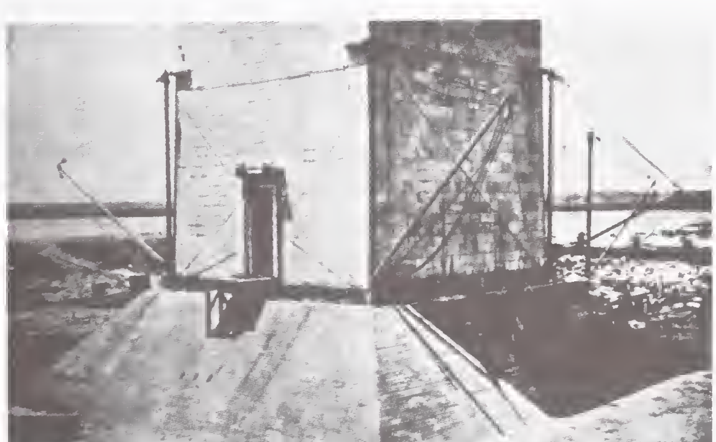
First, the center section of each side was removed and replaced by fresh concrete.

Next, the corners were filled in.

Thirty-six feet beneath the surface, the new foundation weighed 37,000 tons and covered more than three times the previous area.

comes from Egypt, a barbarian country that never had art, I don't believe it will succeed in impressing the American people in a proper way with the virtues and greatness of George Washington." Representative Jasper D. Ward of Illinois argued that the monument had been stopped because "when the unsightly column reared itself so high that they could see it they (the people) did not feel like contributing more to it." John B. Storm of New York, on the other hand, declared that though he might have preferred it had the monument never been started, he was "unwilling that the hundredth anniversary of our existence as a nation should dawn upon us with that monument standing there as a testimony that republics are ungrateful." R. C. McCormick of Arizona agreed that "no greater disgrace, certainly no greater calamity, could possibly befall than that the shaft after once being completed should fall to the ground," but argued that the chief reason for adopting the simple obelisk was its permanency and imperishability. Norton P. Chipman of the District of Columbia backed him up, suggesting there was something special in such a simple, majestic obelisk, "eminently proper as commemorational of the character of Washington, aside from the fact that the early fathers preferred it. . . ."

In the end, Congress appointed an engineer to study the problem and give an estimate for completing the job of raising a simple obelisk, abandoning the expensive pantheon at the base designed by Mills in favor of a massive terrace with a balustrade for statuary, which would cost only $65,000. When the first engineer gave an unfavorable report, the matter was allowed to slide; and only when the actual centennial was at hand did Congress decide to hire another engineer, who after much probing beneath the monument finally agreed it would actually be possible to raise a 600-foot obelisk, provided Congress was willing to



The monument, in 1874, as depicted in *Leslie's Weekly*. Trams were horse-drawn, and the canal was busy with water-borne commerce.

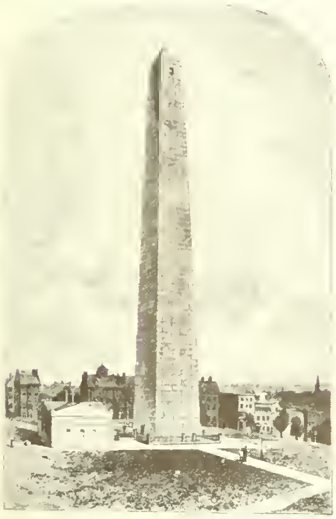
spend the extra money needed to put a whole new foundation beneath the present one. But by now Congress had delayed so long, the centennial was upon them and no real progress had been made.

Not until the first day after the centennial, July 5, 1876, was Senator John Sherman of Ohio able to introduce a resolution asking for $2 million to complete the monument. On August 2, the House dutifully passed the bill to retake possession from the society of the 30 acres and its truncated shaft and appropriate the necessary money to complete the monument.

Some consideration was given to alternative designs, especially one suggested by the American sculptor William Wetmore Story, who wanted to build what he called "an ornamental Lombardy tower," which would have required demolishing 41 feet of the shaft already built, so as to insert several windows. But the advice of George Perkins Marsh, United States minister to Italy, prevailed, and the form of an authentic Egyptian obelisk was retained. However, as nobody knew exactly what constituted an authentic Egyptian obelisk, or in what proportion the pyramidion should stand to the shaft or at what angle, the State Department sent out a circular eliciting information. From Rome, Minister Marsh, an accomplished scholar who had previously been United States consul in Cairo and said he had made sketches of all the known standing obelisks in Egypt, came up with a reply. An obelisk, he warned, was not an arbitrary structure which anyone was free to erect with such form and proportions as might suit his taste and convenience, but that its objects, form and proportions were fixed by the usage of thousands of years, so as to satisfy the cultivated eye. Marsh laid down

The 1834 proposal for an obelisk half the height of the Washington Monument to stand on Bunker Hill. Horatio Greenbough's design was approved by Gilbert Stuart and Daniel Webster.

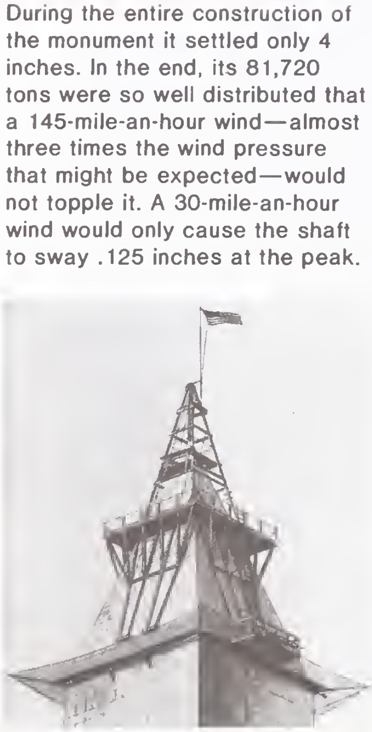
the law that the pyramidion should be one-tenth of the height of the shaft, with its base two-thirds to three-fourths the size of the monument's base. He was categoric in insisting that it would be as great an aesthetic crime to depart from these proportions as it would be to make "a window in the face of the pyramidion or shaft, both of which atrocities were committed in the Bunker Hill monument." If one had to have a window, said Marsh, it should be the exact size of one stone and be supplied with a shutter of the same color so as to be invisible when closed. "And throw out," he concluded, "all the gingerbread of the Mills design and keep only the obelisk." His advice was taken, and a joint commission of Congress was formed to oversee the completion of the monument as Marsh had suggested, $94,474 being voted to stabilize the foundation. Lieutenant Colonel Thomas Lincoln Casey, a forty-two-year-old army engineer, was hired to raise the monument to 555 feet, ten times the size of the base; architect Gustav Friebus was assigned to design the pyramidion with which to top the shaft. It was estimated that $677,000 more would be needed to complete the monument.



The completed monument drawn by Edwin A. Abbey and engraved by A. U. S. Anthony

On January 28, 1879, five boom derricks were erected on the top of the existing shaft with block and tackle and an 8-foot safety net to catch any workmen—none of whom fell or were injured. As a first step, so that building could start in July 1880, the top three courses laid by the Know-Nothings were removed. An iron framework 20 feet high went up first, around which the new courses of blocks

During the entire construction of the monument it settled only 4 inches. In the end, its 81,720 tons were so well distributed that a 145-mile-an-hour wind—almost three times the wind pressure that might be expected—would not topple it. A 30-mile-an-hour wind would only cause the shaft to sway .125 inches at the peak.



The pyramidion in place with security scaffolding and net ready for the Masonic ceremony of laying the aluminum capstone. This pyramidal capstone consisted of 3,765 cubic feet of dressed marble in 262 separate pieces which took thirty days to set. In December 1884 it was successfully raised without incident.

could be laid, with marble on the outside, and a granite backing. By the end of 1880, as Gorringe's obelisk was steaming toward New York, 22 feet of masonry had been laid, each course containing 32 blocks of marble and 24 blocks of granite, raising the monument to a height of 250 feet.

During 1882, as the shaft thinned, the number of blocks hoisted each trip was doubled and another 90 feet were added. In 1883 another 70 feet brought it up to 410. After the 450-foot level no more granite was to be used, only marble, so that during 1884 the shaft could be brought to 500 feet, ready for the 55-foot pyramidion whose 300 tons were to be lifted into place as one piece.

To finish off the obelisk at its apex, an aluminum capstone weighing 100 ounces—the largest single piece of aluminum cast to that time—was to be placed atop the pyramidion on Saturday, December 6, 1884. Placing the capstone required another appropriate Masonic ceremony, and a special scaffold was constructed on which the principal officials might stand. When the day came, a 60-mile-an-hour wind came with it, and thousands held their breath as they gazed up from the Mall at master mason P. N. McLaoughlin, the project superintendent, who successfully placed the capstone. The American flag was unfurled, and the crowd raised a cheer. Cannons brought from Fort Meyer, Virginia, boomed out a hundred-gun salute, and all was ready for the dedication on Washington's Birthday, February 21, 1885.

On dedication day, which dawned cold but clear, the obelisk stood majestic and serene, the tallest monument of masonry then in the world. A sharp wind blowing down the Potomac put a snap into the flags, and the marine band played patriotic tunes as troops and citizens gathered on the snow-encrusted turf around the base. A short address was delivered by Senator Sherman of Ohio. And Myron M. Parker, Most Worshipful Grand Master of the Grand Lodge of Free and Accepted Masons of the District of Columbia, began the Masonic ceremonies, reminding the audience that "the immortal Washington, himself a Freemason, had devoted his hand, his heart, his sacred honor, to the cause of freedom of conscience, of speech and of action, and that from his successful leadership the nation had arisen." As props for the Masonic ceremony there was the same gavel which George Washington had used to lay the cornerstone of the Capitol, the same Bible on which he had taken the oath as president, the same apron made by Madame Lafayette, plus a golden urn containing a lock of Washington's hair passed down by

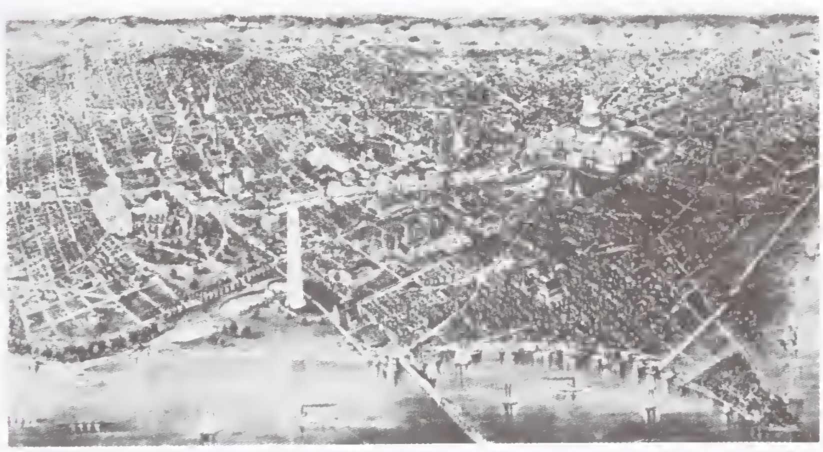
View of the ceremony seen by the crowd through binoculars as Colonel Casey holds his derby against the gale, and motions to Master Mason McLaughlin to cap the monument.

Tourists ascending the monument

every Grand Master of the Grand Lodge of Massachusetts. In conclusion the Grand Chaplain of Masons brought out the same ritual corn, wine, and oil. Then the official procession, headed by President Chester Alan Arthur, marched down Pennsylvania Avenue to the Capitol to hear an address written by former Speaker of the House Robert C. Winthrop, the same sponsor who had given the oration at the laying of the cornerstone thirty-seven years earlier.

Regretting that the monument could not have been hewn from a single stone, like an Egyptian obelisk, Winthrop said he nevertheless took pleasure in the idea that the united stones standing firm and square could serve as a symbol for the national motto, *"E pluribus unum."* John C. Palmer, speaking for the fraternity, declared that Masons were no longer builders of cathedrals and castles, "poems in marble and granite," but of human society whose stones were living men, "their minds enlightened with divine truth, their hearts radiant with discovering the joy of pure love, their souls cherishing—like the ancient Egyptian worshippers of Osiris—the hope of immortality."

Within a year ten thousand citizens had climbed to the top of the obelisk to look out across the tranquil Potomac at the gentle slopes of Mount Vernon, where Washington lay buried, but few among them realized—any more than did the admirers of the Chartres Cathedral or the great pillars of Karnak, except perhaps through a sense of awe—the phenomenal significance of the majestic work of masonry upon which they were supported.

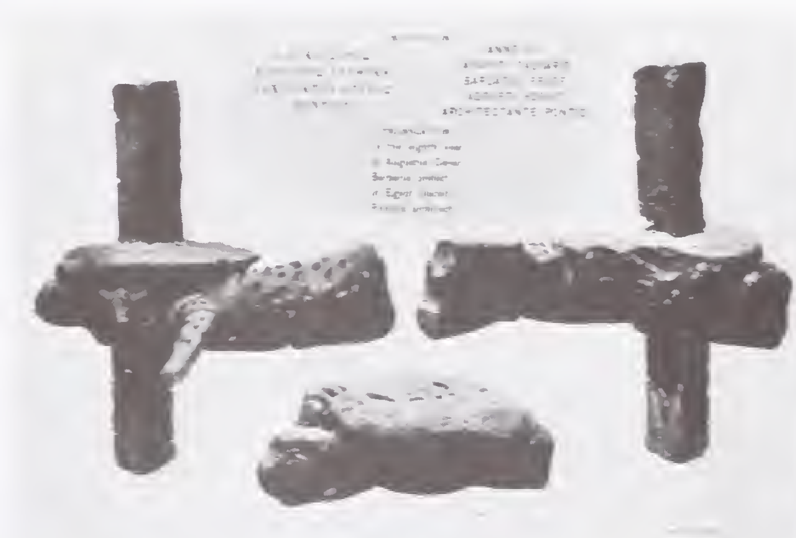


G. BELZONI ESQ.R

16. ATLANTIS IN AMERICA

In January 1880 the United States consul general in Egypt, E. E. Farnam, sent a dispatch from Cairo to the Department of State in Washington reporting that in the course of removing the foundations of the obelisk sent to New York from Alexandria, a "very important historical discovery was made relating to the order of Freemasons, confirming its claim of ancient origin." Farnam referred the department to a further report by the senior Masons Commander Henry Gorringe and Grand Master S. A. Zola, Sovereign Grand Commander of the Supreme Council of the Ancient and Accepted Scottish Rite; Past Grand Master of the National Grand Lodge of Egypt, confirming the discovery beneath the foundations of a granite block, the upper part of which had been cut in the form of a mason's square. Embedded in the mortar were also a mason's trowel of iron or steel, and two granite blocks, one polished, the other unfinished, "the perfect and the rough ashlars of Masonry," representing the master craftsman and the apprentice, all laid out in the correct position to indicate emblems of Masonry—something the report assured could not be the work of chance.

The added discovery of an inscription in both Latin and Greek on one of the bronze astragals which had held up the obelisk indicated it had been erected by the architect



The crabs found in Alexandria with this inscription in Greek and Latin: "Placed by architect Pontius in the eighth year of Augustus Caesar with Barbarus prefect of Egypt."

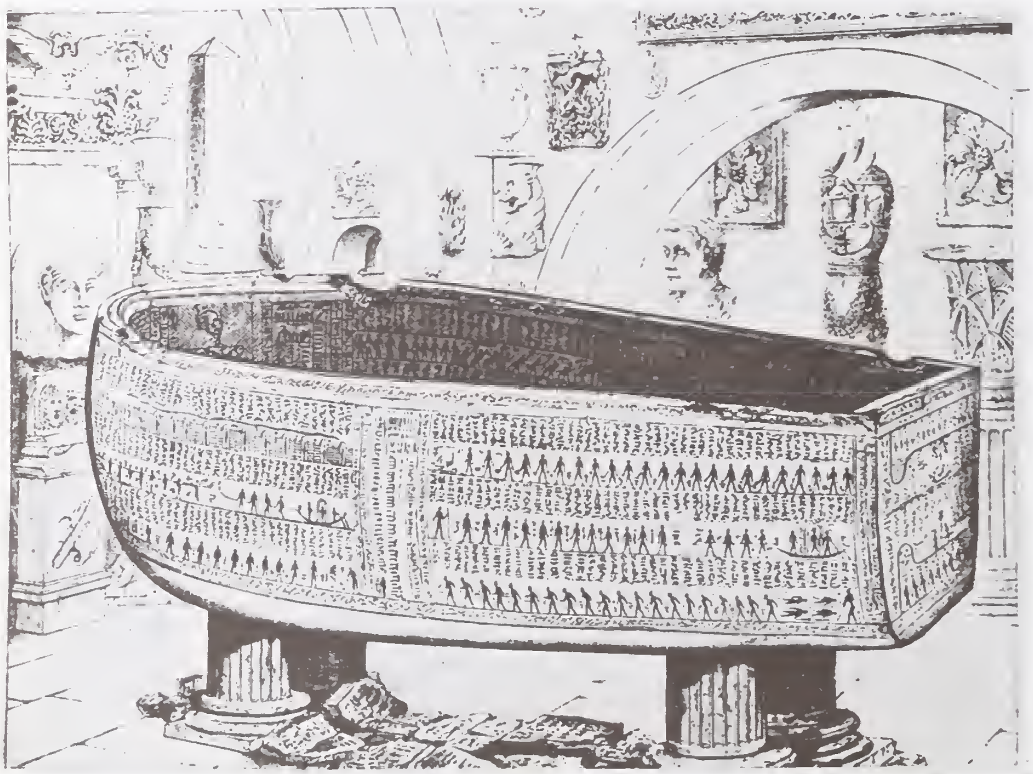
According to Weisse and Gorringe, the decorations on the walls of the mystery chambers in the rock-excavated temple of Seti I and of his son Ramses II (discovered by Belzoni) represent initiation to a Masonic degree. They believe that everything they saw in these structures "indicate the origin of modern Freemasonry for the attitudes, groups, rites, ceremonies, symbols, and signs, have a striking similarity both with Medieval and Modern Freemasonry." According to Weisse, the Isiac mysteries constituted the first Masonic degree among the Egyptians and the mysteries of Serapis, the second. "In the mysteries of Osiris the lesson of death and resurrection of Osiris was symbolically conveyed. The legend of the murder of Osiris was displayed to the affiliate in a scenic manner." All together Weisse and Gorringe describe nine different initiations throughout the thirteen highly ornamented mystery chambers of the temple.

Chambers of the Tomb of Seti

Pontius during the eighth year of Augustus's reign, with Barbarus as prefect of Egypt; and this led the New York Masons to conclude that the obelisk had been raised in Alexandria at the time of the birth of Christ by a group of practicing Masons of whom Pontius was evidently one.

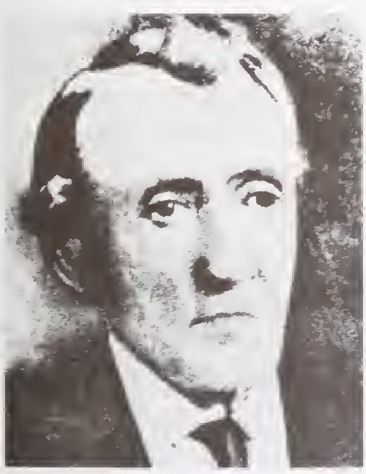
This amazing conclusion enabled Gorringe to launch into a campaign to prove that Masonry had flourished in Egypt at an even earlier period than had been believed. For evidence, he produced thirteen large colored illustrations showing in detail the carved stone panels of the rock-excavated Temple of Seti I (Osimandias) and Ramses II (Sesostris), painted *in situ* by Giovanni Belzoni in 1818. "No Mason," said Gorringe, "can look at the attitudes of this group of Grand Master, Guide, Candidate, and Assistant, without realizing that, if there are Masonic institutions now, there were similar, if not identical ones, about four thousand years ago, in the land of the Pharaohs, and that modern Freemasonry had its prototype in the Masonic Temple of Seti I and Ramses II, where applicants were initiated as Oriental and Occidental Masonic Orders initiate now."

This statement prompted an American Mason, John A. Weisse, to produce a book, *The Obelisk and Freemasonry,* in which he set out to show, among other points, that Masonry had existed in America among so-called Ameri-

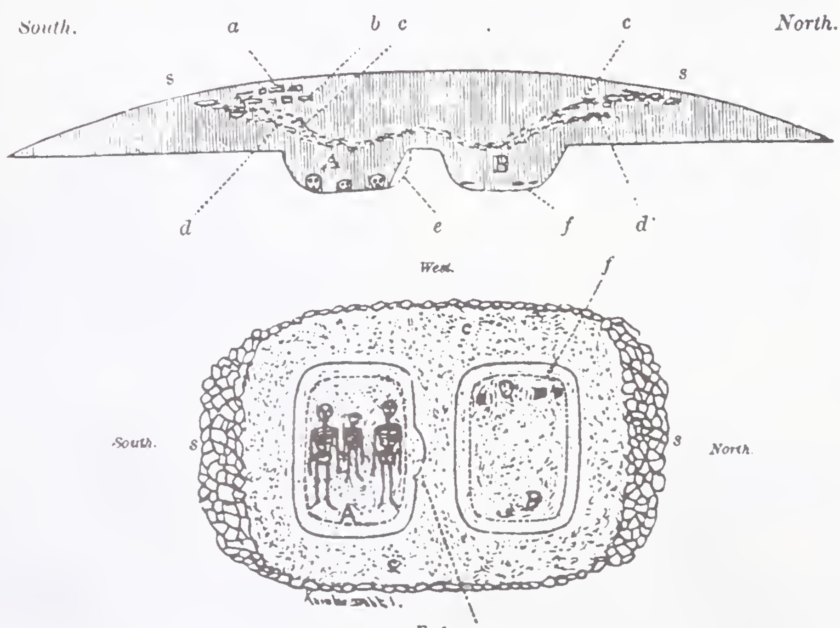


can Indians, long before the arrival of Columbus. Weisse quoted a letter from a William McAdams of Otterville, Illinois, dated April 25, 1880, to the effect that he had spent a considerable time exploring ancient mounds and earthworks, in which he was surprised to find well-known symbols of Masonry, such as circles, squares, and triangles; triangles with squares surrounded by circles; and a circle between parallel lines. "The triangle," wrote McAdams, "ever was and is now an important Masonic symbol. The equilateral triangle was adopted by most of the ancient nations as an emblem of the deity, and was regarded as the most perfect geometric figure. It occurs in Craft and Arch Masonry. In ancient and medieval magic it meant fire when the apex pointed upward, and water when the apex pointed downward."

Next Weisse told the story of a stele found in Iowa in 1877 which came to be known as the Davenport stele. Its history and its import were to make it as remarkable as Egypt's Rosetta Stone. On a cold day in January 1877, an amateur archeologist, the Reverend Jacob Gass, a German-speaking minister of the First Lutheran Zion Church of Davenport, was engaged in opening a small burial mound on what was known as Cook Farm. Aided by seven colleagues, several of whom were also clergymen, these "Sunday archeologists" dug through frozen ground for about 2½ feet, only to discover an intrusive Indian burial of obviously modern date. Later, as they descended into the mound, they uncovered the skeletons for which the mound had evidently been raised; two adults and a child. Beneath their bones the archeologists made an extraordinary find:

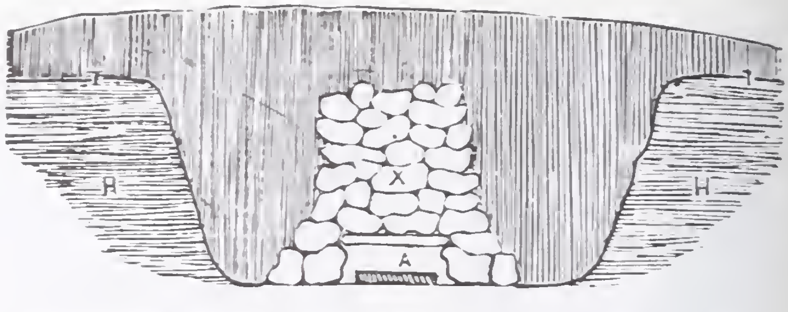


The Reverend Jacob Gass



Plan of Cook Farm mound cavity . . .

. . . in which the tablet was found



a bituminous shale tablet, about 13 inches square, engraved on both sides, as well as a smaller tablet engraved with what appeared to be a zodiac.

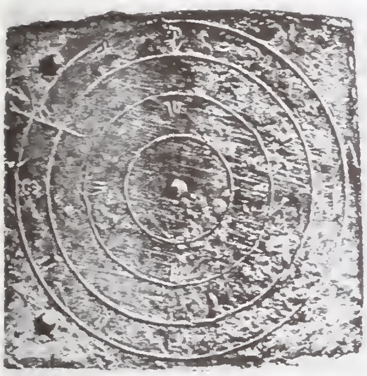
The large tablet showed several dancing figures in what was considered to be a "cremation scene." The opposite side showed Indians and animals around two obelisks pointing at an equilateral triangle. Strange signs, like lettering or glyphs, adorned the stele. Taken to the Davenport Academy of Natural Science (now the Putnam Museum), the tablets aroused great interest: they were believed to be the first discovered phonetic and astronomic monuments assignable to early inhabitants of America.

Charles E. Putnam, lawyer of the Davenport Academy, and later its president, was quickly committed to the validity of this rare archeological find, which he considered of worldwide interest. Encased in plaster casts, the tablets were sent to the Smithsonian Institution for appraisal, along with some background notes on the Reverend Gass, whom he described as of spotless character, "a good classical scholar, well grounded in Hebrew, with a scientific bend of mind." Also included were sworn affidavits from Gass's assistants confirming the manner in which the tablets had been found.

The Putnam Museum in Davenport, Iowa

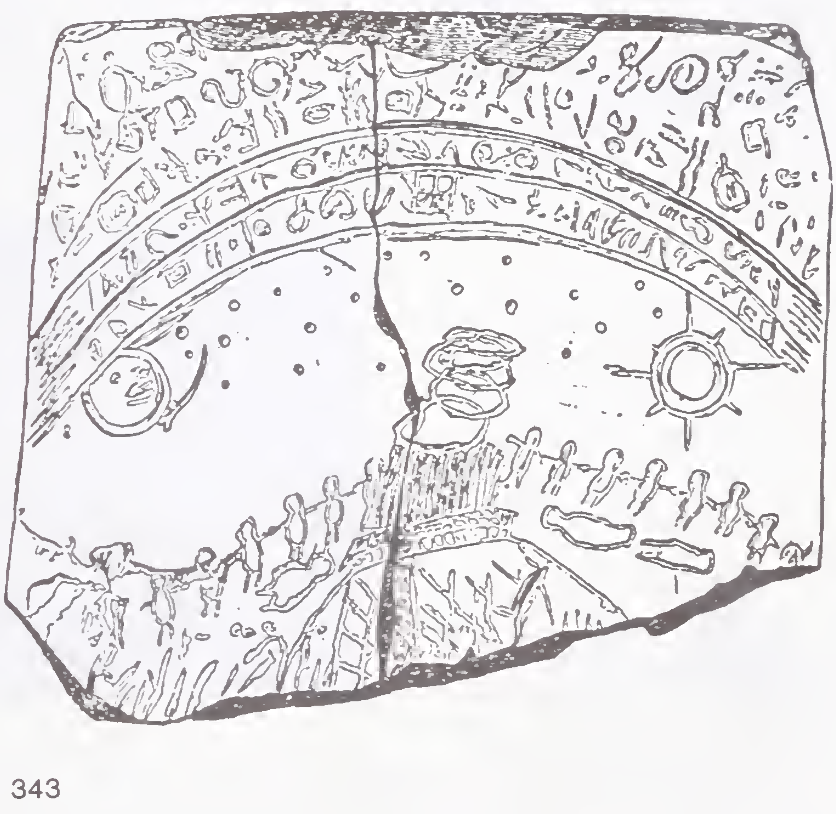
The Smithsonian's first reaction was that the tablets were authentic and of great antiquity. But one of the institution's experts, a Dr. E. Foreman, on closer examination concluded that the so-called "cremation scene" depicted a disembodied Indian spirit going to "a place of probation before its final reception in the place of departed spirits," and that the works therefore "set forth the teaching of the missionary fathers of the Catholic Church, and must be of recent date." Ironically, he added that the Egyptians believed such an inquisitorial function was performed by Osiris, "but we are not apprised that the Indian mythology includes a functionary clothed with similar attributes."

The debate quickly degenerated into acrimony and was drawn out for several years in the columns of such prestigious magazines as *Science* and the *American Antiquarian,* climaxing in an official putdown from the governmental establishment when the Davenport Academy wished to exhibit the tablets at the Columbia Exposition in Chicago in 1894, "to give visitors from all parts of the world a chance to see something that has made a ripple in the scientific world and is only waiting, like the Rosetta Stone, for some Mariette to decipher the story hidden in its hitherto undecipherable hieroglyphs."



Calendar stone tablet

In a monograph in the annual report of the United States Bureau of Ethnology, Cyrus Thomas, its director of archeology, declared unequivocally: "A consideration of all the facts leads us, inevitably, to the conclusion that these



One side of Davenport Stele showing Djed pillar

relics are frauds; that is, they are modern productions made to deceive." Thomas suggested the source of the hieroglyphic inscriptions was none other than the 1872 edition of Webster's *Unabridged Dictionary*, page 1,766, which illustrated various Old World alphabets.

Scholars who had previously taken a favorable position were quick to reverse themselves, and the tablets were labeled frauds. In 1930, when Dr. Henry C. Shetrone, director of the Ohio State Museum, reexamined the tablets, he reconfirmed their fraudulence. And as recently as 1970, Marshall Bassford McKusic, an Iowa archeologist, in a pamphlet titled *The Davenport Conspiracy*, published by the State Archeologist of Iowa City, declared that "by now the fraudulent nature of the tablets should have been accepted by everyone."

For evidence, to prove a conspiracy which he said resulted in "an almost unbelievable degradation of scientific research," McKusic brought out what he characterized as "one of the most detailed case studies of this period of American archeology, and of the history of science in this country."

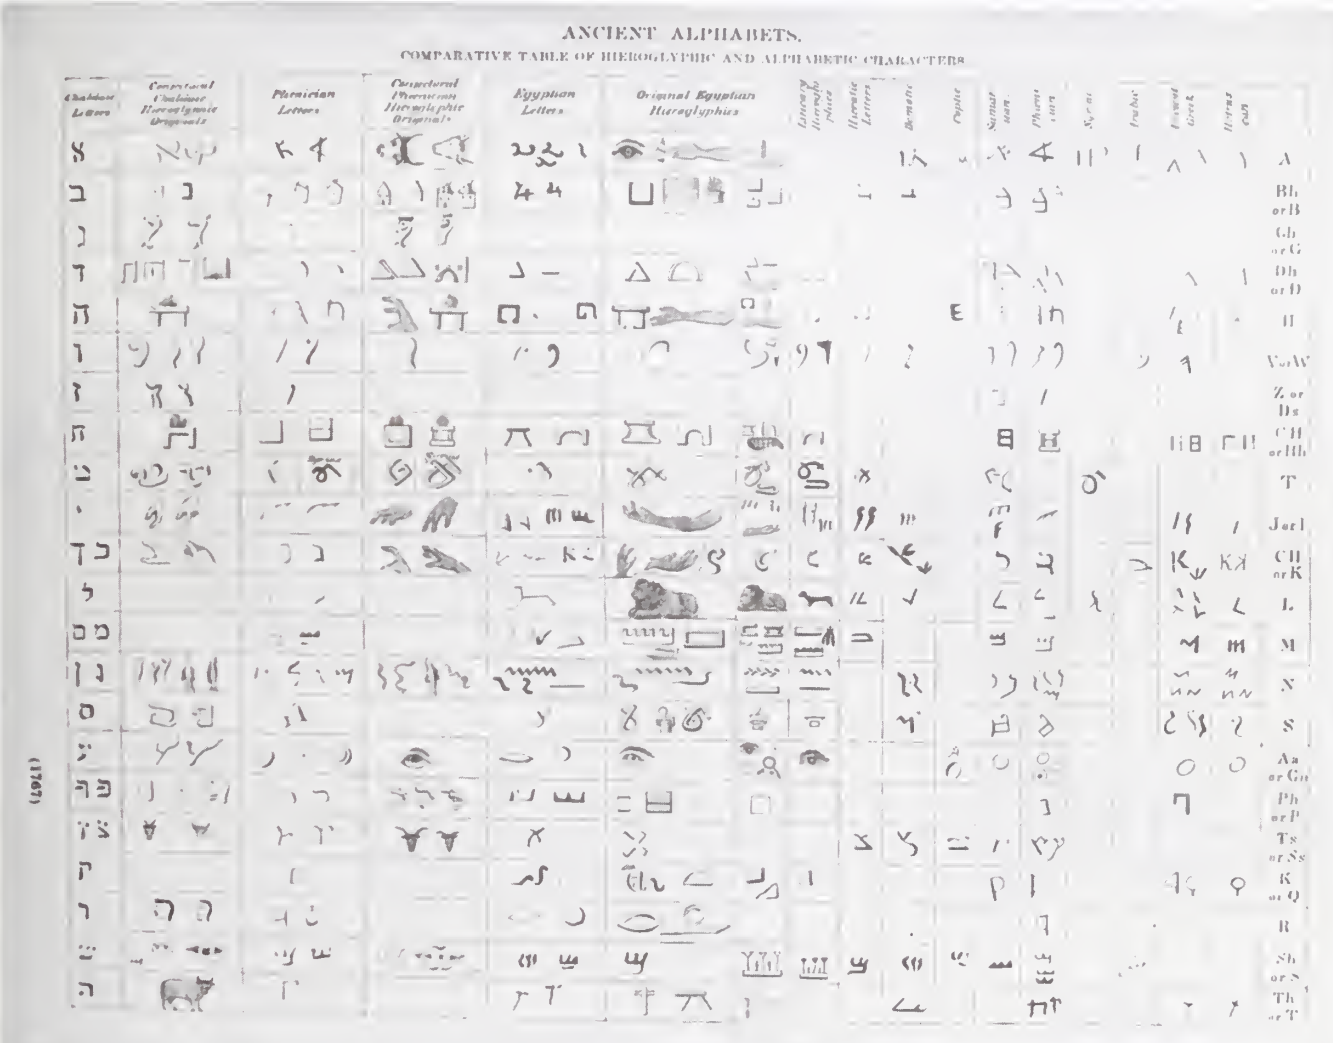
Judge James Wills Bolliger

In this opus, on careful reading, the new evidence turned out to be the drunken confession of a prominent Davenport attorney, Judge James Wills Bolliger, president of the Davenport Museum board, according to which the tablets had been taken from the roof of a whorehouse on the Mississippi River waterfront and then forged by himself and a gang of cronies who frequented the academy, in order to be placed in the mound for the Reverend Gass to discover. As the judge is reported to have told the story: "This group would go to the Academy and have a bull session because there wasn't any place else to go. They used to have a few drinks and just shoot the breeze.

Shingle from the old state house (courtesy of Marshall McKusic)

The janitor was in with us. We had two old almanacs, one German and one Hebrew and we copied out of them and inscribed the hieroglyphs on these slate tablets, and things. We just made up anything that would confuse them, especially Gass."

Ancient alphabets from *Webster's Dictionary* of 1872



Professor Barry Fell

That this confession, and not the tablets, is fraudulent, is now clear at last, thanks to the brilliant scholarship of a Harvard epigrapher, though the shakiness of Judge Bolliger's evidence should have been clear from the fact that at the time he is supposed to have planted the tablet, the judge was only nine years old, and the building in which the academy was to be housed was only dedicated and occupied the following year.

Conclusive proof of the authenticity of the Davenport stele has been adduced by Barry Fell, professor emeritus at Harvard, and president of the Epigraphic Society which he founded. Far from being a forgery, the stele is one of

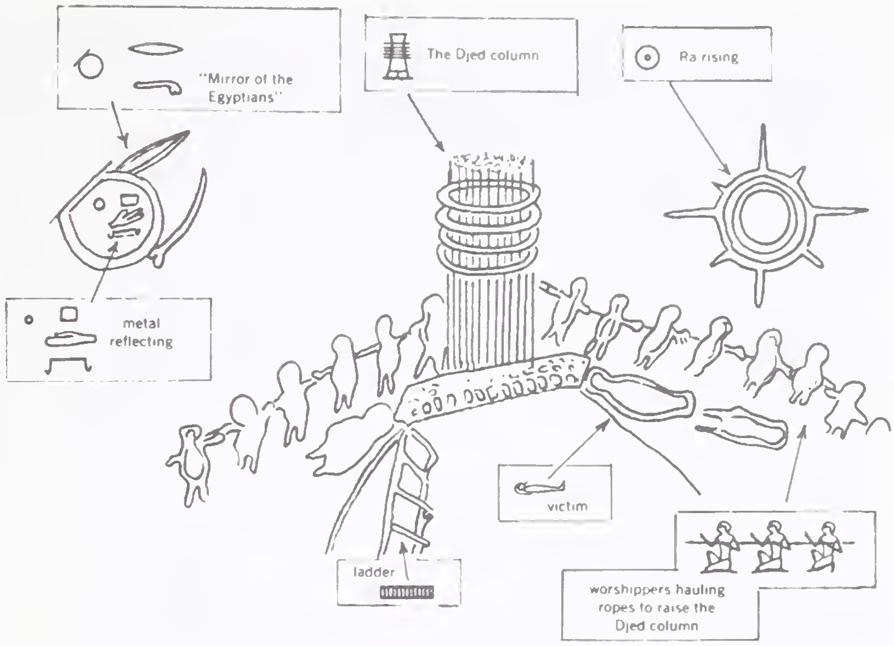
the most important ever found, amounting to an American Rosetta Stone, the only one so far on which occurs a trilingual text in the Egyptian, Iberic-Punic, and Libyan languages. As Fell points out, the Egyptian hieratic text could easily have been deciphered at the time of the tablet's discovery, but was evidently deliberately ignored.

Even more interesting is the content of the text, which elucidates the nature of the ceremony depicted. In the *Occasional Papers* of the Epigraphic Society, Fell gives a word-for-word translation of the Iberian and Libyan texts as they appear on the arched scrolls, each of which reports that the tablet carries a further inscription which will reveal the secret of how to regulate a calendar. This secret is contained in the Egyptian hieratic hieroglyphs, which Fell renders into English:

"To the pillar attach a mirror in such a manner that when the sun rises on New Year's Day it will cast a reflection onto the stone called 'The Watcher.' New Year's Day occurs when the sun is in conjunction with the zodiacal constellation Aries, in the House of Ram, the balance of night and day being about to reverse (the Spring Equinox). At this time hold the Festival of the New Year, and the religious rite of the New Year."



Identification by Fell of various Egyptian captions in the design of the stele

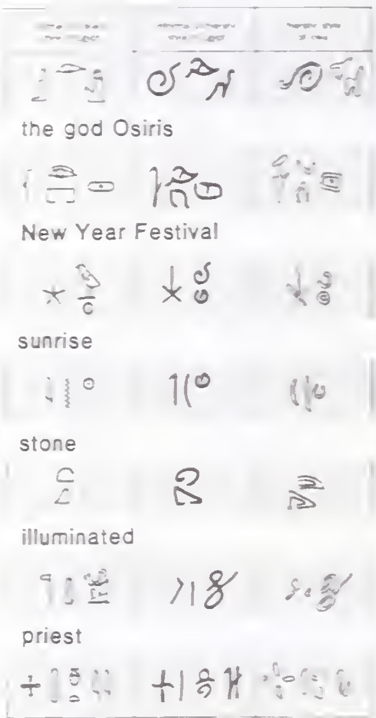
More extraordinary is the depiction referred to as "the cremation scene." With the help of a panel found in a tomb from the Eighteenth Dynasty in Thebes, deciphered by Adolf Erman, Fell shows the scene to represent the Djed Festival of Osiris, the Egyptian celebration of the New Year, which occurs on the morning of the March equinox, now corresponding to March 21, but which Fell says occurred later in March in ancient times.

In this festival, as Fell describes it, parties of worshipers pulling on ropes ceremonially erected a special New Year pillar, called the Djed Column, made of bundles of reeds encircled at the top by rings, representing the backbone of Osiris, in whose honor the column was re-raised each year on the day of the spring equinox. On the left side of the stele is the carving of a mirror, with, beside it, as deciphered by Fell, the Egyptian hieroglyphs for "Mirror of the Egyptians." On the mirror are hieroglyphs that read "reflecting metal." To the right is the rising sun, with the hieroglyph *Ra* (for "Sun god" or "Sun") on the disk of the sun. Stars seen in the morning are above.

On the Erman stele the Egyptian record tells that the ceremony occurred in Koiakh, a word meaning "the month of March." On the Davenport stele, the Egyptian text goes on to say that it is the work of Wnty ("star-watcher"), presumed by Fell to be a priest of Osiris in the Libyan region.

Iowa glyphs compared to Egyptian glyphs, showing the identity between the formal hieroglyphic, the hieratic, and the Iowan signs.

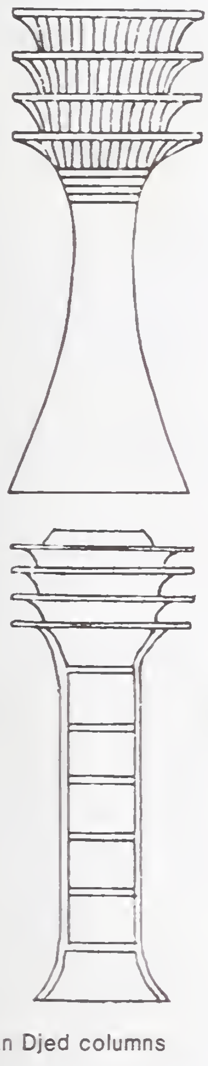


As to how the stele came to Iowa, Fell speculates that though the stone appears to be local, and engraved in America, it was perhaps copied by a Libyan or Iberian astronomer from an older model brought from Egypt, or more likely from Libya.

As to the genuineness of the stele, Fell points out that at the time Gass found the stone, neither the Libyan nor the Iberian scripts had been deciphered, which would have made it impossible for an impostor to produce texts consistent with the hieroglyphic text. Fell says the style of the Egyptian writing could be as old as 1400 B.C.; but he doubts that the stele itself celebrates a ceremony taking place in Iowa earlier than about 800 B.C.. because "we do not know of Iberian or Libyan inscriptions earlier than that date."

What is clear, says Fell, is that Iberian and Punic speakers were living in Iowa in the ninth century B.C., making use of a stone calendar regulator whose Egyptian hieroglyphs they could read. These settlers, says Fell, had presumably sailed up the Mississippi River to colonize the Davenport area; he then hazards the guess that the colonists came in wooden ships commanded by a Libyan skipper of the Egyptian navy, sometime during the twenty-second Libyan Dynasty, the pharaohs of which were energetic men who favored overseas exploration. With them, he says, probably came an astronomer priest, and either he, or one of his successors, engraved the Davenport calendar stone.

On the reverse face of the Davenport tablet the scene depicted is the corresponding equinoctial Hunting Festival, Hunting scene on the reverse side of the Davenport stele above and below two recumbent obelisks. Fell considers this the earliest known example of Micmac script. Unlike the Djed Festival, which is an Indian copy of an Egyptian original, this is the work of an Algonquin Indian dating back perhaps two thousand years. Fell roughly translates the text—which is replete with Egyptian features—as: "Hunting of beasts and their young, waterfowl and fishes." And: "The herds of the Lord (illegible) and their young, the beasts of the Lord."



Egyptian Djed columns

held in September, six months after the Djed Festival, marking the second half of the Celtic year; based, evidently, on the Egyptian year. Fell sees this side of the tablet as being copied from an earlier original by Algonquin Indians about 500 B.C., though possibly as late as A.D. 100.

In the foreground a hunting scene deals with the September butchery and smoking of young wildstock, including waterfowl and fish. In the upper part of the picture are the portions of wildlife left unmolested, labeled in the text "Herds of the Lord." These scenes are explained in a double line of letters running down the center of two prostrate obelisks. The letters read from right to left, toward the center, with the animals facing the reading direction, as is usual with Egyptian glyphs. But why two huge prostrate obelisks should be depicted on a stele in

5. At Philae ( ), modern Aswan, the sun ( ) can stand overhead, casting no shadow. From Philae northward to the coast ( ) is a distance of 5 thousand stades.

6. When the sun casts no shadow at Philae, the shadow it casts at is (angular 2/100ths), i. subtends one fiftieth part of 360°.

Therefore the entire circumference of the earth equals ((5000 divided by 2) times 100) stades

the middle of Iowa, and what was meant by the triangle at which they point, is left unsaid by Barry Fell. However, from another of his papers, dealing with Egyptian-Libyan hieroglyphs found on the wall of a cave in New Guinea, it is clear he understands that for the Egyptians the obelisk functioned geodetically as well as colendrically.

In 1937 an expedition from the Frobenius Institute of the Goethe University of Frankfurt am Main visited a series of limestone caverns on the coast of McCluer Bay, in northwest New Guinea. On the walls they found a number of inscriptions which they were able to establish as having been drawn between 235 and 225 B.C. The incriptions, as deciphered by Fell and his fellow epigraphers, are in ancient Maori, which Fell has shown to be based on ancient Libyan, with elements of Greek, Carthaginian, and occasional Egyptian hieroglyphs.

The writing indicates the author to have been a Captain Maui in the Egyptian navy acting as navigator and astronomer to the expedition's commander, a man named Rata. The expedition, though serving as a squadron of the Egyptian navy, was actually Libyan, says Fell, Libya then being a province of Egypt. As Rata and Maui correspond to the names of traditional leaders in Polynesian tales, the inscriptions also give an historical base to Maori legends. An eclipse, mentioned in the inscriptions as having taken place in November of the fifteenth year of the reigning pharoah, enabled Fell to identify the monarch in question as Ptolemy III, grandfather of the Ptolemy celebrated in the Rosetta Stone, in the fifteenth year of whose reign an eclipse occurred, on November 19, 232 B.C. From the fact that wives and children are indicated as being in the expedition, Fell infers that it was one of those sent out by Ptolemy III "to seek new sources of gold for his enormous gold coinage emission," with a secondary aim of circumnavigating the world, a goal barred to the voyagers by the west coast of America.

The most extraordinary of these inscriptions directly refers to Eratosthenes—then professor of mathematics in charge of the great library of Alexandria—as being an acquaintance of Maui who personally demonstrated for him his method of computing the circumference of the earth by means of obelisks. The glyphs on the walls of the New Guinea cave explicitly show the use of the shadow of an obelisk in determining the angle of the sun's rays, and, by similar triangles, the latitude of the location. The text speaks of how this particular theorem of Eratosthenes, "an astronomer of the Delta country in Lower Egypt," was disclosed to Maui. The text specifies that because the sun's rays intercept the atmosphere at varying angles, and therefore latitudes, when the sun stands overhead at Philae (or Syene), it casts no shadow at the solstice. The text also states that from Philae northward to the coast is a distance of 5,000 stadia. Thus, it explains, when the sun casts no shadow at Philae, the shadow it casts at the coast, 5,000 stadia to the north, is 2/100ths of a full circle; that is to say, 1/50th of 360°, or 7.2°. Therefore, if 5,000 stadia equals 7.2°, the entire circumference of the earth must be 5,000 stadia times 50, or 250,000 stadia.

The first mention of this theorem by the Greek author Kleomedes, about a century after the dating of the inscription in New Guinea, states that Eratosthenes read in a book in the library at Alexandria that on the summer solstice a reflection of the sun can be seen in the water at the bottom of a well at Syene (or Philae) at midday. An additional epigraphic fragment in Maori from Sosorra, as translated by Fell, says textually: "It is a fact that whenever the sun's image is seen in the water at the well at Philae in Egypt, the obelisk erected at Alexandria at that instant is observed to have a shadow."

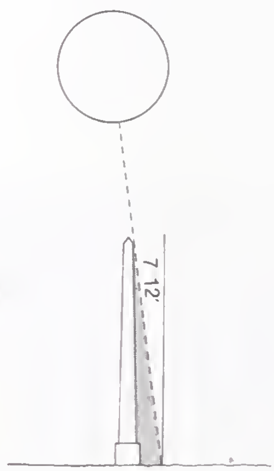
Fell notes that in this section of the calculation, vowels are omitted, with the interesting result that the sequences of residual consonants correspond almost exactly to standard Middle Egyptian forms—where the vowels are similarly omitted. Thus, if the Roman-letter equivalents are inserted in place of the Maori alphabetic signs, the text can be translated directly from the standard dictionary forms of Egyptian as given by Faulkner.

Kirchner related how the Arabs called Heliopolis Ainschems or "the eye of the sun," and that in the temple of the sun there was a marvelous mirror, constructed with great art to flash back the rays of the sun. And the Arab chronicler Maqrizi tells of two obelisks in Heliopolis, one of which was still standing in the fourteenth century, 50 cubits high, tipped with shining brass or electron, whose functions were to mark the extremes of the solar passage at the solstices. "The moment the sun enters the first minute of Capricorn, that is the shortest day of the year, it reaches the southernmost of two obelisks and culminates at its summit. When it reaches the first minute of Cancer, that is to say the longest day in the year, it reaches the northernmost obelisk and culminates at its summit."

According to Professor Pochan, the observation well used by the ancient Egyptians to establish the moment of solstice was not at Elephantine but at Philae, whose latitude was 24° 1′34″. He says that Elephantine was on the Tropic in 3200 B.C., but by the time of Eratosthenes, the Tropic had shifted to 23° 44′8″. The cubit used by Eratosthenes, says Pochan, was the Philae unit of .5275 meters, rather than the Elephantine cubit of .52367. The distance between Alexandria and Philae, which Eratosthenes computed as 7.2°, or 5,000 stadia, was marked by two obelisks at Philae, and was the exact halfway point on the meridian measured by the Egyptians from Alexandria all the way to Meroë, deep in southern Nubia. It shows, says Pochan, that the Egyptians knew the correct dimensions of the planet at least as early as 4800 B.C.

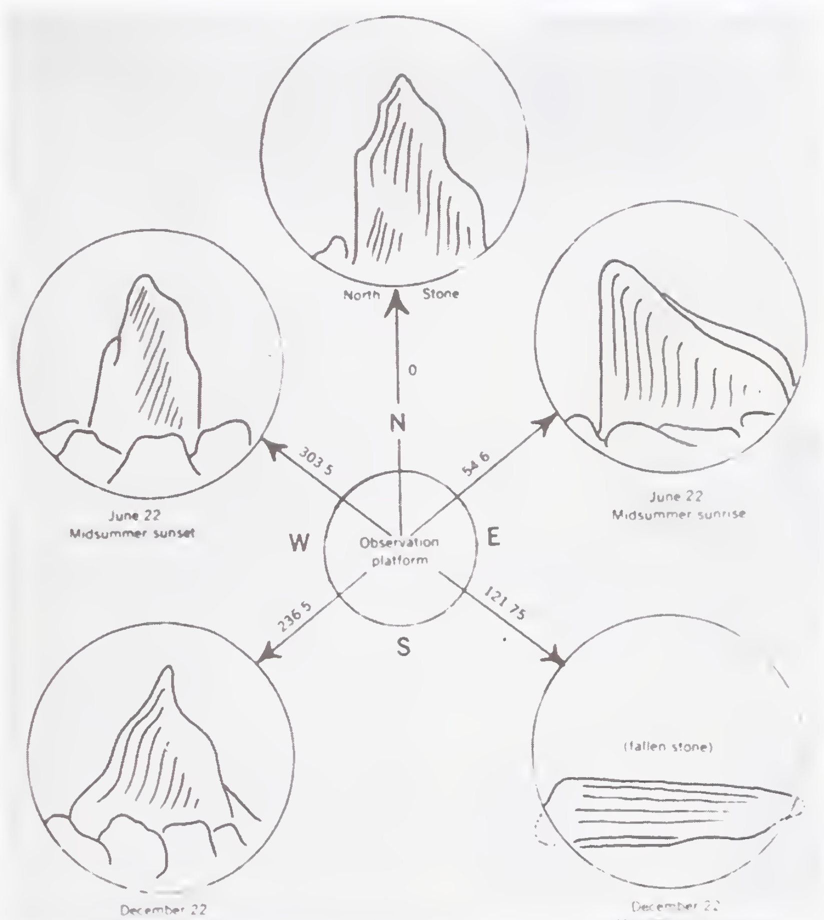


The French professor André Pochan, in a bulletin of the *Royal Geographic Society of Egypt,* points out that in this arrangement at ancient Heliopolis the equinoxial line passed exactly between the two obelisks and that as the sun reached this line it gave rise to the Egyptian word Ph or Pâque which means "reaching or touching the rising sun at Passover." Furthermore, says Pochan, the Egyptians had similar observation devices at Tanis, Hermontis, Esne, Edfu and Thebes, and the glyph for the festival of the Spring equinox was or BaRa(m)—the sun in Ram between two obelisks, or Djed pillars. From this, says Pochan, the Moslems got Bairam or Ramadan.

Thus, according to the French professor, the Egyptian astronomers and geodesists established the equinox with a Djed pillar and a mirror. That they also did so with a well and an obelisk is equally clear. But you have to start on the Tropic of Cancer, or better still exactly at Syene where, at noon of the summer solstice, the sun will pass directly overhead, causing no shadow in a well. And any obelisk, in the same location, of whatever height, will also cast no shadow at noon of the solstice.

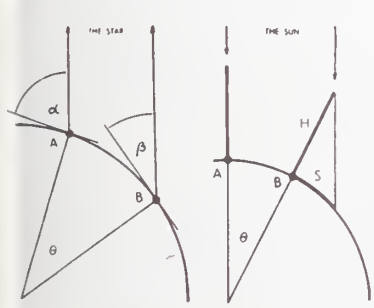
Why the Egyptians placed their sophisticated observatory at Syene at 24°06′ instead of at 23°51′, the actual line of the Tropic, is explained by the late Professor Livio C. Stecchini (in his appendix to *Secrets of the Great Pyramid*). By deciphering a common glyph of three short parallel lines which appears on virtually all the thrones of the pharaohs, Stecchini realized that the Egyptians calculated three different values for the tropic: 24° as a round figure for their mapping; 23°51′ for the actual path of the Tropic; and 24°06 for the actual point of observation at Syene. This, Stecchini explains, was because they knew that in order accurately to achieve the effect of the shadowless well, or shadowless obelisk, on one particular day of the year, they had to place their well or obelisk *half the diameter of the sun, or 15′,* north of the actual Tropic.

Once established that an obelisk casts no shadow at the Tropic at noon of the solstice, it matters not where the obelisk is raised; by knowing its height, and by measuring its shadow at noon of the solstice, the latitude can be established. To mark out a year's solar calendar, all that is needed is an obelisk; its shadow will automatically give the solstices, or longest and shortest days of the year, as well as the equinoxes and four intervening festivals, which can be marked out with horizon stones in a great circle as at Mystery Hill in Salem, New Hampshire, and elsewhere.



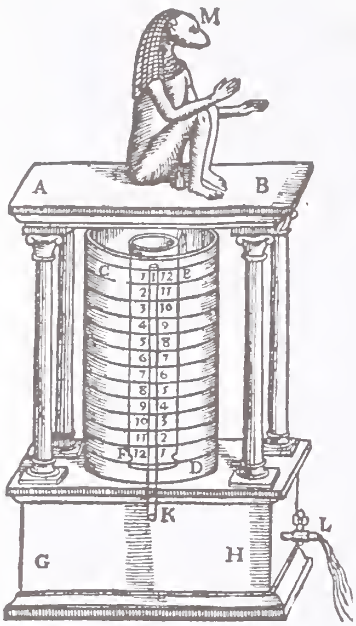
The Calendar Circle at Mystery Hill, New Hampshire, as drawn by Barry Fell and Osborne Stone, with the stone markers seen through a transit telescope from the observation platform marking the point of sunrise and sunset at the solstices and equinoxes

Berriman demonstrates how the circumference of the earth can be estimated by measuring a meridian length from *A* to *B* (between two obelisks several miles apart) and the length of the shadow at *B* when there is none at *A*. The same result is achieved by measuring the difference in angle of elevation of a star observed from two different points.

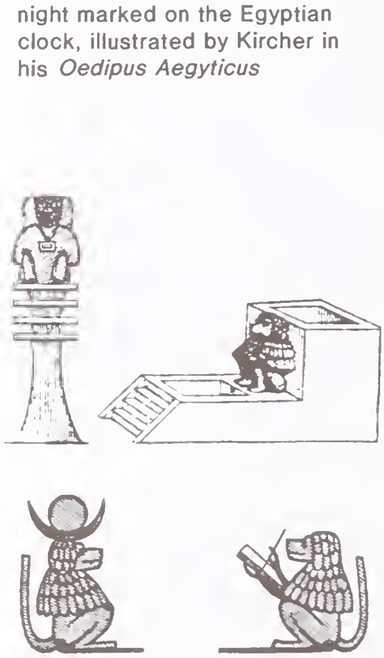


By measuring the distance between two obelisks on the same meridian and comparing their shadows as measured at solstice or equinox, it is simple, accurately, to extrapolate the circumference of the planet. Algernon Edward Berriman, in his *Historical Metrology,* shows that the same result can be obtained by measuring the difference in star angles between two obelisks at a known distance apart.

That the Egyptians used the Djed Column to establish the equinox and with it control their water clocks is clear



Urinating monkey with the twelve equinoctial hours of the day and night marked on the Egyptian clock, illustrated by Kircher in his *Oedipus Aegyticus*



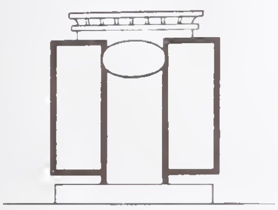
The Kaf-ape, known as the clicking cynocephalus, because its clicks are believed to have preceded human speech, was used to represent the god who taught mankind speech and the hieroglyphs which led to alphabetic letters. By natives in Africa the dogheaded ape is still regarded with respect because it is believed to have an intelligence of the highest order, and can be more cunning than man.

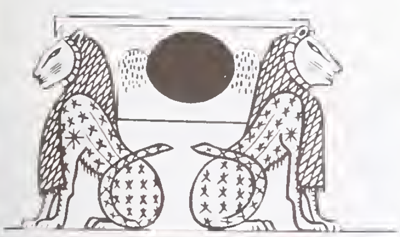
from a carving on the ceiling of the Ramesseion in Thebes which shows a Djed Column surmounted by a cynocephalous monkey producing water from its penis. Horapollo explained the symbol: "To signify the two equinoxes they—the Egyptians—depict a sitting cynocephalus, for at the two equinoxes of the year it makes water twelve times in the day, once in each hour, and it does the same also during the two nights; wherefore not without reason do the Egyptians sculpture a sitting cynocephalus on their Hydrologia (or waterclocks); and they cause the water to run from its member, because the animal thus indicates the twelve hours of the equinox. And lest the contrivance, by which the water is discharged into the Horologium, should be too wide, by discharging the water quickly, does not accurately fulfill the measurement of the hour, neither the one that is too narrow, (for against both of these cautions must be taken, for one that is too wide, by discharging the water quickly, does not accurately fulfill the measurement of the hour, neither the one that is too narrow, since it lets forth the water little by little, and too slowly), they perforate an aperture to the extremity of the member, and according to its thickness, insert in it an iron." Furthermore, as was shown on the base of the Theban obelisk removed by LeBas, the male cynocephalous was used as a symbol of the priest, worshiping the sun at rising, with arms and phallus erect, for which, as Kenneth Grant shows in his *The Magical Revival,* "Horapollo preserved a talisman or gnostic gem in yellow jasper, on which was engraved a cynocephalus, crowned with baton erect, adoring the first appearance of the moon."

In ancient Egypt the passage of time was also registered in the temples by the periodic fluxes of the sacred baboon, the female cynocephalous, or dog-eared ape. As Grant points out, "She was the first Mother of Time in the pre-human phase of symbolism, and the prototype of the clepsydral horologue"—or waterclock.

Horapollo also gives a vivid description of how the ancient priests of Egypt used both male and female cynocephalous to establish the moment of eclipses: "At the exact instant of the conjunction of the moon with the sun, when the moon becomes illumined, then the male Cynocephalus neither sees, nor eats, but is bowed down to the ground with grief, as if lamenting the ravishment of the moon. The female also, in addition to its being unable to see, and being afflicted in the same manner as the male, emits blood from the genitals; hence even to this day Cynocephali are brought up in the temples, in order that from them may be ascertained the exact instant of

Mexican relief in Palenque with the equinoxial lions, recognized by Masons as replete with Masonic symbolism





Equinoctial symbols identical in meaning with similar Mayan glyphs in Yucatán. The two lions represent Shu and Tefnut, guardians of the stability of the rising equinoctial sun.

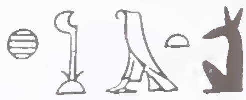
the conjunction of the sun and the moon. And when they would denote the renovation of the moon, they again portray a Cynocephalus in the posture of standing upright and raising its hands to heaven with a diadem on its head. And for the renovation they depict this posture, into which the Cynocephalus throws itself, as if congratulating the goddess, if we may so express it, in that they have both recovered the light."

A clue to the depth and subtlety of the Egyptian use of symbols, and especially animal symbols, to denote philosophic and cosmic realities is given by Grant in his *Cults of the Shadow,* where he points out, with reference to the periodic emanations of the female cynocephalous, that "Time is the menstruum in which all material forms arise, transform and finally dissolve."

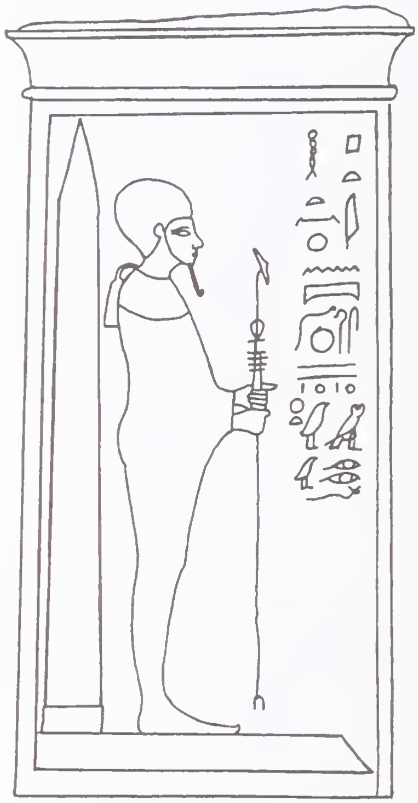
And so, at last, becomes clear the ancient purpose of the obelisk and Djed pillars in what could be called a precataclysmic era. Sometime far back in Egyptian history a geodetic view of the world and an astronomical view of the heavens were put together from a viewpoint that was located on the equator. Seen from this equatorial vantage, the earth was pictured falling off northward toward the North Pole and southward toward the South Pole, at each of which there appeared to be a fixed star for the heavens to revolve around. These poles were symbolized by two obelisks, one for Horus and one for Set, each of whom was considered to hold sway over half the globe, on either side of the equators. A similar division was made of the starry planisphere, from zenith to nadir, Horus charged with the northern half, Set with the southern, each equally responsible for twelve of the day's twenty-four hours—all of this, of course, long before any satanic, sinister, or evil character had been attributed to Set.

East and west, at the ends of the equatorial—and stably equinoctial—line, Shu and Tefnut, supporters of the sky, were pictured as the two lions of the "double-horizon," keepers of the balance between Horus and Set. This equatorial world—where there was obviously no solstice—was known as Apta.

The Jewish historian Josephus, who attributed to the children of Set(h) the invention of astronomy, preserved the tradition of two pillars erected in the land of Siriad, which Plato mentions in the *Timaeus,* but could not locate. According to John Greaves, who measured the Great Pyramid with Burattini in 1639, "these pillars of Seth were in the very same place where Manetho (the Egyptian historian priest of the third century B.C.) placed the pillars of Taht, called Seiread." Gerald Massey, in his two-



Zootypes of Set



Ptah as the universe's djed pillar of stability. Ptah, "the father of fathers," was considered creator of the universe. Fashioned of his own body in his own image was Ra, the Disc of Heaven. In *The Book of the Dead,* Ptah is said to have raised up the gods from inertness, meaning that all the gods were merely other forms of Ptah himself. As master architect of the world, Ptah fashioned the bodies of men on earth and in the Tuat, or heaven. He is depicted as raised upon the level of Maat, or justice, bearing the menat, symbol of well-being and sexual intercourse, the ankh of life, and the djed pillar of stability.

volume *The Egyptians,* says *Seri* in Egyptian is a name for the south, and is also "the mount that is figured as the twofold rock," equivalent to "the pillars of the two horizons, south and north." And, as Massey points out, Seri is also the name of the giraffe—a zootype of Set.

Clearly something must have happened to upset this balanced equatorial view and forced it to be exchanged for one seen from much further to the north. Either the scanners of the sky moved north, or some agency caused a tilt in the planet. In either case, or both, it is clear that the domain of Set was seen to fall away into the underworld. Set's fixed star of the South Pole vanished. Fewer and fewer of the southern stars and constellations still rose above the horizon. And the north celestial pole, as it rose in the sky, became imaged as a dominating mountain, a summit for the gods. But as the ancient priests of Egypt, says Jean-Louis Bernard in his most original *Aux Origines d'Egypte,* were mythologers and astronomers as well as geographers, in their equation Horus came to symbolize the boreal constellation as the home of the gods, while Set, rather than being merely the geographical south, became the fire in the center of the globe. Thus Horus became the cold of the cosmos and Set the telluric heat of the earth.

The story of the two pillars, and the disappearance of the southern one, was kept alive in the Greek myth that tells of the temple of heaven being raised high by two brothers, Trophonios and Agamedes, followed by the sinking of Trophonios into a cave, corresponding to the engulfing of Set as the disappearance of the South Pole below the horizon. Travelers from the equator arriving in the valley of the Nile, 3,000 miles north, apparently continued the device of dividing their new land into two realms, a northern one for Horus, a southern one for Set, staked out by two obelisks.

Legend states that two pillars were reerected at Annu as symbols of the northern and southern poles. Massey says the original meaning of *Annu* or *On* appears to have been "the place of the pillar, or stone, that marked the foundation which preceded the ⊕ (equatorial) sign"; and, notes Massey, a relic of the two poles may be recognized in the two Egyptian cities of Annu—called by the Greeks Hermonthes and Heliopolis. The line between the two obelisks, as Pochan has demonstrated, marked the equinoctial Passover. Further legend relates that eventually the two pillars of Set and Horus were united into the Tat or Djed Column raised at the winter solstice. But here the legend becomes spiritual and eschatological, for it is said in the *Book of the Dead:* "When Osiris-Ptah had built his mansion in the double earth, the two horizons were united. Two pillars at the gateway to his house were Set and Horus." These pillars were portrayed as the double Tat or spiritual Djed stones of eternal stability in the making of Amenta, the Egyptian world of the dead.

Amenta as described by Massey "was the secret but solid earth of eternity opened up by Ptah when he and his followers, the seven Khnemmu, erected the Tat pillar that was founded in the winter solstice as the figure of a stability that was to be eternal." Some further clarity may be obtained in this apparent confusion if the mythological, astronomical, and eschatological views are kept separate, even though the characters and symbols appear and reappear in every scene. Whereas in the myths the Tat pillar represents the sun at the winter solstice, a sun which has the power of returning from the lowest depth and thus completing its eternal round, in the eschatology the Tat column is the god himself in the person of Ptah-Sekeri, or Osiris, the backbone and support of the universe.

The figure of Amsu-Horus rising in the resurrection, or "coming forth" with member erect, has a dual character, says Massey: one in the mythology, one in the eschatology. In the mythology, he images the phallus of the sun and the generative force that fecundates Mother Earth. In the eschatology, the image of erection is repeated as a symbol of the resurrection; and in this phase, the supposed phallic god, the figure of regenerative force, is typical of the resurrection or reerection of the mortal in spirit.

Horus erecting the Tat in Sekhem (Sekhem being the glyph for potency or erectile force) was the raising of Osiris from the sepulcher; it was the father reerected as the son, or the typical resurrection and continuity of the human spirit in the afterlife.

The figure of Amsu-Horus resurrecting or "coming forth," with member erect, had two characters, one in the mythology, one in the eschatology. In the mythology he images the phallus of the sun and the generative force that fecundates Mother earth. In the eschatology the image of the erection is repeated as a symbol of resurrection; and in this phase the supposed phallic god, the figure of regenerative force, is typical of the resurrection or reerection of the mortal in spirit.

From this world, geodetic point of view, further clarity is obtained by postulating some real life cataclysmic event, or even a chain of such events, which affected the mythological characters in their astronomic settings, putting an end to what may have been the legendary and evidently equinoctial Golden Age of Saturn, in a land of "welling waters" where food came of itself and was perpetually renewed with little need for labor.

As the astronomer geodesists moved north, in a world whose axis may have tilted, they seem to have reproduced their former system with its former mythological, astronomical, and eschatological characters, but in a new geodetic and astronomic setting. Upper and lower Egypt were divided into seven nomes (each 1° of latitude) under the starry circle of the Great Bear, the goddess Apt, Taurt or Khept, symbolized by a big-titted female hippopotamus, mother of the cycles of time, with the *meanit,* or bull-roarer by her womb to represent the great generative source of life. Behind her stood a crocodile for the constellation Draco. No wonder the general picture as reconstructed from glyph, text and legend is not always pellucid, and often appears garbled, no doubt by the passage of several thousand years. But the central points remain.

Egyptian star-gods near the north pole. The hippopotamus, or Apet, with the crocodile over its shoulder corresponds to the constellation of Draco, the good dragon that coiled about the pole of heaven to protect the fruit of the Tree of Life. Stecchini says the line held by the figure of Horus marks the earth's polar axis terminating in the bull, Egyptian glyph for the Great Bear. E. A. Wallis Budge saw Horus as "attacking the Great Bear," and despite the overwhelming evidence before him of the vast and sophisticated astronomical science of the Egyptians, he continued to maintain that the Egyptians had "borrowed their knowledge of the Signs of the Zodiac, together with much else, from the Greeks."

The raising of the Djed, or Tat, Column, from a geodetic and astronomic point of view, was the restabilization of the axis of the world, and of the sky. As Livio Stecchini has pointed out, both poles, one for the earth's polar axis, and one for the sun's polar axis, were clearly known to the ancient Egyptians, who differentiated them in their designs, aware that the one formed a small circle around the other, causing the equinoctial point in the heavens, as observed from earth, to advance each year for the twenty-six-thousand-year cycle of the Precession of the Equinoxes.

In the myth in which Shu-Anhur lifts up the heaven from the earth, the Egyptians explain that the pillar of heaven was first erected. This pillar of heaven was envisaged as standing upon the earth; but when, in mythology, the earth was "hollowed out by Ptah," there was formed another earth below, in which the pillar had to be reerected. This pillar of "the double mount" was represented by the double Tat of Ptah as the backbone of that god, who later became Osiris. Eschatologically, when the sky was re-suspended by Ptah in the other world of Amenta, the act was symbolized by raising up the Tat type of stability and support. This not only sustained the sky of the nether world, it also imaged the divine backbone of the universe.

As Gerald Massey, who has the most scholarly, extensive, and intuitive approach to this view, points out in *The*

Egyptians, "knowing as they did that the earth rotates on its axis, afloat in space, the two poles of the earth were signified by the two-fold tat-pillar of Ptah, doubled when Amenta was founded. . . . The two obelisks, then," he notes, "imaged the thrones of the two worlds, the double earth, or earth and heaven, and in Amenta the two pillars form the doorway from the one world to the other."

The power that sustains the universe is Ptah in one cult, Osiris in the other. God and cross are one. The deceased arises from the tomb as Tat for eternity in what is known as the mystery of Tattu.

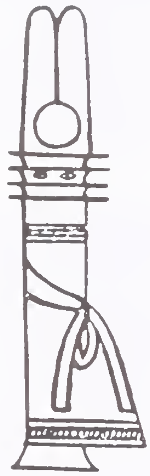
The ceiling zodiac removed from the Temple of Denderah, analyzed by R. A. Schwaller de Lubicz. It shows the circumpolar constellations spiraling rather than circling the pole of the ecliptic, indicating an understanding of the circular wobble made by the earth's north pole around the pole of the ecliptic, which causes the phenomenon of the precession of the equinoxes, whose ages are here identified on the zodiac by special markers on the perimeter.

When Queen Hatshepsut erected her two pillars, she said she had made two obelisks "for him who is the lord of the thrones of the two worlds—of earth and of heaven." The double obelisk, according to Massey, is a cotype of the twofold mount (of the poles) and the two pillars of Tattu, the place where it was shown that earth was fixed and heaven made stable forever on the two pillars of Set and Horus, which had once been the two poles in Equatoria.

The Tat, says Massey, was a figure of the pole, and the four corners, which united "five supports," the fivefold tree of the Egypto-gnostic mystery. Otherwise stated, it was a symbol of the power that sustained the heavens with the supporting pole and the arms of the four quarters. This power was personified in Ptah as well as figured in the Tat.

The tree was first of all a sign of sustenance when the sustainer was the Great Mother, Apt. On this, the type of Ptah was based as the Tat-image of a power that sustained the universe. Osiris-Tat then typified the power that sustained the human soul in death. This symbol Tat was buried with the mummy as a fetish in the coffin. Thus a cult of the cross was founded many thousands of years ago. And thus, says Massey, the genesis of the legend of the cross, like that of the Christ, can be traced in Egypt to the cult of Ptah at Memphis, where the religion of the cross originated; and to Annu or On where it was continued in the cult of Atum-Ra with Ie-em-hetep as the Egyptian Jesus.

Iu-em-hetep, says Massey, was the god Iusa, brought out of Egypt by the Jews—for thirteen thousand years the bringer of goodwill and peace and plenty to the world. "The Christian doctrine of the crucifixion, with the human victim raised aloft as the sin-offering for all the world, is but a ghastly simulacrum of the primitive meaning; a shadowy phantom of the original substance." Fundamentally, according to Massey, the cross was astronomical, a



The raising of Djed, or its "awakening," has been called the mystery of mysteries, or the secret of resurrection. The human body is described as an illusory solid, perishable, but what caused it was a real solid: the original djed, or "word" of Amon-Ra-Ptah. This djed "word," or pillar of Osiris, is described as the base of relative stability, and principle of whatever is durable in the fluctuating Osirian world of becoming and return. Man's job is to learn to make his own djet—or inborn word—secure against destruction. When awakened, man's djet becomes his incorruptible body. It is said to remain a prisoner of earth and Osiris unless Ra comes to deliver it by "untying the rope" or "undoing the knots." The two principles of Ra-Osiris are seen as the life-givers to the human djet, symbolized by the souls of Ra and Osiris shut up in the djed, or pillar. As such they are the two currents of universal life whose source is one, though they are two in nature. This duality is the cause of terrestrial continuity and the endless metamorphosis of the Osirian way. To escape from such slavery the soul of Ptah-Ra must absorb the Osirian: the universal must vanquish the particular.

figure of time, as is any clock. It is a measure of time made visible upon the scale and in the circle of the year instead of the hour. A cross with equal arms denotes the time of equal day and night, a figure of the equinox. Another cross, †, like the Christian cross, with one elongated stem, is a figure of the winter solstice. It is a modified form of the Tat of Ptah on which the four quarters are more obviously portrayed in the four arms. This elongated cross, or Tat, was reerected annually in the depths of the solstice when the darkness lasts some sixteen hours and daylight only eight.

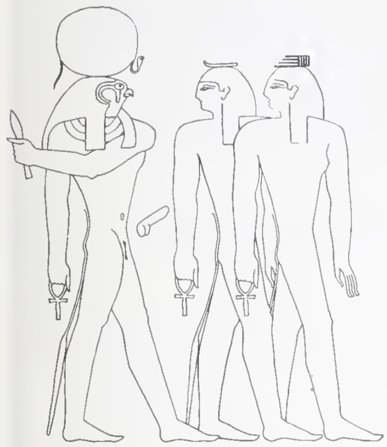
The Tat cross is a type of the eternal Tattu. It was the figure, says Massey, of the all-sustaining, all-renewing, all-revivifying power that was reerected and religiously sought for hope, encouragement, and succor when the day was at its darkest and things were at their worst in physical nature—when the sun was apparently going out.

The Tat—for the time being—was overthrown. The deity suffered and was represented as dead. The god in matter was inert and breathless. Then they raised up the Tat, portraying the resurrecton of the god. "Let the mummy-type of the eternal be once more erected as the mainstay and divine support of all." It was thus, says Massey, that the power of salvation through Osiris-Tat was represented in the mysteries.

The work *Djed* in ancient Egypt meant "stable" or "durable." But it was used not only to represent a cosmic pillar, or sky support; it was also a symbol for revival and resurrection.

At their mystery festivals the Egyptians represented the passion of Osiris, the scandal of his death, and the miracle of his resurrection to a radiant immortality. As E. A. W. Budge points out, the Djed was in very primitive times the symbol of a god to which human sacrifices were offered, and the ground in front of it was "watered" with the blood of human beings, sometimes foreigners, sometimes warriors taken prisoner alive. The victims were slain before the Djed pillar, symbol of Osiris, and their blood was dug into the earth to make it fertile again. Osiris's death was commemorated by eating the body and drinking the blood—later the eucharist or mortuary meal at the Easter equinoctial festival of death and rebirth.

In the previous eon the Great Mother was sacrificed—comparatively young, says Massey, to preserve her from the effects of age, disease, and decrepitude. Her flesh was torn to pieces and her blood drunk to give life to her children. Salvation in this eschatology came from the virgin blood in which Horus was incarnate and made flesh.



According to the Egyptian myths, the divine pair Hu Saa came into the world when Ra in his solitude cut off his sexual organs. The two deities arose from the blood of the sun god.

Later the ritual was performed symbolically with bread and wine in lieu of the body of Osiris-Horus; later still with Jesus. As Massey points out, the Egyptian Horus was continued by the various sects of gnostics under both the names of Horus and Jesus.

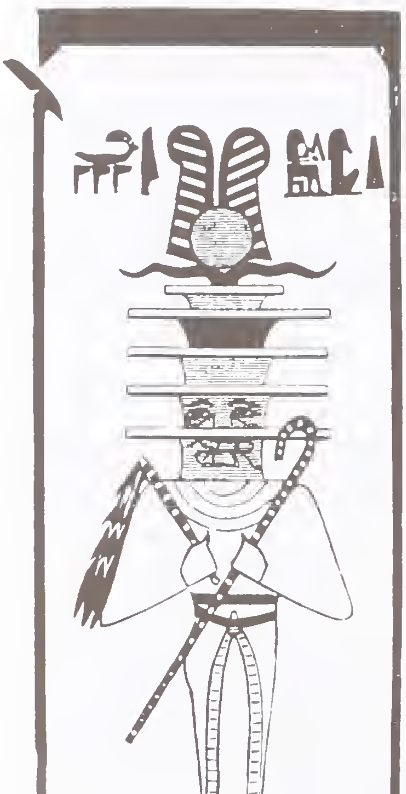
Egypt, says Massey, had anticipated Rome in attaining the "unbloody sacrifice" that was represented by the wafer, or loaf, of Horus as the bread of heaven, which took the place of flesh in the eucharistic meal, while retaining the beer or wine, as substitute for blood, representing the female element.

The earliest form of god-the-father who became a voluntary sacrifice in Egypt was Ptah in the character of Sekari, says Massey. As a solar god he went down into Amenta. There he died and rose again, and this became the resurrection, and the way into a future life as the founder of Egyptian eschatology. Atum, son of Ptah, likewise became a voluntary sacrifice as the source of life. The father who was blended with the mother in Atum, is portrayed as the creator of mankind by the shedding of his own blood. In cutting his member, Atum showed that he was the creator of the blood shed in a voluntary sacrifice. Later, this was ritually done to Attis, Adonis, Tammuz, Bacchus, Dionysus, all facsimiles of Osiris, all castrated on the tree of life, their testicles still glittering on today's Yuletide trees.

The agape was the way of celebrating the resurrection. But death came first. In the Nile Delta, at Busiris, known as "the city of the Djed Column," a great annual festival took place during the last month of the inundation of the Nile when the waters fell off—that is, in September, at the autumn equinox. The ceremony consisted in the dramatization of the death, vigil, and resurrection of Osiris. The final and most sacred act was the erection of the Djed Column, symbol of the backbone of Osiris. When raised upright it meant that Osiris had risen. But not, apparently, in the flesh; in the spirit.

As Rundle Clark, author of *Myth and Symbol in Ancient Egypt,* puts it: "The idea of the Djed Column is that it stands firmly upright—for to be upright is to be alive, to have overcome the inert forces of death and decay. When the Djed is upright it implies that life will go on." The greatest religious achievement of the Egyptians, says Clark, was to take this general fertility god and make him into the savior of the dead; or more exactly, the savior from death. "It was in the soul of Osiris the Egyptians believed they would live on." The rising of Osiris was the central fact in the structure of their universe; this they

There can be little doubt says E. A. Wallis Budge, "that the is a conventional representation of a part of the backbone of Osiris, namely the *sacrum* bone, which, on account of its proximity to the sperm bag, was regarded as the most important member of the body." Tet is the name of a very ancient god whose worship was merged with that of Osiris, and his symbol, says Budge, was the sacrum bone, , placed on a pedestal, which then took the form of the Djed pillar, "which was during the whole of the Dynastic period in Egypt regarded as the backbone of Osiris." The Djed, Tat, or Tet pillar was also the emblem of stability represented by Ptah, "the fourfold support of the universe."



signified by the raising of the Djed, or stability, Column.

Osiris, Clark notes, did not rise up and leave the tomb or underworld. It was his soul that was set free into the life forces of the next year. He was the spirit of Life manifest in sprouting vegetation, in the seed of animal and man, the "orgone" of Wilhelm Reich.

Yet the raising of the column was not the final act of the drama. A loincloth was tied around the middle of the Djed Column, and feathers were stuck in its top. The resulting symbol was treated as a living god, so much so that in the later examples a pair of human eyes were painted onto the column to make the identification with Osiris more emphatic. Around the Djed was tied what Clark calls "a strange object known as a Tit, a knot of cloth or leather." This was the emblem of Isis, or the Mother Goddess. It is the symbol of the blood of Isis, when she gave birth to Horus.

Clark has trouble with this symbolism: "It is presumed that this combination of emblems denotes the Union of Isis and Osiris. . . . This union of male and female obviously has some meaning, but it is impossible to see how it links up with the rest of the symbolism."

Massey has less trouble. He explains the mysterious rag attached to the raised Tat: "It is the feminine garment, or apron, called the garment of shame because it was the garment of impurity to be trampled underfoot when the male and the female were to be made one in spirit, as spirit." And the same feminine garment, Massey points out, "is still worn without shame as the bishop's apron," an apron he traces back to the feminine loincloth first worn by that sex, for what he calls "the most primitive and pitiful of human needs at the time of puberty." The bishop in his apron, says Massey, "like the priest in his petticoat and the clergyman in his surplice, is a likeness of the biune being who united both sexes in one."

So the equinox came to be considered a symbol of equality, of all things being on a level. And promiscuity was a mode of making things fair and even in the sexual saturnalia. High and low, rich and poor, young and old commingled "on the mound, the hill, the high places." To symbolize this equality, a pair of scales was also erected at the equinox, "for with them the equilibrium of the universe was dependent on eternal equity."

The mystery of reproduction was enacted at the festival as a vicarious means of fecundating the Great Mother by the bountiful sowing of human seed. The ritual survived as the agape, or love feast, of the early Christian cult. The phallic festivals were then repeated at both equinoxes; at seed time and at harvest time. The desire was to produce an unlimited supply of food; and the rites of promiscuous sex were designed to help reproduce the fruits of earth and drive away inimical influences of drought and famine.

The women, being the begetters and regenerators, pleaded that their wombs might be replenished, as Isis and Nephthys had done with Osiris's corpse. Women are described by Elie Reclus in *Curious byways of anthropology; sexual, savage and esoteric customs of primitive peoples,* as losing all feeling of modesty, of becoming raging Bacchantes, wild with debauch. "At the Spring equinox," says Reclus "divinized Mother-earth had to be stirred from her winter sleep by lascivious spectacle to excite the spirit of fecundity represented by young women who danced and frolicked or lay down and scraped the ground with their heels . . . so many naked Danaes wooing the fertilizing sun . . . bursting out of all disguises, trappings, ties, and stays of civilization, running amok in all the nudity of nature."

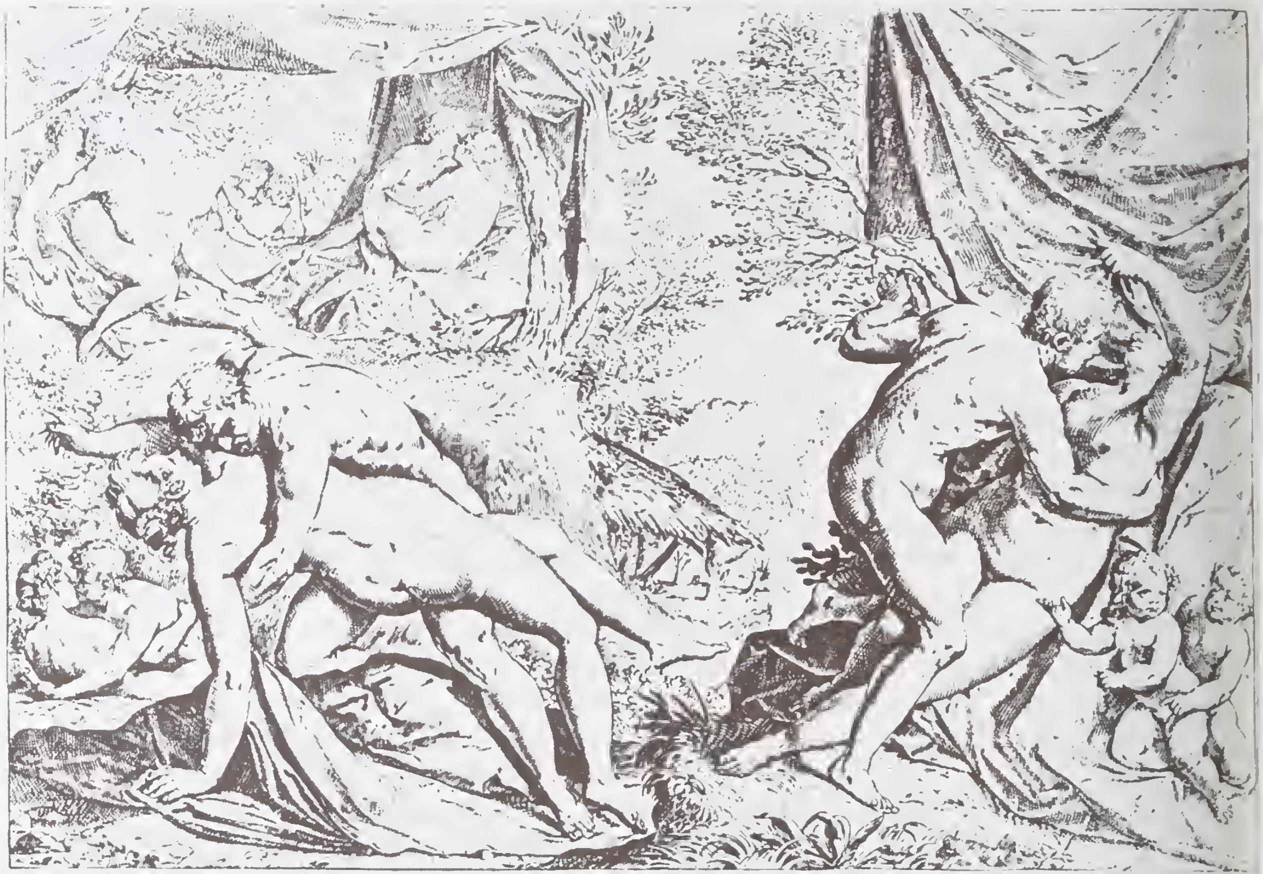
Herodotus reports that in the Delta city of Bubastis 700,000 people assembled to celebrate the annual Festival of the Great Mother, Bast, goddess of strong drink and sexual passion, and that women exposed themselves on boats to watchers on the shores, signifying they were free to all comers, for that occasion only, in service of the goddess, the lioness of heat.

The phallic festival of promiscuous intercourse survived when the mysteries had become religious in Egypt, Greece, and Rome. In Rome the Saturnalia, which was intended to commemorate the carefree era of sexual promiscuity that had once obtained, was a mode of celebrating the fundamental equality of all at the equinoctial period, by means of various leveling customs, in which men and women exchanged their clothes to show the equality of the sexes.

All over the world tribes have reverted to utter promiscuity to celebrate the phallic festival, when "the only law was that of all for all." Reclus describes how with members of marital associations among the Eskimo, each wife must lawfully couple with the man to whom her husband would willingly lend her, and who would lend his own wife in return, holding that "all were made for all, and that sin was for a lawful wife to seek connubium with a bachelor."

In southern India, says Reclus, the Thodigars, at the Festival of Sowing Seed, improvised shelters by the roadside and stocked them with provisions for their wives, calling upon passersby to "procure the public good and ensure an abundance of bread."

Bast has been described as the gentle and fructifying heat of the sun, the very soul of Isis. Not only a pleasure-loving goddess who reveled in music and dance, Bast was protector of pregnant women and of men against disease and evil spirits. But the Hebrew prophet Ezekiel threatened that the joyous young participants of the rites of Bubastics would "fall by the sword and be carried into captivity for their worship of Bast."



Come la palma indicio è di uittoria,
Cosi d' Amor conuenente è il frutto

Quella dolcezza, da cui uien produtto
Il seme, onde Natura, e'l ciel si gloria.

In the world of totem, the raising of a pole served to announce the transformation of pubescent girls into the state of womanhood. The pole, raised high immediately after the ceremony or operation of introcision, was a signal for men from as far away as the pole could be seen to come and enjoy a festival of sexual promiscuity, one at which the freshened girls were "welcomed into communal connubium by the whole totemic group of grown-up males." On this occasion the girls were considered open and accessible to all the males of the group, each of whom had the right to ravish any or as many of the girls as he was able. As Massey explains it, the ritual was a revival of the ancient pretotemic days of totally permissive sexual freedom, free from all taboos.

What has been lost sight of by both the prurient admirer and puritan denigrator of these rites is their spiritual basis as practiced by the Egyptians. The agape, or phallic feast, with its sexual orgies, was a mode of celebrating not only the raising of Osiris, the return of sunshine and revival of vegetation, but the rerising of Horus, prince of Sekhem; Sekhem being the realm of the Akh or "bodies of light," comparable to stars. Horus, erecting the Tat in Sekhem was raising Osiris from the sepulcher; it was the father, reerected as the son in the typical resurrection, and continuity of the human spirit in the afterlife.

The love feast at the equinox on earth symbolized, as Massey explains it, the triumph and regenesis of the soul in Tattu. And the enactment of the "holy kiss," or blending of the sexes in the feast of love, was a dramatic rendering of the union between human nature and the divine, of the original brother and sister, Shu and Tefnut. The "pair of souls" were blended in the Horus of the soul that was to live forever.

According to the mystery of Tattu, in blending back into one the two halves of a soul that was dualized in sex, and dualized in spirit and matter, there was a return to the type beyond sex, from which the soul had bifurcated in the human creation. Thus the two halves of the soul, male and female, Shu and Tefnut, were reunited forever in Tattu.

17. NEEDLING MOTHER EARTH

All over the world, amid all its peoples, in all known ages, obelisk, column, tower, steeple, and menhir have been understood to be phallic symbols, not just of the erect male member, but, as the nineteenth-century English Freemason Hargrave Jennings expresses it, of a "supersensual, superessential, divinely operative celestial 'fire'" —a force which makes things grow, harden, and rise against gravity, fecundating the universe, producing all beings and all life.

Among the Greeks, the most appropriate emblem for the power exercised by this "fire" was considered the dart or arrow—hence the word *obelos*. Every obelisk was a representative in stone of a ray or beam of "far-darting, operative, vivifying fire." It was likewise with the pagodas of China, the towers of India, the minarets of the Muslim, the cairns of Carnac in France, the biblical Jacob's stone, Saint Paul's Cathedral: all, says Jennings, symbolic of the power of creation. And the apex, whether it be the piercing pyramidion of the obelisk or the egg-shaped top of the minaret, represents the glans. The purpose of these phallic symbols, their justification for existence: to venerate the power behind generation, behind production and renovation.

In a 500 page opus on *Phallicism,* and in a 100-page booklet entitled *Obelisks,* Jennings chided his fellow Victorians for believing their science was more advanced than that of the Egyptians, and put forth his view that whereas obelisks, towers, and steeples were representations of the male principle, pyramids, circular forms, rhomboidal or undulating, and serpentine shapes, denoted the female power. Yet all alike, said Jennings, represent the natural motive power which causes and directs the world. Together, the male and female symbols represent the idea of swelling, rising, extending, to be consummated in what Jennings calls "the movement for that grand human act and holy sacrament which secures everything." The pudenda in both male and female he calls magnets, "and their natural, deliriously delightful presentment to each other is magic-magnetism." These phenomenal organs, Jennings observed, "superb and miraculous in their special address and use," are "positive-negative" in man, and "negative-positive" in woman. "Yet both are corporeally and sexually one, in complete coition, or double-tie, or identification of 'two singles' into temporary, absolute 'one single.' "

In these *avant garde* views, Jennings was apparently strongly influenced by Richard Payne Knight's remarkable volume *A Discourse on the Worship of Priapus,* published at the time of the French Revolution, which set out to show that the worldwide worship of generative powers was neither obscene nor depraved. Designed to sell privately, it caused such an uproar in Victorian England that many copies had to be destroyed, so that for almost a century it was hard to find, until recently reprinted. From its sober scholarship Jennings became convinced of the value of the pagan concept that sexuality is the fundamental power of life which animates the universe and brings forth nature in all its beauty and wonder. He also got inspiration from a contemporary, a colonial officer in India, Edward Sellon, described by his Victorian compeers as a "minor pornographer" and by modern commentators as an "industrious lecher," whose booklet, *Annotations on the Sacred Writings of the Hindus,* is, in fact, an equally sober and scientific anthropological description of the mysteries of Tantric sex as practiced in India. In it Sellon describes the religion of the Hindus as being based on the deity Bruhmatma, worshiped through an emblem, a black stone in the shape of a phallus, or Linga, symbolizing the procreative power of nature, which fructified the earth and which manifested in three forms: as the creator Brahma, the preserver Vishnu, and the destroyer Shiva. To create the world, Brahma is described as making himself androgynous, the right half male, the left female.

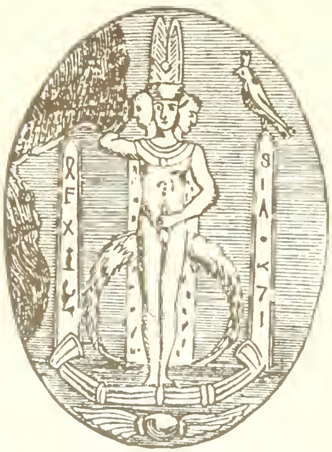
A close analogy was found by Sellon between the rituals of Hindus and those of the Egyptians. He equated Shiva with Osiris, and Sacti with Isis, represented by the same equilateral triangle with a dot in the center, the same emblem of the generative power—two coexisting principles of nature, active and passive, linga and yoni.

Sellon describes Hindu Tantric sexual rituals as being performed with naked temple courtesans or *yoginis,* young and beautiful, representing the goddess Sacti, or power, reciting mantras, becoming sexually excited and inducing promiscuous orgies among the votaries which he qualifies as "very licentious" but constituting a mysterious initiation. He further describes Sacti as represented *in coitu* sitting on Shiva's erect member, just as Isis "the goddess who grants all desires" did with the dead Osiris. Similarly, a statue of Minerva at Sais, who Sellon says was invoked by the union of X and O, or phallus and kteis, he found bore a striking resemblance to Prakriti, the Hindu deity of generation.

In India temples were adorned with the most exquisite of couplings, and everywhere the phallus was worshiped publicly in the form of the linga, the vulva as the yoni. Twelve huge phalli are still objects of veneration today, regularly asperged and strewn with flowers. One, of basalt, at Benares, requires six men to encircle with their arms outstretched. In the villages there were once many small upright lingams as described by Dr. Thomas Inman in his *Ancient Pagan & Modern Christian Symbolism Exposed and Explained;* on these women lowered themselves "having first adjusted their dress so as to prevent interference with their perfect contact with the miniature obelisk." At the time of the Muslim invasion of India, the worship of the linga was still common all over the country, but many were destroyed by the reforming invaders. The most notable lingam, a polished black stone at Somnath in Guzerat, was demolished by Mahmud of Ghezni, but fragments of it ended up in the Kaaba in Mecca, an ancient pre-Islamic geodetic and holy spot.

King Solomon, said Jennings, devoted his energies and wealth to raising phallic or "fire" shrines over high places, and especially in front of the temple in Jerusalem. Though the temple was only 120 feet long, 40 broad, and 60 high, its portico was a large tower 240 feet high, which to Jennings represented an obelisk. On each side of this great spine, at the temple's entrance, were two more handsome phallic columns, over 50 feet high, capped with pomegranates, to represent the Queen of Heaven, or a gravid uterus. To the initiates of Eleusis, who, according to Arnobius, venerate the female yoni in their mysteries, the pomegranate was sacred to Demeter and Persephone, representing the hidden riches within divinized earth. The two columns outside the Temple of Solomon, called by Masons Jachin and Boaz, represent "the fundamental divine polarity which underlies all manifested nature, the two opposites whose union constitutes the symbolic great Work of Alchemy." And to Jennings these columns are the equivalent of the Buddhist pillars erected by their dagobas, or the pillars of Hercules beside Phoenician temples. In Syria the counterpart of these "pillars of Hiram" was the great phallus described by Lucian in *De dea Syria*. According to General J. G. R. Forlong, the image of gold set up by Nebuchadnezzar on the plain of Dura, in the province of Babylon, was also a phallic obelisk, 60 cubits high by 6 in diameter.

Irish round towers, and Osiris swearing by his power



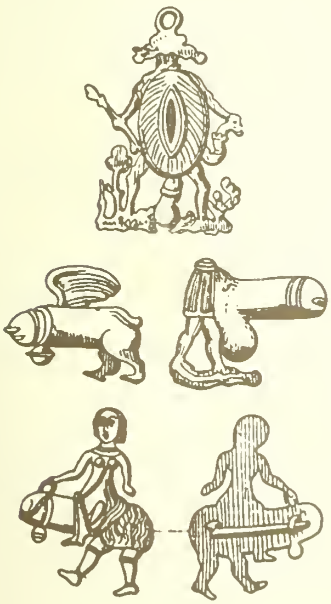
The round towers of Ireland, says O'Brien, author of a book by that title, were all phalli, raised in adherence to the ancient fire-worship of Persia, for the purpose of worshiping the sun, or male principals in the universe, and for studying the revolutions and properties of the planetary orbs.

As for the worship of the lingam in Britain, according to Forlong: "The generality of our countrymen have no conception of the over-ruling prevalence of this faith and of the number of lingam gods throughout our islands. We have been hoodwinked by the unjustifiable term 'crosses' applied to the ancient symbols which were always in the form of obelisks or columns, erected on prominent places." Forlong points out that the Nevern shaft at Pembroke could pass for a Mahadeva lingam in any part of India; the Cheddar shaft on the Mendip Hills and the Chipping column of north Gloucestershire are clearly lingams such as the Assyrians revered. So are the large obelisks of stone found in many parts of the north, such as at Rudstone in Yorkshire, which Pliny says was sacred to the sun. It is 24 feet long above ground and 6 feet broad, weighing 40 tons.

Michael Harrison in *The Roots of Witchcraft* recounts how in England just after World War II he was astonished to discover a widespread cult of the lingam dating back to medieval Britain revealed to him by Professor Geoffrey Webb, formerly Slade Professor of Fine Arts at Cambridge and then Secretary of the Royal Commission on Historical Monuments. Commissioned to survey ancient churches for aerial bomb damage, Professor Webb, an authority on medieval church architecture, was amazed, while studying the interior of an altar whose top slab of stone had been

shifted by an explosion, to find in the interior, unmolested and possibly unseen since the eleventh or twelfth century, a large stone lingam. Later, Professor Webb found that ninety percent of all the churches he examined dating up to the middle of the fourteenth century contained a phallic symbol of the fertility cult concealed within the altar.

Priapus, with an enormous erect member, was placed by Greeks and Romans in gardens as a magical aid to the growth of plants.



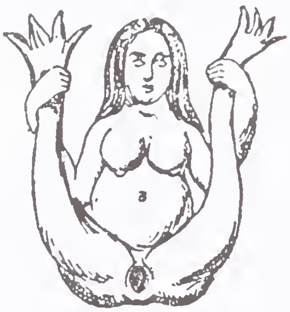
Jennings's fellow Freemason, Godfrey Higgins, author of *Anacalepsys,* considers Stonehenge phallic in its design, possibly a temple built during what he calls the post-Atlantian "First Dispersion." Its upright stone, known as the Friar's Heel, is a lingam or phallus, says Higgins, dedicated to Freia, the Friday lady, or Venus-Aphrodite. "And there to eastward of the holy pointer is the Os Yoni over whose apex the first ray of the rising god of the midsummer solstice shines into the center of the circle."

As a modern lady witch describes the scene at the summer solstice: "It is still thrilling as the sun rises above the phallic monolith, the Friar's Heel or Hell Stone: its rays strike into the feminine womb shape of the so-called 'horseshoe' of great trilithons, making a *hieros gamos,* or Sacred Marriage of heaven and earth."

Throughout Britain there are stones of Neolithic origin believed to possess the ability to promote fertility in barren women, who embraced them in the hope of having offspring. In Carnac childless couples would run naked around a special standing stone, though modern dowsers believe the power that once manifested in that region of trance has since shifted.

In the French Pyrenees, reverence for the phallus in the form of a menhir is still alive today; elsewhere in France, apart from the well-known bishop of Lyons, honored as Saint Foutin, patron of *foutre,* or frigging, there stood near Brest the chapel of Saint Guignole, whose phallus consisted of a long wooden peg traversing his statue and stretching out in front. With scrapings from this peg, votaries made infusions as an antidote to sterility. As the peg was worn down, a blow from behind with a mallet brought it to its pristine prominence.

In Italy, the phallus—also called the *fascinum* because it exercised such a power of fascination by sight alone that it drew all glances to itself—was everywhere in evidence, until the reformed Church. Thereafter a hundred thousand phalli were knocked from pagan statues and rural herms, and in architecture, as Jennings lamented, "the lingam of yore was thickened and wholly encased into a column, so veiled by ornate architecture that none but an awakened and practiced and educated eye could detect the old symbolism."



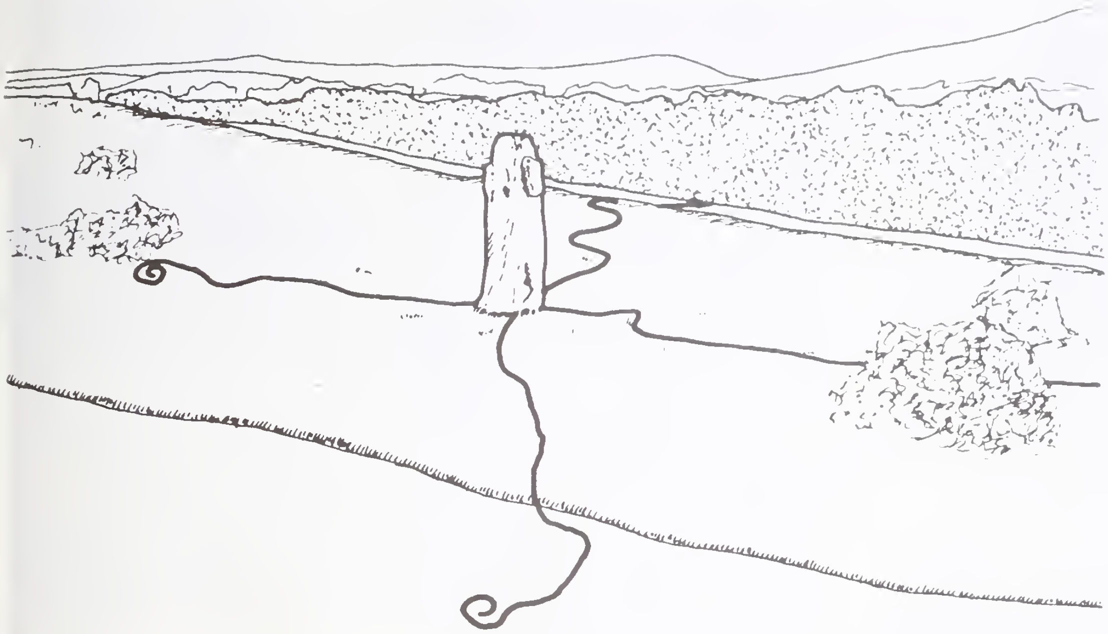
These naked females, representations of the great Fertility Goddess known as Sheila-na-Gigs, strikingly similar to the Yonis venerated by the Tantrics in India, indicate by their frequent appearance on Christian churches, that the old religion was still alive.

Elsewhere the phallus was reduced to a mere charm or amulet against the evil eye. To escape the attention of reformers, yet maintain the magic power of such an amulet, symbolizing coition of the sexual organs, it was tamely reduced to the least explicit of symbols: the hand.

Now modern authors have taken the whole subject of phallicism a step further to show that standing stones, both ancient and modern, are not only phallic symbols, but actual sources, or accumulators, of a power that is real—sexually and psychically stimulating, among its other varying qualities.

Guy Underwood, a dowser, and author of *The Pattern of the Past,* who has devoted a lifetime to unraveling the mystery of cosmic and telluric forces operating in and around the ancient temple sites of Britain, has demonstrated by means of various modern techniques of dowsing for water that the standing stones of the ancients are almost invariably positioned over important hidden sources of water, or "blind springs," as they are known to dowsers—a blind spring being the proper site upon which to sink a well. Not only upright menhirs, but flat supported dolmens, invariably mark blind springs of considerable telluric importance.

Brigadier General William Sitwell, author of *Stones of Northumberland,* describes the majority of standing liths



Waterlines crossing beneath a standing stone as depicted by Tom Graves in *Needles of Stone*. The Welsh water-diviner Bill Lewis has noted a force issuing from these stones which waxes and wanes. His work as an electrical engineer led him to conclude that water moving through a tunnel of earth, and particularly clay, creates a static electric field, and that two streams crossing, even at different levels, increase the field, and that a stone placed over the point of junction acts as an amplifier.

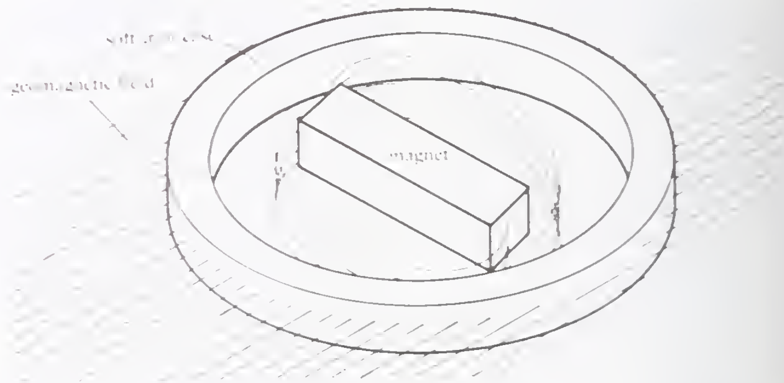
as "magnetic," by which he means that if one places a hand on them one receives the astonishing sensation that they vibrate. Other standing stones give off a tingling sensation of varying intensity, even amounting to an unpleasant shock which also seems to carry with it a shock to the psyche. Tom Graves, another professional dowser, author of *Needles of Stone,* has observed that some monoliths, if you lean against them, feel as if they were rocking slowly backward and forward; others seem to buzz.

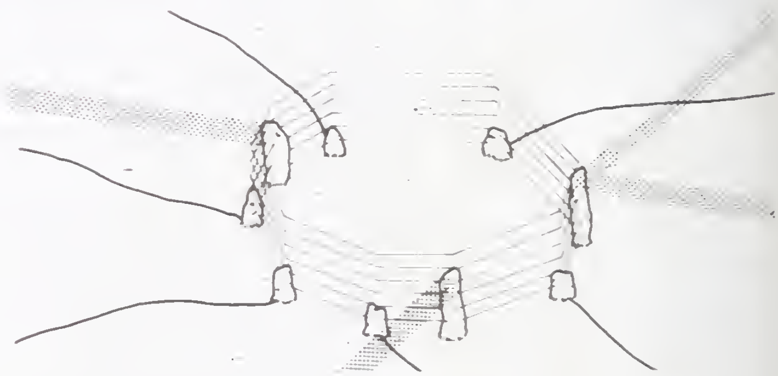
Sitwell has observed that most of Carnac's standing stones have been raised with their smaller end buried in the ground. By measuring the flow of observed current with a sensitive dowsing instrument, Andrew Davidson, in his *Silbury Hill,* found that stones raised in a circle show a predominantly positive or negative current, each one oppositely charged to its neighbor. Davidson further discovered that the polarity changed with the phases of the moon. Dowsing by pendulum at the time of a polarity change, he found that the pendulum would slowly stop, then gain momentum in the opposite direction, the whole process regularly taking several minutes.

John G. Williams, another dowsing researcher, from Herefordshire, showed on TV the power emanating from the stones as a spiral-like force which builds up in the body with the effect of propelling the investigator away from the stone. He says that most standing stones, including the Stonehenge uprights, if properly tapped for their energy, can cause a person to be thrown from them.

Graves describes being knocked flat by a sudden burst of energy from a circle of stones at Rollright in Oxfordshire: "Some kind of energy, possibly derived from the blind spring, at the center of the circle, and implied by the concentric haloes round the center, spread outward from the center and was collected at the perimeter of the circle, to be stored there by 'spinning' the energy from stone to stone." Graves also tells of inserting a small amount of energy into one of what he calls the "gate-latch" stones—which released all the stored energy in one go. "That was what flattened us in its passing." The interesting point, adds Graves, "was that the pulse of energy, whatever it was, seemed to leave the circle at a tangent to the line of the stones, traveling in a dead straight line. I think it went about six miles to the south-west, to a stone called the Hawk stone, and then split off in two different directions from there—or that's what the dowsing results implied."

Tom Graves illustrates the shock a man can receive from a standing stone. "The energy released," he says, "triggers off a violent reflex contraction of the back muscles, throwing him backward as much as ten or fifteen feet."





Graves makes an analogy between the change in a magnetic field caused by a soft-iron shield ring around a magnet and the effect produced by waterlines and overgrounds meeting a "shield ring" of stones. The ring, says Graves, allows the energy to bypass the area, isolating the outside world, as in a Faraday cage, from whatever may go on inside the circle.

That megalithic man must have learned about such accumulations of energy at mounds, standing stones, and circles is clear to modern dowsers who believe these particular spots were used for spiritual benefit, to increase energy and fertility, and to heal—practices which were consciously or unconsciously followed by later builders of churches and cathedrals on the same spots.

Monument found at Nîmes in 1875

Louis Charpentier, in his *Les mystères de la cathédrale de Chartres,* expresses the opinion that the orientation of churches and cathedrals springs from the ancient knowledge of the mysterious forces of earth which he calls "telluric currents," symbolized by the earth serpent, or dragon *vouivre.* The cathedral stands on a large prehistoric mound over a buried chamber, the natural meeting place, says Charpentier, of several powerful streams of telluric current, once the site of a great Druid college. And Juan G. Atienza, in his *Los Supervivientes de Atlantida,* shows that the Templars who helped liberate the Iberian peninsula from the Moors did so on condition that they receive outright ownership from the kings of Spain and Portugal of *all* the major megalithic sites, specifically selected because of some mysterious quality known to the Templars but apparently not to their donors.

Druids, Templars, and witches were clearly aware that some sort of mysterious power emanated from these locations, and the direct physical use of this power appears to have been their secret specialty. As these holy centers were taken over by the Church, and the magic often reduced to superstitious rote, followers of the old religion took to the wilder parts of the country, there to carry on their vivifying rituals.

Modern dowsers claim they can actually see the effect of nighttime dancing around standing stones. Graves describes how the pillars pick up the energy generated by the dancers. "They all glow with the same blue fire. The energy created by the ritual spreads the blue, the color of healing, throughout the countryside, that surrounds these

The central axis of the world, symbolized by the maypole, came to be regarded as a tree with the circumpolar stars—or souls—perched on its branches. Next, it was imaged as a pole with guidelines. "The great god lives fixed in the middle of the sky upon his support, as the universe, symbolized by the guide ropes, revolves around it."

ageless sacred sites." But not all the energies created by the ritual, he says, are necessarily physical. "They can be made physical by the way in which they affect people's attitudes, and thus their actions."

In a report on the perdurance of fertility rituals in Elizabethan England, the Puritan propagandist Philip Stubbs wrote: "Against May, Whitsonday, or other time, all the young men and maides, olde men and wives, run gadding to the woods, grooves, hills and mountains, where they spend all the night in pleasant pastimes," adding that he had heard it credibly reported "that of fortie, three-score, or a hundred maids going to the wood over night, there have scaresly the third part of them returned home again undefiled."

The maypole, as a phallic fertility symbol, used to stand in every village square in England until savagely torn down by sex-hating Puritans. In villages throughout Germany it is still at the ready. The energy produced by dancing around a maypole—a living needle of wood—has to be primed, says Graves, to work toward fertilizing the area. He notes that it is primed and directed by the state of mind of those participating in the dancing: "and what better way of framing a 'fertility' state of mind than spending the night in the woods, engaged in 'pleasant pastimes'?"

The sacred centers, by their accumulation of what Wilhelm Reich called orgone, may have helped to produce mass orgasms, therapeutic, in Reichian terms, to the whole person, as well as the whole countryside. And the suppression by the various churches of these pagan fertility rites may have stunted not only the natural sexuality of those who could no longer enjoy the ritual, but stunted great parts of the land. As Graves puts it: "The enforcement of a 'civilized' life has resulted in the destruction of the countryside and produced the meaninglessness of the life we suffer today."

Paul Screeton, an Englishman from Hastlepool who has written widely on the ancient wisdom, suggests that in prehistoric times the land may have been much more fertile, producing several crops a year, fertilized through fertility rituals. And modern witches, such as Doreen Valiente, author of several books on witchcraft, believe that a certain magical current commences at the equinox or solstice, reaches its peak at the following sabbat, and then declines, until the next station of the sun, when a new magical tide commences, and so on. Thus the tide set in motion at the spring equinox peaks at the witches' May Eve, then slowly ebbs until the summer solstice, when a new impulse commences.

Screeton, in his delightful *Quicksilver Heritage,* points out that the earth's magnetic field is estimated to have been 50 percent stronger in A.D. 500, and could have been even greater in megalithic times. Other observers believe that in earlier times man had a less dense body, more easily attuned to natural sources of power. And megalithic builders may have known how to draw extra energy from the sun—by the use of stone machines. Screeton suggests that prehistoric man, with his megalithic sites, gained control of terrestrial currents through manipulation of solar power, thereby producing a better environment. As the sun passed over the natural centers, it could cause an extra surge of energy, especially at noon, with differing effects at zenith, equinox, and solstice—the main festivals of Bards, Ovates, and Druids along with intervening festivals of Candlemas, Beltane, Lammas, and All Hallows.

John Michell, an avantguardist viewer of this magical world of antiquity, is poetic in his re-creation of the ancient magic: "At certain seasons of the year the dragon passed overhead down a straight line of country, drawing in his wake the fertilizing powers of life. Astronomers observed its passage, astrologers predicted the moment of its appearance, geomancers marked its course with alignment of mounds and stones."

Modern occultists such as Geoffrey Hodson suggest that "etheric rays" from the sun may have helped raise the level of consciousness of participants in rituals, helped cure disease, healed wounds both physical and emotional. Merlin is quoted as saying to Aurelius: "Laugh not so lightly, King. . . . For in these stones is a mystery and a healing virtue against many ailments."

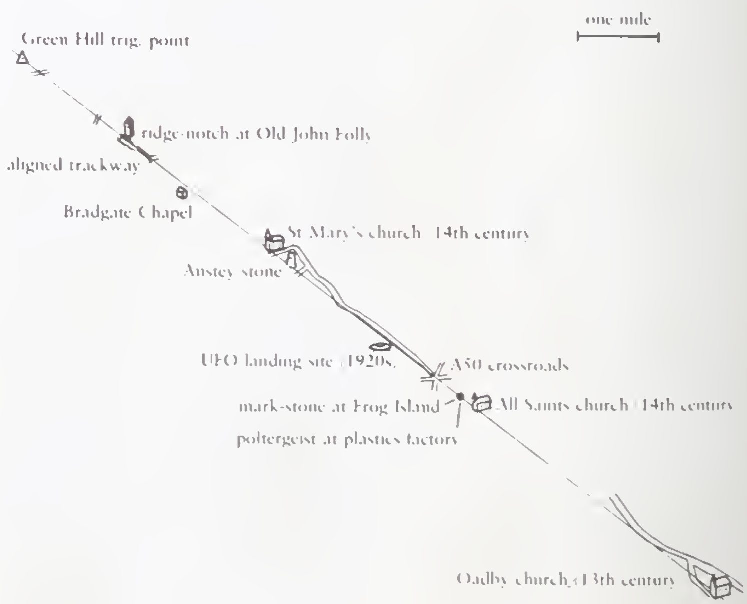
Iris Campbell, a remarkable English psychometrist, believes that in megalithic times the distribution of the colors of the sun was different, with less violet and more blue rays, blue being the color attributed to the etheric or orgone energy. She suggests that in ancient healing centers the monoliths must have been carefully positioned in accord with the solar rays in order to bring about an accurate influx of solar force to the body, not too strong to overwhelm it. Did megalithic man harness cosmic rays, asks Screeton? Were they concentrated, stored, and channeled at stone circles?

The megalithic builders' great interest in eclipses may have been connected with the fact that the sun, in addition to altering the atmosphere's properties, alters the nature of the earth's magnetic currents. An eclipse of the moon has no apparent physical influence on the earth other than the effect it produces on the level of terrestria magnetism.

Jean-Louis Bernard in *Aux Origines de l'Egypte* makes a very good argument that the ancients had learned to capture from outer space and make use of what he calls a "green ray," a ray too intense for humanity to use directly, which needed the science of Toth to be assimilated by man—which could, of course, mean by reflection from the moon! The assimilation was apparently done with megaliths and ultrasonics. The repercussion by stones of the ultrasonic waves caused a vibration in the cerebro-spinal column, says Bernard, and especially at the nape of the neck, which made it very easy to go into trance. The ray was best captured, apparently, on mountain tops or on top of stepped pyramids or ziggurats.

Bernard also finds evidence for a race of giants who opposed the green ray with a telluric force derived from the center of the earth. Coming up through the soles of the feet it affected their legs and their pelvis, rising like static electricity up the cerebro-spinal column. With this telluric force the giants are said to have had the power of paralyzing their adversaries, as a snake does a bird. The result, says Bernard, was a cosmo-telluric war that hastened the biological decline of the giants, ending their stay on earth sometime about 10,000 B.C. coincident with a series of cataclysms which changed the inclination of the earth's axis, shifted the poles, caused the glaciers to withdraw and brought an end to the civilization of the Atlantean archipelago.

All the evidence from the remote past, says John Michell, points to the inescapable conclusion that the earth's natural magnetism was not only known to men



Forty dowsing and electronic experts recently organized the Dragon Project to make a scientific study of the phenomena of the ancient leys in England.

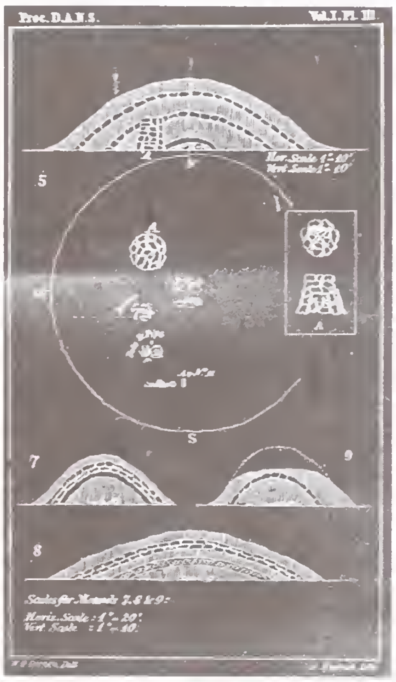
some thousands of years ago, but that it provided them with a source of energy and inspiration to which their whole civilization was tuned. In his words: "From the rocks, mountains and headlands a mysterious current once flowed down avenues of standing stones over mounds and earthworks towards some central hill dedicated to Mercury, the terrestrial spirit. Below the hill an instrument of solar generation produced the spark by which the current became animated and recoiled in a wave of fertility through the hidden veins of the land, urged on by the music and clamor of the rejoicing people."

Much research has recently been done, especially in England, by dowsers and "ley hunters" who claim to have established the existence of power channels linking one megalithic site to another in vast networks of what they call "ley" lines, which they differentiate from the track line, the water line, and the acquastat. Ley lines are straight, point-to-point lines which ley hunters have traced all across Britain, set out with what they describe as the accuracy of a modern surveyor, with alignments precise between standing stones. The existence of leys, they insist, is as obvious as that of electricity, and can be felt by anyone who can feel electricity. Screeton says that leys bear a geometrical relation to each other, either in parallel, or forming isosceles or equilateral triangles, with regularly recurring angles of intersection and standard distances between points. He explains the leys as avenues of "etheric" energy, made visible by trees with spiraled or double trunks, by the flow of what Kipling called "the mysterious earth currents which thrill the clay of our bodies."

A comparison between etheric energies and orgone energy, says Screeton, shows such great similarities it would be surprising if they were not identical. Both are everywhere, and both can be accumulated. Orgone energy as described by Wilhelm Reich is an energy which operates most noticeably on the emotions, but with physical and physiological effects—a sort of basic life force. In constant flow, he said, it provides the medium through which magnetic and gravitational forces manifest their influence. To Michell there is no doubt that the natural flow of force related to the earth's magnetic field is the orgone energy rediscovered by Reich, present everywhere in the universe, mass free, and consequently hard to isolate, except that it appears to be susceptible to being channeled and accumulated.

By placing standing stones on ley lines and their crossing points, Screeton believes, the ancients managed

Herms were raised in the ancient world on every highway and at the corners of any property.



Barrows were discovered to be almost invariably built up of layers of organic and inorganic material—a storehouse, as Graves points out, for the energy known as od, odyle, prana, or Reich's orgone.

to channel, increase, and control the current. Underwood, in his *The Pattern of the Past,* says old walls, hedges, and roads are aligned on track lines which made it possible to divide the land into parcels of convenient size, with precise, unalterable limits, apparently easily divinable and redivinable by priests, as in Egypt after the flooding of the Nile. Since the greatest antiquity, these geodetic lines and patterns have been clearly assigned topographical markings, making them distinguishable to persons initiated into the code. Throughout the Roman empire the limits of lots were identified by standing "herms" mostly with phallus erect.

Screeton notes that where ley lines cross are centers of power associated with magic, the life forces, fertility, "getting high" or tripping, and the appearance of phantoms. Though some of the lines appear to be on a more refined plane than is easily perceived by our basic senses, animals seem to have sensory organs which enable them to perceive such energies.

Other ancient structures associated with standing stones and blind springs are mounds of earth in circular or elongated shapes, known as barrows, believed by archeologists to be mere tombs, but which, in fact, may be "enliveners"—initiatory chambers designed, as is reputed of the Great Pyramid, to awaken the spirit from its hypnotic trance within the body. Whether or not they contain a sepulcher, barrows are built of alternating layers of organic and inorganic matter. Varying from 15 to 150 feet in diameter, there are more than twenty thousand round barrows in Britain alone, though many have been destroyed by farming. On the crest of the hills surrounding Avebury there were once fourteen such round barrows. In the Americas there may have been a hundred thousand.

Long barrows in Britain are dated by archeologists from Neolithic times. About two hundred survive. They are mounds of earth and chalk, 4 to 20 feet high, mostly from 100 to 300 feet long and 30 to 100 feet wide. Set over one or more blind springs, they are mostly oriented east and west, to face the rising and setting sun at the equinox.

Michell believes that chambers in these barrows, made of alternating organic and inorganic material, which is the requirement for a Reichian orgone accumulator, once served that purpose and were used for healing and for expanding consciousness. He and others have noted that these ancient sites are linked in a network that covers all of Britain in a multidimensional ramification of forces—mercurial, or quicksilver lines, as they are called, the domain since antiquity, of Toth, Hermes, Mercury, or Saint Michael.

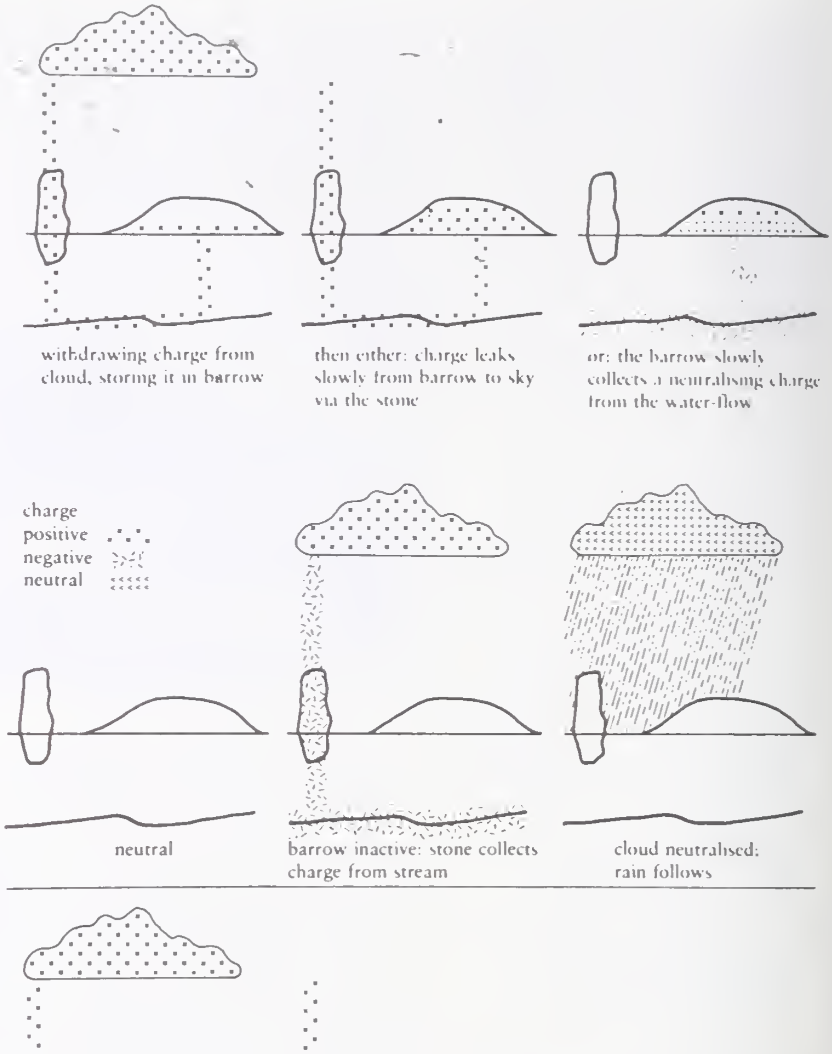
American mounds are, or were, wonders comparable to the pyramids of Egypt, their origin almost as mysterious today as when they were first discovered by immigrants traveling west. Atlantean experts such as Egerton Sykes and Henrietta Mertz are convinced that at least the eastern United States was once part of the Atlantean Empire and that the extraordinary artifacts found in American barrows were the product of descendants of refugees from sunken Atlantis—a notion as quickly derided by conservative archeologists as has been the incontrovertible evidence produced by Barry Fell and his fellow epigraphers of the presence in "Lost America" of Phoenicians, Libyans, Egyptians, Celtiberians, Hittites, and a whole chain of European and Mediterranean followers. Silbury Hill, the largest such mound in England, which, like the Pyramid of Cheops, served, among other purposes, to mark the equinoxes and solstices, is estimated by Richard Atkinson to have required the carefully directed work of 500 men for fifteen years—"a fraction of the gross national product at least as great as that devoted by the United States of America to the whole of its space program."

The Washington Monument attracting a bolt of lightning

Graves has also noted a distinct correlation between megalithic sites and weather patterns—particularly of rainfall and thunderstorm activity, as noted from the weather distribution maps of Britain. He says that he has observed during a thunderstorm that standing stones and church spires gain a visible nimbus, becoming actual glowing points in the landscape. He believes this happens because they collect charge from the springs and streams below them. He says that standing stones have a thunderstorm-control ability similar to lightning conductors. He even plays with the notion that the energy of thunderstorms may somehow be stored in barrows, as energy reservoirs. This may clarify why witches were traditionally credited with the ability to control the weather, and particularly to raise storms.

Graves goes further, believing that standing stones and circles not only controlled thunderstorms in the past; they still do. Megalithic sites, he says, are in the right places, and their shapes and semiconductor properties are such as to help the production of an "electric wind." Dowsers have certainly found that lightning usually strikes directly above the intersection of two or more water lines. Dowsers say that a conductor, placed directly over or even close to a water line, or, better, at an intersection of water lines, should be able to collect charge from the whole area underlying the stream. The effect of a lightning conductor connected to water lines would be to change a potentially violent thunderstorm into an ordinary rainstorm.

Graves illustrates two ways in which thunderstorms may be controlled by the stone-and-barrow system. In the upper drawing a stone collecting negative charge from an underground stream attracts the positively charged cloud, which is neutralized by releasing its rain. In the lower illustration the subterranean stream draws charge from the cloud and stores it in the barrow, which either leaks it back slowly into the sky through the stone or collects a neutralizing charge from the water flow.

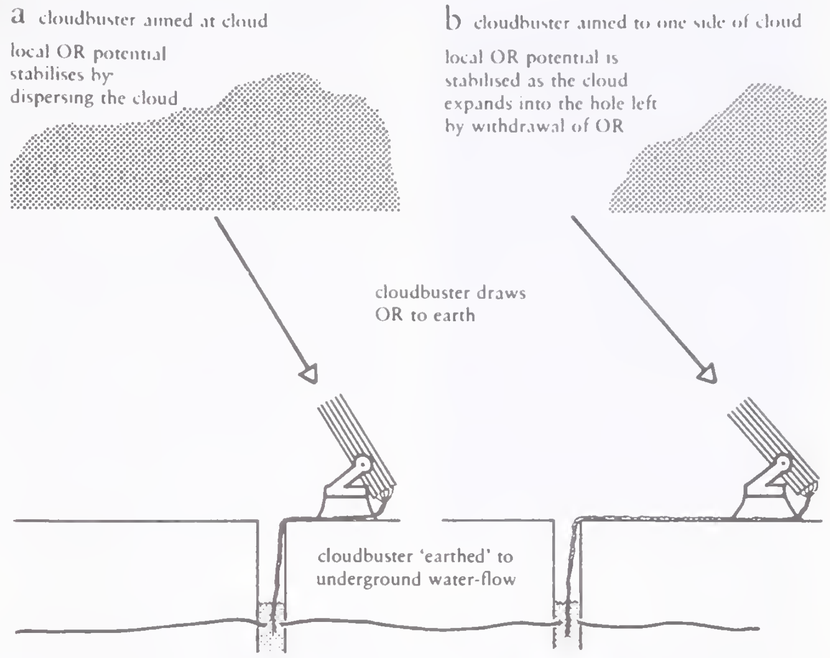


All of which was incontrovertibly demonstrated in real life in modern times by Wilhelm Reich, who showed the relation between lightning and vivifying orgone. In the most scientific manner he accumulated and dispelled great clouds, at will, producing rain where it was wanted; and in the quantities required, or turning the sky back to blue.

In the course of the these experiments, Reich discovered that the orgone energy assumed two forms, "orgone radiation," or OR, and "deadly orgone radiation," or DOR. The former, the healthy manifestation, can be sensed according to Reich as a feeling of "life" and brightness in the atmosphere, visible as bright fast-moving dots of light, or a haze of blue. DOR, on the other hand, is responsible for "dullness" and bleakness in the atmosphere, of the sort that builds up on days before a big storm.

In Chinese geomancy, or *feng shui,* energy flows along the earth's meridians in an interplay of the two prime

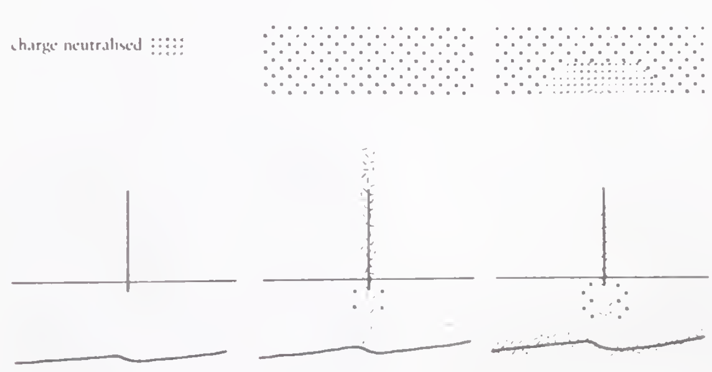
This adaptation from Wilhelm Reich's *Selected Writings,* (Noonday Press, 1960) shows the cloud-buster system he developed at Orgonon, Maine, where he accumulated and discharged rain from a cloud by pointing directly at it 10-foot hollow steel tubes mounted on the back of an old anti-aircraft gun carriage, grounding the received energy into a running stream. If the tubes were aimed near, but not at the cloud, they would cause it to expand and hold more moisture. It was Reich's premise that a hollow tube will push or pull "orgone" energy, which can then be carried away by running water.



forces of yin and yang; the product is know as either *ch'i* or *sha*. The former occurs when yin and yang fuse together in harmony. The latter occurs where they are out of balance, where the primal energies are separated and stagnant. What is this but Reich's chief cause of neurotic ailments in humans—sexual stasis—applied to Mother Earth?

A clear parallel between the British system of standing stones and ley lines and a combination of Chinese *feng-shui* and acupuncture, is drawn by British dowsers. To Graves, Britain's geomancy has every indication of having been a system of earth acupuncture with sacred sites as acupuncture points on energy channels, both sinuous and straight, with standing stones as massive needles, designed to promote a healthy, sexy, fertile earth.

Michell, again, is poetically specific: "These upright stones were essential to the great work of alchemy, which



Graves demonstrates how a lightning conductor placed over a waterline can collect charge from an underground water flow and "literally spray charge up into the sky," causing the same Saint Elmo's fire which so distressed the sailors on the *Cleopatra*.

Tantric tradition describes over 300,000 nadis, or channels of vital force permeating the physical form through which solar and lunar energies ebb and flow to animate the subtler body. Connected to these nadis, the seven chakras are seen as receivers and distributors of the negative lunar and positive solar energies which spiral around the spinal cord, along the path used to raise the kundalini.

formed the climax of all prehistoric ritual, the introduction of solar or atmospheric energy into the terrestrial life current. It is well known that flashes of lightning have an effect on the nitrates of the earth, through which they can be absorbed by plants, thus ensuring the seasonal return of fertility. This process, regarded in the past as the act of union between the earth and the heavens, is indeed necessary for the continuation of life; for if there is no lightning, the earth becomes barren. In order that plants should grow, it is necessary to fuse the electrical current of the atmosphere with the streams of terrestrial energy." In man, energy permeates the body by flowing along the twelve meridians of the acupuncturist from one to the next in a set sequence, making a complete cycle in twenty-four hours, controlled by the sun whose rays are reflected by the moon.

Because the landscape has no obvious organs, no arms, legs, or head, dowsers assume there must be even more meridians or energy lines on the body of earth than on the human body, and that they would be laid out in a far less obvious way than in human acupuncture. In such a system of earth acupuncture, what, asks Graves, could be a more obvious "needle" than a standing stone? Noting that it could be dangerous to use stone needles to heal the land without a suitable and safe means of disposing and dispersing the collected *sha* or DOR drawn up through an earth stake, Graves suggests that the barrow-and-stone weather-control systems were, in fact, designed for just such a dispersal.

But the employment of needles is only part of acupuncture, which also uses moxibustion, or controlled fire. Our civilization, says Graves, has completely concealed the ancient magical use of fire—the beacon fires on Old Beacon Hills. Graves tells of having been with a ley-hunter team at the Dunstable bonfire festival where he enjoyed an extraordinary sense of unity, of nonverbal communication—"so rare in our civilization"—which he and the others felt as each bonfire was lit and linked with the others. Michell describes the scene: "From hilltop to hilltop, the light struck straight across the country, reflected in ponds and moats, transmitted by flashing mirrors, celebrated with music and singing, the whole line illuminated by the flames and by the heavenly light."

As in acupuncture, most of the problems in our modern landscape, says Graves, stem from blockages and disturbances of energy flows, arising from insensitive man-made causes: motorways, high-voltage lines, mining and quarrying. Modern organization has the noxious effect of blocking a natural flow in the energy matrix. Electric pylons appear to have an especially deleterious effect on the fertility of the land.

Another function of the standing stones may have been to communicate from point to point. Analyzing the forces at play on a standing stone, Graves notes that as well as the flow of orgone to and from a needle, underground water flows can produce a regular mechanical vibration in a stone, which can be used to carry a signal.

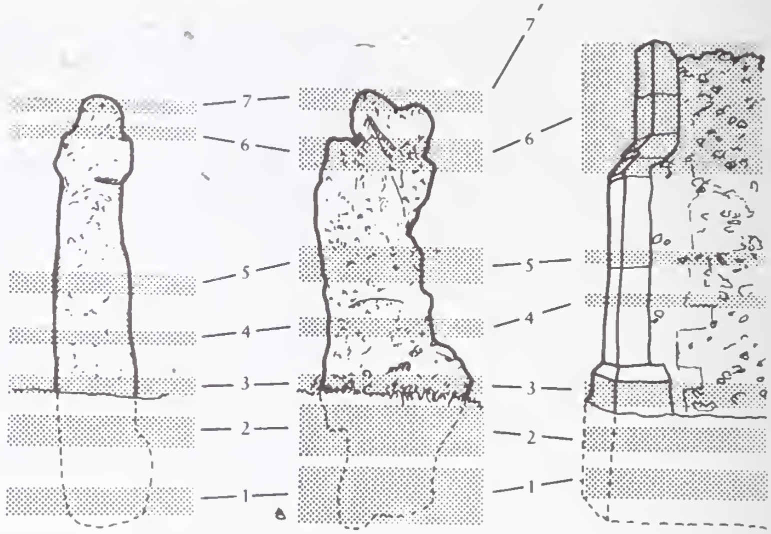
Screeton visualizes the ancients as transmitting messages on standing stones by tapping. He says that in order to pick up the modulated currents, they would use the palm of their hands against the stone, retransmitting the signals by their nervous system to the pineal gland. In other words, they would transmit the message to the mental receptive consciousness and then to the spiritual consciousness.

A number of correspondents, says Graves, have told him that the transmission of complete mental images, or telepathy, is much easier between sacred sites than elsewhere. Graves describes how the King Stone at Rollright was linked to more than a dozen other stones and believes that, if all the minor and irregular links are included, as many as a hundred more could have been linked into Rollright, creating a vast telephone exchange of stone circles and standing stones; from which it would appear that telepathic communication in the present, and clairvoyant communication with the future or the past may be effected through the same occult medium.

The presence of certain types of quartz in standing stones, and most especially in the granite obelisks of Egypt, leads Graves to postulate the possibility of their acting as a sort of stone maser or, as he puns, "leyser." Quartz, in its smallest unit, consists of three molecules of silicon dioxide, arranged in a spiral or screw form, either right- or left-handed. It has the power of rotating in either direction the plane of polarization of light.

Graves finds a parallel between the quartz "seeds" in limestone and the chrome atoms in a ruby, from which a laser can be fashioned. He suggests that it might be possible for the mechanical vibration from the stream of water below a standing stone, or the spiraling energy flow around the stone ("and note," he adds, "the analogy with the old laser spiral flash-tube"), or both, to provide energy to be stored in the quartz "seeds." As with a ruby laser, says Graves, this energy storage should reach a critical or supercritical state, at which time a suitable stimulus could set the whole thing off. He considers a

Graves describes seven energy bands as appearing on standing stones as well as on buttresses. In the illustration (a) is a "Christianized" stone near Postbridge in Devon; (b) is at Rollright; and (c) is the northeast buttress of nearby Knowlton Church. All are drawn to scale, and all, says Graves, are tapping points into a spiral release of some sort of energy. He describes the narrow bands as a "double strength geomagnetic field running horizontally across the stone at various heights." The bands are said to move up and down, following what appears to be a lunar cycle. Two of the bands are usually below ground level; the top one is very close to the peak of the stone.



suitable stimulus to be a gravitational alignment of sun, moon, or planets, which could result in a massive pulse of energy traveling in a straight line—just such a pulse as he accidentally released at Rollright, and which appeared to travel away at right angles to the standing stone.

A German dowsing magazine, quoted by Graves, warns that it is important to beware of quartz in buildings when dealing with "earth engines," for they "change the plane of the radiations from the vertical to the horizontal." Thus, says Graves, if quartz can turn its own "radiations" from the vertical to the horizontal, we would appear to have our "leyser."

The frequency of a crystal's resonance depends on its size, shape, and cut. Were the Egyptian obelisks, which are largely quartz, deliberately cut and shaped like a wireless crystal to vibrate synchronously with another transmitter, the vibrations transmitted through earth like a system of telegraphy? Or were they wireless, going from point to point on ground leyser beams pulsing from quartz?

Such a system would explain how the ancient Egyptians could have used a row of obelisks stretching from the delta to the cataracts—if not to the equator—to transmit instant information of great help in geodetic and astronomical observation. Used east and west, they would resolve the mystery of how the ancients plotted longitude with such extraordinary accuracy, as is evident from a whole series of mysterious prehistoric maps.

Other dowsers describe overgrounds and waterlines as able to carry a code or modulated signal. There are several dimensions in which water can carry a coding, the most obvious being with physical substances, either in solution or suspension. The key, says Graves, is the bent structure of the water molecule. Water that has been blessed or affected by a psychic (such as was demonstrated by the healer Olga Worrall when she changed the molecular structure of water by irradiating it with her hands) is recognizably different, and at some level may be a carrier of nonphysical or metaphysical messages.

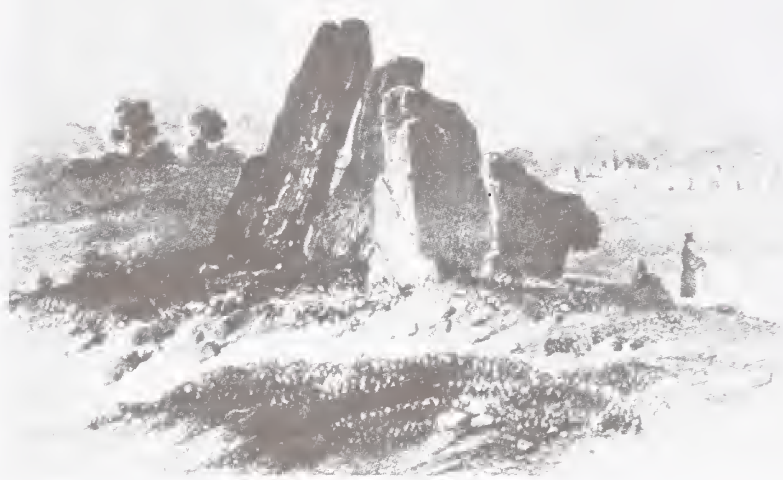
Carlos Castaneda describes what he calls his personality traveling along water courses, apparently for hundreds of miles; which suggests to Graves that water lines as well as overground leys could be used to assist astral traveling. A modern magician told Graves that astral traveling, or projection of the inner personality, is made easier by hitching a ride on the energy that passes along "ley lines" and "overgrounds." And the *feng-shui* concept of "spirit paths," or clearly marked pathways on which the spirits of the dead may travel, suggests, as the Egyptian *Book of the Dead* elaborates, that astral traveling is as much for the dead as for the living.

Did the witches astrally ride the ley lines to their midnight sabbaths at megalithic sites?

18. DIANA AND THE HORNED GOD

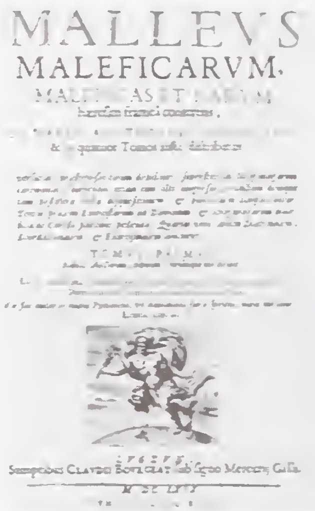
The large phallic stone at Rollright stands on a lonely Cotswold hill by a prehistoric yonic circle 20 miles from the villages of Long Compton and Chipping Norton. In a nearby field, as a witness, stands a cromlech of large stones called by the natives Whispering Knights, silent now except in a high wind. For centuries, if not millennia, Rollright has been a gathering site for witches. On a recent night of full moon, with the soft scent of summer, a coven of witches was dancing around the standing stones to celebrate their sabbath—it was May 12, 1949. Eyewitnesses tell of men and women chanting and dancing under the direction of a leader wearing a goat-bearded mask. An even more recent ceremony at Rollright was described with pictures in *Life International* of May 1964.

The Rollright Stones



Witches performing at Rollright from an article in *Life International* of May 1964

Such ceremonies were possible, after almost half a millennium of witch-burning, because in England, on January 3, 1951, the law against witchcraft was stricken from the books. It had been a long, painful siege since that December 5, 1484, when the appointee of the butcher, Torquemeda, issued a bull, as Innocent VIII, in which he deplored the prevalence of witches and empowered two Dominican monks, Heinrich Kraemer and Jacob Sprenger,



MALLEVS
MALEFICARVM,

Innocent VIII (1484–1492) issued the papal bull *Summis desiderantes effectibus,* which served as justification for pitiless persecution. The bull was prefixed to the Inquisitors' textbook, *Malleus maleficarum,* and called on the wrath of God Almighty against all who did not comply. In his last months, Innocent was kept alive by sucking milk from a young woman's breast, and an attempt to rejuvenate him by blood transfusions resulted in the death of three boys. Contemporary Catholic chroniclers note that he kept a mistress by whom he had two children—a boy who married into the Medicis, and a girl whom he married to his papal treasurer.

to launch a holy war against "this satanic sect." Kraemer and Sprenger were ordered to be given every assistance by bishop, priest, and lay authority. As guidelines for the monstrous pogrom of witches that was to ensue, the two holy brothers produced a primer, the *Malleus maleficorum,* which went into details as gruesome as possible to enable dutiful Inquisitors to force confessions from a tortured body. It became the standard manual for witch-hunting and witch extermination. Michael Harrison, in *The Roots of Witchcraft,* adds the cynical note that the two Dominicans, unable to obtain for so horrid a script approval from the Cologne University censors charged by the Pope with vetting it, resorted to the same device used for the Donation of Constantine: "Nothing daunted, this precious pair of rascals proceeded to forge a document which purported to show the approbation of the Cologne faculty."

As an incentive to the Inquisitors to ferret out their heretical bunnies, it was decreed that the property of a condemned witch was to be divided, after the costs of the trial had been deducted, between Inquisitors and State, with a bonus for informers. And not all witches were poor. The first one condemned in England, Dame Alice Kyteler of Kilkenny, was of considerable means. For the rest, there was that depraved compulsion, described by Wilhelm Reich as the "emotional plague," whereby a pox of sexually malfunctioning "armored" individuals, unable to enjoy the pleasure of natural lovemaking, set about relieving their pent-up sexuality through ripping, tearing, and burning the very flesh they could neither kiss, caress, nor inflame with pleasure.

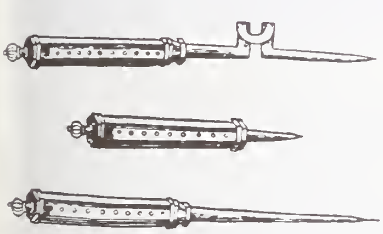
The *Malleus* gave detailed instructions for the selection of suspected witches who could then be tortured until they confessed. If a prisoner muttered, looked at the ground, or did not shed tears, he or she was suspect. As most of the witches were shes, the administration of torture to their frail bodies was both easier and more rewarding.

According to the Church, somewhere on the body of a female witch, the "devil" left his mark, the most obvious of which was a supernumerary nipple—sure sign of dedication to the many-breasted goddess Diana, queen of the witches. And, as the modern medical profession estimates that three out of a hundred women have such vestiges, the chances of netting a witch were considerable. When nothing like a mole or birthmark came readily to finger, it was argued that the mark must have been applied in a subtler manner which required the investigator to indulge in closer scrutiny by totally stripping the suspect naked and subjecting her to a minute inspection, often in front of

Diana's supernumerary nipples were also frowned upon by the majority of moralists because the goddess, with her unbounded generative and nurturing power, could indiscriminately suckle one and all.

Kraemer and Sprenger in *The Hammer of Witches* based their authority for burning witches partly on the teachings of Thomas Aquinas, who maintained there were servants of the devil "more subtle and more dangerous than the heretics"—the witches; and partly on a totally specious reading of Chapter 15 of the Gospel according to Saint John: "If a man abide not in me, he is cast forth as a branch, and is withered; and men gather them, and cast them into the fire, and they are burned."

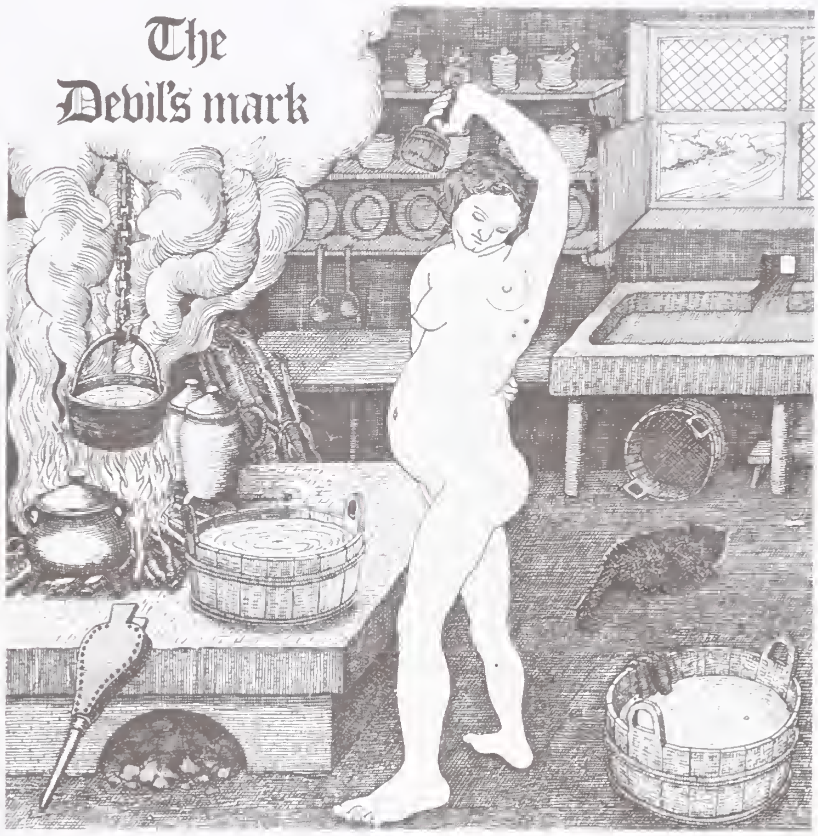
Any blemish on a woman's body—wart, mole, scar, or birthmark—could be used by the Inquisitor as a mark of the devil, sufficient to charge her with witchcraft.



Regular and retractable prickers

a crowd of pruriently curious onlookers, ostensibly impelled to the scene by their religious duty.

To increase the number of hits, the subtle notion was concocted that the devil's mark left a spot insensible to pain, only discernible by an inspector probing with a sharp prick. Thus was raised a whole guild of "witch-prickers," paid only when they discovered a witch, which led to the foolproof system of using an auxiliary retractable prick. The pricker, having painfully, and visibly, drawn blood from several spots on a naked victim, would painlessly plunge the substitute bodkin to the hilt, astounding the crowd, and ensuring his fee for a witch delivered to trial.



Placed in the hands of the actual Inquisitors, the women were scrutinized even further by having the hair of their pudenda shaved and the folds minutely inspected on the excuse that therein was likely to be hidden a small parchment with a magic sigil to use as a talisman against feeling the forthcoming pain of torture. Immediate and sadistic rape of the victim became so common that bishops had to pronounce against the practice. "The victims," report the chronicles, "were so barbarously used that modesty forbids to mention it."

And the chronicles are truly amazing. In 1599 at Dôle, in France, a woman named Antide Collas, found with an abnormality in her sexual conformation that was regarded as explicable only by her having had shameful intercourse with Satan, was repeatedly stripped and scrutinized by doctors and judges, until her disability was officially described as *"un trou qu'elle avait au dessous de sa parti gorrière."* Repeatedly put to torture, the poor woman confessed to having received the deformity from the penis of Satan, and was therefore ritually burned at the stake.

Matthew Hopkins, an unsuccessful attorney, with a pretended commission from Cromwell's Parliament naming him Witch-Finder General, spent two years running down women whose pets might incarnate witches' familiars. In England he revived round-the-clock torture and the medieval ordeal of tossing women into rivers to see if they would drown or if the devil would save them to be burned. He was responsible for several hundred executions before being brought to account for illegal profiteering.

In those rare countries where the torture of witches was illegal, as in England, confessions could still be obtained by the more modern methods of binding the suspect naked to a stool without food or sleep for as many hours or days as it took to break her will; or by walking the victim up and down for days until her feet blistered and

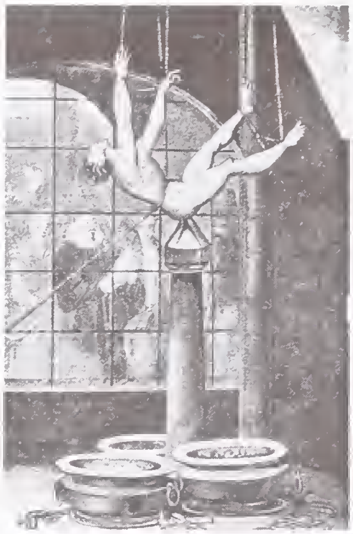
If a victim refused to confess, he or she was subjected to three grades of torture: by cord, by water, and by fire—all in the name of Most Merciful Christ. Torture by cord meant being raised and lowered in jerks to dislocate arms. If this failed to elicit a confession, the victim was flogged and then stretched on the rack till all his members were disjointed. The water cure consisted of having a silk ribbon stuffed down the throat and as many as thirty pints of water forced along it into the body, causing pain beyond description. As an alternative, a cloth was laid over the face so that water poured onto it virtually drowned the victim. Torture by fire meant having one's feet placed in stocks with the soles well greased, so that a blazing brazier could blister and fry them. More painful but less fatal than racking, this torture was in vogue for females, and for a child required to testify against its parents.

Torture was supposed to be administered only once, and be limited to one hour, but if the torturers stopped just short of the hour they could renew the torment indefinitely, varying the fare by inserting red-hot needles under finger and toenails, ripping out the nails with tongs, crushing thumbs in thumbscrews, or reducing the victim's foot to pulp in a leg crusher. Other subtleties were being broken on the wheel and being pierced by an Iron Maiden. To determine how long a victim could be tortured without risk of dying, a physician was present, usually a barber whose sole knowledge of healing was to let blood, apply leeches, or amputate a limb. If the victim confessed under the first bout of torture, he was allowed to be tortured again to ascertain his motives for confessing, and again to induce him to betray his accomplices or sympathizers, accusations which were in turn sufficient to convict a friend or stranger, irrespective of guilt or innocence.

her mind wandered. But of all the systems, the simplest—heads I win, tails you lose—was to bind the witch's thumbs to her big toes and throw her into deep water. If she floated—on the grounds that having rejected the water of baptism, the water now rejected her—she was considered a witch. If she sank, she drowned.

On the Continent, an accused witch could be given two hundred lashes on her bare back before being sent to torture. Teen-age girls were regularly stripped by notaries and scourged until they confessed or agreed to bear testimony against others, including their mothers.

What most interested the Inquisitors was a female victim's description of intercourse with an incubus—a male demon—which they believed to be of extraordinary voluptuous pleasure to the witch. The authors of *Malleus,* declaring such demons to be visible only to the witch, described how a bystander might yet be able to enjoy the sight: "The witches have often been seen lying on their backs in the fields or woods, naked up to the navel, and it has been apparent from the disposition of their limbs and members which pertain to the venereal act and orgasm, as also from the agitation of their legs and thighs, that, all



invisible to the bystanders, they have been copulating with Incubus devils; yet sometimes, howbeit this is rare, at the end of the act, a very black vapour, of about the stature of a man, rises up into the air from the witch."

As a result of the *Malleus*'s system of questioning, thousands of confessions were extracted from women, young and old, in exact conformity with the blueprint questions predetermined by the holy brothers Kraemer and Sprenger. All the judges required was that the victims, under agonizing torture, confirm what they were reported to have done. With no hope of surviving, they would confess, knowing that if they did so, they stood a chance of avoiding having their tongues cut out on the way to the stake, or their mouths scored with a red-hot poker; they might even be mercifully strangled as the fires were lit, instead of being burned alive—no small consolation when it took a minimum half hour to die from smoke and blistering—an ordeal which could be stretched to as long as a day by the application of slow-burning charcoal.

In Munich, of eleven victims on the way to the stake, six had their flesh torn with red-hot pincers, five had their limbs broken on the wheel, one woman had her breasts sliced off, and one man was impaled through the anus with a lance. At Chamonix, in 1462, a woman found guilty of prostituting herself to demons was made to sit naked on a red-hot iron for three minutes before being tied to the stake for burning. All of which was officially done *ad majorem dei gloriam;* and after the burnings, public dinners were held to celebrate "an act pleasing to God."

Various historians specializing in witchcraft, such as the Swiss authority Dr. Guido Bader, estimate that a hundred thousand witches were burned in Germany alone between the fourteenth and eighteenth centuries; the number of victims throughout Europe may be comparable to the millions of Jews far more charitably disposed of by Hitler.

From a Catholic point of view, this gruesome carnage was considered essential, since witchcraft was an overt manifestation of the old pagan religion, which threatened, if it were allowed to flourish, to sweep away the religion of Rome. For the truly believing Inquisitor to destroy a human body with fire was essentially an act of mercy if it meant saving a soul from the torment of eternal fire. To the Catholic, death of the soul through "sin" was worse than death of the body through fire, and sexuality, other than for strict procreation, preferably without pleasure, was the cardinal sin, whetted by all manner of life's desirable experiences, such as feasting, wining, dancing, singing, and being free and naked together. All of which were afforded by the witch's sabbat, a ritual which, when compared with the self-accusatory, misery-ridden worship

To historian Margaret Murray witchcraft was a highly organized "Old Religion" practiced and protected by French and English royalty (as late as under Henry VIII) and by many clergymen who secretly joined in the rites worshiping the horned god and the Mother goddess, even engaging in ritual intercourse and the indiscriminate copulation practiced by the ancient Egyptians and Gnostics, whose rites were precursors of the witches' sabbath.

of the Catholic symbols of pain and death on the cross, was welcomed by the older religionists as beautiful and exciting. Why else would so many witches have risked torture and an agonizing death to attend the sabbat? It was a spiritual, other-dimensional experience as well as a physical pleasure.

There were two kinds of sabbat: one with real bodies, which took place by moonlight in some desolate spot; and the other, to which the witch could travel out-of-body, usually thanks to some psychedelic drug, in what came to be known as the "astral plane," there to cavort with the goddess Diana and her playmates.

That the witches used a special salve to teletransport themselves to this second kind of sabbat has been known since 1600, when Giovanni Battista Porta, in his *Magiae*

The Roman initiate Lucius Apuleius, in his pre-Christian romance of witchcraft, *The Golden Ass,* described seducing Pamphile's maid Fotis to allow him to watch her naked mistress anoint herself with a magic unguent. That he got turned into an ass and had to eat the roses of Isis to be redeemed only adds to the Rosicrucian flavor of the allegory.

naturalis, gave the recipe which contained herbane, belladonna, and mandrake. The resulting ointment, known as "lifting balm," was said to be viscous, with a repulsive green-black color, and an offensive odor. Porta, founder of the Academy of Secrets in Rome, whose meetings were interdicted by the same Clement VIII who burned Bruno, was a teacher of science and inventor of the *camera obscura,* and is credited by John Weisse with being an Italian representative of the Rosicrucians.

Reginald Scot, in his *Discoverie of Witchcraft*, published in 1584, describes naked witches rubbing "all parts of their bodies exceedingly, till they look red, and be very hot, so as the pores may be opened and their flesh soluble and loose. . . ." Scot describes how, on a moonlit night, witches "believe themselves to be carried in the air to feasting, singing, dancing, kissing, culling and other acts of venery with such youths as they love and desire."

More specific are descriptions of witches applying the salve to their labia minora by means of an anointed

An ancient recipe for transvecting ointments is given in *Witchcraft and the Mysteries:* "Grind together into a paste of sufficient quantity to anoint the entire body of the following: *Acarum vulgare,* the blood of a bat, parsley cinquefoil, aconite, yellow watercress, belladonna, sweet flag and pure olive oil in equal parts of half a palm. When this ointment has been kneaded into the consistency of a viscous, light oil, massage it into the naked body covering all parts. Rub vigorously until the skin 'look red and be very hot, so the pores will be open and the flesh loose and pliable.' Finally, face an open window (or door, or lie flat upon a hearth in front of a chimney that is not obstructed to the top) and rub the limbs with pure olive oil, which will seal . . . the skin, that the force of the ointment may rather pierce inwardly, and so be more effectual." Ancient Druids, like modern shamans, claim to be able to accomplish magical flights out of the body. Following the dictates of Hermes Trismegistus, the witches sought to separate from their physical selves and travel

on the astral plane in what theosophists call their "Body of Light." To project the finer body and acquire the faculty of functioning in it, as well as to educate it to fulfill one's wishes was, and is, a fundamental practice of magic. But Israel Regardie, a Reichian therapist and adept of magic, points out that to leave the physical body bereft of its guiding intelligence "is tantamount to extending an open invitation to whatever astral entity, malignant or otherwise, is in the vicinity to take possession." The return to the body, says Regardie, must be attended to with care and precaution. "Upon entering the physical frame a few deep breaths should be deliberately undertaken in order to ensure the close conjoining of the two organisms." John Michell goes further and suggests that Druids and shamans appear to have been able to accomplish magical flights *within* their physical bodies, "often from those very mounds and hilltops where the great heroes of mythology achieved their apotheosis." He adds that there may be something about such places "which attracts those forces capable of modifying the normal influences of gravity, or which, alternately, reacts upon an intensified field of human magnetism to produce circumstances conductive to levitation." Michell then describes how the Druids may have flown. "On the eve of the day when the line, on which stood a chambered mound, became animated by the rising sun, they would enter the mound, seal the entrance and spend the night in accumulating a degree of energy by which the animal magnetism of their bodies became raised to an active pitch. The appearance of the morning sun, stimulating a current of terrestrial magnetism all down the line to the mound, would act on the body charged with energy, enabling it to levitate and to move along paths of a certain level of magnetic intensity." To which Michell soberly adds that as the suggestion has not been proved by experiment, it obviously still leaves a great deal unexplained.

"broomstick." Albert Barrere and Charles Godfrey Leland in their 1899 *A Dictionary of Slang, Jargon and Cant,* equate the term broom handle with the word *dildo,* and the word *broom,* or *plantaginesta,* with the female pudenda.

From various accounts it appears that the broom head was often carved in the shape of a phallus complete with a glans, discreetly disguised by the addition of the broom—a symbol and an artifact in one.

Discussing the greasing of the broomstick and the "nakedness of the rider" Michael Harrison suggests that the word *ride* in this context is but a euphemism for "sexual congress." He further suggests that such phrases as *between witches' legs* are also euphemisms for "inserted" between or within. "Here we have, in the fourteenth and seventeenth centuries," says Harrison, "one of the most ancient ritual objects to be found in religious celebrations, the "ὄλιδβος, olisbos, of boiled or moulded leather, that the sexually excited woman bore in the Bacchic processions; the less 'religious' but more personal surrogate—penis against whose use the German bishops thundered during the thirteenth and fourteenth centuries and, indeed, the artificial penis worn and used by the 'Devil' of the Sabbats."

By placing the anointed broom handle between her lips and prancing around, the witch may clearly have induced a psychedelic trance during which she believed she flew with Diana "to keep a tryst with the Incarnate God." Better to be affected by the salve, the witches appear to have rigorously fasted and abstained from sex for several days before a sabbat. The fifteenth-century author known as Abraham the Jew, writing in *The Book of Sacred Magic,* describes how he watched a witch anoint herself. He says she fell to the ground and lay there for three hours as if dead, and that on regaining consciousness, told him she had flown.

To establish the scientific veracity of this phenomenon, Dr. Erich-Will Peuckert of the University of Göttingen, in Germany, recently mixed up a potion of the salve as directed, with herbane, deadly nightshade, wild celery, and hog's lard, in order to perform an exhaustive experiment. He and a colleague—deliberately kept uninformed as to what might be expected—anointed their bodies with Porta's ingredients, and each fell into a deep sleep which lasted twenty-four hours. When they awoke, each separately wrote his report. To their mutual amazement, each found that he had enjoyed virtually the same erotic dream of flying to a mountaintop and participating in wild orgiastic rites with "demons."

The devil, or Satan, a Judeo-Christian idea, possibly borrowed from the Mesopotamians, was taken and turned by the Dominicans into a useful PR prop for their distorted propaganda. Onto the horned god of the pagan ritual—happy, sexy, wining and dancing and fluting—they foisted a harsh, evil, vindictive, scatological damning-with-hellfire monster—a reflection of their own tormented souls. As Reich has so remarkably documented, obscenity is all in the eye of the beholder, and unwilling or enforced sexual abstinence, far from leading to a Freudian sublimation, is more liable to turn into a self-castrating, voyeuristic compulsion to control, imprison, torture, and execute, the last at last affording the executioner the relief of a dispersal of energy in the form of a black "orgasm."

Occultists explain the experience of these *terre à terre* scientists sharing a similar dream by saying they "traveled" on the inner, or "astral," plane, a more rarefied world, whose substance is described as responsive to both thought and emotion, where one exists during sleep, trance, or after death, in what is known as the body of "desire," the ka of the Egyptian, the kama rupa of the Hindu.

Occultists see the universe as multidimensional interpenetrating worlds, vibrating at different frequencies, with what we call the physical only a restricted part of the spectrum. The energy in the astral world, they consider to vibrate at a higher rate than the physical; but once the adept, using his astral body, learns to handle the bodies of the astral world, they too become solid to the touch.

The secret astral world to which the witch flies in her astral body, by means of an ecstasy-producing unguent—while her physical body lies asleep or in a trance—is described as being divided into seven layers, the highest of which is said to be of extreme beauty, whereas the lowest is frequented by debased souls. Travelers are inclined to exist on the level to which they belong spiritually, like attracting like. It is a world filled by the occultist with many orders of spirits, some of a caliber lower than humans, others much higher. And it is the world of elementals, both "authentic" and "artificial," the latter being described as formed by thought or desire from the tenuous material of the astral plane, beautiful or hideous, protective or menacing, depending on the thought or emotion which has given them life. This they explain as the world of the witch's elementals, of the incubus and the succubus, created by desire, and rendered more or less sexy by the degree of the dreamer's desire. It is a world quite as real to psychologists as it is to occultists. Jean Marquès-Rivière, in his *Tantric Yoga*, says that through Prayoga, "it is possible to visualise and animate certain female entities who are called *succubes*." And Arthur Avalon, in *The Serpent Power*, corroborates that through Prayoga "commerce is had with female spirits."

Modern adepts of Tantric or sexual magic suggest that witches can indeed have "offspring" from their intercourse with incubi, but that these creatures are produced on the astral plane, where any discharge of energy from the physical plane invariably has an effect. Adepts claim that ejaculated semen, whether lodged in the womb or not, still manages to contribute to the creation of forms of a subtler nature. The flow produced by masturbation, sodomy, or fellatio is said by occultists to be taken up by astral entities to reinforce weak organisms already preexisting on the subtler plane. Thus are created the homunculi of the medievalist.

Kenneth Grant gives a simple formula for evoking a succubus: Sleep should be preceded by some form of *karezza* (or sexual intercourse continued without reaching orgasm), during which a sigil symbolizing the desired object is visualized. "In this manner libido is baulked of its natural fantasies and seeks satisfaction in the dream world." Grant adds that when the knack has been acquired the dream can be extremely intense and dominated by a succube, or shadow woman, with whom sexual intercourse occurs spontaneously. The modern expert on witchery, Doreen Valiente, tells of a girl she knows who was loath to have an incubus exorcised because it gave her such sexual pleasure and thrills as she had never experienced from a man. Osman Austin Spare, whose early drawing shows a psychic sexual transport, was said to be able to materialize atavisms from his subconscious and clothe them fleetingly in the sexual ectoplasm (or astral semen) of his "atmospheric copulations." Grant says that occasionally these entities could actually achieve a degree of density sufficient to make them visible and even palpable to other people. Spare called these apparitions "elemental automata" or "intrusive familiars," and says they "frequently copulated among themselves, engendering offspring simultaneously." With them he describes attending sabbaths. But the danger of such acts becoming obsessive or compulsive is indicated by Grant, who says that "such was his hunger that in one night he copulated with eighteen women, calling these outbursts: Dionysiac spasms of pansexualism in which he had visions of all things fornicating all the time." Even so, such transport may be less spiritually degrading than the burning of a witch or the torture of a wise one.

The actual live-bodied sabbat would have had as one of its purposes the initiation of a witch into the art of spiriting herself out of her physical body into the astral world of Diana and Pan. Having learned the ropes, she could apply the unguent at home and astrally meet with her playmates anytime she chose, freed from the miserable bondage of life in a Church-dominated Europe.

Goya's witches

With all this wonderland at the end of a broomstick, it is clear why the witch risked practicing the craft, and *knowing* herself to be, at heart, a spiritual creature with a whole world of similar playmates, she might have come to care less what the executioner did with her mortal body. She might even have learned the mysteries of becoming stable enough out of the body to rise to a level of power at which she could watch, as if self-hypnotized, her body being burned without feeling the pain, as is said to have been the case with some of the Anglican martyrs burned by Bloody Mary, who, wise to their tormenters' folly, could smile and bless their claybound executioners.

Of the actual flesh-and-blood sabbats, rather than the purely "tripping" routines—though there were presumably astral features in both—the most convincing historical analysis is to be found in the two twentieth-century classics of Margaret Alice Murray, *The God of the Witches* and *The Witch Cult in Western Europe*. Discredited by her academic colleagues because she supported James Frazer's *Golden Bough* theories of the sacrificed king, and because she was an Egyptologist rather than strictly a historian of their limited disciplines, Murray nevertheless admirably develops the notion of the sabbat as a ceremony of the Old Religion of the horned God, worshiped for thousands of years, going back to the Egyptian Khoum. She describes how, for camouflage, on the way to the sabbat, the witches, male and female, wore the familiar black-hooded cloaks, so as not to have their features easily recognized.

The sabbat proper, in which any number of covens of witches might participate, was the main ceremony of the craft, celebrated eight times a year on the same days as the Druid festivals of Candlemas (or Walpurgisnacht), Lammas, Halloween, and, of course, the perennial astral stations of the solar orb, the solstices and equinoxes. A lesser festival, the Esbat—from the French to "frolic," or "leave one's worries at home"—was generally celebrated by no more than a single coven of thirteen witches, at the full moon, thirteen times a year.

For further security, the more intimate Esbat might take place in a spooky, lunar spot such as a graveyard, whereas the larger sabbats, more numerously attended, were likely to be held in remote and desolate spots such as Rolling Rock, with its megalithic remains. Many sites in England still carry the names of the former rituals performed at them, such as the Seven Sisters and Dancing Maidens.

Witches perform their rites in the nude within a circle prepared with a consecrated knife, or athane, by high priest or priestess of the coven. By the athane, means of the "astral light" and its denizens can be dispelled or dispersed, and by molding the "astral," or orgone, field within the circle, a protective and power-charged cone can be raised, visible and directable by the will of the coven. Within this circle usually stands an altar with the Tarot symbols of Pentacle for earth, Wand for air, Sword for fire, and Chalice for water. There are also candles, salt, a censer, a bell, and a scourge—the latter not less likely a means of mild control than—as discovered by Reich—a means for liberating sexual energy, so pent-up by enforced restriction that it can no longer find its natural genital outlet. Witches were initiated into three degrees of the craft, with rites similar to those of the Templars, requiring "the fivefold kiss" on feet, knees, groin, breast and lips.

The object of the initiations was spiritual and psychic development of each individual, teaching them how to reach other levels of consciousness and a heightened awareness of reality.

To keep away evil spirits, a circle was invariably drawn around the site of the ritual. W. G. Gray, in his *The Rollright Ritual,* claims he could distinctly sense a magnetic ring a mile in diameter as he approached the magical site. In smaller circles, the witches would raise by their magical powers a cone of energy, visible to the clairvoyant, almost palpable. It is this engendered power which is still used by the craft today for therapy, prophecy, and sexual magic. By concentrating the will on a wish at the moment of orgasm the witch believed her will would be done.

The rule was for all to go naked at the sabbat to allow the magnetic current to flow more freely. For wintery nights, the anointed unguents served the double purpose of insulating the skin and drugging against the cold. And then, there was always the bonfire, the ashes of which were later spread in the fields for fertility.

With their cast-off clothes, the covens were wont to cast off their worldly cares, the distinction of class being lost in the nude as all became one with each other and nature. It was this freedom and beauty, says Doreen Valiente, witch, and informed writer on the craft, which constituted an important ingredient of the religious ecstasy of the pagan ritual. One of the great appeals of the sabbat to women was the freedom it afforded, not only sexually, but as creatures in their own right, rather than the slaves to which they had been reduced by Judeo-Christianity, silenced in church, with few legal rights, unclean since Moses, because of their sex.

At first sight nothing but four lovely ladies, discreetly avoiding any frontal exposure, Dürer's witches actually convey a Hermetic message in that their various hairstyles betray the fact that women of totally different social strata could happily meet as equals during the sabbath.

At the sabbat, they could revert to the matriarchal roles of the pagan world, tending the fire, stewing the pot, collecting the herbs—healers, soothsayers, interpreters of dreams and casters of lots. Among the various rituals of the sabbat was scrying in crystals or in the smoke of the bonfire, to become aware of past lives, and to foretell the future.

Diana, queen of the night, bade her followers feast and drink, sing and dance, to show that they were truly free, both men and women, as naked in their rites as they were naked in their souls, as ecstatic in their loving intercourse as was their stunning goddess of fertility with her phallused mate, the Hornéd God. Hence the feasting, wining, dancing into Bacchic, Dionysian frenzy, chanting to the cosmic goddess to engender that mysterious *élan vital* or "astral light," awaken the secret serpent power that could raise the participants to that universal ecstasy of Bruno, or the Sufi saint Al Hallaj, or any of the other frenzied martyrs of the God of love.

That men and women, pairing off for a deliberately promiscuous intercourse as practiced by the early Gnostics, might have been indulging in an intentionally Christian act of sharing designed to cement the brotherhood of man, was overlooked by the Inquisition, as was the conceit that the ritual might be designed to destroy that most fiendish and bloodthirsty of human devils, the green-eyed jealousy engendered by a compulsion to possess, which—as Wilhelm Reich laid down his life to show—leads only to sadism, servitude, and senseless slaughter. What rational spirit would choose the torment and disaster of war and Inquisition over the ecstatic fertilizing ritual intercourse of the sabbat, in which the greatest pain and damage might be the tearing of a hymen.

Although the early accounts of these sexual orgies tell of their being of the most voluptuous and satisfying kind, enjoyed by women *maxima cum voluptate,* victims of the witch trials were brought to confess to the Inquisitors that the "devil's" member was always cold, hard, and often hurt them.

All of which, by the sexually deviant Inquisitor, was reduced from a symbolic *hierosgamos,* or marriage between heaven and earth, from the world of eros and agape, to an analytic if not pornographic probing for the dimension and consistency of the penis of the Devil.

Gradually, as the persecution intensified, and the covens were thinned out by execution, the craft was forced more and more underground, and security had to be increased to keep out inquisitive spies. Hence the obligation of members to spit or piss on the cross, the most effective measure for identifying a spy who, as a believing Christian, would cringe in fear of hell for urinating on an otherwise harmless symbol. As the repression continued, the craft became the repository of more inverted religious rites and symbols, so that the witches' commitment, as Kenneth Grant puts it succinctly, was not so much to an anti-Christian faith as to the ante-Christian one.

It is also not difficult to see how the image of the sexy, beautiful witch could become distorted into that of the wicked witch of Halloween. At the peak of the persecu-

The esbat, with its full moon, provided a monthly flood tide of astral and psychic power, affecting not only the menstrual flood of women, but the formation of sperm in men. And the witches' ceremonial imbibition of the seminal fluid has found its *raison d'être* in modern science, which has discovered that young virgins need the imbibition because the hormones in sperm set their cycles going.

tion, any old widow, without relief, forced to subsist in rags on the edge of a moor, might be inclined to use what magical powers she could muster against a pharisaiacal Church. Hence the stereotype witch of black magic: old, gaunt, loathsome, toothless, squatting in tombs, feeding on corpses, forcing the dead to reveal the future, "taking a recent corpse and pouring into its breast a mixture of warm menstrual blood, the guts of a lynx, a hyena's hump, the froth of a mad dog."

In France, between 1673 and 1680, at least fifty priests were executed on charges of using the mass and the sacraments for sorcery. In *The Renaissance and the Witch Mania* the author reports the fate of several priests who were brought before a secret court, meeting in a candlelit black-draped room where confessions were extracted by torture and from which there was no appeal. "Father Tournet was found guilty of saying mass on the body of a girl he had made pregnant, with the intention that she should miscarry: she died of fright. . . . Father Gérard was convicted of using a girl's body as his altar and copulating with her during mass. . . ." And so on.

And the black mass, according to the French expert on witchcraft Jules Michelet, came as a revolt against the false Christianity of harsh and narrow-minded Puritans, of the gross injustice and cruelty of Catholic Inquisitor with his butchering secular arm.

As Harrison points out, the extirpation of the Old Religion launched by Kraemer and Sprenger succeeded not only in almost totally destroying the simple fertility cult as it had survived into the fifteenth century, but of substituting for it the false sabbat, or black mass, with its Satan, a totally spurious and totally Christian affair which required that a Host be desecrated only by a consecrated Catholic priest inserting it into the vulva of a naked female which he then asperged with semen. Such a performance conducted with a small piece of bread could only be laughable to a non-Christian.

Yet nobles of the court of Louis XIV hired as many as fifty or sixty authentic Catholic priests to conduct special black masses on the belly of a nude girl stretched across an altar. Madame de Montespan herself lay naked on such an altar in the hope thereby of retaining the favor of the king.

Sade in *Justine* describes such a black mass, during which a young girl is stripped and made to lie belly-down on a large table, with a statue of Jesus between her legs so that the mass can be celebrated on her buttocks. Part of the host, says Sade, was pushed into her "obscene entrance" while the priest "ignominiously crushed it under the repeated lunges of his monstrous tool, shouting blasphemies and emitting foul surges of the torrent of his lubricity over the very body of his Saviour."

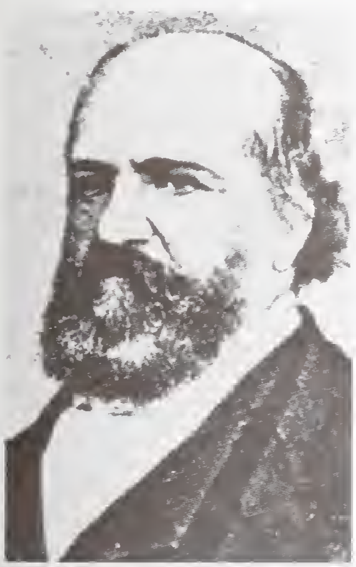
Hardly the spiritual ethics and aesthetics of Diana. And no wonder the witches ran from the horrors of the established society to the refuge of a Rollright circle to learn to master the magic of the astral world and the more spiritual realms stretching beyond, presumably *ad infinitum*.

The religions of the world

19. MAGICIANS OF THE GOLDEN DAWN

The nineteenth century's most renowned magician and expert on the "astral plane" began his career as a Catholic abbot, but soon found himself wondering whether the priests of his chosen religion in fact believed in God. In Paris, his religious schooling—"like a prison where one learns ignorance slowly and with difficulty"—convinced Alphonse-Louis Constant that from a scientific point of view the ancients had been libeled by "the infinite historical ignorance" of the professors of his day.

His fellow seminarians he found "stiff, oily-skinned, greasy-haired, with revolting *soutanes,* their natural mistrust and extreme reserve revealing a mortal coldness."



Lévi identified Mesmer's animal magnetism with "astral light," which he described as a universal medium analogous to the all-pervading ether, "a subtle matter of admirable virtue, for it attracts all that is near it." He called it a unity compounded of opposites which, like a magnet, had opposite poles, and said it responded to the human will, whose "astral body" was made of it. He also called it "the fluidic and living gold of alchemy," avowing that to control it was to master all things. At the same time Lévi warned that astral light "could be an instrument in subservience to fallen spirits," that it was "the terrestrial Mercury to whom sacrifices were ordained by diviners, the fluidic genius of the earth, fatal for those who arouse it without knowing how to direct it; for it is the focus of physical life and the magnetized receptacle of death."

For warmth—though he had already vowed perpetual chastity—the young subdeacon fell into the arms of a pretty Parisienne and never looked back on the priesthood. Yet it did not diminish his religious ideals or his zeal. As a radical writer, and a prolific one, Constant wished to regenerate and universalize religion by a synthesis and rational explanation of its symbols, constituting what he hoped would be "the true Catholic Church," a universal association of all men—and women. An early supporter of women's rights, Constant maintained that "honest" women, to avoid selling their bodies, should be admitted by law to any job they could do as well as a man.

Such notions from a religious progressive earned him frequent and unpleasant sojourns in jail. His writings on magic, which he produced under the pen name of Eliphas Lévi, were, on the other hand, better received, especially in England, where he was welcomed by Hargrave Jennings and Bulwer Lytton both as a friend and as an Hermetic brother who believed, as they did, that the material universe constituted only part of a greater reality whose planes of existence could be explored through other modes of consciousness.

Asked to demonstrate the expertise of his magic in an English country house, Lévi invoked the spirit of Apollonius of Tyre, whom he described as appearing wrapped from head to foot in a gray shroud, "lean, melancholy, and beardless."

Too frightened to pose the questions he had prepared,

Lévi swooned away. Nor could he explain the physical laws by which he claimed to have seen and touched such a phantom. Yet he insisted, "I did see and I did touch. I saw clearly and distinctly, apart from dreaming." And that, the French magus maintained, was sufficient to establish for him the real efficacy of magical ceremonies.

To explain apparitions, he posited, or fell back on, a universal agent called "astral light," a plastic medium upon which thoughts and images can be imprinted, serving as a matrix for all forms, a mirror for the imagination and dreams, a medium which can take up any form evoked by thought, causing it to become manifest even to touch. Through this astral light, Lévi concluded, healing could be accomplished, the weather affected, and such apparent miracles as the raising of Lazarus performed.

The basic function of magic, according to Lévi, is to enable the magician to direct his will more effectively, so as to be master of the "astral light," not affected by it.

Astral light, Lévi explained, consists of two opposing or complementary currents, masculine and feminine, which the magician must balance—a balance symbolized by the androgynous Baphomet of the Templars, with its woman's breasts and male phallus, or by the cabalists' Tree of Life, with its masculine and feminine currents around a mediating column.

Though ostensibly still a Catholic, Lévi became a Free Mason in 1861, initiated into a Parisian Lodge called the Rose of Perfect Silence. The same year he was visited by a young English occultist, Kenneth R. H. Mackenzie, a Master Mason, author of the *Cyclopedia of Masonry,* who claimed to have been initiated into a Continental Rosicrucian fraternity by an Austrian count named Apponyi.

In a detailed report on his visit, Mackenzie told his English brethren how Lévi had shown him the photographic copy of an inestimably rare book containing a prophecy by Paracelsus, illustrated with symbolic figures, predicting the French Revolution, the rise of Napoleon, the downfall of the papacy, the restoration of the Kingdom of Italy, the abrogation of the power of the pope, the downfall of the clergy, and, as a means of restoring general harmony in society, the ultimate ascendancy of the occult sciences. Lévi had also produced for his guest a "cabalistic plate" which he said he had bought on one of the quays along the Seine, and which was the source of a curious story. In a manuscript attributed to Cagliostro—then owned by a Count Braszynsky—the prediction was made that in the nineteenth century, a certain person by the name of Alphonse would clearly understand the meaning of the plate.

"I," said Lévi, "am that Alphonse." He then spent the rest of the interview filling in Mackenzie on the arcane mysteries of magic.

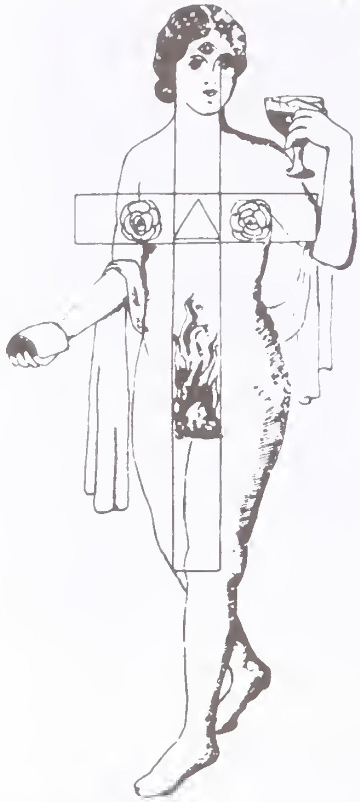
Back in London, Mackenzie shared with his fellow Freemason Hargrave Jennings all he had learned from the French magus. Jennings had meanwhile acquired from the estate of a deceased French occultist, J. B. Ragon, certain rare manuscripts which purported to give details of authentic Rosicrucian degrees and rituals. To perpetuate this wisdom, Jennings and Mackenzie got together with some other enthusiastic occultists such as Robert Wentworth Little to form the Societas Rosicruciana in Anglia, of which Eliphas Lévi was made a Master. Any other Mason with a master's degree interested in the "discovery of the secrets of nature through the symbolism of the art and literature of the past" was welcomed into the society, which began publication of its own organ, *The Rosicrucian,* naming as its Honorary Grand Patron the former British minister to Egypt, author of the Rosicrucian novel *Zanoni,* now Lord Lytton.

The man and woman reaching for each other across the inverted triangles of creative sexuality (appearing in the Rosicrucian *Anthology of Christian Rosenkreutz*) are less obscure in their meaning than the Hermetic Latin surrounding a medieval alchemist, and the captions from Proverbs: "The full soul loatheth the honeycomb; but to the hungry soul every bitter thing is sweet." And "A scorner seeketh wisdom and findeth it not: but knowledge is easy unto him that understandeth."

Among the first to join was Master Mason W. J. Hughan, and he and Jennings became pupils of an extraordinary character, said to be the greatest wizard in England since Merlin, George Pickinghill, who promised to show them how to master various elementals. It was one of their main endeavors to find the proof that the Masonic craft and the rites of the Rosicrucians were descendants of the old religion of the horned god of the Egyptians.

In a five-hundred-page opus, *The Rosicrucians, Their Rites and Mysteries,* Jennings hinted as strongly as he could that these rites and mysteries were of a fundamentally sexual nature, though to make his point in Victorian England he was obliged to resort to some involved and often poetically purple prose. Dancing around the theme of Tantric sex as the basis of the Rosicrucian philosophy, Jennings was almost specific when he pointed out that just as the Masonic seal of Solomon symbolizes the intertwined triangles of male and female, which in conjunction represent life, so the obelisk always indicates the male power derived from the sun, whereas "the pyramid indicates the female corresponding tumefactive or rising power—not submissive, but answeringly suggestive, synchronized in the anatomical clitoris (Greek from sunflower turning to the sun, that eccentric minute object, meaning everything in the Rosicrucian anatomy.)"

Ignored by his contemporaries and pilloried by later critics, Jennings nevertheless went on to produce *The Indian Religion, or Results of the Mysteries of Buddhism,*



William Wynn Wescott (1848–1925), Supreme Magus of the Societas Rosicruciana in Anglia and Worshipful Master of the Masonic research lodge Quator Coronati, translated Eliphas Lévi's work on the Tarot, and originated a groundbreaking work on the Isiac tablet of Cardinal Bembo. He died in South Africa.

in which, though maintaining as did the Theosophists that the human soul was a spark of fire taken from the eternal ocean of light, he argued that divine and supernatural illumination was the only means of arriving at the truth.

Jennings went on to explain that the Fire-Philosophers, the Rosicrucians, and the Illuminati all taught that knowable things both of soul and body were all evolved out of "fire" and finally resolve into it again, but that "this fire is not our vulgar, gross fire, but an occult, mysterious or inner supernatural fire."

The Rosicrucians, said Jennings, "claimed not to be bound by the limits of the present world, but to be able to pass into the next world (inaccessible only in appearance) and to be able to work in it, and to come back safe (and self-same) out of it, bringing their trophies with them. . . ." To this he added that they were merely following in the footsteps of the ancient Egyptians, who, "acquainted with the wonders of magnetism, built a bridge."

To achieve this passage, said Jennings, was the point and purpose of Egyptian, Rosicrucian, and Masonic initiation. Like Saint-Germain he believed that man had not originally been created susceptible to death. "The Rosicrucians contend that diseases are not necessarily incidental to the body . . ."

To drive home the point, Jennings translated from the Latin into English, Robert Fludd's opus on Rosicrucian philosophy, his *Apologia comendiaria fraternitatis de rosea cruce,* originally printed in Leyden in 1616. It hardly caused a ripple.

For several years the Societas Rosicruciana in Anglia progressed without undue notice until a member of its high council, William Wynn Westcott, decided to form an even more secret society. A supreme magus in the order, Westcott was also a London coroner, who, in the course of a lifetime may have conducted as many as ten thousand inquests, a calling which provokes the rumor that his penchant for autopsies involved a greater interest in corpses than in spirits.

Westcott had also acquired a mysterious manuscript, this one in cipher, to which he had managed to find the key—not too difficult a task, as it was the same cipher devised by the Abbot Trithenius and used by alchemists of the fifteenth century, which John Dee had spent ten solid days translating, and examples of which were at hand in the British Museum. The key made possible the transcription of five mystical rituals which Westcott claimed to be Masonic, drawn from the ancient Egyptian texts, but which later exegesists, from their inner content, believed to have

Samuel Liddell MacGregor Mathers in a rare photograph. The picture drawn of him by biographers is of a mother-fixated, sexually impotent male who avoided women and whose real passions were magic and the theory of war, and who was eventually converted to the Church of Rome. With no money, he sold inside information on the stock market to would-be investors. Kept alive by a lady adherent of the Golden Dawn, Anne Horriman, Mathers wrote and translated several important hermetic and occult works, including a lost book on Egyptian symbolism based on his exhaustive study of the Egyptian collection in the Louvre. Crowley accused him (in fiction) of sending his pretty wife out on the boulevards to make money, and of compelling her to undergo an abortion. He is credited by Ithel Colquhoun with being the mastermind behind the Golden Dawn before it was taken over by Crowley.

been concocted some time after Champollion had deciphered the glyphs, perhaps as late as 1870.

Westcott further claimed that the document opened the way to higher degrees of Rosicrucian initiation, to which had been given the high-sounding Latin titles of zelator, theoricus, praticus, and philosophus, used in the eighteenth century by the German rite of The Golden and Rosy Cross. Westcott also maintained that a letter found with the manuscript enabled him to get in touch, through an initiate in Germany, with the actual "Secret Chiefs" of the ancient order, originally introduced into Strict Observance Masonry by Baron von Hund, and that they had granted him permission to form a lodge in England, the Isis-Urania Temple of the Hermetic Order of the Golden Dawn.

This was considered an exciting breakthrough into the realms of higher magic; but as Westcott was no great magician, the real power in the new lodge fell into the eager hands of a character with the given name of Samuel Liddle Mathers, who, because of a Jacobite ancestor ennobled by Louis XV, was pleased to assume the title of McGreggor, comte de Glenstrae, and was not unwilling to have people believe him to be, in reality, James IV of Scotland, not killed at the Battle of Flodden, an adept who had learned, like the comte de Saint-Germain, to become immortal.

A Master Mason, then in his thirties, Mather had acquired a profound knowledge of Egyptology by reading every book he could find in the British Museum on magic, alchemy, symbolism, and the religious mores of ancient Egypt. To an acquaintance who spotted his gaunt, resolute figure in the reading room, he confided: "I have clothed myself with hieroglyphs as with a garment."

Further to explore the various astral planes, Mathers also taught the use of Dr. John Dee's Enochian magic. From the jumbled mass of Dee's papers and diaries, preserved in the British Museum and the Ashmolean Library at Oxford, Mathers managed with some effort to produce a coherent system of Enochian magic which seems to have helped initiates of the Golden Dawn explore the superphysical world of Dee's thirty "aethyrs."

Mathers also partially translated from the German Knorr von Rosenroth's seventeenth-century *Kabalah denudata,* which enabled him to equate the ten sephiroth of the Jewish cabalist's *Tree of Life* with the inner planes of the astral world, "reaching up to a limitless light beyond which nothing more can be known."

To secure his grasp on the Order, and to impose on it obedience, Mathers claimed to have forged a personal

Florence Farr (1866-1917)—Mrs. Edward Emery—mistress of the poet W. B. Yeats and of Bernard Shaw, was a leading member of the Golden Dawn, who specialized in "Scrying the Spirit-Visions." Left by Mathers in charge of the society, she wrote plays dealing with the Egyptian magical tradition. She also ran an avant-garde gallery where the paintings of D. H. Lawrence were seized as shocking.

Moina Mathers, lovely, delicate sister of Henri Bergson, was a clairvoyant who could bring to earth material from the "inner planes." But the sex act was reported to have "filled her with revulsion" and her marriage appeared to have been sexless, at least with her husband.

link with Westcott's "Secret Chiefs," about whom he could say nothing other than that they conveyed to him arcane knowledge, either clairvoyantly, on the astral plane, through automatic writing, or by means of a sort of ouija board, the use of which he said required great skill and attention to avoid interference by opposing "demonic" forces.

Mathers admitted he seldom had seen the "Chiefs" in the flesh, nor did he know their earthly names, but they appeared to him to be human with superhuman powers which were manifested as "transcendent health and vigor, as if they possessed the Elixir of Life." To be close to them, said Mathers, was like being close to a lightning flash during a violent storm.

The grades of initiation in the Golden Dawn were divided into three main levels, the first corresponding to the material world, the second to the astral, the third to the transcendental. Among the more prominent of the hundred-odd members some, like the wife of Oscar Wilde, were determined to practice magic. Others, such as Florence Farr, the actress, and mistress of G. B. Shaw, claimed to be controlled by "a certain Egyptian astral form first contacted through a piece of mummy case." W. B. Yeats, the Irish poet, more interested in inspiration, was introduced by Mathers to the world of symbolic "archetypes," where "images well up before the mind's eye from a deeper source than consciousness or subconscious memory." Yeats described visions which recalled "the planetary images of Ficino and Bruno," and, by concentrating, said he could even transfer symbols to someone else's mind.

In Paris, where he had moved for financial reasons, Mathers found in the Bibliothèque de l'Arsenal another magical system spelled out in a sixteenth-century manuscript, which he translated into English as *The Book of the Sacred Magic of Abra-Melin the Mage*. He claimed it enabled his fellows of the Golden Dawn to attain, through another ancient Egyptian ritual, "knowledge of, and conversation with, their own Holy Guardian Angel."

For some years Mathers continued to run the Golden Dawn from France with the financial help of one of its lady members, who, somewhat neurotic, accused Mathers and his wife, Moira Bergson, sister of the French philosopher, of dabbling in sexual magic. Both denied the charge of having made pacts with qliphotic or demonic forces, but their financial support was rescinded. Worse troubles, as lucidly described by Ellic Howe in his *The Magicians of the Golden Dawn,* were to follow. First Mathers failed to convince his fellow Golden Dawners of the actual existence of his "Hidden Chiefs"; then he admitted he had known all along that the original letters from Germany accrediting the Order had been forged, presumably by Westcott. Quarrels between members of the Golden Dawn accelerated its day toward a sunset. It only remained for the youngest and most energetic of its aspirant magi, Aleister Crowley, to ease Mathers into a personal *daemmerung,* by first taking his side, and then taking his place.

Edward Alexander Crowley in his twenties

Edward Alexander Crowley, better known by the first name of Aleister, was twenty-three and just down from Cambridge when he was initiated, in London's Mark Mason's Hall, into the Golden Dawn as Frater Perdurabo ("I will endure"). Two years later, he was a thirty-third-degree Mason. Within the minimal time he had worked his way up to the top of the complex order of Hermetic degrees concocted by Mathers. This he accomplished with the help of a senior magus, Allan Bennett (Frater Jehi Aour), who broke his oath to supply Crowley with the required secret data, later abandoning the Golden Dawn to become a Buddhist monk.

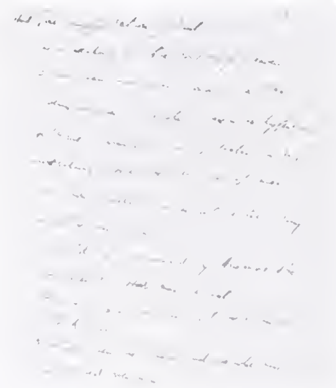
The next step, the contacting of his own guardian angel through the magic of Abramelin the Mage, Crowley could not speed up because it required a concentrated six-month effort which could only take place precisely between the vernal and autumnal equinoxes. To find the right atmosphere of privacy for this magical exercise, Crowley spent £2,000 of his father's inheritance to acquire a pink-washed, one-story lodge called Boleskine, overlooking the murky waters of Loch Ness between Foyers and the Enochian-sounding village of Inverfarigaig.

Exhausted by several months of apparently unsuccessful endeavors, Crowley suddenly reverted to his penchant for exploring exotic corners of the planet and set off for Mexico and the Far East, returning via Ceylon, India, Burma, Baltistan, and Egypt, having tackled and nearly mastered two of the highest unclimbed peaks in Asia. To Egypt he returned with a young bride, Rose Kelley, sister of Gerald Kelley, later Sir Gerald, president of the Royal Academy.

Rose Kelley Crowley

Masquerading through Cairo as a Persian prince called Chio Khan (Hebrew for "the beast"), dressed in flowing golden robes and a jewel-encrusted turban—so that runners would clear a path for him through the crowded streets—Crowley took his bride to honeymoon in the King's Chamber of the Great Pyramid, where he said he demonstrated to her his magical powers by causing the entire chamber to glow a pale lilac with "astral light."

Back in Cairo in an attempt to convince Rose of the



A page from Crowley's handwritten *Book of the Law.* The author, says Crowley, claimed to be a messenger—like Mohammed and others—of the Lord of the Universe, and therefore to speak with absolute authority. The book is said to be a statement of transcendental truth, and to have overcome the difficulty of expressing such truth in human language by what amounts to the invention of a new method of communicating thought. This Crowley describes as not merely a new language but a new type of language. "A literal and numerical cipher involving the Greek and Hebrew Cabbalas, the highest mathematics, etc." The book, says Crowley, ". . . claims to be the utterance of an illuminated mind coextensive with the ultimate ideas of which the universe is composed . . . an intelligence both alien and superior to myself, yet acquainted with my inmost secrets, a discarnate intelligence." Kenneth Grant says of the *Book of the Law* that anyone possessing any capacity for understanding the language of symbolism "will be staggered by the adequacy and accuracy of the summary of the spirit of the Aeon. . . ." It gives the basic law of the new aeon as: "There is no law beyond 'Do what thou wilt' and 'Thou hast no right but to do thy will.' " The theory being that every man and woman each has definite attributes whose tendency, considered in the relation to environment, indicate a proper course in each case. To pursue this course of action, says Grant, is to do one's true will. Hence: "The word of Sin is Restriction."

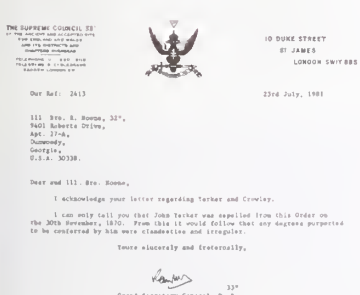
existence of elementals by invoking sylphs, or spirits of the air, Crowley merely managed to put his bride into a mild trance in which she informed him that the Egyptian god Horus awaited him with instructions to sit at his desk at noon on April 8, 1904, to receive a message.

At the appointed hour, Rose—whom Crowley now called by the pretty Arabic equivalent of Ouarda—suddenly spoke over his shoulder in a rich baritone in an English "uncannily perfect and free of ascertainable accent, native or foreign," which identified its owner as Aiwaz, Egyptian minister to the Lord of Silence, Hoor-Paar-Kraat.

On three consecutive days, the deep timbre of the voice "poured forth slowly, steadily, solemn, voluptuous, tender, fierce, in harmony with the message delivered," while Crowley with his Swan fountain pen scribbled and scribbled. Result: a twenty-one-page prose-poem known as the *Book of the Law,* which was to revolutionize Crowley's life, and would, he believed, greatly affect the future of mankind. It announced the advent of a new eon in which Crowley was to become the priest-prince of a new religion, the Age of Horus. He was to formulate a link between humanity and the "solar-spiritual force, during which the god Horus would preside for the next two thousand years over the evolution of consciousness on this planet." The technique used by Crowley to commune with Horus was "to seal the plasma of his astral body in the mentally formed image of a golden hawk—a vehicle of Horus—and in that form explore the subtle aethyrs of the universe, angelic or non-terrestrial dimensions of consciousness not usually experienced."

The message from Aiwaz, whom Crowley understood to be his own guardian angel, convinced him that his mission in life was to give the *coup de grace* to the Age of Osiris with its moribund appendage, the Christian faith, and build on the ruins a new religion based on the law of Thelema—Greek for "will." The theme of this new dispensation Crowley summed up in the dictum "Every man and woman is a star. Do as thou wilt shall be the whole of the law." To which he added the further and even more important proviso of "Love is the law, love under will." But love and affection under the law of Thelema was not to be confused with the possessive kind that breeds pain, jealousy, and hatred. It was to be a Charter of Universal Freedom for every man and woman in the world, each individual considered as the center of his own universe, his essential nature determining his relations with similar beings, and his proper course of action. Crowley's law of Thelema, as an ideal Freemasonry, saw each member of the

Crowley's diploma as a 33° Mason, issued in London, October 1910



THE SUPREME COUNCIL 33°

10 DUKE STREET
ST JAMES
LONDON SW1Y 6BS

Our Ref: 2413

23rd July, 1981

Ill. Bro. R. Boone, 32°,
9401 Roberts Drive,
Apt. 27-A,
Dunwoody,
Georgia,
U.S.A. 30338.

Dear and Ill. Bro. Boone,

I acknowledge your letter regarding Yarker and Crowley.

I can only tell you that John Yarker was expelled from this Order on the 30th November, 1870. From this it would follow that any degrees purported to be conferred by him were clandestine and irregular.

Yours sincerely and fraternally,

33°
Grand Secretary General, R. E.

The Grand Secretary General of the Supreme Council 33° in London declared Crowley and Yarker to have been expelled from the brotherhood of Masons.

human race as unique, sovereign, and responsible only to himself. "In this way," says Crowley, "it is the logical climax of the idea of demorcrary. Yet at the same time it is the climax of aristocracy by asserting each individual equally to be the center of the universe." The conclusion from these premises was that the sole and whole duty of each human being was to discover the purpose for which he or she is fitted and devote every energy to its accomplishment. The *Book of the Law,* said Crowley, opened a path of progress to mankind which would eventually enable the race to strike off the fetters of mortality and transcend the limitations of its entanglement with earth. He also called it "a veritable Golden Bough," an absolute passport through the Amenta of the Egyptians.

By his adepts, the *Book of the Law* was described as containing occult formulae of cosmic scope, "some openly expressed, some veiled in the most complex web of qabalistic ciphers ever woven into a single text." Nor was it just a piece of "automatic writing," said Crowley, but a clearcut message from an intelligence of superhuman power and knowledge, some extraterrestrial transcendental source, "one of the real hidden masters who would thereafter manifest to him."

Crowley describes Aiwaz as appearing to him later in the form of a tall, dark man in his thirties, "well-knit, active and strong, with the face of a savage king, and the eyes veiled lest their gaze should destroy what they saw." The apparition's dress, says Crowley, was not Arab, but suggested Assyrian or Persian, only very vaguely, because "at first I took little note of him as he was like an angel, such as I had often seen in visions, a being purely astral."

Later still Crowley was inclined to believe that Aiwaz was not only "the God or Devil once held holy in Sumer, and mine own Holy Guardian Angel, but also a man as I am, insofar as he uses a human body to make his magical link with mankind, whom he loves, and that he is thus an Ipsissimus, the highest spiritual achievement possible to man, literally his own very self, the head of the Great White Brotherhood."

By this Crowley did not necessarily mean that Aiwaz was a member of the human race, but that he could apparently form for himself a human body, as circumstances indicated, from the appropriate elements and then dissolve it. "I saw him again often in different human guises all equally material."

Acting upon the authority of Aiwaz, Crowley was happy to supplant Mathers and his Golden Dawn by forming a

The poet Victor Neuburg

By some experts, Dee's Enochian language is suspected of being Ur-Semitic, the source of later Semitic tongues. To others it is "the language that lies behind Sanskrit," or even the language of the Atlanteans. It was, in any case, a hieratic tongue to be used in ritual, its vocabulary related to a transcendental world, a sacred alphabet of letters and numbers, in which the letters were also sigils, or glyphs.

new order called Astrum Argentum, or Silver Star, named after Set, or Sirius, of which he claimed our sun was but a reflection, or son. The order, which Crowley considered the truly occult representative of the Great White Brotherhood, was designed to bring out into the open the secret knowledge so painstakingly preserved by initiates. The rituals of the A: A:, as it was glyphed, were to be simpler, including yogic practices Crowley had learned in the East. Their purpose: to prepare humanity for the next stage of its progress—initiation into the solar consciousness of Horus. At first there were few recruits to the A: A:, other than a sycophantic young admirer down from Oxford, the poet Victor Neuburg; but Crowley pressed on. With what was left of the money inherited from his father, he decided to launch a twice-yearly publication, *The Equinox*. The first issue, beautifully bound in white and gold, appeared in March 1909. Crowley described it as the first serious attempt to put before the public the facts of occult science "since Blavatsky's unscholarly hotch-potch of fact and fable, *Isis Unveiled.*" He considered his to be the first attempt in history to treat the subject with scholarship and from the standpoint of science. It contained the technique for assuming a god-form, of ritually evoking and banishing astral, elemental, and planetary entities. In the second issue, in October, true to his promise to reveal the initiatory secrets, Crowley published the neophyte ritual of the Golden Dawn with fifty-four diagrams to illustrate the mysteries. The cat was out; and once he and Neuburg had seen that it was well received, they took off for the North African desert of Algeria to embark on a more ambitious experiment in magic: further exploration of Dee's astral levels with the use of a large topaz as a shew-stone which Crowley would scry while Neuburg scribed.

Crowley says that eventually he learned not to travel in his astral body because he realized that space was not a thing in itself, but merely a convenience enabling one to distinguish objects from each other. When in one of Dee's Aethers or Aires he says he found himself simply in a state characteristic of its nature, his senses receiving its subtle impressions. Thus he claims to have become as cognizant of the phenomena of Dee's worlds as ordinary man is of his. But unable to break into the fourteenth Aire, Crowley had the sudden impulse to use sex to advance his magic. "We accordingly took loose rocks," says Crowley, "and built a great circle, inscribed with the words of power; and in the midst we erected an altar and there I sacrificed myself."

Crowley claimed he was obliged to write his more

According to Kenneth Grant, the barbarous names of evocation and invocation, whether Enochian, Goetic, Gnostic, or Tantric, are peculiarly adapted to unsealing the subconscious, their potency lying chiefly in their being unintelligible to the conscious mind. Crowley says: "The long strings of formidable words which roar and moan through so many conjurations have a real effect in exalting the consciousness of the magician to the proper pitch." He quotes Dee as voicing: "ZODACARE, ECA, OD ZODOMERANU! ODO KIKALE QAA! ZODOREJE, LAPE ZODIREPO NOCO MADA, HOATHATE IAIDA"; or: "Move, therefore, and show yourselves! Open the mysteries of your creation! Be friendly unto me, for I am the servant of the same your God: the true worshipper of the Highest!"

specific explanation in hieroglyphs because it had to do with matters "of which it is unlawful to speak openly under penalty of the most dreadful punishment: but I may say that the essence of the matter was that I had hitherto clung to certain conceptions of conduct which, while perfectly proper from the standpoint of my human nature, were impertinent to initiation. I could not cross the Abyss till I had torn them out of my heart."

Crowley the magician

Francis King, in *The Magical World of Aleister Crowley,* is more specific when he writes that the magus "sacrificed himself in a way which consumed every particle of his ego . . . he deliberately humiliated himself by being Neuburg's passive partner in an act of buggery."

The result, at the moment of joint orgasm, appears to have been a stunning entry into Dee's fourteenth Aire, where Crowley learned "to allow my ego to be totally destroyed so as to unite my spirit with the ocean of infinity."

From then on, said Crowley, sexual acts, which he had indulged in "with casual abandon," became for him a sacrament, a rite to be performed deliberately for the glory of the gods. Buggery, Crowley avowed, other than for religious purposes, was abominable; and to differentiate his magick from the nonsexual variety, he added to the word a *k,* symbol for kteis, Greek for the female genitals.

One of the demons conjured up by man from his own created storehouse

Crowley used *key* and *aethyr* for Dee's *call* and *aire*. A gramophone record of Crowley exists in which he recites the first forty-eight Enochian "calls." It was a language, says Ithell Colquhoun, that had to be vibrated like a mantra, and she suggests that Enochian magic is a Western equivalent to Hindu mantra yoga, and that vocalizing the sound gave access to an Atlantean world, "a superstructure unimaginably attentuated and jewel-clear, which the Egyptian *Book of the Dead* symbolizes as 'the lily of green felspar.' " She believes the Enochian Tables conceal a musical system, a record of frequencies on which the calls should be sent out, and "may even suggest the construction of an instrument." Crowley called the language "very much more sonorous, stately and impressive than Greek or Sanskrit, and the English translations, though in places difficult to understand, contain passages of a sustained sublimity that Shakespeare, Milton and the Bible do not surpass."

Reaching the tenth Aire—which had to be approached backwards, since it had been taken down by Dee for fear of unleashing demonic forces—Crowley realized he must consciously cross what he called the "Abyss," or great psychological barrier separating ordinary men from the "Secret Chiefs," a barrier guarded by the mightiest devil of all, the demon of spiritual chaos, the same Chorozon encountered by Dee. It now became clear to Crowley "that one must look inward and face one's own demons, for they may be the same as those one evokes."

There was a flash of lightning followed by a rumble of thunder, and a voice intoned: "I am the master of Form and from me all forms proceed."

Chorozon, Crowley later explained, represented all the suppressed fears and hostilities which had flourished in his subconscious. By materializing them, and by integrating them openly into his psyche, he says he disposed of their power; as a result of which ordeal he claimed to have earned a higher occult degree than Mathers, becoming a Magister Templi.

Mathers, in London, afraid that all his powers would now be lost by publication in *The Equinox* of the most secret rituals of the Golden Dawn, filed a restraining order against the third issue; and though at first he succeeded with the help of a judge renowned as a Freemason, the judgment was reversed on appeal and the second issue of *The Equinox* appeared intact.

Mathers, who admitted at the trial, under oath, "to raising devils, making himself invisible, transforming men into animals, making gold, making rain, and all the other fabled arts of sorcery," managed to further annoy several occultists by claiming to be *the* chief of the Rosicrucian order. Another such chief, a German, Theodor Reuss, reputed agent of the German secret service, employed to spy on British Marxists, was equally annoyed. As head of the Ordo Templi Orientis, Reuss considered his occult order to be the successor to the Knights Templar, and to be the true successor of the Rosicrucian fraternity, just as his earlier order, the Grand Lodge of Memphis and Misraim, had been the successor to both Cagliostro's Egyptian rite, and to Adam Weishaupt's Order of the Illuminati (OTO).

Reuss had inherited leadership of the OTO a few years earlier from a wealthy Austrian iron founder and high Mason, Karl Kellner, who had died in mysterious circumstances after changing the order's name from the Hermetic Brotherhood of Light to the Order of the Temple of the East, on the grounds that the East was the locus and source

The Hermetic Philosophy.

First Matter of Hermetic Philosophy, or the Font of Miracles. The text that goes with this illustration from the Rudolph Steiner Christian Rosenkreutz Anthology reads: "I am the mixture which preserves everything in nature and makes it alive. I pass from the upper to the lower planes. I am the heavenly dew and the fat of the land. I am the fiery water and the watery fire. Nothing may live without me in time. I am close to all things; in and through all things; nevertheless, unknown." The caption alongside the hermetic drawing reads: "This moisture must be caught, lest it should change into vapor or fume. The two vapors or fumes are the roots of the art."

of the illumination symbolized by the solar-phallic energy.

Reuss called on Crowley in London to accuse him of having revealed the innermost secrets of the ninth degree of the Ordo Templi Orientis. Surprised, Crowley replied he could hardly have done so as he had not been admitted to that degree and could therefore not know its secrets.

Reuss reached for a copy of Crowley's *Book of Lies* and pointed on page forty-six to the Ritual of the Star Sapphire. Crowley was thunderstruck. In his own work—in which he claimed to have surprised the supreme secret of all practical magick by pure chance while lying with a whore—he recognized a reference to sexual magic disguised beneath the symbols of the "rood" for phallus and the "mystic rose" for vagina. The scales fell from his eyes. At last, said he, his suspicion was confirmed that "behind the frivolities and convivialities of Freemasonry lay in truth a secret ineffable and miraculous, potent to control the forces of nature, and not only to make men brethren, but to make them divine."

Reuss was quite categoric: the OTO was a body of initiates in whose hands was concentrated the secret knowledge of *all* oriental orders and of all existing Masonic degrees. Its chiefs were initiates of the highest rank, but not in conflict with the grand lodge of England. It was all clearly stated, said Reuss, in the organ of his Grand Lodge of Memphis and Misraim, a magazine called *Oriflamme,* which spelled out that the order had "rediscovered the great secret of the Knights Templar, the magic of sex, not only the key to the ancient Egyptian and hermetic tradition, but to all the secrets of nature, all the symbolism of Freemasonry, and all systems of religion."

In the secret code of the order, Crowley found *Athanor* to be the name for penis; *blood of the red lion* for semen; *curcubite* or *retort* for vagina. Vaginal liquids were known as the *menstruum of the gluten,* and when mixed with semen, they became *first matter;* further impregnated with magic, they equaled the *Elixir of Life.*

Karl Kellner, the OTO's founder, said Reuss, claimed to have rediscovered the "secret doctrine" during his travels in India, where he had been initiated into Tantrism and the use of the sexual current by a notorious Arab magician, Soliman Ben Aifa, practitioner of an unorthodox form of Sufism, and by two Indian Tantrics, Bhima Sen Pratap and Shri Mahatma Agamya Paramahamsa, initiates of the *vama marg,* or left-hand path, the magical use of sexual energies accomplished with the help of a female companion, or *shakti.*

The OTO, said Reuss, had been founded in the 1890s

by an amalgamation of the original order of Bavarian Illuminati and the Hermetic Brotherhood of Light, an order formed by the American Paschal Beverly Randolph, natural son of a rich Virginian and a mulatto woman said to be of royal Malagasy blood. As a friend of Lincoln's, he is said to have encouraged the president in his aid to Negroes. According to Serge Hutin, Randolph became involved with Freemasonry and the Fraternitas Rosae Crucis, and thanks to his extensive travels in the East had met Tantric initiates who enabled him to produce his main work, *Magia sexualis*.

So the chain linked Reuss and Kellner and Paschal Beverly Randolph back to Hargrave Jennings and the early members of Rosa Crucis in Anglia who had been obliged to keep so secret the fact that they too practiced the secret rituals of Tantric sex which Edward Sellon had described in his book. Suddenly all of Jennings's Hermetic phrases, teetering on the verge of revelation, became easier to comprehend.

Furthermore, says Manley Hall, it is possible that Jean Marie Ragon and Alexandre Lenoir could have been pupils of Saint-Germain when he practiced masonic and rosicrucian rituals in the palace of Prince Karl of Hesse at Eckernforde in 1780-85.

Delighted by Crowley's grasp of Tantric yoga, Reuss offered to initiate him into the highest degree of the OTO, suggesting that his new adept head a British section to be known as Mysteria Mystica Maxima, wherein initiates could be given hints in the lower grades of the whole truth of the power of sexual magic, which would be revealed during the higher degrees.

The first six degrees of the OTO Crowley found to be simply Masonic. In the seventh the initiate was given a

Crowley became convinced that his job was to cure the whole world of sexual repression, a plague that was paralyzing spiritual progress. He wanted sexual expression to be not a legal or a financial or an endured performance but a "magnetic phenomenon"; he wanted love to be a gift to be treasured without shame or hypocrisy. And he saw his mission not merely to illuminate the few, but "to set in motion occult forces which would result in the illumination of all by 2000 A.D." To achieve his goal he determined to study every detail of sexual behavior and bring every sexual impulse up to the region of rational consciousness. To this end he experimented with altered states of consciousness, including hashish, cocaine, and opium. To push his consciousness to its limits, to reach a transcendent state, he used orgiastic practices, believing that in a deathlike trance of the body, the spirit was free to unite with an invoked "god." But he warned: "Sex is, directly or indirectly, the most powerful weapon in the armory of the magician, and precisely because there is no moral guide, it is indescribably dangerous. I have given a great many hints, especially in *Magick* and the *Book of Toth*—some of the cards are almost blatantly revealing; so I have been slapped rather severely over the knuckles for giving children matches for playthings. My excuse has been that they have already got the matches, that my explanations have been directed to add conscious precautions to the existing automatic safeguards."

In *Liber agape* sexual intercourse is referred to as "the sacrifice of the mass": entering the privy chapel is to enter the woman's vagina; to bestow at least one hour in adoration at the altar is sexual play; extolling God in strophe and antistrophe and performing the sacrifice is to achieve orgasm; "the elixir being prepared solemnly and in silence do thou consume it utterly," is to swallow the mingled male and female secretions, described as "the most powerful, the most radiant thing that existed in the whole universe."

glimpse of sexual magic. In the eighth he or she was taught to practice autosexual magic through masturbation. According to Henri Bertreux in *Aux pays du Dragon*, astral energy can be released by a form of massage, or magical masturbation, which stabilizes the astral field of a person, making his or her magnetic force more harmonious. It can then be used as a form of protection against sexual vampirism performed by sexual entities operating in another dimension. "A wall of light," said Crowley, "can be made to encircle the magician charged with solar-phallic power drawn from the sun. . . . Sexual vampires seeing the radiant wall of light are drawn precipitately towards it and dashed to pieces, electrocuted on impact."

In the ninth degree of OTO heterosexual magic was performed involving sexual congress, the essential goal of which was the same as in witchcraft: concentration of the will at the moment of orgasm in order to obtain a wish. As with the witches, Crowley said he performed this magic on the astral plane in his so-called body of light. His imagination, powered by sexual energy, was set to function on an astral level, and, according to Crowley, at the moment of orgasm the sexual organ actually "shines" astrally. The ability to function on the inner, or astral, planes, to travel freely in the realms of light, or inner space, are derived, as Crowley explained it, from a purification and condensation of "vital force," which he described in its densest form as being identical with sexual energy. "The emanations of the 'Body of Desire' of the material being whom one visits," he said, "are, if the visit be agreeable, so potent that one spontaneously gains substance in the embrace."

He explained that in order to transform sexual energy into magical energy, the dormant fire-snake at the base of the spine is awakened. And the function of semen in the ritual is to build up the body of light, or astral body. "As the vital fluid accumulates in the testicles it is consumed by the heat of the roused Fire Snake radiating waves of astral energy whose subtle fumes go to strengthen the inner body."

Curious to discover whether a magician could produce the phenomenon at will through *any* practice of sexual magick, Crowley went with Victor Neuberg to Paris, where they enlisted the help of the correspondent of the *New York Times*, Walter Duranty. Beginning in January 1914 they performed twenty-four rituals of sexual magick in forty-three days, designed to invoke several disembodied entities ranging from Hermes to Jupiter. Crowley kept a diary describing these events, which he wrote up as *Rex*

According to Horapollo, the Egyptians used the falcon as a symbol of the god Horus because of its long life, its piercing sight, its ability to climb straight up and to drink the blood of a victim while flying upside down; also because the female was said to accept the male thirty times a day.

Crowley describes his method for assuming a god form. "By concentrated imagination of oneself in the symbolic shape of any god, one should be able to identify oneself with the idea which he represents." Crowley describes invoking a god form with Neuburg in a locked temple: "On one occasion, the god came to us in human form and remained with us, perfectly perceptible to all our senses, for the best part of an hour, only vanishing when we were physically exhausted by the ecstasy of intimate contact with his divine person, and sank into a sublime stupor; when we came to ourselves he was gone." At other times, Crowley continued the evocation of elemental forces "to visible appearance," and to make various talismans charged with spiritual energy, by means of meditation. He also continued to build up "my (so-called) astral body until it was sufficiently material to be perceptible to the ordinary physical senses of people I should visit in this shape."

de arte regia, listing every sexual act of any form in any possible combination, with the goal to be achieved at the moment of orgasm. Occasionally Duranty would substitute for Neuburg as a partner and "magician joined to magician," they would make the invocation: "Hermes, King of the Rod, appear, bringing the ineffable word!"

To impersonate an Egyptian god-form, mental concentration on the form of the god was required throughout intercourse; one had to imagine the god to have a life of its own. At the moment of climax, a transference of consciousness to that of the image was necessary, "blending the personality of the initiate with that of the god." Crowley still insisted that the practice of buggery was "an abomination" except in magick, and Serge Hutin says Crowley could not have been a homosexual or he would not have been admitted by the Hindu Tantric masters to their secret rites of the "left hand" because homosexuals are excluded—not for moral reasons—but because the normal polarity is reversed, and the magic will not function. Not satisfied with these extraordinary results, Crowley was to develop two more grades of sexual magick for the OTO, based on homosexual ritual.

It was clear to Crowley that the accusations against the original Templars of practicing sodomy and orgies with women had been grounded, but not as understood by their detractors. The Templars were evidently practicing rites they had picked up in the East. G. Legman, in *The Guilt of the Templars,* a composite work by five distinguished English academicians, says the Templars did not practice homosexuality *faute de mieux* but as a formal dedication, betrayed by the ritual nudity required at their secret initiation, and by the scatalogical kisses on mouth, penis and arse, which "clearly could or did end with the fellation or pedication of the recruit by the Templar receiving him." Legman suggests that the whole secret ritual implied or symbolized "a complete erotic itinerary of the recruit's bare body under the guise of ritual kisses." This was followed by the admonition that if at any time he felt the "stirrings of the flesh" (which Legman says could certainly be observed if it occurred while he was kissing the recruit's penis) it was permissible to "unite himself carnally with any of the brethren, and that he was to submit himself passively to them if asked." The neophyte was also told that it was better to satisfy each other than give a bad name to the order by going after the women pilgrims they were charged with protecting. Though it appears, says Legman, that the rich and powerful Templars had all the women they wanted "very handsome and elegant."

That there was more to the Templar ritual than a banal satisfaction of the senses is indicated by the nature of its kiss on the mouth—a hermetic means of transmitting a subtler spiritual breath from initiate to novice.

The Templars appear to have realized long before Wilhelm Reich that society could not be reformed into a peaceful brotherhood so long as repressed sexuality could be distorted into neurosis and aggression, and that any sexual discharge of pent-up vital energy was better than having it turn noxious, as with the torturers and warmongers.

What actual Tantric practices the Templars may have indulged in, whether masturbatory, homosexual, or heterosexual, is not easy to determine; for the brothers were understandably reticent in exposing the fabulous secret of their Order.

Crowley, in his *The Secret Garden,* adds a curious footnote to the Western Christian laws against homosexuality illustrative of the folly of man's misconception in matters of religion: "When the power of the Crescent menaced that of the Cross, sodomy was put down with Draconian rigour because the Turks believed that the Messiah (a reincarnation of Jesus) would be born of the love between two men. Sodomy was thus a religious duty with the Turk; at any moment his passion might be used to bring about the Millenium; so with the Christian it became heresy, and was punished as such!"

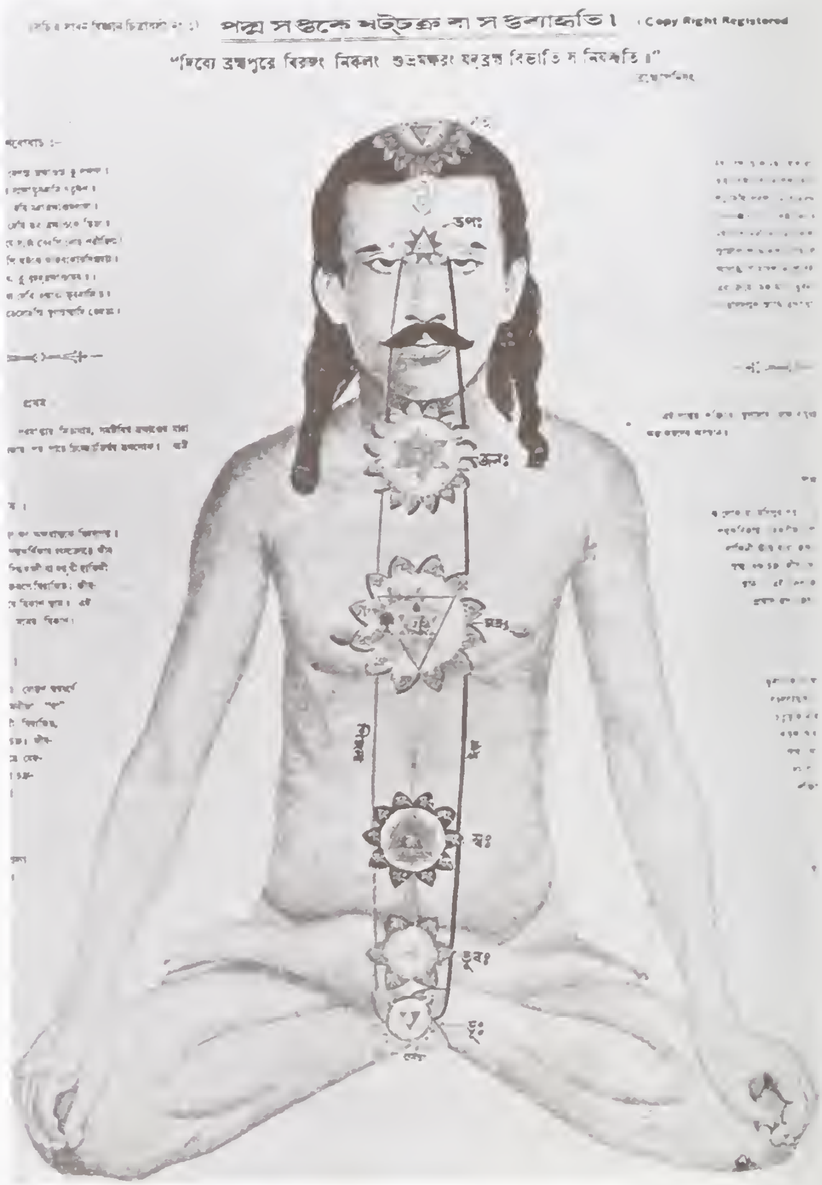
Crowley synthesized his message: "I say to each man and woman: You are unique and sovereign, the center of the universe. However right I may be in thinking as I do, you may be equally right in thinking otherwise. You can only accomplish your object in life by complete disregard for the opinions of other people. . . . My mission is, in short, to bring everyone to the realization and enjoyment of his own kingship, and my apparent interference with him amounts to no more than advice to him not to suffer interference." This, said Crowley, in no way diminishes the advantages of "joint action directed to the attainment of a common purpose."

The Tantrism of the left-hand path, revived in the West by Kellner, was based on the Hindu mystic concept of a mindless universal energy, personified by the goddess Shakti, locked in embrace with the god Shiva, from whose eternal orgasm every factor in the universe is derived.

Practiced by individuals, heterosexually, it is similar to Pico, Ficino, and Bruno's means of slipping through the mesh of sensitive illusion, a sort of magical ascent beyond the world of appearances, during which the participants, in a paroxysm of orgiastic ecstasy, burst forth from the limits of the body to explore the more rarefied regions of the cosmos, to experience directly, as two gods embraced, the consciousness of Shakti and Shiva—at One.

That these secret Tantric practices had flourished in widely scattered cultures from China to Africa, from India to the Middle East, and that they may have come to America and Africa from lost Atlantis was claimed by Gerald Massey; and it was through him that Crowley was able to track sexual magick back to its Egyptian prime, developed from an African source—the same source which took it to Haiti as voodoo.

The essence of Tantric lovemaking is to postpone orgasm by various postures, meditations, incantations, and prayers so as to raise the kundalini.



The liquid known as amrit (ambrosia of the gods), or the elixir of life, is said to flow from the genital outlet of the priestess chosen to represent the goddess. In man the fluid is said to be charged only when the Fire Snake—controlled by a form of yoga involving the anal sphincter—flashes back and forth between the prostate region and the brain. Once the kundalini was raised the human organism was to be used as a condenser to draw in stellar or transmundane energy by tapping the appropriate chakra once it was animated and magnetized. The OTO aimed at using the subtle energies of the Fire Snake for establishing a door into space through which extraterrestrial cosmic rays might enter and manifest on earth, enabling humans to have intercourse with extraterrestrials more evolved than man.

In all Tantric magic, the essential requirement—whether in the ecstasy of couples or the solo rituals of a priestess—involved the raising of the energy known as the serpent of fire, or kundalini. This mysterious energy, described as lying dormant in the lowest of the seven chakras, can be aroused by two distinct methods, called, traditionally, the right- and the left-hand path. The right hand allots supremacy to the male principle, the left to the feminine. As the serpent power is aroused, according to clairvoyants, it climbs up the backbone of the adept, energizing each chakra, till it emerges from the skull—symbolically as a snake's head like those so clearly depicted in Egyptian statuary. The excited chakras are seen clairvoyantly as whirls of multicolored lights, glowing and pulsing along the spinal column, with lesser lights "pulsating like stars throughout the ganglionic network of nerves which constitute the subtle anatomy of man." The aroused chakras are described as petaled lotuses, tuned as receivers of powerful cosmic rays to link the microscopic body to the macroscopic universe.

As adepts describe the rising serpent, it unites with the "many-petalled lotus of the cerebral region" to bring about illumination—or the highest form of initiation—as the current "climbs back from duality to unity by reversing the path it originally took down the chakras to procreate humanity."

Details of the OTO's initiation into Hindu and Tibetan Tantra, including ceremonies involving the use of "exudations" from specially trained priestesses, were brought to a wider public by Crowley's follower Kenneth Grant. Sacred courtesans, experts in ritual eroticism, known in India as *nautch* girls, *manjaris, suvasinis,* or *devadasis,* were exceptionally honored, says Grant, and given advanced education in music, dance, painting, literature, and philosophy. Their magic exudations, known as kalas, from the goddess Kali, have, for centuries if not millennia, been taken by adepts of Tantra as a medicinal elixir, quite possibly the "elixir of life."

David Farren, an ex-Jesuit professor of philosophy who married a witch, says in *Sex and Magic,* it was the Chinese Taoists who dared to use human sexuality in an effort to produce a substance that would provide physical immortality. According to the Taoists, if a man could provoke a woman into producing vaginal secretions while he kept himself from ejaculating, he could then assimilate her own life-force, or yin, while not losing any of his yang. A man who could take ten women in a night was considered well on his way to being one of the legendary immortals.

Adepts of the left-hand path use the kalas, or vaginal essences, by invoking the goddess at the Muladhara chakra, by the female genital outlet. Grant says the Elixir of Eternal Life manifests in the high priestess at the climax of the sacred rite. "The invisible seed (bindu) at the heart of the central yoni represents the 16th Kala." Grant calls the kalas essences, or "rays of time," and suggests that as the earth's aura continues to be impregnated by rays from the stars, new and subtle kalas penetrate human consciousness. The stars, he says, represent, magically speaking, astral consciousness concentrated in the subtle essences of the kalas, or vaginal vibrations. The sixteenth kala, or ray of the moon, which he calls the most secret of all, is "the essence where time stands still, where time is NOT, i.e. NUIT."

To arouse sexuality in the priestess, and to build up her libido, various methods were employed in different cultures. Whereas the Chinese Tantric Taoists are reported to have used infraliminal vibrations from large gongs reverberating just beneath the threshold of normal audile receptivity, the Egyptians, from extant depictions, used what are described as "manipulative techniques of sexo-somniferous magnetization." And whereas the Atlanteans, to arouse the fire-snake, are believed to have applied magnetized metal instruments to the chakras of a priestess, one of Crowley's more eccentric fellows, a Royal Navy commander G. M. Marston, experimenting with the rhythm of tomtoms, was able to lead demure English women to "shameless masturbation and indecent advances."

The goddess Kali was, in any case, invoked at the region of the Muladhara chakra, seat of the kundalini, the zone whose gate is the female genital organ. As the kundalini rises in the temple priestess, Crowleyans describe it vitalizing not only the chakras but a series of secret erogenous zones known as marmas, imbuing them, in the poetic language of Tantra, with nectar, or vibrant energy, causing each sacred lotus to generate subtle effluvia, or kalas, of great potency, considered by Crowley the "Magick Light," the Hadit, or Set of the *Book of the Law,* the Aub or Ob of the voodoo.

The science of the marmas, says Kenneth Grant, is highly complex, and only communicated under cover of secrecy during an initiation. According to Havelock Ellis, only fourteen of the seventeen bodily secretions known to Tantrics have been recognized by Western science. The fifteenth and sixteenth, which are known to orientals, only manifest, says Grant, in the vaginal emanations of the fully trained and developed suvasini. Crowley and his fellow adepts found that the kalas differ in chemical composition according to the phases of the feminine cycle, the age and condition of the woman, the phases of the moon, the relative location of the stars—which, if nothing else, indicates that the Paracelsian notions of the effect of planets and stars on humans contained greater wisdom than his contemporaries were able to accept, a notion more fully developed by the clairvoyant scientist Rudolf Steiner.

In the world of Tantra, the sixteenth kala is represented by the invisible seed, or "bindu," the catalyst that makes the "virgin" glow and emanate the nectar, or amrit, which contains in its fragrance the ultimate essence—the elixir of life. Bindu, or semen, is represented by a point or dot at

Crowley said the ancients did not obtain their ductless-gland extracts from brainless dead cats, dogs, or pigs, but from living humans, where the substance was of greater value. "The urine of a healthy young female which contains the internal secretions from various organs of therapeutic value and health-giving importance is used as the medium for the imbibition of tonics.

the heart of a triangle, or yoni. Shades of the Davenport stele!

An essential part of the Tantric ritual is the vibration of mantras, or magical sounds. Whereas the creative mantra of the fire-snake is the familiar Masonic and voodooistic Om or Aum, the mantra that effects the gradual release of the sixteenth kala, as described by Grant, is one of the most guarded secrets of the left-hand path, consisting of sixteen syllables each vibrated for one kala.

In the *vama marg* ritual the resulting elixir, or "secret seed of the stars," is caught on a leaf and is absorbed orally by the magician without contact with the priestess, whose supersensitivity aroused by sexuality could be short-circuited by a touch.

Imbibition of the kalas, charged with the upward-directed kundalini current, is said by Crowleyans to transform human consciousness and make possible communication with transcendental entities: the sport of Apollonius, de Molay, Ficino, Pico, Dee, Cagliostro, Lévi, and their followers.

Conversely, Grant warns, the intake of the downward-directed venom brings man into contact with the demonic world of the lower elementals, where only a powerful adept may venture with impunity. The sixteenth kala is also said to bisexualize those who absorb it in the prescribed manner; hence the representation of Shakti gods as androgynous, like the Baphomet of the Templars.

Thus the source of the vital elixir sought by the alchemist and adept of yore was exuded from a human female flower. Crowley adds that the secretions of the endocrine, or ductless, glands from a healthy young female are much finer and much better for human imbibi-

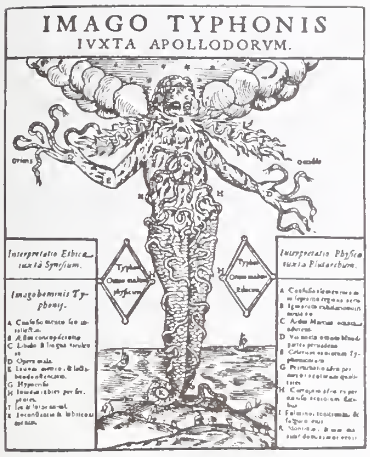
Budge describes Tuart as the wife of Set, or Typhon, also known as Apt. Her common title was "mistress of the gods" and "bearer of the gods." One of her forefeet rests upon the symbol of magical power, which, says Budge, probably represents a part of her organs of generation. To de Lubicz, she is the womb, considered as volume, one that embodies and materializes substance. She is the sky when considered as three-dimensional space that engenders all volumes. She is a *mammal* because she symbolizes the function of nourishing or quantitative multiplication brought about by selective affinity.

tion than those used by modern medics and extracted from the dead glands of animals which lack the essences of humans.

Understanding the ritual of the *vama marg,* says Grant, gives meaning to the Hermetic opening of Crowley's *Book of the Law,* where in the first stanzas, it proclaims, "Behold! it is revealed by Aiwass [spelled differently at different times by Crowley for numerological reasons] the minister of Hoor-paar-kraat. The Khabs is in the Khu, not the Khu in the Khabs." Incomprehensible, until it is realized that *khabs* in Egyptian means "star," and *khu* is the female essence, or magical power. Interpreted thus, it is the starlight which resides in the magical power of the female generative essence. Stars, rays, flowers, essences, perfumes, oils, unguents, times, cycles, emanations—all, as Grant points out, are concentrated in the black goddess Kali, the flower, the living symbol of time.

In his *The Magical Revival,* Grant goes on to show how Crowley's use of sex as a means of gaining access to the invisible worlds, and other planes of dimension, was a return to the rituals of predynastic times in Egypt, where the great mother goddess Tuart was worshiped through sexual rites which were then exported to India and the East, and later perpetuated in a more or less decadent form in the *orgia* of the Greco-Roman mysteries. The Egyptian predynastic tradition, known as Draconian, or Typhonian, is traced by Grant from an earlier African mystery system, similar to voodoo, possibly derived from Atlantis. According to his analysis of the Crowleyan data, the Draconian cult in Egypt was the cult of the fire-snake, based on "magnetism, intercourse with spirits, and elemental manifestations seen clairvoyantly. The astral body was an observed fact, and indicated spiritual survival after death."

The contention is clearly that the "mysteries" moved from ancient Egypt to Sumer, India, Tibet, and China, where they flowered into the Taoist Tantras. That the oriental systems were based upon the Draconian-Typhonian cults of ancient Egypt is deduced by Grant from the many Egyptian terms in the texts of the Tantras, particularly those of India. Shakti, or power, the central concept of the Tantras, he equates with the Egyptian Sekht, or Sekmet, consort of the gods, typified by the heat of the southern sun, or the sexual heat of the lioness. Khart in Egypt is Horus, child of the god; in India the son of the sun god is Kartikeia. The Egyptian sun god On is the Vedic Ong or Om. Sesheta, which typifies the female period, is Sesha in Hindi.



Kircher's rendition of Typhon, whom the Greeks identified with Set, son of the earth (Geb) and of the sky (Nut), reputed to have torn himself violently from his mother's womb. Originally a beneficent god of Upper Egypt, Set was arbitrarily declared by the priests of Horus to be "unclean," though his worship was one of the oldest cults in the country. Representing the cosmic opposition of darkness to light, Set and Horus were understood to be facets of a single source. In the murky mythology, Set murders and dismembers the body of his brother Osiris, and persecutes the widow Isis and her son Horus until the latter revenges his father.

The predynastic Egyptians worshiped the feminine principle, the great mother goddess represented by the seven stars of Ursa Major and her child Sirius the dog star, or Set. Sirius was also represented by the same symbol as his mother, whom he is supposed to have fecundated. Those Draconians or Typhonians, says Grant, oblivious of the role of the male in the biological mysteries of creation, worshiped the "whore and her bastard," later typified as Virgin and Child. And so, back to the mother goddess of the witches and the old religion.

To the ancient Egyptians, Ursa Major was Ta-Urt, goddess of the mysteries of time and cycles, from whose name Crowley derived the Tarot's use for divining past and future. Ta-Urt was also known as Serk, to whom the dog-star Sirius, or Set, was sacred. During the Draconian migration from Egypt to Sumer, says Grant, Set became Shaitan, and then Aiwaz in Babylonian Akkad.

One of the names for Set was an upright stone or pillar, and Grant points out that the gemantic number for IHVH, the name that cannot be uttered by Jews, was twenty-six, which he equates with the middle pillar, or phallus, twenty-six being also the gemantic formula for the phallus in function, or extended in action.

The Sabean form of Set, which was Sevekh, later became Sebek-Ab-Ra, meaning "lamb of Ra," or "lamb of the sun." This Grant equates with the solar-phallic energy perpetuated by the gnostics as Abrahadabra, Had being Chaldean for Set.

The Sabean cult of the stars was followed first by a cult of the moon with the moon god Thoth, lord of the double light, who replaced Set; though Grant points out that Thoth's symbol, the dog-headed cynocephalous ape, is a continuation of the dog symbol of Set. The moon cult was in turn superseded by the solar cult of the Osirian, or Ammonite, supporters of male supremacy, with its deleterious effects down to the present.

Conflict between the Draconian-Typhonian worship of the feminine principle and the solar masculine cult, says Grant, split Egypt for centuries, yet the Draconian tradition "lingered on into the dark dynasties whose monuments were gradually laid waste by the solar cultists who abhorred all reminders of the Sabean origins of their theology." It was a conflict, says Grant, which lasted from the predynastic eras to the final fall of the Draconian cult, around the time of the Seventeenth Dynasty (variously estimated by Egyptologists as between 1650 and 1570 B.C.).

An effort to revive the Draconian cult of Sabek-Ra, or

In *Across the Gulf,* volume six of the *Equinox,* Crowley described in opalescent language his reconstruction of what he called his own life as a priest in the Twenty-sixth Dynasty, "when I was ANKH-F-N-KHONSU and brought about the Aeon of Osiris to replace that of Isis." The name, he said, means "his life in Khonsu"—Khonsu being the moon god of Thebes. Crowley regarded the recovery of "past lives" through overcoming the obstacle of past deaths as essential to "understanding the general object of existence." Grant adds that the Ankh, or sandal strap, the glyph of Venus, symbolizes the ultimate transcendence of individual consciousness.

Those who do not read Crowley's work with care, says Grant, miss the deeper implications; yet, properly understood, it presents the most precise and austere code of conduct ever enunciated. But because it implies the total freeing of sex from the shackles of the convential, "it creates an immediate resistance in the mind unprepared for New Aeon attitudes." Spiritual attainment, said Crowley, was "incompatible with bourgeois morality," and he opined that the social and moral inhibitions and restrictions of his day were a crime against nature for which a severe toll would be exacted. The

Set, was made by a Theban priest of the Twenty-sixth Dynasty, Ankh-af-na-Khonsu, in the seventh century B.C. And the effort of this Theban priest of the Saite Period throws light on Crowley's hypnotic involvement with Set and Aiwaz. Crowley maintains that *he* was that Theban priest. "Tradition asserts that we forget our previous incarnations, because the shock of death erects a barrier; wihout assenting to this theory, I will say that having trained myself to face the fact of Death without mental disturbance, I found myself able to recall my last death."

Crowley recalled not one, but many past lives; very few of which, says Grant, "were outstanding in a worldly sense." Some, as described by Crowley, were "of almost uncompensated wretchedness, anguish and humiliation," voluntarily undertaken, he says, so he might resume his work "unhampered by spiritual creditors."

Crowley says he found it difficult to remember his "magical mistakes," and was "barred from remembering details of a tremendous magical catastrophy in the remote past." Its effect he describes as being hurled from a series of incarnations in which he was a high initiate, "to climb painfully once more to my present state." There was thus a large gap in his magical memory, "a shape of shame and horror which I have not yet found courage to unveil." In volume one, part ten of the *Equinox,* Crowley gives details of the life of Ankh-af-na-Khonsu, and of his failure to reinstate the worship of Set.

As a result of this failure, says Grant, the faint echoes of the ancient cult died down, and in their stead came "the flood of grotesque occult lore and debased sorcery that was to wash away the last vestiges of Egypt's glory." The remaining few dynasties saw merely an acceleration of this process of degeneration. "It was not till many centuries had elapsed that the Draconian Current reawakened, not in Africa but in Asia in the guise of the Tantras of the Left Hand Path."

Crowley's memories of a life as a Roman named Marius Aquila and those of a Cretan priestess called Aia are relatively banal, but those of a disciple of Lao-Tse, and author of the *King Khang King,* give meaning to the art of clearing the blocks which veil man's memory of the past.

John Blofeld, in his *The Wheel of Life,* refers to adepts of Taoist Tantra in China who, controlling their consciousness, were able to achieve what he calls "a relative immortality," with no need to preserve a physical body in order not to "die" in one body and be reborn without losing the train of their identity; although, says Blofeld, the alternate aim was "total absorption in the Goddess, mere mention of sex, he said, "draws man into a blind spasm of lust, either exploding into priapism or camouflaged into shocked indignation." Only when people can contemplate any given sexual idea without emotion of any kind will they be on their way to freedom. Crowley saw as his object to release their minds from bondage—or, better, themselves from the bondage of their minds. In the end, says Grant, Crowley left a loose-knit network of occult groups using the Ophidian current (kundalini) to prepare human consciousness for intercourse with the denizens of other dimensions.

accomplished through Tantric sexual union with the priestess who embodies her." To the Taoist, the purpose of raising the kundalini appears to have been the creation of an astral body that would survive both death and the dissolution of consciousness.

In his *Confessions*, Crowley gives a brief view of a life shortly before Mohammed when his goal was "to bring Oriental wisdom to Europe and restore paganism in a purer form." He describes being present at a "council of Masters" in which various illumined ones were appointed to undertake different adventures. "Mohammed, Luther, Adam Weishaupt, the man we knew as Christian Rosenkreutz, and many servants of science were chosen. Some of the movements have succeeded more or less, some have failed entirely. . . ." Crowley, adds Grant, would not have referred to Weishaupt as a master unless he knew him to be far advanced upon the path in a magical or mystical sense.

In *Heart of the Matter,* which Crowley wrote under the pseudonym of Khaled Khan, or "Sword of God," he claimed to have been a reincarnation of the warrior who delivered the Arabs from the stranglehold of Christianity at the Battle of Damascus—in 1126. Crowley's next encounter with Tantra may have been in an incarnation in which he switched sides—a game often played by disembodied spirits. "I was involved," he said, "in the catastrophe which overtook the Order of the Temple."

This was followed by a less noble life as Pope Alexander VI, the Borgia menace, of which Crowley, in a masterpiece of understatement, reflected that "I failed in my task of crowning the Renaissance through not being wholly purified in my personal character," adding by way of exculpation: "An appropriate trivial spiritual error may externalize as the most appalling crimes."

Crowley's next three lives, in terms of the magic of obelisks, are more to the point. As Sir Edward Kelley, the Tantric adept and scryer friend of Dr. John Dee, Crowley maintained he misunderstood certain messages that referred to the New Aeon of Horus announced by Aiwaz. But as to the genuineness of the Keys Crowley submits that the best guarantee is "the fact that anyone with the smallest capacity for Magick finds that they work."

Grant suggests that Crowley, using Dee and Kelley's system of scrying with Enochian language, was able to go far beyond what they had managed to acquire at the beginning of the seventeenth century, and that by systematically exploring Dee's Aethyrs, he was able to "penetrate unknown dimensions of consciousness outside space

If it is of any consolation to those who believe that Crowley the heretic deserved the same flames that devoured Bruno, or the same jail that asphyxiated Cagliostro and Reich, he or she may rest assured that armored society did its very damnedest, decade after decade, to vilify Crowley in every possible way, publicly calling for the execution of "the wickedest man in the world" or longing to put him in jail forever; and had it not been that throughout his life he never committed the smallest infraction of the law, they might have succeeded. The press in Britain launched a campaign of libel comparable to if not worse than that provided by Morande, achieving for London the honor of producing the very worst as well as the very best of periodic pressings. Stevenson has provided a limpid analysis of how grossly and deadly unjust a press attack such as Beaverbrook's can be against a man unsupported by the vast sums it takes to bring suit. And once in a newspaper's morgue a libel lives forever. Whatever else Crowley may have achieved in his life, historian Robert Amadon says of him "This man is the greatest, and perhaps the only magician of the twentieth century in the West." Approaching death, Crowley asked fellow Mason Gerald Yorke to have him embalmed in the Egyptian manner; then he reconsidered, saying: "Since I already look like a mummy, I want to be cremated." Yorke admitted he was beginning to believe that AIWAZ could more

and time," and thus obtain solutions to many cosmic problems.

But the surprising chain is by no means over. Next, Crowley says he was born into the body of none other than Count Alessandro Cagliostro. This time his remembrances of events differ somewhat from those given by most Cagliostro biographers, though they make as much sense, and may be every bit as "historical." As Cagliostro, said Crowley, "I was born in a brothel, kept by my mother's mother. My mother was half Arab, my father presumably some rich traveller." There was, Crowley added, "a profound horror and gloom antecedent to this birth."

The mystery of Cagliostro's marvelous pomade, so good for ladies' skin, may at last have been revealed by Crowley in his most recent incarnation. Like the so-called Sicilian Magus, Crowley kept himself in revenue for a while in London by selling, for 2 guineas a jar, an effective pomade for ladies' complexions, whose prime ingredient was his own semen.

And the elixir of life promoted by Cagliostro may well have been Tantric kalas obtained from Serafina. Serge Hutin, the French professor who has written on every known occult subject, and especially on both Tantra and Cagliostro, suggests that the magus and Serafina may well have been a natural Tantric couple, and that the highest level of the Egyptian rite corresponded to an act of ritual sacred marriage, or *hierosgamos*.

Hutin further suggests that Mozart, privy to this secret, deliberately cast Papageno and his simple bride Papagena as symbols of common marriage, whereas in Tamino and Pamina, he represented a couple initiated into the world of Tantric love by none other than the Egyptian magus Sarastro-Cagliostro.

To cap this train of quite fantastic coincidences, Crowley next described his most recent death: "I found myself able to recall my last death and so pick up many memories of my previous life as Eliphas Lévi."

In his *Magick in Theory and Practice,* Crowley pointed out that Lévi's death occurred about six months before his own birth in 1875. Crowley thus found the explanation for his immediate pleasure and incomprehensible familiarity with a certain district in Paris's fifth arrondissement, by the rue de l'Ancienne Comédie. Lévi had lived in that neighborhood for several happy years.

Taken in series, these lives form a linkage. In Crowley's incarnation as Crowley he "expressly and unequivocally describes his work as the rediscovery of the Sumerian accurately be named Eyewash, and that Crowley was a pseudo-messiah, not a prophet, yet he did not doubt "that this extraordinary man was a genius and a gifted teacher of the highest mystical illumination." In the end Crowley admitted that he might have "failed at everything" but that he nonetheless stood by his life's work and message: "I have not failed at love for the only abiding love affair of my life is the one I have with God! Oh my beautiful God! I swim in thy heart like a trout in the mountain torrent. I leap from pool to pool in my joy. . . ." Whether Crowley's was the God of all, or only of Crowley, at his funeral Louis Wilkinson read aloud the magus's "Hymn to Pan": "Thrill with lissome host of the light./O man My man!/Come careening out of the night/Of Pan! Io Pan,/And I rave; and I rape and I rip and I rend/Everlasting, world without end,/Manikin, maiden, maenad, man/In the might of Pan./Io Pan! Io Pan Pan! Pan! Io Pan." Crowley's god, whose manifestation occurs at high noon, *en marquant midi,* he equated with Hadit and conceived that at the precise moment that man becomes Pan his point of view is dissolved into Nuit—pure nothingness: "for all is naught." To paraphrase Crowley, when a man, growing in consciousness by repeated acts of love under will, expands his consciousness to embrace all other consciousness, he becomes Pan: i.e., one with all. Omne, Aum, Amen, Amoun.

Tradition of Set"—precisely what he was supposed to have been doing as Ankh-af-na-Khonsu in the Twenty-sixth Dynasty. In the past, says Grant, several adepts attempted the rehabilitation of the worship of Set, among them Adam Weishaupt, Cagliostro, Eliphas Lévi, and Helena Blavatsky; but all failed. Only Crowley, he notes, succeeded, "because he had received initiation of a higher order." Using the hermetic numeration of the Golden Dawn degrees, Grant classes Cagliostro and Mathers as $7^\circ=4^\square$, Blavatsky and Levi as $8^\circ=3^\square$, and Weishaupt as possibly $9^\circ=2^\square$. Whereas Crowley, according to his own verdict, reached the highest grade of $10^\circ=1^\square$ or Ipsissimus.

In this rarefied air Crowley found himself "free from all limitations whatsoever, including good and evil." Across the abyss, says Crowley, the words of the Enochian Key "thrilled me with a meaning I had never suspected, each curse concealing a blessing . . . I understood that sorrow had no substance; that only my ignorance and lack of intelligence had made me imagine the existence of evil."

Grant considers that Crowley's crossing of the abyss, thanks to the power of the *Book of the Law,* which he calls "the utterance of an illumined mind co-extensive with the ultimate ideas of which the universe is composed," enabled him to "unite his consciousness with the universal cause, shift the center of gravity from himself to God," and so "proclaim his word (Thelema) as Allah and Buddha proclaimed theirs." But Grant's co-editor of *The Confessions of Aleister Crowley,* John Simonds, less partial to the self-proclaimed Ipsissimus, says that this is where Crowley made a false step, suggesting that "he illegally assumed this most exalted grade, and that it choked him." Prophets being seldom honored in their own country, the truth, as Bacon declared on the cover of his New Atlantis, remains to be known: *Tempora patet occulta veritas.*

But whereas Crowleyans claim it to be the imperative duty of the theurgist to thoroughly investigate in his "Iridescent Body of Light" the upper levels of Astral Light before transcending to a higher plain, Gopi Krishna, author of several works on Kundalini yoga, wisely says that almost all great spiritual teachers have pointed out the danger of succumbing to the lure of psychic power or visionary experiences on the Astral or mental plain, "For these constitute entanglements for the soul as confusing and as hard to shake off as the entanglements of earth." To perform surprising feats with invisible psychic or other cosmic forces, says Gopi Krishna, is descending again to the plain of earth.

20. RETURN OF THE PHOENIX

A Journal of Scientific Illuminism was the subtitle given by Crowley to *The Equinox,* and Kenneth Grant has no doubt that Crowley took the term *illuminism* from Weishaupt, adopting with it his glyph of the point in the circle as a secret cipher for the order, a glyph which is preternaturally sexual and Tantric. It represents, says Grant, the yin and the yang of China, the Chockmah and Binah of the Cabala, the Odnada and Obatala of Africa, the Kamakala and Tribindu of India, the caduceus of Mercury, the Nuit and Hadit of Egypt. In Hadit, Crowley saw the emblem of consciousness: a ray of light projected in the dark of night. Nuit, in Crowley's cosmology, was nothing that can be thought of or in any way formulated by the mind of man, "the infinite and eternal void or inner space, the undying darkness, symbolized by the yoni." Yet Crowley saw it as the hidden source of light, for Nuit can be stirred into being by Hadit, symbolized by the point, the male coefficient, typified by the phallus. In Crowley's words, "the infinitely great Nuit and the infinitely small Hadit unite in explosive rapture and the ensuing holocaust generates the event." In union the poles of Nuit and Hadit produce the objective universe.

In the macrocosm the immortal principle is represented by the sun, in the microcosm by the phallus. As the sun drenches the earth with its creative rays, the phallus drenches the womb with its seed. Yet the symbolism, note Crowley and Grant, is imperfect, for neither the sun nor the phallus in itself has power beyond that which flows through it from another source. In the case of the sun, they say, this power is refracted through Sirius, the star of Set. Set to them represents the light of initiation, "the opener of man's consciousness to the rays of the Undying God who is typified by Sirius, the Sun in the South."

To Crowleyans, in the new Aeon of Horus, Isis will rediscover the immortal principle in Osiris, and man, consciously using the formula of Love Under Will, will advance his spiritual development.

The old Aeon of Isis, according to Crowley, glorified matter, the mother, the body. The old Aeon of Osiris, denying the body, glorified the spirit in the afterlife; with its appendage, the Christian Era, it was characterized by

Horus the younger dominating the reptilian symbols of attachment to earth. Crowley maintained that hidden within the young Horus were two poles of energy, which he called HOOR-PAAR-KRAAT (or Harpocrates, the Greek god of silence or withdrawal) and RA-HOOR-KHUIT (KRUMACHIS or HERAHATY), Lord of the Balance, or Double Horizon—i.e. of the two equinoxes. This left for Set the two solstices, with the sun at zenith and nadir. Two birthdays were assigned to Jesus by the Christian Fathers, one at the winter solstice, the other at the vernal equinox. This system, says Massey, was based on the birthdays of the double Horus, the dual form of the solar god in Egypt, child first, adult at the vernal equinox. In Egypt, Massey points out, the year began with the summer solstice, when the sun descended from its midsummer height, lost its force, and lessened in size. This represented Osiris born of the Virgin Mother as the child Horus, the diminished infantile sun of autumn, who descended into hades, where he was transformed into the virile Horus and rose again at Easter, the sun of the resurrection, Horus of the two horizons. To the Egyptians, Osiris, as the child Horus, comes to earth to enter matter and becomes mortal. His father is Seb, the earth, whose consort is Nu, the bearer, one of whose names is MERI, the Lady of Heaven.

blood and agony, Osiris, the god of the Dead, exemplifying the Christian cult with its emphasis on death, suffering, and sorrow. Yet Isis, copulating with the dead Osiris, brought forth the child Horus, or unified cosmic consciousness, to produce, as Grant expresses it, the balance of these extremes in the realization of the identity of matter and spirit of male and female—a realization that comes through the union of opposites.

In Crowley's new aeon, man is no longer "to die to his body" in order to experience everlasting life; he will know, says Grant, that he never was a body, and realizing that he was never born, and therefore never died, that the body is a mere play of spirit undergoing ceaseless transformations, he will know that the spirit endures forever, triumphant, changeless, yet ever new. "Subject and object will be realized as one. Death, as understood, or rather misunderstood, by earlier cults will be finally and experientally transcended, abolished, nullified."

Grant further elaborates on Crowley by explaining that in the Aeon of Horus the dualistic approach to religion will be transcended through the abolition of the present notion of a God external to oneself. The two will be united. "Man will no longer worship God as an external factor, as in Paganism, or as an internal state of consciousness, as in Christianity, but will realize his identity with god." The new Aeon of Horus, based on the union of male and female polarities, will involve the magical use of semen and ecstasy, culminating in an apotheosis of matter—"in the realization that the old Gnostic notion that matter is not dual but one with the Spirit"—symbolized by the androgynous Baphomet of the Templars and the Illuminati.

Robert Anton Wilson, in his *Cosmic Trigger: The Final Secret of the Illuminati,* a more factual sequel to his fictional *The Illuminatus Trilogy,* came to the striking conclusion that at last he understood the secret of the Illuminati to be sexual. "They are not the fantasy of right-wing paranoids. The Illuminati was one of the names of an underground mystical movement using sexual yoga in the Western World." Wilson explains that "the veils of obscurity and mystery around such figures as Giordano Bruno, John Dee, Cagliostro, the original Rosicrucians, and Crowley himself, as well as various other key figures in the conspiracy, had nothing to do with politics or plots to take over the world. It was a screen to protect them from persecution by the Holy Inquisition in earlier centuries and from puritanical policemen in our time."

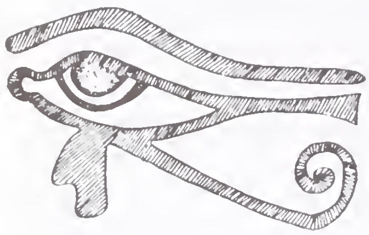
Wilson says that when he remarked to Timothy Leary—then in Vacarilla Prison for having experimented with hallucinogenics—that Giordano Bruno, "the first philosopher in history to suggest that there were Higher Intelligences in this galaxy," used Tantric sex, Leary replied: "It was obvious from Bruno's own writings. Sex-magic is *always* the first of the secrets."

Dr. Walter Huston Clark, in his *Chemical Ecstasy,* claims that most human beings normally only perceive less than .5 percent of known pulsations in the universe, but that people who take the metaprogramming substances soon assert contact with higher intelligences.

Wilson postulates that the "angels" who spoke to John Dee were extraterrestrials, but that Dee, unable to comprehend them in those terms, considered them, as have other shamans and mystics, to be "messengers from God." Wilson further adduces Gurdjieff's allegory in support of the notion that a group of interstellar intelligences already evolved to stages less mammalian than ours, are watching us all the time, and, occasionally, intervening to accelerate our evolution toward their level. He then quotes Leary and Dr. Jack Sarfatti to the effect that the mysterious entities—whether angels or extraterrestrials—reported by visionaries, rather than being members of races already evolved to this level, "may be ourselves in the future!"

Hassan-Ibn-Sabbah, mystic philosopher initiated into the sect of Ismaili and known as the Old Man of the Mountain, formed his own sect to practice the ecstasy of the Sufis. Surrounded by a vast library in his Castle of Alamut, the biggest outside of Baghdad, he found a way of mixing hashish with henbane so that a man could gain inflexible determination. Magre says that Persians, Indians, and Chinese all used hashish and opium and other plants to promote the emergence of the astral "double" and attain early degrees of ecstasy.

In *The Sirius Mystery,* Robert K. Temple devotes much space to demonstrating that to the ancient initiates Isis was a symbol of Sirius, and Osiris a symbol of the dark companion of Sirius. But, as Wilson points out, Temple was unaware of Crowley and Eliphas Lévi's insistence that the traditional secret revealed in the Eleusinian mysteries was that "Osiris was a black God." As Wilson reports,



Horus, said Isha Schwaller de Lubicz, is the key to Egyptian theology. "In the beginning and throughout time the universal Horus is the axis of the animating soul of the world. . . . He is the animator of preternatural Adamic Man before his fall into dualization. . . . The fall into matter creates his antagonist Seth, who through his constant opposition manifests the latent powers of Horus in nature." Seth is everything that tends to contrast and fix spirit in matter, a situation he seeks to perpetuate. Horus strives for the triumph of spirit in matter, light in darkness. His struggle with Seth makes history. In the eschatology, Horus the victorious becomes in the human being the supernatural Horus who reunites the divided complements and resolves all opposition. The Christian revelation introduces the god-man, Christ-Horus, incarnate in the human being. But after victory Horus returns to the black whence he came to start a new battle. He never rests.
Massey points out that the Gnostic Jesus is the Egyptian Horus, and in the gnostic iconography of the Roman catacombs, child Horus reappears as the mummy-babe who wears the solar disc. "Royal Horus is represented in the cloak of royalty, and the phallic emblem found there witnesses to Jesus being Horus of the resurrection." Massey lists among the numerous types of Horus repeated in Rome as symbols of an alleged historic Jesus. Horus as Ichtus, the fish; Horus as the bennu, or phoenix; Horus as the dove; Horus as the *bambino;* and Horus as the reversed triangle.

George H. Williamson, in *Other Tongues, Other Flesh,* claims that a secret order on earth has been in contact with Sirius for thousands of years and that its emblem is the Eye of Horus. Williamson, an early "contactee" of the 1950s, also claims to have met flying saucerites from Sirius and prints huge chunks of their language. Among these, Wilson found a few of the words that were almost identical with the "angelic language used by Dr. John Dee, Aleister Crowley and other magi of the Illuminati tradition."

As Grant describes the new aeon, a race will be propagated of magically generated beings able to probe extraterrestrial dimension. And the next stage in the advancement of evolution on the planet "will be achieved by a willed congress with extra-terrestrial entities of which, in a sense, Aiwaz is the immediate messenger to humanity."

When Theodor Reuss died in 1922 he nominated Crowley as his successor, and the German OTO lodges accepted him as chief. Reuss had also granted other charters outside Germany, and Gerald Encausse, the great French occultist, known as Papus, was chief of the OTO in France as well as of the French rite of Memphis and Misraim. In Berlin, Rudolph Steiner, who had broken away from the Theosophical Society to found the Anthroposophical Society, better to fulfill his Rosicrucian ideals, formed, as deputy Grand Master of the OTO, a chapter of its grand council known as Mysteria Mystica Aeterna.

Since childhood Steiner had been aware of spirit beings and their workings, and had found a whole universe permeated through and through by spirit activity. To Steiner, matter was spirit manifesting in material form: both man and the physical world were of a spiritual origin, and both had a spiritual destiny. The real ego, said Steiner, is spirit, and lives in a world of spirits. To Steiner this supersensible reality behind physical reality was directly perceptible, and he claimed that the knack, once a normal human faculty, could be reacquired, universally. Through his own clairvoyance Steiner was already able to give contemporary scientists answers to puzzling problems in physics.

To his own science, based on his understanding of the supersensible world and its relation to ordinarily perceived phenomena, Steiner gave the name Anthroposophy, *sophia* being "wisdom" and *anthropos* "man," the latter, with the former, capable of understanding the secrets of the universe by attaining ever higher levels of consciousness. And Steiner described in detail how man can shift

Ba, depicted as a bird with a human head, represents the human soul that goes back and forth between heaven and earth. It can be seen ranging about a tomb hoping the shade will emerge free from its bonds to the earth. Ba is the life-giving power in nature, the breath whose departure causes death. Pure, formless spirit, immeasurable, indivisible, unfractionable, free, and mobile, it needs an objective means if it is to manifest but it cannot be confined in a body. From Ba derives everything that constitutes the world and its final perfection. Ba, in its divine nature, is man's kinship with the creator, realizable through consciousness.
Ka assimilates Ba and generates a new being. Ka individualizes and binds the spirit. Ka is the attractive force that causes and fixes Ptah's incarnation in matter. Ka is the carrier of all powers of manifestation and the activator of cosmic functions. The original Ka is the creator of all Kas of nature: mineral, vegetable, animal. Man's individual Ka comprises his inherited and his personal character and defines his destiny. But Ka is not the slave of fate, because it is not part of nature. The soul is not subject to the stars: it is free and can alter its course. Man's higher Ka, the highest part of his spiritual being, the consciousness of the heart, is in touch with his lower Ka, or the aspects of Ptah imprisoned, which the consciousness of spiritual Ka alone can liberate, with the help of Ba.

his consciousness, as if tuning a radio, to different points of view from which he is aware of operating subtler bodies than the physical, etheric, astral, spiritual; and that man's life, on its various levels, is related to the universe of stars, sun, planets; that out of the physical body, or between death and birth, man lives in the spirit world of the stars in endless relationship with the divine spiritual beings of the star world.

All of which was evidently perfectly understood by the ancient Egyptians, who gave different names, such as Ka, Ba, Khaibit, Shout, Khu, and Sekhem to the various bodies, all equally real, but operating in different dimensions. To the Egyptian there were three basic worlds: the most immediate being this earthly one of everyday consciousness. Then came Amenta, the realm of the mummified Osiris, a sort of purgatory in which spirits of the dead made up for their earthly errors. Then came Tuat, or heaven.

Crowley's personal secretary and follower, Israel Regardie, who became a Reichian psychologist, describes Amenta and Tuat as two aspects, inferior and superior, of the astral plane of the occultist, every yard of which had been mapped out for the Egyptian theurgist, and its qualities noted, together with the names of the guardian watchers of the pylons through which the defunct soul had to pass in order to gain admission to some other of the halls of the kingdom of Osiris. Only on what it already understood of the strange "astral" world into which, reawakening from the defunct body, it suddenly found itself in the shape of an astral body, could the spirit get through Amenta to Tuat. If previously initiated into the mysteries of this strange world, while still alive, it could better cope, says Regardie, progressing on its mastery of the magic words contained in the *Book of the Dead,* described as "the most ancient yet detailed grimoire for those who will come forth in the light of full consciousness." As Gerald Massey puts it: "The object of the words of power, the magical invocations, the funeral ceremonies, the purgatorial trials, is the resurrection of the spirit to life everlasting." And he sums up the ordeal: "Learn the *Book of the Dead* in life and it becomes the Book of Life in death."

The spirit in Amenta pleads that his "mouth be opened," that his memory return so that he may utter the words of power required to handle the shifting world of astral forms. And memory, Massey explains, is restored to the deceased through the words of power stored up in life, to be remembered in death. Practice for this occasion

According to occultist Gerard Encausse, the Cabala constitutes the most complete teaching of the mysteries of Egypt to have survived, as elaborated by medieval Jewish authors on the basis of gnostic and Neoplatonist speculations. He says that all the secret religious societies—Gnostics, Templars, Rosicrucians, Martinists, and Freemasons—used the teachings of the Cabala, which aimed at giving man knowledge of his relationship to God and the universe, which may be regarded as an elaboration of the numbers 1 to 10 arranged in a geometric design connected by twenty-two paths. This Tree of Life represents the manner in which God's essence emanates from the nothingness beyond creation through ten stages into the visible world. The Sefiroth arranged to the right of the tree are male qualities, to the left, female. The lower levels represent love and nature. At the bottom stands the kingdom of Malkuth, the subconscious. As man rises in consciousness, he realizes his sacred origin, and can invoke the angels and archangels, until he reaches the level where he realizes that All is in One and One is in All.

The whole process of creation, said de Lubicz, occurs between the numbers 1 and 2; duality is

could be achieved in life during trance, when the spirit, leaving the body, could assume any form, at will, traveling anywhere under any guise.

In Amenta, the object is to avoid what is known as "the second death," which awaited those beyond purgation who once more lost consciousness; all of which makes of the gamut of earth, heaven and hades, but various states of consciousness, from the most illumined to the blacked-out, of which, in the end, the conscience of man is the only true judge, being both the knower and the known.

How is it that all this wisdom, sensed by gnostic, Templar, Rosicrucian, and Mason, was lost and only surfaced intelligibly with modern clairvoyants such as Crowley and Steiner? Michel Vladimirovitch Skariatine, an émigré Russian, who spent his life studying the ancient wisdom and wrote about it under the pen name of Enel, recognized in the Hebrew Cabala a mixture of Egyptian and Chaldean teachings, but found them often improperly put together, full of obscurities and even contradictions. So he went to the source: the sacred glyphs of the Egyptians. Puzzled by a language with so many homonyms and homophones, often with meanings diametrically opposed, Enel concluded that Champollion's phonetic decipherment, though it made possible pronunciation of the glyphs, concealed a further symbolic meaning, sensed by Champollion, but almost unanimously denied by succeeding Egyptologists until the Second World War.

The brilliance of the Egyptian form of writing, says Enel in his *La langue sacré,* is the fact that it can contain more than one meaning, conveying an overt, and often banal phonetic significance, available to anyone, plus a Hermetic meaning available only to the initiate. The texts containing the overt credo of the Egyptian people, the funerary prayers, and the representations of life beyond the tomb, which needed to be available to all, were written phonetically. Yet they also contained the esoteric teaching of the initiates, designed only for adepts. The structure of the hieroglyphs made it possible to form a word with one direct meaning, read phonetically, and a recondite, mysterious meaning, symbolically.

The purely magical texts, written solely for the adept, says Enel, were not even given a phonetic sense, and were therefore untranslatable by Egyptologists, who concentrated solely on the phonetic approach, without pursuing the symbolic sense, the only one which could reveal the religious and philosophic doctrines of ancient Egypt. As Enel puts it: "Able to describe the body of Egyptian glyphs they ignored the soul which gave it life."

the fundamental character of the created universe. "This duality is the principle of sexuality. At the same time, duality implies a comparison within a succession of phenomena which produces the cerebral consciousness." Spirit, or formless substance, is passive, the feminine principle in the cosmos, but becomes generative when acted upon by the "verb." And all, de Lubicz felt, is manifest by its opposite. There would be no dark without light; nor any way to know light except by shadow. And just as a corporeal obstacle creates touch, so a liquid environment creates taste, and terrestrial or corporeal emanations create odor. In the course of "evolution" the energies within the different states of matter have developed the senses. As the river creates its bed, so light creates the eye, and sound creates the ear. The causal energy becomes mineral, the mineral becomes plant, the plant becomes animal, the animal becomes man, and man becomes Cosmic Man, the Saint, Buddha, Jesus (Jehoshuah). But Nature, said de Lubicz, only shows us the closed, Osirian cycle, which renews itself spirally in its progression towards the liberation of consciousness. Here the essential theme is reincarnation, with its karmic consequences, which forms a "wheel of elimination" moving toward liberation. It is the law *for all*. Punishment is reincarnation; but reincarnation is also a divine mercy that allows one to be redeemed. This is true justice, without cruelty, without threat, a justice everyone can accept. But it was only for the masses that ancient Egypt maintained the Osirian cult of renewal and reincarnation. To the temple elite it taught the Horian principle: Horus the Redeemer. The redeemer—the Unction of the Divine Verb—was the Christ within, but only for the man who realized it within himself. Throughout historical Egypt, said de Lubicz, the common people lived in the Osirian faith, which is a teaching of renewal, evolution through reincarnation of the living soul. Man lived then under the sky, under the ordinances of the heavens.

Neither through Coptic, nor through Greek, according to Enel, is it possible to understand the symbolic meaning of the hieroglyphs: the only route is via the Hebrew Cabala, offspring of the ancient Egyptian tradition. The object of the hidden symbols, he realized, was also to conserve for eternity the ancient knowledge of the mechanics of the solar system and the measurements of time and space accessible to human comprehension—a fact amply demonstrated by the extraordinary data encoded into the Great Pyramid of Cheops.

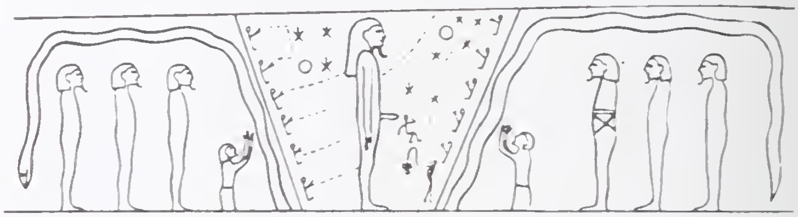
Enel believes the conquerors who brought this wisdom to Egypt were refugess from Atlantis, who came to found a colonial reflection of their powerful civilization with its sophisticated religion. Certainly the wisdom and science of ancient Egypt appears along the banks of the Nile already in flower, developed in some previous location, presumably the equinoctial land of the Golden Age of Saturn.

The twenty-six phonetic signs of the Egyptian alphabet, says Enel, also serve to describe the principles of creation, spelling it out in bold strokes as the ancients envisaged it. The glyph  , *B* symbolizes a perpendicular raised on a plain, such as the raising of an obelisk. As Enel deciphers its cosmic meaning, cosmic forces agitating inert matter attack the surface with the involutive spiraling force of  , *Bn;* and by means of an evolutive spiraling force raise it to  , *Nb*.

The action of these forces creates combinations of the four elements—fire, water, air, and earth—all of which derive from the same *MW,*  , the basic mother, or *mater*. Unformed mass  , which is *q,* is transformed into organized matter  , *p*. The glyph for the current which descends and ascends through twisted interlacings to manifest spirit on the material plane is  .  is to envelope in matter. And  is eternity, or the body of Ra which was and which will be. The creative verb  , Ra, by its action produces the realization of the declared verb *Nou,* or protomatter, father of all the gods, and of all manifestation in the universe.

From the primordial waters of Nou came into being the self-engendered Atum rising up as a primeval hill, the symbol for which came to be the temple hill of the sun at Heliopolis, dwelling place of this high god manifesting as light and symbolized as an obelisk. The mount was now the image of mother earth, the great bringer forth, and "the pillar of heaven", or obelisk, was the symbol of fatherhood, "the rock that begot." "Oh Atum! When you came into being you rose up as a High Hill. You shone as

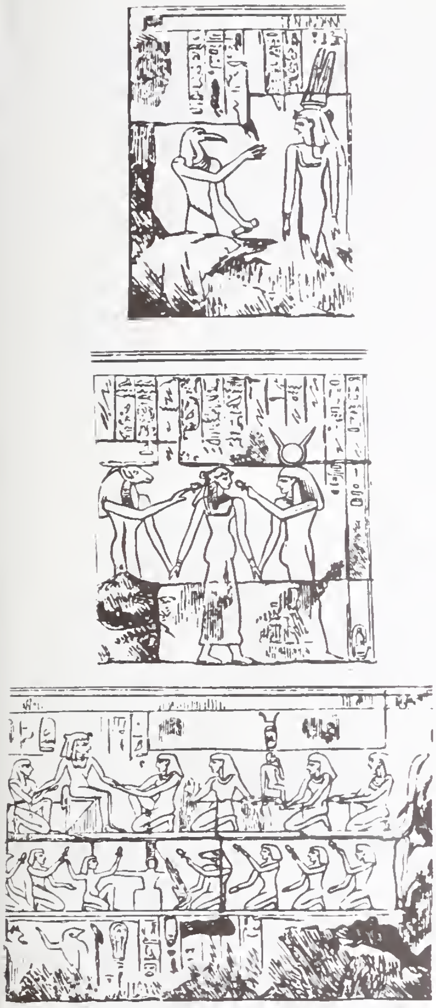
the Benben stone (or obelisk) in the Temple of the Phoenix at Heliopolis." The phoenix, or bennu bird, was, of course, the symbol of both Ra and Osiris. "For the Heliopolitan," says R. T. Rundle Clark in *Symbol and Myth in Ancient Egypt,* "morning was marked by the shining light on an erect pillar or pyramidion on a support or shaft which could reflect the rays of the rising sun. At the beginning, a light bird, the Phoenix, had alighted on the sacred stone, an obelisk, known as the Benben, to initiate the great age of the visible God."



When Atum, the aboriginal deity and ultimate but hidden godhead, at first alone in the universe, came into being, symbolized by the primeval serpent in the dark waters of the abyss, his act was symbolized as autoerotic. "In one sense," says Rundle Clark, "he is the Atum figure of Heliopolis performing creation by masturbation." Noting that masturbation was the most popular creation motif throughout Egyptian history, Clark quotes a pyramid text to the effect that Atum proceeded to masturbate himself in Heliopolis: "he put his penis in his hand that he might obtain the pleasure of emission thereby; and there were born brother and sister, Shu and Tefnut."

And so all of creation came into being. Shu, the elemental force representative of air, breath, the wind, was, in Africa, most especially the breeze of dawn and evening, the very breath of life, imaged by the Egyptians as a panting lion crouched upon the horizon, lifter-up of the darkness of the night sky. Tefnut, the other supporter

The symbolism of Nut, Geb, and Shu is based on the legend that originally earth and sky were together in total sexual union. Thus when the sky descends ritually upon the earth, Nut is impregnated by Geb. But Nut's father, Shu, so loved her, he separated her from her mate Geb, and, as air, held her aloft with his arms. Nut then gave birth to the stars and allowed them to sail across her belly.



This annunciation scene on the walls of the Temple of Luxor, says Massey, shows Thoth, the divine word, or *logos*, hailing the virgin queen, announcing she is to give birth to the coming son or sun. In the next scene the god Kneph (in conjunction with Hathor) gives life to the queen. Kneph, says Massey, is the Holy Ghost, or spirit that causes conception. Impregnation is apparent from the virgin's fuller form. Next, the mother is seated on the midwife's stool, the child in the hands of a nurse. In the scene of adoration (*below*) the child is enthroned, receiving homage from the gods and gifts from three wise men. The child announced, incarnate, born, and worshiped, says Massey, was the representative of the Aten-sun, the child-Christ of the Aten cult, the miraculous conception of the ever-virgin mother in the sky.

of the atmosphere, and eventually of world order, was moisture. Together Shu and Tefnut produced Seb (or Geb) the earth god, a phallic fellow, father of food, symbolized by the goose of plenty, and Nut, the sky goddess, who were kept apart by the atmosphere of Shu until Thoth, the god of wisdom, took pity on them and allowed them to unite to produce Osiris, Horus the Elder, Set, Isis, and Nephthys, all, in this guise, members of the solar system. And much of what actually occurred in the cataclysmic past of our system may be explained by the myth of the castration, death, and resurrection of Osiris as Horus the Younger, the returning sun, weakened after the tilt of the pole. Immanuel Velikovski, when asked which of the heavenly bodies in our sky suffered castration, replied laconically: Saturn, or Osiris. A remark about which a whole book might be written.

Gerald Massey complains that the wisdom of the Egyptians, hidden in their hieroglyphic language—at once their knowledge of both the physical and spiritual cosmos, obtainable in trance—was never really understood by Semite, Greek, or Roman. But Africans and American Indians could still summon spirits and commune with them, and even make them appear for others to see, or could travel to them in a trance. Among the Christians, says Massey, only the sects of gnostics, and such individual gnostics as Saint Paul, could detach from their bodily condition.

Tracing the texts of the Gospels of the Christian canon to their sources in ancient Egypt, Massey found that "from beginning to end they contain the Drama of the Mysteries of the Luni-Solar God, narrated as human history." The gnostics, he says, understood them to be mythical; the Christians took them for fact.

From the texts it is clear to Massey that the doctrine of the incarnation had been evolved and established in the Osirian religion at least four thousand years and possibly ten thousand years before it was "purloined and perverted in Christianity." It is so ancient that the source and origin had been forgotten and the direct means of proof lost sight of or obliterated except among the gnostics, who sacredly preserved their fragments of the ancient wisdom, "with here and there a copy of the *Book of the Dead,* done into Greek or Aramaic."

Massey claims sufficient warrant to affirm that Christ-the-anointed was a mystical figure which originated as the Egyptian mummy in the twofold character of Osiris in his death and Osiris in his resurrection; that is, as mortal

Horus, the Karast, and as Horus divinized as the anointed son. "Say what you will, or believe what you may, there is no other origin for Christ-the-anointed than Horus the Karast, anointed son of god the father."

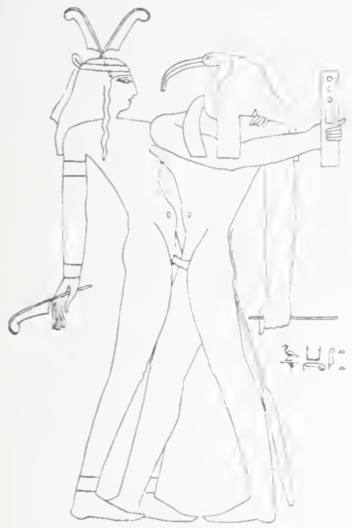
Furthermore, says Massey, none of those initiated in the esoteric wisdom ever looked upon the Kamite Iusa, or gnostic Horus, Jesus, Tammuz, Krishna, Buddha, Witoba, or any other of the many saviors as historic personalities. A gnostic arose in another life as a spirit, not as a human being. Egypt had no doctrine of the physical resurrection of the dead. All of these notions Massey considers a perversion of the original wisdom.

The creation of evil Massey considers a miscreation traceable to the Akkadian, Babylonian, Assyrian, and Hebrew theologies. Hebrews and Babylonians, he says, confused the Uraeus-serpent of life with the serpent of death. The tree of life was changed by the Babylonians into the tree of death. The serpent that offered fruit for food as Rannut, representing Mother Earth, was transformed into the evil serpent that "brought death into the world." The same types which represented evil in the Babylonian mythology represented good in the Egyptian. A god of eternal torment is a Christian ideal not an Egyptian one. "Theirs was the all-parental god, Father and Mother in one, whose heart was thought to bleed in every wound of suffering humanity, and whose son was represented in the character of the comforter." The Great Mother, no matter how hideously portrayed, was not originally evil, but the bringer-forth and renewer of life in earth and water. Nor, says Massey, were the elemental offspring evil; though imaged as monsters or zootypes, they were not wicked spirits as made out to be by the Euphrateans—the devils of Western theology.

The Egyptians, says Massey, "had no fall of man to encounter in the fallacious Christian sense. Consequently they had no need of a redeemer from the effects of that which had never occurred." There was indeed a fall, he says, but it was "from the foothold first attained by the Egyptians to the dismal swamp of the Assyrian and Hebrew legends."

Nor did the Egyptians rejoice over the death of their suffering savior "because his agony and shame and bloody sweat were falsely supposed to rescue them from the consequences of broken laws; on the contrary, they taught that everyone created his own Karma here, and that the past deeds made the future fate."

In Massey's reading of the Egyptian texts, Horus did what he did for the glory of his father, not to save the

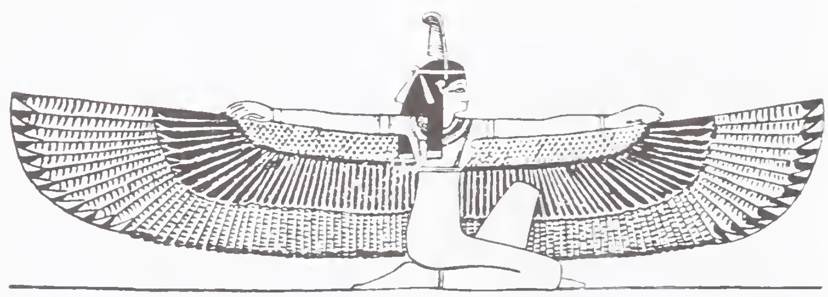


The Egyptian myths couple Maat, the protectoress of Truth and the Ibis-god Thoth, patron of Wisdom.

Maat, the female counterpart of Thoth, daughter of Ra, helped Ptah and Khnemu carry out the orderly creation ordered by Thoth. Goddess of the unalterable laws of heaven, she is "straight," "just," "true," "genuine," and "steadfast," and her emblem is the feather. All feminine neters, said Isha de Lubicz, are only revelation and manifestation of the great universal mother, for whom Maat is the divine wisdom that links the "divine" and the "natural" through consciousness. "Maat is universal consciousness, the consciousness of all consciousnesses."

souls of men from having to do the same. There was no vicarious salvation in the Egyptian view. Horus symbolized the justification of the righteous, not of the wicked. He did not come to save sinners from taking the trouble to save themselves. "He was an exemplar," notes Massey, "a model of the divine sonship; and his followers were to conform to his example."

For the Egyptian, eternal life was the ultimate reality. His god was just and righteous. The Egyptian did not pray for mercy, nor seek sentimental forgiveness for his sins. He knew his conduct now would count for the life hereafter. He must speak and act the truth. The standard of law was set up as Maat, the eternal rule of right. The Egyptian's creed was to fulfill Maat. Judgment with justice. The wickedness of the soul, said Hermes, is ignorance. Virtue is knowledge.



That the quest in Egypt was for the Christ within, the Christ of the Essene and the Gnostic, was at last driven home after World War II by an Alsatian archeologist with a Baltic title, R. A. Schwaller de Lubicz, who demonstrated that the sophisticated system of physics and metaphysics developed by the ancient Egyptians to account for the mechanics and purpose of the cosmos. With de Lubicz, Egyptology gained a true adept, not one of the ditchdigger or grave robber type of the nineteenth century, nor one of those of the twentieth who used the Rosetta Stone in a quest not for the Rose on the Cross, but for the acquisition of the rosette of the Legion of Honor.

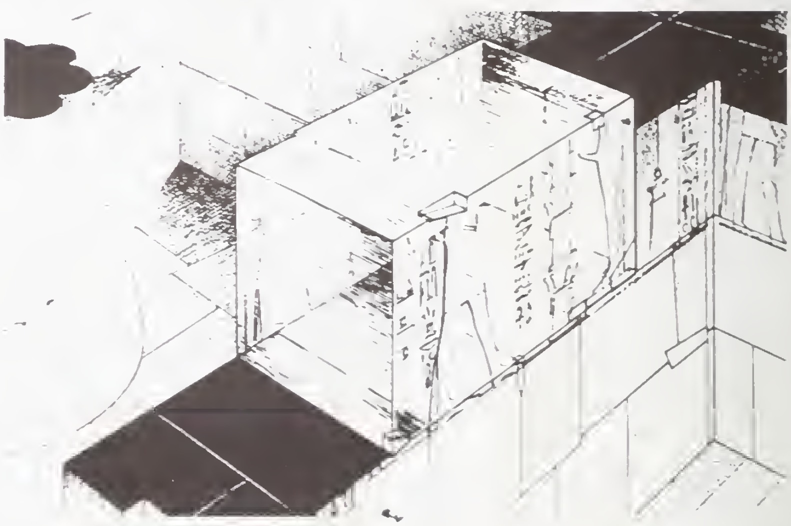
Like Rosenkreutz, Cagliostro, and Crowley, de Lubicz arrived in Egypt already an initiate, having worked his way through the disciplines of theosophy, anthroposophy, yoga, alchemy—for which he had a special laboratory—and the wisdom of the East. He too studied with Moslem and Sufi masters in North Africa. And his wife Isha, who was to put the initiatory wisdom of Egypt into the form of two novels, *Her-Bak Chick-Pea,* and *Her-Bak, Egyptian Initiate,* arrived in Egypt with six years of strict classical

Knowledge, wrote de Lubicz, can only be synthetic, so it can only be intelligibly transcribed by an architectural monument; that is to say, by a *simultaneity of plane and volume*, accompanied in Egypt by the symbolism of writing, of image, and of statuary. "To this is added an entire architectural *grammar*, represented by the form of the stone blocks, their joints, overlappings, by their 'transparencies' and 'transpositions' on the walls. There is also a subtle grammar where the finishing of an engraving or its rough aspect, the absence of essential parts—such as the eye, or the navel—the introversion of the right with the left, etc., come to play the role of accents, declinations, conjugations, or conjunctions."
The ancients had an accurate knowledge of the centers of life and intelligence, said de Lubicz, and knew all about the brain. In the temple, each vital center of the human body is clearly marked. "The glands and the vital relationships between the organs are figured by the scenes showing their correspondences with the *Neters* who control them; this throws a great light on the true sense of the pharaonic pantheon and on pantheism in general."
Isha pointed out that the advantage of the Egyptian teaching is that the authentic texts are in the very place where they were inscribed, unaltered by successive transcribers. The number, key, and symbol of the texts allows direct access to the esoteric meaning hidden beneath the apparent meaning. If you take note of anomalies in the texts, said Isha, the various arrangements of letters in each word, the different forms used for the same letter, the color of the signs, you will decipher the riddles. The *secret message* is in the fundamental metaphysical significance of the individual letters and their syllabic arrangement *irrespective* of the overt text, which may be perfectly banal. "All traditional teachings," said Isha de Lubicz, "considered the fire in the spinal column as the evolutionary element in man.

Egyptology, through which she had acquired a key to the secret reading of the hieroglyphs. In the miasmic underworld of modern Egyptological exegesis, the analytical commentaries appended to her fiction threw the clearest light onto the complex system of Egyptian symbology enshrouding its cosmological theology.

In the same Temple of Ramses II at Luxor where Champollion spent five months and Lebas fifteen, de Lubicz and his wife spent fifteen years. With the help of her daughter, Lucie Lamy, they devoted the years between 1937 and 1952 to measuring and reproducing with extraordinary finesse and accuracy the entire stonework, including every glyph, every stele, every joint. As a team they were able to find what Bruno and Kircher and Cagliostro had all intuited, the key to the Hermetic philosophy and religion secreted in the ancient glyphs. The Temple of Luxor they found to be a vast stonework symbol incorporating the totality of Egyptian wisdom: science, mathematics, geodesy, geography, geometry, medicine, astronomy, astrology, magic, myth, art, and symbolism. To de Lubicz this vast library, containing the totality of knowledge pertaining to universal creative power, embodied in the building itself, constituted the greatest achievement of New Kingdom Egypt.

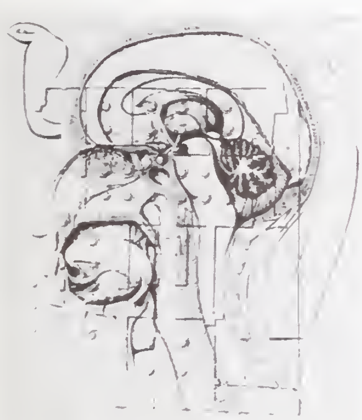
Not that the team could have made their discoveries any sooner. As late as 1881, when Gorringe researched the obelisks of Thebes, the temple was still covered by several meters of dirt and windblown sand. Only its southernmost part was accessible to view. In 1885 Gaston Maspero, director of antiquities for the Egyptian government, made the first serious attempt at excavating the area, revealing footings of walls, pylons, and columns buried beneath millennial layers of detritus. Thereafter the



backbreaking work was continued under the supervision of a series of archeologists down to the recent author of *The Obelisks of Egypt,* Labib Habachi.

As collaborators at Luxor, de Lubicz added to his team the expertise of a French Egyptologist, Alexandre Varille, who had worked ten years for the Luxor Archeological Institute, and an archeologist-architect, Clement Robichon, who had been digging in north Karnak for the French Institute of Oriental Archeology. And during the whole of their long stay in Luxor, Lucie Lamy copied, with minute care, the plans, bas-reliefs, and inscriptions on the walls of the Temple of Luxor, which enabled de Lubicz, when back in France, to compose over the next ten years his monumental work *Le temple de l'homme,* in which he was able to spell out that the Luxor temple symbolically represented man, cosmic man, in whom all the laws ordering the universe are inscribed.

The awakening of this fire, asleep at the base of the sacrum, and its passage through the different centers of the body, were part of the practical initiation into the acquisition of human mastery." To this she added: "The energy *ner,* active fire of the world, is specialized in man's marrow as *sa,* his vitality. A man who succeeds in becoming conscious of it can augment and use it at will. This controlled power is *wscr.* A man who has mastered it, is *ser.*" Isha explained: "The Sethian power of the testicles of Seth is mastered and sublimated into superhuman power." And she was explicit about the method: "It is through renenutet that the djed, the pillar of Osiris, is raised in nature and man, and it is she who when man has reawakened the fire of life in his djed leads it to the summit, the frontal ureaus that is the third eye of Horus. . . . This eye of fire masters the neters "or 'gods' and rules their blind powers."



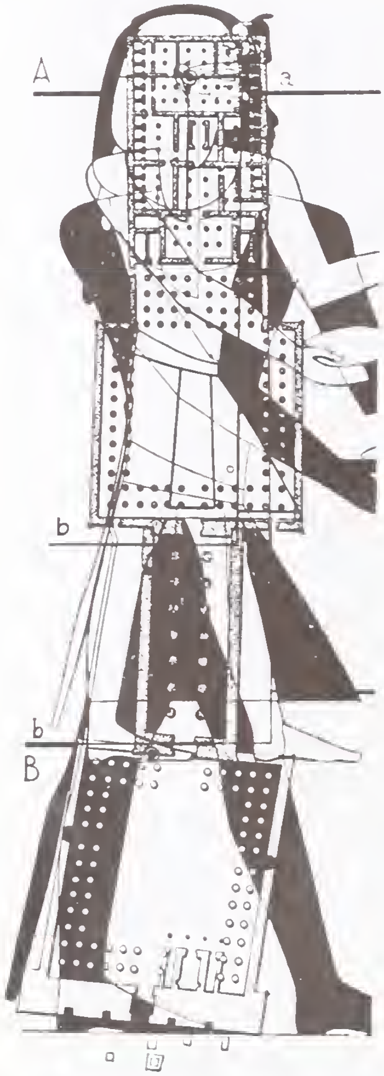
With this notion de Lubicz caused as great a shock to staid Egyptologists as had Champollion a century earlier. Yet R. T. Rundle Clark was to admit, at last, that "in recent years it has come to be realized that Egyptian art is nearly all symbolism. The architectural arrangements and decoration were a kind of mythical landscape. This was worked out down to the last detail of the furnishing; everything had a meaning or could be made to have one. Columns, capitals, walls, window-lattices, drainage outlets, gateways, screens and shrines all had significant traditional schemes. An Egyptian temple simultaneously appealed to the eye and the imagination."

De Lubicz discovered that it was by means of the harmonic relations in its design as a whole, and by the endlessly varied parts of its structure, that the temple, together with the mythological vignettes intaglioed in high or low relief, became a library in stone, one which told in bold lines the story of the creation of man, indicating his development stage by stage: a temple which recreated in artistic form man's relationship to the universe.

The proportions which de Lubicz found in the temple were those of pre-Adamic man, man before the Fall, and of perfected man, who, through his own efforts, regains his cosmic consciousness. Man, says de Lubicz, if he understands himself perfectly, understands the universe. "Man is not an image, a condensation of the Universe; man *is* the Universe."

The same theme is echoed by Kenneth Grant. "As man goes on unveiling and understanding the powers of his own constitution, he realizes that the macrocosm is contained within him, not *vice versa,* for Man—being the

To de Lubicz, the Temple of Luxor was a unique monument in that although all the initiatory temples of Egypt had as their goal the projection of the universe in man, at Luxor "the form and the proportions of the architecture superimpose themselves on the complete body of man which brings to the inscriptions (hieroglyphic ritual, bas-reliefs, transparencies, transpositions, relations given through the joints and geometric keys) a value of biological revelation, according to their situation on the human body, which in this case, plays the role of an atlas for the vital *functions*."



only complete Microcosm—he alone of all orders of existence has a link with, or possesses within himself, the potential of the entire gamut of manifestation."

De Lubicz formulated the axiom in what he calls his doctrine of athropocosm: We have nothing to discover outside of ourselves. The universe is neither an "imagination" nor a "will," but a projection of human consciousness. The reason for life, says de Lubicz, is to become conscious of self. The goal of life is cosmic consciousness, beyond all transient, mortal contingencies. The universe, he says, presents only an evolution of consciousness, from beginning to end, which is the return to its Cause. Thus the aim of every initiatory religion is to teach the way that leads to this ultimate merging.

Yet the ancient Egyptians distinguished two types of consciousness: an intelligence which *knows* this universe without having to reason it, and a cerebral intelligence, which de Lubicz qualifies as that of "fallen" Adamic man. Cerebral consciousness, peculiar to the animal kingdom and the human animal, requires the faculty of registering notions that are only acts of comparison, and this faculty the Egyptians located in the cerebral cortex and the double cerebral lobes.

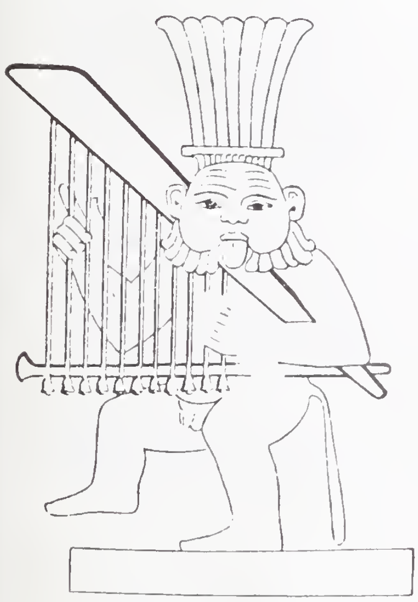
Cerebral man, says de Lubicz, is not a creator; his or her free will only allows for a decomposition of what is there, and the choice among the pieces with which to reconstruct an artificial whole. Cerebral man distinguishes what creates from what is created, and tries to separate the giver from the receiver, as if futilely hoping to sever the north from the south pole of a magnet.

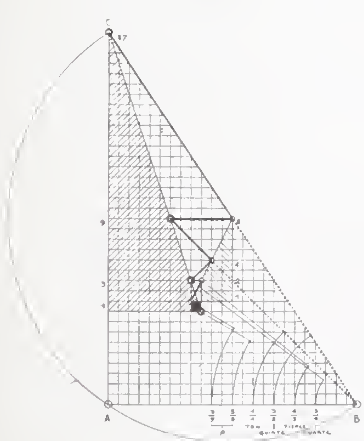
But the Temple of Luxor does not deal with cerebral man, rather with the spiritual being which inhabits a human body. To de Lubicz the temple served to guide the civilization of the Nile Valley toward the gestation of divine humanity out of the transitory human form. "The goal of the Temple was to elevate our being towards the Being which animates all." All of the temples extending along the length of the Nile represent together a global teaching, each temple consecrated to a divine principle, developing a particular theme, inseparable from the whole, just as the entire pantheon of Egyptian gods represent facets of a single supreme being.

In Egypt the temple was the expression of a self-perpetuating group of initiates responsible for keeping intact a wisdom, based on a precise knowledge of universal laws, throughout Egypt's long history, a sacred science passed on through myth, ritual, and music, based on number and measure, incorporated into structures and built into tombs and temples.

It was the same knowledge passed on to the builders of the great medieval cathedrals—a profound understanding of universal harmonic, rhythmic, and proportional laws, and a precise knowledge of the manner in which to employ these laws to create a desired effect. And the dimensions of the temple, like those of the Great Pyramid of Cheops, resolve themselves into fractions of terrestrial and cosmic measure. What stunning simplicity to build into the base of the Great Pyramid the foot to measure seconds of arc, 1.296 billion of which make the circumference of the earth, and a foot and a half, or cubit, to measure seconds of time *and* arc, $\frac{1{,}296{,}000{,}000}{1\frac{1}{2}}$ being the number of seconds of time *and* cubits in one revolution of the planet, or 864,000,000.

The Neter Bes, Egyptian god of music





An analysis of number had already been published by de Lubicz in 1917. There he explained that "properly to understand the real successive steps of creation one must first know the development of abstract number: how the many are derived from the one. Because it is evident," he wrote, "that the first Unity, or uncaused cause is indivisible. As a prime unity it is purely qualitative and without quantity."

Through an endless symphony of measures one slips with de Lubicz past Alice's looking glass into the world of Parmenides and Zeno, where everything is always one no matter how you slice it. Numbers are but names applied to the functions and principles upon which the universe is maintained. The interplay of numbers causes the phenomena of the physical world. Frequency oscillating between two poles produces the form apprehensible to the senses. The body, the earth, the stars, are but complex vibratory systems with harmonic overtones. To be, is to be in harmony with the universe. Man and the universe are linked harmonically. This is the message of the Sufi saints.

In Egypt the de Lubicz family found themselves dealing not with the remains of a corpse, but with "a witness to an active presence." For the ancient Egyptians the entire temple had to live. Its intricate alignments, its multiple asymmetries, made the whole temple oscillate about its several axes. The secret of its life, as discovered by de Lubicz, was the harmonic play of number, proportion, measure, and orientation. "We must once and for all conceive of the pharaonic temple," says de Lubicz, "as a seed in the process of bearing its fruit."

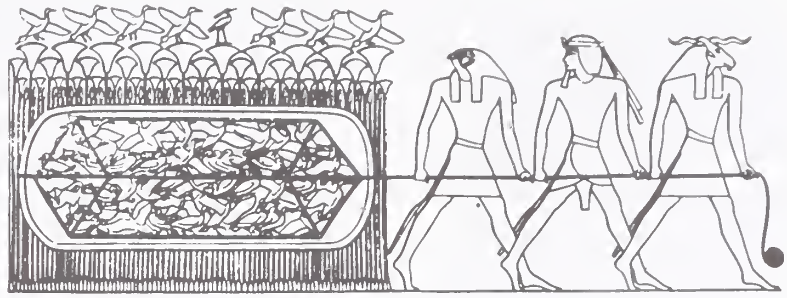
An exhaustive study of a single wall of a room within the covered temple, said de Lubicz, would require a book in itself. The orientation axes linking the temple to cosmic influences, the stone joints pointing to the physiological functions of the human body, the geometrical functions covering the numerical relations appropriate to the locations of the temple, the dimensions of the figures, the offerings, the attributes, the situation of the hieroglyphs in relation to the images and their ritual meaning—all must be taken into account. Each stone of the walls of the temple, he said, is cut according to preestablished measures; similarly, the stone beds were chosen according to an exact knowledge of the scene which was to be drawn there; the joints are situated in such a way as to cut, with intention, the head, feet, hands, attributes, etc. of the figures to be drawn. All of this concerns the hieroglyphic writing. The epigraphy alone never reveals the secret teaching of the sages. It is necessary to learn to *read the images.*

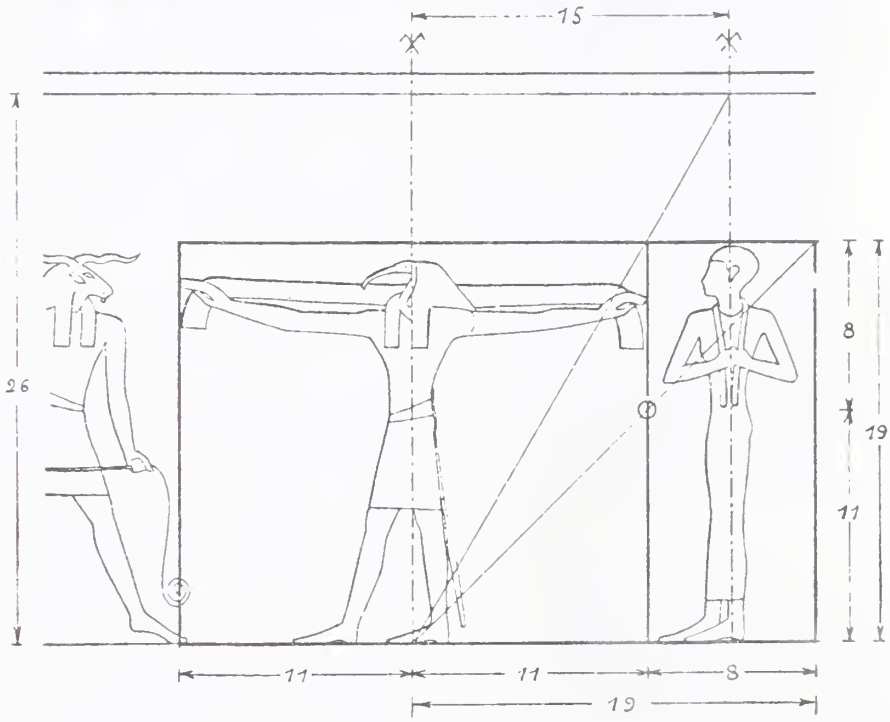
The Temple of Luxor is called Apet or Ipet of the Land of the South. The very name, says de Lubicz, is cabalistic. Ipet is the ancient Egyptian name of the female hippopotamus, symbol of the gestating womb. *Ipet,* he points out, derives from the root *ip,* which means "to count" or "to enumerate." Consequently gestation is identified with the act of counting, or multiplication. Phi, or the Golden Section, plays a dominant role in de Lubicz's identification of the Temple with man. He shows how the Golden Section, in no way a dead number, lies at the heart of what he calls the "primordial scission" of the One, engendering a universe that is both asymmetric and cyclical. Phi is the symbol of generation, of procreation, of growth in all directions; "it is the fire of life, the male action of sperm, the *logos* of the gospel of St. John," a symbol to which all of nature subscribes, from molluscs to giant redwoods, from the structure of bones to the ages of growth in man.

The discrete phases of growth as marked and carved into the temple stand in harmonious relationship to earlier and later stages. The various sections of the human body stand in complex but always harmonious relationship to each other. The entire temple explains the secret functions of the human organs and nerve centers. Every vital center is indicated. But these edifices, as Kircher was intuitively aware, speak a language addressed to spiritual man. And the architecture of the ancients was a living language. Only with the invention of printing, as Bruno lamented, was architectural teaching dethroned, the spirit eliminated, leaving the empty letter.

Like Enel, Schwaller de Lubicz saw the hieroglyphs not as overt phonetic signs, but as deeper Hermetic symbols conveying the subtle metaphysical realities of what he calls the "sacred science of the pharaohs." He saw in the glyphs a means of communicating the intuitively understood essence of life, one which slips through the net of language, something that can be glimpsed, like an aura, by not being viewed directly. The Egyptian symbols, says de Lubicz, were used as a deliberate means of evoking a deeper, spiritual understanding, as opposed to merely conveying information. They were pictorial devices to evoke an idea or a concept entirely, a complete hierarchy of meaning, bypassing intellect, moving straight to "the intelligence of the heart." They were magical symbols to evoke the form bound in the spell of matter. To be grasped, the symbol demanded a shift in consciousness, the same sort of shift which occurs when the print on the page of a novel is transformed into images of life.

This relief appears on the west side of the south wall of the hypostyle hall in Karnak, part of a scene called "Hunting Birds." In an adjoining relief, the figures of Thoth and Sechat were sculpted in relief by Seti I then intaglioed under Ramses II. In the hunting scene a net is filled with birds in a thicket of papyrus reeds surmounted by seven birds in flight separated in groups of three and four by a phoenix, or bennu bird. The horizontal rope is pulled by Horus with his falcon head, watched by the young pharaoh, while in the next panel, the horned Khnoum looks toward Thoth, master of numbers and measure, with his arms outstretched, indicating a fathom of 6 feet or 4 cubits. His proportion, said de Lubicz, indicates the essential numbers for a hexagon, the division of a cycle by six, and the means of translating curved into linear measure. This is no banal hunting scene, de Lubicz observed, but a symbolic one, tied to mythology. This is the location where Set was caught in a net by Horus. Sechat, standing by Toth, is described as the one who will conceive and raise the royal child, who, as Ra, will mount the throne of Horus. Here, said Schwaller, is a cabalistic scene which indicates the capture of an abstraction. He then proceeded to analyze the meaning of each single symbolic thread in the net.





The advantage of the system of symbols over the phonetic, says de Lubicz, is that the meaning of symbols lasts indefinitely, from lifetime to lifetime; and the fundamental purpose of the initiatory texts is to convey the truth of resurrection and reincarnation. To anyone unconvinced of this truth, the glyphs, says he, will remain a dead letter. And not only did the glyphs have a cosmic meaning, they were further amplified by the sound attributed to them, which, when reverberated, could magically key in the past. The technique was rediscovered by L. Ron Hubbard in Dianetics, where the mere repetition of a key word can bring into focus in full three-dimensional color and sound a whole scene from the past, no matter how remote. The whole of history, the whole of the "akashik record," is available to man merely by tuning his consciousness, perhaps by reciting a mantra. For cerebral man is but a shadow of the cosmic creature—whether aboriginal or umbilically tied to the darkness of Nuit—whose will, under love, can make the universe magically manifest.

The mythology of ancient Egypt abounds in sexual tales. Rundle Clark says "it shows that the Egyptians lived much closer to the dark Powers of the unconscious than we realize." During a truce between Horus and Seth, they go off to rest. In the night Seth violates Horus. Horus runs to his mother, Isis, with Seth's seed in his hand. Isis cuts off her son's "contaminated" hand and throws it into the water. In revenge Isis obtains some of her son's semen and sprinkles it on a lettuce in Seth's garden. Seth (who eats nothing but lettuce) becomes pregnant with the seed of Horus. Before the judges Seth claims that Horus is unworthy of the royal office because he allowed Seth to bugger him. Anthony S. Mercatante has another version: "During the night Seth had an erection and thrust his penis between Horus's legs in an attempt to rape him. But Horus put his hands between his thighs, catching Seth's semen."

Horus avenges his father's death by stealing the seed of Set's testicles.

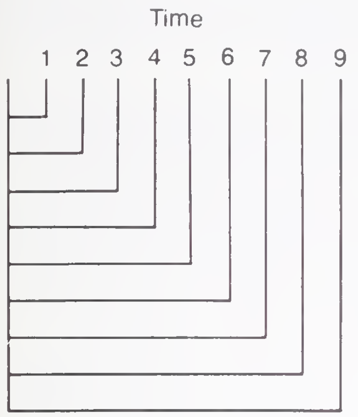
The gods of the Egyptians, called *neters,* phonetically related to nature, represented the powers of the cosmos—gravity, levity, magnetism, and light. They were concealed behind animal masks because, along the road of evolution, animals come to symbolize certain states of nature. And following the stages of life, as the principals took on different aspects, so did their names. Ptah, Sekhmet, and Nefertoum became Amon, Mut, and Khonsu in the human genesis. Ptah, says de Lubicz, a pure fire fallen to earth to be solidified as an obelisk in Memphis, became, in Amon, a water of lunar or solar fire. That which has been in Sekhmet a venusian water, becomes Mut, a lunar water, the former warm, the latter cold. It is necessary, says de Lubicz, to see in Amon a liquid coagulation substance, like the masculine sperm, and in Mut a substance liquid as well but susceptible of being coagulated by Amon.

Aor is the Egyptian word for "magic light," or electricity. It was the name de Lubicz received in the course of his own initiatory development. Aud or Od, also magic light, is the vibration of Set. Set and Horus, sometimes called Neter-wy, are "the two *neters,*" aspects of the universal light, one dark, material, fixed, contracted, satanic—Set; the other radiant, spiritual, penetrating, open—Horus. The paternal, constricting, styptic power of sperm, contracting, causes spirit to materialize. But spirit, says de Lubicz, fights to free itself by a counterreaction which is movement.

The biblical cabala speaks of a fallen archangel who brings with him the remembrance of the divine light, the chaos composed of Set, the mephitic Satan, and it speaks of Horus-Lucifer, who carries the light and causes it to reappear. This, says de Lubicz, is the same story which the pharaonic cabala describes as the struggle between Set and Horus—builders of the temple which is man. It is the eternal conflict in every creature who undergoes the contradictory attraction of the two powers: the horian, immutable light, and the sethian—atavisms attached to terrestrial form.

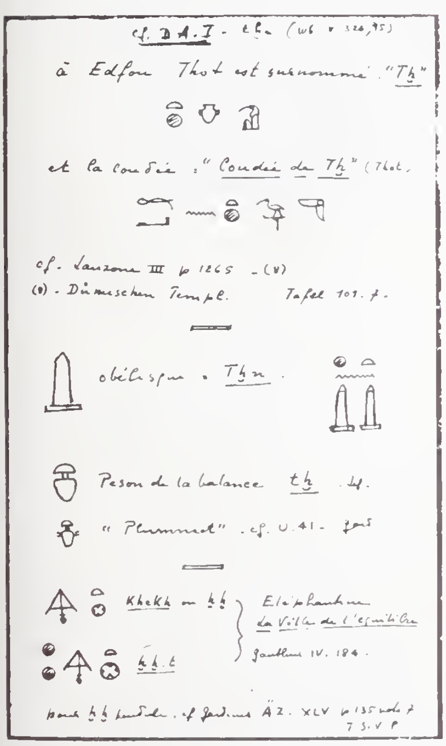
And Set and Horus are gravity and levity, aspects of the same fundamental energy. In Mesoamerica, Quetzalcoatl and Tezcatlipoca are depicted Januslike; one aspect dilates, the other contracts, and all of life is in the cyclical pulse between the two. This pulsation, this gravitational, levitational swing of the pendulum the Egyptians knew to be the heart of the matter, as their glyphs clearly show:

Among the unpublished papers of de Lubicz, written just before his death, is a monograph in which he shows how



Side = time
Surface = the distance covered
These surfaces superimposed one on the other form a stepped pyramid. As the distance covered increases by the square of the time it does so at a constant acceleration.
(from de Lubicz's notes)

Lucy Lamy's notes deciphering the Egyptian understanding of the fundamentals of physical science symbolized by the heart, plumate, and obelisk



the Egyptian obelisk incorporates the formula for gravity, with a geometric acceleration which grows by squares. This was an idea already formulated in *The Lost Solar System Discovered,* a remarkable mathematical opus produced in the middle of the nineteenth century by an obscure but brilliant researcher, John Wilson, who pointed out that the sectional axis of the obelisk may be regarded as symbolic of time, velocity, and distance, or the generator of lines, areas, and solids. With his equations Wilson endeavored to establish that obelisks represent the laws of motion when a body falls near the surface of the earth, or when a planet revolves in orbit. By his analysis of the pyramidal and hyperbolic temples of the past, he interpreted the ancient theory of the laws of gravitation as the key to understanding the mechanics of celestial motion.

The obelisk, according to Wilson, was called "the finger of God" because it indicates the laws by which the universe is governed. $\top$, said Wilson, is the symbol of time and distance as a body descends to earth. $\perp$ is the symbol for velocity and distance. The *crux ansata,* or sacred Tau, , symbol of the divinity of Osiris, he interpreted as symbolic of time, velocity, and distance of a falling body which cannot descend beyond the surface of the attracting orb or sphere. "But this sacred type of the eternal laws," he said, "appears to have become more and more obscure as the days of science declined, till ultimately it ceased to be intelligible; when, instead of this spiritual symbol, a physical one, palpable to the senses and adapted to the capacity of the unlearned, was substituted, and so the Phallic worship became embodied and revered in the religious rites of Egypt, India, Greece and Rome."

That the pull of gravity is the same for all falling bodies, and that only the mass of a body varies according to its distance from the center of the earth, depending on latitude and height above sea level, was known to the Egyptians millennia before Galileo. And they also knew that the force of gravity for any locality can be obtained by the number of oscillations in a plumb bob within a certain time—the number of swings in a pendulum being the same no matter what its weight. What varies the effect is the length of the string.

Sir William Flinders Petrie, founder of the British School of Archaeology in Egypt, and promulgator of scientific archaeology, showed how the double remen, a diagonal of one of the many Egyptian cubits, that of 29.161 inches, is virtually the natural length of a pendulum which swings 100,000 times in twenty-four hours at the latitude on which

Memphis lies. "There would have been no difficulty to the Egyptians," says Petrie, "in developing the use of his familiar plumb-bob to find this result."

And Livio C. Stecchini, perhaps the greatest scholar of the science of measure, that primary discipline without which there can be no physics, suggested, before his death, that the size of the base of each obelisk may have been deliberately designed to indicate the height above sea level at which the obelisk was raised.

To ferret out the truth, more research is needed into pylon, pyramid, and obelisk; but these two great pioneers in Egyptological physics and metaphysics, de Lubicz and Stecchini, have indeed left their mark. In his unfinished book on the canonical Jesus, Stecchini points out that whereas Hebrew justice was based on the strictest law of giving fair measure, when the spirited Nazarene suggested giving back five in return for three or not rewarding the fellow who buried his talent, they quickly nailed him to a cross.

Isha de Lubicz described her husband's final moments on earth as his features became illumined by an ecstatic smile. "Reality," he said, "is not at all what one imagines. . . . One must look in silence, without wishing to see . . . and accept pure nothingness . . . for what man calls nothing, *that* is Real: Oh, we are so blind! Isha, I will show you. The worst impediment to illumination has been my mental being. I see its game now. It has been my enemy all my life. I did not believe it could be so fierce! I sensed it was an obstacle, but I did not recognize all its ruses, all the forms it could take to mislead me. It is terrifying, Isha. I wish you too could see it, so as to help others free themselves from fear; for it is the mental which creates fear and doubt. . . . What is real is outside time and beyond 'good and evil.' It is not what appears to the senses."

POSTSCRIPT

Just as I forewent a final caption to the phoenix, a young friend appeared on my doorstep fresh from Egypt, unaware of the content of this book, and, unsolicited, began to recount adventures in the Saqqara region with a clairaudient lady. For some time my friend has been studying Egyptian glyphs, hoping to reconstitute the original sounds of the ancient language.

It was the full moon of the vernal equinox. In a Saggara tomb he found that his clairaudient friend could chant without understanding them the invocations to the Neters, or gods, appearing on the walls while my friend ad-libbed a translation. To their surprise they both felt a presence; forthwith the lady began to chant a stream of messages from what purported to be the ancient gods of Egypt, invoked by the sound of her voice. And what did they say? According to my friend, nothing more phenomenal than to express their pleasure that human beings had once more found the means of communicating with them for the welfare of the planet, and a preoccupied warning that we have become so out of touch with mother earth she may be on the point of spewing out the toxins with which we have poxed her body.

I did not press my friend, for he and the lady intend to publish the entire story of their contact, with all that was said and done. But it made me wonder about Dee and Crowley and company, and I thought again of Isha de Lubicz's statement that "to know a thing's real name is to know its power. And to pronounce it exactly is to free its

Was Crowiey on the track? To some extent, without questicn. Though he may or may not have garbled the answer. Isha de Lubicz is more crystalline when she has her aspirant initiate Her-bak ask about the meaning of three Egyptian words: "I am looking for the relation between *za,* magic power, *sa,* back, and *saa,* Sage." To which his master answers: "The power *za* has nothing to do with the projection of thought or will, unless in a popular reading and by extension. This word gives the active power of the fire whose channel is the vertebral column . . . there are various centres of residence and radiation in our body. It may be Sethian fire, consuming, destructive, when it is constrained or switched to sex or brain. That is why the back is said to belong to Seth. But when this fire is subtilised it is vivifying, quickening. This is the true magic fire, triple in its nature, giver of life or death."

"Is it a power to be feared then!" exclaims Her-bak. "Is it in all men?"

"It is latent in them," answers his guru, "but few know how to make use of it wisely, very few how to master it. It reaches its perfection in him when a man, being quickened, radiates it without effort of his own, life a life-giving sun. Such a man is *saa,* a wise man, in whom the Horus-fire masters the Seth-fire and subjects it to his service. The same fire as yet unevolved gives the characteristics and signature of the personality *sa* or *za* and in its spermatic capacity it transmits paternal characters to the son *sa* or *za*."

Another modern guru, Gopi Kirshna, wants to put modern men of science onto the trail of kundalini, which he calls "the greatest mystery of creation still lying unsolved and even unattended before us . . . a force present in the human body that is drawing humankind toward a sublime state of consciousness inconceivable for even the most intelligent mind that has not experienced it." Gopi Krishna is convinced that man is evolving toward a state of awareness in which the reality behind the universe can become perceptible, if only the activity of the reproductive mechanism can be made to stream inward and upward. "This reversal," he says, "true for both men and women, causes an amazing transformation in the cerebro-spinal system, leading to an explosion of consciousness. . . . On the arousal of kundalini, the nectarean substance flows into the head [as radiant, living energy] and then circulates in the body."

As he describes the phenomenon, the reproductive system is employed as a transfer center, where the life-energies are transformed into an ever more volatile and radiant energy that streams upward into the brain. This transformation, he explains, is built on the copiously produced "ambrosia" of the reproductive mechanism, working day and night. "The ambrosia is the nectarlike reproductive secretion which, at the highest point of ecstasy, pours into the brain with such an intensely pleasurable sensation that even the sexual orgasm pales into insignificance before it. This unbelievably rapturous sensation—pervading the whole of the spinal cord, the organs of generation and the brain—is nature's incentive to the effort directed at self-transcendance, as the orgasm is the incentive to the reproductive act." Like Bruno, Gopi Krishna asks: "Is the creator, or God, of such limited intelligence that he should build man in such a way that the sexual urge is the most awful impulse in him, attended with such an intense pleasure, and then rule that he is not to touch it?" Of course not: the object of the process is to release the self-conscious mind of man more and more from "the thraldom of the subconscious, to enable it to touch levels of cognition which, in its present fettered condition, it can never reach."

During the course of a genuine mystical experience, says Gopi Krishna, a higher dimension of consciousness intervenes, eclipsing the normal individuality, partially or wholly, for a period. "It then seems as if a new world, a new order of existence, or superhuman being has descended into view. There is an unmistakable enhanced perception of lights, color, beauty, goodness, virtue, and harmony which lend to superworldly appearance to the whole experience."

How the transformation of the genes is effected through a rejuvenative activity of the reproductive system, or the arousal of the Serpent Power, how the seminal fluid in men is sent in a cascading stream of radiant energy to the brain, and in women in the form of hormones and secretions—a secret so closely guarded by adepts of the past—Gopi Krishna promises to reveal in detail as a solution the problems of mankind. Certainly the arbitrary imposition of intolerable dogma enforced by torture cannot but be the very last form of rational brotherly or loving government. Yet it is what we have had for two thousand years. As the Founding Fathers of this republic fully understood, the only way for humans of different religious persuasions to live peaceably together is to live under the common law and refuse to fight or impose in matters or religion. This is what the obelisk stands for on the mall in Washington, D.C.

And the self-appointed arbiters of morality may learn the difference between erotic, livening, enamoring, and generative sex on the one hand and the world of porno, which can only exist under restriction, for who would deliberately look upon the corrupt if, all around, the woods and fields were full of young Dianas and their hornéd lovers.

Crowley suggested that nine-tenths of social misery not due to poverty arises from the hallucination of personal jealousy and ill-regulated passion. "There shall be no property in human flesh," says Aiwaz in *The Book of the Law*. "Nobody has the right to say what anyone else shall or shall not do with his or her body." Establish this principle of absolute respect for others, says Crowley, and the whole nightmare of sex is dispelled. "Blackmail and prostitution automatically lose their *raison d'être*."

As for contraception, abortion, sexual stasis, overpopulation, and the wars that ensue, for some millennia the

Chinese Taoist and the Hindu Tantric have solved these problems by the practice of highly satisfactory sexual intercourse without ejaculation, not the gross Roman notion of *coitus interruptus* but the more salubrious *coitus ad infinitum,* satisfying sexually and emotionally to both men and women, leading to a mystic fusion of the two in one.

So let us be loving and free, and intrepid, and let us stop arming and killing. For Augustine warned, karma imposes that every sword thrust pierces its wielder. Let us return to the gospel of the canonical Jesus, let us gently turn Roma back into Amor.

BIBLIOGRAPHICAL NOTE

In the filed bibliography for this opus there are over a thousand titles, far too many to list, yet each of value in its way; and I must have consulted thrice that many. The masters on the subject of obelisks, Michele Mercati, Anathasius Kircher, Georg Zoega, Cesare d'Onofrio, and above all, Erik Iversen, are credited in the text wherever possible. Some authors, such as Serge Hutin, have written a score of books every one of which touches on some facet of the subject. Books on or about Aleister Crowley fill several shelves. To have listed every volume on every subject dealt with would be tedious to all but the rare scholar who could not find them for himself. Rather than burden publisher and reader with an endless list, I am, through the publisher, available at any time to answer any bibliographical question and indicate the whereabouts of any publication hard to find.

INDEX

"Then this most holy land, the seat of palaces consecrated to divinity, and of temples, shall be full of sepulchres and dead bodies. O, Egypt, Egypt, fables alone shall remain of thy religion, and these, such as will be incredible to posterity, and words alone shall be left engraved in stones, narrating thy pious deeds."—Hermes Trismegistus

CHILDREN OF THE SOIL

PART V
THE RADIANCE OF LIFE

Acknowledgments

The authors wish to express their gratitude to all who have helped them in the compilation of this book, which required extensive research in Europe, the Soviet Union, and the United States.

They are especially grateful to the staff of the U.S. Library of Congress and in particular to Legare H. B. Obear, Chief of the Loan Division, and to his most helpful assistants. In the Stack and Reader Division, they wish to thank Dudley B. Ball, Roland C. Maheux, William Sartain, Lloyd A. Pauls, and Benjamin Swinson, who saved them much anxiety by caring for their shelved books.

Thanks are also due to Robert V. Allen of the Slavic and Central European Division, and Dolores Moyano Martin, of the Latin American Division, Library of Congress, and to Lida L. Allen of the National Agricultural Library, Beltsville, Maryland.

Very special thanks are due to two Muscovite scientists, biophysicist Dr. Viktor Adamenko, well known for his research on bio-energetics, and Professor Sinikov, Director of Studies; of the Timiryazev Academy of Agricultural Sciences, both of whom kindly and promptly replied to requests for data and references unavailable in the United States, as did M. Rostislav Donn, Commercial Counselor of the French Embassy in Moscow.

Lastly the authors are grateful to their respective helpmates, without whom the book would never have reached the printer.

Introduction

Short of Aphrodite, there is nothing lovelier on this planet than a flower, nor more essential than a plant. The true matrix of human life is the greensward covering mother earth. Without green plants we would neither breathe nor eat. On the undersurface of every leaf a million movable lips are engaged in devouring carbon dioxide and expelling oxygen. All together, 25 million square miles of leaf surface are daily engaged in this miracle of photosynthesis, producing oxygen and food for man and beast.

Of the 375 billion tons of food we consume each year the bulk comes from plants, which synthesize it out of air and soil with the help of sunlight. The remainder comes from animal products, which in turn are derived from plants. All the food, drink, intoxicants, drugs and medicines that keep man alive and, if properly used, radiantly healthy are ours through the sweetness of photosynthesis. Sugar produces all our starches, fats, oils, waxes, cellulose. From crib to coffin, man relies on cellulose as the basis for his shelter, clothing, fuel, fibers, basketry, cordage, musical instruments, and the paper on which he scribbles his philosophy. The abundance of plants profitably used by man is indicated by nearly six hundred pages in Uphof's *Dictionary of Economic Plants.* Agriculture--as the economists agree--is the basis for a nation's wealth. Instinctively aware of the aesthetic vibrations of plants, which are spiritually satisfying, human beings are happiest and most comfortable when living with flora. At birth, marriage, death, blossoms are prerequisites, as they are at mealtime or festivities. We give plants and flowers as tokens of love, of friendship, or homage, and of thanks for hospitality. Our houses are adorned with gardens, our cities with parks, our nations with national preserves. The first thing a woman does to make a room livable is to place a plant in it or a vase of fresh cut flowers. Most men, if pressed, might describe paradise, whether in heaven or on earth, as a garden filled with luxuriant orchids, uncut, frequented by a nymph or two.

Aristotle's dogma that plants have souls but no sensation lasted through the Middle Ages and into the eighteenth century, when Carl von Linné, grandfather of modem botany, declared that plants differ from animals and humans only in their lack of movement, a conceit which was shot down by the great nineteenth-century botanist Charles Darwin, who proved that every tendril has its power of independent movement. As Darwin put it, plants "acquire and display this power only when it is of some advantage to them."

At the beginning of the twentieth century a gifted Viennese biologist with the Gallic name of Raoul Francé put forth the idea, shocking to contemporary natural philosophers, that plants move their bodies as freely, easily, and gracefully as the most skilled animal or human, and that the only reason we don't appreciate the fact is that plants do so at a much slower pace than humans.

The roots of plants, said France, burrow inquiringly into the earth, the buds and twigs swing in definite circles, the leaves and blossoms bend and shiver with change, the tendrils circle questingly and reach out with ghostly arms to feel their surroundings. Man, said Francé, merely thinks plants motionless and feelingless because he will not take the time to watch them.

Poets and philosophers such as Johann Wolfgang von Goethe and Rudolf Steiner, who took the trouble to watch plants, discovered that they grow in opposite directions, partly burrowing into the ground as if attracted by gravity, partly shooting up into the air as if pulled by some form of antigravity, or levity.

Wormlike rootlets, which Darwin likened to a brain, burrow constantly downward with thin white threads, crowding themselves firmly into the soil, tasting it as they go. Small hollow chambers in which a ball of starch can rattle indicate to the root tips the direction of the pull of gravity.

When the earth is dry, the roots turn toward moister ground, finding their way into buried pipes, stretching, as in the case of the lowly alfalfa plant, as far as forty feet, developing an energy that can bore through concrete. No one has yet counted the roots of a tree, but a study of a single rye plant indicates a total of over 13 million rootlets with a combined length of 380 miles. On these rootlets of a rye plant are fine root hairs estimated to number some 14 billion with a total length of 6,600 miles, almost the distance from pole to pole.

As the special burrowing cells are worn out by contact with stones, pebbles, and large grains of sand, they are rapidly replaced, but when they reach a source of nourishment they die and are replaced by cells designed to dissolve mineral salts and collect the resulting elements.

This basic nourishment is passed from cell to cell up through the plant, which constitutes a single unit of protoplasm, a watery or gelatinous substance considered the basis of physical life.

The root is thus a water pump, with water acting as a universal solvent, raising elements from root to leaf, evaporating and falling back to earth to act once more as the medium for this chain of life. The leaves of an ordinary sunflower will transpire in a day as much water as a man perspires. On a hot day a single birch can absorb as much as four hundred quarts, exuding cooling moisture through its leaves.

No plant, says France, is without movement; all growth is a series of movements; plants are constantly preoccupied with bending, turning and quivering. He describes a summer day with thousands of polyplike arms reaching from a peaceful arbor, trembling, quivering in their eagerness for new support for the heavy stalk that grows behind them. When the tendril, which sweeps a full circle in sixty-seven minutes, finds a perch, within twenty seconds it starts to curve around the object, and within the hour has wound itself so firmly it is hard to tear away. The tendril then curls itself like a corkscrew and in so doing raises the vine to itself.

A climbing plant which needs a prop will creep toward the nearest support. Should this be shifted, the vine, within a few hours, will change its course into the new direction. Can the plant see the pole? Does it sense it in some unfathomed way? If a plant is growing between obstructions and cannot see a potential support it will unerringly grow toward a hidden support, avoiding the area where none exists.

Plants, says France, are capable of *intent*- they can stretch toward, or seek out, what they want in ways as mysterious as the most fantastic creations of romance.

Far from existing inertly, the inhabitants of the pasture-or what the ancient Hellenes called *botane*-appear to be able to perceive and to react to what is happening in their environment at a level of sophistication far surpassing that of humans.

The sundew plant will grasp at a fly with infallible accuracy, moving in just the right direction toward where the prey is to be found. Some parasitical plants can recognize the slightest trace of the odor of their victim, and will overcome all obstacles to crawl in its direction.

Plants seem to know which ants will steal their nectar, closing when these ants are about, opening only when there is enough dew on their stems to keep the ants from climbing. The more sophisticated acacia actually enlists the protective services of certain ants which it rewards with nectar in return for the ants' protection against other insects and herbivorous mammals.

Is it chance that plants grow into special shapes to adapt to the idiosyncrasies of insects which will pollinate them, luring these insects with special color and fragrance, rewarding them with their favorite nectar, devising extraordinary canals and Horal machinery with which to ensnare a bee so as to release it through a trap door only when the pollination process is completed?

Is it really nothing but a reflex or coincidence that a plant such as the orchid *Trichoceros parviflorus* will grow its petals to imitate the female of a species of fly so exactly that the male attempts to mate with it and in so doing pollinates the orchid? Is it pure chance that night-blossoming flowers grow white the better to attract night moths and night-flying butterflies, emitting a stronger fragrance at dusk, or that the carrion lily develops the smell of rotting meat in areas where only flies abound, whereas flowers which rely on the wind to cross-pollinate the species do not waste energy on making themselves beautiful, fragrant or appealing to insects, but remain relatively unattractive?

To protect themselves plants develop thorns, a bitter taste, or gummy secretions that catch and kill unfriendly insects. The timorous *Mimosa pudica* has a mechanism which reacts whenever a beetle or an ant or a worm crawls up its stem toward its delicate leaves: as the intruder touches a spur the stem raises, the leaves fold up, and the assailant is either rolled off the branch by the unexpected movement or is obliged to draw back in fright.

Some plants, unable to find nitrogen in swampy land, obtain it by devouring living creatures. There are more than five hundred varieties of carnivorous plants, eating any kind of meat from insect to beef, using endlessly cunning methods to capture their prey, from tentacles to sticky hairs to funnel-like traps. The tentacles of carnivorous plants are not only mouths but stomachs raised on poles with which to seize and eat their prey, to digest both meat and blood, and leave nothing but a skeleton. Insect-devouring sundews pay no attention to pebbles, bits of metal, or other foreign substances placed on their leaves, but are quick to sense the nourishment to be derived from a piece of meat. Darwin found that the sundew can be excited when a piece of thread is laid on it weighing no more than 1/78,000 of a grain. A tendril, which next to the rootlets constitutes the most sensitive portion of a plant, will bend if a piece of silk thread is laid across it weighing but .00025 of a gram.

The ingenuity of plants in devising forms of construction far exceeds that of human engineers. Man-made structures cannot match the supply strength of the long hollow tubes that support fantastic weights against terrific storms. A plant's use of fibers wrapped in spirals is a mechanism of great resistance against tearing not yet developed by human ingenuity. Cells elongate into sausages or Hat ribbons locked one to the other to form almost unbreakable cords. As a tree grows upward it scientifically thickens to support the greater weight.

The Australian eucalyptus can raise its head on a slim trunk above the ground 480 feet, or as high as the Great Pyramid of Cheops, and certain walnuts can hold a harvest of 100,000 nuts. The Virginia knotweed can tie a sailor's knot which is put to such a strain when it dries that it snaps; hurling the seeds to germinate as far as possible from mother.

Plants are even sentient to orientation and to the future. Frontiersmen and hunters in the prairies of the Mississippi Valley discovered a sunflower plant, *Silphium laciniatum,* whose leaves accurately indicate the points of the compass. Indian licorice, or *Arbrus precatorius,* is so keenly sensitive to all forms of electrical and magnetic influences it is used as a weather plant. Botanists who first experimented with it in London's Kew Gardens found in it a means for predicting cyclones, hurricanes, tornadoes, earthquakes and volcanic eruptions.

So accurate are alpine flowers about the seasons, they know when spring is coming and bore their way up through lingering snowbanks, developing their own heat with which to melt the snow.

Plants which react so certainly, so variously, and so promptly to the outer world, must, says Francé, have some means of communicating with the outer world, something comparable or superior to our senses. France insists that plants are constantly observing and recording events and phenomena of which man-trapped in his anthropocentric view of the world, subjectively revealed to him through his five senses-knows nothing.

Whereas plants have been almost universally looked upon as senseless automata, they have now been found to be able to distinguish between sounds inaudible to the human ear and color wavelengths such as infrared and ultraviolet invisible to the human eye; they are specially sensitive to X-rays and to the high frequency of television.

The whole vegetal world, says Francé, lives responsive to the movement of the earth and its satellite moon, to the movement of the other planets of our solar system, and one day will be shown to be affected by the stars and other cosmic bodies in the universe.

As the external form of a plant is kept a unit and restored whenever part of it is destroyed, Francé assumes there must be some conscious entity supervising the entire form , some intelligence directing the plant, either from within, or from without.

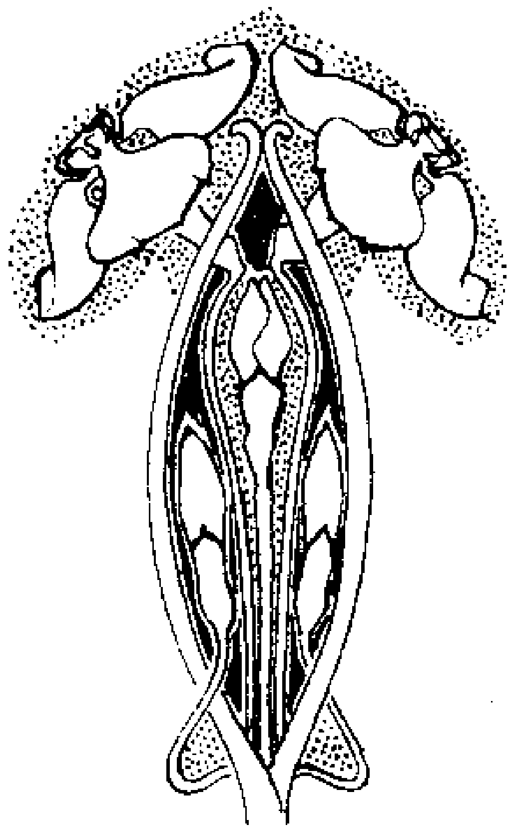
Over half a century ago Francé, who believed plants to be possessed of all the attributes of living creatures including "the most violent reaction against abuse and the most ardent gratitude for favors," could have written a *Secret Life of Plants,* but what he had already put into print was either ignored by the establishment or considered heretically shocking. What shocked them most was his suggestion that the awareness of plants might originate in a supramaterial world of cosmic beings to which, long before the birth of Christ, the Hindu sages referred as "devas" and which, as fairies, elves, gnomes, sylphs and a host of other creatures, were a matter of direct vision and experience to clairvoyants among the Celts and other sensitives. The idea was considered by vegetal scientists to be as charmingly jejune as it was hopelessly romantic.

It has taken the startling discoveries of several scientific minds in the 1960s to bring the plant world sharply back to the attention of mankind. Even so there are skeptics who find it hard to believe that plants may at last be the bridesmaids at a marriage of physics and metaphysics. Evidence now supports the vision of the poet and the philosopher that plants are living, breathing, communicating creatures, endowed with personality and the attributes of soul. It is only we, in our blindness, who have insisted on considering them automata. Most extraordinary, it now appears that plants may be ready, willing, and able to cooperate with humanity in the Herculean job of turning this planet back into a garden from the squalor and corruption of what England's pioneer ecologist William Cobbett would have called a "wen."

Part I

MODERN RESEARCH

CHAPTER I
Plants and ESP



The dust-grimed window 01 the office building lacing New York's Times Square reflected, as through a looking glass, an extraordinary corner 01 Wonderland. There was no White Rabbit with waistcoat and watch chain, only an elfin-eared fellow called Backster with a galvanometer and a house plant called *Dracaena massangeana.* The galvanometer was there because Cleve Backster was America's foremost lie-detector examiner; the dracaena because Backster's secretary felt the bare office should have a touch of green; Backster was there because of a fatal step taken in the 1960s which radically affected his Iife, and may equally affect the planet.

Backster's antics with his plants, headlined in the world press, became the subject of skits, cartoons, and lampoons; but the Pandora's box which he opened for science may never again be closed. Backster's discovery that plants appear to be sentient caused strong and varied reaction round the globe, despite the fact that Backster never claimed a discovery, only an uncovering of what has been known and forgotten. Wisely he chose to avoid publicity, and concentrated on establishing the absolute scientific bona fides of what has come to be known as the "Backster Effect."

The adventure started in 1966. Backster had been up all night in his school for polygraph examiners, where he teaches the art of lie detection to policemen and security agents from around the world. On impulse he decided to attach the electrodes of one of his lie detectors to the leaf of his dracaena. The dracaena is a tropical plant similar to a palm tree, with large leaves and a dense cluster of small flowers; it is known as the dragon tree (Latin *draco)* because of the popular myth that its resin yields dragon blood. Backster was curious to see if the leaf would be affected by water poured on its roots, and if so, how, and how soon.

As the plant thirstily sucked water up its stem, the galvanometer, to Backster's surprise, did not indicate less resistance, as might have been expected by the greater electrical conductivity of the moister plant. The pen on the graph paper, instead of trending upward, was trending downward, with a lot of sawtooth motion on the tracing.

A galvanometer is that part of a polygraph lie detector which, when attached to a human being by wires through which a weak current of electricity is run, will cause a needle to move, or a pen to make a tracing on a moving graph of paper, in response to mental images, or the slightest surges of human emotion. Invented at the end of the eighteenth century by a Viennese priest, Father Maximilian Hell, S.J., court astronomer to the Empress Maria Theresa, it was named after Luigi Galvani, the Italian physicist and physiologist who discovered "animal electricity." The galvanometer is now used in conjunction with an electrical circuit called a "Wheatstone bridge," in honor of the English physicist and inventor of the automatic telegraph, Sir Charles Wheatstone.

Backster's antics with his plants, headlined in the world press, became the subject of skits, cartoons, and lampoons; but the Pandora's box which he opened for science may never again be closed. Backster's discovery that plants appear to be sentient caused strong and varied reaction round the globe, despite the fact that Backster never claimed a discovery, only an uncovering of what has been known and forgotten. Wisely he chose to avoid publicity, and concentrated on establishing the absolute scientific bona fides of what has come to be known as the "Backster Effect."

The adventure started in 1966. Backster had been up all night in his school for polygraph examiners, where he teaches the art of lie detection to policemen and security agents from around the world. On impulse he decided to attach the electrodes of one of his lie detectors to the leaf of his dracaena. The dracaena is a tropical plant similar to a palm tree, with large leaves and a dense cluster of small flowers; it is known as the dragon tree (Latin *draco*) because of the popular myth that its resin yields dragon blood. Backster was curious to see if the leaf would be affected by water poured on its roots, and if so, how, and how soon.

As the plant thirstily sucked water up its stem, the galvanometer, to Backster's surprise, did not indicate less resistance, as might have been expected by the greater electrical conductivity of the moister plant. The pen on the graph paper, instead of trending upward, was trending downward, with a lot of sawtooth motion on the tracing.

A galvanometer is that part of a polygraph lie detector which, when attached to a human being by wires through which a weak current of electricity is run, will cause a needle to move, or a pen to make a tracing on a moving graph of paper, in response to mental images, or the slightest surges of human emotion. Invented at the end of the eighteenth century by a Viennese priest, Father Maximilian Hell, S.J., court astronomer to the Empress Maria Theresa, it was named after Luigi Galvani, the Italian physicist and physiologist who discovered "animal electricity." The galvanometer is now used in conjunction with an electrical circuit called a "Wheatstone bridge," in honor of the English physicist and inventor of the automatic telegraph, Sir Charles Wheatstone.

In simple terms, the bridge balances resistance, so that the human body's electrical potential—or basic charge—can be measured as it fluctuates under the stimulus of thought and emotion. The standard police usage is to feed "carefully structured" questions to a suspect and watch for those which cause the needle to jump. Veteran examiners, such as Backster, claim they can identify deception from the patterns produced on the graph.

Backster's dragon tree, to his amazement, was giving him a reaction very similar to that of a human being experiencing an emotional stimulus of short duration. Could the plant be displaying emotion?

What happened to Backster in the next ten minutes was to revolutionize his life.

The most effective way to trigger in a human being a reaction strong enough to make the galvanometer jump is to threaten his or her well-being. Backster decided to do just that to the plant: he dunked a leaf of the dracaena in the cup of hot coffee perennially in his hand. There was no reaction to speak of on the meter. Backster studied the problem several minutes, then conceived a worse threat: he would burn the actual leaf to which the electrodes were attached. The instant he got the picture of flame in his mind, and before he could move for a match, there was a dramatic change in the tracing pattern on the graph in the form of a prolonged upward sweep of the recording pen. Backster had not moved, either toward the plant or toward the recording machine. Could the plant have been reading his mind?

When Backster left the room and returned with some matches, he found another sudden surge had registered on the chart, evidently caused by his determination to carry out the threat. Reluctantly he set about burning the leaf. This time there was a lower peak of reaction on the graph. Later, as he went through the motions of pretending he would burn the leaf, there was no reaction whatsoever. The plant appeared to be able to differentiate between real and pretended intent.

Backster felt like running into the street and shouting to the world, "Plants can think!" Instead he plunged into the most meticulous investigation of the phenomena in order to establish just how the plant was reacting to his thoughts, and through what medium.

His first move was to make sure he had not overlooked any logical explanation for the occurrence. Was there something extraordinary about the plant? About him? About the particular polygraph instrument?

When he and his collaborators, using other plants and other instruments in other locations all over the country, were able to make similar observations, the matter warranted further study. More than twenty-five different varieties of plants and fruits were tested, including lettuce, onions, oranges, and bananas. The observations, each similar to the others, required a new view of life, with some explosive connotations for science. Heretofore the debate between scientists and parapsychologists on the existence of ESP, or extrasensory perception, has been fierce, largely because of the difficulty of establishing unequivocally when such a phenomenon is actually occurring. The best that has been achieved so far in the field, by Dr. J. B. Rhine, who initiated his experiments in ESP at Duke University, has been to establish that with human beings the phenomenon seems to occur with greater odds than are attributable to chance.

Backster first considered his plants' capacity for picking up his intention to be some form of ESP; then he quarreled with the term. ESP is held to mean perception above and beyond varieties of the established five sensory perceptions of touch, sight, sound, smell, and taste. As plants give no evidence of eyes, ears, nose, or mouth, and as botanists since Darwin's time have never credited them with a nervous system, Backster concluded that the perceiving sense must be more basic.

This led him to hypothesize that the five senses in humans might be limiting factors overlying a more "primary perception," possibly common to all nature. "Maybe plants see better *without* eyes," Backster surmised: "better than humans do with them." With the five basic senses, humans have the choice, at will, of perceiving, perceiving poorly, not perceiving at all. "If you don't like the looks of something," said Backster, "you can look the other way, or not look. If everyone were to be in everyone else's mind all the time it would be chaos."

To discover what his plants could sense or feel, Backster enlarged his office, and set about creating a proper scientific laboratory, worthy of the space age.

During the next few months, chart after chart was obtained from all sorts of plants. The phenomenon appeared to persist even if the plant leaf was detached from the plant, or if it was trimmed to the size of the electrodes; amazingly, even if a leaf was shredded and redistributed between the electrode surfaces there was still a reaction on the chart. The plants reacted not only to threats from human beings, but to unformulated threats, such as the sudden appearance of a dog in the room or of a person who did not wish them well.

Backster was able to demonstrate to a group at Yale that the movements of a spider in the same room with a plant wired to his equipment could cause dramatic changes in the recorded pattern generated by the plant just *before* the spider started to scamper away from a human attempting to restrict its movement. "It seems," said Backster, "as if each of the spider's decisions to escape was being picked up by the plant, causing a reaction in the leaf."

Under normal circumstances, plants may be attuned to each other, said Backster, though when encountering animal life they tend to pay less attention to what another plant may be up to. "The last thing a plant expects is another plant to give it trouble. So long as there is animal life around, they seem to be attuned to animal life. Animals and people are mobile, and could need careful monitoring."

If a plant is threatened with overwhelming danger or damage, Backster observed that it reacts self-defensively in a way similar to an opossum—or, indeed, to a human being—by "passing out," or going into a deep faint. The phenomenon was dramatically demonstrated one day when a physiologist from Canada came to Backster's lab to witness the reaction of his plants. The first plant gave no response whatsoever. Nor did the second; nor the third. Backster checked his polygraph instruments, and tried a fourth and a fifth plant; still no success. Finally, on the sixth, there was enough reaction to demonstrate the phenomenon.

Curious to discover what could have influenced the other plants, Backster asked: "Does any part of your work involve harming plants?"

"Yes," the physiologist replied. "I terminate the plants I work with. I put them in an oven and roast them to obtain their dry weight for my analysis."

Forty-five minutes after the physiologist was safely on the way to the airport, each of Backster's plants once more responded fluidly on the graph.

This experience helped to bring Backster to the realization that plants could intentionally be put into a faint, or mesmerized, by humans, that something similar could be involved in the ritual of the slaughterer before an animal is killed in the kosher manner. Communicating with the victim, the killer may tranquilize it into a quiet death, also preventing its flesh from having a residue of "chemical fear," disagreeable to the palate and perhaps noxious to the consumer. This brought up the possibility that plants and succulent fruits might *wish* to be eaten, but only in a sort of loving ritual, with a real communication between the eater and the eaten—somehow akin to the Christian rite of Communion—instead of the usual heartless carnage.

"It may be," says Backster, "that a vegetable appreciates becoming part of another form of life rather than rotting on the ground, just as a human at death may experience relief to find himself in a higher realm of being."

On one occasion, to show that plants and single cells were picking up signals through some unexplained medium of communication, Backster provided a demonstration for the author of an article appearing in the Baltimore *Sun,* subsequently condensed in the *Reader's Digest.* Backster hooked a galvanometer to his philodendron, then addressed the writer as if it were *he* who was on the meter, and interrogated him about his year of birth.

Backster named each of seven years between 1925 and 1931 to which the reporter was instructed to answer with a uniform "No." Backster then selected from the chart the correct date, which had been indicated by the plant with an extra high flourish.

The same experiment was duplicated by a professional psychiatrist the medical director of the research ward at Rockland State Hospital in Orangeburg, New York, Dr. Aristide H. Esser. He and his collaborator Douglas Dean, a chemist at Newark College of Engineering, experimented with a male subject who brought along a philodendron he had nursed from a seedling and had cared for tenderly.

The two scientists attached a polygraph to the plant and then asked the owner a series of questions, to some of which he had been instructed to give false answers. The plant had no difficulty indicating through the galvanometer the questions which were falsely answered; Dr. Esser, who at first had laughed at Backster's claim, admitted, "I've had to eat my own words."

To see if a plant could display memory, a scheme was devised whereby Backster was to try to identify the secret killer of one of two plants. Six of Backster's polygraph students volunteered for the experiment, some of them veteran policemen. Blindfolded, the students drew from a hat folded slips of paper, on one of which were instructions to root up, stamp on, and thoroughly destroy one of two plants in a room. The criminal was to commit the crime in secret; neither Backster nor any of the other students was to know his identity; only the second plant would be a witness.

By attaching the surviving plant to a polygraph and parading the students one by one before it, Backster was able to establish the culprit. Sure enough, the plant gave no reaction to five of the students, but caused the meter to go wild whenever the actual culprit approached. Backster was careful to point out that the plant could have picked up and reflected the guilt feelings of the culprit; but as the villain had acted in the interests of science, and was not particularly guilty, it left the possibility that a plant could remember and recognize the source of severe harm to its fellow.

In another series of observations, Backster noted that a special communion or bond of affinity appeared to be created between a plant and its keeper, unaffected by distance. With the use of synchronized stopwatches, Backster was able to note that his plants continued to react to his thought and attention from the next room, from down the hall, even from several buildings away. Back from a fifteen-mile trip to New Jersey, Backster was able to establish that his plants had perked up and shown definite and positive signs of response—whether it was relief or welcome he could not tell—at the very moment he had decided to return to New York.

When Backster was away on a lecture tour and talked about his initial

1966 observation, showing a slide of the original dracaena, the plant, back in his office, would show a reaction on the chart at the very time he projected the slide.

Once attuned to a particular person, plants appeared to be able to maintain a link with that person, no matter where he went, even among thousands of people. On New Year's Eve in New York City, Backster went out into the bedlam of Times Square armed with a notebook and stopwatch. Mingling with the crowd, he noted his various actions, such as walking, running, going underground by way of subway stairs, nearly getting run over, and having a mild fracas with a news vendor. Back at the lab, he found that each of three plants, monitored independently, showed similar reactions to his slight emotional adventures.

To see if he could get a reaction from plants at a much greater distance, Backster experimented with a female friend to establish whether her plants remained attuned to her on a seven-hundred-mile plane ride across the United States. From synchronized clocks they found a definite reaction from the plants to the friend's emotional stress each time the plane touched down for its landing.

To test a plant's reaction at still greater distances, even millions of miles, to see if space is a limit to the "primary perception" of his plants, Backster would like the Mars probers to place a plant with a galvanometer on or near that planet so as to check by telemeter the plant's reaction to emotional changes in its caretaker at ground control on earth.

Since "telemetered" radio or TV signals traveling via electromagnetic waves at the speed of light take between six and six and one-half minutes to reach Mars and as many to return to Earth, the question was whether an emotional signal from an earthbound human would reach Mars faster than an electromagnetic wave or, as Backster suspects, the very instant it was sent. Were the round-trip time for a telemetered message to be cut in half it would indicate that mental or emotional messages operate outside time as we conceive it, and beyond the electromagnetic spectrum.

"We keep hearing about non-time-consuming communication from Eastern philosophic sources," says Backster. "They tell us that the universe is in balance; if it happens to go out of balance someplace, you

can't wait a hundred light-years for the imbalance to be detected and corrected. This non-time-consuming communication, this oneness among all living things, could be the answer."

Backster has no idea what kind of energy wave may carry man's thoughts or internal feelings to a plant. He has tried to screen a plant by placing it in a Faraday cage as well as in a lead container. Neither shield appeared in any way to block or jam the communication channel linking the plant to the human being. The carrier-wave equivalent, whatever it might be, Backster concluded, must somehow operate beyond the electromagnetic spectrum. It also appeared to operate from the macrocosm down to the microcosm.

One day when Backster happened to cut his finger and dabbed it with iodine, the plant that was being monitored on the polygraph immediately reacted, apparently to the death of some cells in Backster's finger. Though it might have been reacting to his emotional state at the sight of his own blood, or to the stinging of the iodine, Backster soon found a recognizable pattern in the graph whenever a plant was witnessing the death of some living tissue.

Could the plant, Backster wondered, be sensitive on a cellular level all the way down to the death of individual cells in its environment?

On another occasion the typical graph appeared as Backster was preparing to eat a cup of yogurt. This puzzled him till he realized there was a chemical preservative in the jam he was mixing into the yogurt that was terminating some of the live yogurt bacilli. Another inexplicable pattern on the chart was finally explained when it was realized the plants were reacting to hot water being poured down the drain, which was killing bacteria in the sink.

Backster's medical consultant, the New Jersey cytologist Dr. Howard Miller, concluded that some sort of "cellular consciousness" must be common to all life.

To explore this hypothesis Backster found a way of attaching electrodes to infusions of all sorts of single cells, such as amoeba, paramecium, yeast, mold cultures, scrapings from the human mouth, blood, and even sperm. All were subject to being monitored on the polygraph with charts just as interesting as those produced by the plants.

Sperm cells turned out to be surprisingly canny in that they seemed to be capable of identifying and reacting to the presence of their own donor, ignoring the presence of other males. Such observations seem to imply that some sort of total memory may go down to the single cell, and by inference that the brain may be just a switching mechanism, not necessarily a memory storage organ.

"Sentience," says Backster, "does not seem to stop at the cellular level. It may go down to the molecular, the atomic and even the subatomic. All sorts of things which have been conventionally considered to be inanimate may have to be re-evaluated."

Convinced of being on the track of a phenomenon of major importance to science, Backster was anxious to publish his findings in a scientific journal so that other scientists could check his results. Scientific methodology requires that a recorded reaction be repeatable by other scientists at other locations, with an adequate number of repetitions. This made the problem more difficult than anticipated.

To begin with, Backster found that plants can quickly become so attuned to human beings that it is not always possible to obtain exactly the same reactions with different experimenters. Incidents such as the "fainting" which occurred with the Canadian physiologist sometimes made it look as if there were no such thing as the Backster Effect. Personal involvement with an experiment, and even prior knowledge of the exact time an event was scheduled, was often enough to "tip off" a plant into noncooperation. This led Backster to the conclusion that animals subjected to excruciating vivisection may pick up the intent of their torturers and thus produce for them the very effects required in order to end the ordeal as rapidly as possible. Backster found that even if he and his colleagues discussed a project in their waiting room, the plants, three rooms away, could be affected by the imagery apparently generated by their conversation.

To make his point, Backster realized, he would have to devise an experiment in which all human involvement was removed. The entire process would have to be automated. Altogether it took Backster two and a half years and several thousand dollars, some of it provided by the Parapsychology Foundation, Inc., then headed by the late Eileen Garrett, to devise the right experiment and perfect the fully automated equipment necessary to carry it out. Different scientists of varying disciplines suggested an elaborate system of experimental controls.

The test Backster finally chose was to kill live cells by an automatic mechanism at a random time when no humans were in or near the office, and see if the plants reacted.

As sacrificial scapegoats Backster hit upon brine shrimp of the variety sold as food for tropical fish. It was important to the test that the victims demonstrate great vitality because it had been noted that tissue that is unhealthy or has begun to die no longer acts as a remote stimulus, is no longer capable of transmitting some type of warning. To see that brine shrimp are in good form is easy: in a normal condition, the males spend their whole time chasing and mounting females.

The device for "terminating" these playboy creatures consisted of a small dish which would automatically tip them into a pot of boiling water. A mechanical programmer actuated the device on a randomly selected occasion so that it was impossible for Backster or his assistants to know when the event would occur. As a control precaution against the actual mechanism of dumping registering on the charts, dishes were programmed at other times to dump plain water containing no brine shrimp.

Three plants would be attached to three separate galvanometers in three separate rooms. A fourth galvanometer was to be attached to a fixed-value resistor to indicate possible random variations caused by fluctuations in the power supply, or by electromagnetic disturbances occurring near or within the experiment's environment. Light and temperature would be kept uniform on all plants, which, as an extra precaution, would be brought from an outside source, passed through staging areas, and hardly handled before the experiment.

Plants selected for the experiment were of the *Philodendron cordatum* species because of its nice large leaves, firm enough to withstand comfortably the pressure of electrodes. Different plants of the same species would be used on successive test runs.

The scientific hypothesis which Backster wished to pursue was, properly phrased in the vernacular of science, that *"there exists an as yet* *undefined primary perception in plant life, that animal life termination can serve as a remotely located stimulus to demonstrate this perception capability, and that this perception facility in plants can be shown to function independently of human involvement."*

The experimental results showed that the plants did react strongly and synchronously to the death of the shrimp in boiling water. The automated monitoring system, checked by visiting scientists, showed that plants reacted consistently to the death of the shrimp in a ratio that was five to one against the possibility of chance.

The whole procedure of the experiment and its results were written up in a scientific paper published in the winter of 1968 in Volume X of *The International Journal of Parapsychology* under the title "Evidence of Primary Perception in Plant Life." It was now up to other scientists to see if they could repeat Backster's experiment and obtain the same results.

More than seven thousand scientists asked for reprints of the report on Backster's original research. Students and scientists at some two dozen American universities indicated they intended to attempt to duplicate Backster's experiments as soon as they could obtain the necessary equipment.* Foundations expressed interest in funding further experiments. The news media, which at first ignored Backster's paper, went into a flurry of excitement over the story once *National Wildlife* had the courage to take the plunge in February of 1969 with a feature article. This attracted such worldwide attention that secretaries and housewives began talking to their plants, and *Dracaena massangeana* became a household word.

Readers seemed to be most intrigued by the thought that an oak tree could actually quake at the approach of an axman, or that a carrot could shiver at the sight of rabbits, while the editors of *National Wildlife* were concerned that some of the applications of Backster's phenomenon to medical diagnosis, criminal investigation, and such fields as espionage were so fantastic that they dared not as yet repeat them in print.

Medical World News of March 21, 1969, commented that at last

*Backster has been loath to give out the names and places of these establishments so as not to have them importuned by outsiders until they have accomplished their tests and can make pondered announcements of their results at times of their own choosing.

ESP research might be "on the verge of achieving the scientific respectability that investigators of psychic phenomeña have sought in vain since 1882 when the British Society for Psychical Research was founded in Cambridge."

William M. Bondurant, an executive of the Mary Reynolds Babcock Foundation in Winston-Salem, North Carolina, produced a grant of $10,000 for Backster to pursue his research, commenting: "His work indicates there may be a primary form of instantaneous communication among all living things that transcends the physical laws we know now —and that seems to warrant looking into."

Backster was thus able to invest in more expensive equipment, including electrocardiographs and electroencephalographs. These instruments, normally used for measuring electrical emissions from heart and brain, had the advantage of not putting current through the plants, merely recording the difference in potential they discharged. The cardiograph enabled Backster to obtain readings more sensitive than the polygraph; the encephalograph gave him readings ten times more sensitive than the cardiograph.

A fortuitous occurrence led Backster into another whole realm of research. One evening, as he was about to feed a raw egg to his Doberman pinscher, Backster noticed that as he cracked the egg one of his plants attached to a polygraph reacted strenuously. The next evening he watched again as the same thing happened. Curious to see what the egg might be feeling, Backster attached it to a galvanometer, and was once more up to his ears in research.

For nine hours Backster got an active chart recording from the egg, corresponding to the rhythm of the heartbeats of the chicken embryo, the frequency being between 160 and 170 beats per minute, appropriate to an embryo three or four days along in incubation. Only the egg was store-bought, acquired at the local delicatessen, and was unfertilized. Later, breaking the egg and dissecting it, Backster was astonished to find that it contained no physical circulatory structure of any sort to account for the pulsation. He appeared to have tapped into some sort of force field not conventionally understood within the present body of scientific knowledge.

The only hint as to what sort of world he had wandered into came to Backster from the amazing experiments in the energy fields around plants, trees, humans, and even cells, carried out at the Yale Medical School in the 1930s and 1940s by the late Professor Harold Saxton Burr, which are only just beginning to be recognized and understood.

With these considerations Backster temporarily abandoned his experiments with plants to explore the implications of his egg discoveries, which appeared to have profound implications for the origin-of-life research—and are the makings of another whole book.

CHAPTER 2

Plants Can Read Your Mind

While Backster was developing his experiments in the eastern United States, a heavy-set research chemist working with International Business Machines in Los Gatos, California, was challenged to give a course in "creativity" for IBM engineers and scientists. It was only after Marcel Vogel had taken on the job that he realized the enormity of it. "How does one define creativity?" he found himself asking. "What is a creative person?" To answer these questions, Vogel, who had studied for years to become a Franciscan priest, began writing an outline for twelve two-hour seminars which he hoped would represent an ultimate challenge to his students.

Vogel's own probings into the realm of creativity had started when he was a boy, curious to know what caused the light in fireflies and glowworms. Finding little on luminescence in the libraries, Vogel informed his mother that he would write a book on the subject. Ten years later *Luminescence in Liquids and Solids and Their Practical Application* was published by Vogel in collaboration with Chicago University's Dr. Peter Pringsheim. Two years after that, Vogel incorporated his own company, called Vogel Luminescence, in San Francisco, which became a leader in the field. Over a period of fifteen years Vogel's firm developed a variety of new products: the red color seen on television screens; fluorescent crayons; tags for insecticides; a "black light" inspection kit to determine, from their urine, the secret trackways of rodents in cellars, sewers, and slums; and the psychedelic colors popular in "new age" posters.

By the mid-1950s Vogel became bored with his day-to-day tasks of administering a company and sold it to go to work for IBM. There he was able to devote his full time to research, delving into magnetics, optic-electrical devices, and liquid crystal systems, developing and patenting inventions of crucial significance to the storage of information in computers, and winning awards which adorn the walls of his San Jose home.

The turning point in the creativity course which Vogel was asked to give at IBM came when one of his students gave him an *Argosy* magazine with an article on Backster's work entitled "Do Plants Have Emotions?" Vogel's first reaction was to throw the article into the wastebasket, convinced that Backster was just another charlatan unworthy of serious consideration. Yet something about the idea gnawed at his mind. A few days later, Vogel retrieved the article, and completely reversed his opinion.

The article, read aloud to his seminar students, aroused both derision and curiosity. Out of this ruckus came the unanimous decision to experiment with plants. That same evening, one student called Vogel to announce that the latest issue of *Popular Electronics* referred to Backster's work, and included a wiring diagram for an instrument called a "psychanalyser," which would pick up and amplify reactions from plants and could be built for less than twenty-five dollars.

Vogel divided his class into three groups and challenged them to repeat some of Backster's accomplishments. By the end of the seminar, not one of the three teams had achieved any success. Vogel, on the other hand, was able to report that he had duplicated certain of Backster's results, and proceeded to demonstrate how plants anticipate the act of having their leaves torn, react with even greater alarm to the threat of being burnt or uprooted—more so even than if they are actually torn, burnt, or otherwise brutalized. Vogel wondered why he alone seemed to be successful. As a boy, he had been interested in anything which might explain the workings of the human mind. After dipping into books on magic, spiritualism, and hypnotic technique, he had given stage demonstrations as a teen-age hypnotist.

What particularly fascinated Vogel were Mesmer's theory of a universal fluid whose equilibrium or disturbance explained health or disease, Coué's ideas of autosuggestion as they related to painless childbirth and self-betterment, and the postulates of various writers on "psychic energy," a term popularized by Carl Jung, who, though he differentiated it from physical energy, believed it to be incommensurable.

Vogel reasoned that, if there was a "psychic energy," it must, like other forms of energy, be storable. But in what? Staring at the many chemicals on the shelves of his IBM laboratory, Vogel wondered which of them could be used to store this energy.

In his dilemma, he asked a spiritually gifted friend, Vivian Wiley, who went through the chemicals laid out for her and said that, in her judgment, none offered any promise of a solution for Vogel's problem. Vogel suggested she ignore his preconceived ideas about chemicals and use anything which might intuitively occur to her. Back in her garden, Vivian Wiley picked two leaves from a saxifrage, one of which she placed on her bedside table, the other in the living room. "Each day when I get up," she told Vogel, "I will look at the leaf by my bed and *will* that it continue to live; but I will pay no attention to the other. We will see what happens."

A month later, she asked Vogel to come to her house and bring a camera to photograph the leaves. Vogel could hardly believe what he saw. The leaf to which his friend had paid no attention was flaccid, turning brown and beginning to decay. The leaf on which she had focused daily attention was radiantly vital and green, just as if it had been freshly plucked from the garden. Some power appeared to be defying natural law, keeping the leaf in a healthy state. Curious to see if he could get the same results as his friend, Vogel picked three leaves from an elm outside his IBM laboratory; at home he laid them on a plate of glass near his bed.

Each day, before breakfast, Vogel stared concentratedly at the two outer leaves on the glass for about one minute, exhorting them lovingly to continue to live; the center leaf he assiduously ignored. In a week, the center leaf had turned brown and shriveled. The outer leaves were still green and healthy-looking. Most interesting to Vogel, the severed stems of the live leaves appeared to have healed the wounds caused by being ripped from the tree. Vivian Wiley continued her experiments and later showed Vogel the saxifrage leaf which she had kept green and alive for two long months while the control leaf was completely dehydrated and brown.

Vogel was convinced that he was witnessing the power of "psychic energy" in action. If the power of the mind could keep a leaf green way past its time, Vogel wondered what its effect might be on liquid crystals, an intensive study of which he was pursuing for IBM.

Trained in microscopy, Vogel had taken hundreds of color slides of liquid crystal behavior magnified up to three hundred times; when screened, they rival the works of a gifted abstract artist. While making the slides, Vogel realized that, by "relaxing his mind," he could sense activity not visually revealed in the microscopic field.

"I began to pick up things at the microscope which eluded others, not with ocular vision but with my mind's eye. After becoming aware of them," says Vogel, "I was led by some form of higher sensory awareness to adjust the lighting conditions to allow these phenomena to be optically recordable to the human eye or to a camera."

The conclusion at which Vogel arrived is that crystals are brought into a solid, or physical, state of existence by *pre-forms,* or ghost images of pure energy which *anticipate* the solids. Since plants could pick up intentions from a human, that of burning them, for example, there was no doubt in Vogel's mind that intent produced some kind of energy field.

By the fall of 1971, finding that his microscopic work was taking up most of his time, Vogel abandoned his research on plants. But when an article on this research quoting Dr. Gina Cerminara, psychologist and author of a popular book on the seer Edgar Cayce, appeared in the San Jose *Mercury*, and was wired by the Associated Press throughout the world, Vogel was besieged on the telephone for information, and was thus stimulated to continue.

Vogel realized that before he could observe with precision the effects on plants of human thoughts and emotion he would have to improve his technique of affixing electrodes to the plant leaves in such a way as to eliminate random electromagnetic frequencies, such as the hum of near-by vacuum cleaners, major sources of spurious data—or engineer's "noise"—which could cause the pen recorder to drift on the chart, and which obliged Backster to conduct most of his experiments between midnight and dawn.

Vogel also found that some of the philodendrons he worked with responded faster, others more slowly, some very distinctly, others less distinctly, and that not only plants but their individual leaves had their own unique personality and individuality. Leaves with a large electrical resistance were especially difficult to work with; fleshy leaves with a high water content were the best. Plants appeared to go through phases of activity and inactivity, full of response at certain times of the day or days of the month, "sluggish" or "morose" at other times.

To make sure that none of these recording effects was the result of faulty electroding, Vogel developed a mucilaginous substance composed of a solution of agar, with a thickener of karri gum, and salt. This paste he brushed onto the leaves before gently applying carefully polished one-by-one-and-a-half-inch stainless-steel electrodes. When the agar jelly hardened around the edges of the electronic pickups, it sealed their faces into a moist interior, virtually eliminating all the variability in signal output caused by pressure on leaves when clamped between ordinary electrodes. This system produced for Vogel a base line on the chart that was perfectly straight, without oscillations.

Having eliminated random influences, Vogel began a new round of experiments in the spring of 1971 to see if he could establish the exact moment when a philodendron entered into recordable communication with a human being. With a philodendron attached to a galvanometer which produced a straight base line, Vogel stood before the plant, completely relaxed, breathing deeply and almost touching it with outspread fingers. At the same time, he began to shower the plant with the same kind of affectionate emotion he would flow to a friend. Each time he did this, a series of ascending oscillations was described on the chart by the pen holder. At the same time Vogel could tangibly feel, on the palms of his hands, an outpouring from the plant of some sort of energy.

After three to five minutes, further release of emotion on Vogel's part evoked no further action from the plant, which seemed to have "discharged all its energy" in response to his ministrations. To Vogel, the interreaction between himself and the philodendron appeared to be on the same order as that evoked when lovers or close friends meet, the intensity of mutual response evoking a surge of energy until it is finally expended and must be recharged. Like lovers, both Vogel and the plant appeared to remain suffused with joy and contentment.

In a botanical nursery, Vogel found that he could easily pick out a particularly sensitive plant by running his hands over a group until he felt a slight cooling sensation followed by what he describes as a series of electrical pulses, indicating a powerful field. Increasing the distance between himself and the plant, Vogel found, like Backster, that he could get a similar reaction from it, first from outside the house, then from down the block, and even from his laboratory in Los Gatos, eight miles away.

In another experiment, Vogel wired two plants to the same recording machine and snipped a leaf from the first plant. The second plant responded to the hurt being inflicted on its neighbor, but *only when Vogel was paying attention to it!* If Vogel cut off a leaf while ignoring the second plant, the response was lacking. It was as if Vogel and the plant were lovers on a park bench, oblivious of passers-by until the attention of one lover became distracted from the other.

From his own experience, Vogel knew that masters of the art of Yoga, and teachers of other forms of deep meditation such as Zen, are unaware of disturbing influences around them when in meditative states. An electroencephalograph picks up from them quite a different set of brain waves than when the same persons are alert to the everyday world around them. It became clearer to Vogel that a certain focused state of consciousness on his part seemed to become an integral and balancing part of the circuitry required to monitor his plants. A plant could be awakened from somnolence to sensitivity by his giving up his normally conscious state and focusing a seemingly extra-conscious part of his mind on the exact notion that the plant be happy and feel loved, that it be blessed with healthy growth. In this way, man and plant seemed to interact, and, as a unit, pick up sensations from events, or third parties, which became recordable through the plant. The process of sensitizing both himself and the plant, Vogel found, could take only a few minutes or up to a half hour.

Asked to describe the process in detail, Vogel said that first he quiets the sensory responses of his body organs, then he becomes aware of an energetic relationship between the plant and himself. When a state of balance between the bioelectrical potential of both the plant and himself is achieved, the plant is no longer sensitive to noise, temperature, the normal electrical fields surrounding it, or other plants. It responds only to Vogel, who has effectively tuned himself to it—or perhaps simply hypnotizes it.

Vogel now felt confident enough to accept an invitation to make a public demonstration with a plant. On a local TV program in San Francisco, the plant, coupled to a pen recorder, gave a live illustration of varying states of Vogel's mind, running from irritation at an interviewer's questions to quiet tracings established when Vogel was in harmonious intercommunication with the plant. For the producer of ABC's television program *You Asked for It*, Vogel also demonstrated the plant's response to his or another person's thoughts, including a sudden release of strong emotion on command, followed by the act of his quieting the plant to normal reactions to its environment.

Invited to lecture to audiences who had heard of his experimentation, Vogel said unequivocally: "It is fact: man can and does communicate with plant life. Plants are living objects, sensitive, rooted in space. They may be blind, deaf, and dumb in the human sense, but there is no doubt in my mind that they are extremely sensitive instruments for measuring man's emotions. They radiate energy forces that are beneficial to man. One can feel these forces! They feed into one's own force field, which in turn feeds back energy to the plant." The American Indians, says Vogel, were keenly aware of these faculties. When in need, they would go into the woods. With their arms extended, they would place their backs to a pine tree in order to replenish themselves with its power.

When Vogel began to demonstrate plants' sensitivity to "states of attention" different from the supposed awareness which most humans like to call consciousness, he discovered that the reaction of skeptics or hostile observers could produce strange effects on him. By paying attention to negative attitudes emanating from an audience, Vogel found he could isolate the individuals emitting them and counter their effect with a deep breath, learned in Yoga instruction. He would then switch his mind to another mental image just as if he were turning a dial to a different setting.

"The feeling of hostility, of negativity, in an audience," says Vogel, "is one of the main barriers to effective communication. To counteract this force is one of the most difficult tasks in public demonstration of these plant experiments. If one cannot do this, the plant and therefore the equipment will 'go dead' and there is no response until a positive tie can be reestablished.

"It seems," he says, "that I act as a filtering system which limits the response of a plant to the outside environment. I can turn it off or on so that people and plant become mutually responsive. By charging the plant with some energy within me, I can cause the plant to build up a sensitivity for this kind of work. It is extremely important that one understand that the plant's response is, in my opinion, not that of an intelligence in plant form, but that the plant becomes an extension of oneself. One can then interact with the bioelectric field of the plant, or through it, with the thought processes and emotions in a third person."

Vogel concluded that a Life Force, or Cosmic Energy, surrounding all living things is sharable among plants, animals, and humans. Through such sharing, a person and a plant become one. "This oneness is what makes possible a mutual sensitivity allowing plant and man not only to intercommunicate, but to record these communications via the plant on a recording chart."

Because his observations indicated there was an interchange, even a commingling or fusion of energies when plant and man commune, Vogel wondered whether an exceptionally sensitive individual could get *into* a plant, as was reported of the sixteenth-century German mystic Jakob Boehme, who, as a young man, became illumined and described being able to see in another dimension.

Boehme said he could look at a growing plant and suddenly, by willing to do so, mingle with that plant, be part of the plant, feel its life "struggling toward the light." He said he was able to share the simple ambitions of the plant and "rejoice with a joyously growing leaf."

One day Vogel was visited in San Jose by Debbie Sapp, a quiet, self-effacing girl who impressed Vogel with her initial ability to enter into instant rapport with his philodendron, as established by his instrumentation.

When the plant was entirely calm, he asked her, point blank: "Can you get into that plant?" Debbie nodded assent, and her face took on an attitude of quiet repose, of detachment, as if she were far away in another universe. Immediately the recording pen began to trace a pattern of undulations revealing to Vogel that the plant was receiving an unusual amount of energy.

Debbie later described what happened in writing:

> Mr. Vogel asked me to relax and project myself into the philodendron. Several things took place as I began to carry out his request.
>
> First, I wondered exactly how I could get inside a plant. I made a conscious decision to let my imagination take over and found myself entering the main stem through a doorway at its base. Once inside, I saw the moving cells and water traveling upward through the stem, and let myself move with this upward flow.
>
> Approaching the spreading leaves in my imagination, I could feel myself being drawn from an imaginary world into a realm over which I had no control. There were no mental pictures, but rather a feeling that I was becoming part of, and filling out, a broad expansive surface. This seemed to me to be describable only as pure consciousness.
>
> I felt acceptance and positive protection by the plant. There was no sense of time, just a feeling of unity in existence and in space. I smiled spontaneously and let myself be one with the plant.
>
> Then Mr. Vogel asked me to relax. When he said this, I realized I was very tired but peaceful. All of my energy had been with the plant.

Vogel, who was observing the recording on the chart, noticed an abrupt stop when the girl "came out" of the plant. On later occasions, when the girl "re-entered" the plant, she was able to describe the inner makeup of its cells and their structure in detail. She specifically noted that one of the leaves had been badly burned by an electrode. When Vogel detached the electrode, he found a hole almost all the way through the leaf.

Vogel has since tried the same experiment with dozens of other people, having them go into a single leaf and look at the individual cells within it. All gave consistent descriptions of various parts of the cellular body down to the detailed organization of the DNA molecules. From the experiment, Vogel came to the conclusion: "We can move into individual cells in our own bodies and, depending on our state of mind, affect them in various ways. One day, this may explain the cause of disease."

The ability to go into a plant and analyze what part of it is hurt was demonstrated on TV film on Good Friday, 1973, when Vogel and Dr. Tom Montelbono, who had been working with him for over a year, were filmed during plant experimentation by a TV production team from CBS. It was highly embarrassing to both researchers that the plant seemed not to respond. Vogel asked Montelbono to see if there was something wrong with the electroding. Instead of tampering with the electrodes, Montelbono, to the astonishment of the CBS technicians, sat where he was and after a moment's concentration announced that damaged cells in the upper right-hand corner of the electroded part of the leaf were shorting the electrical circuit. In the presence of the TV men the electrodes were removed and the leaf was found to be damaged exactly where Montelbono had said.

Because Vogel knows that, among all humans, children are the most "open-minded," he has begun to teach children how to interact with plants. First, he asks them to feel a leaf, describe its temperature, consistency, and texture in detail. Next, he lets them bend leaves and become aware of their resilience before going on to pet the leaves gently by stroking their upper and under sides. If his pupils take pleasure in describing to him the sensations they feel, Vogel asks them to take their

hands away from the leaves and try to feel a force or energy emanating from them. Many of the children instantly described a rippling or tingling sensation.

Vogel noticed that those children who felt the strongest sensations were wholly engrossed in what they were doing. Once they felt the tingling, he would say: "Now completely relax and feel the give-and-take of the energy. When you feel it pulsing, gently move your hand up and down over the leaf." Following his directions, the young experimenters could easily see that, when they brought their hands down, the leaves fell away. By continued repetition of this motion, the leaves would begin to oscillate. With the use of both hands, the experimenters could actually get a plant to sway. As they gained confidence, Vogel urged them to move further and further away from the plant.

"This is basic training," says Vogel, "to develop an expanded awareness of a force which is not visible. The awareness established, they see they can operate with this force."

Adults, according to Vogel, are much less successful than children, which leads him to surmise that many scientists are not going to be able to repeat his or Backster's experiments in laboratories. "If they approach the experimentation in a mechanistic way," says Vogel, "and don't enter into mutual communication with their plants and treat them as friends, they will fail. It is essential to have an open mind that eliminates all preconceptions before beginning experiments." Indeed, Vogel was told by one doctor working at the California Psychical Society that he had had not a single result, though he had worked for months. The same is true for one of Denver's most renowned psychoanalysts.

"Hundreds of laboratory workers around the world," says Vogel, "are going to be just as frustrated and disappointed as these men until they appreciate that the empathy between plant and human is the *key*, and learn how to establish it. No amount of checking in laboratories is going to prove a thing until the experiments are done by properly trained observers. Spiritual development is indispensable. But this runs counter to the philosophy of many scientists, who do not realize that creative experimentation means that the *experimenters must become part of their experiments.*"

This highlights the difference in approach between Vogel and Backster, indicating, perhaps, that Vogel is establishing a type of hypnotic control over his plants, whereas Backster says that his plants, left strictly alone, will quite normally react to their environment.

Vogel says that even when a person *can* affect a plant, the result is not always a happy one. He asked one of his friends, a clinical psychologist, who had come to see for himself if there was any truth to the plant research, to project a strong emotion to a philodendron fifteen feet away. The plant surged into an instantaneous and intense reaction and then, suddenly, "went dead." When Vogel asked the psychologist what had gone through his mind, the man answered that he had mentally compared Vogel's plant with his own philodendron at home, and thought how inferior Vogel's was to his. The "feelings" of Vogel's plant were evidently so badly hurt that it refused to respond for the rest of the day; in fact, it sulked for almost two weeks. Vogel could not doubt that plants have a definite aversion to certain humans, or, more exactly, to what those humans are thinking.

This being true, Vogel considered it possible, one day, to read a person's thoughts through a plant. Something of the sort had already taken place. Vogel had asked a nuclear physicist to mentally "work" on a technical problem. As the man was cogitating, Vogel's plant registered a series of tracings on the recorder for 118 seconds. When the tracing fell back to base line, Vogel informed his scientist friend that he had stopped his train of thought. The friend corroborated.

Vogel wondered if he had actually captured a process on a chart via a plant. After a few minutes, he asked the physicist to think of his wife. When the physicist did so, the plant again recorded a tracing, this time for 105 seconds. It seemed to Vogel that, right before him in his living room, a plant was picking up and passing on a man's mental impressions of his wife. If one could interpret such tracings, could one not know what the man was thinking?

After a break for a cup of coffee, Vogel almost casually asked his friend to think once more of his wife in the same way he had thought of her before. The plant registered another 105-second-long tracing very similar to the first. To Vogel this was the first time a plant seemed to have recorded a similar thought spectrogram and duplicated it.

"By pursuing such experiments," says Vogel, "we may have a means of technically identifying energies coming from the human mind, translating them, and feeding them back into an as yet undeveloped device. A whole evening of thinking may be made explicit."

Entertaining a group of skeptical psychologists, medical doctors, and computer programmers at his house, Vogel let them look over his equipment for hidden devices and gimmicks which they insisted must exist, then asked them to sit in a circle and talk so as to see what reactions the plant might pick up. For an hour the group conversed on several topics with hardly a response from the plant. Just as they had all concluded that the whole thing was a fake, one of them said: "How about sex?" To their mutual surprise, the plant came to life, the pen recorder oscillating wildly on the chart. This led to speculation that talking of sex could stir up in the atmosphere some sort of sexual energy such as the "orgone" discovered and described by Dr. Wilhelm Reich, and that the ancient fertility rites in which humans had sexual intercourse in freshly seeded fields might indeed have stimulated plants to grow.

The plant also responded to spooky stories told in a darkened room lit only by a red-shaded candle. At certain points in a story, such as: "The door of the mysterious cabin in the forest began slowly to open," or, "Suddenly there appeared around the corner a strange man with a knife in his hand," or "Charles bent down and raised the lid of the coffin," the plant seemed to pay closer attention. To Vogel, this was evidence that a plant can measure "figments of the imagination," being converted to energy by the group as a whole.

Dr. Hal Puthoff, a physicist at the Stanford Research Institute in Palo Alto, invited Vogel and five other scientists to witness the effects he was getting by hooking up a chicken egg to the electro-psychometer, or "E-meter," developed by L. Ron Hubbard, the founder of Scientology. The E-meter's function is almost identical to that of the psychoanalyzer which Vogel had first used with his seminar students. Puthoff attempted to demonstrate that the egg wired to the E-meter would respond when another egg was broken. He broke three separate eggs, but nothing happened. After asking Puthoff if he could try, Vogel put his hand over an egg and related to it exactly as he had learned to relate to his plants. In one minute, the needle on the E-meter's galvanometer dial began to move and finally "pinned." Vogel backed ten feet away and got gyrations from the needle by opening and closing his hands. Though Puthoff and several others present tried to do the same, all failed.

The needle's movement, once thought to be affected by resistance on the skin of humans attached to electrodes, is known as Galvanic Skin Response, or GSR. Since plants have no skin, in the human sense, the term for the effect on plants has been changed to Psycho-Galvanic Response, or PGR.

"The PGR," says Vogel, "exists not only in plants, but in all living forms. The directive action of the mind focuses this energy and, on command, releases the force in a series of pulses which can pass through glass, metals, and other materials. No one yet knows exactly what they are."

In Russia, a psychic called Nina Kulagina can turn the needle of a compass without touching it but she has to do it with her hands near the compass; more impressive feats have been demonstrated at Stanford University, especially by the remarkably sensitive Ingo Swann, who attributes his success to techniques he learned in Scientology. With nothing but his will power, Swann has been able to affect a mechanism in the university's most thoroughly shielded "quark" chamber, buried deep underground in a vault of liquid helium, impenetrable to any known wave length of the electromagnetic spectrum, astonishing the academic physicists who watched him perform what they considered to be an impossible feat.

Vogel stresses that experiments with plants can be extremely dangerous to those who do not have the ability properly to alter their states of consciousness. "Focused thought," says Vogel, "can exert a tremendous effect on the body of a person in a higher mental state, if he lets his emotions interfere."

No one, says Vogel, who is not in sound bodily health should become involved with plants or any other kind of psychic research. Though he has not been able to prove it, Vogel feels that a special diet of vegetables, fruits, and nuts, rich in minerals and proteins, allows the body to build the kind of energy necessary for such work. "One draws energy at high levels," he said, "and this requires good nutrition."

Asked how the higher energies, such as thought, might operate on the physical bodies of living organisms, Vogel says he has now begun to speculate on the strange properties of water. As a crystallographer, he is interested in the fact that, unlike most salts, which have one crystalline form, core samples of glacier ice have more than thirty different forms. "Uninitiated persons, when first looking at them," says Vogel, "could conclude that they were observing as many different substances. And they would be right in their own way because water is a real mystery."

Vogel makes the prediction, which he stresses is as yet far from established fact, that since living things all have a high water content, the vitality of a person must be in some way related to the rate of respiration. As water moves around the body and through its pores, charges are built. Vogel's first clue about his postulate on water came from the fact that some "psychics" have lost several pounds of body weight during sessions in which they expended vital, or psychic, energy. "If we could weigh a person doing psychic research on a sensitive scale," suggests Vogel, "we would find that there is a loss of weight in each case. It is a water loss, as it is in persons who go on crash diets."

Whatever the future brings, Vogel believes that his research with plants can help man to the recognition of long-ignored truths. By developing simple training kits, which he is presently designing, he thinks he can teach children to release their emotions and watch the effects in a measurable way.

"They can thus learn the art of *loving,*" says Vogel, "and know truly that when they think a thought they release a tremendous power or force in space. By knowing that they *are* their thoughts, they will know how to use thinking to achieve spiritual, emotional, and intellectual growth.

"This is no machine to measure brain waves or any gimmick to help people to become seers or mystics," Vogel insists, "but one to help children to become *simple, honest human beings.*"

Asked to sum up the importance of his research with plants, Vogel replied: "So much of the ills and suffering in life comes from our inability to release stresses and forces within us. When a person rejects us, we rebel inside and we *hold on to this rejection.* This builds a stress which, as Dr. Wilhelm Reich showed so long ago, becomes locked in as muscular tension, and if not unlocked, depletes the body's energy field and alters its chemistry. My research with plants indicates one pathway to deliverance."

For Marcel Vogel, plants have opened new horizons. The vegetal kingdom seems capable of picking up messages of intent, benign or malicious, that are inherently more truthful than when translated into words—a talent which all human beings may share but which they have momentarily occluded.

Two young Californian students of humanistic psychology and Hindu philosophy, Randall Fontes and Robert Swanson, have now pursued Vogel's quarry into unbeaten ground. Using sophisticated equipment lent them by the IBM researcher, they have made a series of discoveries so surprising that despite their youth they have been granted funds and equipment by established universities to further probe the mysteries of plant communication.

Fontes' and Swanson's first discovery came virtually by accident when one noticed that the other's yawning was being picked up by a plant in the form of energy surges. Instead of ignoring the phenomenon as improbable, the two students followed up the clue remembering that in ancient Hindu texts an exaggerated yawn was considered a means by which a tired person could be recharged with vivifying *shakhti*, a postulated energy filling the universe.

With the help of Dr. Norman Goldstein, a professor of biology at State University in Hayward, California, Fontes went on to discover an electrical potential traveling from cell to cell in the ivy philodendron which gives a strong indication of the presence of a hitherto unsuspected simple nervous system. As a result, Fontes has been invited to direct a project at the Science Unlimited Research Foundation in San Antonio, Texas, on the effects of human consciousness on living organisms. Meanwhile, Swanson is cooperating in the setting up of a parapsychologically oriented counseling center at the John F. Kennedy University in Martinez, California, where one of Swanson's goals is to determine just which people affect plants telepathically and which do not.

CHAPTER 3

Plants That Open Doors

Next to probe the mysteries of plant communication was an "electronics specialist" from West Paterson, New Jersey, who happened to hear Backster interviewed on a radio program hosted by Long John Nebel. An assiduous investigator of ESP and of the phenomenon of remote hypnotism, Pierre Paul Sauvin was equally at home in the "state of the art" and "feasibility considerations" of the engineer, mostly because of his training and employment for several large corporations, including Aerospace and International Telephone and Telegraph.

When Long John—a professional skeptic—roped Backster into a corner to get him to describe some practical uses for his discovery of primary perception in plants, Backster first suggested the exotic notion that in jungle warfare soldiers in dangerous territory could wire up the local plants to act as "stress alarm indicators" and avoid being ambushed. "But if you really want to make a psychologist sit up and take notice," Backster told Long John, "you could instrument a plant to activate a small electric train, getting it to move back and forth on no other command than that of human emotion."

This notion, though singularly impractical, could be spelled out in Sauvin's electronics jargon as an "anxiety response device," and so fired him that he turned his bachelor quarters in a house overlooking the Passaic River into a Merlin's cave of electronic equipment.

Sauvin claims that many of his insights and ideas for inventions come to him in psychic flashes, as if he were merely acting as a medium. He says he sometimes gets the factual data necessary for an invention without fully understanding the principle, or how it relates to the whole, and must get further details by questions addressed to "levels beyond."

Using high-voltage generators which produce the sort of lightning arcs usually associated with Dr. Frankenstein, Sauvin can put 27,000 volts through his body and remotely activate a large doughnut bulb filled with helium to serve as an electronic ouija board, its dark rings flowing in one direction or the other in answer to his questions. He also developed a system guaranteed to hypnotize *anyone,* even the most recalcitrant, by placing the subject on an unstable platform in a pitch-black room and swaying before him a rainbow pattern of light that causes him to lose his balance.

With such exotic expertise it was not long before Sauvin had a toy electric train running round a track and reversing its direction through nothing but his thought and emotion relayed to a plant. He was able not only successfully to demonstrate the phenomenon before an audience of sixty in Madison, New Jersey, but to make the train start and stop at will under the klieg lights of a television studio.

As the engine moved around the track it would activate a switch leading to Sauvin's body in such a way as to give him a sharp electric shock. Just ahead on the track, another switch was wired to a galvanometer attached to an ordinary philodendron. As the philodendron picked up Sauvin's emotional reaction at being shocked, the galvanometer needle would jump and throw the switch, reversing the train. The next step was for Sauvin simply to remember the sensation of being shocked and project it in order for the plant to activate the switch.

Though Sauvin had long been interested in parapsychology and was fascinated with the psychological implications of a plant responding to human thought and emotion, his main preoccupation was the development of a foolproof plant device that could be activated by any human being. For Sauvin's purposes it did not matter whether the plant was in any way rational or feeling, so long as it could reliably pick up his emotional signal and trigger the switch. Whether plants were "conscious" or not, Sauvin was convinced they had an energy field similar to the energy field generated by a human being, and that somehow an interaction of these fields could be put to use. The problem was to develop equipment sensitive enough to take advantage of the phenomenon in an absolutely reliable way.

Perusing the endless stream of trade journals that passed across his desk as a technical writer for ITT, Sauvin was struck by a series of articles in *Popular Electronics*, on unusual electronic circuits and exotic weaponry, by a mysterious writer named L. George Lawrence. The author, intrigued by the Russian development of animal guidance systems for training cats to pilot nonjammable air-to-air missiles right onto target, speculated in his articles on training plants to respond to the presence of selected objects and images, evidently for a similar purpose. Rumored to be a high government official involved in security research writing under a pseudonym, Lawrence is in fact a European-born engineer, formerly a professor of audio-visual arts at San Bernardino College in California, presently the director of his own independent research institute.

Unfortunately, the components for sophisticated circuits such as those devised by Lawrence—though worth mere pennies, in terms of materials—would cost thousands of dollars of engineering man-hours to produce, and were in any case not available on the market. But from one of Sauvin's jobs as a specifications engineer on a large government contract he had salvaged what might be just the right pieces—some phase-looplocked discriminators pressed into microelectronic silicon wafers that had been junked by the lab as unfit for the temperature requirements of space.

With these "chips" Sauvin was able to build a Wheatstone bridge for measuring electrical potential with alternating instead of direct current, and an automatic gain control circuit by means of which he hoped to be able to distinguish very fine changes in the energy fields of plants. The sensitivity achieved was one hundred times greater than could be obtained with Backster's galvanometer and eliminated enormous amounts of electronic "noise."

What Sauvin was now measuring was no longer voltage amplitude but phase shift, or the fine lag between two running voltages. The result gave Sauvin an instrument roughly comparable to an ordinary light-dimmer switch, in which a plant leaf acted as the switch. Variations of apparent resistance in the leaf would cause a light to get brighter or dimmer depending on the response of the plant to outside effects.

As soon as his device was functioning, Sauvin set about monitoring plants around the clock. To catch the tiniest nuances of phase shift Sauvin hooked his plants to an oscilloscope, a big electronic green eye with a figure eight of light whose loops changed shape as the current from a plant varied, making patterns much like the fluttering of the wings of a butterfly. Simultaneously, a varying tone was produced by current run through an amplified tone oscillator which enabled Sauvin to hear minute changes in vibrations, and know how his plants were reacting. A bank of tape recorders kept a permanent record of the oscillating tone, along with a monotonous beep every second from a WWV international time-signal broadcast. With a stopwatch Sauvin could run a check on the effect he was having on his plants from a distance, whether down the street, at ITT, or off on a holiday.

Some of Sauvin's Merlin equipment now came into its own, especially a complex system of automatic phone-answering and recording devices. For some years Sauvin had been carrying on a moonlighting operation writing for various specialized magazines, under various pseudonyms while retaining his regular job. To keep his cover and not arouse the displeasure of his masters at ITT and yet be able to consult with his editors and answer their queries any time during the day, Sauvin had devised an ingenious system. By means of a small radio transmitter strapped to his leg and a battery of automated and preprogrammed tape machines at home he could communicate via his home phone, receiving messages and giving answers, all from his desk at ITT. For various editors to identify themselves to Sauvin's automatic equipment he developed such simple tricks as having an editor run his finger along a pocket comb close to the phone mouthpiece, generating an easily identifiable sound wave which would trigger from the automatic equipment the appropriate reply. As a cover for his own low-toned conversations from his desk, Sauvin developed the habit of humming to himself most of the time he was at work, soon becoming known as the "hummer" of ITT.

This Rube Goldberg equipment served Sauvin admirably for remote-controlled communication with his plants. He could call his own number and speak to his plants directly; he could monitor the tones of their response via the amplified audio-oscillator, and from wherever he might be he could control the light, color, temperature, or recording equipment in his quarters.

When electroding his plants Sauvin gradually realized that like Vogel he could obtain the best results from plants with which he established a special mental rapport. This he would accomplish by putting himself into a light trance, wishing the plant well, tenderly touching or washing its leaves, till he could feel his own energy emanations entering and interplaying with those of the plant.

Like Backster, Sauvin found that his plants reacted most strongly to the death of living cells in their environment, and most consistently to the death of human cells. He also found in the course of his various experiments that the simplest signal he could transmit to his plants, extrasensorily, to which they would respond with a sharp enough reaction, was to give himself a light electric shock, the very simplest method being to swivel his desk chair and then ground the accumulated static charge by touching his finger to his metal desk. His plants several miles away would react with an instant surge. Just as with the train experiment, Sauvin eventually found that he merely needed to remember or re-feel a shock for his plants to pick up the signal, even from as far away as his holiday cottage eighty miles north of his West Paterson lab.

As Sauvin's main problem remained that of getting his plants to be sharply attuned to his person rather than to their immediate enviro ment, when he was away for several days, he had to devise some mea of attracting his plants' attention even more effectively than addressi them over the long-distance phone. As his plants reacted most strong to any damage done to himself or to any part of his own energy fie he experimented with *remotely* killing a few cells of his body in t presence of the plants. The system worked admirably. The problem w to obtain cells that would remain alive for protracted periods. Blo worked well enough, hair was difficult to kill, but sperm worked best all, because, as Sauvin explained, it was easier to obtain than bleedi and much less painful.

These experiments led Sauvin to wonder if plants might not react ju as well to emotions of pleasure and joy as to pain and shock. Not on was he tired of shocking himself, he was afraid that repeated shocks his plants, even indirect ones, might be unpleasantly loading his karm Sauvin soon found that his plants did react to joy and pleasure, but wi wave patterns that were not sharp enough to trigger a switch reliab Undaunted, Sauvin decided on a more daring experiment. During holiday with a girl friend at his lakeside cottage he established that h plants, eighty miles away, would react with very high peaks on the to oscillator to the acute pleasure of sexual climax, going right off the t at the moment of orgasm. All of which was very interesting and cou be turned into a commercially marketable device for jealous wives monitor their philandering husbands, by means of a potted begonia. B it was not yet conducive to a simple, foolproof system of getting a pla to trigger a switch consistently.

There was no question in Sauvin's mind that he could affect a pla at a distance; but he could not rely on the system for any really sensiti fail-safe purpose because his plant might at any time react to som stimulus in its own environment, such as the sudden appearance of a c or of a bird outside the window snapping up an insect. Sauvin therefo wired three plants, each set in a different room, and thus in a differe environment, to a single circuit which could only be activated if all thr plants reacted synchronously. By keeping the plants in separate enviro ments Sauvin hoped the required stimulus would be synchronous on when it came from him, wherever he might be. This was still not positively foolproof, because at times one plant or the other might not fully react to the stimulus, but it was a step forward in that it prevented any random stimulus from affecting all three plants at once.

Sauvin was now anxious to release his data confirming Backster's findings and to make public his own contribution to a science which he felt had a potential for the world no less great than Marconi's use of radio waves. But in a country where government and industrial executives are less interested in the quaint notion of communing with nature than in developing sophisticated weapons of offense and the gadgetry of mind surveillance, Sauvin had a hard time finding either a sponsor or an audience.

Unable to interest the mass media, or such conservative journals as *Science* or *Scientific American*, Sauvin decided to angle his material to the engineering and mechanical journals to which he was already a regular contributor. To incite the interest of the editor of a car magazine he concocted a story about a device that would enable him to start his car by remote control by means of thought waves to a plant. With the help of a small radio transmitter this proved to be a simple enough operation, the only technical difficulty being the designing of a gadget that would give just the right pressure to the ignition key, repeat the pressure if the engine failed to catch, and release pressure the moment it did.

The device was designed to appeal to a citizen with the prospect of being able to wake up on a frosty morning and get his car and heater started while still comfortably enjoying his breakfast. But for Sauvin there was one defect: a plant was not really needed; the device could be operated directly by radio. To include his beloved plants in a worthwhile gadget attractive to automobile and home owners, Sauvin cooked up a system whereby a man returning on a snowy night could approach his garage and signal his pet philodendron to open the doors. Here the plant's function of responding only to its master would make it admirably burglar-proof.

To arouse the interest of serious scientists who might wish to provide Sauvin with the necessary funds for a proper lab, Sauvin hit upon the idea of showing that an airplane could be flown by thought control wit the aid of his plants attached to his sensitive devices. For years Sauvin already a licensed pilot, had enjoyed the hobby of flying model plane some with a wing spread as large as six feet, controlling them entirel from the ground by radio signals, getting them to bank, loop, speed up slow down, and even land. By a slight adaptation to his transmitte equipment Sauvin is able to start, stop, or affect the speed of a mode plane in flight by transmitting a thought to a plant.

In the sensitivity of plants Sauvin also saw a means of detecting potential hijacker at an airport before such a criminal could board plane and endanger passengers. He therefore suggested "Operation Sky jack," a system whereby plants could be used in conjunction with galva nometers and other sensitive devices to pick up the turbulent emotion of a hijacker being screened by security, the problem at an airport bein to safeguard not only the lives of passengers but their rights as citizen not to be subjected to unwarranted search.

Already the U.S. Army has taken an interest in the project. At For Belvoir, Virginia, funds have been provided for research on plants. Th Army is interested in devising ways of measuring the emotional re sponses of people via plants, without having to sensitize the plants t a special person beforehand.

The Navy is also showing interest. Eldon Byrd, an operations analy with the Advanced Planning and Analysis Staff of the Naval Ordnan Laboratory in Silver Spring, Maryland, has been duplicating Backster experiments with some success. A member of the American Society fo Cybernetics and senior member of the Institute for Electrical and Ele tronic Engineers, Byrd attached the electrodes of a polygraph to th leaves of a plant, and has been observing definite fluctuations of th polygraph needle as the plant responds to various stimuli. Like Backste Byrd found that by merely thinking of harming a plant's leaf it w possible to make the polygraph needle jump. Byrd's experiments i volved monitoring a plant's reaction to stimuli from water, infrared ar ultraviolet light, fire, physical stress, and dismemberment.

Byrd believes the galvanometrical effect produced by a plant is n caused by electrical resistance in the leaf, but by a change of bi potential in the cells from outside to the inside membrane, as defined by the Swedish Dr. L. Karlson, who has shown that a cluster of cells can change polarity, though the energy which causes cells to become polarized is not known. Byrd believes that a voltage change in the cells is what is being measured, and that it is the mechanism of consciousness which causes the change in potential.

Byrd's research supports Backster's observations that plants exhibit a quality of awareness and an empathy to other organisms that are stimulated in their presence. Like Backster, Byrd also found a major problem in his experiments to be the plants' tendency to "faint" under excess stress, suddenly ceasing to respond even to the most basic stimuli, such as light and heat. Like Backster and Sauvin, Byrd was able to demonstrate on television a plant's reaction to various stimuli, including his *intent* to burn it. On camera Byrd got a plant to respond to his shaking a spider in a pill box. The plant responded with about a second's delay, the response continuing as long as a minute. He also got a strong reaction when cutting the leaf from another plant.

Byrd, who has a master's degree in medical engineering from George Washington University and is a member of Mensa, a worldwide organization whose primary requirement is an extremely high intelligence quotient, has no ready solution to explain the apparent response of plants to human thoughts, and is open to widely disparate explanations, including alterations of the earth's magnetic field, supernatural and spiritual phenomena, and the mysterious mechanics of bioplasma. In a paper presented in 1972 to the American Society of Cybernetics, Byrd reviewed numerous Russian experiments with thought transmission via "bioplasma," which certain Soviet scientists claim to be a previously undiscovered form of energy.

In May, 1973, Byrd began to set up an experiment to instrument the tiny leaves of *Mimosa pudica,* which are so sensitive that they collapse when touched. Byrd believes that, by using a thin wire barely touching a mimosa leaf, he can pick up through a special amplifier minute changes in voltage or resistance. Also available to Byrd is one of the world's finest chart recorders, made in West Germany by Siemens, which shoots out more than three feet of recording paper per second with the patterns recorded by a jet of ink only a few microns wide. With these devices Byrd hopes to be able to pick up plant reactions which have hitherto gone unnoticed.

Byrd is also planning to work with a primitive marine alga, *Acetabularia cremulata,* which, though two inches long, is made up of only a single cell. If this monocellular plant exhibits the "Backster Effect," Byrd will then surgically remove its nucleus. If it then fails to respond, Byrd hopes this will offer proof that the genetic material in the nuclei of plant cells is chiefly responsible for plant response.

A revolutionary new lie-detector device known as a Psychological Stress Evaluator has also been made available to Byrd, along with lab space and facilities, by Allan Bell, inventor of the device, who is president of Dektor Counter Intelligence Systems, a firm he recently formed with two other ex-intelligence officers. The device, tested by monitoring twenty-five segments of the television program *To Tell the Truth,* is said to have picked the persons who were telling the truth with 94.7 percent accuracy. The theory behind the device is that the human voice normally operates in both audible frequencies and inaudible frequency modulations, except when a person is under stress. According to the inventors of the device, when the inaudible FM vibrations disappear from the voice under stress, the ear does not note the difference, but the machine can trace the fluctuations on a chart. Byrd is now working on a means of adapting the device for employment in conjunction with plants.

In Japan a soft-spoken doctor of philosophy and successful electronics engineer from Kamakura, a charmingly gardened retreat not far from Yokohama harbor, has developed a similar lie detector into a device with the most fabulous results yet achieved in the plant kingdom. A regular consultant on lie detection for the Japanese police, Dr. Ken Hashimoto read about Backster's laboratory experiments and decided to wire one of the family cactuses to an ordinary polygraph by means of acupuncture needles.

His intent was more revolutionary than Backster's, Sauvin's or Byrd's. He hoped to enter into actual conversation with a plant; to do so he counted on an improvement he had made in the Japanese procedure for lie detection. To simplify and make less expensive the process of police interrogation, Dr. Hashimoto developed a system, similar to Dektor's, whereby nothing more than a cassette tape is needed to record the reactions of a suspect. Electronically transposing the modulations of the suspect's voice, Hashimoto was able to produce on a paper a running graph reliable enough to pass muster in a Japanese law court.

It now dawned on Hashimoto that by reversing the system he might be able to transform the tracings from a graph into modulated sounds, giving voice to a plant. His first experiments with a cactus similar to the giant saguaro of California and the Arizona desert, but much smaller, were a failure. Loath to conclude that either Backster's reports or his own equipment was defective, Hashimoto decided that it might be he who was having trouble communicating with the plant, despite the fact that he is one of Japan's leading researchers into psychic phenomena.

His wife, on the other hand, who loves plants and is renowned for her "green thumb," soon got sensational results. As Mrs. Hashimoto assured the plant that she loved it, there was an instant response from the cactus. Transformed and amplified by Dr. Hashimoto's electronic equipment, the sound produced by the plant was like the high-pitched hum of very-high-voltage wires heard from a distance, except that it was more like a song, the rhythm and tone being varied and pleasant, at times even warm and almost jolly.

John Francis Dougherty, a young American from Marina Del Rey, California, who witnessed one of these conversations, says it sounded as if Mrs. Hashimoto, speaking in modulated Japanese, was being answered by the plant in modulated "cactese." Dougherty further reports that the Hashimotos became so intimate with their plant that they were soon able to teach it to count and add up to twenty. In answer to a query as to how much two and two make, the plant would respond with sounds which, when transcribed back into inked tracings, produced four distinct and conjoined peaks.

Dr. Hashimoto, who got his doctorate from Tokyo University, and is chief of the Hashimoto Electronics Research Center, as well as managing director and chief of research for the Fuji Electronic Industries—which produce the huge animated electrical signs that illumine Tokyo

—has since demonstrated the adding capacities of his cactus to audiences all over Japan.

Asked to explain the phenomenon of his talking and adding cactus, Dr. Hashimoto, who is also, surprisingly, one of Japan's best-selling authors—his *Introduction to ESP* is in its sixtieth printing and his *Mystery of the Fourth Dimensional World* is in its eightieth—answered that there are many phenomena that cannot be explained by the theories of present-day physics. He believes there is a world beyond the present three-dimensional world defined by physics, that this three-dimensional world is merely a shadow of a fourth-dimensional, nonmaterial world. He further believes that this fourth-dimensional world controls the three-dimensional material world through what he calls "mind concentration" or what others call psychokinesis, or mind-over-matter.

The possibilities of such mind control being used for either good or evil on this planet is the problem now facing these researchers. Since Sauvin's ordination as a minister at the Psychic Science Temple of Metaphysics, he has become a strong pacifist, abhorrent of the use of thought-controlled weapons against animals and plants as well as humans. Though he has taken out business certificates on such devices—which put him on record as the inventor—he is loath to disclose his most sensitive invention, code-named Device 13, for fear that it could quickly be developed by the Department of Defense into a foolproof thought-controlled guided missile. The temple's spiritual leader, the Reverend R. William Daut, is a trumpet medium, one who communicates with those who have departed by going into trance and having a trumpet levitate in a semidarkened room; through it the voices of the departed speak. Made of three pieces of aluminum in the shape of a cheerleader's megaphone, the trumpet has no electronic or other gimmicks. The voices simply seem to materialize out of thin air, at times recognizable as individuals known to the listeners and at others as guiding spirits; often included are such extraneous sound effects as the distant barking of dogs.

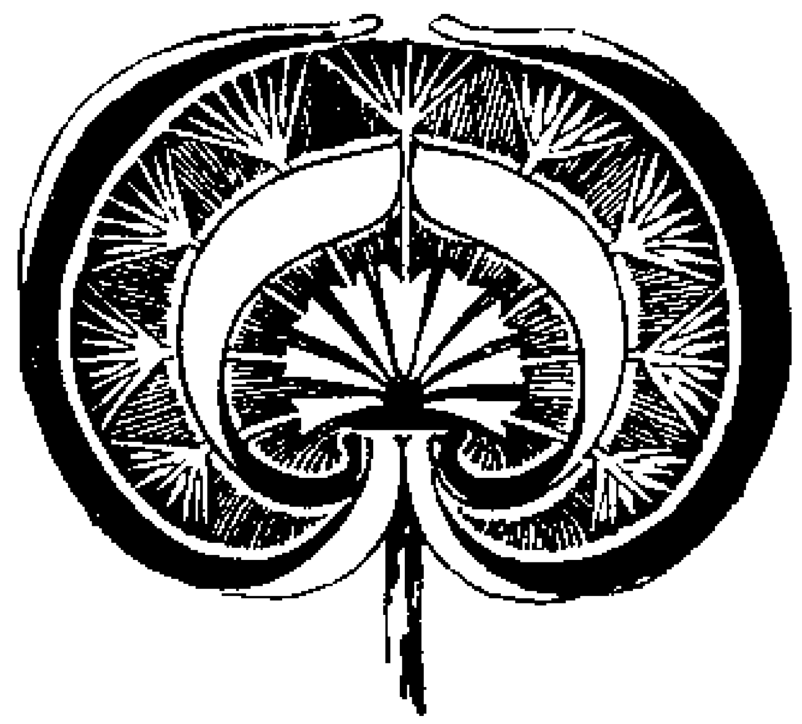
Sauvin says the purpose of the exercise is to convey enlightenment, to give profound and beautiful inspirational messages on wisdom, love, and the continuity of life. True religion, says Dr. Daut, is universal intelligence. "There is no death. There are no dead. Reformation is never denied us, here or hereafter."

The trumpet system, says Sauvin, is no more unusual than that of the Oracle at Delphi or of the talking statues of the initiate priests of ancient Egypt; the doctrines, familiar since the erection of temples, include: the fatherhood of God, the brotherhood of man, immortality of the soul, communication between departed human spirits and living mortals, personal responsibility with compensation and retribution, a path of eternal progress open to every soul by the path of eternal good, nature's laws, both spiritual and physical, and now communion with plants.

If communication of nonverbal messages turns out, as the evidence hints, to transcend limitations of time and space, and to take place via some spectrum of energies which is unrelated to what humans call "electromagnetic," the idea of a dialogue with unseen intelligences active in planes beyond that of man's self-limitations, such as was practiced by mystics of the caliber of Jakob Boehme, may no longer seem far-fetched. If we find the means to receive such messages we may reopen the doors to the cosmos.

CHAPTER 4

Visitors from Space



One day late in October of 1971, a blue Volkswagen "bug" carrying some unusual scientific equipment drove into Oak Grove Park near Temecula, a tiny southern California village near the Pechenga Indian Reservation, not far from the famous Mount Palomar Observatory. Out of the driver's seat stepped a forty-seven-year-old Silesian-born electronics engineer—L. George Lawrence. With a field assistant he had come to this remote desertlike spot to record signals from wild-growing oak trees, cacti, and yuccas. Lawrence chose the park because, in his words, it is "an electromagnetic 'deep-fringe' area, with no man-made interferences, and thus ideal for getting clean, uncontaminated plant reactions."

An important difference between Lawrence's apparatus for capturing plant signals and that of Backster, Vogel and Sauvin is that it incorporates, in a temperature-controlled bath, living vegetal tissue shielded behind a Faraday tube that screens out even the slightest electromagnetic interference. Lawrence found that living vegetal tissue is able to perceive signals far more delicately than electronic sensors. It is his belief that *biological* radiations transmitted by living things are best received by a *biological* medium.

Lawrence's equipment also differs significantly from that of the other experimenters in that it dispenses with the need to use electrodes on plants if they are far enough away from their neighbors to rule out signal interference, as is usually the case in desert areas. Instead, Lawrence simply trains a lensless tube with a wide aperture—the optical axes of which parallel the design axis of the Faraday tube—at a target plant. At greater distances he substitutes a telescope for the lensless tube, and makes the plant more visible by hanging a white cloth on it.

Lawrence's living tissue can pick up a directional signal from distances up to *one mile away.* To stimulate his plant subjects into distinct reactions he "dumps a premeasured quantity of electricity into them," activating the stimulus by remote control with a timer which allows him to walk or drive back to the sensing station. His exploratory experiments are made during colder seasons when most vegetation is dormant, so as to be doubly sure that spurious signals from other plants are not garbling his measurements.

Perturbations in the living tissue of his recorder are detected, not visually through a penrecorder, but aurally by means of a continuous, low even whistle, similar to that produced by a sine-wave generator, which changes into a series of distinct pulses whenever it is disturbed by signals from a plant.

On the day of their arrival at Oak Grove Park in 1971 Lawrence and his assistant took a break for a late-afternoon snack, seating themselves about ten yards from their instrument, which was left pointing randomly at the sky.

As Lawrence bit into a Hebrew National knockwurst, the steady whistling sound from his equipment was interrupted by a series of distinct pulsations. Lawrence, who had not yet digested the knockwurst, but had well digested the Backster effect, thought the signals might have been caused by his killing some of the cells in the sausage. Second thoughts reminded him that kosher sausage is biologically dead. As Lawrence checked his instrumentation, the audio signal, to his amazement, continued to produce a distinct chain of pulses for over half an hour before the even whistle returned, indicating that nothing more was being received. The signals had to be coming from somewhere, and since his device had been continuously pointed upward toward the heavens, Lawrence was faced with the fantastic thought that *something or someone was transmitting from outer space.*

The implications of the phenomenon were such that on their way home Lawrence and his partner could not avoid discussing them though, for the moment, they decided not to make public their finding in the event that not true signals but "bugs" in their equipment could have produced what they had heard. The possibility of life beyond earth was both disturbing and exciting to them. Hints about life elsewhere have so far been vague, including the discovery of "organized elements" or organisms in meteorites, and infrared spectra on Mars, which imply organic molecules. There are also rare nonrandom radio interstellar signals whose reception was claimed by Tesla and Marconi, but they were so ridiculed that they were finally reduced to silence; and there are intergalactic radio emissions from pulsars.

Loath to jump to a premature conclusion that he had picked up an intelligent signal from trillions of miles away through a plant tissue, Lawrence spent several months improving his equipment into what he termed a "biodynamic field station designed for interstellar signal reception."

By April of 1972, his equipment was sufficiently refined for him to attempt to point it once more in the same direction which had brought the reaction at the time of the sausage biting. As a laser expert and author of the first technical book on that subject to appear in Europe, Lawrence had carefully noted the direction in which his apparatus had been pointing and had determined that it was aligned on Ursa Major, a seven-star constellation in the region of the north celestial pole, popularly called the Big Dipper. To insure that the equipment would be located as far away from life forms as possible, Lawrence drove out to the Pisgah Crater, a volcanic butte at twenty-three-hundred-feet elevation in the middle of the arid Mojave Desert. The crater is surrounded by some thirty square miles of flat lava beds with not so much as a blade of grass. Aligning his telescope—coupled with the Faraday tube, a camera, an electromagnetic interference monitor, and the tissue chamber—to celestial coordinates 10 hours 40 minutes plus 56 degrees, which gave him the general direction for Ursa Major, Lawrence switched on his audio signal. After a ninety-minute interval, his equipment again picked up a recognizable, though briefer, pattern of signals. According to Lawrence, the periods between rapid series of pulses ranged from approximately three to ten minutes over a stretch of several hours as he monitored a single spot in the heavens.

Having thus successfully repeated his 1971 observations, Lawrence began to wonder whether he had not accidentally stumbled on a scientific discovery of major proportions. He had no idea from where the signals might be coming or what or who was sending them, but it seemed to him highly possible that galactic drift played some role in their origin. "The signals might be spilling over from the galactic equator, which has a dense star population," said Lawrence. "We could be getting something from that area rather than from the Big Dipper."

After the Mojave Desert confirmation of his first observations, Lawrence continued tests from his residence-laboratory, pointing his machine at the same coordinates, leaving it on round the clock. Lawrence says that he had to wait weeks and sometimes months for the signals to come through but, when they did, the reception of something was unmistakable. One signal produced a brr-r-r-r-r beep-beep-beep type of audio pulse which Lawrence maintains no earthly entity has achieved.

Pressed to speculate on the nature of the strange signals, Lawrence stated: "I don't believe they are directed at earthlings. I think we are dealing with transmissions between peer groups, and because we don't know anything about *biological communications* we are simply excluded from these 'conversations.' I also believe that the energy transmitted must be fantastically high since our instrumentation is not at all sophisticated and it would take a tremendous amount of power to create any response in it from such astronomical distances. The signals, therefore, may be of an emergency nature. Something may be happening up there and someone may be desperately calling for help."

Deciding that his findings may be of crucial significance and could herald a new and as yet unimagined system of communication, Lawrence has sent a copy of his October, 1971, tape, together with a seven-page report, to the Smithsonian Institution in Washington, D.C., where it is preserved as a potentially historical scientific document. The report concludes:

> An apparent train of interstellar communication signals of unknown origin and destination has been observed. Since interception was made by biological sensors, a biological-type signal transmission must be assumed. Test experiments were conducted in an electromagnetic deep-fringe area, the equipment itself being impervious to electromagnetic radiation. Follow-up tests revealed no equipment defects. Because interstellar listening experiments are not conducted on a routine basis, the suggestion is advanced that verification tests should be conducted elsewhere, possibly on a global scale. The phenomenon is too important to be ignored.

Lawrence says the instrumentation tape, as a mere audio presentation, is unpleasant to listen to, but reviewers of the tape have conceded that "a fascinating degree of enchantment" tends to emerge after the tape has been played back three or more times, typically over a period of weeks.

The tape contains a short, incremental series of deep harmonious oscillations resembling nonsense chatter or background modulations. An intelligent character of the overall pulse train is implied by discrete spacing patterns, apparent repetitions of sequences, and highly attenuated electromagnetic noise.

Lawrence looks forward to the day when he can arrange for computer analysis of the taped signals, which might be able to provide additional clues to their nature. They are far too rapid to allow manual extraction of the data. Even so, he is not too optimistic that such analysis can produce concrete results. "If the signals are of a personal nature, no means known to modern computer technology will be able to decipher them," he says. "We simply do not have today bionic-type computers which could collect seemingly random data and come up with a concise and rational readout."

Lawrence's most important conclusion, that biological-type sensors are needed in order to intercept biological signals, applies particularly to communications from outer space. As he puts it: "Standard electronics are next to worthless here, since 'bio-signals' apparently reside outside of the known electromagnetic spectrum."

Lawrence points out that in the 1950s scientists who had previously insisted that our small planet was unique in the universe began to admit, on the basis of careful celestial observations and other inferences, that we may not be alone in the cosmic immensity, and to concede the possible existence of extraterrestrials, whose development might be far superior to our own.

In the early nineteenth century Karl Friedrich Gauss—the German mathematician and physicist for whom an electromagnetic unit of magnetic flux density is named—proposed that man might make known his presence on earth to cosmic beings by cutting huge swaths hundreds of miles long in the Siberian taiga to form a right angle. This was followed by the suggestion of the Austrian astronomer J. J. von Littrow that geometric canals be dug in the Sahara, filled with kerosene, and set aflame at night; and the recommendation of the French scientist Charles Gros that a vast mirror be built to reflect sunlight directly at Mars.

These farfetched ideas were updated when, in the summer of 1927, radio observations were made which in the framework of then existing knowledge seemed to imply that earth might be under the scrutiny of communications satellites of extraterrestrial origin. Jorgen Hals, a Norwegian radio engineer, while listening to a short-wave radio station transmitting from Eindhoven in the Netherlands, heard weird echoes for which he could not account. Nor could a number of Dutch and British professors and technicians who carried out a series of experiments to confirm Hals's findings.

The puzzling anomaly was all but forgotten until the early 1950s, when various specialists began to put forward a theory of extraterrestrial interference to explain it. The theorists intrepidly assumed the intermittent existence of an interstellar communications probe designed, first, to monitor solar systems for intelligent life, then retransmit radio-frequency emanations from such life, including earthlings, back to a distant "home-world." Though these far-out interpretations were discounted, even mocked, by the mainstream of scientific opinion, their critics became far less vocal when another series of observations was made, this time involving a television signal which appeared to have been received after a mysterious delay of over three years.

In September, 1953, C. W. Bradley of London picked up the call letters of the American station KLEE-TV in Houston, Texas, on his living-room television tube. Over the next several months the same letters were observed on TV screens in the offices of Atlantic Electronics Ltd. in the English city of Lancaster. What was eerie about these receptions was not that the TV signal had been sent from so far away, since this happens often enough to cause no surprise, but that the signal had been sent about three years prior to the time of its reception, the call letters KLEE having been changed to KPRC in 1950. Explanations that the signals could have been stored in a "plasma cloud" hovering above the earth which released the data in a broadcast for all to see gave no reasons as to how this could have been done or why, and suggestions that the whole thing was merely a meaningless—though extremely expensive—hoax seem far-fetched.

Spurred by the mysteries of these phenomena, American researchers began seriously to consider interstellar communications via radio. But radio was soon ruled out after it was realized that its wavelengths could be absorbed by interstellar gas clouds and nebulae, blocked by various shielding layers around hoped-for faraway target planets, or affected by cosmic radio noise. Only one possible wavelength remained to reach such targets, the much shorter and more penetrating one emitted by neutral galactic hydrogen.

But terrestrials still hoped to receive radio waves from space. In 1960 Dr. Frank Drake initiated Project Ozma—named for the princess who became ruler of the fictional kingdom of Oz—which used a huge circular radio telescope eighty-five feet in diameter at the National Radio Astronomy Observatory near Greenbank, West Virginia. Drake and his colleagues hoped to detect possible intelligent extraterrestrial transmissions from the regions of two nearby stars, Tau Ceti and Epsilon Eridani. Only recently was it discovered that orbiting Epsilon Eridani is a massive planet six times the weight of Jupiter, largest of the nine planets now known to revolve around the sun.

Although Ozma failed to obtain results, scientists are still hotly pursuing the subject of communication with extraterrestrial intelligences, the phrase being now shortened into the acronym CETI.

In the summer of 1971, a group of American scientists at the National Aeronautics and Space Administration's Ames Research Center completed studies for a new Project Cyclops, which proposed a network of ten thousand radio dish telescopes, forming a collective surface of several square kilometers, to be mounted on rails and spread across one hundred square miles of the New Mexican desert. Requiring a cybernetic "nervous system" of brand-new supercomputers, Cyclops was estimated by Charles Seeger of New Mexico State University to cost five billion dollars. In light of the stringent cutbacks in the U.S. space-research funding, it is unlikely that Cyclops will become a reality. This leaves the field to a huge radio telescope more than half a kilometer in diameter currently under construction at the Astrophysical Observatory in the Soviet Crimea.

All of these projects, Lawrence complains, assume that signals must come by radio since that is the most efficient means of communication known to the scientists of this planet. If they converted to his idea of receiving biological signals, Lawrence feels they would have a much better chance. The notion is echoed by Joseph F. Goodavage, author of *Astrology: The Space Age Science*, who, in an article for *Saga* magazine (January, 1973), stated: "Rigid enforcement of established Scientific Method, as a kind of quasi-religion—with its burdensome ritual and tradition—may be the most serious obstacle in the path of direct communication between *Homo sapiens* and other civilizations that may be thriving throughout interstellar, intergalactic space."

Employed as an instrumentation engineer for a Los Angeles space-science corporation, Lawrence decided to design some more sophisticated transducers—or converters of one type of input energy into another type of output energy. Knowing that a mechanical device which could use heat, environmental pressure, electrostatic fields, and gravitational changes simultaneously was not up to the task, he theorized that a plant might be able to turn the trick because it had the necessary components built in by nature.

When he began to study the problem in 1963, Lawrence found he could get no help from plant specialists and biologists because none of them knew enough physics, and especially electronics, to visualize what he was driving at. In his search for a biological system for radiating and receiving signals, Lawrence began by going over the experiments made in the 1920s by the Russian histologist Alexander Gurwitsch and his wife, who proclaimed that all living cells produce an invisible radiation. Gurwitsch had noticed that the cells in the tips of onion roots seemed to be dividing at a definite rhythm. Believing this due to an extra unexplained source of physical energy, Gurwitsch wondered whether it might not come from nearby cells.

To test out his theory he mounted one root tip in a horizontally oriented thin glass tube to act as a ray gun. This he pointed at a similar onion root tip, also protected in a tube, but with a small area on one side exposed naked to serve as a target. After three hours of exposure, Gurwitsch examined sections from the target root under his microscope. When he compared the number of cell divisions, he found 25 percent more in the exposed, irradiated area. The receiver root had seemingly picked up a vital energy from its sender neighbor.

To try to block the emission, Gurwitsch repeated the experiment with a thin shield of quartz between the roots, but obtained essentially the same results. However, when the quartz was coated with gelatin, or a simple sheet of glass was substituted, no enhanced cell division could be observed. Since glass and gelatin were known to block various ultraviolet frequencies on the electromagnetic spectrum, Gurwitsch concluded that the rays emitted by the cells of an onion root tip must be as short as or shorter than ultraviolet. Because they apparently increased cell division, or "mitosis," he called them "mitogenetic rays."

Gurwitsch's findings had created a furor in the scientific world as laboratories hastened to check them. Since the wavelengths claimed for the new rays were more powerful than the ultraviolet frequencies which reach the earth from the sun, many biologists could not believe that living processes were capable of generating them. In Paris two researchers reported similar results; in Moscow one of Gurwitsch's own countrymen showed that he could increase the budding of yeast more than 25 percent by exposing it to "mitogenetic" rays from onion roots.

A pair of scientists at the Siemens and Halske Electric Company near Berlin came to the verdict that the radiation was a fact; and in Frankfort, a researcher actually succeeded in measuring it, not through its effect on vegetal life, but with electrical instruments. On the other hand, equally reliable Anglo-Saxon investigators could detect no effects. In the United States, when the prestigious Academy of Sciences issued a report that Gurwitsch's discovery was not replicable, and therefore strongly suggested it might be the product of his imagination, Gurwitsch was sped into limbo.

Though Lawrence lacked an ultraviolet spectrometer to detect "mitogenetic" radiation, he was fascinated by Gurwitsch's system of *directing* the energy. His observations also nudged Lawrence almost involuntarily to the position that there was a psychological, or "mental," factor involved in Gurwitsch's maverick work. Continuing to probe further with a sensitive high-impedance device of his own design, Lawrence sought to discover whether individual cells in a quarter-inch slice of onion, attached to a Wheatstone bridge and an electrometer, would react to various stimuli. He found that they seemed to respond to irritations such as a puff of smoke, or even to his mental image of their destruction, in about one hundred milliseconds, or one tenth of a second.

What seemed most odd to Lawrence was that the reaction of the onion tissue seemed to change depending on whether he, or someone else, was directing thought at it. People with "psychic gifts" seemed to elicit much stronger responses than the practical-minded Lawrence. As he commented: "If one can cause, or get something to cause, harm to a cell—assuming that the cell has a cellular consciousness—the reaction pattern in it will change from experimenter to experimenter."

About this time Lawrence came across Backster's work and decided to build a sophisticated psycho-galvanic analyzer or plant response detector. With his new equipment, Lawrence got a series of "wild" tracings from his plants; but, because of what he retrospectively calls his "ignorance and classical Prussian orthodoxy," he ascribed these effects to faults in his instrumentation. Nevertheless, his suspicion that plant tissues could pick up human thought and emotion slowly became more concrete in the light of Backster's achievements. Lawrence was reminded that years previously Sir James Jeans, the British astronomer, had written that "the stream of human knowledge is impartially heading toward a non-mechanical reality: the Universe begins to look more like a great *thought* than a great machine. Mind no longer appears as an accidental intruder into the realm of matter. We are beginning to suspect that we ought rather to hail it as the creator and governor of this realm."

In October of 1969, Lawrence began to publish a series of popular articles based on his reading and research, the first of which appeared as "Electronics and the Living Plant" in *Electronics World*. Lawrence told his readers that, for the first time in the millennia since the first green leaves poked their heads out of Paleozoic swamps, plants were at last beginning to be studied for their "electrodynamic properties."

Four main questions, said Lawrence, were starting to attract serious attention: Could plants be integrated with electronic readouts to form major data sensors and transducers? Could they be trained to respond to the presence of selected objects and images? Were their alleged supersensory perceptions verifiable? Of the 350,000 plant species known to science, which were the most promising from the electronic point of view?

Providing detailed instructions for investigating the behavior of living plant cells with microelectrodes, Lawrence also reported that in the "Moon Garden" developed by Republic Aviation at Farmingdale, New York, scientists had been able in the 1960s to induce what appeared to be "nervous breakdown" and "complete frustration" in plants being tested as possible space foods and that, even earlier, in his laboratory at East Grinstead, Sussex, England, L. Ron Hubbard, founder of Scien tology, had noted that plants dislike certain types of artificial light, such as the cold light emitted by sodium street lamps, which can cause them to come out in a cold sweat clearly visible on their foliage.

Lawrence warned his readers that work with plants was not just a matter of electronic expertise and that working with the Backster Effect involved much more than the mere ability to construct top-quality electronic equipment. "There are certain qualities here," he wrote, "which do not enter into normal experimental situations. According to those experimenting in this area, it is necessary to have a 'green thumb' and, most important, a genuine love for plants."

Half a year later Lawrence followed up his revelations with an even more controversial article in the same magazine, entitled "Electronics and Parapsychology." Lawrence's article began by asking: "Does man possess latent sensitivities that have been stifled by modern communications systems?" He then pointed out that although the fledgling science of parapsychology, long suspect because of an occult background, was having to fight for acceptance, the application of electronic instruments was permitting dramatic new experiments and bringing forth stunning discoveries which might rival the orthodox communications arts and sciences currently in use.

Stressing that the need for machine systems capable of testing ESP in an unbiased, impartial manner had been recognized fifty years ago, when an Italian scientist, Federico Cazzamalli, developed an ultra-high-frequency apparatus for testing human telepathy, Lawrence reported that the Italian's experiments had never been repeated because the Fascist dictator Benito Mussolini had declared the work secret.

A fascinating offspring of Cazzamalli's ideas and machine, continued Lawrence, is an apparatus called the "Integratron," researched by George W. van Tassel, a self-taught inventor living in Yucca Valley, California, not far from the Giant Rock airport. Developed over twenty years, and still under construction, van Tassel's contrivance is housed in a non-metallic domelike structure thirty-eight feet high and fifty-eight feet in diameter, which looks like an astronomical observatory. It is an electrostatic, magnetic generator with armatures over four times larger than any others in existence. The *Proceedings* of van Tassel's College of Universal Wisdom state that the fields generated by his machine encompass its entire structure and this is why the dome contains no nails, bolts, or metal but is held together like a Chinese puzzle and is six times stronger than the commercial building code requires. When completed it promises, says van Tassel, not only to help solve the problem of extraterrestrial communication, but to afford such possibilities as rejuvenation of body cells, an antigravity force, and the ultimate of psychic experiences: time travel.

What puzzles orthodox scientists and makes skeptics of many of them is a lack of any working theory to cover this kind of phenomenon. One scientist, Dr. W. G. Roll, in his presidential address to the 7th Annual Convention of the Parapsychological Association held in Oxford, England, in 1964, postulated "psi-fields," which might be analogous to electromagnetic or gravitational fields, possibly possessed by all objects, living and nonliving, which could react with known physical fields and with one another. Another theory, put forward by Dr. G. D. Wasserman at the Ciba Foundation Symposium in 1956, leans on quantum mechanics. Wasserman suggests that "psi-fields," which enable persons to have paranormal experiences, are due to the reception of inconceivably small "quanta of energy," far more minute than those which can be absorbed by matter fields of classical physics.

The Backster Effect and other related considerations, says Lawrence, "lead to the idea that psi is but a part of a so-called 'paranormal matrix' —a unique communications grid which binds all life together. Its phenomena apparently work on a multi-input basis which operates beyond currently known physical laws." Within this framework, says Lawrence, plants, after sensitization or conditioning by their owners can reach a state of communication in which they are able to react to their owners' emotions or states of mind even when they are far away.

In the June, 1971, issue of *Popular Electronics,* Lawrence provides any researcher wishing to investigate communication with plants with detailed diagrams and a parts list for a "response detector" allowing for extremely sensitive tests.

Warning that constant repetition was an important factor in such testing, Lawrence stated that if a plant specimen is stimulated continuously, badly injured, or infrequently watered, it would tire quickly, or even lapse into shock and die. Researchers were therefore cautioned to be gentle with their plants and allow them to recuperate after experimentation. The area in which plants live must be quiet, added Lawrence, "so that the stimuli can be effectively applied with a minimum of power-line noise or disturbances from radio-frequency transmission to cause faulty indications."

Lawrence's ideas about plants were corroborated and elaborated by the experience of a Czech publisher and student of physiological psychology, Jan Merta, now living in Canada, whose psychic gifts allow him to plunge an iron bar into a blacksmith's forge, heat it to incandescence, then calmly brush sparks off its white-hot end with his bare hand as easily as he would rub dust from a shelf.

Freshly settled in Canada, Merta supported himself for two months by working as a troubleshooter for a large Montreal grower and importer of tropical plants. When clients in office and residential buildings complained that their plants were getting sick, Merta was sent to ascertain the trouble. Because he also took care of thousands of plants in the firm's extensive greenhouses, Merta noticed that the effects of loneliness produced when a plant is taken away from hundreds of its friends often caused it such a shock that it would pine, even die; however, when returned to the greenhouse, it immediately perked up and regained its normal green health.

As the result of hundreds of "house calls," Merta noticed that plants throve better when constantly communicated with by office workers and home owners than if left to themselves. Examples of the majestic *Ficus benjamini,* nearly thirty feet tall, transported from Florida, though in excellent condition upon arrival, when placed around a fountain in a shopping center's indoor circular solarium started to wilt within two days in spite of careful watering and feeding. Yet those in heavily traveled passageways leading to the solarium retained their radiant vigor. To Merta this was a sure sign that the *Ficus* enjoyed being admired by the passers-by.

In 1970, when Lawrence read that in the Ukraine radio frequencies and ultrasonic vibrations had been used to stimulate cereal grain seeds to produce higher yields as far back as the early 1930s and that the United States Department of Agriculture had successfully experimented in the same way, he gave up his college position and set about independently developing advanced equipment with which he hopes that seed grains can be provoked, on a commercial scale, to grow better and faster. "If a plant seedling can be stimulated on a parapsychological basis, as the famous plant breeder Luther Burbank knew, then I don't see why," says Lawrence, "we can't transmit specific signals to whole fields of crops to stimulate their growth without all these damned soil-killing fertilizers."

In the February, 1971, issue of *Popular Electronics* Lawrence presented his own experimental arrangement to test his theories about stimulating plant growth in an extremely high-voltage electrostatic field. It is the invention and use of cheap chemical fertilizers, he asserted, which has suppressed the ideas of countless engineers about how to nourish plants electrically. With nitrate pollution from these fertilizers threatening the world's ecological panorama and its water supply, he urges that these ideas be revived.

Acting on his own advice, Lawrence is working up patent applications on special sound-type plant stimulation techniques, which he is combining with Backster Effect methods in order to stimulate his plants in a wireless fashion. This effort has turned Lawrence the engineer into Lawrence the philosopher. "There was a time, when I was a child, when the whole world seemed alive and knowing," he wrote in *Organic Gardening and Farming*. "Trees were friends and as George Eliot put it: 'Flowers see us and know what we're thinking about.' Then came a time when plants just grew, silently and without emotion. But today, I'm entering a second childhood, as least as far as plants are concerned."

Lawrence, torn between his interest in stimulating plant growth electrically and his projects to achieve interstellar communication, feels that the effort to contact extraterrestrial life is more important in the long run because "if routine results can be achieved in CETI, many questions attached to riddles in the plant kingdom will be answered as a consequence.

On June 5, 1973, the research division of Anchor College of Truth in San Bernardino announced that it was inaugurating the world's first biological-type interstellar communications observatory under the direction of L. George Lawrence, now also a vice-president of Anchor. For the new research program Lawrence has designed what he calls a Stellartron, which combines in one three-ton instrument the features of a radio telescope and the biological signal-receiving system of the biodynamic field station.

Anchor president, Ed Johnson, told the press that since radio astronomy had failed to detect intelligent signals from space, the college was backing Lawrence's idea that radio transmission was out of date and that biological communication should be given a trial.

Pointing out that in our own galaxy alone there are some 200 billion stars, Lawrence says that if one assumed each of them to have at least five companion planets, a total of one trillion might consequently be available for study. Even if only one planet in a thousand has intelligent life this would amount to one billion in our galaxy alone. Multiplied by the ten billion galaxies believed to comprise the observable universe, then there may be 10,000,000,000,000,000,000 planets capable of sending some kind of signal to Earth.

Anchor's founder, Reverend Alvin M. Harrell, thinks that contact with another race in the universe will trigger a tremendous explosion of knowledge. As Harrell says: "Given the destructive brutality of humankind, we may expect any newly discovered civilization to be infinitely more loving and compassionate than we are."

"Perhaps plants are the true extraterrestrials," Lawrence observes, "for they converted an early mineral world into a habitat suitable for man by processes that border on near-perfect magic! What remains to be done now is to remove all traces of occultism and make plant response, including communications phenomena, a verifiable component of orthodox physics. Our instrumentation concepts reflect this effort."

If Lawrence is on the right track, the ardently desired prospect of producing hardware to move man into the vastness of interstellar space on Columbian voyages of discovery will be rendered as obsolete as Columbus's flagship, *Santa Maria*. Lawrence's research, suggesting as it does that intelligences are communicating instantly across distances requiring millions of light-years to reach, indicates that what is needed is not spaceships but the proper "telephone numbers" to contact them. Though the work is still in an exploratory stage, his biodynamic field station may be a step toward plugging into the universal switchboard, with plants as the pretty, cheerful and efficient co-operators.

CHAPTER 5

Latest Soviet Discoveries

In Russia, millions of newspaper readers were introduced to the ideas that plants communicate their feelings to man in October, 1970, when *Pravda* published an article entitled "What Leaves Tell Us."

"Plants talk . . . yes, they scream," declared the official organ of the Communist party. "It only *seems* that they accept their misfortunes submissively and silently bear pain." *Pravda*'s reporter, V. Chertkov, tells how he witnessed these extraordinary goings-on in Moscow when he visited the Laboratory for Artificial Climate at the renowned Timiryazev Academy of Agricultural Sciences.

Before my eyes a barley sprout literally cried out when its roots were plunged into hot water. True, the plant's "voice" was registered only by a special and extremely sensitive electronic instrument which revealed a "bottomless vale of tears" on a broad paper band. As though it had gone crazy, the recording pen wriggled out on the white track the death agony of the barley sprout, although, to look at the little plant itself, one would never have guessed what it was going through. While its leaves, green as ever, stood upright, the plant's "organism" was already dying. Some kind of "brain" cells within it were telling us what was happening.

Pravda's reporter also interviewed Professor Ivan Isidorovich Gunar, head of the academy's Department of Plant Physiology, who, together with his staff, had performed hundreds of experiments, all of which confirm the presence of electrical impulses in plants similar to the well-known nerve impulses in man. The *Pravda* article noted that Gunar talked about plants as he would about people, distinguishing their individual habits, characteristics, and proclivities. "He even appears to converse with them," Chertkov wrote, "and it seems to me that his plants pay attention to this good, graying man. Only persons invested with certain power are like this. I have even been told of a test pilot who talked to his misbehaving airplane, and I myself have met an old captain who talked with his ship."

When Gunar's chief assistant, Leonid A. Panishkin, a former engineer, was asked by the *Pravda* reporter why he gave up the technology in which he was trained in order to work in Gunar's laboratory, he replied: "Well, there I used to be involved with metallurgy; here there is life." He was echoed by another young laboratory worker, Tatiana Tsimbalist, who affirmed that since she had come to work with Gunar she had "learned to look at nature with different eyes."

Panishkin said he was particularly interested in searching out those conditions which might best suit the specific needs of plants and how "our green friends"—as the *Pravda* reporter termed them—react to light and darkness. By using a special lamp which shone with the same intensity as the sun's rays reaching earth he had found that plants tired in an overextended day and needed rest at night. He hoped that it might one day be possible for plants to turn lights on or off in a greenhouse at will: "a live electric relay."

The studies of the Gunar team may open up new vistas in plant breeding, since in their laboratory it has been found that individual plants more resistant to heat, cold, and other climatological factors can be "selected" within minutes by testing them with their instruments, although these qualities have heretofore taken geneticists years to establish.

In the summer of 1971, an American delegation from the Association for Research and Enlightenment (ARE), founded by the seer and healer Edgar Cayce at Virginia Beach, Virginia, visited Russia. The Americans —four medical doctors, two psychologists, one physicist, and two educators—were shown a film by Panishkin entitled *Are Plants Sentient?* The film demonstrated effects produced on plants by environmental factors such as sunlight, wind, clouds, the dark of night, the tactual stimulus from flies and bees, injuries produced by chemicals and burning, and even the very proximity of a vine to a structure to which it might cling. The film showed further that the immersion of a plant in chloroform vapor eliminates the characteristic biopotential pulse normally apparent when a leaf is given a sharp blow; it also indicated that the Russians are now studying the characteristics of these pulses to establish the relative degree of a plant's health.

One of the American doctors, William McGarey, head of the ARE medical research center in Phoenix, Arizona, stated in his report that the intriguing part of the movie was the method used to record the data. Time-lapse photography made the plants seem to dance as they grew. Flowers opened and closed with the coming of darkness as if they were creatures living in a different time zone. All injury-induced changes were recorded by a sensitive polygraph attached to the plants.

In April, 1972, *Weltwoche*, a Swiss newspaper published in Zurich, came out with an account of both Backster's and Gunar's work which it said had taken place simultaneously and independently. That same week the Swiss article was translated into Russian in a weekly review of the foreign press, *Za Rubezhom* (*Abroad*) published in Moscow by the USSR's Union of Journalists, under the caption: "The Wonderful World of Plants." These scientists, said the Russian version, are "proposing that plants receive signals and transmit them through special channels to a given center, where they process the information and prepare answering reactions. This nervous center could be located in root tissues which expand and contract like heart muscle in man. The experiments showed that plants have a definite life rhythm and die when they don't get regular periods of rest and quiet."

The *Weltwoche* article also caught the attention of the editors of the Moscow newspaper *Izvestiya,* who assigned their reporter M. Matveyev to do a story for the paper's weekly magazine supplement. Though the newsman referred to Backster's suggestion that plants might have memory, language, and even rudiments of altruism, he strangely omitted Backster's most startling discovery, that his philodendron had perceived his *intent* to harm it.

Deciding (the *Izvestiya* reporter told his readers) that a "sensation was being propagated in Western newspapers," Matveyev traveled to Leningrad, where he interviewed Vladimir Grigorievich Karamanov, director of the Laboratory of Biocybernetics of the Institute of Agrophysics, in order to get an authoritative opinion.

The Institute of Agrophysics was founded over forty years ago at the behest of the renowned solid-state physicist, Academician Abram Feodorovich Ioffe, who became particularly interested in the practical application of physics to the design of new products, first in industry, then in agriculture. After the institute opened its doors, Karamanov, then a young biologist, was inspired by Ioffe to familiarize himself with the world of semiconductors and cybernetics and, in due course, began building microthermistors, weight tensiometers, and other instruments to register the temperature of plants, the flow rate of fluid in their stems and leaves, the intensity of their transpiration, their growth rates, and characteristics of their radiation. He was soon picking up detailed information on when and how much a plant wants to drink, whether it craves more nourishment or is too hot or cold. In the first issue of *Reports of the USSR Academy of Sciences* for 1959, Karamanov published "The Application of Automation and Cybernetics to Plant Husbandry."

According to the *Izvestiya* reporter, Karamanov showed that an ordinary bean plant had acquired the equivalent of "hands" to signal an instrumental brain how much light it needed. When the brain sent the

"hands" signals, "they had only to press a switch, and the plant was thus afforded the capability of independently establishing the optimal length of its 'day' and 'night.' " Later, the same bean plant, having acquired the equivalent of "legs," was able instrumentally to signal whenever it wanted water. "Showing itself to be a fully rational being," the account continued, "it did not guzzle the water indiscriminately but limited itself to a two-minute drink each hour, thus regulating its water need with the help of an artificial mechanism.

"This was a genuine scientific and technical sensation," concluded the *Izvestiya* reporter, "a clear demonstration of twentieth-century man's technical abilities."

Asked whether he thought Backster had discovered something new, Karamanov somewhat condescendingly replied: "Nothing of the sort! That plants are able to perceive the surrounding world is a truth as old as the world itself. Without perception, adaptation does not and cannot exist. If plants had no sense organs and didn't have a means of transmitting and processing information with their own language and memory, they would inevitably perish."

Karamanov, who throughout the interview made not a single comment on plants' ability to perceive human thought and emotion—Backster's really sensational discovery—and seemed oblivious of Backster's success in getting his philodendron to recognize a "plant assassin," rhetorically asked the *Izvestiya* reporter: "Can plants discern shapes? Can they, for instance, differentiate a man causing them hurt from another who waters them?" Replying to his own question, while at the same time putting Backster into what he considered to be a proper perspective for Soviet readers, Karamanov said: "Today I cannot answer such a question. And not because I doubt that Backster's experiments were immaculately set up and repeatedly performed, though perhaps a door slammed, or a draft wafted into the room, or something else. The fact is that neither he, nor we, nor anyone else in the world is yet ready to decipher *all* plant responses, hear and understand what they 'say' to one another, or what they 'shout' at us."

Karamanov also predicted that in the long run it would be possible cybernetically to direct all the physiological processes of plants not, as he put it, "for the sake of sensation, but for the advantage of plants themselves." When plants are able to auto-regulate their environment and establish optimal conditions for their own growth with the help of electronic instruments, said Karamanov, this should be a long step toward larger harvests of cereal grains, vegetables, and fruits. Making clear that the achievements were not just around the corner, Karamanov added, "We are not still learning to talk with plants and understand their peculiar language. We are working out criteria which will help us to control the life of plants. Along this difficult but fascinating road, a multitude of surprises still await us."

The *Izvestiya* article was followed that summer by a story in the monthly magazine *Nauka i Religiya* (*Science and Religion*), which has the dual aim of putting forward the latest findings in world science while at the same time playing down—in a section headed "The Theory and Practice of Atheism"—the church-defended notion of a spiritual world hierarchically beyond that of man.

The article's author, engineer A. Merkulov, going further than the *Izvestiya* weekend supplement, recounted how the plant of the "American criminologist" Backster had not only responded to the scalding death of brine shrimp but also to the killer of its vegetal neighbor. Such response to people's moods, added Merkulov, had also been detected at the state university in Alma Ata, capital of the Soviet Kazakh Republic, the apple orchard of the Soviet Union. There scientists have found that plants repeatedly react to their owners' illnesses and to their emotional states.

Noting that plants had long ago been shown to have "short-term memory," Merkulov said that this fact too had been confirmed by the Kazakh scientists. Beans, potatoes, wheat, and crowfoot (*Ranunculus*) after proper "instruction" seemed to have the capability of remembering the frequency of flashes from a xenon-hydrogen lamp. The plants repeated the pulsations with what Merkulov called "exceptional accuracy," and since crowfoot was able to repeat a given frequency after a pause as long as eighteen hours it was possible to speak of "long-term" memory in plants.

The scientists next went on, according to Merkulov, to condition a

philodendron to recognize when a piece of mineralized rock was put beside it. Using the system developed by Pavlov with dogs, whereby he discovered the "conditioned reflex," the Kazakh scientists simultaneously "punished" a philodendron with an electrical shock each time a mineralized ore was placed next to it. They reported that, after conditioning, the same plant, anticipating the hurtful shock, would get "emotionally upset" whenever the block of ore was put beside it. Furthermore, said the Kazakh scientists, the plant could distinguish between mineralized ore and a similar piece of barren rock containing no minerals, a feat which might indicate that plants will one day be used in geological prospecting.

Merkulov concluded his reportage with the idea that the *control* of all processes in plant growth was the ultimate goal of all the new experimentation. In an institute of physics in the Siberian city of Krasnoyarsk, he wrote, "Physicists are even now regulating the growth of a monocellular seaweed, *Chlorella*. Experiments are continuing and becoming increasingly complex, and there is no doubt that in the not-distant future scientists will be able to control the growth, not only of the simplest, but of higher plants."

Merkulov beguiled his readers with the idea that this control might well be possible over great distances. "By studying how to 'understand' plants," he prophesied, "man may create automatic contrivances which themselves will watch over fields in such a way that, at any given moment, they can satisfy the every need of crops. The day is not far away when scientists will also work out a theory on the adaptation and resistance of plants to unpleasant conditions in their environment which will encompass how they react to irritants, and to stimulators and herbicides as well."

Toward the end of 1972 Soviet readers were given more food for thought in an article "Flower Recall" published in the popular color-illustrated *Znaniya Sila* (*Knowledge Is Power*), one of the many magazines issued by the Knowledge Society, the leading organization for popular science in the USSR. This time its author was not a news-hungry journalist or an inspired engineer but a professor and doctor of psychological sciences, V. N. Pushkin. Far from suggesting that the

American criminologist Backster had really not discovered anything new, Pushkin began with a complete description of Backster's shrimp experiment. He then let his readers in on the fact that one of his young colleagues, V. M. Fetisov, had made him aware of Backster's accomplishments in the first place, and had been so determined to work with the Backster Effect that he had persuaded Pushkin to take part in the experiments. Fetisov brought an ordinary potted geranium from his home and attached it to an encephalograph.

As Fetisov was making his first attempts to get a response from his pet plant, Georgi Angushev, a Bulgarian student working up a dissertation in psychology at the Lenin Pedagogical Institute in Moscow, heard about the Fetisov-Pushkin experiments and came to their laboratory to see what was going on. Pushkin described Angushev as a talented researcher with many qualities, the most important of which to their "psycho-botanical experiments," as he termed them, was the fact that the Bulgarian was an excellent hypnotist.

Fetisov and Pushkin surmised that a hypnotized person should be able to send emotions to a plant more directly and spontaneously than a person in a normal state. Hypnotizing a young girl by the name of Tanya, who was described by Pushkin as of "lively temperament and spontaneous emotionality," they first implanted in her the notion that she was one of the most beautiful women in the world, then the notion that she was freezing in harsh raw weather. At each change in the girl's mood the plant, which was attached to an encephalograph, responded with an appropriate pattern on the graph. "We were able," says Pushkin, "to get an electrical reaction as many times as we worked, even to the most arbitrary commands."

To obviate criticism that the plant's response was only the result of chance events taking place in the room, the Muscovite psychologists switched on their encephalograph and let it run for long periods between their experiments. But the instrument never registered any reaction of the kind evoked in the plant by the emotions suggested to a hypnotized subject.

Pushkin and Fetisov decided to see whether the plant could detect a lie, as Backster had claimed. It was suggested to Tanya that she think

of a number from 1 to 10. At the same time she was told she would never reveal the number, even if pressed to do so. When the researchers counted slowly from 1 to 10, pausing after each digit to inquire whether it was the one she had thought of, each time Tanya responded with a decisive "No!" Though the psychologists could not see any difference in her answers, the plant gave a specific and clear reaction to her internal state when the number 5 was counted. It was the number which Tanya had selected and promised not to reveal.

In his conclusion Pushkin stated that he felt strongly that by pursuing the course initiated by Backster it might be possible to make advances into the thorny problem of the human brain's functioning, which Pavlov over half a century ago had called the "crown of earthly nature." Seizing the opportunity for a political remark, Pushkin reminded those who might look askance at his and Fetisov's new research that at the opening of Moscow Institute of Psychology in 1914 Pavlov had declared that the task of unlocking the mysteries of the brain and its activity was "so unexpressibly enormous and complex that it depends on the totality of thought's resources, namely, complete freedom, and bold deviation from set patterns of research."

Using Pavlov as a shield against what he obviously thought would be attacks from his professional colleagues, Pushkin stressed that the renowned physiologist's statement was as up to date in 1972 as when he had made it. Lest his message not ring clear, he added: "Experience in the development of natural sciences, especially physics, has shown that one should not fear new discoveries, however paradoxical they might seem at first glance."

In his conclusion, the Moscow professor speculated that vegetal cells in the flower react to processes taking place in the nervous system of human subjects or in what is vaguely referred to as their "emotional states." Seeking a meaning for the flower's reaction, Pushkin wrote: "Perhaps between two informational systems, the plant cells and the nervous system, a specific link exists. The language of the plant cell may be related to that of the nerve cell. These wholly different living cells seemed to be able to 'understand' one another."

Pushkin further theorized that in the cells of a flower there take place processes somehow related to mentation and asserted that man's psyche—a word which he says is as yet entirely undefined even by the "ologists" of his own discipline—and the perception, thought, and memory connected to it are all just a specialization of processes existing at the level of vegetal cells.

Pushkin asserts that this conclusion is most important since it will open new thinking about the origin of the nervous system. Noting that in the development of science many different answers have been proposed for what constitutes the actual informational material in human thought, Pushkin skipped lightly over various theories, ranging from the one that holds nerve cells to be elements of a living cybernetic computer to the one which claims that not the cells but the molecules of matter within them may be the basic informational units.

"What is actually irritating the flower?" asked Pushkin, then answered that it might turn out to be some kind of biophysical structure, the ejection of which beyond the confines of the human organism takes place the moment a marked emotional state is reached and carries information about the person from whom it is ejected. Whatever the truth may turn out to be, continued Pushkin, one thing is sure: "Research into the plant and man interrelationships can shed light on some of the most urgent problems in contemporary psychology."

The magic and mystery of the world of plants lying behind these scientific doings have also recently become the subject of a new book entitled *Grass* by a popular slavophile writer, Vladimir Soloukhin, which appeared in four issues of the three-million-circulation magazine *Nauka i Zhizn (Science and Life)* at the end of 1972. Born a country boy in a village outside the ancient city of Vladimir in northern Russia, Soloukhin became fascinated with the *Pravda* account of Gunar's work and wondered why it had not evoked more excitement among his fellow Russians.

"Perhaps the elements of memory in plants are superficially treated," he writes, "but at least there they are in black and white! Yet no one calls his friends or neighbors, no one shouts in a drunken voice over the telephone: Have you heard the news? Plants can feel! They can feel pain! They cry out! Plants remember everything!"

When Soloukhin began to telephone his own friends in excitement he learned from one of them that a prominent member of the Soviet Academy of Sciences, working in Akademgorodok, the new town inhabited almost exclusively by research scientists on the outskirts of Siberia's largest industrial center, Novosibirsk, had stated:

> Don't be amazed! We too are carrying out many experiments of this kind and they all point to one thing: plants have memory. They are able to gather impressions and retain them over long periods. We had a man molest, even torture, a geranium for several days in a row. He pinched it, tore it, pricked its leaves with a needle, dripped acid on its living tissues, burned it with a lighted match, and cut its roots. Another man took tender care of the same geranium, watered it, worked its soil, sprayed it with fresh water, supported its heavy branches, and treated its burns and wounds. When we electroded our instruments to the plant, what do you think? No sooner did the torturer come near the plant than the recorder of the instrument began to go wild. The plant didn't just get "nervous"; it was afraid, it was horrified. If it could have, it would have either thrown itself out the window or attacked its torturer. Hardly had this inquisitor left and the good man taken his place near the plant than the geranium was appeased, its impulses died down, the recorder traced out smooth—one might almost say tender—lines on the graph.

In addition to a plant's ability to recognize friend and foe, Soviet researchers also noted that one plant supplied with water can somehow share it with a deprived neighbor. In one institute of research a cornstalk planted in a glass container was denied water for several weeks. Yet it did not die; it remained as healthy as other cornstalks planted in normal conditions nearby. In some way, say Soviet botanists, water was transferred from healthy plants to the "prisoner" in the jar. Yet they have no idea how this was accomplished.

As fantastic as this may seem, a kind of plant-to-plant transfer has been taking place in England in experiments begun in 1972 by Dr. A. R. Bailey. Two plants in an artificially lit greenhouse in which temperature, humidity, and light were carefully controlled were suffering from lack of water. Bailey and his collaborator measured the voltages generated between two parts of both plants. When one plant was watered from the outside through plastic tubes, the other plant reacted. As Bailey told the British Society of Dowsers: "There was no electrical connection between them, no physical connection whatsoever, but somehow one plant picked up what was going on with the other."

Soloukhin, in his book *Grass,* the title of which conveys, as with Carl Sandburg, Walt Whitman, or Pete Seeger, the most extended meaning of the word "grass," or indeed everything growing, took to task the lack of sensitivity to the vegetal world around them on the part of the Soviet populace. Targets of his criticism included agricultural bureaucrats, individual collective farmers, lumber executives, and even salesgirls in Moscow flower shops.

"Human observation," writes Soloukhin ironically in the opening chapter of *Grass,* "is so precise that we begin to notice the very air we breathe only when it is insufficient for our needs. More exactly, I should say 'value' rather than 'notice.' We do not really value air, or even think about it, so long as we can breathe normally, without difficulty." He adds that, though man prides himself on his vast array of knowledge, he is like a radio technician who knows how to repair a receiver without understanding the theoretical essence of radio waves, or like our cavemen ancestors who put fire to use while unaware of the process of rapid oxidation. Even today, says Soloukhin, we squander heat and light yet have not the slightest clue to, or interest in, their original essence.

Man is equally callous, says Soloukhin, about the fact that the land around him is green. "We trample grasses into dirt, we strip the land with bulldozers and caterpillar treads, we cover it with concrete and hot asphalt. Disposing of wastes from our infernal industrial machines we dump upon it crude oil, rubbish, acids, alkalis, and other poisons. But is there that much grass? I, for one, can imagine man in a boundless, grassless wilderness, the product of a cosmic, or perhaps humanly noncosmic, catastrophe."

Seeking to re-evoke wonder for nature in the hearts of an overurbanized Soviet youth, Soloukhin tells the story of a prisoner who, incarcerated in a dank cell, finds among the pages of an old book, given him by a kindly jailer, a tiny seed smaller than a pinhead. Overcome with emotion at the first visible sign of real life he has seen for years, the prisoner imagines that the microscopic seed is all that remains from the

former luxuriant and festive plant kingdom in the great world outside the prison. Planting the seed in a bit of earth in the sole corner of the cell afforded a ray of sunlight, and watering it with his tears, the prisoner waits for a wonder to unfold.

Soloukhin accepts this wonder as a true miracle ignored by man only because it is repeated thousands of billions of times daily. Even if all the world's chemical and physical laboratories with their complex reagents, precise analyses, and electronic microscopes were placed at the prisoner's disposal, he continues, even if the prisoner studied the seed's every cell, atom, and atomic nucleus, he still would not be able to read the mysterious program lying within the seed, to lift the impenetrable veil which could cause it to transform itself into a juicy carrot, a branch of sweet-scented dill, or a radiant-colored aster.

Soloukhin was fascinated with the statement by I. Zabelin, doctor of geographical sciences and Moscow University professor, who in his article "Dangerous Delusions" in one of the USSR's leading opinion forums, *Literaturnaya Gazetta,* wrote: "We are only beginning to comprehend the language of nature, its soul, its reason. The 'inner world' of plants is hidden from our gaze behind seventy-seven seals." Though these lines were in no way emphasized in the printed column, says Soloukhin, "they appeared to me as bold-face type."

During a trip to Paris, Soloukhin was happy to observe florist shops scattered in all, and even the poorest, districts of the French capital. Finding a decent bouquet of flowers in the Soviet capital, he says, can become the object of a day-long search.

Soloukhin has recently attacked the obtuse views of Soviet agricultural officials. Writing in the October, 1972, issue of *Literaturnaya Gazetta,* he deplores the abandon with which generations-old natural Russian meadowlands have been allowed to deteriorate while fields needed for cereal crops are being plowed and planted to grasses for animal fodder. "We could cover Europe with hay and green grass from our meadows and build a haystack extending from the Mediterranean to Scandinavia," writes Soloukhin. "Well, why don't we?" His rhetorical question only provoked an angry rebuttal from the USSR's Deputy Minister of Agriculture, who insisted on upholding the status quo.

In a battle similar to that taking place in the United States and other countries, Soloukhin is unremittingly denouncing unecologically minded industrialists in his country, who are turning the rivers and lakes into cesspools, and despoiling its forests, all in the name of increased production. Seeking to reverse a half century of Communist dicta, this "passionate lover of nature, its defender and bard"—to quote one of Soloukhin's publishers—exhorts his countrymen to cooperate with, rather than subdue, nature.

That the Soviets are bent on introducing the idea of substituting for the burning of coal, oil, and natural gas—three forms of preserved solar energy originally captured by plants—new, more direct, and pollution-free ways to tap the sun was revealed by an article in the first 1973 issue of *Khimiya i Zhizn (Chemistry and Life).* The article pointed to the research of the American Nobel Prize winner Melvin Calvin in photosynthesis, wherein he discovered that plant chlorophyll under the influence of the sun's rays can give up electrons to a semiconductor such as zinc oxide. Melvin and his co-workers created a "green photoelement," which produced a current of approximately 0.1 microamperes per square centimeter. After several minutes, said the Soviet magazine, the plant chlorophyll becomes desensitized or "exhausted," but its life could be extended by the addition of hydroquinone to the salt solution which acts as an electrolyte. The chlorophyll seems to act as a kind of electron pump passing electrons from the hydroquinone to the semiconductor.

Calvin has calculated that a chlorophyll photoelement with an area of ten square meters could yield a kilowatt of power. He has theorized that in the next quarter century such photoelements could be manufactured on an industrial scale and would be a hundred times cheaper than silicone solar batteries now being experimented with.

Even if the direct conversion of sunlight into energy via plant chlorophyll is not realized by the year 2000, says *Chemistry and Life,* it wouldn't put too much of a burden on man to wait a few decades longer when he considers the millions of years it took to convert plants into coal.

As Soviet readers were being offered the notion that plants could one day directly produce energy for man's needs from the sun, Professor Gunar, together with an increasing number of young Soviet scientists,

was continuing to probe the awareness of plants to determine, for instance, how their reactions may serve as an index of frost, cold, and heat resistance in varieties of barley and cucumbers and of disease potentials in potatoes.

A clue to where Professor Gunar got the original inspiration to launch his series of detailed and ongoing studies on plants, which were to have such repercussions throughout the Soviet republics, is to be found in an article published in 1958 by A. M. Sinyukhin. This colleague of Gunar's refers to an outstanding Indian physiologist and biophysicist whose work was buried during his lifetime by Western science and hardly ever cited since his death. As early as 1920 Kliment Arkadievich Timiryazev, in whose honor the Moscow Agricultural Academy is named, heralded this work as introducing a new epoch in the development of world science. This unheralded genius, wrote Timiryazev, developed an apparatus, startling in its simplicity and sensitivity, to counter the entrenched idea of the German botanists that communication in plant tissue was simply hydrostatic. In so doing, he was able to measure in hundredths of a second the time needed for a signal to travel along the stems of various plants.

Sinyukhin made clear that the USSR's plant men were so impressed by the achievements of this Indian scientist that they were going to mount a research campaign based directly upon his long-ignored conclusions. In December, 1958, a pontifical meeting was held in the main conference hall of the USSR Academy of Sciences in celebration of the hundredth anniversary of the Indian sage's birth. Three leading academicians summed up for the huge crowd assembled the fantastic breakthroughs which the Indian had made not only in plant physiology but in physics and in the vital and up to then unheard-of links between these distinct disciplines.

"Many years, during the course of which whirlwind developments have taken place in biophysics," said A. V. Lebedinskii, one of the leading Russian pioneers in radiobiology and space medicine, "separate us from the time this Indian's work appeared. But, reading his works today, one still senses in them an unexpected and fruitful source of a whole chain of ideas in contemporary science."

In this great work, said another speaker, "The green world of plants, seeming to us so immobile and insensitive, came miraculously to life and appeared no less, and often even more, sensitive than animals and man."

Six years later the Soviet Union honored this neglected scientist by publishing in two handsomely illustrated volumes his selected works, together with copious commentaries including one entire book which had first made its appearance over half a century before, in 1902: *Response in the Living and Non-Living.* In these works Sir Jagadis Chandra Bose managed to accomplish the essential requirement of the twentieth century: an amalgamation of the wisdom of the ancient East with the precise scientific techniques and language of the modern West.

PART II

PIONEERS OF PLANT MYSTERIES

CHAPTER 6

Plant Life Magnified 100 Million Times

On the eastern coast of the subcontinent of India, in the old state of Bengal, there stands on four acres of ground off the Acharya Prafullachandra Road, north of Calcutta University, a complex of buildings made of fine grayish and purple sandstone in the classical design of pre-Mohammedan India. The main edifice, known as the Indian Temple of Science, bears an inscription: "This temple is dedicated to the feet of God for bringing honor to India and happiness to the world."

Just inside the entrance are glass cases containing a series of intriguing instruments devised more than fifty years ago to measure the growth and behavior of plants, down to their minutest detail, by magnification of these processes up to 100 million times. The instruments stand in their cases, in mute testimony to the genius of a great Bengali scientist whose work united in one man the fields of physics, physiology, and psychology, and who found out more about plants than anyone before and perhaps after him, but who remains almost unmentioned in classical histories of subjects in which he specialized.

The buildings and their gardens are the Institute of Research built by Sir Jagadis Chandra Bose, of whose work in the field of plant physiology the *Encyclopaedia Britannica* could only say, nearly half a century after his death, that it was so much in advance of his time it could not be precisely evaluated.

When Bose was still a child, his father had already painfully discerned in 1852 the main impact of the British education system on Indian children: the imposition of a slavish and monotonous imitation of all things Western and the requirement to learn by rote. The senior Bose, therefore, sent his son to a simple village *pathasala* rather than a colonial primary school.

At the age of four the boy was carried to his classroom on the shoulders of a reformed gang robber, or *dacoit,* who could find employment after a long jail term with no one but Bose's father. From this *dacoit* the boy absorbed stories of savage battles and adventurous escapades, but was also exposed to the natural goodness of a man who had been befriended after being rejected by society as a criminal. "No nurse," Bose wrote in his later life, "could have been kinder than this leader of lawless men. Though he scoffed at the juridical strictures of society, he had the deepest veneration for natural moral law."

Bose's early contacts with the peasantry also were crucial to his own appreciation of the world. Much later he told an academic gathering: "It was from those who till the ground and make the land blossom with green verdure, from the sons of fisher-folk who told stories of the strange creatures that frequented the depths of mighty rivers and of stagnant pools, that I first derived a lesson of that which constituted true manhood. From them, too, I drew my love of nature."

When Bose graduated from St. Xavier's College, his brilliant teacher Father Lafont was so impressed by the young man's aptitude in physics and mathematics that he wanted him to go to England and read for the Civil Service examinations. Bose's father, who had personally experienced the deadening nature of that profession, advised his son to become, not an administrator, but a scholar, with the prospect of ruling nobody but himself.

At Christ College Bose was taught physics, chemistry, and botanical sciences by such luminaries as Lord Rayleigh, discoverer of argon in the air, and Francis Darwin, son of the evolutionary theorist. Having passed his tripos examinations, Bose went on to take a bachelor's degree in science the following year at London University. But when Bose was appointed professor of physics at Calcutta's Presidency College, reputedly the best in India, the appointment was protested by the college's principal and by the director of Bengal's public instruction, who maintained the all too usual view that no Indian was competent to teach science.

To get back at Bose for being recommended over their heads by a letter from the Postmaster General to the Viceroy, they offered him a special appointment at a salary only half that of the English professors, and gave him no facilities to carry on research. In protest Bose refused to touch his monthly salary check for three years, which obliged him to live in bitter deprivation, the more so as his father had fallen heavily into debt.

That Bose was brilliant as a teacher was attested by the fact that no roll call had to be instituted in his classroom, which was always packed to the walls. Bowing to his obvious talents, the authorities who had snubbed him finally gave him a position at full pay.

Although Bose had no resources other than his own salary, a twenty-square-foot room to serve as a laboratory, and an illiterate tinsmith whom he trained as his mechanic, he began work in 1894 to see if he could improve the instruments recently devised by Heinrich Rudolph Hertz to transmit "Hertzian" or radio waves through the air. Hertz, who died that same year at the premature age of thirty-seven, had startled the world of physics by fulfilling in his laboratory the prediction of the Scottish physicist James Clerk Maxwell, nearly twenty years before, that the waves of any "electrical disturbance in the ether"—the variety and scope of which was far from known—would, like those of visible light, be reflective, refractible, and polarizable.

While Marconi in Bologna was still trying to transmit electric signals through space without wires, a race he was to win officially against similar efforts by Lodge in England, Muirhead in the United States, and Popov in Russia, Bose had already succeeded. In 1895, the year before Marconi's patent was issued, at a meeting in the Calcutta town hall, presided over by Sir Alexander Mackenzie, the lieutenant-governor of Bengal, Bose transmitted electric waves from the lecture hall through three intervening walls—and Mackenzie's portly body—to a room seventy-five feet away, where they tripped a relay which threw a heavy iron ball, fired off a pistol, and blew up a small mine.

Bose's accomplishments now began to attract the attention of the British Royal Society (equivalent of the academy of sciences in other countries), which, at Lord Rayleigh's behest, invited Bose to publish a paper in its proceedings on the "Determination of the Wave Length of Electric Radiation," and offered him a subsidy from its parliamentary grant for the advancement of science. This was followed by Bose's being awarded a doctorate of science by London University.

The *Electrician*, leading journal in its field, came forward to suggest that, on the basis of Bose's work, it might now become practical to place electromagnetic transmitters in lighthouses and receivers on ships to offer mariners a "third eye" capable of penetrating fog.

In England Bose gave a lecture on his apparatus for investigating electromagnetic waves before a meeting of the British Association for the Advancement of Science in Liverpool, which so impressed Lord Kelvin that he limped up to the ladies' gallery to congratulate Bose's beautiful wife in the most glowing terms on her husband's brilliant work. This triumph was followed in January, 1897, by an invitation to address the Royal Institution at one of its Friday Evening Discourses, which, since the institute's establishment, had become the principal venue for announcements of fresh and momentous investigations and discoveries.

Of Bose's address the *Times* wrote: "The originality of the achievement is enhanced by the fact that Dr. Bose had to do the work in addition to his incessant duties and with apparatus and appliances which

in this country would be deemed altogether inadequate." The *Spectator*, echoing this accolade, announced: "There is something of rare interest in the spectacle of a Bengali of the purest descent lecturing in London to an audience of appreciative European savants upon one of the most recondite branches of modern physical science."

Back in India, Bose was buoyed to find that a communication signed by Lord Lister, president of the Royal Society, and by other scientific luminaries, had been sent to the Secretary of State for India, recommending that a center for research and advanced teaching in physics "worthy of that great Empire" be established under Bose's direction at Presidency College.

Despite this recommendation, and an immediate grant by the Imperial Government of £40,000 to set up the center forthwith, mean-minded, jealous functionaries in the Bengal Education Department succeeded in so tying up the project that it never came to fruition. Only the gesture of his fellow Bengali, the poet Rabindranath Tagore, later to win the Nobel Prize for literature, alleviated Bose's disappointment: Tagore came specially to greet him and not finding him at home left a huge magnolia blossom in token of his tribute.

Doggedly pursuing his research whenever the press of his teaching duties in the backbiting climate of the college offered him a spare moment, Bose published in 1898 four papers on the behavior of electric waves, in the *Proceedings of the Royal Society* and in Great Britain's foremost popular scientific journal, *Nature*.

In 1899 Bose noticed the strange fact that his metallic coherer for receiving radio waves became less sensitive if continuously used but returned to normal after a period of rest. This led him to the conclusion that metals, however inconceivably, might exhibit a recovery from fatigue similar to that which took place in tired animals and people. Further work began to convince Bose that the boundary line between so-called "nonliving" metals and "living" organisms was tenuous indeed. Spontaneously moving from the domain of physics into that of physiology, Bose began a comparative study of the curves of molecular reaction in inorganic substance and those in living animal tissue.

To his awe and surprise, the curves produced by slightly warmed magnetic oxide of iron showed striking resemblance to those of muscles. In both, response and recovery diminished with exertion, and the consequent fatigue could be removed by gentle massage or by exposure to a bath of warm water. Other metal components reacted in animal-like ways. A metal surface etched with acid when polished to remove all trace of the etching exhibited reactions in its acid-treated sections which could not be elicited in those nontreated. Bose ascribed to the affected sections some kind of lingering memory of the treatment. In potassium he found that the power of recovery was almost totally lost if it was treated with various foreign substances; this seemed to parallel the reactions of muscular tissue to poisons.

In a presentation to the International Congress of Physics, held in 1900 at the Paris Exhibition, entitled "De la Généralité des Phénomènes Moléculaires Produits par l'Electricité sur la Matière Inorganique et sur la Matière Vivante," Bose stressed the "fundamental unity among the apparent diversity of nature," concluding that "it is difficult to draw a line and say that here the physical phenomenon ends and here the physiological begins." The congress was *"bouleversé"* by Bose's earth-shaking suggestion that the gulf between the animate and inanimate might not be as broad and unspannable as generally believed; its secretary declared himself "stunned."

The enthusiasm of his fellow physicists was, however, not matched by the coterie of physiologists who were invited the following September to a meeting of the physics section of the British Association for the Advancement of Science at Bradford. Because Bose's research overlapped onto territory which they considered their private preserve, the physiologists listened with hostile silence while Bose read a paper contending that Hertzian waves could be used as a stimulating agent on tissues, and that metal response was analogous to that of tissues. To meet the physiologists on their ground, Bose meticulously adapted his experiments to an accepted "electromotive variation" to which they were accustomed, and again got similar curves of muscles and metals responding to the effects of fatigue or of stimulating, depressing, and poisoning drugs.

Shortly thereafter it dawned on Bose that if the striking continuity between such extremes as metals and animal life were real he should also

be able to get similar effects in ordinary vegetable plants, which, because they were held to have no nervous systems, were universally reckoned as unresponsive. Picking several horse-chestnut leaves from a tree in the garden next to his lab, Bose found that they responded to various "blows" in much the same way as had his metals and muscles. Excited by the results, he betook himself to his greengrocer and purchased a bag of carrots and turnips, which, of all vegetables, appeared the most stolidly nonsentient, and found them to be highly sensitive. When he chloroformed plants, Bose discovered that they were as successfully anesthetized as animals, and that when the narcotic vapor was blown away by fresh air like animals they revived. Using chloroform to tranquilize a huge pine tree, Bose was able to uproot it and transplant it without the usually fatal shock of such operations.

When Sir Michael Foster, secretary of the Royal Society, came to Bose's laboratory one morning to see for himself what was happening and Bose showed the Cambridge veteran some of his recordings, the older man said jocularly: "Come now, Bose, what is the novelty of this curve? We have known it for at least half a century!"

"But what do you think it is?" Bose persisted quietly.

"Why, a curve of muscle response, of course!" said Foster testily.

Looking at the professor from the depths of his haunting brown eyes, Bose said firmly: "Pardon me, but it is the response of metallic tin!"

Foster was aghast. "What?" he shouted, jumping from his chair, "Tin? Did you say tin?"

When Bose showed him all his results, Foster was as thrilled as he was astounded. On the spot, he invited Bose to give an account of his discoveries at another Friday Evening Discourse at the Royal Institution and offered to communicate his paper personally to the Royal Society in order to secure his priority. At the evening meeting of May 10, 1901, Bose marshaled all the results obtained over four years and demonstrated each one of them with a comprehensive series of experiments before ending with a peroration:

> I have shown you this evening autographic records of the history of stress and strain in the living and non-living. How similar are the writings! So similar indeed that you cannot tell one apart from the other. Among such phenomena, how can we draw a line of demarcation and say, here

the physical ends, and there the physiological begins? Such absolute barriers do not exist.

It was when I came upon the mute witness of these self-made records, and perceived in them one phase of a pervading unity that bears within it all things—the mote that quivers in ripples of light, the teeming life upon our earth, and the radiant suns that shine above us—it was then that I understood for the first time a little of that message proclaimed by my ancestors on the banks of the Ganges thirty centuries ago: "They who see but one, in all the changing manifoldness of this universe, unto them belongs Eternal Truth—unto none else, unto none else!"

Bose's lecture was warmly received and to his surprise his views went unchallenged, despite the metaphysical note at its end. Sir William Crookes even urged that the last quotation not be omitted when the address was published. Sir Robert Austen, one of the world's authorities on metals, praised Bose for his faultless arguments, saying, "I have all my life studied the properties of metals and am happy to think that they have life." He confessed confidentially that he had formed a similar opinion but had been rebuffed when he had once hesitantly hinted at it before the Royal Institution.

A month later, when Bose repeated his lecture and demonstrations before the Royal Society, he received an unexpected blow from "the grand old man of physiological science in England," Sir John Burdon-Sanderson, whose principal work had been a study of muscle behavior and the movements of the Venus's flytrap to which Darwin had first called his attention. As Burdon-Sanderson was *the* authority on electro-physiology, all turned to him to open the discussion which followed Bose's speech.

Burdon-Sanderson began by complimenting Bose on his acknowledged work in physics but followed with the remark that it was "a great pity" that he had wandered from his own field of study to areas which belonged properly to the physiologist. Since Bose's paper was still under consideration for publication he suggested that its title be changed from "Electrical Response in . . ." to "Certain Physical Reactions in . . . ," thus leaving to the physiologists the term "response" with which physicists should not be concerned. As for the electrical responses of ordinary plants, which Bose had described at the end of his address, Burdon-

Sanderson denied categorically that such were possible, since "he himself had tried for many years past to obtain them and had never succeeded."

In his reply Bose said candidly he understood that the *facts* experimentally demonstrated were not questioned by his critic. If, therefore, he was not being impugned on the basis of this evidence, but was being asked to make modifications which altered the whole purpose and meaning of his presentation, on the basis of *authority* alone, he would have to decline. It seemed to Bose inexplicable, he said, that any doctrine could be advocated before the Royal Society which suggested that knowledge could not advance beyond known bounds. Unless he was shown on scientific grounds where his experiments were faulty or defective, he would insist his paper be published as he had written it. At the end of his rebuttal, when no one rose to break the icy silence which hung over the hall, the meeting was adjourned.

Because of doubt thrown on his work by so eminent an expert as Burdon-Sanderson, and to put down a younger man who had so outspokenly challenged his senior, the society voted not to follow up Bose's "preliminary notice" with the full publication of his paper in its *Proceedings*, and instead buried it in its archives, a fate which had befallen other notable papers in the past. To Bose, who all his life had listened to Britishers lecture against the evils of the Indian caste system, the vote seemed to evidence the existence of a not dissimilar system within British science itself. At the institution's laboratories, Bose was consoled by Lord Rayleigh, who told him that he too had been subjected to ceaseless attacks from chemists because, as a physicist, he had had the temerity to predict that a hitherto unsuspected new element would be found in air, a prediction shortly to be verified by his discovery, with the help of Sir William Ramsay, of argon.

The controversy with the physiologists elicited the interest of Bose's former teacher Professor Sidney Howard Vines, the well-known botanist and vegetable physiologist at Oxford, who called on Bose and asked if he could witness Bose's experiments. Vines brought with him T. K. Howes, who had succeeded T. H. Huxley at the British Museum's Department of Botany at South Kensington. When the men saw Bose's plant respond to stimulus, Howes exclaimed: "Huxley would have given years of his life to see this experiment." As secretary of the Linnean Society, he told Bose that, since his paper had been refused for publication by the Royal Society, not only would the Linnean accept it but also he would invite Bose to repeat all his experiments before the physiologists, particularly his opponents.*

As a result of this new presentation to the Linnean Society, on February 21, 1902, Bose was able to write to his friend Tagore: "Victory! I stood there alone, ready for hosts of opponents, but in fifteen minutes the hall was resounding with applause. After the paper, Professor Howes told me that as he saw each experiment, he tried to get out of it by thinking of a loophole of explanation, but my next experiment closed that hole." The president of the Linnean Society wrote Bose a few days later: "It seems to me that your experiments make it clear beyond doubt that all parts of plants—not merely those which are known to be motile—are irritable, and manifest their irritability by an electrical response to stimulation. This is an important step in advance, and will, I hope, be the starting point for further researches to elucidate what is the nature of the molecular condition which constitutes irritability, and the nature of the molecular change induced by a stimulus. This would doubtless lead to some important generalities as to the properties of matter, not only living matter, but non-living matter as well."

Since ordinary plants and their different organs exhibited electrical response indicative of excitation under mechanical and other stimuli, it puzzled Bose that they gave no sign of this excitement by *visible movement.* Unlike the mimosa leaf, which, if irritated, abruptly collapses, owing to a contraction of its cushion-shaped base, or pulvinus, other plants seem, at least to the eye, placidly unconcerned when scraped, burned, or otherwise interfered with. Back home in Calcutta, it suddenly hit Bose that the contraction in the mimosa was magnified by its long leaf stalk. To similarly magnify a suspected contraction in other plants,

*The Linnean Society, named after Carl von Linné or Linnaeus (1707–1778), the great Swedish botanist whose *Genera Plantorum* is considered the starting point of modern systematic botany, was organized at the end of the eighteenth century when Sir J. E. Smith, its first president, acquired Linnaeus' botanical library from his widow.

he designed a special optical lever with which he was able to demonstrate visually that *all the characteristics of the responses exhibited by animal tissues were also found in those of plants.*

Bose communicated the results of these new and extended investigations in December, 1903, in a series of seven papers to the Royal Society, which immediately planned their publication the following year in its "Philosophical Transactions," a series reserved for only the most significant and momentous scientific findings. However, as the papers were being readied for the printer, underhanded intrigues and prejudicial insinuations, which had almost suppressed his Linnean Society offering, began anew and, with Bose unable to refute them from far-off India, won the day.

Convinced by Bose's opponents that his theories should not be officially printed, and without waiting for his detailed records, the society changed its august mind and once again filed Bose's papers in its archives. To Bose this vacillation by the society only justified his decision, taken two years before, no longer to rely wholly upon the acceptance of others before presenting his astonishing discoveries to the world. "Although," as he put it, "I thought I was much too lazy to write books, I was forced into it." To guarantee that the substance of the lectures he had given in London, Paris, and Berlin should receive the widest possible circulation, Bose completed a book-length account of all his experimentation up to the middle of 1902, which was published the same year under the title *Response in the Living and Non-Living.*

Herbert Spencer, the great British synthetic philosopher, very much alive to the important scientific advances of his time, despite his entry at eighty-three into the last year of his life, personally acknowledged Bose's volume with the regret that it was too late for him to incorporate its data into his own massive *Principles of Biology.* Two years later, Professor Waller, one of Bose's most adamant opponents, quietly inserted into his new book, without even mentioning Bose's name, the Bengali's assertion that "any vegetable protoplasm gives electrical response."

Bose then began to concentrate on determining how *mechanical* movements in plants might be similar to those in animals and humans.

Since he knew that in plants there was respiration without gills or lungs, digestion without a stomach, and movements without muscles, it seemed plausible to Bose that there could be the same kind of excitation as in higher animals but without a complicated nervous system.

Bose concluded that the only way to find out about the "unseen changes which take place in plants" and tell if they were "excited or depressed" would be to measure visually their responses to what he called "definite testing blows" or shocks. "In order to succeed in this," he wrote, "we have to discover some compulsive force which will make the plant give an answering signal. Secondly, we have to supply the means for an automatic conversion of these signals into an intelligent script. And, last of all, we have ourselves to learn the nature of these hieroglyphics." In this single statement Bose mapped out for himself a course for the next two decades.

He first began by improving his optical lever into an optical pulse recorder. Consisting of a pair of drums over which revolved a continuous paper band driven by clockwork, this device picked up movements in the plant which were translated through a movable lever attached to a set of mirrors which reflected a beam of light onto the paper. The excursion of the shifting spot of light, followed by means of a sliding inkwell with an ink sponge protruding from it, made visible for the first time movements in plant organs which had thus far remained hidden to the scientific world.

With the aid of this instrument, Bose was able to show how the skins of lizards, tortoises, and frogs as well as those of grapes, tomatoes, and other fruits and vegetables behaved similarly. He found that the vegetal digestive organs in insectivorous plants, from the tentacle of a sundew to the hair-lined flap of a pitcher plant, were analogous to animal stomachs. He discovered close parallels between the response to light in leaves and in the retinas of animal eyes. With his magnifier he proved that plants become as fatigued by continuous stimulation as animal muscles, whether they were hypersensitive mimosas or undemonstrative radishes.

Working with the *Desmodium gyrans*, a species whose continuously oscillating leaves recall the motion of semaphore flags and led to its

common appellation, telegraph plant, Bose found that the poison which could stop its automatic ceaseless pulsation would also stop an animal heart and that the antidote for this poison could bring both organisms back to life.

Bose demonstrated the characteristics of a nerve system in mimosa, a plant whose leaflets are symmetrically arranged on each leaf with several leaves stemming from more or less the same point, the whole leaf system borne on small branchlets or petioles issuing from the main stem.

When Bose electrically shocked the stem or touched it with a hot wire, the base of the nearest petiole collapsed within seconds, to be followed, after another interval, by the folding of the leaves at its end. Connecting a galvanometer to the petiole, Bose recorded an electrical disturbance between these two points of reaction. If he touched the tip of a leaf with a hot object, first the leaflets closed and then the base segment drooped.

Bose interpreted these actions as due to electrical excitation, which, in turn, produced mechanical responses; this was also what happened in the animal nerve-muscle unit, where the nerve carried the electric impulse and the muscle contracted in response. Bose later proved that identical results could be produced in both plant and animal systems by cold, anesthesia, or the passage of a weak current.

Bose showed that in mimosa there exists the same kind of "reflex arc" which causes us to withdraw our fingers instantly from a hot stove before pain can be felt. When Bose touched the tip of one leaf on a three-leaf petiole he saw that the leaflets of the disturbed leaf gradually closed, starting from the tip; then the petiole collapsed; lastly, the other two leaves closed from the base upward.

In *Desmodium gyrans*, or the telegraph plant, Bose found that if the cut end of a detached leaflet was dipped in water in a bent glass tube it recovered from the shock of its amputation and began to pulsate anew. Was this not like an excised animal heart which can be kept beating in Ringer's solution? Just as the heart stops beating when blood pressure is lowered and starts again when pressure is raised, Bose found the same was true for the pulsation of the *Desmodium* when the sap pressure was increased or decreased.

Bose experimented with heat and cold to ascertain the optimal conditions under which plant movement was best elicited. One day he found that when all motion stopped in his plant, it suddenly shuddered in a way reminiscent of the death spasm in animals. To determine exactly the critical temperature at which death occurred, he invented a morograph, or death recorder. While many plants met their end at sixty degrees Centigrade, individual plants exhibited variations depending on their previous histories and ages. If their power of resistance was artificially depressed by fatigue, or poison, the death spasm would take place with temperatures as low as twenty-three degrees Centigrade. At death, the plant threw off a huge electrical force. Five hundred green peas could develop five hundred volts, said Bose, enough to fulminate a cook but for the fact that peas are seldom connected in series.

Though it had been thought that plants liked unlimited quantities of carbon dioxide, Bose found that too much of this gas could suffocate them, but that they could then be revived, just like animals, with oxygen. Like human beings, plants became intoxicated when given shots of whiskey or gin, swayed like any barroom drunkard, passed out, and eventually revived, with definite signs of a hangover. These findings together with hundreds of other data were published in two massive volumes in 1906 and 1907.

Plant Response as a Means of Physiological Investigation ran to 781 pages and detailed 315 separate experiments. These went against an entrenched notion, which Bose thus explained: "From the plausible analogy of the firing off of a gun by pulling a trigger, or the action of a combustion engine, it has been customary to suppose that all response to stimulus must be of the nature of an explosive chemical change, accompanied by an inevitable rundown of energy." Bose's experiments, on the contrary, showed him that in plants their movement, the ascent of their sap, and their growth were due to energy absorbed from their surroundings, which they could hold latent or store for future use.

These revolutionary ideas, and especially the finding that plants had nerves, were received with veiled hostility among botanists. The *Botanical Gazette* commended Bose for a path-breaking achievement, but held that his book was "not without errors into which the author has fallen by reason of some unfamiliarity with his materials."

Even as the botanists grumbled, Bose sent to the printer a second, equally massive, volume, *Comparative Electro-Physiology*, setting forth 321 additional experiments; its findings also clashed with current teaching and doctrine. Instead of emphasizing the accepted wide range of specific differences between the reactions of various plant and animal tissues, Bose consistently pointed to a real continuity between them. The nerve, universally held to be typically nonmotile, he showed capable of indisputable movement, which could more delicately be ascertained by mechanical than by electrical means. Whereas plants were considered to lack all power of conducting true excitation, Bose showed they were in fact possessed of this power.

Even more heretically, Bose held that the isolated vegetal nerve is indistinguishable from animal nerve: "So complete, indeed, has that similarity between the responses of plant and animal, of which this is an instance, been found," wrote Bose, "that the discovery of a given responsive characteristic in one case has proved a sure guide to its observation in the other, and that the explanation of a phenomenon, under the simpler conditions of the plant, has been found fully sufficient for its elucidation under the more complex circumstances of the animal."

Going even further, Bose maintained that when electromotive intensity was above or below a certain range the law of polar effects of currents, established by Pflüger, was overturned; in addition, a nervous impulse, supposed to lie beyond any conceivable power of visual scrutiny, attended by a change of form, was entirely capable of direct observation.

The authoritative scientific magazine *Nature*, left gasping by both volumes, wrote of the first: "In fact, the whole book abounds in interesting matter skillfully woven together and would be recommended as of great value if it did not continually arouse our incredulity." Of the second, *Nature* was equally ambivalent in its attitude. "The student of plant physiology," said the reviewer, "who has some acquaintance with the main classical ideas of his subject, will feel at first extreme bewilderment as he peruses this book. It proceeds so smoothly and logically, and yet it does not start from any place in the existing 'corpus' of knowledge, and never attaches itself with any firm adherence. This effect of detachment is heightened by the complete absence of precise reference to the work of other investigators." There were, of course, no other investigators; and the reviewer, limited by the compartmentalized science of his day, had no way of knowing he was dealing with a genius half a century ahead of his time.

In a short statement Bose summed up his philosophy: "This vast abode of nature is built in many wings, each with its own portal. The physicist, the chemist and the biologist come in by different doors, each one his own department of knowledge, and each comes to think that this is his special domain unconnected with that of any other. Hence has arisen our present division of phenomena into the worlds of inorganic, vegetal and sentient. This philosophical attitude of mind may be denied. We must remember that all inquiries have as their goal the attainment of knowledge in its entirety."

One of the blocks to the acceptance by plant physiologists of Bose's revolutionary findings was their inability to construct the delicate instruments he had devised. Yet the mounting opposition to his basic thesis that responses in plants are similar to those due to the nervous system of animals convinced Bose that he should develop an even more refined set of instruments for automatic stimulation and recording of response. He therefore designed a resonant recorder, capable of measuring time up to 1/1000 of a second, to make rapid movement in plants apparent, and an oscillating recorder to reveal the slowest movement in plants.

With the assistance of his new recorder Bose got results on the nervous impulse so convincing that this time they were published in the Royal Society's *Philosophical Transactions.* In the same year Bose published his third massive volume of experimentation, *Researches in Irritability of Plants;* 376 pages; 180 experiments.

In 1914, Bose left for Europe on a fourth scientific mission, this time carrying not only his various instruments but specimens of *Mimosa pudica* and *Desmodium gyrans* to illustrate his lectures. In England he demonstrated before audiences at Oxford and Cambridge how a plant touched on one side would shiver and react on the other. He addressed evening meetings of both the Royal Institution and the Royal Society of Medicine, where Sir Lauder Brunton, who had made experiments on

insectivorous plants for Charles Darwin in 1875, remarked that all the subsequent physiological experimentation he had seen since then was "crude in comparison with yours in which you show what a marvellous resemblance there is between the reactions of plants and animals."

The vegetarian and antivivisectionist George Bernard Shaw, having witnessed in Bose's laboratory, through one of Bose's magnifiers, a cabbage leaf going through violent paroxysms as it was scalded to death, dedicated his own collected works to Bose, inscribing them: "From the least to the greatest living biologist." A repentant animal physiologist who had cast the single vote preventing publication of plant research by the Royal Society came up to Bose to confess his misdeed and said, "I could not believe that such things were possible and thought your oriental imagination had led you astray. Now, I fully confess that you have been right all along." Bose, letting bygones be bygones, never divulged his name.

Bose's research was for the first time vividly recorded for the public in the British publication *Nation:*

> In a room near Maida Vale there is an unfortunate carrot strapped to the table of an unlicensed vivisector. Wires pass through two glass tubes full of a white substance; they are like two legs, whose feet are buried in the flesh of the carrot. When the vegetable is pinched with a pair of forceps, it winces. It is so strapped that its electric shudder of pain pulls the long arm of a very delicate level which actuates a tiny mirror. This casts a beam of light on the frieze at the other end of the room, and thus enormously exaggerates the tremor of the carrot. A pinch near the right-hand tube sends the beam seven or eight feet to the right, and a stab near the other wire sends it far to the left. Thus can science reveal the feelings of even so stolid a vegetable as the carrot.

The acclaim which came in the British Isles was repeated in Vienna, where it was the consensus of eminent German and Austrian scientists that "Calcutta was far ahead of us in these new lines of investigation."

Back in India, where the governor of Bengal had arranged for a huge meeting, headed by the sheriff of Calcutta to greet him, Bose spoke of the pursuit, under extreme difficulty, of his investigation of the extraordinary slowness of growth in plants. To conceive of this it is only necessary to state that if the annual growth of a tree is liberally estimated to be five feet, it would take one thousand years to cover a mile.

In 1917, at a huge meeting of students held to honor the knighthood bestowed upon Bose, the chairman remarked that he should be looked upon not as a mere discoverer of scientific truths, but as a Yuga Pravartak, or one who has brought about a new epoch of synthesis in scientific development. This compliment was to Bose small music compared to the opening of his own Institute for Research on the thirtieth of November, on the occasion of his fifty-ninth birthday.

During his speech at the ceremony, Bose, who had declined to patent the device which could have made him, instead of Marconi, the inventor of wireless telegraphy, and had consistently resisted the blandishments of industrial representatives to turn his ideas into profits, stated that it was his particular desire that any discoveries made at his new institute would become public property and that no patents would ever be taken out on them. "Not in matter, but in thought, not in possessions, but in ideas, are to be found the seeds of immortality," Bose told the assembled crowd. "Not through material acquisitions, but in generous diffusion of ideas can the true empire of humanity be established. Thus, the spirit of our national culture demands that we should forever be free from the desire of utilizing knowledge for personal gain."

A year after the foundation of the institute, Bose convened a meeting, sponsored by the governor of Bengal, to announce that, after eight years of struggle, he had finally been able to devise a brand-new instrument, the crescograph. Through the use of two levers, this extraordinary invention not only produced a ten-thousand-fold magnification of movement, far beyond the powers of the strongest microscope, but could automatically record the rate of growth of plants and their changes in a period as short as a minute.

With this instrument Bose showed the remarkable fact that in countless plants, growth proceeds in rhythmic pulses, each pulse exhibiting a rapid uplift and then a slower partial recoil of about a fourth the distance gained. The pulses in Calcutta averaged about three per minute. By watching the progress of the movement on the chart of his new invention, Bose found that growth in some plants could be retarded and even

halted by merely touching them, and that in others rough handling stimulated growth, especially if they were sluggish and morose.

To determine a method which would allow him *instantly* to show the acceleration or retardation of a plant's growth in response to a stimulant, Bose now devised what he called a "balanced crescograph," which would allow the plant to be lowered *at the same rate* at which it was growing upward, thus reducing the marking of its growth on the chart to a horizontal line and allowing any changes in *the rate* to express themselves as curves. The method was so extremely sensitive that Bose was able to detect variation of the rate of growth as hyper-minimal as 1/1500 millionths of an inch per second.

In America, *Scientific American*, referring to the significance of Bose's findings for agriculture, wrote: "What is the tale of Aladdin and his wonderful lamp compared to the possibilities of Dr. Bose's Crescograph? In less than a quarter of an hour the action of fertilizers, food, electric currents and various stimulants can be fully determined."

Bose also elucidated the mysteries of tropistic movements in plants, or their tendency to move in response to an external stimulus. At the time of his research, botanists could no more explain these tropisms than could Molière's medical student who passed his exam by answering the question "Why does opium make one sleep?" with the tautology "Because it has a dormitive virtue."

The roots of plants are called "geotropic," because they burrow into the soil. Because their shoots flee the earth they are said to be imbued with "negative geotropism." To heighten this nonsense, branches are said to start out laterally from the shoot by "diageotropism." Leaves turn to light because they are "heliotropic" or "phototropic." If, disobeying this rule, they turn away from light, then they are "negatively phototropic." Roots questing water are described as "hydrotropic," and those bending against the flow of a stream "rheotropic." The tendril's touch is known as its "thigmotropism."

As the botanist Sir Patrick Geddes wrote: "Intellectual activities have their verbalisms, their confusions and misdirections and these may also accumulate into what are practically diseases. Every science, of course, needs its technical terminology but all have suffered from the verbosity of nomenclatures and, notoriously, botany most of all. Thus—apart from the systematic names for each and every species and order which are of course indispensable—there are some fifteen or twenty thousand technical terms in the botanical dictionaries of which many have survived into modern textbooks to the perplexity of the student." In an essay, commenting on the strange power of big words like "heliotropism," Bose said that they usually acted like some malevolent magic to kill curiosity.

Though it was beginning to be finally accepted that plants did possess conducting tissue analogous to animal nerve, it was now urged by plant specialists that the sensibility of plants was, if it did in fact exist, of a very low order. Bose demonstrated that this was not the case.

He showed the tropism exhibited by tendrils to be the result of two fundamental reactions: a direct stimulus inducing contraction and an indirect stimulus causing expansion. In the curvature of the plant organ, the convex side was electrically positive, the concave side negative. Since the human organ most readily available and most sensitive to the perception of electric current is the tip of the tongue, Bose decided to match its detective ability against that of the sensitive leaflet of the *Biophytum* plant. Hooking up a tongue and a leaflet, he passed a current through both organs, gradually increasing the amperage. When the current reached an intensity of 1.5 micro-amperes, or 1 1/2 millionths of the standard electrical unit of current, the leaflet shimmered in response but the overrated tongue had nothing to relate about the current until the intensity had been increased threefold.

With the same instrumentation, Bose showed that plants of all kinds are sensitive. He found "a stoutish tree will give its response in a slow and lordly fashion whereas a thin one attains the acme of its excitement in an incredibly short time."

During Bose's trip to London and Europe in 1919 and 1920, the distinguished scientist Professor John Arthur Thomson wrote in the *New Statesman:* "It is in accordance with the genius of India that the investigator should press further towards unity than we have yet hinted at, should seek to correlate responses and memory expression in the living with their analogs in organic matter, and should see in anticipation the lines of Physics and Physiology and of Psychology converging and

meeting. These are questionings of a prince of experimenters whom we are proud to welcome in our midst today."

The usually reserved *Times* wrote: "While we in England were still steeped in the rude empiricism of barbaric life, the subtle Easterner had swept the universe into a synthesis and had seen the *one* in all its changing manifestations." But even those bold statements and the announcement that Bose was to be made a fellow of the Royal Society, in May, 1920, could not stem the all-too-familiar intimations of the doubters and pedants. Bose's old adversary Professor Waller, upsetting the general atmosphere of cordiality and recognition, wrote to the *Times* to question the reliability of Bose's magnetic crescograph and to ask for a demonstration of it in a physiological laboratory before experts. When the demonstration, which took place at London University on April 23, 1920, was a complete success, Lord Rayleigh joined with several colleagues in a letter to the *Times* stating: "We are satisfied that the growth of plant tissues is correctly recorded by this instrument and at magnification of one million to more than ten million times."

Bose wrote to the *Times* on May 5:

> Criticism which transgresses the limit of fairness must inevitably hinder the progress of knowledge. My special investigations have by their nature presented extraordinary difficulties. I regret to say that during a period of twenty years, these difficulties have been greatly aggravated by misrepresentation and worse. The obstacles deliberately placed in my path I can now ignore and forget. If the result of my work, by upsetting any particular theory, has aroused the hostility here and there of an individual, I can take comfort in the warm welcome which has been extended to me by the great body of scientific men in this country.

During still another trip to Europe in 1923, the year that saw the publication of Bose's detailed 227-page work *The Physiology of the Ascent of Sap,* the French philosopher Henri Bergson said, after hearing Bose lecture at the Sorbonne: "The dumb plants had by Bose's marvelous inventions been rendered the most eloquent witnesses of their hitherto unexpressed life story. Nature has at last been forced to yield her most jealously guarded secrets." More Gallicly humorous, *Le Matin* stated: "After this discovery we begin to have misgivings, when we strike a woman with a blossom, which of them suffers more, the woman or the flower?"

In 1924 and 1926 there appeared two more volumes of experiments totaling more than five hundred pages: *The Physiology of Photosynthesis* and *The Nervous Mechanism of Plants.* In 1926 Bose was nominated a member of the League of Nations Committee on Intercultural Cooperation, along with a physicist, Albert Einstein, a mathematician, H. A. Lorentz, and a Greek literary scholar, Gilbert Murray. The assignment had the advantage of taking Bose to Europe annually. Still the Indian Government had to be jolted into awareness of the importance of Bose's work. In 1926 Sir Charles Sherrington, president of the Royal Society, Lord Rayleigh, Sir Oliver Lodge, and Julian Huxley all signed a memorial to the Viceroy of India pleading for the expansion of the institute.

Back in Europe in 1927, the year which saw the appearance of his *Plant Autographs and Their Revelations,* Bose was presented by Romain Rolland with a signed copy of his new novel, *Jean Christophe,* inscribed "To the Revealer of a New World." Later, comparing Bose to Siegfried, who had learned the language of birds, Rolland said: "In the European scientist the steeling of the mind to the interpretation of nature has often been accompanied by a withering of the feeling for beauty. Darwin bitterly lamented the fact that his research in biology had completely atrophied his appreciation of poetry. With Bose it is otherwise."

In 1928, the same year that Bose brought out his last book, the 429-page *Motor Mechanisms of Plants,* one of the greatest plant physiologists of modern times, Professor Hans Molisch of Vienna, decided, after hearing Bose lecture in the Austrian capital, to go to India and work with the Bengali. Before leaving the subcontinent he wrote to *Nature:* "I saw the plant writing down its rate of assimilation of gaseous food. I also observed the speed of the impulse of the excitement in plants being recorded by the resonant recorder. All these are more wonderful than fairytales."

All his life Bose had stressed to a scientific community steeped in a mechanistic and materialistic outlook, and increasingly divided and subdivided into specialized cubbyholes, the idea that all of nature pulsed

with life and that each of the interrelated entities in the natural kingdom might reveal untold secrets could man but learn how to communicate with them. In the lecture hall of his institute, under a bronze, silver, and gold relief of the Hindu sun god rising in his chariot for his daily cosmic fight against the powers of darkness—which Bose had first seen depicted in an ancient cave fresco at Ajanta—Bose, now in retirement, summed up his scientific philosophy.

> In my investigations on the action of forces on matter, I was amazed to find boundary lines vanishing and to discover points of contact emerging between the Living and the non-Living. My first work in the region of invisible lights made me realize how in the midst of luminous ocean we stood almost blind. Just as in following light from visible to invisible our range of investigation transcends our physical sight, so also the problem of the great mystery of Life and Death is brought a little nearer solution, when, in the realm of the Living, we pass from the Voiced to the Unvoiced.
>
> Is there any possible relation between our own life and that of the plant world? The question is not one of speculation but of actual demonstration by some method that is unimpeachable. This means that we should abandon all our preconceptions, most of which are afterward found to be absolutely groundless and contrary to facts. The final appeal must be made to the plant itself and no evidence should be accepted unless it bears the plant's own signature.

CHAPTER 7

The Metamorphosis of Plants

Why botany, a potentially fascinating subject dealing with plants, living and extinct, their uses, classification, anatomy, physiology, geographical distribution, should have been from the beginning reduced to a dull taxonomy, an endless Latin dirge, in which progress is measured more by the number of corpses cataloged than by the number of blossoms cherished, is perhaps the greatest mystery in the study of plant life.

While young botanists still struggle today through the jungles of Central Africa and along the Amazon in search of polysyllabic victims to add to the 350,000 already on the books, what makes plants live, or why, does not appear to be the purview of the science, nor has it been since the fourth century B.C. when Theophrastus, the Lesbian disciple of Aristotle, first cataloged a couple of hundred species in his nine books *On the History of Plants* and six *On the Causes of Plants.* The Christian era merely raised the rolls to four hundred medicinal plants with the publication of *De Materia Medica* by a Greek physician to the Roman army, Dioscorides, shortly after the Crucifixion, an event which put the quietus on the subject for another thousand years. Throughout the Dark Ages, the books of Theophrastus and Dioscorides remained the standard texts in botany. Even though the Renaissance brought aesthetics into the field, with lovely woodcuts in large herbals such as those of Hieronymus Bock, it could not rip botany from the rigorous grip of the taxonomist.

By 1583 a Florentine, Andreas Caesalpinus, had classified 1,520 plants into fifteen classes, distinguished by seed and fruit. He was followed by the Frenchman Joseph Pitton de Tournefort, who described some 8,000 species of plants in twenty-two classes, chiefly according to the form of corolla—the colored petals of the flower. This brought sex into the picture. Although Herodotus had reported almost half a millennium before Christ that the Babylonians distinguished two sorts of palms, and would sprinkle the pollen from one onto the flower of the other in order to secure the production of fruit, it was not till the end of the seventeenth century that it was realized that plants were sexual creatures with a flourishing sex life of their own.

The first botanist to demonstrate that flowering plants have sex and that pollen is necessary for fertilization and seed formation was a German, Rudolf Jakob Camerarius, a professor of medicine and director of the botanical gardens at Tübingen, who published his *De Sexu Plantorum Epistula* in 1694. The idea that there could be a sexual difference in plants caused general astonishment, and Camerarius' theory was fiercely combated by the current establishment. It was considered "the wildest and most singular invention that ever evolved from a poet's mind." A heated controversy lasted almost a generation before it was finally established that plants had sexual organs and could therefore be elevated to a higher sphere of creation.

Even so, that plants have female organs in the form of vulva, vagina, uterus, and ovaries, serving precisely the same functions as they do in woman, as well as distinct male organs in the form of penis, glans, and testes, designed to sprinkle the air with billions of spermatozoa, were facts quickly covered by the eighteenth-century establishment with an almost impenetrable veil of Latin nomenclature, which stigmatized the labiate vulva, and mis-styled the vagina; the former being called "stigma," the latter "style." Penis and glans were equally disfigured into "filament" and "anther."

Whereas plants had been going through countless millennia of improvement to their sexual organs, often in the face of staggering climatic changes, and had invented the most ingenious methods for fecundating each other and for spreading their fertile seed, students of botany, who might have delighted in the sexuality of plants, were frustrated by such terms as "stamens" for the male and "pistils" for the female organs. Schoolchildren might have been fascinated to learn that each corn kernel on a cob in summer is a separate ovule, that each strand on the pubic corn silk tufted around the cob is an individual vagina ready to suck up the pollen sperm brought to it on the wind, that it may wriggle the entire length of the stylized vagina to impregnate each kernel on the cob, that every single seed produced on a plant is the result of a separate independent impregnation. Instead of struggling with archaic nomenclature, teenagers might be interested to learn that each pollen grain impregnates but one womb, which contains but one seed, that a capsule of tobacco contains, on an average, 2,500 seeds, which require 2,500 impregnations, all of which must be effected within a period of 24 hours in a space less than one-sixteenth of an inch in diameter. Instead of using the wonders of nature to stimulate the budding minds of their pupils, Victorian teachers misused the birds and the bees to denature their own sexuality.

How many universities even now draw the parallel between the hermaphroditic nature of plants, which bear both penis and vagina in the same body, with the "ancient wisdom" which relates that man is descended from an androgynous predecessor? The ingenuity of some plants in avoiding self-fertilization is uncanny. Some kinds of palm trees even bear staminate flowers one year and pistillate the next. Whereas

in grasses and cereals cross-fertilization is insured by the action of the wind, most other plants are cross-fertilized by birds and insects. Like animals and women, flowers exude a powerful and seductive odor when ready for mating. This causes a multitude of bees, birds, and butterflies to join in a Saturnalian rite of fecundation. Flowers that remain unfertilized emit a strong fragrance for as many as eight days or until the flower withers and falls; yet once impregnated, the flower ceases to exude its fragrance, usually in less than half an hour. As in humans, sexual frustration can gradually turn fragrance into fetor. Similarly, when a plant is ready for impregnation, there is an evolution of heat in the female organ. This was first noted by the celebrated French botanist Adolphe Théodore Brongniart in examining a flower of the *Colocasia odorata,* a tropical plant grown in greenhouses for the beauty of its foliage. This plant, at the time of flowering, presents an increase of temperature that Brongniart compared to an attack of fever, repeating the phenomenon for six days, daily from three to six in the afternoon. At the proper time for impregnation Brongniart found that a small thermometer fastened to the female organ marked a temperature eleven degrees Centigrade higher than any other part of the plant.

The pollen of most plants has a highly inflammable character; when thrown on a red-hot surface it will ignite as quickly as gunpowder. Artificial lightning was formerly produced on the theatrical stage by throwing the pollen grains of the *Lycopodium* or club mosses onto a hot shovel. In many plants the pollen diffuses an odor bearing the most striking resemblance to the seminal emission of animals and man. Pollen, which performs the same function in almost precisely the same manner as does the semen of animals and men, enters the folds of the plant vulva and traverses the whole length of the vagina, until it enters the ovary and comes in contact with the ovule. Pollen tubes elongate themselves by a most remarkable process. As with animals and humans, the sexuality of certain plants is guided by taste. The spermatozoa of certain mosses carried in the morning dew in search of females, is guided by its taste for malic acid toward the delicate cups at the bottom of which lie moss eggs to be fertilized. The spermatozoa of ferns, on the other hand, liking sugar, find their females in pools of sweetened water.

Camerarius' discovery of sex in plants set the stage for the generator of systematic botany, Carl von Linné, who dubbed the corolla petals "curtains of the nuptial bed." A Swede, who latinized his name to Linnaeus from a favorite linden tree while studying for the priesthood, he divided the plant world into species principally on the basis of variations in the male sexual organ or pollen-bearing stamens of each plant. With his penchant for looking, Linnaeus recognized some six thousand different species of plants. His system, referred to as the "sexual system," was considered "a great stimulus to students of botany." But his monumental method of latinized classification turned out to be as sterile as that of any voyeur who only looks at bodies. Still in use today under the unwieldy title of "binomial nomenclature," the system grants to each plant a Latin name for species and genus, to which is added the name of the person responsible for first naming it; thus the garden pea you eat with chops is the *Pisum sativum Linnaeum.*

This mania for registration was but a hangover of scholasticism. As Raoul Francé, true lover of plants, described Linné's efforts, "Wherever he went the laughing brook died, the glory of the flowers withered, the grace and joy of the meadows was transformed into withered corpses whose crushed and discolored bodies were described in a thousand minute Latin terms. The blooming fields and the storied woods disappeared during a botanical hour into a dusty herbarium, into a dreary catalogue of Greek and Latin labels. It became the hour for the practice of tiresome dialectic, filled with discussions about the number of stamens, the shape of leaves, all of which we learnt only to forget. When the work was over we stood disenchanted and estranged from nature."

To break away from this taxonomania, to put life and love and sex back into the plant world, took real poetic genius. In September of 1786, eight years after the death of Linnaeus, a tall, handsome man of thirty-seven, extremely attractive to women, who had been spending his holidays at Karlsbad taking the waters and strolling with the ladies in the woods on long botanical expeditions, suddenly rebelled against the whole system. "Secretly and stealthily" he abandoned mistress and friends to go south toward the Alps. Incognito, with only his servant aware that they were heading for *das Land wo die Citronen bluehen,*

the traveler, in real life privy councilor and director of mines for the Duchy of Saxe-Weimar, was delighted at the beauty and variety of the southern vegetation beyond the Brenner Pass. This secret trip to Italy, the culmination of years of longing, was to constitute a climax in the life of Germany's greatest poet, Johann Wolfgang von Goethe.

On his way to Venice he stopped to visit the botanical gardens of the University of Padua. Strolling among the luxuriant verdure, most of which grew only in hothouses in his native Germany, Goethe was overcome with a sudden poetic vision; it was to give him insight into the very nature of plants. It was also to give him a place in the history of science as the precursor of Darwin's theory of organic development, an achievement as little appreciated by his compeers as it was extolled by a later generation. The great biologist Ernst Haeckel considered Goethe to stand with Jean Lamarck "at the head of all the great philosophers of nature who first established a theory of organic development, and who are the illustrious fellow workers of Darwin." For years Goethe had been distressed by the limitations involved in a merely analytical and intellectual approach to the plant world, typified by the cataloging mind of the eighteenth century, and of a theory of physics, then triumphant, which submitted the world to blind laws of mechanics, to a *"jeu de rouages et de ressorts sans vie."*

While still at the university in Leipzig, Goethe had rebelled against an arbitrary division of knowledge into faculties which cut up science into rival disciplines. In Goethe's nostrils university science had the stench of a corpse whose limbs have rotted apart. Disgusted at the petty contradictions of university savants, the young poet, whose early verses glowed with a passionate delight in nature, sought knowledge elsewhere, avidly studying galvanism and mesmerism and pursuing the electrical experiments of Winkler. Already as a child he had been fascinated by the phenomena of electricity and magnetism, struck by the extraordinary phenomenon of polarity. Cured in his late teens of a dangerous throat infection by a Rosicrucian doctor, Johann Friedrich Metz, Goethe was suddenly overwhelmed by the urge to apprehend the tremendous secret displayed all around him in constant creation and annihilation; he was thus led to books on mysticism and alchemy in pursuit of the secret forces of nature. There he discovered Paracelsus, Jakob Boehme, Giordano Bruno, Spinoza, and Gottfried Arnold.

To Goethe's delight he found magic and alchemy "quite other than obscure superstitious practices with the object of creating illusion or malefice." It was then, according to Christian Lepinte, author of *Goethe et l'occultisme,* that Goethe began "to aspire with all his strength to shatter the framework of a mechanized universe, to find the living science capable of revealing to him the ultimate secret of nature." From Philippus Aureolus Theophrastus Bombastus von Hohenheim, or Paracelsus, Goethe learned that the occult, because it deals with living reality and not dead catalogs, might come closer to the truth than science, and that the sage unveiling the secrets of nature was not necessarily profaning a forbidden sanctuary but might be walking in the footsteps of divinity, a person privileged to look deeply into the mystery of souls and of cosmic forces.

Above all, Goethe learned that the treasures of nature are not discovered by one who is not in sympathy with nature. He realized that the normal techniques of botany could not get near to the living being of a plant as an organism in a cycle of growth. Some other form of looking was needed which could unite itself with the life of the plant. To obtain a clearer picture of a plant, Goethe would tranquilize himself at night before going to sleep by visualizing the entire cycle of a plant's development through its various stages from seed to seed. In the splendid ducal gardens at Weimar, in the Gartenhaus quarters given to him by the Duke, Goethe developed an acute interest in living plants, an interest which was sharpened by his friendship with the sole local apothecary, Wilhelm Heinrich Sebastian Buchholz, who kept a garden of medicinal herbs and plants of special interest and with whom Goethe built up a private botanical garden.

In the grander botanical gardens of Padua, where Paracelsus had preceded him, Goethe was most impressed by a high, broad wall of fiery red bells, *Bignonia radicans,* that glowed enchantingly. He was also attracted by a palm because he was able to discern in its fanlike quality a complete development from the simple lance-shaped leaves near the ground, through successive separations, up to a spatulate sheaf where a branchlet of blossoms emerged, strangely unrelated to the preceding

growth. From the observation of this complex series of transitional forms Goethe obtained the inspiration for what was to become his doctrine of the *metamorphosis of plants.* In a flash he realized what had been accumulating in his mind through long years of association with plants: the fan palm showed clear, living proof that *all* the lateral outgrowths of the plant were simply variations of a single structure: the leaf.* Goethe saw that propagation and prolification of one organ into another was simply a process of metamorphosis. He saw that each organ though outwardly changed from a similarity to a dissimilarity had a virtual inner identity.

At Goethe's request the Padua gardener cut from the fan palm an entire sequence of modifications which Goethe carried away with him in several pasteboard containers, where they lasted several years. As for the palm tree, it still stands in the Padua botanical gardens despite numerous intervening wars and revolutions.

With his new way of looking at plants Goethe came to the conclusion that nature, by bringing forth one part through another, could achieve the most diversified forms through modification of a single organ. "The variation of plant forms, whose unique course I had long been following, now awakened in me more and more the idea that the plant forms round about us are not predetermined, but are happily mobile and flexible, enabling them to adapt to the many conditions throughout the world, which influence them, and to be formed and re-formed with them."

Goethe also recognized that the process of development and refinement of form in plants worked through a threefold cycle of expansion and contraction. The expansion of foliage was followed by a contraction into calyx and bracts; there followed a splendid expansion into the petals of the corolla and a contraction into the meeting point of stamen and stigma; finally there came a swelling into fruit followed by a contraction into seed. This six-step cycle completed, the essential plant was ready to start all over again.

Ernst Lehrs' thoughtful evaluation of Goethe in *Man or Matter* says

*Sir George Trevelyan in a chapter on Goethe's plant metamorphosis in his forthcoming book on architecture, points out that by "leaf" Goethe did not mean the stem leaf, which is itself a manifestation of the basic organ. Some other word, says Trevelyan, is needed, such as "phyllome," to imply the archetypal ideal organ which underlies every organ of the plant and is able to transfer one part into another.

that another natural principle is implicit in this cycle for which Goethe did not coin a specific term, "although he shows through other utterances that he was well aware of it, and of its universal significance for all life." Lehrs calls this principle that of renunciation.

> In the life of the plant this principle shows itself most conspicuously where the green leaf is heightened into the flower. While progressing from leaf to flower the plant undergoes a decisive ebb in its vitality. Compared with the leaf, the flower is a dying organ. This dying, however, is of a kind we may aptly call a "dying into being." Life in its mere vegetative form is here seen withdrawing in order that a higher manifestation of the spirit may take place. The same principle can be seen at work in the insect kingdom when the caterpillar's tremendous vitality passes over into the short-lived beauty of the butterfly. In the human being it is responsible for that metamorphosis or organic process which occurs on the path from the metabolic to the nervous system, and which we came to recognize as the precondition for the appearance of consciousness within the organism.

Lehrs marvels at the powerful forces which must be at work in the plant organism at the point of transition from its green to its colored parts. They enforce, says Lehrs, a complete halt upon the juices that rise up right into the calyx, so that these bring nothing of their life-bearing activity into the formation of the flower, but undergo a complete transmutation, not gradually, but with a sudden leap.

> After achieving its masterpiece in the flower, the plant once more goes through a process of withdrawal, this time into the tiny organs of fertilization. After fertilization, the fruit begins to swell: once more the plant produces an organ with a more or less conspicuous spatial extension. This is followed by a final and extreme contraction in the forming of the seed inside the fruit. In the seed the plant gives up all outer appearance to such a degree that nothing seems to remain but a small, insignificant speck of organized matter. Yet this tiny, inconspicuous thing bears in it the power of bringing forth a whole new plant.

Lehrs points out that in its three successive rhythms of expansion and contraction the plant reveals the basic rule of its existence.

> During each expansion, the active principle of the plant presses forth into visible *appearance;* during each contraction it withdraws from outer embodiment into what we may describe as a more formless pure state of *being.* We thus find the spiritual principle of the plant engaged in a kind of breathing rhythm, now appearing, now disappearing, now assuming power over matter; now withdrawing from it again.

Goethe saw in the changeableness of all the external characteristics of plants nothing but appearance; he drew the conclusion that the nature of the plant was not to be found in these characteristics, but had to be sought at a deeper level. The thought became more and more alive in him that it might be possible to develop all plants from a single one. This small conceit was destined to transform the science of botany, indeed the whole concept of the world: with it came the idea of *evolution.* Metamorphosis was to become the key to the whole alphabet of nature. But, whereas Darwin was to assume that external influences, like mechanical causes, work upon the nature of an organism and modify it accordingly, to Goethe the single alterations were various expressions of the archetypal organism *(Urorganismus),* which possesses within itself the capacity to take on manifold forms, and which at a particular time takes on that form which is best suited to the conditions of the external environing world. Goethe's *Urorganismus* is a sort of Platonic idea in the eye of the created mind.

Aristotle's philosophy teaches that, besides original matter, another principle is necessary to complete the triune nature of every particle, and this is form: an invisible, but still, in an ontological sense of the word, a substantial being, really distinct from matter proper. Thus, as the theosophist Helena Blavatsky interprets Aristotle, in an animal or a plant, besides the bones, the flesh, the nerves, the brains, and the blood, in the former, and besides the pulpy matter, tissues, fibers, and juice in the latter, there must be a substantial form, which Aristotle named, in the horse, the horse's *soul;* which Proclus identified as the *demon* of every mineral, plant, or animal; and which was later categorized by medieval philosophers as the *elementary spirits* of the four kingdoms.

Trevelyan explains the kernel of Goethe's philosophy as lying in a metaphysical concept of nature.

> The godhead is at work in the living, not in the dead; it is present in everything in the process of development and transformation, not in what has already taken shape and rigidified. Thus, reason in its strivings towards the divine is concerned with putting to use what has already developed and grown torpid.

Seeing that every part of the plant is a metamorphosis of the archetypal "leaf" organ, Goethe came to the conception of an *archetypal* plant, or *Ur-pflanze*, a supersensible force capable of developing into myriad different forms. This, says Trevelyan, is no single plant, but a force that holds the potentiality of every plant form within it.

> All plants are thus seen as specific manifestations of the archetypal plant which controls the entire plant kingdom and gives the value to nature's artistry in creating forms. It is in ceaseless play within the world of plant form, capable of moving backwards and forwards, up and down, in and out, through the scale of forms.

Summing up his discovery, Goethe asked, "If all plants were not modeled on one pattern, how could I recognize that they are plants?" Filled with delight, Goethe declared he could now invent plant forms, even if they had never been realized on earth before.

From Naples Goethe wrote to his friend and fellow poet in Weimar, Johann Gottfried von Herder: "I must tell you confidentially that I am very close to the secret of the creation of plants, and that it is the simplest thing one could imagine. The archetypal plant will be the strangest creature in the world, which nature herself ought to envy me. With this model and the key to it, one can invent plants endlessly which must be consistent—that is, if they did not exist, yet they could exist, and not some artistic or poetic shadows and appearances but possessing inner truth and inevitability. The same law can be applied to everything living." Goethe now pursued the idea "with joy and ecstasy, lovingly immersing myself in it in Naples and Sicily," applying the idea to every plant he saw, writing reports to Herder on what took place "with as much enthusiasm as was manifested over the finding of the lost silver piece in the gospel parable."

For two years Goethe observed, collected, studied phenomena in detail, made many sketches and accurate drawings. "I pursued my botanical studies, into which I was guided, driven, forced—and then held captive by my interest." Back in Germany after two years in Italy, Goethe found that the new vision of life he had acquired was incomprehensible to his fellow countrymen.

> From Italy, rich in forms, I was plunged back into formless Germany, exchanging a sunny sky for a gloomy one. My friends, instead of comforting me and drawing me back to them, drove me to despair. My delight in things remote and almost unknown to them, my sorrow and grief over what I had lost, seemed to offend them. I received no sympathy, no one understood my language. I could not adjust myself to this distressing situation, so great was the loss to which my exterior senses must become reconciled. But gradually my spirit returned and sought to preserve itself intact.

Goethe set his thoughts on paper in a first essay, "On the Metamorphosis of Plants," in which he traced "the manifold specific phenomena in the magnificent garden of the universe back to one simple general principle," and stressed nature's method of "producing in accord with definite laws, a living structure that is a model of everything artistic." The essay, which was to generate the science of morphology in plants, was written in an unusual style, different from contemporary scientific writings in that it did not pursue each idea to its full conclusion but, in a cryptic manner, left room for interpretation. "Well satisfied with my brochure," says Goethe, "I was flattered to believe myself auspiciously launched on a career in science. But the same thing happened to me that I had experienced in purely literary work; once more, at the very outset, I was repulsed."

Goethe's regular publisher refused the manuscript, telling him he was a literary man, not a scientist. Goethe found it hard to understand why the publisher would not print the brochure when, "merely by risking six sheets of paper at the very most he might have retained for himself a prolific, reliable, easily satisfied author, who was just getting a fresh start." When the brochure was printed elsewhere Goethe was further surprised to find it completely ignored by botanist and public alike.

> The public [said Goethe] demand that every man remain in his own field. Nowhere would anyone grant that science and poetry can be united. People forgot that science had developed from poetry and they failed to take into consideration that a swing of the pendulum might beneficently reunite the two, at a higher level and to mutual advantage.

Goethe then made the mistake of giving away copies of the brochure to friends outside his immediate circle. These friends, said he, were by no means tactful in their comments.

> No one dared to accommodate himself to my method of expressing myself. It is most tormenting not to be understood when one feels sure himself, after a great stress and strain, that one understands both one's self and one's subject. It drove one to insanity to hear repeated again and again a mistake from which one has himself just escaped by a hair's breadth, and nothing is more painful than to have the things that should unite us with informed and intelligent men give rise instead to unbridgeable separation.

To his newly acquired friend and fellow poet Johann Christoph Friedrich von Schiller, Goethe gave a spirited explanation of his theory of the metamorphosis of plants, with graphic pen sketches of a symbolic plant. "He listened and looked with great interest, with unerring comprehension, but when I had ended he shook his head, saying: 'That is not an experience, that is an idea.'" Goethe was taken aback and a little irritated. Controlling himself he said: "How splendid that I have ideas without knowing it, and can see them before my eyes." From the argument Goethe was left with the philosophic concept that ideas must be clearly independent of space and time, whereas experience is restricted to space and time. "The simultaneous and successive are therefore intimately bound together in an idea, whereas they are always separated in experience."

It was eighteen years after the Congress of Vienna before references to the metamorphosis of plants began to appear in botanical texts and other writings, and thirty years before it was fully accepted by botanists. When the essay became known in Switzerland and France people were astonished to find that a poet "normally occupied with moral phenomena associated with feeling and power and imagination, could have achieved such an important discovery."

Late in life Goethe added another basic idea to the science of botany. With his perception carefully attuned to nature he realized—a generation before Darwin was to approach the same subject—that vegetation had a tendency to grow in two distinct ways: vertically and spirally. With

his poet's intuition Goethe labeled the vertical tendency, with its sustaining principle, male; the spiral tendency, which conceals itself during the development of the plant but predominates during blossoming and fruiting, he labeled female. "When we see," said Goethe, "that the vertical system is definitely male and the spiral definitely female, we will be able to conceive of all vegetation as androgynous from the root up. In the course of the transformation of growth the two systems are separated, and take opposite courses to be reunited on a higher level."

Goethe held a lofty and comprehensive view of the significance of the male and female principles as spiritual opposites in the cosmos. Lehrs elaborated on it: "In order that spiritual continuity may be maintained within the coming and going multitude of nature's creations, the physical stream must suffer discontinuity at certain intervals. In the case of the plant this discontinuity is achieved by the breaking asunder of the male and female growth-principles. When they have reunited, the type begins to abandon either the entire old plant or at least part of it, according to whether the species is an annual or a perennial one, in order to concentrate on the tiny seed, setting, as it were, its living seal on it."

To Goethe the fact that the action of the root of a plant is directed earthward toward moisture and darkness, whereas the stem or trunk strives skyward in the opposite direction toward the light and the air, was a truly magical phenomenon. To explain it Goethe postulated a force opposite, or polar, to Newton's gravity, to which he gave the name "levity." "Newton," says Lehrs, "explained to you—or at least was once supposed to explain, why an apple fell; but he never thought of explaining the exact correlative but infinitely more difficult question, how the apple got up there." The concept led Goethe to a picture of the earth as being surrounded and penetrated by a field of force in every respect the opposite of the earth's gravitational field.

"As the gravity field decreases in strength," says Lehrs, "with increasing distance from the center of the field, that is, in the outward direction, so does the levity-field decrease in strength with increasing distance from its periphery, or in the inward direction. . . . This is why things 'fall' under the influence of gravity and 'rise' under the influence of levity." Lehrs adds that if there were no field working outward toward the cosmic periphery, the entire material content of the earthly realm would be reduced by gravitation to a spaceless point, just as under the sole influence of the peripheral field of levity it would dissipate into the universe. "Just as in volcanic activity heavy matter is suddenly and swiftly driven heavenwards under the influence of levity, so in a storm does light matter stream earthwards under the influence of gravity."

Goethe, taking his inspiration from the Rosicrucian Aurea Catena of 1781, presumed to be authored by Herwerd von Forchenbrun, saw the whole universe as being moved by opposite polar forces which manifest as light and dark, or plus and minus in electricity, or oxidation and reduction in chemistry.

In his old age Goethe conceived the earth to be an organism animated by the same rhythm of inspiration and evaporation as a plant or an animal. He compared the earth and her hydrosphere, in which he included the humid atmosphere and its clouds, to a great living being perpetually inhaling and exhaling. He said:

> If she inhales, she draws the hydrosphere to her, so that, coming near her surface, it is condensed to clouds and rain. This state I call water-affirmative [*Wasser-Bejahung*]. Should it continue for an indefinite period, the earth would be drowned. This the earth does not allow, but exhales again, and sends the watery vapours upwards, where they are dissipated through the whole space of the higher atmosphere. These become so rarefied that not only does the sun penetrate them with its brilliance, but the eternal darkness of infinite space is seen through them as a fresh blue. This state of the atmosphere I call water-negative [*Wasser-Verneinung*]. For, just as under the contrary influence, not only does water come profusely from above, but also the moisture of the earth cannot be dried and dissipated—so, on the contrary, in this state not only does no moisture come from above, but the damp of the earth itself flies upwards; so that, if this should continue for an indefinite period, the earth, even if the sun did not shine, would be in danger of drying up.

The actual phenomenon of light Goethe considered to be inscrutable, but disagreed with Newton's concept that light waves were light itself and that light was composed of various colors. Goethe considered light waves to be the physical manifestation of eternal light. He saw light and dark to be polar opposites, with a series of colors formed by their interaction: darkness was not complete passive absence of light: it was

something active, something that opposed itself to light and interplayed with it. He imagined light and dark as being related like the north and south poles of a magnet. If darkness were absolute void, said Goethe, there would be no perception looking into the dark. The importance Goethe attached to his theory of color is clear from his statement late in life that "I do not attach importance to my work as a poet, but I do claim to be alone in my time in apprehending the true nature of color."

When Goethe died on March 22, 1832, twenty-seven years before Darwin was to proclaim his principle of organic evolution, he was considered Germany's greatest poet, with a universal mind capable of compassing every domain of human activity and knowledge. But as a scientist he was considered a layman.

Though a genus of plants, the Goethea, was named for him, as was a mineral, goethite, it was as a courtesy to a great man more than to a scientist. In due course Goethe was credited with having coined the word "morphology" and of having formulated the concept of botanical morphology which persists to this day. He was credited with the discovery of the volcanic origin of mountains, with establishing the first system of weather stations, with being interested in connecting the Gulf of Mexico with the Pacific Ocean, and with wanting to build steamships and flying machines; but the scope of Goethe's formulation of the metamorphosis of plants had to await the advent of Darwin to be fully appreciated, and even then it was largely misunderstood.

As Rudolf Steiner was to write, almost a hundred years later,

> It was from observations similar to those of Goethe that Darwin proceeded when he asserted his doubt as to the constancy of the external forms of genera and species. But the conclusions which the two thinkers reached were entirely unlike. Whereas Darwin considered that the whole nature of the organism was, in fact, comprised in these characteristics, and came to the conclusion, therefore, that there is nothing constant in the life of the plant, Goethe went deeper and drew the inference that, since those characteristics are not constant, what is constant must be sought in something else which lies beneath changeable externalities.

CHAPTER 8

Plants Will Grow to Please You

Goethe's poetic notion that a spiritual essence lies behind the material form of plants was put on a firmer basis by a medical doctor and a professor of physics at the University of Leipzig. Credited with over forty papers on such subjects as the measurement of electrical currents and the perceptions of colors, Gustav Theodor Fechner came to his profound understanding of plants in a totally unexpected way. In 1839 he began to stare at the sun in the hope of discovering the nature of afterimages, those strange pictures which seem to persist on the retina of the eye even after the cessation of normal visual stimulus.

A few days later, Fechner was horrified to realize that he was going blind. Exhausted from overwork, and unable in his new affliction to face his friends and colleagues, he retired to a darkened room with a mask over his face, to live in solitude praying for recovery.

One spring morning three years later, sensing that his sight had been restored, he emerged into the light of day. Joyously walking along the Mulde River he instantly recognized that flowers and trees along its banks were what he called be-souled. "As I stood by the water and watched a flower, it was as though I saw its soul lift itself from the bloom and, drifting through the mist, become clearer until the spiritual form hung clearly above it. Perhaps it wanted to stand on the roof of its budding house in order better to enjoy the sun. Believing itself invisible, it was quite surprised when a little child appeared."

While still in semi-seclusion Fechner began setting down a series of similar remarkable impressions. The result was *Nanna, or the Soul-Life of Plants,* published in Leipzig in 1848, which though scathingly rejected by his fellow academicians, became so popular that it was still being printed in Germany three-quarters of a century later.

In his introduction, Fechner explained that he happened on the title by accident. At first he thought of calling his new book *Flora,* after the Roman goddess of flowers, or *Hamadryas,* after the wood nymphs which the Hellenes recognized as living only as long as the trees of which they were the spirit. But he rejected the first as too botanical, the second as too classically stiff and antiquarian. One day, while reading Teutonic mythology, Fechner learned that Baldur, god of light, had, like Actaeon peeping at Diana, secretly gazed upon the naked form of the flower princess Nanna as she bathed in a stream. When her natural loveliness was enhanced by the energy over which Baldur ruled, his heart, said the legend, was pierced, and the marriage of Light and Flowers became a foregone conclusion.

Fechner's awakening to the soul life of plants turned him from professing physics to professing philosophy, of which branch of knowledge he was given a chair at Leipzig the same year that *Nanna* appeared. However, even before his realization that plants had undreamed-of sensitivity, Fechner had concerned himself with cosmic problems in his *Little Book of Life After Death,* posthumously published in Dresden in

1936, and in *Comparative Anatomy of the Angels,* a work which he considered so risqué that he wrote it under the pseudonym of Dr. Mises.

In the *Little Book* Fechner put forward the idea that human life was lived in three stages: one of continuous sleep from conception to birth; one of half wakefulness, which humans called terrestrial life; and one of fuller alertness, which began only after death. In *Comparative Anatomy* he traced the path of evolution from monocellular organisms through man on to angelic higher beings spherical in form and capable of seeing universal gravitation as ordinary humans perceive light, of communicating not acoustically but through luminous symbols.

Fechner introduced *Nanna* with the concept that believing whether plants have a soul or not changes one's whole insight into nature. If man admitted to an omnipresent, all-knowing, and almighty god who bestowed animation on all things, then nothing in the world could be excluded from this munificence, neither plant nor stone nor crystal nor wave. Why would universal spirit, he asked, sit less firmly in nature than in human beings, and not be as much in command of nature's power as it is of human bodies?

Anticipating Bose's work, Fechner further reasoned that if plants have life and soul, they must have some sort of nervous system, hidden perhaps in their strange spiral fibers. Going beyond the limitation of today's mechanistic physiology, Fechner referred to "spiritual nerves" in the universe, one expression of which was the interconnection of celestial bodies, not with "long ropes," but with a unified web of light, gravity, and forces as yet unknown. The soul, said Fechner, receives sensations, in a manner analogous to that of a spider which is alerted to outside influences by its web. It seemed reasonable to Fechner to accept the idea that plants have nerves, their purported absence being due to man's ignorance rather than to any innate vegetal deficiency.

According to Fechner, the psyche of plants is no more linked to their nervous system than is the soul of man to a human body. Both are diffused throughout, yet separated from all the organs which they direct. "None of my limbs anticipates anything for itself," wrote Fechner, "only I, the spirit of my whole, sense everything that happens to me."

Fechner created a new branch of learning called *psychophysics,* which

abolished the artificial separation between mind and body and held the two entities to be only different sides of one reality, the mind appearing subjectively, the body objectively, as a circle is either concave or convex depending on whether the observer stands inside it or outside. The confusion resulted, said Fechner, because it was difficult to hold both points of view simultaneously. To Fechner all things express in different ways the same *anima mundi,* or cosmic soul, which came into existence with the universe, is its conscience, and will die when and if the universe dies. Basic to his animate philosophy was the axiom that all life is *one* and simply takes up different shapes in order to divert itself. The highest good and supreme end of all action is the maximum pleasure not of the individual but of all, said Fechner, and on this he based all his rules for morals.

Since spirit to Fechner was a deistic universal, it was useless to refer to souls as wholly individual, whether vegetal or human. Nonetheless souls provided the only criteria for forming a conception of other souls and making themselves known to them by outward physical signs. To the undoubted irritation of today's prevalent school of behaviorist, "carrot-and-stick" psychology, Fechner also maintained that in its soul alone was the true freedom of any creature.

Because a plant is rooted, it necessarily has less freedom of movement than an animal, Fechner declared, though by moving its branches, leaves, and tendrils as it sees fit it behaves much like an animal which opens its claws upon capture or runs away when frightened.

More than a century before experiments in the Soviet Union apparently convinced the Russians that plants can regulate their own needs with the help of man-designed instrumentation, Fechner asked, "Why should we believe that a plant is not any less aware of hunger and thirst than an animal? The animal searches for food with its whole body, the plant with portions of it, guided not with nose, eyes or ears but with other senses." It seemed to Fechner that "plant people," calmly living their lives in the spots of their rooting, might well wonder why human bipeds keep rushing about. "In addition to souls which run and shriek and devour, might there not be souls which bloom in stillness, exhale fragrance and satisfy their thirst with dew and their impulses by their burgeoning?" Could not flowers, Fechner asked, communicate with each other by the very perfumes they exude, becoming aware of each other's presence by a means more delightful than the verbiage and breath of humans, which is seldom delicate or fragrant except, by coincidence, in lovers?

"From *inside* comes the voice," wrote Fechner, "and from inside comes the scent. Just as one can tell human beings in the dark from the tone of their voices, so in the dark, every flower can be recognized by its scent. Each carries the soul of its progenitor." Flowers having no fragrance he likened to animals which live alone in the wilds, and those with perfume to gregarious beasts. In the end, posited this German sage, was it not one of the ultimate purposes of human bodies to serve vegetal life, surrounding it by emitting carbon dioxide for the plants to breathe, and manuring them with human bodies after death? Did not flowers and trees finally consume man and, by combining his remains together with raw earth, water, air, and sunlight, transform and transmute human bodies into the most glorious forms and colors?

Fechner's "animism," for which he was so wrathfully castigated by his contemporaries, led him to issue, two years after *Nanna*, a book on atomic theory, in which, long before the birth of particle physics, he argued that atoms were centers of pure energy and the lowest elements in a spiritual hierarchy. The following year he brought out *Zendavesta*, its title inspired by the sacred writings of the ancient Zoroastrians, who claimed that their great religious leader Zarathustra had taught his people how to breed the food plants that still today form our chief source of nourishment. The original *Zendavesta* might be considered the first textbook on agriculture. Fechner's work was characterized by the younger American philosopher William James as a "wonderful book by a wonderful genius." Its fascinating and complex philosophy contained such concepts as that of "mental energy," which appealed strongly to Sigmund Freud and without which the edifice of psychoanalysis might never have been built.

Though Fechner heroically attempted to put forward what his contemporaries, and many present-day philosophers, would call "an idealistic view of reality," he ceaselessly tried to reconcile it with the methodology of modern science, in which he was trained.

Perhaps this was why the Leipzig physician and physicist, characterized as one of the most versatile thinkers of the nineteenth century, was so excellent an observer of the details of the vegetable world surrounding him. In *Nanna* he described the sex organs of plants—which in humans St. Paul considered so uncomely—as marvels of beauty, lyricizing on the manner in which plants lure insects to wriggle into their genitalia to drink the hidden nectar and thus shake fertilizing pollen from the anthers of some distant blossom onto the stigma of their petals. Fechner marveled at how plants could devise the most sophisticated systems to spread their species, how the puffball waits to be trodden upon in order to produce a cloud of minute spores which are carried a great distance by the wind, how the maple casts off propeller seeds that spin away with a passing breeze, how fruit trees seduce birds, beasts, and man into distributing their seeds afar, neatly packaged in nourishing manure, how viviparous water lilies and ferns reproduce tiny but perfect plants on the surface of their leaves.

Fechner also expatiated on plant roots, the sensitive tips of which enable plants to maintain a sense of direction, and on the climbing tendrils of plants which, searching for purchase, repeat perfect circles in the air.

Though Fechner's work was not taken seriously in his own time, one Englishman, whose life ran parallel to Fechner's, had the daring to recognize that some mysterious force in plants had the characteristics of sentience or intelligence. After publishing his earthshaking *Origin of Species* in 1859, Charles Robert Darwin devoted the greater part of his remaining twenty-three years not only to an elaboration on his theory of evolution but to a meticulous study of the behavior of plants.

In his 575-page *The Power of Movement in Plants*, published just before his death, Darwin developed in a more scientific way than Fechner the idea that the habit of moving at certain times of day was the common inheritance of both plants and animals. The most striking part of this similarity, he wrote, was "the localization of their sensitiveness, and the transmission of an influence from the excited part to another which consequently moves."

Though this seemed to imply that Fechner might have been correct in stating that plants, like animals, had nervous systems, Darwin stopped short of making this assertion because he could find no such system. Nevertheless, he could not get out of his mind that plants must have sentient ability. In the very last sentence of his massive volume, referring to the properties of a plant's radicle—that part of its embryo which develops into the primary root—he stated boldly: "It is hardly an exaggeration to say that the tip of the radicle acts like the brain of one of the lower animals: the brain being seated within the anterior end of the body, receiving impressions from the sense organs, and directing the several movements."

In an earlier book, *The Fertilization of Orchids,* published in 1862, one of the most masterful and complete studies on a single species of plant life ever to appear, Darwin set forth in highly technical language the way insects caused the fertilization of those unusual flowers, which he had learned of by sitting on the grass for hours and patiently watching the process.

In more than a dozen years of experiments conducted on fifty-seven species of plants Darwin found that products of cross-pollination resulted in more numerous, larger, heavier, more vigorous and more fertile offspring, even in species that are normally self-pollinating, and he put his finger on the secret of the production of such copious amounts of pollen. Though the odds were millions to one against it, if the pollen of an immobile plant could mix with a faraway relative, its offspring were likely to attain what came to be known as "hybrid vigor." Of this Darwin wrote that "the advantages of cross-fertilization do not follow from some mysterious virtue in the mere union of two distinct individuals, but from such individuals having been subjected during previous generations to different conditions, or to their having varied in a manner commonly called spontaneous, so that in either case their sexual elements have been in some degree differentiated."

For all his academic preciseness, the thrust of Darwin's theory of evolution and of the survival of the fittest indicated that something more than chance was in play. That this something might accommodate to the wish of man was the next extraordinary development.

In 1892, ten years after Darwin's death and five years after Fechner's, a fifty-two-page nurseryman's catalog, *New Creations in Fruits and Flowers,* published in Santa Rosa, California, created a sensation in the United States. Unlike similar booklets, which had thus far included not more than half a dozen novelties among the hundreds advertised, this catalog contained not a single plant known to man.

Among its horticultural marvels were a hardwood giant Paradox walnut, which, growing as fast as a spongy pulpwood, could form a hedge tall enough to screen a house within a few years; a giant daisy, named for Mount Shasta, with mammoth snow-white petals; an apple, sweet on one side and sour on the other; and a cross between a strawberry and a raspberry which, though it did not fruit, seemed as strange to followers of the theory of natural selection as would the mating of a chicken with an owl.

When the catalog finally made its way six thousand miles to the Netherlands, it caught the eye of an Amsterdam professor, Hugo De Vries, in the process of rediscovering the modern science of genetics—originated in the mid-nineteenth century by the Austrian monk Gregor Johann Mendel, but buried during his lifetime in the shelves of his monastery library. De Vries, later to be celebrated for carrying forward Darwin's life work with his own theory of mutation, was flabbergasted by the catalog and the apparent ability of one man to bring into the world botanical specimens undreamed of by nature. To satisfy his curiosity, De Vries set off across the world to visit the catalog's publisher, who turned out to be a New England transplant to California, Luther Burbank, whose feats with plants led to the new transitive verb *to burbank,** and his reputation as the "Wizard of Horticulture" was to infuriate botanists unable to understand the magic of his methods.

When De Vries came to Santa Rosa and saw growing in the "wizard's" front yard a fourteen-year-old Paradox walnut larger than the Persian variety four times its age and a monkey-puzzle tree which could stun passers-by by dropping twenty-pound nuts on their heads, he was dumbstruck that in the little cottage where Burbank worked there was

* *Webster's New International Dictionary,* 2d ed., lists: "Burbank, *v.t.* To modify and improve (plants or animals) esp. by selective breeding. Also to cross or graft (a plant). Hence, figuratively, to improve (anything, as a process or institution) by a selecting of good features and rejecting of bad, or by adding good features.

neither library nor laboratory and that Burbank's work notes were kept on tearings from brown-paper bags or the backs of letters and envelopes.

Throughout the evening the bewildered De Vries, who had expected files of carefully recorded data which might reveal Burbank's secrets, questioned the plant breeder, only to be told that his art was basically "a matter of concentration and the rapid elimination of non-essentials." As for his laboratory, Burbank told De Vries: "I keep it in my head."

The Dutch scientist was no more perplexed than were hundreds of his American confrères who, lacking any rational explanation for Burbank's methodology, often branded the wizard a charlatan. Burbank's own evaluation of the botanical fraternity did little to appease their collective ire. In 1901 Burbank told the San Francisco Floral Congress:

> The chief work of the botanists of yesterday was the study and classification of dried, shriveled plant mummies whose souls had fled. They thought their classified species were more fixed and unchangeable than anything in heaven or earth that we can now imagine. We have learned that they are as plastic in our hands as clay in the hands of the potter or color on the artists' canvas and can readily be molded into more beautiful forms and colors than any painter or sculptor can ever hope to bring forth.

Unlike the narrower minds which such simple and truthful statements drove to frenzy, De Vries, accepting Burbank as a natural-born genius, wrote of his work that "its value for the doctrine of evolution compels our highest admiration."

As his biographers almost inadvertently make clear, Burbank was and remains an enigma. Born in 1849 in the rural Massachusetts village of Lunenburg, the lasting impressions from his schooling came from his reading of Henry David Thoreau and of the other great naturalists Alexander von Humboldt and Louis Agassiz. But even these were overshadowed when he devoured, shortly after its publication in 1868, Charles Darwin's massive two-volume *The Variation of Animals and Plants Under Domestication.* Burbank was deeply impressed by its theme that organisms, when removed from their natural conditions, vary.

While still in Massachusetts, Burbank one day happened upon a seed ball in his patch of potatoes—a vegetable which almost never sets seed

and is therefore propagated from the buds, or "eyes," of its tuber. Because he knew that potato seeds, if they could be found, would not grow tubers true to type, and instead would produce a curious batch of mongrels, he excitedly thought that one of them might develop into a potato miracle. One of the twenty-three seeds in the ball gave rise to an offspring that managed to double the average yield. Smooth, plump, an excellent baker, the new potato, unlike its red-skinned progenitor, was creamy-white.

Burbank received $150 from a Marblehead seedman for his discovery and the compliment that it was the best potato the seedman had ever eaten. Christened the "Burbank," it was later widely planted by growers in the San Joaquin River delta town of Stockton, California, who gratefully presented to Burbank its solid gold miniature replica. Today it dominates the U.S. potato market. Three days after the original sale—following the terse advice he later gave to a New England farmer who asked him what he should raise on some newly acquired acreage, "Enough money to go to California"—Burbank was on a cross-continental train.

Shortly after Burbank's arrival in Santa Rosa, Darwin's *The Effects of Cross and Self Fertilisation in the Vegetable Kingdom* came out, and Burbank was particularly struck by a challenging introductory statement: "As plants are adapted by such diversified and effective means for cross-fertilization, it might have been inferred from this fact alone that they derived some great advantage from the process." To Burbank, this sentence seemed both a blueprint and a command. If Darwin had drawn plans, he would carry them out.

Burbank's first chance for fame came in the spring of 1882 when a variety of plums known as prunes were coming into their own in hundreds of California orchards as a new money-making fruit, easily dried and thus easily shipped and slow to spoil. In March a canny banker in the neighboring town of Petaluma, fearful lest he miss the bonanza, asked Burbank if he could deliver twenty thousand young prune trees for a two-hundred-acre planting by December. Everyone else, said the worried banker, had told him this was impossible. Burbank knew that if the man had given him two years nothing would have been simpler than to sprout plum trees from seed, bud them with prunes in the late summer, and after cutting off the original plum tops, watch them develop into prune seedlings the year following. How, he asked himself, could he turn the same trick in eight months?

It then struck Burbank that almonds, a member of the genus *Prunus*, would sprout much faster than the hard stones of plums. After buying a sackful of the oval-shaped nuts, Burbank forced them to sprout in warm water, copying a method he had used with corn in Massachusetts, which allowed him to beat other farmers to the market by more than a week. Even so, the little seedlings were not ready for budding until June, and time was running short. With a cash advance from the banker, Burbank hired all available nursery help in the region. They worked around the clock; when the job was finished, Burbank prayed that his tiny seedlings would grow into trees as tall as the average woman in the four months remaining before the contract called for delivery. His luck held; before Christmas he was able to deliver 19,500 trees to the overjoyed banker. Other nurserymen were left gasping at the feat, which not only produced a $6,000 windfall for Burbank but taught him that mass production was one of the keys to prodding out of nature secrets she was normally unwilling to give up.

Thus began Burbank's pomological revolution, which led to the development of new prunes and plums—including one, the Climax, which tasted like a pineapple, and another which tasted like a pear—that today still account for over half of California's giant crop; the ever-popular Burbank July Elberta peach, a luscious Burbank Flaming Gold nectarine, a bush-type chestnut, which bore a crop six months after its seed was put in the ground, a white blackberry the color of an icicle, and two quinces that were so good that most nurseries still stock no other.

In developing new fruit, Burbank was so adept and fast that he could race through thousands of cross-pollinations while orthodox plant specialists in laboratories were pedantically poring over sheaves of notes involving only a few dozen. It was no wonder that the schoolmen increasingly accused him of trickery, mainly of buying his "new creations" abroad. For Burbank, convinced that plants, like people, would behave differently when away from home, would order, from as far away as Japan and New Zealand, experimental varieties to cross with home-

grown standbys. Burbank introduced over a thousand new plants, which, if evenly spaced over his working career, would have amounted to a never-before-seen specimen every three weeks. Despite the backbiting cavils from envious and narrow-minded scientists, this miracle making was heralded by professional experts big enough to recognize genius when they saw it, even if it passed their understanding.

Liberty Hyde Bailey, the universally recognized dean of American botany, who had earlier told a world horticultural congress that "man could not do much to produce variations in plants," came from Cornell University to see what Burbank was doing to create such a furor. He left Santa Rosa stupefied and wrote the same year in an issue of *World's Work* magazine:

> Luther Burbank is a breeder of plants by profession, and in this business he stands almost alone in this country. So many and so striking have been the new plants that he has given to the world that he has been called the "Wizard of Horticulture." This sobriquet has prejudiced a good many people against his work. Luther Burbank is not a wizard. He is an honest, straight-forward, careful, inquisitive and persistent man. He believes that causes produce results. He has no other magic than that of patient inquiry, abiding enthusiasm, an unprejudiced mind, and a remarkably acute judgement of the merits and capabilities of plants.

This was a delight to Burbank, who smarted from the ugly rumors circulated about his work in the halls of academe. He told a packed lecture hall at Stanford University that "Orthodoxy is ankylosis—nobody at home: ring up the undertaker for further information!" Professor H. J. Webber, a geneticist in charge of plant breeding at the U.S. Department of Agriculture, maintained that Burbank had single-handedly saved the world nearly a quarter of a century in plant-breeding time. David Fairchild, who spent years exploring the world for new plants which might prove commercially useful in the United States, though baffled by Burbank's methods, summed up his impressions of his visit to Santa Rosa in a letter to a friend: "There are those who say Burbank is not scientific. It is true only in the sense that he has tried to do so much, and has been so fascinated by the desire to create that he has not always noted and labeled the footsteps which he has taken."

Just watching Burbank at work took the breath away from countless observers. On his experimental farm in nearby Sebastopol, where forty thousand Japanese plums or a quarter of a million flowering bulbs could be seen growing at the same time, Burbank would walk down a row of thousands of plants—whether tiny seedlings just breaking ground or chest-high flowers nearing maturity—and without breaking his stride pick out those likely to succeed. One wide-eyed county farm adviser described this in his own words: "He'd go along a row of gladioli, yanking out the ones he didn't want as fast as he could pull them up. He seemed to have an instinct that told him if a tiny plant would grow up to bear the kind of fruit or flowers he wanted. I couldn't see any difference between them, even if I stooped and looked closely, but Burbank did no more than glance at them."

Burbank's catalogs described his results in such a way that readers could imagine he had thousands of workers and several genies helping him: "Six new gladioli, the best of a million seedlings." "The growing of 10,000 hybrid clematis plants for several years to get a final six good ones." "Discarding 18,000 calla lilies in order to get one plant." "My Royal Walnut can outgrow ordinary walnuts eight to one and promises to revolutionize the furniture business and also perhaps the cord-wood industry."

When, on the 18th day of April, 1906, the same earthquake which all but devastated San Francisco reduced Santa Rosa to a mass of flaming splinters and rubble, the overwhelmed citizens were further stunned that not a pane of glass in Burbank's huge greenhouse not far from the center of town was even cracked.

Burbank was less amazed than his fellow townsmen, though careful not to broach the subject directly in public, surmising that his communing with the forces of nature and the cosmos and his success with plants might well have protected his greenhouse.

His indirect allusions to the personalization of his plants are illustrated by an article he wrote in 1906 for *Century Magazine:*

> The most stubborn living thing in this world, the most difficult to swerve [he asserted] is a plant once fixed in certain habits. Remember that this plant has preserved its individuality all through the ages; perhaps it is one which can be traced backward through eons of time in the very rocks themselves. Do you suppose, after all these ages of repetition, the plant does not become possessed of a will, if you so choose to call it, of unparalleled tenacity?

To Manly P. Hall, founder and president of the Philosophical Research Society of Los Angeles and a student of comparative religion, mythology, and esoterica, Burbank revealed that when he wanted his plants to develop in some particular and peculiar way not common to their kind he would get down on his knees and talk to them. Burbank also mentioned that plants have over twenty sensory perceptions but, because they are different from ours, we cannot recognize them. "He was not sure," wrote Hall, "that the shrubs and flowers understood his words, but he was convinced that by some telepathy, they could comprehend his meaning."

Hall later confirmed what Burbank told the famous yogi, Paramahansa Yogananda, about his development of the spineless cactus, a years-long procedure during which Burbank at first had to pull thousands of cactus thorns from his hands with pliers, though in the end the cacti grew without thorns. "While I was conducting my experiments with cacti," said Burbank, "I often talked to the plants to create a vibration of love. 'You have nothing to fear,' I would tell them. 'You don't need your defensive thorns. I will protect you.'" Burbank's power of love, reported Hall, "greater than any other, was a subtle kind of nourishment that made everything grow better and bear fruit more abundantly. Burbank explained to me that in all his experimentation he took plants into his confidence, asked them to help, and assured them that he held their small lives in deepest regard and affection."

Helen Keller, deaf and blind, after a visit to Burbank, wrote in *Outlook for the Blind:* "He has the rarest of gifts, the receptive spirit of a child. When plants talk to him, he listens. Only a wise child can understand the language of flowers and trees." Her observation was particularly apt since all his life Burbank loved children. In his essay "Training of the Human Plant," later published as a book, he anticipated the more humane attitudes of a later day and shocked authoritarian parents by saying, "It is more important for a child to have a good nervous system than to try to 'force' it along the line of book knowledge at the expense of its spontaneity, its play. A child should learn through a medium of pleasure, not of pain. Most of the things that are really useful in later life come to the children through play and through association with nature."

Burbank, like other geniuses, realized that his successes came from having conserved the exuberance of a small boy and his wonder for everything around him. He told one of his biographers: "I'm almost seventy-seven, and I can still go over a gate or run a foot race or kick the chandelier. That's because my body is no older than my mind—and my mind is adolescent. It has never grown up and I hope it never will."

It was this quality which so puzzled the dour scientists who looked askance at his power of creation and bedeviled audiences who expected him to be explicit as to how he produced so many horticultural wonders. Most of them were as disappointed as the members of the American Pomological Society, gathered to hear Burbank tell "all" during a lecture entitled "How to Produce New Fruits and Flowers," who sat agape as they heard him say:

> In pursuing the study of any of the universal and everlasting laws of nature, whether relating to the life, growth, structure and movements of a giant planet, the tiniest plant or of the psychological movements of the human brain, some conditions are necessary before we can become one of nature's interpreters or the creator of any valuable work for the world. Preconceived notions, dogmas and all personal prejudice and bias must be laid aside. Listen patiently, quietly and reverently to the lessons, one by one, which Mother Nature has to teach, shedding light on that which was before a mystery, so that all who will, may see and know. She conveys her truths only to those who are passive and receptive. Accepting these truths as suggested, wherever they may lead, then we have the whole universe in harmony with us. At last man has found a solid foundation for science, having discovered that he is part of a universe which is eternally unstable in form, eternally immutable in substance.

Had he known of Fechner, Burbank would have agreed with him "that it is a dark and cold world we sit in if we will not open the inward eyes of the spirit to the inward flame of nature."

CHAPTER 9

Wizard of Tuskegee

That plants were able to reveal their hidden secrets upon request was accepted as normal and natural by a remarkable genius born just before the Civil War, the agricultural chemist George Washington Carver, who overcame the handicap of his slave descent to be heralded in his own lifetime as the "Black Leonardo."

During a stunningly creative career, with methods as incomprehensible to his fellow scientists as were those of his professional forebears the alchemists, Carver turned the lowly peanut, considered useful only as hog food, and the unknown sweet potato into hundreds of separate products, ranging from cosmetics and axle grease to printer's ink and coffee.

From the time he was able to get about by himself in the countryside young Carver began to display an uncanny knowledge of all growing things. Local farmers in Diamond Grove, a tiny community in the foothills of the Ozarks in southwestern Missouri, remembered the weak-looking boy roving for hours through their holdings, examining plants and bringing back certain varieties with which he could miraculously heal sick animals. On his own, the child planted a private garden in a remote and unused bit of bottomland. With the remnants of coldframes and other stray material he built a secret greenhouse in the woods. Asked what he was forever doing all by himself so far from the farmyard, Carver replied firmly if enigmatically, "I go to my garden hospital and take care of hundreds of sick plants."

Farmers' wives from all over the countryside began bringing him their ailing house plants, begging him to make them bloom. Gently caring for them in his own way, Carver often sang to them in the same squeaky voice which characterized him in manhood, put them in tin cans with special soil of his own concoction, tenderly covered them at night, and took them out to "play in the sun" during the day. When he returned the plants to their owners, and repeatedly was asked how he could work his miracles, Carver only said softly: "All flowers talk to me and so do hundreds of little living things in the woods. I learn what I know by watching and loving everything."

Enrolling in Simpson College in Indianola, Iowa, Carver supported himself through his skill as a laundryman by doing shirts for students, then transferred to the Iowa State College of Agriculture. There among his most lasting impressions was the statement of his best-loved teacher, Henry Cantwell Wallace, editor of the popular *Wallace's Farmer*, that "nations endure only as long as their topsoil." Carrying a heavy load of course work and employed by churches as an entirely self-taught organist, Carver found time to take Wallace's six-year-old grandson on long walks into the woods to talk with plants and fairies, little suspecting that the hand he was holding would be that of a Secretary of Agriculture, and later, two years before Carver's own death, Vice President of the United States.

By 1896, Carver had his master's degree and was invited to join the

faculty. However, when the founder and president of the Normal and Industrial Institute, Booker T. Washington, who had heard of Carver's brilliance, asked him to come to Tuskegee, Alabama, and run the institute's agricultural department, Carver decided, like Sir Jagadis Chandra Bose, that he could not let the prospect of a comfortable and well-paying post on the Iowa State faculty dissuade him from serving his own people. So he accepted.

Carver had not been back in the South more than a few weeks when he discerned that the main problem facing the flat land spreading out in hundreds of square miles around him was its slow poisoning through monotonous planting year in year out of a single crop, cotton, which for generations had been sucking fertility out of the soil. To counteract the despoliation by thousands of sharecroppers, he decided to set up an experimental station. There he had a private laboratory, christened "God's Little Workshop," in which he would sit for hours communing with plants and into which he never allowed a single book to penetrate.

For his students at Tuskegee he made his lectures as simple and yet as thoroughgoing as possible. When the chancellor of the University of Georgia, W. B. Hill, came to Tuskegee to see for himself if it was true that a Negro professor was as brilliant as rumor had reported, he declared that Carver's presentation on the problem of Southern agriculture was "the best lecture that it has ever been my privilege to attend." Carver's students were greatly impressed that each morning he would rise at four o'clock to walk in the woods before the start of the working day and bring back countless plants with which to illustrate his lectures. Explaining this habit to friends, Carver said, "Nature is the greatest teacher and I learn from her best when others are asleep. In the still dark hours before sunrise God tells me of the plans I am to fulfill."

For more than a decade Carver worked daily on experimental plots of soil trying to discover exactly how to change Alabama's enthrallment by "ol' debbil cotton." On one nineteen-acre plot he put no commercial fertilizer, benefiting it instead with nothing but old dead leaves from the forest, rich muck from the swamps, and barnyard manure. The plot furnished such bountiful harvests of rotated crops that Carver came to the conclusion that "in Alabama the very fertilizers which existed in almost unlimited supply were allowed to go to waste in favor of commercially sold products."

As a horticulturalist, Carver had noticed that the peanut was incredibly self-sufficient and could grow well in poor soil. As a chemist, he discovered that it equaled sirloin steaks in protein and potatoes in carbohydrates. Late one evening while pondering the problem in his workshop Carver stared at a peanut plant and asked, "Why did the Lord make you?" In a flash, he received the briefest of answers: "You have three things to go by: compatibility, temperature, and pressure."

With this slim advice Carver locked himself in his laboratory. There, throughout a sleepless week, he began breaking down the peanut into its chemical components and exposing them by trial and error to different conditions of temperature and pressure. To his satisfaction he found that one-third of the little nut was made up of seven different varieties of oil. Working round the clock, he analyzed and synthesized, took apart and recombined, broke down and built up the chemically differentiable parts of the peanut until at last he had two dozen bottles, each containing a brand-new product.

Leaving his laboratory, he convoked a meeting of farmers and agricultural specialists and showed them what he had been able to do in seven days and seven nights. He begged his audience to plow under the soil-destroying cotton and plant peanuts in its stead, assuring them that it would produce a cash crop far more valuable than its sole existing use as food for pigs might indicate.

The audience was doubtful, the more so when Carver, asked to explain his methods, replied that he never groped for them but that they came to him in flashes of inspiration while walking in the woods. To allay their doubts he began to issue bulletins, one of which stated incredibly that rich, nutritious, and highly palatable butter could be made from the peanut, and that whereas it took one hundred pounds of dairy milk to make ten pounds of butter, a hundred pounds of peanuts could produce thirty-five pounds of peanut butter. Other bulletins showed how a cornucopia of products could also be extracted from the sweet potato, a tropical vine of which most Americans had never heard, that throve in the South's cotton-debased soil. When World War I broke out, and the

shortage of dyestuffs presented itself as a serious national problem, Carver rambled at daybreak through the mist and dew, inquiring of his plant friends which of them could alleviate the deficit. From the leaves, roots, stems, and fruits of twenty-eight volunteers he coaxed 536 separate dyes, which could be used to color wool, cotton, linen, silk, and even leather, producing 49 of them from the scuppernong grape alone.

At last his labors attracted national attention. When it was bruited that at Tuskegee Institute they were saving two hundred pounds of wheat per day by mixing two parts of ordinary flour with a new flour derived from sweet potatoes, a flock of dieticians and food writers interested in cooperating with the wartime drive to economize on wheat came to investigate. They were served delicious breads made from the mixed flours, along with a sumptuous lunch of five courses each made from peanuts or sweet potatoes, or, like Carver's "mock chicken," from the two combined. The only other vegetables on the table were sheep sorrel, pepper grass, wild chicory, and dandelions, served as a salad to illustrate Carver's assertion that plants growing in nature were far better than those from which the natural vitality had been removed in cultivation. The food experts, who realized that Carver's contributions might go a long way to helping the war effort, rushed to telephone their papers, and Carver, who had become known to scientists the year before when he was elected a fellow of Great Britain's famous Royal Society, now appeared in the headlines.

Invited to Washington, Carver dazzled government officials with dozens of products, including a starch valuable to the textile industry which later became a component in the glue of billions of U.S. postage stamps.

Next it came to Carver that peanut oil could help the atrophied muscles of polio victims. Results were so astonishing that he had to set aside one day each month to treat patients who came to his laboratory on stretchers, crutches, or canes. This feat remained as unheralded in medicine as the application of castor-oil packs, recommended about the same time by the "sleeping prophet," Edgar Cayce, with which doctors of an intrepidly investigative frame of mind are only today beginning to achieve startling, and wholly inexplicable cures.

By 1930, the peanut's one-time worthlessness had been converted, through Carver's clairvoyance, into a quarter of a billion dollars for Southern farmers, and had created a huge industry. Peanut oil alone was valued at $60 million a year and peanut butter was establishing itself as one of the favorite foods of even the poorest American child. Not satisfied with his achievements, Carver went on to make paper from a local Southern pine tree which ultimately helped to spur lumberers to cover millions of Southern acres with productive forests where only scrub woods had existed.

In the midst of the depression, Carver was again invited to Washington to testify before the powerful Ways and Means Committee of the U.S. Senate, which was considering the Smoot-Hawley tariff bill designed to protect struggling American manufacturers. Dressed in his usual, seemingly eternally durable, two-dollar black suit, with an ever-present flower in its buttonhole and a home-made necktie, Carver, upon his arrival at Union Station, was rebuffed by a waiting porter who, when Carver asked him to help him with his bags and direct him to Congress, replied: "Sorry, Pop, I ain't got time for you now. I'm expecting an important colored scientist coming from Alabama." Patiently Carver hefted his own bags to a taxi which took him to Capitol Hill.

Though the committee had accorded him no more than ten minutes to testify, when he began his presentations and took from his bag face powders, petroleum substitutes, shampoos, creosote, vinegar, wood-stains, and other samples of the countless creations concocted in his laboratories, the Vice President of the United States, testy "Cactus Jack" Garner from Texas, overruled protocol and told Carver he could have as much time as he liked because his demonstration was the best that he had ever seen presented to a Senate committee.

In half a lifetime of research Carver, though he created fortunes for thousands, rarely took out a patent on any of his ideas. When practical-minded industrialists and politicians reminded him of the money he might have made had he only afforded himself this protection, he replied simply: "God did not charge me or you for making peanuts. Why should I profit from their products?" Like Bose, Carver believed that the fruit of his mind, however valuable, should be granted free of charge to mankind.

Thomas A. Edison told his associates that "Carver is worth a fortune" and backed up his statement by offering to employ the black chemist at an astronomically high salary. Carver turned down the offer. Henry Ford, who thought Carver "the greatest scientist living," tried to get him to come to his River Rouge establishment, with an equal lack of success.

Because of the strangely unaccountable source from which his magic with plant products sprang, his methods continued to be as wholly inscrutable as Burbank's to scientists and to the general public. Visitors finding Carver puttering at his workbench amid a confusing clutter of molds, soils, plants, and insects were baffled by the utter and, to many of them, meaningless simplicity of his replies to their persistent pleas for him to reveal his secrets.

To one puzzled interlocutor he said: "The secrets are in the plants. To elicit them you have to love them enough."

"But why do so few people have your power?" the man persisted. "Who besides you can do these things?"

"Everyone can," said Carver, "if only they believe it." Tapping a large Bible on a table, he added, "The secrets are all here. In God's promises. These promises are real, as real as, and more infinitely solid and substantial than, this table which the materialist so thoroughly believes in."

In a celebrated public lecture, Carver related how he had been able to call forth from the low mountains of Alabama hundreds of natural colors from clays and other earths, including a rare pigment of deep blue which amazed Egyptologists, who saw rediscovered in it the blue color found in the tomb of Tutankhamen, as bright and fresh after so many centuries as it was when it had been first applied.

When Carver was eighty or thereabouts—his exact date of birth never having been established since no records were kept for slave children—he addressed a meeting of chemists in New York as World War II was erupting in Europe.

"The ideal chemist of the future," said Carver, "will not be satisfied with humdrum day-to-day analysis, but is one who dares to think and work with an independence not permissible heretofore, unfolding before our eyes a veritable mystic maze of new and useful products from material almost or quite beneath our feet and now considered of little or no value."

Not long before Carver's death a visitor to his laboratory saw him reach out his long sensitive fingers to a little flower on his workbench. "When I touch that flower," he said rapturously, "I am touching infinity. It existed long before there were human beings on this earth and will continue to exist for millions of years to come. Through the flower, I talk to the Infinite, which is only a silent force. This is not a physical contact. It is not in the earthquake, wind or fire. It is in the invisible world. It is that still small voice that calls up the fairies."

He suddenly stopped and after a moment of reflection smiled at his visitor. "Many people know this instinctively," he said, "and none better than Tennyson when he wrote:

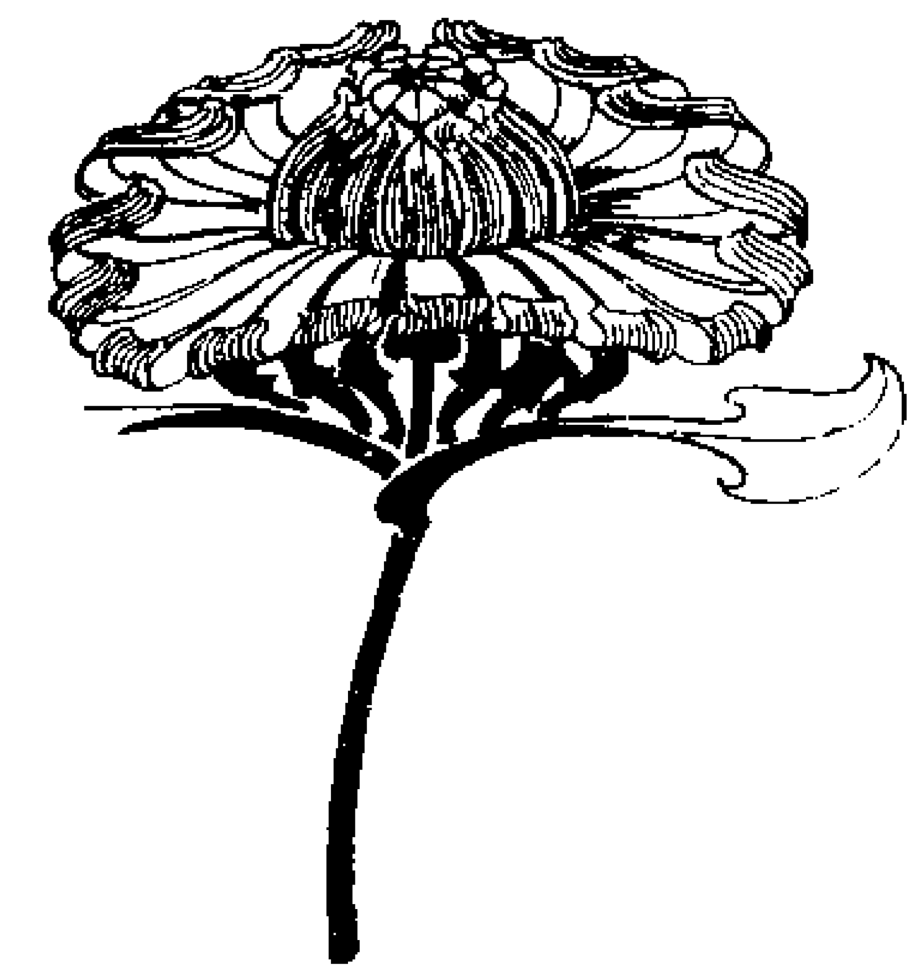
> "Flower in the crannied wall,
> I pluck you out of the crannies,
> I hold you here, root and all, in my hand,
> Little flower—but *if* I could understand
> What you are, root and all, and all in all,
> I should know what God and man is."

PART III

TUNED TO THE MUSIC OF THE SPHERES

CHAPTER 10

The Harmonic Life of Plants



The strangest experiment Charles Darwin ever performed on a plant was to sit before his *Mimosa pudica,* or touch-me-not, and play to it his bassoon in close enough proximity to see if he could stimulate its pinnae, or feathery leaflets, into movement. The experiment failed but was exotic enough to stimulate the renowned German plant physiologist Wilhelm Pfeffer, author of the classic *Handbuch der Pflanzenphysiologie,* into attempting, also unsuccessfully, to provoke stamens of *Cynararea,* a small genus of erect herbs, into response by means of sound.

In 1950 when Professor Julian Huxley, the biologist grandson of Thomas Henry Huxley and brother of novelist Aldous, was visiting Dr.

T. C. Singh, head of the department of botany at Annamalai University south of the Tamil-speaking city of Madras, he found his host studying through a microscope the live streaming of protoplasm in the cells of *Hydrilla verticillata,* an aquatic plant of Asian origin with long transparent leaves. Aware of both Darwin's and Pfeffer's experiments, Huxley was struck by the idea that the magnification might be sufficient for his host to see if the streaming process could be affected by sound.

Because the streaming of protoplasm in vegetation begins to speed up after sunrise, Singh placed an electrically operated tuning fork six feet from a *Hydrilla,* and microscopically observed that the fork's note, broadcast for half an hour just before 6 A.M., caused the protoplasm to stream at a speed normally attained only much later in the day.

Singh next asked his young assistant, Stella Ponniah, an accomplished dancer and violinist, if she would play notes on her instrument while standing near a *Hydrilla.* When the girl stroked her strings at a certain pitch, the protoplasm's streaming was again accelerated.

Because the *raga,* a traditional form of South Indian devotional song, has a tonal system which can produce a deep religious feeling and specific emotions in a listener, Singh decided to try its tones on the *Hydrilla.*

Lord Krishna, the eighth and principal avatar and incarnation of the Hindu deity Vishnu, was reputed to have promoted with music enthralling growth and bewitching verdure in Vrindavan, a city on the banks of the Jamuna River in north-central India long famous for its saint-musicians. Much later a courtier of the famous Moghul emperor Akbar is reported to have been able to perform such miracles with his songs as to bring on rain, light oil lamps, vernalize plants and induce them to blossom simply by intoning *ragas* at them. This appealing idea is confirmed in Tamil literature, which refers to the eyes, or buds, of sugar cane growing vigorously in response to the mellifluous buzzing of speckled beetles and to the profuse oozing of sugary nectar from the golden flowers of *Cassia fistula* when serenaded with heart-melting melodies.

Knowing this ancient lore, Singh asked his assistant to play the South Indian tune *"Maya-malava-gaula raga"* to mimosas. After a fortnight, to Singh's intense excitement, he discovered that the number of stomata

per unit area in the experimental plants was 66 percent higher, the epidermal walls were thicker, the palisade cells were longer and broader than in control plants, sometimes by as much as 50 percent.

Encouraged to further experimentation, Singh requested Gouri Kumari, a lecturer at Annamalai's Music College, to play a *raga* known as the *"Kara-hara-priya"* to some balsam plants. Kumari, a virtuoso, played for twenty-five minutes each day, on a fretted lutelike instrument usually fitted with seven strings, the *veena* traditionally associated with Saraswati, goddess of wisdom. During the fifth week, the experimental balsams began to shoot ahead of their unserenaded neighbors and, at the end of December, had produced an average of 72 percent more leaves than the control plants, and had grown 20 percent higher.

Singh then experimented on a vast number of species, such as common asters, petunias, cosmos, and white spider lilies, along with such economic plants as onions, sesame, radishes, sweet potatoes, and tapioca.

Each of these species Singh entertained for several weeks just before sunrise with more than half a dozen separate *ragas,* one per experiment, played on the flute, violin, harmonium, and *veena;* the music lasted a half hour daily, scaled at a high pitch, with frequencies between one hundred and six hundred cycles per second. From all this experimentation Singh was able to state, in the magazine of the Bihar Agricultural College at Sabour, that he had "proven beyond any shadow of doubt that harmonic sound waves affect the growth, flowering, fruiting, and seed-yields of plants."

As a result of his success, Singh began wondering whether sound, properly prescribed, could spur field crops to greater yields. From 1960 to 1963 he piped the *"Charukesi raga"* on a gramophone via a loudspeaker to six varieties of early, medium, and late paddy rice growing in the fields of seven villages located in the state of Madras and in Pondicherry on the Bay of Bengal, and got harvests ranging consistently from 25 to 60 percent higher than the regional average. He also was able musically to provoke peanuts and chewing tobacco into producing nearly 50 percent more than normal. Singh further reported that merely by dancing the *"Bharata-Natyam,"* India's most ancient dance style, without musical accompaniment and executed by girls without trinkets on their ankles, the growth of Michaelmas daisies, marigolds, and petunias was very much accelerated, causing them to flower as much as a fortnight earlier than controls, presumably because of the rhythm of the footwork transmitted through the earth.

Replying to a question which he thought would "naturally bristle up" in the minds of his readers, as to exactly what caused the effect on plants, Singh explained that in his laboratories he could visually demonstrate that the fundamental metabolic processes of plants in relation to transpiration and carbon assimilation under the excitation of musical sound or rhythmic beat were very much accelerated and increased over 200 percent compared to controls. "The stimulated plants," wrote Singh, "are energized to synthesize greater quantities of food during a given period of time, which naturally leads to greater yields." Singh also reported that his method of musical stimulation has even increased the chromosome count of certain species of water plants and the nicotine content of tobacco leaves.

Though the Indians of the subcontinent, both ancient and modern, appear to have been the first to produce a significant effect on plants with music or sound, they are by no means the only ones. In the Milwaukee, Wisconsin, suburb of Wauwatosa, a florist, Arthur Locker, began piping music into his greenhouses in the late 1950s. The difference he observed in flower production before and after the broadcasts was sufficiently marked to convince Locker that music powerfully contributed to horticulture. "My plants grew straighter, germinated quicker, bloomed more abundantly," he said. "The colors of the flowers were more striking to the eye, and the blooms lasted longer than usual."

At about the same time a Canadian engineer and gentleman farmer, Eugene Canby, of Wainfleet, Ontario, broadcast the violin sonatas of Johann Sebastian Bach to a test plot of wheat and produced a crop not only 66 percent greater than average but with larger and heavier seeds. Since the wheat growing in those areas of the plot where the soil was inferior did just as well as those growing in the richest earth, it seemed to Canby that Bach's musical genius was as good as or better than nutrients.

In 1960 in the agricultural community of Normal, Illinois, a botanist

and agricultural researcher, George E. Smith, learned of Singh's experiments while chatting with the farm editor of his local newspaper. The following spring, Smith, somewhat skeptically, planted corn and soybeans in flats and divided them between two identical greenhouses, both kept precisely at the same level of temperature and humidity. In one of the greenhouses he installed a small record player, its speaker directed toward the experimental plants, and played George Gershwin's "Rhapsody in Blue" twenty-four hours a day. According to Smith's report to his employer, Mangelsdorf and Bros., Inc., wholesale field seed suppliers in St. Louis, Missouri, the Gershwin-inspired seedlings sprouted earlier than those given the silent treatment, and their stems were thicker, tougher, and greener.

Smith, still skeptical, was not satisfied with his subjective observations. Removing ten corn and ten soybean plants from each of the greenhouses, he carefully cut them at ground level and immediately weighed them on apothecary scales. To his surprise the ten corn plants which had been enjoying Gershwin's music weighed 40 grams and those deprived of it only 28 grams; the corresponding soybean plants' weights were 31 and 25 grams respectively.

The following year Smith continuously broadcast music to a small plot of Embro 44XE hybrid corn from the day of its planting to harvest time. The plot produced 137 bushels to the acre as against only 117 bushels for an untreated plot of similar corn growing under the same conditions. Smith noted that the musically entertained corn also grew more rapidly and uniformly and silked earlier. The larger yield per acre was due not to an increase per plant but to a greater survival of plants in the plot. To make sure that his tests were not due to chance, Smith laid out four corn plots in 1962 planted not only with the same Embro 44XE but also with another highly prolific hybrid, Embro Departure. The first plot was treated to the previous year's music, the second left silent, and the third and fourth offered only ear-splitting continuous notes, one with a high pitch of 1,800 cycles a second, the other with a low pitch of 450. At harvest time the Departure plants stimulated with music produced 186 bushels per acre as against only 171 for the silent plot. But those exposed to the high note outdid themselves to achieve nearly 198 bushels; those subjected to the low note topped 200. Gains for the Embro 44XE were less pronounced, though Smith had no idea why.

Pressed by his neighbors from several counties around to explain his results, Smith speculated that sound energy might increase molecular activity in the corn, and added that thermometers placed in the plots indicated that soil temperature was inexplicably two degrees higher directly in front of the loudspeaker. Smith was perplexed that the edges of the leaves of those corn plants growing in the slightly heated earth appeared a little burned, but thought this might be due to excessive exposure to musical vibrations. There were many unresolved mysteries, said Smith, one of whose Kansas friends had told him that high-frequency waves had been used successfully to control insects in stored wheat and that the same wheat planted later germinated faster than untreated grain.

The frequencies on the so-called sonic spectrum, unlike those on the so-called electromagnetic spectrum, relate to vibrations in matter, the medium in which they travel, and result from the rate of its compression and expansion. Thus a sound wave can pass through air, water, and other fluids, an iron bar, a table top, a human being, or a plant. Because human ears can pick up only those frequencies from 16 to about 20,000 cycles per second, they are known as "audio," or "sonic," frequencies. Below them are inaudible subsonic frequencies, some of which result from pressure applied slowly, such as that produced with a hydraulic jack, which become so slow they are measured not in cycles per second but in seconds per cycle. Above them are ultrasonic frequencies also inaudible to the human ear but affecting man's being in a variety of ways which are not fully known. Extremely high frequencies on this spectrum, ranging from hundreds to thousands of millions of cycles per second, can be perceived as heat on the skin and are therefore termed "thermal," though because they too cannot be audially detected could just as well be considered ultrasonic.

After his experimentation was given publicity all over North America, Smith received a letter from Peter Belton of the research branch of Canada's Department of Agriculture, who informed him that he had broadcast ultrasonic waves to control the European corn-borer moth,

whose larvae extensively damage growing corn. "At first we tested the hearing ability of this moth," wrote Belton. "It was obvious that moths could hear sounds at about 50,000 cycles. These high-pitched sounds are much like those made by bats, the moth's natural enemy. We planted two plots of corn, each ten feet by twenty, and divided them with sheets of plastic eight feet tall, capable of stopping this sound frequency. Then we broadcast the bat-like sound across two of the half-plots from dusk till dawn throughout the period the moths lay their eggs." Belton informed Smith that nearly 50 percent of his ripe corn ears were damaged by larvae in the silent plots but only 5 percent suffered injury in the plots where the moths had supposedly suspected bats might be lurking. A careful count also revealed 60 percent fewer larvae in the sound plots, and the corn was three inches taller.

In the mid-1960s the varied efforts of Singh and Smith aroused the curiosity of two researchers at Canada's University of Ottawa, Mary Measures and Pearl Weinberger. Like L. George Lawrence, they were conversant with discoveries by Russians, Canadians, and Americans that ultrasonic frequencies markedly affect the germination and growth of barley, sunflower, spruce, Jack pine, Siberian pea tree, and other seeds and seedlings. The experiments indicated, albeit inexplicably, that enzyme activity and respiration rates in plants and their seeds increased when they were stimulated by ultrasonic frequencies. However, the very frequencies which stimulated some plant species inhibited others. Measures and Weinberger wondered whether specific *audible* frequencies in the sonic range would be as effective as music in enhancing the growth of wheat.

In a series of experiments lasting more than four years, the two biologists exposed the grains and seedlings of spring Marquis and winter Rideau wheat to high-frequency vibrations. They found that, depending on how long the wheat seeds had been vernalized, the plants responded best to a frequency of 5,000 cycles a second.

Baffled by their results, the two researchers could not explain why audible sound had resulted in accelerated growth so striking that it seemed to promise to double wheat harvests. The effect could not have been produced by breaking chemical bonds in the seeds, they wrote in the *Canadian Journal of Botany*, since, to do this, one billion times as much energy as was added by the sound frequencies would be required. Instead, they suggested that sound waves might produce a resonant effect in the plant cells, enabling the energy to accumulate and affect the plant's metabolism. In the July, 1968, issue of *Prevention* magazine J. I. Rodale reported that Weinberger "is coming to believe that basic farm equipment of the future will include an oscillator for production of sound waves and a speaker."

Asked to confirm whether her experiments might result in application of sound to wheat seed planted in extended acreage, Dr. Weinberger stated in 1973 that large-scale tests were going forward in Canada, the United States, and Europe to determine the practicability of their idea.

Weinberger's observations are echoed by four scientists at the University of North Carolina at Greensboro, who have discovered that experimental "pink" noise, which, at 20 to 20,000 cycles per second and 100 decibels, sounds to the ear about the same as the noise received 100 feet away from a 727 jet plane about to take off, caused turnips to sprout much faster than those left silently in the ground. Professor Gaylord T. Hageseth, a physicist and leader of the research team, says that his findings have stirred up interest at the U.S. Department of Agriculture, which is studying the team's proposals to awaken seeds planted in hot regions such as California's San Joaquin Valley, where temperatures ranging above 100 degrees Fahrenheit induce dormancy in lettuce seeds. If awakened by sound irradiation, lettuce might produce two crops per season instead of one, say Hageseth and his colleagues, who also suggest that sound waves could be used to make weeds germinate before a field is planted. The weeds could then be plowed under to allow a crop to grow in a weed-free field.

Since broadcasting airport-level noise all over the countryside is hardly appealing, the North Carolina team has been working, like Measures and Weinberger, to find particular wavelengths or combinations to produce the desired effects at lower decibel levels. By the beginning of 1973 they had discovered that the germination rate in turnips seemed to speed up when the turnips were exposed to a frequency of 4,000 cycles per second.

An interesting and eventually very controversial series of experiments on the effects of music on plants began in 1968 when Dorothy Retallack, a professional organist and mezzo soprano, who gave concerts at Denver's Beacon Supper Club from 1947 to 1952, felt herself at loose ends when her eight children went off to college. Not to be the sole member of the family without a degree, Mrs. Retallack surprised her hard-working physician husband with the announcement of her own enrollment for a degree in music at Temple Buell College. Required to come up with a laboratory experiment in biology, Mrs. Retallack vaguely recalled reading an article about George Smith's playing disc jockey to his cornfields.

Following Smith's lead, Mrs. Retallack teamed with a fellow student, whose family provided an empty room at home and furnished two groups of plants, which included philodendron, corn, radishes, geraniums, and African violets. The neophyte experimenters suspended Gro-Lux lights over one group and played the taped musical notes B and D struck on the piano every second, alternating five minutes of those wearisomely repetitive sounds with five minutes of silence. The tape played continuously twelve hours a day. During the first week, the African violets, drooping at the start of the experiment, revived and began to flower. For ten days all the plants in the sound group seemed to thrive; but at the end of two weeks the geranium leaves began to yellow. By the end of the third week all the plants, some of which had been actually leaning away from the source of the sound as if blown by a strong wind, had died, with the unaccountable exception of the African violets, which somehow remained outwardly unaffected. The control group, allowed to grow in peace, flourished.

When she reported these results to her biology professor, Francis F. Broman, and asked if she could do a more elaborately controlled experiment for credit in his course, he reluctantly consented. "The idea made me groan a little," said Broman afterward, "but it was novel and I decided to okay it, even though most of the other students laughed out loud." Broman made available to Dorothy Retallack three new Biotronic Mark III Environmental Chambers fifty-six feet long, twenty-six feet high, and eighteen feet deep, recently purchased by his department, similar in shape but much larger than home fish aquariums, which allowed for precise control of light, temperature, and humidity.

Allotting one chamber for a control group, Mrs. Retallack used the same plants, with the exception of the violets, as in the first experiment, setting them in identical soil and affording them equal amounts of water on schedule. Trying to pinpoint the musical note most conducive to survival, each day she tried an F note, played unremittingly for eight hours in one chamber and three hours intermittently in another. In the first chamber her plants were stone dead within two weeks. In the second chamber, the plants were much healthier than controls left in silence.

Mrs. Retallack and Professor Broman were nonplused by these results; for they had no idea what could be causing the disparate reactions, and could not help wondering whether the plants had succumbed to fatigue or boredom or had simply been "driven out of their minds." The clear-cut experiments aroused a spate of controversy in the biology department, with both students and professors either dismissing the whole effort as spurious, or intrigued by the inexplicable outcome. Two students, following Mrs. Retallack's lead, ran an eight-week experiment on summer squashes, broadcasting music from two Denver radio stations into their chambers, one specializing in heavily accented rock, the other in classical music.

The cucurbits were hardly indifferent to the two musical forms: those exposed to Haydn, Beethoven, Brahms, Schubert, and other eighteenth- and nineteenth-century European scores grew *toward* the transistor radio, one of them even twining itself lovingly around it. The other squashes grew away from the rock broadcasts and even tried to climb the slippery walls of their glass cage.

Impressed with her friends' success, Mrs. Retallack ran a series of similar trials early in 1969 with corn, squash, petunias, zinnias, and marigolds; she noticed the same effect. The rock music caused some of the plants first to grow either abnormally tall and put out excessively small leaves, or remain stunted. Within a fortnight all the marigolds had died, but only six feet away identical marigolds, enjoying the classical strains, were flowering. More interestingly, Mrs. Retallack found that even during the first week the rock-stimulated plants were using much

more water than the classically entertained vegetation, but apparently enjoying it less, since examination of the roots on the eighteenth day revealed that soil growth was sparse in the first group, averaging only about an inch, whereas in the second it was thick, tangled, and about four times as long.

At this point, various critics sourly suggested that the experiments were invalid because such variables as sixty-cycle hum, the "white sound" heard from a radio tuned to a frequency not occupied by a radio transmitter, or the announcers' voices emitted by the radio sets had not been taken into account. To satisfy these cavils, Mrs. Retallack taped rock music from records. She selected the extremely percussive rock renditions of Led Zeppelin, Vanilla Fudge, and Jimi Hendrix. When plants leaned away from this cacophony, Mrs. Retallack rotated all the pots 180 degrees, only to see the plants lean in the opposite direction. This convinced the majority of critics that the plants were definitely reacting to the sounds of rock music.

Trying to determine what it was about rock that so jarred her plants, Mrs. Retallack guessed that it might be the percussive component in the music and started yet another experiment in the fall. Selecting the familiar Spanish tune "La Paloma," she played one version of it performed on steel drums to one chamber of plants and another version played on strings to a second. The percussion caused a lean ten degrees *away* from the vertical in Mrs. Retallack's plants, but nothing compared to the rock. The plants listening to the fiddles leaned fifteen degrees *toward* the source of the music. An eighteen-day repeat of the same experiment using twenty-five plants per chamber including squash from seed and flowering and leaf-type plants from greenhouses produced largely similar results.

Now Mrs. Retallack wondered how the effects of what she called "intellectual mathematically sophisticated music of both East and West" would appeal to plants. As program director for the American Guild of Organists, she chose choral preludes from Johann Sebastian Bach's *Orgelbüchlein* and the classical strains of the *sitar,* a less-complicated Hindustani version of the south Indian *veena,* played by Ravi Shankar, the Bengali Brahmin.

The plants gave positive evidence of liking Bach, since they leaned an unprecedented thirty-five degrees *toward* the preludes. But even this affirmation was far exceeded by their reaction to Shankar: in their straining to reach the source of the classical Indian music they bent more than halfway to the horizontal, at angles in excess of sixty degrees, the nearest one almost embracing the speaker.

In order not to be swayed by her own special taste for the classical music of both hemispheres Mrs. Retallack, at the behest of hundreds of young people, followed Bach and Shankar with trials of folk and "country-western" music. Her plants seemed to produce no more reaction than those in the silent chamber. Perplexed, Mrs. Retallack could only ask: "Were the plants in complete harmony with this kind of earthy music or didn't they care one way or the other?"

Jazz caused her a real surprise. When her plants heard recordings as varied as Duke Ellington's "Soul Call" and two discs by Louis Armstrong, 55 percent of the plants leaned fifteen to twenty degrees *toward* the speaker, and growth was more abundant than in the silent chamber. Mrs. Retallack also determined that these different musical styles markedly affected the evaporation rate of distilled water inside the chambers. From full beakers, fourteen to seventeen milliliters evaporated over a given time period in the silent chambers, twenty to twenty-five milliliters vaporized under the influence of Bach, Shankar, and jazz; but, with rock, the disappearance was fifty-five to fifty-nine milliliters.

When the office of public information at Temple Buell got wind that Mrs. Retallack was the first grandmother ever to be graduated from its college, it informed Olga Curtis, a reporter on the Denver *Post,* about her extraordinary doings with plants. Mrs. Retallack set up a brand-new experiment for Curtis in which she compared the effects of rock with that of string quartets by such twentieth-century composers as Schoenberg, Webern, and Berg. The point of choosing the largely twelve-tone music of these neo-classicists was to see whether its dissonances, like those of rock, would also cause the plants to cringe. They did not. Root examination showed that the specimens in the rock chamber were scrawny, whereas those subjected to the avant-garde music were comparable to control plants.

On June 21, 1970, the *Post*'s weekend supplement *Empire Magazine*

came out with a color-illustrated four-page spread entitled "Music That Kills Plants," which won for Curtis an annual award by the National Federation of Press Women. Syndicated by Metro Sunday Newspapers, the piece appeared all over the United States, spawning a new generation of articles with such titles as "Bach or Rock: Ask Your Flowers," "Mother Is Knitting Earmuffs for Our Petunias," and more alarmingly, "It Shouldn't Happen to Teenagers." Tying rock music to the proliferation of drugs among American youth, one writer for the popular right-wing *Christian Crusade Weekly* sanctimoniously wrote: "The Scripture admonishes the sluggard to go to the ant! Perhaps the druggard should go to the plant!"

From an avalanche of mail Mrs. Retallack learned that her experiments had elicited the interest of hundreds of readers, including a passel of professors who asked for her published scientific works. Spurred by the unsolicited interest, Retallack, together with Professor Broman, prepared a nine-page scientific paper, "Response of Growing Plants to a Manipulation of Their Sonic Environment," and sent it in to *Bio-Science Magazine,* published by the American Institute of Biological Sciences. They received a turndown, in the form of a review by Dr. Robert S. Leisner, stating that though one could draw a "highly tentative" conclusion that sound affects plant growth, the Retallack-Broman conclusions were hardly novel in light of the earlier work of Weinberger and Measures in Ottawa.

Meanwhile, Mrs. Retallack was called by CBS television and asked to set up a Rock-versus-Shankar experiment for filming with time-lapse cameras. Almost sick with nervousness lest her charges not deliver their message for the CBS technicians, Mrs. Retallack was relieved when the plants performed as if they knew they were scheduled for a nationwide broadcast. Aired on Walter Cronkite's newscast on October 16, 1970, the program added another enormous pile to her correspondence, which included a number of reports which researchers around the country wanted to share with her.

From them Dorothy Retallack learned that two North Carolina State University professors, L. H. Royster, of the Department of Mechanical and Aerospace Engineering, and B. H. Huang, of the Department of

Biological Engineering, had teamed with C. B. Woodlief, a researcher at Fiber Industries in the town of Shelby, to perform an experiment written up in the *Journal of the Acoustical Society of America* as "Effect of Random Noise on Plant Growth." The threesome, who realized that the effects of proliferating noise pollution on animals and man had been studied but that similar effects on plant systems had been overlooked, put twelve male sterile tobacco plants into an environmental control chamber with constant soil and temperature conditions. From a Bruel and Kraer random-noise generator they harried the plants with noise frequencies ranging from 31.5 to 20,000 cycles per second and concluded that growth rate in each plant decreased 40 percent.

Another correspondent was Dr. George Milstein, of Long Island City, New York, a retired dental surgeon turned teacher of horticulture at the New York Botanical Garden. After some of his patients had presented him with exotic plants the names of which no florist could be sure of, Milstein had dipped into botanical sources, become fascinated with the vegetal world, and begun growing exotic and colorful Bromeliads, an extended plant family which includes specimens as diverse as the pineapple and Spanish moss.

Learning of the Canadian research on wheat, he decided to see how sonics would affect other plants. Selecting a wide variety of house plants and two bananas, he subjected them to sonic vibrations delivered directly through the air or transduced through the soil of their pots or through their stems. Assisted by an NBC sound engineer, Milstein found that a continuous low hum at 3,000 cycles per second accelerated the growth of most of his subjects and even caused some of them to bloom six full months ahead of their normal schedule.

When Pip Records, a division of Pickwick International, Inc., asked him to make a record of stimulatory sounds for plants, it insisted that the record also contain music. Milstein accordingly embedded the stimulating hum in the record's musical selections. In an insert in the disc's jacket, "Growing Plants Successfully in the Home," Milstein, after giving precise information on the best kind of light, humidity, ventilation, temperature, watering, fertilizer, and pots, stated that just as all plant growth and flower development are stimulated by light

vibrations, so it is logical to assume that the vibrations of sound energy can also exert a beneficial influence on horticulture. Milstein recommended that for best results the record be played daily.

When the record attracted attention in the United States and other countries, Milstein was pestered in the mail and over the telephone by hundreds of persons who wanted to know what kind of music best suited plants, and whether his research accorded with that of Dorothy Retallack and tied in with that of Cleve Backster. Milstein blew up. Mrs. Retallack's experiments, he says, have nothing to do with science, since "plants can't hear." Appalled at what he calls the total fakery of comparing plants to people, and disgusted at the "dishonesty" on the part of those promoting the record, he says he is tired of the repeated allegations that he used *music* to enhance plant growth.

Asked to comment on Cleve Backster's work, the dentist turned horticulturist said: "Backster must be, at best, self-deluded since no one who has studied botany or physiology could ever agree that plants, whose tissues differ completely from those of animals and man, have minds or emotions and can be frightened by a mental threat."

As secretary of the Society of American Magicians, Milstein, who performed magic to work his way through college, said he had investigated hundreds of so-called "psychic phenomena" and never found a case in which the person claiming a given psychic power could perform under test conditions. "At least Backster isn't collecting money the way some other charlatans are," said Milstein, "but I don't want any part of his research because everything he says he has discovered can be disproved."

Milstein's dogmatic statement was paralleled by those of various professors at Temple Buell. The *New York Times*, which published a feature article on Mrs. Retallack's work on February 21, 1971, stated that the academicians seemed to "cringe and die" quite as much as Dorothy Retallack's acid-rock-exposed plants when it was suggested to them that Backster could be serious. "They find the whole thing an excruciating embarrassment," the *Times* stated, then quoted one of the college's own biologists as saying, "We have been ridiculed professionally." Dr. Cleon Ross, a plant physiologist at Colorado State University, though he reluctantly agreed to discuss the subject of the effect of sonic energy on plants with the *Times* reporter, Anthony Ripley, when asked to comment on Backster's discovery that plants respond to human thought, only blurted out: "Pure garbage!"

At Utah State University, Dr. Frank B. Salisbury of the Plant Science Department was a bit kinder. "I don't know what to make of it all," protested the professor about the effect of music on plants. "It's been going on since 1950. There was a report at the 1954 International Botanical Congress by a man from India who played violins to plants. I hate to just out-and-out say it's all baloney, but there's been an awful lot of pseudo-science in this field for years. Most of this stuff just doesn't have the right kind of experimentation. Until that comes along I don't believe any of it."

Her own unequivocal results caused Mrs. Retallack to wonder whether the nationwide craze for acid rock among the younger generation might not be deleterious to their development. Her doubts about the effects of rock increased when she read an article in the Napa, California, *Register* stating that two doctors had reported to the California Medical Association that of forty-three musicians playing amplified hard-rock music forty-one had suffered permanent hearing loss.

Some of Denver's rock buffs also seemed deeply impressed by Mrs. Retallack's experiments. One long-haired musician, peering into the rock-suffused biotronic chamber, said to her: "If rock is doing *that* to plants, man, I wonder what it's doing to me?" Mrs. Retallack wants to continue her experiments in order to collect enough scientific data to give the young musician a reasoned answer. One test she envisions will involve playing musical tapes backward to see if they produce effects similar to or different from the same tapes played in the normal direction.

When she began writing a short book on her experiments, *The Sound of Music and Plants*, published in early 1973, Mrs. Retallack was inspired with a line from Oscar Hammerstein she had sung years before as the star of *The Sound of Music* in Denver's summer opera: "The hills are alive with the sound of music, with songs they have sung for a thousand years."

Delving in libraries to find material with which to give a philosophical underpinning to her experimental work, she came across a declaration in the *Book of the Secrets of Enoch* that everything in the universe, from the herbs of the field to the stars of the heavens, had its individual spirit or angel, and noted that Hermes Trismegistus was reputed to have stated that plants had lives, minds, and souls, even as did animals, men, and higher beings. Hermes, named "thrice greatest" by the Greeks and from whose name the word "hermetic" is derived, was regarded as the originator of Egyptian art, science, magic, alchemy, and religion.

That musical sound lies within the very hearts of atoms is the contention of a professor of chemistry, now retired after a long career at Johns Hopkins University, Donald Hatch Andrews. In his book, *The Symphony of Life*, Andrews invites readers to join him on an imaginary journey inside a magnified calcium atom taken from the bone beneath the tip of his forefinger. Inside the atom, says Andrews, there are shrill tones dozens of octaves above the highest tones of a violin, the music of the atomic nucleus, the tiny particle at the center of the atom. If one listens closely, he continues, one is aware that this music is far more complex than familiar church music. There are many dissonant chords like those found in the music of today's modern composers.

The whole purpose of dissonant music, according to Cyril Meir Scott, the English composer and theosophist, was to break up thought forms, which, settling over whole countries and people, turn them stagnant with lethargy or rampant with madness. It is an occult musical fact, says Scott, that discord—used in its moral sense—can alone be destroyed by discord, the reason for this being that the vibrations of intrinsically beautiful music are too rarefied to touch the comparatively coarse vibrations of all that pertains to a much lower plane.

So far, no researcher with the exception of Hans Kayser, the German author of *Harmonia Plantarum* and other mathematically learned books on the relation of sound intervals to the growth of plants, seems to have become interested in the octaval correspondences between the shapes of plants and musical notes. Kayser observed that if one projects all tones within the space of one octave—in the same manner that the astronomer and astrologer Johannes Kepler worked out in his *Harmonice Mundi* for the solar planetary system—and sketches their angles in a specific way, one obtains the prototype of leaf form. The interval of the octave, the basis for music making and indeed all sensation, thus contains within itself the form of the leaf.

Not only does this observation lend new "psychological" support to Goethe's metamorphosis of plants, which derive their development from the leaf form, but it casts new light on the ingenious classificatory system developed by Linnaeus. When one considers, says Kayser, that a passion flower contains two ratios, a *five*-part petal and stamen arrangement and a *three*-part pistil, even if one rejects a logically reasoning intelligence, one must admit that in the soul of plants are certain form-carrying prototypes—in the passion flower's case musical thirds and fifths—which work, as in music, to shape the blossom forms as intervals. It is from this point of view that Linnaeus' system acquires a "psychic" rehabilitation, concludes Kayser, for, with his "sexual" classification scheme, the famous Swedish botanist hit on the psychic nerve of plants.

What humans are able to perceive consciously with their limited senses is but a minute fraction of what vibrationally affects them. The so-called scentless daisy may be as sweet-smelling as the rose—if people had the olfactory ability to detect the particles the daisy throws off. Efforts to prove that a given sonic vibration will affect plants or man may, far from resolving the interaction of music and life, be only unraveling a wondrously resonating tapestry of influences into its separate, unrelated threads.

CHAPTER 11

Plants and Electromagnetism

Just as plants respond to the wavelengths of music, so also are they continually being affected by wavelengths of the electromagnetic spectrum, from earth, moon, planets, cosmos and from a proliferation of man-made devices; only it remains to be established exactly which are beneficial and which are harmful.

One evening in the late 1720s a French writer and astronomer, Jean-Jacques Dertous de Mairan, was watering a series of pet *Mimosa pudica* in his Paris drawing room when he noticed to his surprise that the disappearance of the sun appeared to be causing the sensitive plants to fold their leaves just as they did when touched by his hand. A true searcher, esteemed by his contemporary Voltaire, Mairan did not instantly conclude that his plants were "simply going to sleep" as darkness fell. Instead he waited for the sun to rise again and put two of the mimosas in a pitch-dark closet. At noon he noticed that their leaves remained wide open; but at sunset they shut just as promptly as the ones on the drawing-room table. The plants, concluded Mairan, must be able to "sense" the sun without "seeing" it.

As to the cause of this effect, Mairan—whose scientific investigations ranged from the rotational movement of the moon and the physical properties of the aurora borealis to the reason for light in phosphors and the peculiarities of the number 9—could offer no solution. In his report to the French Academy he lamely suggested that his plants must be under the influence of an unknown factor in the universe, and that because hospitalized patients seemed to get extremely weak at certain times they too might be subject to the same force.

Some two and a half centuries later, Dr. John Ott, who runs the Environmental Health and Light Research Institute at Sarasota, Florida, was struck by Mairan's observations, which he was able to confirm, and wondered if this "unknown energy" could penetrate a massive amount of earth, the only shield known to be able to block so-called "cosmic radiation."

Ott took six mimosa plants down a mine shaft at noon to a point 650 feet beneath the earth's surface. Unlike those in the dark of Mairan's closet, Ott's subterranean specimens immediately closed their leaves without waiting for sunset; they did so even when incandescent bulbs were lit all around them. Except for the fact that he related the phenomenon to electromagnetism, of which little was known in Mairan's time, Ott was as much in the dark about the cause of it as had been his eighteenth-century French predecessor.

Mairan's contemporaries had known about electricity only what the Hellenes had passed on to them concerning the properties of amber, or *electron,* as they called it, which when vigorously rubbed attracted a feather or a piece of straw. Before Aristotle, it had been known that lodestone, a black ferrous oxide, could also exert an equally inexplicable attraction on iron filings. Since this material was found in liberal quantities in a region of Asia Minor called Magnesia, it was dubbed *magnes lithos,* or magnesian stone, a term shortened to *magnes* in Latin and to *magnet* in English.

First to link electricity and magnetism was the sixteenth-century savant William Gilbert, whose medical skill and philosophical erudition won him appointment as personal physician to Queen Elizabeth I. Announcing that the planet itself was a globular magnet, Gilbert attributed to the lodestone a "soul," since it was "part and choice offspring of its animate mother, the earth." Gilbert also discovered that materials other than amber could be caused to attract light objects if friction was applied to them. He designated them "electrics" and coined the term "electric force."

For centuries the attractive forces in amber and lodestone were thought to be "penetrating etheric fluids" (whatever *they* might be), emitted by the substances. Even fifty years after Mairan's experiments, Joseph Priestley, known principally as the discoverer of oxygen, wrote in his popular textbook on electricity:

> The earth and all the bodies we are acquainted with, without exception, are supposed to contain a certain quantity of an exceedingly elastic and subtle fluid which philosophers have agreed to term electric. The moment any body becomes possessed of more or less than its natural quantity, very remarkable effects arise from it. The body is said to be electrified and is capable of exhibiting appearances which are ascribed to the power of electricity.

By the twentieth century real knowledge about magnetism had progressed very little. As Professor Silvanus Thompson stated in his Robert Boyle lecture just before World War I, "Those occult qualities of magnetism which for centuries have excited the admiration of mankind are still *occult,* not in the sense only that they need to be investigated by experiment, but that their ultimate cause still remains unexplained." In a text published right after World War II by Chicago's Museum of Science and Industry, it is stated that human beings still do not know why the earth is a magnet, how magnetic materials can be mechanically affected by other magnets at a distance from them, why electric currents have magnetic fields about them, or even why tiny atoms of matter, small as they are, occupy such empty but prodigious volumes of energy-packed space.

In the three and one half centuries since Gilbert's famous work *De Magnete* was published, many theories have been proposed to explain the origin of geomagnetism but none is satisfactory.

The same can be said for contemporary physics, which has substituted for the idea of an "etheric fluid" a spectrum of undulating radiations called "electromagnetic radiations," ranging from enormous macropulsations, lasting several hundred thousand years each, with wavelengths millions of miles long, to super-rapid energy pulses alternating 10,000,000,000,000,000,000,000 times a second, with wavelengths measuring an infinitesimal ten billionths of a centimeter. The first type are associated with such phenomena as the reversal of the earth's magnetic field, the second with the collision of atoms, usually those of helium and hydrogen, moving at incredibly high speeds and converted to radiant energy termed "cosmic rays." In between lie countless bands of energy waves, including gamma rays, originating in the nuclei of atoms; X-rays, originating in their shells; a collection of frequencies which because they can be perceived with the eye are called light; those used in radio, TV, radar, and a growing multitude of applications from space research to electronic cooking.

The electromagnetic waves differ from sound waves in that they can travel not only through matter but through "nothing," racing at a speed of 186 million miles per second through vast regions of the cosmos which previously was thought to contain a medium called "ether" but is now held to be almost a perfect vacuum. But no one has yet explained exactly how they travel. As one eniment physicist complained to the authors, "We just don't know the mechanism for the damn thing."

In 1747, Jean Antoine Nollet, a French abbot and physics tutor to the dauphin, was informed by a German physicist in Wittenberg that water, which normally issued drop by drop from a capillary tube, would run out in a constant stream if the tube was electrified. After repeating the German's experiments and adding some of his own, Nollet, as he later put it, "began to believe that this electrical virtue employed in a certain manner might have some remarkable effect on organized bodies

which can be looked upon, in some way, as hydraulic machines prepared by nature itself." Nollet put several plants in metallic pots next to a conductor and was intrigued to note that the rate of their transpiration increased. In a long series of experiments, Nollet carefully weighed not only daffodils but sparrows, pigeons, and cats and found they lost weight faster if electrified.

Wondering how electrical phenomena might influence seeds, Nollet planted several dozen mustard grains in two tin containers and electrified one of them from 7 to 10 A.M. and from 3 to 8 P.M. seven days running. At the end of the week, every grain in the electrified container had sprouted and grown to an average height of 15 to 16 French *lignes;* the *ligne* is an old French measure, the twelfth part of an inch, or about 2.25 millimeters. Of the nonelectrified seeds the three which had broken ground were only 2 to 3 *lignes* tall. Though he had no idea why, Nollet could only suggest in his book-long report to the French Academy that electricity somehow had profound effects on the growth functions of life forms.

Nollet's conclusion was formulated a few years before the announcement rocked Europe that Benjamin Franklin had been able to collect a charge of electricity from lightning by flying a kite during stormy weather outside Philadelphia. When the bolt struck a metal point on the kite's frame, it had run down the kite's wet string into a Leyden bottle, a device developed in 1746 at the University of Leyden, whereby electricity could be stored in water and discharged in a single sudden burst. Theretofore, only static electricity obtained with an electrostatic generator had been storable in a Leyden jar.

As Franklin was now collecting electricity from clouds, the brilliant astronomer Pierre Charles Lemonnier, who was admitted to the French Academy at twenty-one and later acclaimed for his discovery of the obliquity of the ecliptic, determined that a permanent state of electrical activity exists in the earth's atmosphere even on a clear and sunny day, but exactly how the omnipresent charges interact with plants remained veiled in mystery.

The next efforts to adapt atmospheric electricity to the fructification of plants came in Italy. In 1770 a Professor Gardini stretched a number of wires above a productive monastery garden in Turin. Within a short time, many of the plants began to wither and die. When the monks dismantled the wires, the garden revived. Gardini hypothesized that either the plants had been deprived of a natural supply of electricity necessary to their growth or that they had received an overdose. When Gardini heard from France that the brothers Joseph-Michel and Jacques-Etienne Montgolfier had sent aloft an enormous balloon filled with heated air to carry two passengers on a ten-kilometer, twenty-five-minute trip over Paris, he recommended that this new invention be practically applied to horticulture by attaching a long wire to it along which electricity could be conducted from great heights into fields and gardens below.

These French and Italian reports caused little stir among the scientific pundits of the day, who, even then, were beginning to pay more attention to the effects of electricity on inert, rather than on living, bodies. Nor were they impressed when yet another clergyman, Abbé Bertholon, came out in 1783 with a full-scale treatise, *De l'Electricité des Végétaux.* A professor of experimental physics at French and Spanish universities, Bertholon gave strong support to Nollet's idea that by altering the viscosity, or flow resistance, of fluids in living organisms electricity could change their growth functions. He cited the report of an Italian physicist, Giuseppe Toaldo, that in a row of jasmine bushes the two which were next to a lightning conductor grew thirty feet tall whereas all the others attained only four feet.

Bertholon, who was considered something of a sorcerer, had a gardener stand on a slab of insulating material and sprinkle vegetables from an electrified watering can. He reported that his salads grew to an extraordinary size. He also invented what he called an "electrovegetometer" to collect atmospheric electricity by means of an antenna, and pass it through plants growing in a field. "This instrument," he wrote, "is applicable to all kinds of vegetal production, everywhere, in all weather; and its utility and efficacity cannot be ignored or doubted except by timid souls who are not inspired by discoveries and who will never push back the barriers of the sciences but will remain eternally within the narrow confines of a cowardly pusillanimity which, to palliate it, is too

often given the name of prudence." In his conclusion, the abbot boldly suggested that one day the best fertilizer for plants would come in electrical form "free from the sky."

The exciting notion that living things interacted and indeed were imbued with electricity advanced a giant step in November, 1780, when the wife of a Bolognese scientist, Luigi Galvani, accidentally discovered that a machine used to generate static electricity caused the severed leg of a frog to jump spasmodically. When his attention was called to it, Galvani was surprised and instantly wondered whether electricity was not in fact a manifestation of life. Deciding on Christmas Day that it was, he wrote in his workbook: "The electrical fluid should be considered a means to excite nervo-muscular force."

For the next six years Galvani worked on the effects on muscular motion of electricity until he happened accidentally to discover that his frogs' legs would twitch just as well without the application of an electric charge if the copper wires they hung from were blown by the wind against an iron railing. Realizing that the electricity in the three-part circuit had to be coming from the legs or the metals, Galvani, who believed it to be a living rather than a dead force, decided it was associated with the animal tissue and ascribed the reaction to a vital fluid or energy in the frogs' bodies which he termed "animal electricity."

Galvani's findings at first received warm support from his compatriot Alessandro Volta, a physicist at the University of Pavia in the Duchy of Milan. But when Volta repeated Galvani's experiments and found he could elicit the electrical effect only when two different metals were used, he wrote to Abbot Tommaselli that it was obvious that the electricity came, not from the frog's legs, but from "the simple application of two metals of different quality." Concentrating on the electrical properties of metals, Volta was led in 1800 to the invention of a pile of alternating zinc and copper discs with a piece of wet paper sandwiched between each two layers. Instantly chargeable, it could be used to produce electric current at will, not only once, like the Leyden jar, but thousands of times, and thus for the first time researchers were freed from their dependence on static or natural electricity. This first ancestor of our electric storage cell disclosed an artificial dynamic or kinetic electricity, which all but obliterated Galvani's notion of a special vital energy in living tissues.

Though at first Volta had accepted Galvani's findings, he later wrote: "If we deprive animal organs of any electrical activity of their own and abandon this attractive idea which Galvani's beautiful experiments suggested, these organs can be regarded simply as electrometers of a new kind and of a marvelous sensitivity." Despite Galvani's prophetic assertion, just before his death, that one day the analysis of all the necessary physiological aspects of his experiments "would provide better knowledge of the nature of the life forces, their different duration, according to variations in sex, age, temperament, illnesses, and even the very constitution of the atmosphere," scientists neglected his theories and denied them in practice.

A few years earlier, unknown to Galvani, the Hungarian Jesuit Maximilian Hell had revived Gilbert's idea of "soul-like" characteristics in the lodestone being transmitted to ferrous metals; and with this idea had invented a singular arrangement of magnetized steel plates to cure his own persistent rheumatism. His friend the Viennese physician Franz Anton Mesmer, who picked up an interest in magnetism by reading Paracelsus, was impressed with Hell's subsequent cures of a variety of afflictions in others, and embarked on a long series of experiments to check them. In so doing Mesmer became convinced that living matter had a property susceptible to being acted upon by "earthly and celestial magnetic forces," which in 1779 he called "animal magnetism" and to which he devoted a doctoral thesis entitled "The Influence of the Planets on the Human Body." Learning that a Swiss priest, J. J. Gassner, was healing patients by touch, Mesmer successfully adopted Gassner's technique and proclaimed that some people, himself included, were better endowed with the "magnetic" force than others.

Though it seemed that these startling discoveries of bioelectrical and biomagnetic energy might open the door to a new age of research which could unite physics with medicine and physiology, the door was again slammed shut for more than a century. Mesmer's success in treating cases, where others had failed, provoked his Viennese medical colleagues to jealousy. Attributing his cures to witchcraft and the devil, they organized a commission to investigate his claims. When the commission reported unfavorably, Mesmer was expelled from the medical faculty and told to give up his practice.

Moving in 1778 to Paris, where he found "people more enlightened and less indifferent to new discoveries," he made a powerful convert to his new methods of Charles D'Eslon, first physician to the court of the brother of Louis XVI, who introduced Mesmer to influential circles. It was not long before the French physicians grew as angry and jealous as had their Austrian counterparts. Their clamor forced the king to appoint a royal commission to investigate Mesmer's claims, despite the fact that D'Eslon at a meeting of the medical faculty of the University of Paris had championed Mesmer's scientific contribution as "one of the most important of our age." When the commission, whose members included the director of the French Academy of Sciences—which in 1772 had solemnly ruled that meteorites did not exist—and whose chairman was the American ambassador, Benjamin Franklin, returned a verdict that "animal magnetism is nonexistent and can have no salubrious effect," Mesmer's great popularity, held up to public ridicule, began to wane. Retiring to Switzerland, he completed, one year before his death in 1815, his most important work: *Mesmerism or the System of Reciprocal Influences; or The Theory and Practice of Animal Magnetism.*

In 1820, Hans Christian Oersted, a Danish scientist, found that a compass needle placed near a current-carrying wire always turned so that the needle became perpendicular to the wire. When the current was reversed, the compass needle pointed in the opposite direction. The fact that a force could act on the compass needle indicated that a magnetic field existed in the space around the wire. This led to one of the most profitable discoveries in the history of science when Michael Faraday in England and Joseph Henry in the United States independently realized the opposite phenomenon was equally valid, that a magnetic field could induce an electric current if the wire were moved through it. Thus the "generator" was invented, and with it a whole new world of electrical appliances.

Today, books on what man can *do* with electricity fill seventeen 100-foot shelves of stacks in the Library of Congress, but what electricity *is* and why it functions are as much a mystery as they were in Priestley's day. Modern scientists still have no idea of the composition of electromagnetic waves. They simply use them for radio, radar, television and toasters.

Because of such a lopsided concentration on the mechanical properties of electromagnetism, only a corporal's guard of individuals has paid attention over the years to how and why electromagnetism might affect living things. A notable exception was Baron Karl von Reichenbach, a German scientist from Tübingen who in 1845 had discovered wood-tar products, including creosote, used for the preservation of above-ground fencing and underwater pilings. He became aware that specially gifted persons whom he termed "sensitives" could actually see a strange energy emanating from all living things and even from the ends of bar magnets; this energy he called *Odyle* or *Od.* But, though his works were translated into English by a distinguished medical doctor, William Gregory, appointed professor of chemistry at the University of Edinburgh in 1844, as *Researches into the Forces of Magnetism, Electricity, Heat and Light in Relation to the Force of Life,* his attempts to prove its existence to his physicist contemporaries in England and on the continent were rejected out of hand.

Reichenbach indicated the reason why his "odic force" was spurned when he wrote: "Whenever I began to touch on the subject, I felt at once that I was harping on a string of an unpleasant tone. They coupled Od and sensitivity in their minds with so-called 'animal magnetism' and 'Mesmerism' and with that all sympathy was at an end." The coupling was entirely unjustified, in that Reichenbach had clearly stated that though the mysterious odic force might resemble animal magnetism and was associated with it, it also could exist quite independently.

Years later, Wilhelm Reich contended that "the energy with which the ancient Greeks and the moderns since Gilbert were dealing was a basically different energy from that with which the physicists are dealing since Volta and Faraday, one obtained by the movement of wires in magnetic fields; different not only with regard to the principle of its production, but *fundamentally* different."

Reich believed that the ancient Greeks, with the principle of friction,

had discovered the mysterious energy to which he gave the name "orgone," so similar to Reichenbach's Od and to the ether of the ancients. Reich claimed that orgone is the medium in which light moves, and the medium for electromagnetic and gravitational activity, that it fills all space, though in different degrees and concentration, and is even present in vacuums. He considered it the basic link between inorganic and organic matter. By the 1960s, shortly after Reich's death, the evidence for the electrical basis of organisms was becoming overwhelming. As D. S. Halacy, a writer on orthodox science, praided it simply: "The flow of electrons is basic to practically all life processes."

The difficulties encountered in the period between Reichenbach and Reich stemmed partly from the vogue in science for taking things apart, rather than studying them as functioning wholes. Simultaneously the gulf widened between workers in what came to be known as the "life sciences" and physicists who more and more would believe only what they could see or instrumentally measure. In between, chemistry concentrated on increasingly varied and smaller separate entities, which in their artificial recombination offered a cornucopia of fascinating new products.

The first artificial synthesis in the laboratory of an organic substance, urea, in 1828, seemed to destroy the idea that there was a special "vital" aspect in living things. The discovery of cells, the purported biological counterparts of the atoms of classical Greek philosophy, suggested that plants, animals, and man himself were merely different associations of these building blocks or chemical aggregates. In this new climate, few took initiative to delve deeper into the effects of electromagnetism on life. Nevertheless, individualistic mavericks occasionally brought forward an idea on how plants might respond to external cosmic forces and thus kept the findings of Nollet and Bertholon from expiring.

Across the Atlantic in North America, William Ross, testing claims of the Marquis of Anglesey that seeds sprouted faster when electrified, planted cucumbers in a mixture of black manganese oxide, table salt, and clean sand, watered with dilute sulphuric acid. When he applied an electric current to the mixture, the seeds sprouted well ahead of those in a similar but nonelectrified mixture. A year later, in 1845, the first issue of the London *Journal of the Horticultural Society* published a long account of the "Influence of Electricity on Vegetation" by an agronomist, Edward Solly, who, like Gardini, suspended wires in the air over garden plots, and, like Ross, tried burying them under the soil. But of Solly's seventy experiments with various grains, vegetables, and flowers, only nineteen were of any benefit, and nearly as many were harmful.

The conflicting results of these researchers made it obvious that the amount, quality, and duration of electrical stimulation was of crucial importance to each form of vegetal life. But since physicists lacked instrumentation to measure its specific effects, and still knew little about how electricity, artificial or atmospheric, actually operated on plants, the experimental field was left to persistently curious horticulturalists or out-and-out cranks. Still, various observations showing that vegetation had an electric quality continued to be recorded.

In 1859 an issue of the London *Gardeners' Chronicle* published a report of light flashes passing from one scarlet verbena to another and noted that the phenomenon could best be seen during crepuscular periods when a thunderstorm approached after a long spell of dry weather. This validated an observation of Goethe's that the flowers of oriental poppies could be seen flashing at dusk.

It was not until the latter part of the century that new vistas were opened in Germany onto the exact nature of the electricity in the air which Lemonnier had discovered. Julius Elster and Hans Geitel, who specialized in the spontaneous emission of radiation from inorganic substances which was coming to be called "radioactivity," began a vast study of atmospheric electricity. This disclosed that the soil of the earth continually emits electrically charged particles into the air. Called *ions* from the neuter present participle of the Greek verb, *ienai*, meaning "to go," these particles were either atoms, groups of atoms, or molecules regarded as having a net positive or negative charge after gaining or losing electrons. Lemonnier's observation that the atmosphere was continually filled with electricity at last had some kind of material explanation.

Since on a clear day in good weather the earth has a negative electrical charge while the atmosphere is positive, electrons stream skyward from

the soil and plants. During storms the polarity is reversed, the earth becoming positive and the base of the cloud layer negative. Because there are at any time an estimated three to four thousand "electrical" storms raging over the surface of the globe, the charges lost by the earth in those areas favored by balmy weather are thus replaced, and a seesawing balance of electrical gradients maintained.

As a result of the ever-present flow of electricity, the voltage, or electric pressure, increases at higher altitudes. Between the head of a six-foot man and the ground he stands on, it is 200 volts; from the top of the Empire State Building to the sidewalks around it, 40,000 volts; in the interval between the lowest layers of the ionosphere and the earth's surface, 360,000 volts. Though this sounds dangerous, not much shocking power can be generated because there is little current flow. The chief difficulty in harnessing this vast reservoir of energy and putting it to work is lack of precise knowledge of exactly how it functions and of the laws which govern its operations.

A new attack on the application of atmospheric electricity to the growth of plants began when a Finnish scientist of eclectic interests, Selim Lemström, made four expeditions to the subpolar regions of Spitsbergen, northern Norway, and Lapland from 1868 to 1884. An expert on polar light and earth magnetism, Lemström theorized that the luxuriant vegetation in those latitudes, which popular opinion ascribed to the lengthened days of their summers, was actually attributable to what he called "that violent electrical manifestation, the aurora borealis."

As it had been known from the time of Franklin that sharp points were especially attractive to atmospheric electricity—an observation which led to the development of the lightning rod—Lemström reasoned that "the sharp points of plants acted like lightning rods to collect atmospheric electricity and facilitate the exchange of charges of the air and the ground." Lemström conducted studies on the rings in cross-sections of fir-tree trunks and found that the annual growth fully correlated with periods of high aurora and sunspot activity, the effects being most pronounced as one traveled north.

When he came home to verify these observations by experimentation, Lemström connected a series of flowers in metal pots to a static generator by an overhead network of wires sixteen inches above them and a pole set into the soil as a ground. Other pots he "left to nature." After eight weeks, the electrified plants showed gains in weight of nearly 50 percent over their electrically deprived neighbors. When he transferred his apparatus into a garden he not only more than doubled the yield of strawberries but found them to be much sweeter; his harvest from barley plants increased by one-third.

In a long series of experiments conducted as far south as Burgundy, Lemström's results varied not only with specific vegetables, fruits, and cereals but also with temperature, moisture, and the natural fertility and manuring of the soil. Lemström reported his success in 1902 in a book *Electro Cultur,* published in Berlin, and the term was included in Liberty Hyde Bailey's *Standard Cyclopedia of Horticulture.*

The English translation of Lemström's book, entitled *Electricity in Agriculture and Horticulture,* which appeared in London two years after the German original, acerbically, yet truthfully, as it turned out, warned in its introduction that, since the whole complicated subject was connected with no less than three separate sciences, physics, botany, and agronomy, it might not seem "particularly attractive" to scientists. This caveat was not needed for one of his readers, Sir Oliver Lodge. After achieving singular distinction in the field of physics, Lodge went on to demonstrate his open-mindedness by joining the London Society for Psychical Research and brought out a dozen books which advanced his conviction that whole worlds lay beyond the physical.

Lodge determined to obviate Lemström's time-consuming difficulties in moving his wire network upward as his plants grew; to allow the movement of people, animals, and farm equipment through his electrified fields, he suspended his grid on insulators attached to high poles. During one growing season Lodge was able to increase the per-acre yield of Canadian Red Fife wheat by 40 percent and was pleased that the bakers who used flour ground from it claimed it produced bread of a far better quality than that made from the wheat they were normally furnished.

After working with Lodge, his collaborator, John Newman, adapted

the system to achieve over 20 percent increase in wheat yields in Evesham, England, and in potatoes dug at Dumfries, Scotland. Newman's strawberries were not only vastly more productive than nonelectrified equivalents but, like Lemström's, were more succulent and sweet; his sugar beets tested out as having greater than normal sugar content. Of passing interest, Newman published his report, not in a botanical journal, but in the fifth edition of the *Standard Handbook for Electrical Engineers,* brought out by McGraw-Hill in New York. Ever since, it has been more the engineering fraternity than the plant men who have assiduously pursued electrocultural efforts.

CHAPTER 12

Force Fields, Humans and Plants

Because their profession calls upon them for practical solutions to problems no matter how difficult they appear at first glance, engineers, unlike researchers in pure science, are less concerned with *why* or *how* something works than with *whether* it will work. This attitude frees them from the shackles of theory, which in the history of science has often caused pedants to disregard the brilliant new findings of geniuses because there was no theoretical basis to support them.

When an ingenious Hungarian refugee, Joseph Molitorisz, who escaped from his Soviet-occupied homeland and took an engineering degree, came across Abbé Nollet's ideas about electro-osmosis, he started thinking about how the Frenchman's efforts could be applied to agricultural problems. It seemed strange to Molitorisz that a redwood can raise its sap more than three hundred feet whereas the best man-designed suction pump can pull water up less than a tenth of that distance. There was evidently something about trees and electricity that defied laws of hydrodynamics in standard engineering. At an agricultural research station run by the U.S. Government near Riverside, California, Molitorisz decided to adapt what he had learned from Nollet's insights to citrus orchards. In an early experiment, he ran current through citrus seedlings. When the current flowed in one direction, the growth of the tiny trees was speeded up; when the direction was reversed, the seedlings shriveled. Evidently, the electricity somehow abetted the natural flow of electric current present in the plants or, when severed, blocked it. In another experiment, partly inspired by his reading of Abbé Bertholon, Molitorisz applied a fifty-eight-volt current to six branches of an orange tree but left another six branches untouched, only to discover that within eighteen hours sap was freely circulating in the "powered" branches while in the untouched branches there was very little sap flow.

One of the problems of harvesting oranges is the fact that their fruit does not all ripen simultaneously and must be laboriously hand-picked over many days if it is not to rot on the branches. Molitorisz theorized that picking costs might be reduced if he could get a tree to drop its ripe fruit through electrical stimulation. By wiring one orange tree to a source of direct current, he got it to drop its ripe fruit but retain the still-green oranges on its branches. Even with this success he could not get funds for additional experimentation; but Molitorisz, who has also invented an "electrical flower pot" which can keep flowers alive much longer than is normally possible, believes that one day it will be easy to harvest electrically the fruit of an entire citrus orchard and obviate the necessity of raising pickers into the trees.

While Molitorisz was working on the West Coast, another engineer, Dr. Larry E. Murr, of the Materials Research Laboratory at the Pennsylvania State University, became the first to simulate artificially in the laboratory the electrical conditions of short thunderstorms and long periods of rainy weather. After seven years of work in his man-made "mini-climate," he was able to get significant increases in plant growth by carefully regulating the voltage field strength over plants in lucite pots set on an aluminum plate to serve as one electrode, the other supplied by an aluminum wire mesh hung from insulating poles. Other voltages, he found, severely damaged the leaves of plants. Murr reached the conclusion that "whether or not we can augment acreage yield by maintaining artificially devised electric fields over crop areas is still a matter for speculation. The cost of achieving such gains by large-scale outdoor installations might be much more than they are worth. Nevertheless, the possibility exists."

Dr. George Starr White, who published a book entitled *Cosmo-electric Culture,* discovered that metals like iron and tin could facilitate plant growth if bright pieces were dangled from fruit trees. His evidence was corroborated by Randall Groves Hay, an industrial engineer from Jenkintown, New Jersey. Where Hay attached metallic Christmas tree balls to tomato plants, they would bear their fruits earlier than normal. In his own words: "At first, my wife would not let me hang the balls on the plants because she said it would look just too ridiculous. But when fifteen potted tomatoes hung with balls started to ripen in cold, inclement weather long before those of any other grower, she allowed me to continue."

The experiments of James Lee Scribner, an electronic engineer in Greenville, South Carolina, who worked thirty years in radio with electronic bathing of seeds, have resulted in a rival to Jack's beanstalk. Scribner wired an aluminum pot to an ordinary electric outlet. Spread between the electrodes was a wet metallic mix made up of millions of zinc and copper particles, which, when dried, allowed electricity to filter between the electrode strips. A butterbean planted in the pot grew to the amazing height of twenty-two feet, though similar beans normally never exceed two feet. At maturity it produced *two bushels* of delicious beans. Scribner believes that

> it is the electron that is responsible before the photosynthesis can take place, for it is the electron that magnetizes the chlorophyll in the plant cell that makes it possible for the photon to assert itself and become a part of the plant in the form of solar energy. It is also this magnetism that

> draws the molecules of oxygen into the ever expanding chlorophyll cells of the plant, and so we must assume that moisture is in no way integrated into the plant through any absorption process whatsoever, for the integration of moisture is purely an electronic one. The so-called root pressure (moisture droplets) appearing on plant surfaces is not root pressure at all, but an abundance of electrons working with the rather excessive water energy in the bed.

Scribner's findings on seeds had apparently been anticipated in the 1930s, when the Italian Bindo Riccioni developed his own system for electrically treating seeds at the rate of five tons per day by allowing them to flow through parallel plate capacitors at about five meters per second. From the treated seeds Riccioni reported harvests from 2 to 37 percent greater than the national average, depending on soil and weather conditions. His work was interrupted by World War II, and his 127-page book, translated into English only in 1960, does not thus far seem to have stimulated further experimentation in the United States or Western Europe.

In the Soviet Union, however, a commercial processing plant to treat seeds with electrical energy, with a 2-ton-per-hour capacity, was reported in 1963. Results indicated that yields for the green mass of corn jumped 15 to 20 percent over the average, oats and barley 10 to 15 percent, peas 13 percent, and buckwheat 8 to 10 percent. What promise this pilot project might hold to relieve Russia's persistent grain shortages was not mentioned. To an agricultural industry which has relied almost wholly on artificially produced chemicals not only to fertilize its soil but to rid its crops of marauding pests, the electrocultural horizons being opened up afresh by engineers seem either unnecessary or a threat. This explains why almost no money has been made available for more investigation.

A former director of the United States Department of Agriculture's Division of Agricultural Engineering Research, E. G. McKibben, complained as far back as 1962 that this policy was extremely short-sighted. In an address to the American Society of Agricultural Engineers McKibben said: "The importance and the possibilities of the application of electromagnetic energy in its many forms to agriculture are limited only by the creative imagination and physical resources available. Electromagnetic energy is probably the most basic form. It, or something closely related to it, appears to be the basic substance of all energy and all matter and the essential fabric of all plant and animal life." McKibben stressed that as yet undreamed-of developments and accomplishments might be reasonably attained if only much more support was put behind electrocultural efforts; but his plea has thus far fallen on deaf ears.

Even before McKibben made his appeal, brand-new discoveries about the influence of magnetism on vegetation were coming to light. In 1960 L. J. Audus, a professor of botany at London University's Bedford College, while trying to find out exactly how plants respond to gravity, stumbled onto the fact that their roots are sensitive to magnetic fields and published a pioneering paper, "Magnetotropism, a New Plant Growth Response," in *Nature.* Nearly simultaneously, two Russians, A. V. Krylov and G. A. Tarakanova, issued their report in Moscow, showing that tomatoes ripen inexplicably faster nearer the south than the north pole of a magnet.

In Canada, Dr. U. J. Pittman, of the Agricultural Research Station in Lethbridge, Alberta, had observed all across the North American continent that the roots of various domestic and wild cereal grains, as well as those of a number of species of weeds, consistently aligned themselves in a north-south plane parallel to the horizontal force of the earth's magnetic field. He found that the earth's magnetism speeded up the germination of Chinook and Kharkov wheat, Compana barley, Eagle oats, Redwood flax, and common fall rye if the long axes of the seeds and embryo ends were oriented toward the north magnetic pole. "When Granny insisted that her pumpkin seeds be planted pointing north," wrote Pittman in *Crops and Soils Magazine,* "she may have been dead right!"

In the United States, the possibility of large-scale application of the occult force of magnetism to agriculture arose when in Denver, Colorado, still another engineer, Dr. H. Len Cox, chanced to read an article in a 1968 issue of *Aviation Week and Space Technology* which reported that infrared photos taken from NASA satellites seemed to indicate that wheat plants attacked by pests, or otherwise incapacitated,

had an entirely different "electromagnetic signature" from those in a field expected to produce a bumper crop. Intrigued by a phenomenon for which he had no explanation, Cox, a space scientist, after dipping into the electrocultural literature, asked a metallurgist friend whether he knew of any magnetizable substance which could make plants grow faster and more fruitfully.

When the metallurgist suggested that deposits of a useless ferrous ore, magnetite, totaling billions of tons, were easily accessible in nearby Wyoming, Cox brought back a truckload and ground it into powder. After charging it in a magnetic field of undisclosed strength and mixing it with trace minerals, he sifted it into the soil of a garden plot where it could come into contact with the roots of red and white radishes. Though the green tops of the maturing plants seemed no different from similar radishes allowed to grow normally in a neighboring plot, when Cox pulled his "activated" vegetables from the ground, he saw results beyond his wildest expectations. Not only were the activated radishes on an average twice as large as the controls, but the fact that their tap roots were three to four times as long indicated that root stimulation seemed to have produced the increased growth. The remarkable effect on radishes was also obtained for other root vegetables, such as rutabagas, turnips, and carrots, and also for green plants such as beans, lettuce, broccoli, and oyster plant.

When Cox's Electroculture Corporation began selling the new product in ten-pound cans in 1970, users reported not only that they got much larger yields but that the vegetables produced had a far better flavor, corroborating Lemström's report on his strawberries and Sir Oliver Lodge's bakers' comments on their bread. Others reported that irises doubled the number of blossoms on a single stalk no matter whether they were planted with or without fertilizer, and a plastic surgeon told Cox that when he had put the magnetized ore among the roots of one of two ponderosa pine seedlings in his lawn, the little tree had grown in one summer four times as high as its neighbor.

Asked how the "activator" works Cox replied: "It is still a mystery. No one knows how it functions any more than doctors know why aspirin has its effect. Disappointing to nurserymen and city-dwelling plant lovers is the odd fact that the magnetized powder produces no results when shaken into flower pots or greenhouse flats. To work it has to go into the soil of the earth itself." One explanation for this anomaly is that the ferrous oxide—which when magnetized is called lodestone—radiates its power only when in contact with what Gilbert, in his day, called "its animate mother."

Whatever the ultimate solution to the problem, in the two decades following World War I startling new discoveries were coming to light in laboratories suggesting that mysterious radiations in the natural environment might be far more crucial to the well-being of plants and animals than had hitherto been suspected.

In the early 1920s Georges Lakhovsky, a Russian-born engineer living in Paris, had begun a series of books which suggested that the basis of life was not matter but immaterial vibrations associated with it. "Every living thing emits radiations," stressed Lakhovsky, and advanced the revolutionary new theory that cells, the essential organic units of all living things, were electromagnetic radiators capable, like wireless sets, of emitting and absorbing high-frequency waves.

The essence of Lakhovsky's theory was that cells are microscopic oscillating circuits. In electrical parlance such an oscillating circuit requires two basic elements: a capacitor, or source of stored electric charge, and a coil of wire. As the current from the capacitor flows back and forth between one end of the wire and the other, it creates a magnetic field which oscillates at a certain frequency, or so many times per second. If such a circuit is greatly reduced in size, very high frequencies are obtained; Lakhovsky believed this to be what occurs in the microscopically tiny nuclei of living cells. In the small twisted filaments within cellular nuclei Lakhovsky descried the analogs to electrical circuits.

In his *L'Origine de la Vie*, published in 1925, Lakhovsky set forth a number of startling experiments upholding the idea that disease is a matter of disequilibrium in cellular oscillation, that the fight between healthy cells and pathogens, such as bacteria or viruses, is a "war of radiations." If the radiations of the microbes are stronger, cells begin to oscillate aperiodically and became "diseased." When they cease to oscillate, they die. If the cellular radiations gain ascendance, the microbes

are killed. In order that a diseased cell be restored to health, Lakhovsky felt it should be treated by means of a radiation of appropriate frequency.

In 1923, Lakhovsky designed an electrical apparatus emitting very short waves (with lengths of two to ten meters) which he called a "radio-cellulo-oscillator." In the surgical clinic of the famous Salpêtrière hospital in Paris he inoculated geraniums with cancer-producing bacteria. When the plants had developed tumors the size of cherry stones, one of them was exposed to radiation from the oscillator. During the first days the tumor grew rapidly, but after two weeks it suddenly began to shrink and die; after a second two-week period it fell off the afflicted plant. Other geraniums treated over different time periods also shed their cancers under the effect of oscillator radiations.

Lakhovsky saw these cures as supporting his theory. The cancer had been overcome by the *enhancement* of the normal oscillations of healthy cells in the geraniums. This was quite opposite to the approach of the radium specialists, who proposed that the cancer cells be destroyed by external radiation.

In the development of his theory Lakhovsky was faced with the problem of the origin of the energy necessary for the normal production and maintenance of cellular oscillations. It did not seem probable to Lakhovsky that the energy is produced within cells any more than the energy in an electric battery or a steam engine is internally produced. He therefore came to the conclusion that the energy is externally derived from cosmic radiation.

To try to establish the cosmic origin of the energy, Lakhovsky decided to dispense with the device he had dreamed up to produce artificial rays and tap natural energy from space. In January, 1925, he picked one of a series of geraniums previously inoculated with cancer and surrounded it with a circular copper spiral thirty centimeters in diameter, its two unjoined ends fixed in an ebonite support. After several weeks he found that whereas all the control geraniums inoculated with cancer had died and dried up, the plant ringed with the copper spiral was not only radiantly healthy but had grown twice as high as uninoculated controls.

These spectacular results led Lakhovsky into a complex theory as to how the geranium had been able to pick up from the vast field of waves in the external atmosphere the exact frequencies which enabled its cells to oscillate normally and so powerfully that the cancer-afflicted cells were destroyed.

To the multitude of radiations of all frequencies emanating from space and unceasingly traversing the atmosphere Lakhovsky gave the generic name "universion." He concluded that some of them, filtered by the spiral, were brought specifically into action to restore the degenerating cells of the diseased geranium to healthy activity.

The universion, or collectivity of universal radiation, was not, in Lakhovsky's mind, to be associated with the notion of a complete vacuum in space with which physicists had replaced the ether of the nineteenth century. To Lakhovsky the ether was not the negation of all matter but a synthesis of radiation forces, the universal plexus of all cosmic rays. It was a ubiquitous and all-pervading medium, into which disintegrated elements were consigned and transformed into electrical particles. Lakhovsky believed that with the recognition of this new concept the bounds of science could be extended and a basis laid for an attack on the most absorbing problems of life, including telepathy, the transmission of thought, and, by inference, man's communication with plants.

In March of 1927 Lakhovsky wrote a communication, "Influence of Astral Waves on Oscillations of Living Cells," which was presented to the French Academy by his friend the eminent biophysicist and discoverer of diathermy, Professor Jacques Arsène d'Arsonval.

By March of 1928, the geranium with the spiral around it had attained the abnormal height of four and one-half feet and was flourishing even in winter. Sure that by his work on plants he had stumbled on a new therapy of unimaginable importance to medicine, Lakhovsky went on to develop a sophisticated therapeutic device for human beings which he called a "multi-wave oscillator." It was successfully used in French, Swedish, and Italian clinics to cure cancerous growths and lesions brought about by radium burns; goiters; and a variety of diseases regarded as incurable. When Lakhovsky, fleeing the Germans who had occupied Paris and were seeking him out as a prominent anti-Nazi, came

to New York in 1941, the physiotherapy department of a large New York hospital employed his multi-wave oscillator successfully to treat arthritis, chronic bronchitis, congenital hip dislocation, and other ills, and a Brooklyn urologist and surgeon, though he would not reveal his name, stated that he had used it on hundreds of patients to arrest bodily disturbances unamenable to other treatment. When Lakhovsky died in 1943, his astonishing findings, which laid the basis for radiobiology, were left unpursued by the medical profession, and today use of the multi-wave oscillator for medical treatment is officially banned by U.S. health authorities.

While Lakhovsky was working in Paris, at the Texas State University a team headed by Professor E. J. Lund devised a way to measure electrical potentials in plants. In a series of experiments lasting more than ten years, Lund showed that plant cells produce electric fields, currents, or impulses which, as Bose had implied, could serve as "nervous systems." Lund further demonstrated that the growth of plants is triggered by these electrical nervous systems rather than by growth hormones, or auxins, as was previously believed, and that the auxins are summoned and even transported by the cell-generated electric fields to the place where growth is known to occur.

In an important but little-known book, *Bioelectric Fields and Growth*, Lund put forward the revolutionary finding that the electric pattern in plant cells changes nearly a half hour before the diffusion of hormones in them can be effective and growth detected.

Meanwhile, the research of the Russian Alexander Gurwitsch, which inspired L. George Lawrence to begin his study of the potentialities of biocommunication, despite its rejection by the U.S. Academy of Sciences, began to get a new lease on life. The distinguished bacteriologist at Cornell University, Professor Otto Rahn, was amazed to find that whenever any of his laboratory workers fell ill they appeared to cause the death of yeast cells with which they were experimenting. A few minutes' exposure to their fingertips even at a distance would kill vigorous cells of this carbohydrate-fermenting fungus. Further investigation showed that a chemical compound excreted from the hands and face of the sick technicians was responsible; but exactly how it acted at a distance was a mystery. Rahn went on to prove that the continually renewed tissue of the cornea of the eye, as well as most wounds and cancer tumors, emit radiation; he set these and other findings down in a book, *Invisible Radiation of Organisms*, which, on the whole, was ignored by his colleagues.

Because most physicists still had no better means of detecting all this new and strange radiation than they did Mesmer's "animal magnetism" or Reichenbach's "odic force," the idea that living tissue could emit or respond to vibrations of energy was greeted with skepticism. The questioning light thrown on discoveries such as Lakhovsky's, Gurwitsch's, and Rahn's was also focused on those of a surgeon, George Washington Crile, founder of the Cleveland Clinic Foundation, who published *The Phenomena of Life: A Radio-Electrical Interpretation* in 1936. The result of a lifetime of research, it offered evidence that the living organism is specifically adapted to the formation, storage, and use of electrical energy, the genesis of which was, according to Crile, ultra-microscopic units or furnaces in protoplasm which Crile called radiogens.

Three years before his book appeared, Crile pointed out in an address to the Congress of the American College of Surgeons that it would be possible for future skilled radio-diagnosticians to detect the presence of disease before it became outwardly apparent. For his efforts Crile was ridiculed by both his medical colleagues and by cellular biologists, who accused him of having no solid grasp of the literature.

The effects of electromagnetic energy on living cells, both healthy and diseased, which most doctors and medical researchers, including cancer specialists, have yet honestly to confront, were finally to be revealed by the magic of time-lapse photography. Because most plants grow very slowly they look as unchanging to the human eye as if petrified. Only by looking away from plants for several hours or, better, for several days, can one notice that they are different from the plastic flowers and shrubs which are supplanting living plants in florist shops across the world.

In 1927, an Illinois teen-ager, staring at the buds on a large apple tree in his front yard, wondering when they would open into flowers, realized that if he could take pictures of them in regular sequence he would be able to watch the buds unfold before his eyes.

Thus began the career of John Nash Ott, whose pioneering interest in time-lapse photography led him to unveil new mysteries in the kingdom of plants.

To experiment with exotic varieties of plants Ott built a small greenhouse, where he found that each variety of plant presented to him as many problems as would a different tribe to an anthropologist. Many of his charges seemed to act like temperamental prima donnas with deep psychological disturbances. As he consulted with university botanists and research scientists on the staffs of large companies, little by little the basic biological causes for his plants' misbehavior became clear: they were extremely sensitive not only to light and temperature but to ultraviolet, TV and X-rays.

Ott's discoveries about light and temperature may lead to the explanation of many botanical mysteries, not the least of which is the tremendous size of plants growing high in the mountains of central Africa.

Over thirty years ago the English author Patrick Synge in his book *Plants with Personality* suggested that though no one had been able to produce a satisfactory theory on the origin of giantism in plants, it perhaps might happen on account of a complement of peculiar environmental conditions, namely, a low but moderately constant temperature, a consistently high humidity, and a strong intensity of ultraviolet light due both to the altitude and to the equatorial location.

In the European Alps vegetation growing high up tends toward dwarfism, but in the Mountains of the Moon, or Ruwenzori as the Africans call them, Synge encountered heathers "as mighty as great trees" and found shell-pink impatiens with flowers two inches across.

On the extinct volcano Mount Elgon, rising fourteen thousand feet on the Kenya-Uganda border, Synge found lobelias, which in England are tiny blue-flowered plants, growing nearly thirty feet tall, "like gigantic blue and green obelisks." He photographed them half covered with snow and with icicles hanging from the tips of their leaves. But when the same plants were brought back to England, they could not survive outdoors even in the mild winters of Surrey.

Synge's idea accorded with the hypothesis of the French chemist Pierre Berthelot, that it is the continuous presence of electricity high in the Alpine ranges that accounts for the luscious growth of plants in very poor soil. If the conditions enumerated by Synge are someday simulated by researchers, perhaps these giant plants will be successfully grown at sea level.

Ott's experiments in time-lapse photography were to lead him to the discovery that different wave lengths of light have a fundamental effect on photosynthesis, the process by which green plants convert light to chemical energy and by means of it synthesize organic compounds from inorganic ones, turning carbon dioxide and water into carbohydrates, with a release of oxygen. To attack this problem, he spent months building equipment which would allow him to take microscopic pictures of the streaming of protoplasm in the cells of Elodea grass while it was stimulated by direct unfiltered natural sunlight. Exposed to the sun's rays, the chlorophyll-containing bodies, called chloroplasts, which are the principal agents of photosynthesis, streamed in an orderly fashion around the edges of the obloid cells. But when the ultraviolet light in the sunlight was filtered out, some of the chloroplasts would drop out of the streaming pattern and huddle, immobile, in the corners. Cutting out the colors from the blue end of the spectrum toward the red increasingly slowed the chloroplast action.

Particularly fascinating to Ott was the fact that, at the day's end, all the chloroplasts slowed down and stopped no matter how intensely they were subjected to artificial light. Only when the sun rose the next day would they resume the normal streaming pattern.

Ott realized that if the basic principles of photochemistry, as they applied to plant photosynthesis, had analogs in the animal world then, as the proponents of color-therapy have long maintained, various frequencies of light might affect the physical well-being of humans by acting on the body chemistry in a way similar to the action of certain drugs on nervous and mental disorders.

In 1964 an article in *Time* magazine spurred Ott to research the effect of TV radiation on plants and humans. The story suggested that symptoms of nervousness, continuous fatigue, headaches, loss of sleep, and vomiting in thirty children under study by two U.S. Air Force physicians were somehow related to the fact that all of these children were watching TV from three to six hours on weekdays and from twelve to twenty

hours on weekends. Though the doctors had concluded that the children were afflicted by prolonged idleness in front of the set, Ott wondered if some sort of radiation might not be at issue, particularly that of X-rays, which lie beyond ultraviolet in the energy spectrum.

To test this idea, Ott covered half of the picture tube of a color TV set with a sixteenth of an inch of lead shielding, normally used to block out X-rays. The other half he covered with heavy black photographic paper capable of stopping visible and ultraviolet light, but allowing other electromagnetic frequencies to penetrate.

Ott placed six pots of bean sprouts in front of each half of the TV tube, a pair at three different levels from top to bottom. As a control, six more pots, each with its three bean sprouts, were placed outdoors, fifty feet from the greenhouse where the TV set was located.

At the end of three weeks, both the lead-shielded beans and those growing outdoors had risen to a height of six inches and appeared healthy and normal. The beans shielded from the TV only by the photographic paper had been distorted by toxic radiations into a vine-type growth. In some cases the roots appeared to have grown incongruously upward out of the soil. If TV radiation could make monsters of bean plants what might it do to children?

Several years later, when Ott was discussing the distortion of the beans with space scientists, he was told that the root growth of his bean plants exposed to radiation resembled that of wheat seedlings in a bio-capsule in outer space, where it was thought to be due to the weightless condition from lack of gravity. Some of the scientists seemed intrigued by his idea that not weightlessness but a general background radiation of an unspecified energy might cause the eccentric root growth.

Since general background radiation coming from the zenith, or the point directly overhead, penetrates through less of the earth's atmosphere and is therefore more powerful than that coming in at any other angle, Ott thinks that roots of plants grow downward to get away from the radiation directly above them.

Similar experiments showed that white rats exposed to the same radiation which caused the wild growth in the beans became increasingly hyperactive and aggressive, then progressively lethargic, to a point where it was necessary to push them to make them move in their cages.

Ott noticed further that after he set up his TV in the greenhouse, rats in an animal-breeding room fifteen feet away produced litters of only one or two babies, as against a norm of eight to twelve, even though two building partitions intervened between the TV set and the pregnant mothers. When the TV set was removed, it took six months for the breeding to return to normal.

Because of increasing difficulty in maintaining discipline in schools, children who are hyperactive or have difficulty concentrating have over recent years been administered so-called behavioral modification drugs or "peace pills." This practice has aroused a storm of controversy among parents, doctors, government officials and even Congressmen. Though it has not been publicly suggested, Ott wonders whether this hyperactivity—and increasingly reported forms of lethargy including prolonged sleep—may be a result of exposure to radiation from TV sets. When Ott offered to repeat his experiments cost-free for technicians at RCA's Bio-Analytical Laboratory, the director of research not only hastily declined but was later quoted as saying, "It is utterly impossible for any TV set today to give off harmful rays."

Ott knew, however, that since the radiation from a TV tube is contained in an extremely narrow band on the electromagnetic spectrum, biological systems sensitive to this narrow spike of energy could be as overstimulated by it as they would be by light focused through a magnifying glass. The only difference is that, whereas the magnifier concentrates the light in one direction, the specific energy emitted from the TV can travel in any direction where it meets no obstruction. "If one-half of a milli-roentgen doesn't appear to be a cause for worry," says Ott, "then it can be pointed out that a pound of gold can also be called one-half of a thousandth of a ton. And it is easy to juggle the decimal point in infinitesimal amounts without realizing the true relationships involved. Eighty degrees Fahrenheit is a comfortable temperature level but one has only to double this figure to reach a point where most forms of life on earth could no longer exist."

Ott's belief that electromagnetic radiation affects plants and animals in many unsuspected ways increased when he was called by Paramount

Pictures in Hollywood to make time-lapse photos of flowers for a new picture, starring Barbra Streisand, based on the Broadway musical hit *On a Clear Day You Can See Forever.* In the story the heroine numbers among her extrasensory abilities that of making flowers grow as she sings to them. The studio wanted Ott to begin work immediately on geraniums, roses, irises, hyacinths, tulips, and daffodils for inclusion in this part of the film.

To duplicate as nearly as possible natural rays of outdoor sunlight, Ott had developed a new full-spectrum fluorescent tube, with added ultraviolet. Because he had a tight deadline, he knew that only if the flowers would grow under the new lights could he hope for success. To his relief, all the flowers grew well. But Ott noticed that the best results came when the flowers were placed under the center, rather than the ends, of the fluorescent tubes. He knew that the tubes worked on the same principle as the cathode guns in TV sets or in X-ray machines, but at much lower voltages, so low in fact that textbooks stated they could not produce harmful radiation. Suspecting the textbooks might be wrong, Ott placed two sets of ten parallel tubes end to end so that there were twenty cathodes in close proximity. When he sprouted the same kind of potted beans used in the TV experiments, he was startled to see that the ones close to the cathodes were stunted whereas those both at the center of the tubes and ten feet away from them appeared normal.

After many more experiments with beans, Ott became certain that they are far more sensitive to trace amounts of radiation than the standard radiation-measuring equipment presently available. This, he thinks, is because whereas the instruments pick up only a single reading of energy the biological systems are exposed to its cumulative effects.

Ott was next confronted with the possibility that light frequencies could affect the development and growth of cancer.

His initial clue that there was a connection between light frequencies and cancer came when a physician in charge of cancer research at one of New York's largest hospitals agreed to ask fifteen human cancer patients to spend as much time as possible outdoors in natural sunlight without their glasses and avoid artificial light sources, including television.

By the end of the summer the doctor told Ott that it was the consensus of all those assisting in the project that fourteen of the patients had shown no further advancement in tumor development.

In the meantime, Ott had aroused the interest of a leading Florida ophthalmologist, who explained to him that a layer of cells in the retina of the eye, with no function in vision, showed abnormal response to tranquilizing drugs and asked if he would run toxicity tests of the drugs by utilizing microscopic time-lapse photography. Ott used a phase-contrast microscope equipped with a complete set of colored filters, which permit the outline and details of cell structure to be clearly seen without killing them with stain as was previously necessary. This technique revealed that exposure to the wavelengths of blue light elicited abnormal pseudopodical activity in the pigment of the retinal cells whereas red light caused the cell walls to rupture. Even more interesting was the fact that when the cells were fed, by adding fresh media to the slide chambers, cell division was not encouraged at constant temperature, but if the temperature was lowered during the feeding accelerated division would take place within sixteen hours.

During their work the researchers also noticed that just before sunset the activity of the pigment granules within the cells would slow down and would return to normal only the next morning. It seemed to Ott that they were behaving just like the chloroplasts in the cells of Elodea grass. Perhaps plants and animals had more similarities in their basic functioning than had hitherto been suspected.

Ott suggests that the responses of chloroplasts and the pigment granules in retinal epithelial cells may be "tuned" to the natural light spectrum of sunlight, under which all life on this earth has evolved. "It would thus appear," he says, "that the basic principles of photosynthesis in plants, where light energy is recognized as a principal growth-regulating factor, might carry over from plant life and be equally important as a growth-regulating factor in animal life through control of the chemical or hormonal activity."

Other studies of cellular behavior have led Ott to conclude that malillumination or malradiation may be as important as malnutrition in the initiation of disease.

At the 1970 meeting of the American Association for the Advancement of Science, Dr. Lewis W. Mayron, in his discussion of Ott's research with bean plants and rats exposed to TV radiation, concluded that "the radiation has a physiological effect both on plants and animals which appears to be chemically mediated." Mayron also commented on Ott's experiments with the effects of fluorescent tubes on beans, stating: "The implications for human health are enormous when one considers the magnitude of the use of fluorescent lighting in stores, offices, factories, schools and homes."

With generous support from the Evelyn Wood Foundation, Ott has carried on studies on what effects TV sets might have on children with behavioral problems. With the cooperation of Mrs. Arnold C. Tackett, principal of a school which devotes itself to such children in Sarasota, Florida, Ott made checks of home TV sets watched by the youngsters and found measurable amounts of X-ray radiation in most of them, especially those which had run for long hours without overhaul. The parents agreed to get the children to spend much more time playing outdoors during the summer vacation and to sit far back from the TV while watching it.

By November of the new school year, Mrs. Tackett was able to report that the behavioral problems of children so treated were markedly diminished.

By the late 1960s the U.S. Congress had passed a Radiation Control Act by a vote of 381 to 0. Florida Representative Paul Ropes, co-author of the act, credited Ott with "getting us all started on the road toward control of radiation from electronic products." Ott credits his plants with showing him the way to the light.

Since the work of Gurwitsch, Rahn, Crile, and the proponents of electroculture all supported the earlier contentions of Galvani and Mesmer that living things have electrical or magnetic properties, it was strange that no one had suggested that they must also have about them the same electromagnetic fields as those accepted in the world of particle physics. This was exactly the theory boldly advanced by two Yale University professors, one a philosopher, F. S. C. Northrop, the other, like Galvani, a medical doctor and anatomist, Harold Saxton Burr.

By asserting that electrical fields are the very organizers of life systems, Northrop and Burr offered chemists a new basis on which to explain how the thousands of separate constituents they had uncovered might be put together. They suggested to the biologists that their long hunt might be over for the "mechanism" which assures that all the cells of the human body, replaced every six months, are properly aligned. This appeared to revitalize the rejected theories of Mesmer's animal magnetism and Galvani's animal electricity and provide a seemingly tangible underpinning for the airy "élan vital" of the French philosopher Henri Bergson, and the "entelechy" of the German biochemist Hans Driesch.

To prove their theory, Burr and his laboratory colleagues constructed a voltmeter of a new design, which drew no current from life forms to be studied and thus could not disrupt the total fields around them. Twenty years of research with this device and its more sophisticated descendants revealed to Burr and several of his associates astonishing things about the vegetal and animal world. Dr. Louis Langman, an obstetrician and gynecologist who worked with Burr's technique, found for example that the precise moment of a woman's ovulation can be measured with great accuracy and that some women ovulate over the entire menstrual cycle, in some cases without menstruation. Though the detection procedure is extremely simple, and in no way counters the rhythm method of birth control of the Catholic Church, it has yet to filter down to millions of women who would like to learn better how, or how not, to have children.

Burr himself determined that malignancies could be detected in certain organs before any clinical signs could be observed, and that the rate of healing in wounds could be reliably measured. The future location of a chick's head could be found and pinpointed in the egg from which it would hatch, without breaking it, during the first day of its incubation.

Turning to the world of plants, Burr measured what he came to call "life-fields" around seeds, and found that profound changes in the voltage patterns were caused by the alteration of a single gene in the parent stock. Even more potentially interesting to plant breeders was his discovery that it is possible to predict how strong and healthy a future plant will be from the electrical diagnosis of the seed which produces it.

Because, of all living things, they seemed the most enduring and the least motile, Burr charted the life fields of trees on the Yale campus and at his laboratory in Old Lyme, Connecticut, over nearly two decades. He found that recordings related not only to the lunar cycle and to sunspots, which flare up at intervals with many years between them, but revealed cycles recurring every three and six months that were beyond his explanation. His conclusions seemed to make less suspect the long-mocked practices of generations of gardeners who claimed that their crops should be planted according to the phases of the moon.

One of Burr's students, Leonard J. Ravitz, Jr., who was to become a psychiatrist, was able to measure depths of hypnosis with the Burr-discovered techniques as far back as 1948. He went on to the not surprising conclusion that all humans are in hypnotic states most of the time, even when wide awake.

The continuous charting of life fields in people indicates a cyclic rise and fall of voltage, the peaks and valleys of which correlate to the periods when they feel good or bad, "up" or "down." By plotting the curves in advance it is possible to predict highs and lows weeks in advance, as the students of bio-rhythms have proposed, going back to the time when they were first theorized by Dr. Wilhelm Fliess, whose letters were so encouraging to Sigmund Freud during the years of Freud's self-analysis.

Burr's life work, as further developed by Ravitz, indicates that the organizing field around the "bodies" of living things *anticipates* the physical events within them and suggests that the mind itself, as Marcel Vogel maintains, can, by modulating the field, affect positively or deleteriously the matter with which it is held to be associated. But these signposts had yet to be read by the leaders of organized medicine, and Burr's work has only recently begun to be seriously considered.

Medical pundits are now in for a further shock due to a startling discovery in 1972 at the Institute of Clinical and Experimental Medicine in Novosibirsk, a burgeoning industrial city of over a million people on the banks of Siberia's mighty river Ob, which strongly supports the findings of Gurwitsch, Rahn and Crile.

S. P. Shchurin and two colleagues from the Institute of Automation and Electrometry have been awarded a special diploma by the USSR

State Committee for Inventions and Discoveries for discovering that cells can "converse" by coding their messages in the form of a special electromagnetic ray.

The experimenters placed identical tissue cultures in two hermetically sealed vessels separated by a wall of glass, then introduced a lethal virus in one of the chambers which killed the colony of cells inside it. The second colony remained wholly unaffected. However, when they replaced the glass divider with a sheet of quartz glass and again introduced killing viruses to one of the colonies, the Soviet scientists were astonished to see that the second colony also met the same fate as the first, even though the viruses could not possibly have penetrated the barrier. Other first and second colonies of cells, separated by the quartz glass, both perished when only the first colony was murdered with chemical poisons or lethal radiation and the second left unexposed. What killed the second colony in each case?

Since ordinary glass does not permit ultraviolet rays to pass but quartz glass does, it seemed to the Soviet scientists that here was a key to the mystery. They recalled that Gurwitsch had theorized that onion cells could emit ultraviolet rays, and they resurrected his ideas from the limbo to which they had been consigned in the 1930s. Working with an electronic eye amplified by a photomultiplier and registered by a self-recorder which traced a graph marking the energy levels on a moving tape, they found that when life processes in the tissue cultures remained *normal,* the ultraviolet glow, invisible to the human eye but detectable as oscillations on the tape, remained *stable.* As soon as the affected colony began to battle against its infection, the radiation intensified.

Reports on this work in Moscow newspapers disclosed that, however fantastic it might seem, the ultraviolet radiation from the afflicted cells *carried information* encoded in the fluctuation in intensity which was somehow received by the second colony, just as words are transmitted and received in dots and dashes in the Morse code.

Since the second colony seemed in each case to die in exactly the same way as the first, the Soviets realized that it was as dangerous for healthy cells to be exposed to the transmitted signal of dying cells as it was for them to be exposed to viruses, poisons, and lethal radiation. It appeared

that the second colony upon receiving the alarm signal from the dying first colony began to mobilize for resistance and that its very "restructuring for war" against a nonexistent enemy proved as fatal as if it had indeed been attacked.

Moscow newspapers suggested that the Novosibirsk work may help to pinpoint what inner reserves the human body possesses to resist disease and quoted Shchurin on how it may help to open new horizons in diagnosis: "We are convinced that the radiation is capable of giving the first warning about the beginning of malignant regeneration and of revealing the presence of particular viruses. At the present time the early identification of many ailments, for instance the numerous forms of hepatitis, presents major difficulties."

Thus, fifty years after his work, his countrymen have finally brought recognition to Gurwitsch's brilliant research. Coincidentally they have also validated the work of another obscure compatriot, Semyon Kirlian, who has managed to capture on film extraordinary pictures of the force fields around humans and plants so accurately described and measured by Burr and Ravitz.

CHAPTER 13

The Mystery of Plant and Human Auras

The long train was on the last leg of its journey from Moscow to Krasnodar, a south Russian inland port on the Kuban River, two hundred miles northwest of the volcanic Elbrus, Europe's highest mountain peak in the Greater Caucasus range.

In one of its "soft" cushioned cars reserved for Soviet officials, a plant specialist, bored with watching the flat countryside, still only partly recovered in 1950 from the Nazi ravages of the "Great Patriotic War," reopened his satchel to check the condition of two similar leaves which he had plucked in a greenhouse before leaving the Soviet capital. Relieved to see that the leaves were still sparkling fresh and green in their bedding of moist cotton wool, he sat back in his fauteuil to admire the approach of the Caucasian piedmont.

Late that evening in a small Krasnodar apartment, a corner of which was fitted out as a miniature laboratory, Semyon Davidovich Kirlian, an electrician and amateur photographer, and his wife, Valentina, were making some adjustments to equipment they had begun building two years before the Nazi attack on their country.

With their new invention they had discovered they could photographically reproduce—without lens or camera—a strange luminescence which seemed to issue from all living things but was unapprehensible by the human eye.

A knock on the door surprised them, as no visitor was likely to call at that time of evening; they were even more surprised when a total stranger announced he had come all the way from Moscow to see if they could make for him photographs of the strange energy which he had heard they alone could make visible on film. From his brief case the stranger pulled the two identical leaves and handed them to the Kirlians.

Excited at the prospect that their discovery was to be put to an official test, the Kirlians stayed up till after midnight, but were disappointed to note that while they could make excellent pictures of energy flares from one of the leaves, they could get only a weak facsimile from the other. They worked on through the night, trying to get photos of the luminescence as similar as the leaves themselves, but were wholly unsuccessful.

In the morning, crestfallen, they showed their results to the scientist, who shouted in amazement: "But you've found it! You've proven it photographically!" He explained that one leaf had been plucked from a healthy plant, the other from a diseased specimen. Although the two leaves appeared identical to the human eye, the pictures plainly differentiated between them. Illness was evidently manifest in a plant's energy field before becoming visible as a symptom in its physical body.

That plants, as well as animals and human beings, have fields of fine sheaths of subatomic or protoplasmic energy which permeate the solid physical bodies of molecules and atoms was a centuries-old allegation by seers and philosophers. This extra dimension or "aura" depicted in ancient iconography around the bodies of saints, with golden halos around the heads, has been referred to by persons gifted with extrasensory perception since the beginnings of recorded history. By laying film or plate in contact with an object to be photographed and passing through the object an electric current from a high-frequency spark generator which put out 75,000 to 200,000 electrical pulses per second, the Kirlians had come across a way of photographing this "aura"—or something akin to it.

Leaves from plants, sandwiched with film between the electrodes of their device, revealed a phantasmagoria hitherto restricted to clairvoyants, a micro-universe of tiny starry points of light. White, blue, and even red and yellow flares were pictured surging out of what seemed to be channels in the leaves. These emanations, or force fields round a leaf, became distorted if the leaf was mutilated, gradually diminishing and disappearing as the leaf was allowed to die. The Kirlians were next able to magnify this luminescence by adapting their photographic processes to optical instruments and microscopes. Rays of energy and whirling fireballs of light appeared to shoot out of plants into space.

The Kirlians also examined all kinds of "inanimate" substances, including metal coins. Each had a different luminating pattern. Most interesting was the fact that while a two-kopeck coin showed only a constant glow around its edges, human fingertips seemed to shoot forth flaming energy in bursts like miniature volcanoes.

After their photographic demonstration of pathology in the leaf from the sick plant for the Muscovite visitor, it was another ten years before the Kirlians began to emerge from obscurity in the USSR.

In the early 1960s Dr. Lev Fedorov of the USSR's Ministry of Public Health, struck by the possibilities of the new photography for medical diagnosis, awarded the Kirlians a first research grant but when Fedorov died soon thereafter, official funding from Moscow began to dwindle and academic skeptics were once more in control.

It was only when a journalist took up the Kirlians' story that interest was again aroused. "This situation," wrote I. Belov, "is as bad as before the revolution, when the evil hand of Tsarist bureaucrats determined there was too much uncertainty in novelty. *Twenty-five years have passed* since the Kirlians made their discovery, yet the Ministries in charge still haven't released the funds."

Belov's effort had its effects. In 1966, a conference bringing together many scientists interested in all aspects of what was coming to be called "biological energy" was held in Alma Ata, capital of the Kazakh Republic. In proceedings of the conference, entitled *Problems in Bioenergetics*, a Moscow biophysicist, Viktor Adamenko, joined with the Kirlians to author a seminal paper "On Research of Biological Objects in High-Frequency Electrical Fields." The paper stressed the enormous difficulties of studying the spectrum of "electrobioluminescence" but added that when these are overcome, "we will be able to obtain important information about bioenergetic processes in a living organism."

For all the mounting Soviet interest, it was another three to four years before American science—which had branded as fake Wilhelm Reich's 1939 discovery of a life energy in plants and humans which he called orgone—paid attention to the new developments. What attracted this attention was not the Soviet scientific publications but a book, *Psychic Discoveries Behind the Iron Curtain*, by two North American journalists, Sheila Ostrander and Lynn Schroeder, which appeared in the summer of 1970.

Excited by what she had read in the Ostrander-Schroeder volume, a former Broadway actress, now professor at the Neuropsychiatric Institute of the University of California at Los Angeles, Thelma Moss, Ph.D., wrote to Russia and received an invitation to visit Professor Vladimir Inyushin at Alma Ata.

Working with several colleagues, Inyushin had written up his research into the Kirlians' work in 1968 in a book-long scientific paper: *The Biological Essence of the Kirlian Effect.* Though Kirlian himself had maintained that the strange energy in his pictures was caused by "changing the nonelectrical properties of bodies into electrical properties which are transferred to film," Inyushin and his collaborators went several steps further. They declared that the bioluminescence visible in Kirlian pictures was caused not by the electrical state of the organism but by a "biological plasma body" which seemed to be only a new word for the "etheric" or "astral" body of the ancients.

In physics plasma is defined today as an electrically neutral, highly ionized gas composed of ions, electrons, and neutral particles which has been called the "Fourth State of Matter" (after solids, liquids, gases).

As far back as 1944, as the Allied armies were storming "Fortress Europe," a book by the Russian V. S. Grishchenko, *The Fourth State of Matter,* appeared in French in Paris. Credit for coining the term bioplasma may thus belong to Grishchenko. The same year the discoverer of "mitogenetic radiation," A. G. Gurwitsch, published his book in Moscow entitled *The Theory of a Biological Field,* summing up twenty years of work.

Inside the "bioplasmic" body, said Inyushin, processes have their own labyrinthine motion, different from the energy pattern in the physical body, yet the bioplasmic body is not a chaotic, but a whole unified organism which acts as a unit, is polarized, gives off its own electromagnetic fields, and is the basis for "biological" fields.

When Thelma Moss arrived on an evening flight in Alma Ata, she was invited by Inyushin to visit his laboratory and lecture to his students. Elated, she went to sleep sure that she would be the first American scientist to visit a Soviet institution engaged in studying Kirlian photography. The following morning when Inyushin came to pick her up at her hotel, he regretfully told her that "permission for the visit had not come from Moscow."

Moss was nevertheless able to learn from Inyushin that during six years of research with Kirlian photography he had been able to note that specific areas of the human body revealed characteristic colors which might prove significant in medical diagnoses. The clearest photos, he told Moss, were those taken at four o'clock in the afternoon, the worst at midnight. When Moss asked Inyushin point-blank if his "bioplasma" body was what occult Western literature refers to as the "aura" or the "astral" body, he said: "Yes!"

In ancient philosophies and in Eastern and Theosophical teaching, the energy body which duplicates the human body is also called the etheric body, fluidic body, or prephysical body. It is believed to be the unifying agent for the material body, a magnetic area where immaterial or subatomic vortices of the cosmos are transformed into the individual, the channel through which life communicates with the physical body, the medium for telepathic and clairvoyant projection. For decades scientists have been trying to find a way to make this body visible.

While Moss was in Alma Ata, the eminent American psychiatrist Montague Ullman, director of the department of psychiatry at the Maimonides Medical Center in New York City, was simultaneously interviewing Viktor Adamenko in Moscow.

Ullman was informed, somewhat to his surprise, that Adamenko and other Soviet scientists had been able to determine that the "bioplasma" not only undergoes a drastic shift when placed in a magnetic field but is concentrated at hundreds of points in the human body which seem to correspond to the ancient Chinese system of acupuncture points.

Thousands of years ago the Chinese mapped seven hundred points on the human skin as paths along which they believed a life force or vital energy to circulate. The Chinese insert needles at these points to correct imbalances in the energy flow, and to cure disease. Spots where the Kirlian lights flared most brilliantly on a human body appeared to match the acupuncture points mapped by the Chinese.

Adamenko is still unsure about Inyushin's attribution of the phenomena to a "bioplasma body," because there is as yet no "rigorous proof" of its existence, and therefore prefers to define the visible emanations as "a cold emission of electrons from the live object into the atmosphere."

In the United States this "cold emission of electrons" is almost universally translated as a "corona discharge," which is compared to the static electricity emitted by a person after walking across a carpet and touching a grounded metal. The name is derived from the faintly colored luminous ring which surrounds celestial bodies and is visible through a haze or thin cloud or the luminous irregular envelope of highly ionized gas outside the chromosphere of the sun. But giving it an academic name has explained neither its substance nor its function.

As president of the American Society for Psychical Research, Ullman found it extremely interesting that Dr. Anatoli Podshibyakin, a Kiev electrophysiologist, had discovered that bioplasma, if that is what it is, *instantly* reacts to changes on the surface of the sun even though cosmic particles, ejected by the sun, take about two days to reach the earth.

Many parapsychologists view man as an enmeshed, integral part of life on earth and in the universe. They maintain he is linked to the cosmos via his bioplasmic body, and reacts to changes in the planets as well as to the moods and illnesses of others, to thought, emotion, sound, light, color, magnetic fields, the seasons, cycles of the moon, tides, thunderstorms, strong winds and even levels of noise. If there is a change in the universe and environment, say the parapsychologists, a resonance is produced in the vital energy of the human body which in turn affects the physical body. It is through his bioplasmic body that parapsychologists believe a man can be in direct contact with a living plant.

Still another U.S. parapsychological researcher, Dr. Stanley Krippner, director of the extraordinary Dream Laboratory at the Maimonides Medical Center in New York—where pictures have been successfully directed at sleepers in order to produce in their minds desired dreams—trekked to Russia in the summer of 1971. While in Moscow, Krippner was the first American invited to give an address on parapsychology to the Institute of Psychology in the Academy of Pedagogical Sciences. The lecture was attended by some two hundred psychiatrists, physicists, engineers, space scientists, and cosmonauts in training.

Krippner found out that Genady Sergeyev, a neurophysiologist working at the Ukhtomskii Military Institute in Leningrad, had made Kirlian photographs of Nina Kulagina, a sensitive who can, by simply passing her hand over but not touching them, move paper clips, matches, cigarettes, and other objects on a table top.

Sergeyev's photographs revealed that while Kulagina performs these psychokinetic feats, the "bioplasmic field" around her body expands and pulses rhythmically and *a ray of luminescence seems to shoot out of her eyes.*

In the fall of 1971, William A. Tiller, chief of the Materials Science Department at Stanford University (Palo Alto, California) and one of the world's experts on crystals, was the first American physicist invited by Edward Naumov, chief coordinator for Technical Parapsychology in Moscow, to investigate Kirlian photography in the USSR.

Although, like Moss and Ullman, Tiller was not permitted to visit Soviet laboratories, he was able to spend several days with Adamenko. When he returned to the United States, Tiller recommended in a highly technical report that the Kirlian method and devices, among others,

were "so important to parapsychological and medical investigations that attention should be focused on immediate construction of such devices and the duplication of the Soviet results."

Tiller, who like Adamenko does not see the need for postulating any new "bioplasma," and substitutes for it the "cold emission of electrons," has been building extremely sophisticated equipment for taking Kirlian photographs in his Palo Alto laboratory.

One of the first actually to make Kirlian-type pictures in the United States was Thelma Moss, who worked on the project with one of her students, Kendall Johnson. With their apparatus, Moss and Johnson were the first Americans to take color photos of leaves and pick up almost every region of the visible spectrum. American coins, appropriately enough, come out in red-white-and-blue, as do photos of the energy from the fingertips of the human hand.

Henry C. Monteith, an electrical engineer in Albuquerque, New Mexico, working at home, put together an apparatus consisting of two 6-volt batteries, a vibrator used to power automobile radios, and an ignition coil sold at all auto-supply stores. Like the Russians, Monteith found that a live leaf gave beautiful and varied self-emissions that cannot be adequately explained by conventional theory. He was further mystified when he discovered that a dead leaf gave, at most, only a uniform glow. Exposed to only 30,000 volts, the dead leaf did not reveal anything at all on film, even when bathed in water, but the live leaf shimmered in a radiance of self-emissions.

As the potential implications of a photographic process in existence for more than thirty years—which seemingly gave substance to the notion of the existence of an *aura,* a subject considered by most Western scientists to be on the "lunatic fringe" of investigatory effort—began to be realized in the United States, demand mounted for more hard information. Stanley Krippner enlisted the cooperation of several financial backers and organized the First Western Conference on Kirlian Photography and the Human Aura in the spring of 1972 at Manhattan's United Engineering Center, where a crowd of doctors, psychiatrists, psychoanalysts, psychologists, parapsychologists, biologists, engineers and photographers packed the ground-floor auditorium to overflowing. At the conference startling pictures by Moss and Johnson were shown of a leaf before and after being pricked. Done with Kirlian techniques, the photo of the wounded leaf revealed an enormous blood-red pond of energy in its center which took the place of the bright azure and pinkish hue which showed up before the pricking.

The mystery of the link between human emotional or psychic states and emanations radiating from the fingertips is deepened by Moss's further finding that pictures of both her own and Kendall Johnson's fingers differ from day to day and hour to hour.

Since the photos of leaves change with variations in parameters, Moss conjectures that "at whatever frequency we take a picture, we are resonating, or vibrating at the same frequency, *with one particular aspect of the material;* thus, not a whole picture, but different pieces of information are picked up."

Tiller speculated that the radiation or energy coming out of a leaf or a human fingertip actually might be coming from whatever is present *prior to the formation of solid matter.* This, says Tiller, "may be another level of substance, producing a hologram, a coherent energy pattern of a leaf which is a force-field for organizing matter to building itself into this kind of physical network."

Tiller thinks that even if part of the network were cut away, the forming hologram would still be there. Apparently this is just what the Russians have been able to prove with a plant leaf. A picture printed in the *Journal of Paraphysics* (published in Downton, Wiltshire, England) shows a Russian Kirlian photograph of a leaf with one part cut away. Yet, where nothing would show ordinarily, the outline of the missing part of the leaf remains.

That this was not just Russian subterfuge was strikingly confirmed when Douglas Dean made photos of the fingertip of a New Jersey healer, Ethel de Loach, whose files bulge with successful case histories. One picture, taken while the healer was at rest, showed only a dark blue radiation streaming out of the skin and revealing the tip of the long nail. A second picture, shot when she was asked to heal, revealed in addition to the blue radiation an enormous orange and red flare leaping out of a point below the actual fingerprint. Both pictures were subsequently

published on the cover of the medical journal *Osteopathic Physician.* Kirlian photos of faith healers reveal a smaller glow after healing, while those healed have greater emanations, indicating some sort of energy flow from the hands of the healer into the body of the patient, giving substance to Galvani's and Mesmer's theory of "animal magnetism."

At the Human Dimensions Institute at Rosary Hill College in Buffalo, New York, one of the professors, Sister M. Justa Smith, a Catholic nun and biochemist, began thinking that healing energy coming from or through a healer's hands would have to affect the enzyme system *before* diseased cells could change to a state of health. Sister Justa—who had finished a doctoral dissertation proving that magnetic fields increase, while ultraviolet light decreases, enzyme activity—after engaging the cooperation of a healer, found that when he was in an "optimum psychological state," or good mood, the energy coming from his hands could activate the pancreatic enzyme trypsin in a way which compared to the effects of a magnetic field measuring from 8,000 to 13,000 gauss. (Human beings normally live in a magnetic field of 0.5 gauss.) Sister Justa is continuing experimentation to find out whether a healer can activate other enzymes in the body and whether this activation can be of help to the maintenance of health.

How magnetic fields affect life and how they might be related to the energy of the "aura" is a mystery only beginning to be unveiled. In recent years scientists have found, for instance, that snails perceive extremely weak magnetic fields and, since they can also distinguish their direction, could be said to incorporate structures which behave like navigational compasses.

Jan Merta, whose own projections of what he terms "auric energy" have not only turned dowsing devices held in a doctor's hands against the doctor's will and efforts to prevent it, but also so disturbed the magnetic components of the video tape recording the procedure that the film blacked out while supposedly recording a crucial sequence, has developed a whole theory about auras, part of which suggests that magnetic fields might significantly affect a learning process. Merta took thirty mice and housed them in small cages made of transparent plastic. Ten of them were exposed to the south pole, ten to the north pole, with field strength of 5–10 gauss of a bar magnet. The third ten were left untreated. With an ingenious learning device Merta was able to establish that those mice which had lived under the influence of a magnetic field were not only more active than the nonmagnetized mice, but somehow were able to learn quicker.

It would seem that some correlation exists between the activity of the "bioplasmic" or "auric" fields—if that is what they are—around living things and their subjection to various types of radiation. Certainly there is no doubt, in light of the pioneering Soviet work and its American confirmation, that the health, physical or emotional, of plants and animals can be objectified with the Kirlian technique.

The main strength of the Russian research, according to Professor Tiller, is that "it has been able to provide us with detectors and devices with which we can begin to show cause-effect relationships between psycho-energetic phenomena and the kind of read-outs which our colleagues find acceptable and that our logical system has come to accept as proof. We're *at that stage of naïveté* that we need this proof."

The first Kirlian conference was so successful that a second meeting was held in New York's Town Hall in February 1973. One of the most striking presentations was that of Dr. John Pierrakos, a Greek-born psychiatrist who showed detailed drawings of auras which he can visually perceive around plants, animals and human beings and which he is able to monitor in continual movement around neurotically and psychotically disturbed patients. In her book *Breakthrough to Creativity*, published in 1967, Shafica Karagulla, M.D., reported how many physicians use their observations of the human energy field in their diagnostic work. Because they were guarded about discussing their unusual abilities outside their own circle, Karagulla did not refer to any of them by name. Pierrakos is perhaps the first physician publicly to state that his perceptions of the human aura assist him in his diagnoses.

"Man is an eternal pendulum of movement and vibration," Pierrakos told the Town Hall audience. "His spirit is captured in a body in which forces throb and pulsate like the beat of a heart. Often, they thunder and quake in his body with strong emotions that shake the very foundations of his physical being. Life goes on, rhythmically and quietly pulsating with the warm feeling of love or cascading with avalanches of violent

emotion, for movement and pulsation is life. When movement diminishes, the person becomes ill, and when the movement stops, the person is dying."

Pierrakos likened human bodies to time capsules in which biological functions are performed "for a century or so" after which the capsule changes the shape of its existence. "During this time, like the flower that brings the blossom and the seed that brings the flower and the fruit, man's time capsule has to become aware of what is going on within and without." To do so, asserted Pierrakos, we must describe and understand, fuse and integrate two attributes: *life energy* and *consciousness* —the former seen as the aura around the body with gradations similar to that of the atmosphere which thins as it proceeds outward from the earth. Though to his Hellenic ancestors energy was "something producing movement," Pierrakos holds that this nebulous definition should be made more precise. "Energy is a living force emanated by consciousness," he suggests. "By observing the energetic field emanating from the body—not unlike the steam over boiling water which, correctly observed, gives an idea of the water's nature—I get an idea of what is happening in the body," Pierrakos said.

In his pictures, Pierrakos illustrated the three layers he sees around most of his patients. The first, a dark band no more than one-sixteenth to one-eighth of an inch thick, lies close to the skin and looks like a transparent crystalline structure. The second, a broader dark blue layer, reminiscent of a cluster of iron filings, forms an ovoid envelope around the body when seen from the front. The third is a lightish blue haze of radiant energy which, when the patient is in good health, extends several feet away from the body and accounts for why we describe happy zestful persons as "radiant."

Pierrakos also showed how in patients with disturbances there are interruptions in these layers and changes in their colors of which he can see only the grosser aspects. When a psychotic patient told Pierrakos that she was "secure" because another person stood next to her constantly "on guard," he asked her to let him see this other person. All at once he noticed a mass of light blue-gray energy in the shape of a human body next to his patient.

The energy field of plants can also be severely affected by disturbed patients, says Pierrakos. "In some experiments with plants conducted in my office with Dr. Wesley Thomas, we found that a chrysanthemum's field contracts markedly when a person shouts at it from a distance of five feet, and loses its blue-azure color, while its pulsation diminishes to one third. In repeated trials, keeping live plants more than two hours daily near the heads of screaming patients (a distance of three feet away), the lower leaves started falling down and the plant withered within three days and died."

Pierrakos related that the number of pulsations the energy field emits per minute is also an indication of the internal state of a human being. The pulsations are much slower in older persons than in children, and in sleep than in wakefulness.

Since the direction of the flow of energy on the front of the body starts in the midriff and proceeds downward in a sort of curving L toward one of the legs and upward in an inverted L to the opposite shoulder, then reverses this flow on the back side of the body, the whole energy pattern around the body forms a figure 8. Put together in symbolic form, the two pairs of L shapes, front and back, have from time immemorial been represented in cultures throughout the world as the *swastika,* a Sanskrit word for "well-being."

The same kind of energy field observable in humans is seen by Pierrakos macrocosmically over the ocean with miles-high fountains of radiation bursting forth from narrower bands of pulsation below. Since the amount of activity in this earthly aura plotted by Pierrakos against the time of day reveals the lowest ebb just after midnight and the highest shortly following noon, this directly correlates with Rudolph Steiner's account of how the chemical ether is exhaled and inhaled by our planet.

A research team of physicists and electronics specialists is currently seeking to objectify Pierrakos' "sensitive" sight. Under the auspices of the Center for Bio-Energetic Analysis they are developing a means of detecting the radiations of the human animal and plant auras with a sensitive photomultiplier tube, an instrument which measures photons or light energy from the "etheric" field around a body. In a preliminary report they stated in Town Hall that, to date, their work indicates strongly that human beings radiate a strange field, detectable by the tube, the properties of which remain to be analyzed and explained.

Pierrakos, who can also see the energy pumping forth from plants and trees, warns of the danger of comparing the phenomena revealed by Kirlian photography to known radiations such as X-rays. "The study of the aura could become completely mechanized and objectified without reference to the great phenomena of life within the entity," he says.

In this observation Pierrakos is not far from the philosopher-mathematician Arthur M. Young, inventor of the Bell helicopter, who stresses that in back of the whole hierarchy of active energies, known or unknown, may lie *intent.* "Content requires substance," says Young, "whether by reference to actual physical objects or to human feelings or emotion. Substance is indeed what the work connotes, that which stands under—*sub stance*—the interactions of the physical world. To the physicist this is *energy.* To the human being it is *motivation.*"

Through *motivation* or *intent,* or some other agency of will, is it possible for living forms to effect changes in their own physical systems? Is it possible for plants and men—which materialists assert are only renderable at death into so much compost, soap, or chemicals—to grow the way they want?

In the Soviet Union, a country which was originally founded on the most materialist of philosophies, the developments resulting from Kirlian photography have raised certain profound questions about the true nature of life—vegetal, animal and human—about mind and body, about form and substance. Thelma Moss believes that research in the field has actually become of such great scientific importance to both the Russian and U.S. governments that they are keeping their official efforts strictly secret. Nevertheless, a spirit of friendly rivalry and of cooperation has arisen between groups, thus far small, of Russian and American scientists.

As Semyon Kirlian put it in a letter to the First Western Conference to take up the implications of his work, "the new research will have such enormous significance that an impartial assessment of the methods will be carried out only by minds in succeeding generations. The possibilities are immense; indeed, they are practically inexhaustible."

PART IV

CHILDREN OF THE SOIL

CHAPTER 14

Soil: The Staff of Life

Despite Carver's prescient observations on how to bring life back to the cotton-debased soils of Alabama by rotating crops and fertilizing the soil with natural humus, the farmers of that state—and those in every other state of the Union—have since Carver's death been lured by the promise of large profits to deal with the land, not in a natural, but in an artificial way in order to force from it every ounce of productivity. Instead of exerting patient and tender efforts to keep their soils in natural balance they have been seeking to subjugate nature rather than cooperate with her. Everywhere there are indications that in the process of being raped rather than loved, nature is protesting. If the process goes on, the victim may die of bitterness and indignation, and with her all that she nurtures.

An example—one among thousands—is Decatur, Illinois, a farming community in the heart of the United States cornbelt. As the summer of 1966 was drawing to a close, steamingly hot and sultry, the corn stood in the fields as high as an elephant's eye, promising a bumper crop in every direction, perhaps eighty to a hundred bushels to the acre. In the twenty years since World War II the farmers had almost doubled the land's yield in corn by the use of nitrate fertilizers, unaware of the deadly danger they were courting.

The following spring one of Decatur's seventy-eight thousand townsmen—whose living depended indirectly on the success of the corn harvest—noticed that a cup of drinking water from his kitchen faucet tasted funny. As the water was supplied directly from Lake Decatur, an impoundment of the Sangamon River, he took a sample to the Decatur Health Department for testing. Dr. Leo Michl, a Decatur health official, was alarmed to find that concentrations of nitrate in the waters of Lake Decatur and the Sangamon River itself were not only excessive but potentially lethal.

Nitrate, in itself innocuous to the human physical constitution, can become deadly when converted by intestinal bacteria; these combine nitrate with the blood's hemoglobin into methemoglobin, which prevents the natural transport of oxygen in the bloodstream. This can cause a disease known as methemoglobinemia, which kills by asphyxiation; infants are particularly susceptible to it. Many cases of the mysterious epidemics of "crib death" are now attributed to it.

When a Decatur newspaper ran a feature suggesting that the city's water supply had become polluted with excessive nitrate and that fertilizers being poured on the surrounding cornfields might be the source of the trouble, the story exploded like a bombshell in the cornbelt communities. At the time of the water analysis, farmers were resorting almost exclusively to nitrogen fertilizer as the cheapest, and indeed the only, means to produce over eighty bushels of corn to the acre, an amount dictated by the economics of corn production as necessary to realize a profit. Corn, or maize as it is known in the English-speaking world outside North America, is a heavy consumer of nitrogen, which,

under *natural* conditions, is stored in the soil as a part of its humus, a brown-black material composed almost wholly of decayed vegetable matter.

For countless ages before man began to till the soil, humus was accumulated by return to the soil of vegetation which died and rotted. When man began to harvest crops he saw to it that humus, rich in nitrogen and other elements upon which plants depend, was replaced in the form of animal wastes and straw, the components of barnyard manure. In many countries of the Far East, man's own excrement, euphemistically termed "night soil" by Westerners, is applied to the land instead of being allowed to float away through sewage systems into rivers.

An almost inexhaustible supply of such a natural manure is still available to Decatur in nearby Sioux City, Iowa, America's heartland city on the Missouri River, where millions of animals have been fed and slaughtered and from which they have been shipped to the nation's retail markets for over half a century. A pile of steer manure has accumulated longer than a football field. This mountain of organic waste, which poses a headsplitting disposal problem to the city fathers, could easily be processed into natural soil-enlivening products were anyone interested in saving the soil. Nor is the Sioux City manure pile an exception. Dr. T. C. Byerly, leader of the USDA's waste-disposal programs, states that wastes from livestock operations in the United States are presently equal to those produced by the entire U.S. population and that by 1980 they will double in size.

Instead of returning this natural humus-nitrogen to the soil, the farmers chose to apply artificial nitrogen fertilizers. In Illinois alone the consumption rose from ten thousand tons in 1945 to well over half a million tons in 1966, and is rising constantly. Since the amount of nitrogen applied is more than the corn can naturally take up, the excess washes out of the soil into the local rivers: in the case of Decatur, all the way into the drinking cups of citizens.

Joe Nichols, a physician and surgeon who founded the Natural Food Associates in Atlanta, Texas, reported that a survey on farms throughout the Middle West disclosed that the corn growth was so heavily fertilized with synthetic nitrogen that it was unable to convert carotene into vitamin A and that the cattle feed produced from it was also deficient in vitamins D and E. Not only were the cattle not gaining weight but they were not even reproducing as well as they should have, and, as a result, the farmers were losing money. When certain strains of corn were cut for silage, the nitrate content was so high the silos blew up and the juice that ran out killed every cow, duck, and chicken unfortunate enough to drink it. Even when silos did not explode, the nitrogen-laden corn in them became lethal, in the form of nitrous oxide fumes sufficient to kill a man unsuspectingly breathing it.

The swirl of controversy which broke upon the Illinois cornbelt when the truth became public had already arisen in scientific circles when Dr. Barry Commoner, director of the Center for the Biology of Natural Systems at Washington University in St. Louis, Missouri, presented a prophetic paper on the relation between nitrogen fertilizer and the nitrate level in Midwestern rivers at the annual meeting of the American Association for the Advancement of Science. Two weeks later, a vice-president of the National Plant Food Institute, a lobby whose goal is to protect the interests of the $2-billion American fertilizer industry, sent copies of Commoner's paper for rebuttal to soil experts at nine major universities. Because they had spent most of their careers advising farmers that the best way to insure bountiful crops is to apply artificial fertilizers to the land, many scientists in these centers of academic learning were as irritated at Commoner's allegations as were the fertilizer-lobby officials and rushed to take up cudgels in the lobby's and their own defense.

An exception was Washington University's Dr. Daniel H. Kohl, an expert in the process of photosynthesis, who concluded that the problem was so serious the fate of the planet might be at stake. When he joined Dr. Commoner to ascertain, by isotopic analysis, exactly what was happening to the excess nitrogen fertilizer in Illinois soils, his efforts were immediately and viciously attacked by his departmental colleagues on the grounds that such work was not a proper part of the department's goal of pure research.

Dr. Commoner in his book *The Closing Circle* challenged his aca-

demic colleagues by pointing out that the new technology allowing more corn to be produced on less acreage than before might be a success economically but was ecologically a disaster. Commoner characterized the nitrogen-fertilizer industry in its hurtling dash for profits as one of the "cleverest business operations of all time." Evidence suggests that in the presence of artificial nitrogen, the natural fixation of nitrogen from the air by soil bacteria stops and, as a result, it is increasingly difficult for farmers to give up the use of the artificial product. Like addictive drugs, fertilizer nitrogen creates its own demand, the buyers having been "hooked" on the product.

Dr. William Albrecht, a professor of soil science at the University of Missouri, who, more than a quarter of a century ago was almost single-handedly struggling to stress the importance of healthy soil to crops, animals, and men, states that, with respect to analyzing fodder, cows are more intelligent than people. Regardless of how tall and green forage looks to the eye when grown with an excess of artificial nitrogen, says Albrecht, the cow will refuse it and will eat the surrounding grass shorter and shorter. "Though the cow cannot classify forage crops by variety name, or by tonnage yield per acre, she is more expert than any biochemist at assessing their nutritional value."

Albrecht's years of research were admired by the director of studies of France's National Veterinary School at Alfort, near Paris, Dr. André Voisin. In 1959 Dr. Voisin produced a book, *Soil, Grass and Cancer*, which was translated into English by the secretary of the Irish Agricultural Organization Society and published by New York's Philosophical Library. The thrust of Voisin's important work is that man, in his effort to produce food for an exploding world population, has forgotten that his body comes from soil or, as the Bible put it, "dust and ashes."

Voisin's realization that plants and animals are intimately associated with the soil where they are born was strengthened when he visited the Ukraine and saw that, within a few generations, the giant dappled Percheron draft horses, developed on the soils of a French district south of Normandy, had dwindled to the size of Cossack horses, though their bloodlines had been kept pure by the Soviets and their conformation remained the same, though miniaturized. This should remind us, says

Voisin, that all living things are biochemical photographs of their environment. Our ancestors, he says, were well aware of the fact that the dust of the soil itself is what finally determines vigor and health.

Developing his theme that the soil makes the plant, the animal, and man, Voisin exposed his readers to a fascinating panoply of data which illustrates that animals and plants on the land, not chemists in laboratories, are the supreme judges of agronomic methods. Voisin also provided copious examples to prove that, by itself, chemical analysis of foodstuffs, plants, and soil is wholly insufficient to the evaluation of their essence. Voisin points out that chemists work mainly on "analytical groups," which can be said to be "mere creations of their minds." Noting that farmers have long been given advice on the nutrition of their animals on the basis of certain tests for nitrogen content, Voisin quotes the 1952 Nobel Prize winner in chemistry, R. L. M. Synge, who stated that it was wholly presumptuous in this way to conclude anything about the real nutritive qualities of grass, or human food.

The dean of agriculture at the University of Durham in England was so impressed with Voisin's lecture to the British Society of Animal Production in 1957 that he summed it up for the assembled audience, saying: "As Monsieur Voisin has forcibly explained to us, a herbage which appears ideal to the chemist as judged by his analysis is not necessarily ideal for the cow."

While Voisin was in England, he visited one farm on which the incidence of a disease known as grass tetany afflicting a 150-head herd of cattle was particularly high. Voisin learned from the farm owner that his livestock had been foraging, not on seasoned pastureland, but on new sowings of young grass to which enormous applications of industrial fertilizer, particularly potash, had been applied. Voisin told the farmer that when potash is applied to grass and other forage plants, the plants gorge themselves immediately and indulge in "luxury consumption." This results in an enormous increase of the potash content of the plants in a very short time and diminishes the quantity of other elements absorbed, such as magnesium, the lack of which leads directly to tetany.

When a local veterinary arrived at the farm to care for some of the stricken animals, Voisin asked him whether he knew to what extent his

client had employed potash to fertilize his grazing land. The animal doctor, who had no idea that he was talking to one of the most distinguished French representatives of veterinary science, curtly replied: "This question concerns the farmer. My role is to care for sick animals and to cure them." Voisin was aghast at this stock reply. "I think," he wrote, "that it is not merely a question of healing the animal or man stricken by disease, it is necessary to heal the soil so as not to have to heal the animal or man."

To Voisin it appears that the rise of the artificial fertilizer industry has caused man mechanically and unthinkingly to rely to such an extent on its products that he has forgotten his intimate relationship with the soil as nature made it, that his adulteration of the dust from which he springs may be sealing his destiny on planet earth. Though this predicament is hardly a century old, its progression has been geometric in the proliferation of degenerative diseases in both animal and man consequent on the overuse of artificial fertilizers.

It all started with Baron Justus von Liebig, a famous German chemist who published an essay in 1840, interestingly entitled *Chemistry in Its Application to Agriculture and Physiology.* In this essay he appeared to indicate that everything required by living plants was to be found in the mineral salts present in their ashes once the plants had been incinerated to destroy all the organic matter they contained. Though this theory ran directly counter to centuries of agricultural practice, and indeed to common sense, the visual results of the application of artificial fertilizers composed of nitrogen, phosphates, and potash, together with calcium oxide, or lime, seemed to prove Liebig's theory, and later resulted in the skyrocketing climb of fertilizer production by the chemical industry, of which the figures for Illinois are but one example among thousands.

Dr. Albrecht of the University of Missouri terms this sudden blind dependence upon nitrogen, phosphorus, and potassium, the main constituents of artificial fertilizers, or NPK—as they are known in chemistry—an "ash mentality," since ashes suggest the idea of *death* rather than life. Like a senile yet undeposable king, the ash theory still rules the world's agricultural realms, despite the attack on it by a far-seeing minority of individuals, a group collectively called "organic agriculturalists," who have seized upon Justus von Liebig as the progenitor of what they see as a worldwide cataclysm.

Already at the turn of the century, as the fertilizer industry was getting into stride, a British doctor and medical researcher, Robert McCarrison, later knighted for his thirty years' service as head of the Nutrition Research Agency for the Imperial Government of India, and director of its Pasteur Institute at Coonoor, had come up with a contrary conclusion after spending a period of time working among the peoples of the remote Gilgit Agency, a rugged, mountainous area south of the Wakhand Valley, which is Afghanistan's "tail."

McCarrison was struck by the fact that the Hunzas, an ancient people claiming descent directly from the soldiers of Alexander the Great, not only could walk 120 miles at a stretch in the roughest mountain country in the world, or cut two holes in a winter lake and swim from one to the other under the ice for the fun of it, but, with the exception of an occasional eye inflammation due to badly ventilated fires in their huts, were wholly free of disease and lived to a great age. McCarrison also found the Hunzas' health to be matched by their superior intelligence, wit, and urbanity; though they were numerically few and their neighbors warlike, they were rarely attacked—because they always won.

As neighboring people living in the same climate and geographical conditions were afflicted with many diseases which never appeared among the Hunzas, McCarrison began a comparative study of the dietary practices of Gilgit Agency peoples which he extended to various races all over India. By feeding diverse Indian diets to rats—foolish enough to eat whatever humans will eat—McCarrison found that his rats reflected the conditions of growth, physique, and health of the people eating the same foods. The rats which ate the diets of the peoples such as the Pathans and Sikhs increased their body weight much faster and were much healthier than those ingesting the daily fare of peoples like Kanarese and Bengalis. When offered the food of the Hunzas, which was limited to grain, vegetables, and fruits, along with unpasteurized goat milk and the butter made from it, the rodents appeared to McCarrison the healthiest ever raised in his laboratory. They grew rapidly, were apparently never ill, mated with enthusiasm, and had healthy offspring.

When they were killed and autopsied at twenty-seven months—the equivalent of fifty-five years in humans—nothing whatsoever was wrong with their organs. Most amazing to McCarrison was the fact that throughout their lifetimes they were gentle, affectionate, and playful.

Contrasted to these "Hunza rats" others contracted precisely the diseases of the people whose diets they were being fed and even seemed to adopt certain of their behavioral characteristics. Illnesses revealed at autopsy filled a whole page. All parts of their bodies, from womb and ovary to skin, hair, and blood, and respiratory, urinary, digestive, nervous and cardiovascular systems, were afflicted. Moreover, many of them, snarling and vicious, had to be kept apart if they were not to kill each other.

In laboratory work based on the newly discovered accessory food factors, named *vitamins* in 1921 by the Polish-born American biochemist Casimir Funk, McCarrison was able to prove that pigeons given a diet which in people produces goiter developed polyneuritis. What was surprising to McCarrison was that other healthy birds fed on normal diets harbored the same microbes but did not get ill. McCarrison believed it was the faulty diet which led to the microbic triumph, not the presence of the microbes themselves.

During a lecture to the British College of Surgeons McCarrison described how, in the course of more than two years, his rats fed on the diets of the more vigorous and well-developed Indian races never fell ill. But the *British Medical Journal*, in a leading article on McCarrison's address, concentrated only on the diseases which diet would help to prevent and completely overlooked the astonishing fact that the radiant health of a group of people could be transferred dietarily to a group of rats, simply by diet. Doctors, used to textbook explanations that pneumonia was due to exhaustion, chills, a blow on the chest, the pneumococcus microbe itself, weakness in old age, or other illnesses, were unimpressed with McCarrison's finding that, in every case, his Coonoor laboratory rats had fallen ill with pneumonia because of faulty food. The same was true for diseases of the middle ear, peptic ulcers, and other afflictions.

American medical circles were no more receptive to the basic truth which McCarrison was propounding than their British colleagues. During a Mellon lecture delivered before the Society for Biological Research at the University of Pittsburgh, where McCarrison spoke on "Faulty Food in Relation to Gastro-Intestinal Disorders," they listened impassively as he said of the Hunzas: "Indeed their buoyant abdominal health has, since my return to the West, provided a remarkable contrast with the dyspeptic and colonic lamentations of our highly civilized communities." Then as now, the weight of McCarrison's evidence that Hunzas enjoy a remarkably disease-free and long life failed to mobilize any medical-research expedition to Hunza land. His stunning data were buried in the *Indian Journal of Medical Research.*

Only when a British doctor, G. T. Wrench, brought out a book, *The Wheel of Health,* in 1938 was McCarrison's evidence given broad public exposure. In the introduction to his work Wrench asked thought-provokingly why, as students, young doctor aspirants were always presented with sick or convalescent people for their teaching and never with the ultrahealthy. It was abhorrent to Wrench that medical schools—presuming that knowledge about health in its fullness was picked up by a baby at its birth—taught only disease. "Moreover," wrote Wrench, "the basis of our teaching upon disease is pathology, namely the appearance of that which is dead from disease." Then, as today, it seems the emphasis was on *pathology,* not natural health. Neither Wrench's admonition nor the startling evidence of McCarrison—who after retiring as a major general became physician to King George V—seemed to have any effect on the health authorities of the United States and other countries. In 1949 Dr. Elmer Nelson, in charge of nutrition at the U.S. Food and Drug Administration, was reported by the Washington *Post* to have declared in court: "It is wholly unscientific to state that a well-fed body is more able to resist disease than a less well-fed body. My overall opinion is that there has not been enough experimentation to prove that dietary deficiencies make one more susceptible to disease."

Some time before McCarrison arrived in the Gilgit Agency, Albert Howard, a young mycologist and agricultural lecturer to the Imperial Department of Agriculture at Barbados in the West Indies, concentrating on fungus diseases of sugar cane, came to the conclusion that the

true cause for plant diseases would never be found by researchers sequestered in small laboratories and greenhouses full of flowerpots. As he put it: "In Barbados I was a laboratory hermit, a specialist of specialists, intent on learning more and more about less and less." Because another part of his job was to tour the Windward and Leeward Islands and advise people on how to grow cacao, arrowroot, peanuts, bananas, citrus fruits, nutmegs, and a host of other plants, Howard found that he learned much more from men in actual contact with the land and its abundance than he ever had in his botany classes.

He began to detect a fundamental weakness in the organization of the research into plant pathology. "I was an investigator of plant diseases," he wrote, "but I had myself no crops on which I could try out the remedies I advocated. It was borne in on me that there was a wide chasm between science in the laboratory and practice in the field."

Howard's first big chance to combine theory and practice came in 1905, when he was appointed imperial botanist to the Government of India. In the Bengali town of Pusa, site of the agricultural research station about to be founded by Lord Curzon, then Viceroy to India, Howard decided to see whether he could create, on a seventy-five-acre holding, plants with such health that they would not require poison sprays to resist disease. Howard took as his teachers, not learned plant pathologists, but the natives of the region. He felt that, since the crops grown by cultivators around Pusa were remarkably free of pests, he would make an in-depth study of Indian agricultural practices. As he put it, he "speedily found my reward."

By following the practices of the Indians, who used no pesticides or artificial fertilizers but returned to the land carefully accumulated animal and vegetal wastes, Howard was so successful that by 1919 he had learned "how to grow healthy crops, practically free from disease, without the slightest help from mycologists, entomologists, bacteriologists, agricultural chemists, statisticians, clearing-houses of information, artificial manures, spraying machines, insecticides, fungicides, germicides, and all the other expensive paraphernalia of the modern experimental station."

Howard was further astonished that his herd of work oxen, the ordinary power unit of Indian agriculture, when fed only the produce from his fertile land, never came down with foot-and-mouth disease, rinderpest, septicemia, and other cattle diseases, which frequently devastated herds of the modern experimental stations. "None of my animals were segregated," he wrote; "none were inoculated; they frequently came into contact with diseased stock. As my small farmyard at Pusa was only separated by a low hedge from one of the large cattle-sheds on the Pusa estate, in which outbreaks of foot-and-mouth disease often occurred, I have several times seen my oxen rubbing noses with foot-and-mouth cases. Nothing happened. The healthy, well-fed animals failed to react to this disease exactly as suitable varieties of crops, when properly grown, did to insect and fungous pests—no infection took place."

Howard recognized that the entire basis for eliminating disease in plants and animals was the fertility of the soil and that the first prerequisite for all subsequent work was the bringing of the whole Pusa experiment station to the highest state of fertility. To do this he determined to copy the age-long practices of China and build a large-scale system for utilizing farm wastes to turn them into humus.

Unfortunately, while the idea was taking shape in his mind, the Pusa agricultural research organization had developed to the point where, as Howard saw it,

> A series of watertight compartments—plant breeding, mycology, entomology, bacteriology, agricultural chemistry and practical agriculture—had become firmly established. Vested interests were created which regarded the organization as more important than its purpose. There was no room in it for a comprehensive study of soil fertility and its many implications by one member of the staff with complete freedom of action. My proposals involved "overlapping," a defect which was anathema both to the official mind (which controlled finance) and to a research institute subdivided as Pusa always had been.

Howard therefore laboriously collected funds to found a new center, the Institute of Plant Industry, at Indore, three hundred miles northeast of Bombay, where he had complete freedom of action. Since the fundamental prerequisite for growing cotton, the principal commercial crop around Indore, was raising soil fertility, Howard was in his element. He

accordingly developed what came to be known as the "Indore process" of humus production. Within a short time he found not only that the yields of his cotton were three times those of the surrounding countryside but that the cotton was remarkably free of diseases. "These results," Howard later wrote, "were progressive confirmation of the principle I was working out—the connection between land in good heart and disease-free crops; they were proof that as soon as land drops below par, disease may set in." Howard was firmly convinced that the two most important goals were to keep the texture of his soils right and not to overwork his land beyond a volume of operations for which it had sufficient natural reserves.

Based on his findings, Howard wrote a book, *The Waste Products of Agriculture: Their Utilization as Humus*, which was greeted with favorable and even enthusiastic reviews around the world. But, when the book was circulated to agricultural scientists working on cotton problems in research stations all over the British Empire, the reception was hostile and even obstructive. This was because Howard's successful methodology challenged the ingrained beliefs that *breeding methods alone* could improve cotton yields and the quality of plant fibers, and disease was to be reduced by *direct assault with pesticides*.

Furthermore, the time factor was ridiculed. How could one possibly waste several years bringing the land back into what Howard called "good heart"? This would demand the abandonment of chemical fertilizers and the time-consuming production of Indore compost, a mixture of decaying animal and plant matter at a ratio of three to one. Howard clearly saw the threat he posed to the established order: "The production of compost on a large scale might prove to be revolutionary and a positive danger to the structure and perhaps to the very existence of a research organization based on the piecemeal application of the separate sciences to a complex and many sided biological problem like the production of cotton."

Research workers on many other crops throughout the Empire took the same dour view as that of the cotton specialists and they were strongly supported by the moguls of the burgeoning artificial fertilizer and pesticide industries.

When Howard went home to England at the end of 1935, he was invited by the students of the School of Agriculture at Cambridge University to address them on "The Manufacture of Humus by the Indore Method." Because he had distributed printed copies of his remarks beforehand in order to insure that a lively discussion would follow his lecture, practically the whole staff of the school was present when he mounted the lecture platform. But since he had been so consistently attacked by plant specialists in England, India, and other parts of the world, it was no surprise to Howard that nearly all of the school's faculty from chemists to plant breeders to pathologists heatedly opposed his remarks. Only the student body seemed enthusiastic and, as Howard recalled, vastly amused at finding their teachers on the defensive and vainly endeavoring to bolster up the tottering pillars supporting their temple. "Here again I was amazed by the limited knowledge and experience of the world's agriculturists disclosed by this debate. I felt I was dealing with beginners and that some of the arguments put forward could almost be described as the impertinences of ignorance." It was obvious from this meeting that little or no support for organic farming would be obtained from the agricultural colleges and research institutes of Great Britain.

Howard was correct. When later he read to the British Farmers' Club a paper on "The Restoration and Maintenance of Fertility," representatives of experimental stations and of the fertilizer industry in the audience poured ridicule on his ideas. To their protestations Howard replied that he would shortly have his answer "written onto the land itself." Two years later Sir Bernard Greenwell, who had meticulously followed Howard's directions on his two estates, gave an account to the club which more than bore out Howard's findings. But the scientists and the fertilizer salesmen, knowing that success was the one unanswerable argument in favor of organic farming, failed to attend the lecture.

Despite the truculence of these vested interests, Howard, like McCarrison, was knighted by the British Crown for his achievements. Yet only a few sensible individuals began to follow his lead. One of these was Lady Eve Balfour, who since childhood had suffered bad bouts of rheumatism and continual head colds each winter from November to April. Learning

of Howard's research just before World War II, she initiated an Indore-type operation on her own farm at Haughley in Suffolk. Instead of bakers' loaves she ate bread made only from whole-grain flour ground from her own compost-benefited wheat. During the winter following the change in her overall diet, she was entirely free from colds for the first time in her life and was no longer bothered with rheumatic pains in prolonged periods of cold, damp weather.

During the war, Lady Eve's book *The Living Soil* appeared in heavily rationed England. The result of long detective work in libraries and interviews with health specialists who were convinced of the soundness of Howard's and McCarrison's views, it amassed a compendium of scattered data on the links between humus-grown plants and the health of animals and humans fed upon them. Lady Eve compared man's prideful "conquest of nature" with the conquest of Europe taking place under the Nazis. "As Europe is in revolt against the tyrant," she wrote, "so is nature in revolt against the exploitation of man."

Lady Eve soon discovered that her piglets, attacked at the age of one month by a disease called white scour, which the textbooks explained was due to iron deficiency, and for which accordingly they recommended doses of chickweed or other plants rich in that element, could be cured equally effectively by being fed actual soil from fields rich in humus to which no chemical fertilizers had been applied, whereas soil from land "exhausted" from the application of fertilizers had no effect upon the disease's progress.

About the same time Friend Sykes, a British farmer and breeder of thoroughbred horses, attracted by Howard's ideas, bought a 750-acre derelict farm in Wiltshire at nearly one thousand feet altitude, overlooking the Salisbury Plain, on which the land had been completely farmed out. Sykes's previous experience as an agricultural consultant had taught him that specialized farms, on which only certain crops or one variety of animals were raised, resulted in the inevitable weakening of stock and plants by disease. He came to see that outbreaks of disease could be completely eradicated by an "enlightened practice of good husbandry," particularly the introduction of mixed agriculture.

A student of ecology long before the subject became a household word, and an opponent of DDT more than ten years before Rachel Carson shocked the world with her *Silent Spring*, Sykes wrote in his *Food, Farming and the Future*, published in 1951: "The first thing that Nature does when she has been treated with poison is to battle against it and try to breed a resistant strain of the form of life that is being attacked. If the chemist persists in his poisonous methods, he often has to invent more and stronger poisons to deal with the resistance that Nature sets up against him. In this way, a vicious cycle is created. For, as a result of the conflict, pests of a hardier nature and poisons still more powerful are evolved; and who is to say that, in this protracted struggle, man himself may not ultimately be involved and overwhelmed?"

Sykes's experience with his crops, based on his intuition that the soil had a *latent fertility* which could be brought out simply by being tended, and without the application of any fertilizer whatsoever, was little short of fantastic. Sykes had the soil on one twenty-six-acre field analyzed. The laboratory report indicated severe deficiencies of lime, phosphate, and potash and appended a recipe of artificial fertilizers to correct the condition.

Ignoring the report, Sykes simply plowed and harrowed his field and, *without adding any fertilizer*, sowed oats. To the amazement of his neighbors he got a crop yielding ninety-two bushels per acre, which was followed by an equally successful crop of wheat. After tilling the soil again throughout the summer, he again sent a sample of it to the laboratory and found that only a deficiency of phosphorus remained, the lime and potash having been completely restored. In spite of the unanimous views of experts that cereal crops could not be successfully grown without a heavy dressing of phosphates, Sykes merely subsoil plowed the acreage and achieved a harvest of wheat larger than the first one. Subsoil plowing digs deeper into the ground and aerates this otherwise packed and useless earth. When Sykes ordered his subsoiler plow in Chantry, the agent who took his order said: "What on earth do you want a tool like that for in this God-forsaken country? My firm has been in business over a hundred years and has never supplied such an implement before." Sykes's wheat crop, which had been undersown with rye grasses and clover, produced two and a half tons of hay to the acre in one cut the

following year. Sykes then replowed his land, planted it to oats, and was rewarded with a crop yielding over one hundred bushels to the acre. A third laboratory analysis of his soil showed no deficiencies whatsoever.

Sykes described this procedure in an essay, "Farming for Profit with Organic Manures as the Sole Medium of Re-Fertilization," in which he concluded that he had made his livestock healthy, his plants disease free without poison sprays, and had been able to plant the same varieties of wheat, barley, and oats from their seeds six consecutive years in a row although other farmers had had to make changes.

Having achieved among his other successes a reversal of the trend in seed degeneration which has led to increasing dependence by farmers on hybrid varieties that are of questionable nutritional value, Sykes teamed with Lady Eve Balfour and others to form the Soil Association, the principal object of which was to unite people, of whatever country, working for a fuller understanding of the vital relationships among the soil, plants, animals, and man. Its philosophy centered on the idea that, when quality is sacrificed to quantity, total food supply diminishes.

The Soil Association began a research project on land donated in Suffolk, the referees for which stated:

> Humanity has been badly frightened by the invention of the atomic bomb. Yet the slower but more widespread devastation wrought by exhausting the soil upon which we depend for subsistence, is ignored by the majority of people, who think of calamity only in terms of disaster or war. Wasteful exploitation of the soil's fertility is due in part to the desire for quick cash returns, but in a greater degree to ignorance. Many scientists and agriculturalists now realize that their knowledge of the natural processes underlying soil fertility is incomplete. They recognize that these processes are only partly explicable in terms of agricultural chemistry and that the purely inorganic approach to the study of soil science is a line of thought as dead as the mechanical determination of nineteenth-century physics. "Dead" is the appropriate word; for the missing factor is that of life itself.

Shortly before the organization of the Soil Association in Britain, J. I. Rodale, editor of a health magazine in Pennsylvania, also came across the work of Sir Albert Howard. "To say I was stunned," wrote Rodale afterward, "would be a definite understatement. Surely the way food is grown has something to do with its nutritional quality. Yet this theory had not found its way into the articles of any of the health magazines I was reading. To physicians and nutrition specialists carrots were carrots were carrots." In 1942 Rodale bought a farm of his own in Emmaus, Pennsylvania, and set about publishing Sir Albert Howard's book, *An Agricultural Testament.* He then launched a journal, *Organic Gardening and Farming,* which today, after three decades of growth, has some 850,000 subscribers. A companion magazine to enlighten the public on the links between health and organically grown foods, called *Prevention,* was started by Rodale in 1950 and now circulates to over one million readers increasingly anxious about the quality of American food.

For his efforts in fighting for integrity in foods Rodale was harassed by the U.S. Federal Trade Commission, which sought to stop the sale of his book *The Health Finder* because it was advertised as being able to "help the average person to remain comparatively free of many terrible diseases." Rodale fought the case in court in a battle which cost him nearly a quarter of a million dollars. He won hands down but was not able to sue the government to recoup his losses.

Rodale's campaign began to challenge the usual view of people living in the cities and suburbs of the United States—and this is the vast majority—that soil is a static, inert substance. He challenged the use of the word *dirt* as a synonym in English for *soil.* The former is used to mean something mean, contemptible, or vile, whereas soil is alive and clean.

Below its surface the earth teems with organisms. Earthworms, called *Annelida* after the Latin word for rings, because they are made of one hundred to two hundred ringlike segments, each an independent miniature body, burrow in the ground to depths of more than the height of a tall man, acting as nature's plow, eating the soil as they move, ejecting it again as castings to produce rich topsoil. Called by Aristotle the "intestines of the soil," they could also be considered its vascular system, since, when they are lacking, soils get hard-packed as if their arteries had hardened.

In 1881, a year before his death, Charles Darwin brought out a book, *The Formation of Vegetable Mould through the Action of Worms,* in

which he made the statement that, without worms, vegetation would degenerate to the vanishing point. He estimated that in a single year more than *ten tons* of dry earth per acre passed through the digestive systems of earthworms and that in a field well populated with them *one inch* of topsoil would be created *every five years.* Darwin's earthworm book moldered on the shelf for fifty years before it was re-examined; even then his ideas did not penetrate into the curricula of the agricultural schools, and it is not realized that with heavy application of chemical fertilizers and pesticides, a field can lose its entire earthworm population, so important for keeping it in a state of health necessary to the production of nutritious crops.

The favorable action of earthworms is often mocked, though in an experiment run about 1950 their ability to improve poor soil was definitely demonstrated. Twenty barrels were filled with impoverished soil and planted with grass. Half the barrels contained live, the other half dead, worms so that all shared identical amounts of organic matter. Each barrel was treated with an equal amount of organic fertilizer. The barrels with the live worms produced four times as much grass.

Just after World War I, Dr. William Beebe, first to explore the ocean in a bathysphere, decided after a bird-collecting expedition in Brazil that he needed something to do on the sea journey back to New York: so he decided to examine jungle soil. Working on shipboard with a magnifying glass and an old bag of earth mold and decaying leaves, Beebe found himself plunged into a strange world of miracles. By the time he reached New York Harbor Beebe had discovered in his soil over five hundred separate specimens of life; he believed that more than twice as many remained to be identified.

If Beebe had resorted to the microscope, and thus come across bacteria, he would have been helpless to count them. Sir E. John Russell, in his book *Soil Conditions and Plant Growth,* says that in one tiny gram of soil treated with farmyard manure there are some twenty-nine million bacteria; however, where chemical fertilizers were used, the number was cut almost in half. In an acre of rich earth, bacteria are estimated to weigh more than a quarter of a ton; as they die, their bodies become converted to humus, enriching the soil in a natural way.

In addition to bacteria are myriads of other microscopic organisms:

actinomycetes, filamentous forms resembling both bacteria and fungi; tiny algae, related to seaweeds; protozoa, animals made up of a single cell apiece; and the strange chlorophyll-less fungi themselves, ranging from one-celled forms to branched bodies, including yeasts, molds, and mushrooms.

The vegetative part of one kind of fungus associates with the roots of many green plants in a way beneficial to both that is still mysterious. Though it seems to have escaped the attention of many agricultural scientists, these fungi, called "mycorrhizae," were discovered by Dr. M. C. Rayner in England to have their threads consumed by tree roots with which they were associated. Traveling in France, Sir Albert Howard found that the roots of the healthiest vines for wine grapes were rich in mycorrhizae. No artificial fertilizers had ever been used on the vines, yet they were noted for the high quality of their wines.

Another great advantage of natural agriculture, well known to yesterday's farmer, has been forgotten in the highly specialized mono-crop agriculture of today: the advantage of symbiosis in plants. As the Russian essayist Vladimir Soloukhin has pointed out in *Grass*, modern Soviet agronomy has lost all feeling for the benefits of plant companionships. Though the specialists mock the idea that cornflowers growing in a field of waving rye have a salubrious effect on this cereal crop and consider the blue-blossomed plants—known to Americans as bachelor's buttons—as only noxious weeds, Soloukhin asks: "If the cornflower were an evil weed, would not the farmers of the world have grown to hate it before the appearance of the learned agronomists?"

How many botanists, asks Soloukhin, realize that the first sheaf of rye harvest was lovingly decorated with a cornflower wreath and placed in front of an icon, or that cornflowers were held by country folk to supply bees with abundant nectar for honey even in the driest weather? Suspecting that all this folk wisdom had a solid basis in fact, Soloukhin checked in scientific literature and found evidence supporting the accuracy of peasant intuition. He read that if a hundred wheat grains are mixed with twenty seeds from the ox-eye daisy the sprouting wheat will be overwhelmed, but that if only one daisy seed is added, the wheat will grow better than if no daisies come up in its field. The same is true for rye and cornflowers.

Soloukhin's view on plant symbiosis supports that of an American professor of botany and conservation, Dr. Joseph A. Cocannouer who, while Sir Albert Howard was working in India, ran the Department of Soils and Horticulture at the University of the Philippines for a decade and set up an extensive research station in Cavite province. In his book *Weeds: Guardians of the Soil*, published nearly a quarter of a century ago, Cocannouer sets forth the thesis that, far from being harmful, plants usually considered noxious and troublesome, such as ragweed, pigweeds, purslane, and nettles, bring up minerals from the subsoil, especially those which have been depleted from the topsoil, and are excellent indicators of soil conditions. As companion crops they help domesticated plants to get their roots down to food which would otherwise be beyond their reach.

Writing of the "law of togetherness of all things," Cocannouer warned that the whole of world agriculture was beginning to ignore it. "In America," he wrote, "in our frenzied efforts to take advantage of high prices for agricultural products, we are mining our soils instead of farming them." The same was beginning to be true of Europe, he added, where, since World War II, few farmers have been practicing the *law of return*.

Farmers are becoming more and more mechanical-minded, says Cocannouer, one of whose best friends told him: "You and your Nature stuff! That's all very well in theory . . . but starving people are looking to America for food. We've got to feed 'em. We've got to mechanize our agriculture and make our land produce to its limit!"

Today, Americans live in a country where food production is supposed to be the world's most efficient. Yet food prices have continued to rise. The cliché holds that back in 1900 one U.S. farmer could feed only five people besides himself and that today he can feed thirty. But Michigan University food scientist Georg Borgstrom says these mathematics are illusory. At the turn of the century farmers, in addition to working their land and raising livestock, delivered their own milk, butchered their own animals, churned fresh farm butter, salted meat, baked bread, and farmed with draft animals for which they produced feed. Now these draft requirements are fulfilled by expensive machinery using increasingly costly and depletable fossil fuels, and the husbandman's arts have been taken over by factories. In less than twenty-five years several million poultry raisers, whose chickens roamed the land ingesting all sorts of natural vegetable and mineral products as well as insects, have disappeared, to be replaced by some six thousand semiautomated outlets where broilers, packed wing to wing in cages, are fed diets full of artificial supplements.

All these off-farm activities figure in the high cost and dubious quality of food. In fact, if one divides the twenty-two million workers building farm machinery and farm-to-market roads, delivering and processing farm produce and engaged in other food-production tasks, it becomes clear that it takes about the same number of people to feed Americans today as it did in 1900.

Cocannouer nevertheless realized that the views of his nature-scoffing friend were bound to prevail. He was in despair that no publicity had been given Luther Burbank's firm belief that all agricultural learning should begin with a study of nature.

Now there are signs that the agricultural worm may at last be turning and that university scientists are beginning to wake up to the views propounded long ago by McCarrison, Howard, and Rodale. As if they were discovering something new, Drs. Robert F. Keefer and Rabindar N. Singh, agricultural researchers at West Virginia University in Morgantown, issued a press release on March 4, 1973, to the effect that "what man eats is determined partly by the fertilizer that farmers put on their crops." In their experiments the two professors say that they have determined that the amounts of trace elements in sweet and fodder corn, so important in the diets of animals and humans, are dropping dramatically owing to the kinds and amounts of fertilizers grown in some soils.

Their somewhat belated rediscovery of this basic truth has also reinforced a survey conducted in eleven Midwestern states, where it was found that the iron, copper, zinc, and manganese content in corn has fallen off severely in the past four years. The application of huge doses of nitrogen fertilizer such as that which has alarmed the citizens of Illinois, may, says Singh, "have far-reaching effects on the health of animals and men." He adds that work of another of his West Virginia

colleagues shows that fertilization of pastures with high rates of nitrogen may produce changes in the milk of grazing animals, as revealed by feeding it to rats.

In light of the findings of such pioneers as McCarrison, Howard, Albrecht, Voisin, Sykes, and Lady Eve Balfour, the West Virginia professors' research comes very late in the day, and their caution seems somewhat ludicrous in the face of mounting rates for degenerative diseases in the United States.

It is a strange fact that U.S. medical schools, concerned mainly with the study of diseased tissues and bodily systems and organs rather than with healthy people, do not even have a single fundamental course on nutrition in their curricula.

CHAPTER 15

Chemicals, Plants and Man

In the early nineteenth century an American of English descent named Nichols cleared hundreds of acres of rich virgin land in South Carolina, on which he grew crops of cotton, tobacco, and corn so abundant that with the revenue he built a big house and educated a large family. Not once in his lifetime did he add anything to the soil. When it became depleted and his crops dwindled, he cleared more land and continued his exploitation. When there was no more land to be cleared the family fortunes declined.

Nichols' son, grown to manhood, looked at the poverty-stricken acreage, took Horace Greeley's advice and moved west to Tennessee, where he cleared two thousand acres of virgin land; like his father he planted cotton, corn, and tobacco. When his own son was grown to manhood, the land was once more so depleted from having living things taken from it and none returned that he moved on to Horse Creek in Marengo County, Alabama, there to purchase another two thousand acres of fertile soil and raise a family of twelve children on the proceeds; the town became Nicholsville; Nichols became the owner of a sawmill, a general store, and a gristmill. This man's son also grew up to see devastation where his father had grown rich. He decided to move further west and settled in Parkdale, Arkansas, where he bought one thousand acres of good land on the bayou.

Four moves in four generations. Multiplied by thousands, this is the story of how Americans raised food on a continent which was there for the taking. The great-grandson of the original Nichols, together with thousands of other farmers, inaugurated a new era. After World War I he began by farming his new acreage, instead of just mining it, adopting the new government-recommended artificial fertilizers. For a time his cotton crops prospered, but soon he noticed that his pest population was much worse than it had been. When the bottom fell out of the cotton market his son Joe decided that medicine, not farming, was to be his career.

At the age of thirty-seven Joe Nichols was a full-fledged physician and surgeon in Atlanta, Texas, when he suffered a massive heart attack which nearly killed him. He was so frightened that for weeks he gave up his practice to consider his situation. All he had been taught in medical school, plus the opinions of his colleagues, suggested his prognosis was extremely doubtful. There was no answer for his affliction beyond nitroglycerin pills, which alleviated his chest pains but caused equally painful headaches. With nothing better to do than to leaf through the ads of a farming magazine, Nichols casually came across the line "People who eat natural food grown in fertile soil don't get heart disease."

"Pure quackery! Quackery of the worst sort," said Nichols of the magazine, which was *Organic Gardening and Farming,* edited by J. I. Rodale. "He isn't even a doctor!"

Nichols remembered that for lunch on the day of his massive heart attack he had consumed ham, barbecue meat, beans, white bread, and pie, which he considered a healthy meal. As a doctor he had advised hundreds of patients on diet. But a line in the magazine nagged him: What *was* natural food? What *was* fertile soil?

At the local library the librarians were helpful in bringing Nichols books on nutrition. He also scoured the medical literature, but could find no answer to what constituted natural food.

"I had an A.B. and an M.D. degree," says Nichols, "was fairly intelligent, had read a lot, owned a farm, but I didn't know what was natural food. Like many another American who hadn't really investigated the subject, I thought natural food meant wheat germ and black molasses, and that all natural-food addicts were faddists, quacks, and nuts. I thought you made land fertile by dumping commercial fertilizer on it."

Now, more than thirty years later, Joe Nichols' thousand-acre farm near Atlanta, Texas, is one of the showplaces of the state; he has never again been afflicted with a heart attack. He ascribes both successes to the advice which he took from Sir Albert Howard's book *Agricultural Testament* and Sir Robert McCarrison's *Nutritional and Natural Health.* On his farm, not another ounce of chemical fertilizer went into the land, nothing but natural compost.

Nichols realized that all his life he had been eating "junk food," food produced from poisoned land, food that had led straight to a massive heart attack. A third book, *Nutrition and the Soil* by Sir Lionel J. Picton, convinced him that the answer to metabolic disease, whether it was heart trouble, cancer, or diabetes, was indeed natural, poison-free food grown on fertile soil.

The food we eat is digested and absorbed from the intestine into the bloodstream. Essential nutrients are carried to the individual cells all over the body, where repair work is done by metabolism, the process by which stable nonliving matter is built up into complex and unstable living material, or protoplasm. The cell has an amazing capacity to repair itself provided it gets proper ingredients through proper nutrition; otherwise it becomes stunted or goes out of control. The cell, or basic unit of life where metabolism occurs, needs essential amino acids, natural vitamins, organic minerals, essential fatty acids, unrefined carbohydrates, and several more as yet unknown, but presumably natural, factors.

Organic minerals, like vitamins, are found in balanced proportions in natural food. The vitamins themselves are not nutrients, but substances without which the body cannot make use of nutrients. They are parts of an extremely complex, intricately interrelated whole.

In "balance" means that all the nutrients used by the tissues must be available to the cell simultaneously. Furthermore the vitamins essential to proper nutrition and good health must be natural. There is a great difference between natural and synthetic vitamins, not a chemical but a biological difference. There is something missing in the artificial that is of biological or life-enhancing value. Not yet widely accepted, this fact has been unequivocally established by the work of Dr. Ehrenfried Pfeiffer, a biochemist and follower of the great natural scientist and clairvoyant Rudolf Steiner. Dr. Nichols thinks the Pfeiffer techniques can reveal exactly why natural foods or those containing natural vitamins and minerals and enzymes—another chemical compound, of vegetable or animal origin, which causes chemical transformation—are superior to those grown and preserved with chemicals.

When Pfeiffer came to the United States at the outbreak of World War II, and settled at Three-Fold Farm in Spring Valley, New York, he worked out Steiner's "Biodynamic" system for making composts and for treating the land, and set up a laboratory to investigate living things without breaking them into chemical constituents.

Before his arrival in the United States Pfeiffer had developed in his native Switzerland a "sensitivity crystallization method" to test finer dynamic forces and qualities in plants, animals, and humans than had thus far been detectable in laboratories. Dr. Steiner, who had given a series of esoteric lectures at the Silesian estate of Count Keyserling in the 1920s for agronomists concerned about the falling productivity of their crops, had asked Pfeiffer to find a reagent which would reveal what Steiner called "etheric formative forces" in living matter. After months of tests with Glauber's salt, or sodium sulfate, and many other chemicals, Pfeiffer discovered that if a solution of copper chloride to which extracts of living matter had been added was allowed to evaporate slowly over fourteen to seventeen hours it would produce a crystallization pattern determined not only by the nature but by the quality of the plant from which the extract was taken. According to Pfeiffer, the same *formative forces* inherent in the plant and acting to bring about its form and shape would combine with living growth forces to form the pattern of crystal arrangement.

Dr. Erica Sabarth, current director of the Pfeiffer-established laboratory in Spring Valley, showed the authors rows of beautiful crystallizations, looking like exotic undersea corals. She pointed out how a strong, vigorous plant produces a beautiful, harmonious, and clearly formed crystal arrangement radiating through to the outer edge. The same crystallization made from a weak or sick plant results in an uneven picture showing thickening or incrustation.

Pfeiffer's method, says Sabarth, can be applied to determine the inherent quality of all sorts of living organisms. When a forester sent Pfeiffer two seeds taken from different pine trees, and asked if he could detect any difference in the trees themselves, Pfeiffer submitted the seeds to his crystallization tests and found that, whereas one crystal picture was an example of harmonious perfection, the other was distorted and ugly. He wrote to the forester that one of the trees should be a fine specimen, the other must have a serious defect. By return mail the forester sent Pfeiffer enlarged photographs of two grown trees: the trunk of one was mast straight; the other was so crooked it was useless for lumber.

At Spring Valley Pfeiffer developed an even simpler and less time-consuming method to demonstrate how life veritably pulsates from living soils, plants, and foods, but not from inorganic minerals, chemicals, and synthetic vitamins, which are dead. Requiring none of the complex equipment of the standard chemical laboratory, it uses circular filter-paper discs fifteen centimeters in diameter, provided with a small hole in the center for insertion of a wick. The discs are laid in open petri dishes in which stand small crucibles containing a 0.05 silver-nitrate solution. This solution climbs up through the wick and spreads over the discs until it has expanded about four centimeters from the center.

From the brilliant-colored concentric patterns Pfeiffer has been able

to disclose new secrets of life. Testing natural vitamin C taken from such products as rose hips, he established that the pattern of vitality was far stronger than from artificial vitamin C, or ascorbic acid. Rudolf Hauschka, a follower of Rudolf Steiner, suggests that vitamins are not chemical compounds that can be synthetically produced but "primary cosmic formative forces."

Before his death, Pfeiffer pointed out in his own booklet *Chromatography Applied to Quality Testing* that Goethe had stated a truth more than 150 years ago which is of the utmost importance with regard to the recognition of natural biological quality: *The whole is more than the sum of its parts.* "This means," wrote Pfeiffer, "that a natural organism or entity contains factors which cannot be recognised or demonstrated if one takes the original organism apart and determines its component parts by way of analysis. One can, for instance, take a seed, analyse it for protein, carbohydrates, fats, minerals, moisture and vitamins, but all this will not tell its genetic background or its biological value."

In an article, "Plant Relationships as Made Visible by Chromatography," published in the winter, 1968, issue of *Bio-Dynamics,* a periodical to further soil conservation and increase fertility in order to improve nutrition and health, Sabarth stressed that the chromatographic technique "especially reveals the quality, even the living force of the organism." She added that she plans to explore the possibilities of the method not only as it applies to seeds and fruits but with regard to the roots of plants and all the other plant parts.

In modern processed foods the vitamins, trace elements, and enzymes are arbitrarily removed, mostly so as to render the food more durable. As Nichols puts it: "They remove the life, in effect, killing it, so that it will not live and die later."

The leading culprits in the way of poisonous foods picked by Nichols are the bleached flour that goes into white bread, white sugar, refined table salt, and hydrogenated fats. One of the most innocent-looking of comestibles, the normal soda cracker eaten with soup, contains all of the above-mentioned noxious elements. "It is junk," says Nichols, "which leads straight to heart disease."

From long before the so-called dawn of history bread has been a basic nutrient for man. In mythology, the origin of domesticated grains is attributed to Attis or Osiris. In the ruins of Swiss lake dwellers remains of bread have been found which was baked at least ten thousand years ago.

A grain or berry of wheat consists basically of a hard nutty kernel called the germ at one end, a nub of solid starchy endosperm on which the kernel feeds when planted as a seed until its roots can grow, and three layers of protective husk collectively called bran. Essential enzymes, vitamins and minerals, including iron, cobalt, copper, manganese, and molybdenum are in the germ and husk. Other grains—barley, oats, rye, corn—have analogous constructions, and bread can be made from all of them. Wheat germ is one of a very few places in nature in which the entire vitamin B complex is found, hence bread was called "the staff of life." Whole wheat also contains traces of barium, a shortage of which in the human body can lead to cardiac disease, and vanadium, also essential to the health of the heart.

From time immemorial wheat berries have been ground between two circular stones. Until the advent of steam power the mills were worked by hand, the first steam mill being erected in London in 1784. In stone mills, the entire grain was ground into flour. In that process some of the husk was reduced to powder, which gives color to whole meal. In Deuteronomy 32, verse 14, man is enjoined to eat "the fat of the kidney of wheat"—meaning the germ. The development of iron rollers, by a Frenchman in the early nineteenth century, brought with it a separation of wheat germ, bran, and endosperm. Iron rollers were first used in place of stones in 1840 by the Hungarian Count Szechenyi in his mill in Pest. In 1877 a satisfactory roller mill was imported from Vienna to England. Soon they were employed in Canada. Governor Washburn of Minnesota, a miller, brought the Hungarian process to Minneapolis and began to devitalize American flour. By 1880 their use was universal.

From a commercial point of view the roller mill had three advantages over the old grinding stones. By separating the husk and germ from the starchy flour, the miller had two products for sale instead of one. The husk and germ were sold as "offal," or animal fodder. Removal of the germ made it possible to keep the flour in good condition for a much

longer time, which increased the miller's profit. When the roller mill was introduced it became possible to adulterate wheat with 6 percent of added water. For this the germ had to be removed or the flour would not keep. It could then be sold separately.

In so-called "enriched" white bread, with the vitamins and minerals removed, nothing is left but raw starch, which has so little nutritive value that most bacteria won't eat it. Into this insipid starch synthetic chemicals are arbitrarily injected, which form only part of the missing vitamin B complex, and are not properly ingestible by human beings because they are not "in balance." For thirty years white flour was bleached with nitrogen trichloride, in what is known as the "agene process." This uses a poison which affects the central nervous system. It gives puppies fits, and may contribute to mental illness in humans. In 1949 millers voluntarily changed to chlorine dioxide for bleaching. This, says Nichols, is also a poison. Other chemicals used to "improve" flour include benzoyl peroxide, potassium bromate, ammonium persulfate, and even alloxan. Chlorine dioxide destroys the remaining vitamin E in flour, and causes the starch to swell, which is a boon to the baker. Researchers in England found that removal of the natural vitamin E from bread reduces the intake of a workman from about a thousand units a day to between two and three hundred.

To compound this trouble, just as white flour was being introduced into England so was margarine, the invention of another Frenchman, as a cheap substitute for butter, devoid of vitamins A and D. The general health of the country deteriorated. Men from northern England and southern Scotland, large and powerful during the Napoleonic Wars, became short and frail and unfit for military service by the time of the Boer War. A commission set up to investigate the phenomenon concluded it was caused by men moving to the cities, where they lived not on wholesome country bread but on white bread and white sugar. In 1919 when the U.S. Public Health Service announced a definite connection between overrefined flour and the diseases of beri-beri and pellagra—vitamin-deficiency diseases of which over 100,000 cases were reported in Mississippi alone—the millers went into action, not to change the flour, but to get the Public Health Service to shut up. Within six months the Public Health Service abjectly issued a "correction" to its bulletin. White bread, they said, was perfectly wholesome—if eaten in conjunction with an otherwise adequate diet of fruit, vegetables, and dairy products. As Gene Marine and Judith Allen were to remark in reporting the story in their recent book *Food Pollution:* "So is cardboard."

The next villains in this melodrama of life are white sugar and glucose, the heavy syrup fruits are packed in and the sweetener for most soft drinks. In the seventeenth century, European manufacturers developed a process by which after eight weeks of hard labor sugar could be refined to something approximating whiteness. This whiteness, at first so expensive, caused white sugar to be considered by the poor more worthy of being consumed. White sugar, says Nichols, is one of the most dangerous food items on the market. All the good part, the molasses, the vitamins, and minerals, are removed. There is nothing left but carbohydrates and calories—of which we have too many already. The refining is now done for purely commercial reasons; the sugar keeps better. White sugar can be stored in hundred-pound cloth sacks for years in dirty warehouses and still be sold for a profit.

Most table syrup, says Nichols, is nothing but cornstarch treated with sulfuric acid, then artificially colored and flavored. Unlike natural fruit sugars, honey, molasses, or maple syrup, it goes straight into the bloodstream, causing instant hyperglycemia—or too much sugar in the blood. This drowns the human cells in sugar. The pancreas, heeding the alarm, puts out too much insulin and produces a state of hypoglycemia, or *too little* sugar in the blood. This seesawing, says Nichols, is the cause of the vicious but ubiquitous coffee break: when a man begins his day with refined sugar in his coffee and glucose on his cereal or pancakes, he shoots his blood full of sugar, which triggers a pancreas reaction. By ten o'clock he has hypoglycemia; so he has sweetened coffee or a soft drink or a candy bar. This fills his blood with instant sugar. Again the pancreas reacts. By noon he is down again; and so on throughout the day. A side effect of hypoglycemia is that it causes a lowering of resistance, makes a person nervous and not mentally alert, an easier prey to viral and bacterial diseases.

One of the less-suspected poisons on the dining-room table is com-

mon refined salt or sodium chloride. Not in small doses, but over a long period, it can cause high blood pressure and heart disease. Sea salt contains trace minerals in balance, but by the time the salt hits the supermarket it has been refined to pure sodium chloride with all trace minerals removed. Furthermore it is treated under high heat with sodium silicate, a drying agent, which makes it free flowing in wet weather. This, says Nichols, disturbs the delicate balance of sodium and potassium in the cells of the heart. The delicacy of chemical combinations is such that if the two basic elements of table salt were to be taken separately in the same amounts, they would kill immediately.

The next and even more vicious cause of heart disease, says Nichols, is hydrogenated fats. These include most of the fats and oils commonly found in shortening, in store-bought peanut butter, and in practically all commercial bakery products, crackers, cookies, and breads. Much ice cream is made from mellorine, a cheap hydrogenated oil. Hydrogenation consists in using a heated nickel catalyst to force hydrogen into the gaps between the carbon atoms of linoleic acid. This prevents the resulting fatty oil from going rancid; but it also destroys essential fatty acids. These, says Nichols, not being absorbable by the body cells, have to go somewhere in the body, and end up lining the blood vessels, causing heart disease.

DDT and other pesticides also go straight to the seed oil of corn or cotton. There is no way to remove them, and they are cancer causing. Though DDT has largely been banned, its successors Dialdrin, Aldrin, and Heptaclore, are equally insidious. "Personally," says Nichols, "I wouldn't have corn oil in my kitchen." He recommends any of the cold-pressed oils, such as olive oil, or safflower oil, which yield a wonderfully clear, almost transparent, oily fluid.

Nichols points out that whereas natural rice is one of the best foods in the world, and is one of the richest sources of natural vitamin B complex, white processed rice is nothing but raw starch, an item already superfluous in the high-carbohydrate American diet. American missionary wives in the Philippines managed to kill off hundreds of prisoners in the local jails by philanthropically substituting polished rice for natural rice in the prison diets, causing beri-beri.

The peanut butter which Carver went to such pains to produce is now mostly being made from rancid peanuts, says Nichols, since the food chemists have learned to clean it up, deodorize it and decolor it so that it can be sold to unsuspecting mothers. By one means or another and with hundreds of toxic additives to choose from, chemists can fix food so that it is very difficult for the citizen to tell that the food is going or has already gone bad.

One of the most important items in human diet is protein, which provides eight essential amino acids, the building blocks of the body. There are twenty-two amino acids. Eight are called essential for the adult, ten are necessary for growing children. If those are included, the body can build the others.

Meat is the most popular source of protein in the United States; but the prime steak of today has come from beef that has been force-fed for 180 days with low-quality-protein hybrid grains sprayed with poison insecticides. These go straight into the fat of the meat, especially into the marbling, and, says Nichols, lead straight to heart disease. To put an extra 20 percent weight on cattle—and produce a multimillion-dollar profit—the cattle raisers feed their animals diethylstilbestrol (DES), which can be carcinogenic in both men and women.

Though the FDA finally banned DES in the spring of 1973, it has now been replaced by a compound called Synovex, which contains estradol benzoate, considered by many experts to be cancer-causing. Says Dr. Mortimer Lipsett, "Whatever dangers you want to attribute to DES, you can attribute to Synovex." Beef, steers, hogs, sheep, and poultry are also still getting sixteen other drugs, singly or in combination, which the FDA suspects are carcinogenic when ingested by humans. To detect excess amounts of the toxin in meat, even if the entire army were to join the federal meat inspectors of the FDA, it is unlikely they could stop the chemicals getting to your table. And a huge proportion of our meat is never inspected. Of the ten billion frankfurters eaten in one recent year in the United States, about three and a half billion were consumed within the states where they were manufactured; hence they were not inspected.

The organ meat of animals, says Nichols, is only edible if the animal

has been fed organically. The livers of prime animals are confiscated much of the time because they contain abscesses and toxic substances. Commercially grown chickens have arsenic and stilbestrol in their bodies and much of it winds up in the liver. The liver is the detoxifying organ of the body, and that's where these poisons go. Store-bought eggs are mostly infertile, do not taste as good as fertile eggs, and are nowhere near as good for you, says Nichols, because there is a subtle biological difference. Hens that lay commercial eggs are cooped up where they cannot move, have seldom if ever seen a rooster, let alone been caught by one. "How," asks Nichols, "can an unhappy hen lay a good egg?"

In the pyramid of life, plants play an essential role, as man cannot ingest essential elements directly from the soil. They must be brought to him through the good graces of living plants, which likewise feed all animals, directly or indirectly. Via plant and animal our bodies grow out of the soil. Microorganisms break up the chemicals in the soil and make them acceptable to plants. Plants can synthesize carbohydrates from the air, rainfall, and sunshine. But, before the life processes can convert these carbohydrates into amino acids and proteins, they must have help from the soil fertility. Neither man nor animal can synthesize the necessary proteins from the elements. Animals can only assemble them from the amino acids, providing the necessary kinds and amounts of each can be collected or produced by plants with the help of microbes.

Protein-producing plants demand a long list of elements from the soil: nitrogen, sulfur, and phosphorus are required to make part of the protein molecule; calcium and lime are also required; and magnesium, manganese, boron, copper, zinc, molybdenum, and other elements are needed in connection with protein construction, even if only in such small amounts as are called "trace."

If the soil is not properly fertile, not teeming with microorganisms, the whole process goes out of kilter or grinds to a halt. To keep the microorganisms alive, great quantities of decaying organic matter need to be added to the earth. On the forest floor dead plant matter and dead animal matter go back into the land. Leaf mold, through decay, continues to give life to the land, returning to the soil what the tree took as nutrient.

It should be obvious that soil is vital to health. Healthy soil, properly composted, with the right bacteria, fungi, and earthworms, free from chemical fertilizers and pesticides, produces strong, healthy plants which naturally repel pests. Healthy plants make strong, healthy animals and strong, healthy human beings. Poor land grows poor food—poor in vitamins, minerals, enzymes, and proteins; this produces poor, sick people. Worn out land causes people to leave the farms and go live in the slums.

It's a strange fact, but plants grown on well-balanced, fertile soils do not have the same attraction for insects as those grown on poor soils, artificially stimulated by chemical fertilizers. Fertile soils have a natural immunity to insects and disease, just as a properly nourished body has an immunity to disease. Bugs and worms tend to gravitate toward a plant, or a field of plants, that has already been weakened by disease or improper development.

The end result of chemical farming, says Nichols, is always disease: first to the land, then to the plant, then to the animal, then to man. "Everywhere in the world where chemical farming is practiced the people are sick. The only ones to benefit are the companies that produce the chemicals."

Simultaneous with the application of fertilizers, the chemical companies began to douse the land with chemical pesticides, abetted by the government and with the tacit support of university professors. Three hundred million pounds of different chemical poisons are now produced under twenty-two thousand different brand names, which result in the destruction of wild life and essential insect and microbe life. Of mass spraying, Dr. George J. Wallace, Michigan University zoologist, went on the record to say that it "poses the greatest threat that animal life in North America has ever faced—worse than deforestation, worse than illegal shooting, worse than drainage, drought, oil pollution, possibly worse than all these decimating factors combined."

Not only wild life but fish in fresh water and even in the ocean are gradually being poisoned by a combination of insecticides and herbicides. Yet the DDT which wiped out fish and small game left its prime target, the boll weevil, flourishing. Despite the application of chemical pesticides the insects are gaining the upper hand, doing $4 billion worth of damage to crops each year. And no amount of argument appears to put over the fact that *healthy* crops are naturally pest resistant, keeping the insects at bay.

In the book *Silent Spring,* which Justice William O. Douglas called "the most important chronicle of the century for the human race," Rachel Carson made clear that the environment, which supports human life, is being stressed to the point of collapse. As Friend Sykes foresaw, doctors attribute to DDT and its more poisonous descendants the rise in leukemia, hepatitis, Hodgkin's disease, and other degenerative diseases. A correlation between the rise in the birthrate of mentally retarded children and the increase in the use of fertilizers and poisonous chemicals is stunning. Twenty thousand mentally retarded children were born in 1952. There were 60,000 by 1958; six years later the figure had risen to 126,000, and by 1968 it was well over half a million. Nowadays one child in eight is born mentally retarded in the United States, according to Dr. Roger J. Williams, discoverer of pantothenic acid and director of the Clayton Foundation Biochemical Institute in Texas, the first biochemist to be elected president of the American Chemical Society.

When Nichols realized what was happening to the country as a result of both chemical fertilization and chemical pesticides he took two steps. He went organic on his farm, and he sought other doctors and scientists who had made the same discoveries. Together they organized Natural Food Associates, of which Nichols became the first president. Their object was to start correcting the situation with a nationwide campaign to get the facts before the people, on the grounds that only an aroused public opinion could save America from poor food grown on poor soil. Nichols says he was determined to tell everyone just how to get natural food: "No matter how old you are, which sex you are, what color you are, where you live—north, south, east, or west, on an isolated farm or in a big city apartment."

By any means they could, Nichols and the NFA blasted the shibboleth that America is the best-nourished, healthiest nation on the face of the globe. "Nothing," said Nichols, "could be farther from the truth.

The truth is that America is the most fed and the worst nourished nation on earth. America today is suffering from a biological blight. We are facing metabolic disaster. We are a nation of sick people. Heart disease is rampaging through America; it is our Public Enemy number one. It is the leading cause of death among Americans. Fifty years ago coronary thrombosis was rarely seen by a physician. Today it strikes even the young. . . . Cancer, diabetes, arthritis, dental caries, and other metabolic diseases are rapidly increasing. Even children are falling victim to them."

Listing the facts, Nichols reported that sixteen hundred autopsies showed that in every one of the patients past the age of three years there was already disease in the aorta, the main artery of the body that carries blood from the left ventricle of the heart to all the organs and parts except the lungs. In every patient past the age of twenty, disease was already in the coronary artery.

"This should be evidence enough that practically everybody in the United States today has cardiovascular disease. We have an epidemic. And we have an epidemic of cancer. Cancer is now the leading cause of death, after accidents, in children under fifteen years of age. Babies are born with cancer! The American Cancer Society says cancer will eventually strike one in every four Americans now living. Can a nation call itself healthy when one of four must expect to get cancer, when three of four who get cancer will die of it?"

Almost immediately the agricultural chemical industry and the food processors attempted to discredit the NFA, calling them food faddists, quacks, and charlatans. They were accused of being "unscientific." The initial detractors were soon joined by the U.S. Department of Agriculture and the U.S. Department of Health, Education and Welfare, operating through the Food and Drug Administration, and even the American Medical Association. University professors, in search of fat grants, supported the claims of the FDA. A campaign was launched to make Americans believe that what the Natural Food Associates were saying was pure myth. Newspaper and magazine articles, even entire books, were published in a huge effort to destroy the effect of NFA and its credibility with the public.

The U.S. Department of Health, Education and Welfare put out a bulletin, "Food Facts vs. Food Fallacies," in which it called everything Nichols said a myth. To discredit Natural Food Associates and their objectives the AMA and the FDA organized a "Congress on Quackery," which toured the United States, holding seminars on food faddism and quackery. As Nichols put it, "They were really after men and women whose espousal of 'natural foods' or 'organic foods' or 'health foods' threatened to lower the profits of the food industry."

The stars of the show were Dr. Fred Spare and Dr. Jean Mayer, chairman of the Department of Nutrition at Harvard University's Medical School, who insisted that to get a proper balanced diet all an American had to do was go into the nearest grocery store and get a variety of the four food groups: fruit and vegetables; milk and dairy products; cereals; meat and eggs. The U.S. Public Health Department launched an all-out propaganda campaign, supported by the food processors and chemical trusts that make the poisonous food additives. Science editors, food editors, and medical editors in the daily newspapers joined their ranks.

When the NFA tried to tell the country that DDT was a cancer-producing chemical they were labeled quacks and faddists; their charges called a myth. In the end—after more than a decade of poisoning—the FDA itself was finally obliged to label DDT a dangerous poison, though pressure from agricultural interests caused the FDA to revoke its ban on DDT in milk, and establish a legal tolerance for the amount of DDT allowable in milk.

Although Australian investigators charged that BHT, or butyl-hydroxy-toluene, an anti-oxidant (originally used to preserve color motion-picture film), which turned up in processed foods, was teratogenic, that is, it interfered with the development of an embryo, the FDA allowed BHT as a freshness preserver. When newsmen questioned FDA about its research they were told the papers were secret. In the end it turned out there were only two reports on BHT in the FDA files—both written by members of the staff of the makers of BHT.

In 1960 the panel on food additives in President Eisenhower's Science Advisory Committee, which included members of the National

Academy of Sciences, university professors, and representatives of the Rockefeller Foundation and of cancer research institutes, stated that "Americans today are better fed and in better health than at any time in history. . . . The integrated contributions of the engineering, agricultural and chemical sciences have resulted in increasing quantities of uniformly high-quality and pure foods which have contributed demonstrably to the physical well being of the nation."

Thirteen years later FDA Commissioner Charles C. Edwards was still insisting that it was "established" that the vitamin content of food is not affected by the soil foods are grown in. "Vitamin or mineral deficiencies," he stated, "are unrelated to the great majority of symptoms like tiredness, nervousness, and rundown conditions." He then proclaimed that: "Scientifically it is inaccurate to state that the quality of soil in the United States causes abnormally low concentration of vitamins or minerals in the food supply produced in this country. . . . There is no relationship between the vitamin content of foods and the chemical composition of the soil."

But there is still hope if we get back on the track, says Nichols, if we begin to cleanse the poisons from every link of the food chain, so as to restore the country to proper nutrition and avoid the long decline that blighted North Africa and the Near East. To do so, and save the nation from metabolic disaster, says Nichols, we must change from an economy of exploitation to one of conservation. In the long run the country must give up chemical fertilizers and gradually revive the soil organically. Organic fertilizer can now be bought in a sack or packaged just like ordinary commercial fertilizer, and at no greater cost. Deposits of raw rock phosphate and potash with marine trace minerals and other deposits are readily available.

A great advantage of organic rock fertilizers is that after a few years of application they are no longer needed. Whereas the chemical farmer is obliged to put on more and more fertilizer each year, the organic farmer can put on less and less. Eventually the organic farmer will make more money, as it will cost him less to operate.

Organic farmers say it is not true that a man with extensive acreage cannot find enough organic matter. He has been told, says Nichols, that

he must steal from one acre to get natural fertilizer for another acre; but in fact he can grow his own organic matter on every acre, by following a few simple rules. And the organic method can be applied to any kind of agriculture. All animal manures, garbage, perhaps even sewage sludge, can be composted and returned to the land. If we could halve the waste of these materials, says Nichols, we could double the fertility of our soils and thus double the food supply.

The restoration of soil fertility, according to organic farmers, would go a long way toward solving problems of floods and water shortages which cannot be solved until organic matter is restored to the soil. The usual 100 pounds of soil in East Texas won't hold 30 pounds of water. But 100 pounds of humus will hold 195 pounds of water like a sponge. Fertile soil is usually dark in color and soft to the touch. When it rains the water soaks into this soil.

The construction of dams on rivers will never completely solve the water problem, say the organic farmers. The underground water level will continue to fall until organic matter is restored to the topsoil. As Nichols puts it: "We must learn to trap the raindrop right where it falls, instead of washing our topsoil into the rivers." A third of the arable topsoil in the U.S. has already been washed into the sea over the years, and is still being lost faster than it can be replaced. During floods, millions of tons of rich topsoil are washed downstream. Soil erosion costs half a million acres of land a year. We live from about eight inches of topsoil, containing earthworms, bacteria, fungi, and other microscopic forms of life, that provides us with vegetation, trees, insects, and animals. The only inexhaustible wealth is a fertile soil. Topsoil is the greatest natural resource of any nation; civilizations of the past have been destroyed when their fertile soils were lost.

In the coming age of famine, says Nichols, proper nutrition from a fertile soil will be the first source of wealth. And we must stop contaminating the rest of the planet. He warns that the massive use of commercial fertilizer in the so-called underdeveloped nations of the world will bring them the same massive increase in metabolic disease that we already have in America. Yet the chemical companies keep pouring out propaganda and pressure for greater consumption of their product. Dr. Raymond Ewell, vice president for research at the State University of New York at Buffalo, who has been considered one of the world's leading chemical economists, says blithely that if "Asia, Africa and Latin America are not using quantities of fertilizer approaching 30 million tons by 1980, they are almost certain to be engulfed in widespread famine."

Nichols, on the other hand, says that if we continue to exploit and teach exploitation of the soil here and abroad, the result will inevitably be war, just as it was when Japan went into Manchuria looking for protein from the soybean. Peace in this world, says Nichols, depends on conservation of natural resources, not their exploitation.

CHAPTER 16

Live Plants or Dead Planets

Among the independent farmers of the nation still working the land, a band of hardy individuals have finally realized that the blandishments of the artificial fertilizer and pesticide salesmen are questionable and are setting about to avoid the harmful results of chemical farming before it is too late.

Hereford is not only the name of a popular breed of beef cattle developed in one of the English counties bordering on Wales, it is also a small town on the upper reaches of the Palo Duro River, which runs through the Texas Panhandle, a 170-mile-square area of the Lone Star State which, about a century ago, was a wild short-grass prairie roamed by thousands of American bison. For millennia the flat plains of Deaf Smith County, of which Hereford is the seat, produced a rich herbage and a variety of succulent weeds whose roots extended through two to four feet of clay-loam topsoil into the *calicahi,* a subsoil rich in calcium and magnesium, drawing up these elements and depositing them as they died on the surface to maintain a vital protein-rich graze for the wild bovines. The minerals in the soil were delicately balanced and the humus naturally provided by the dying vegetation along with the bovine droppings was sufficient to hold its own against the harsh climate, hot and dry in summer, bitterly cold in the snow-sparse winters. It was only half a century ago that farming began in the region; the first furrows were cut into the land by the metal moldboards of plows; golden grain was sown as far as the eye could reach. Where the land was not planted, herds of cattle replaced the buffalo.

As the years went by, the farmers realized that deep plowing was hurting rather than helping the soil. So they switched to breaking up the rich clay-loam to a depth of merely six to eight inches with chiseling tools pulled by low-horsepower tractors. At the same time they were delighted to discover that water from underground aquifers could be pumped up and applied to the soil to supplement the rainfall from thunderstorms which intermittently turned the prairie skies into a dark panoply of lightning-threaded cumulus and the creeks into "rivers a mile wide and an inch deep."

By the time the children of the first generation of farmers had grown into manhood, things had begun to go wrong in Deaf Smith County. Dissatisfied by smaller harvests obtained from depleted soil, farmers began adding artificial fertilizers to their land as recommended by agricultural research stations and academic advisers. In less than a decade disaster was in sight. The chemicals were burning up the organic material in the soil, upsetting the delicate natural balance of minerals. As a result, the soil began to dissipate. When mixed with irrigation water it coagulated into enormous clods weighing up to fifty pounds each. To break them up the farmers had to resort to huge 135-horsepower tractors capable of dragging enormous chiseling tools through the bricklike consistency of their land. Some of the farmers, appalled at the prospect of

an end to irrigation farming in the Panhandle, owing to the unmindful application of the wrong kind of nutrients to the once rich land, were determined to react.

One of these, Frank Ford, after graduating from Texas Agricultural and Mechanical University, purchased an eighteen-hundred-acre farm in Hereford on which the land was badly eroded because of the prevailing agricultural practices. "There were gullies so deep you could hide a tractor in them," Ford recalls, but today they have all been filled and the land terraced and leveled smooth.

Ford committed himself to organic farming, using natural manures on his acreage and putting a complete stop to the use of pesticides, substituting in their stead ladybugs to kill brown mites and other pests. He also banished herbicides. Refusing to be persuaded, like other farmers, that his seeds should be chemically treated against wireworms and rust, he resolved that he would not plant any seeds he could not eat.

In addition to farming, Ford put capital into Arrowhead Mills, which specializes in the production of high-quality stone-ground flour with no preservatives, as well as other whole, natural foods. To assure himself a steady supply of organic products Ford had to persuade his fellow farmers to adopt organic methods. Attracted by his fair prices, a group of them have now organized the Deaf Smith County Organic Farmers Association, with the aim of not only growing healthier food but of protecting and improving the soil of West Texas.

Working with this group is Fletcher Sims, Jr., who came to the Texas Panhandle in 1949. One thing that caught Sims' attention was the fact that the first feedlots for cattle opened in the Panhandle, about 1965, were beginning to pile up tons of cattle manure which no one knew how to dispose of. Within a few years the waste from one lot two miles from his home in Canyon, Texas, downriver from Hereford, had collected into a pile over fifty feet high, covering forty acres, or more than thirty football fields, requiring a fleet of bulldozers and other equipment worth a quarter of a million dollars to pack. Sims further estimates that feedlots throughout the nation contain millions of cubic yards of manure which will eventually become worthless as fungi reduce them to minerals.

At the same time it seemed to Sims that the agricultural schools were going out of their way to misuse the cattle wastes on the land. At Texas A and M nearly one thousand tons of manure per acre was being plowed three feet under the soil, which Sims knew can do only violence to both soil and manure, since in the process topsoil is buried, subsoil exposed, and the manure prevented from becoming aerobically fermented. Another Texas college was pumping an organic slurry onto fields at concentrations that killed the crops; and an experimental station not far from Canyon was dumping raw manure at the rate of three hundred tons per acre onto soil on the premise that it is only a waste product to be disposed of. Other scientists were suggesting that building materials be made from manure, one group in the state of Washington even working on how to make livestock feed with it.

In the face of what Sims considered these sad and asinine approaches, he realized that the manure could best be turned into valuable compost. Dr. Joe Nichols introduced Sims to the compost work that had been done for years in Pfeiffer's research laboratory at Spring Valley, New York.

During several visits to Spring Valley Sims learned that compost making goes through distinct phases: one in which original starches, sugars, and other components are broken down by bacteria, fungi, and other organisms; a second in which the new materials are consumed by microorganisms to build up their own bodies. It was of the utmost importance, Sims was told, that the right kind of microfauna and microflora be present and that the second phase be timed correctly so that there would not be too much loss of organic matter.

"If compost is not worked properly," Sabarth told Sims, "the original proteins and amino acids break down into simple chemical compounds. In other words, organic matter gets lost as carbon dioxide, or as nitrogen escaping as ammonia and nitrates. Many gardeners think of their composts as being 100 percent organic because all their original materials are organic. But nature isn't that simple. Living cells have 70 to 90 percent water, only 15 to 20 percent proteins, amino acids, carbohydrates, and other carbon compounds. Only 2 to 10 percent is mineral: potash, calcium, magnesium, and the trace elements that are inorganic. The organic compounds can be preserved in the bodies of the microorganisms. They escape when they become free in some stage of the breakdown. The N, P, and K concept comes into its own only when compost has been mineralized, but by then the biological values have been lost. In compost making you need to have a quick method for telling whether bacterial action is breaking down nitrogen-containing compounds too fast, which is indicated by the ammonia smell. If compost piles heat too fast they must be turned to interrupt the ammonia production so that bacteria rebuild more stable nitrogen compounds in bacterial protein."

The standard tests of the American Organization of Agricultural Chemists, Sabarth informed Sims, cannot reveal the state of matter in which organic materials are present since they rely on combustion or oxidation of compounds. The ashes give only the total amount present, but say nothing as to whether they originate from minerals or from living cells and tissues. Pfeiffer's colored chromatograms so well define the various stages of fermentation, whether decomposition, humus formation, or mineralization, that after years of work the laboratory was able to develop a Biodynamic compost starter with a proper population of microorganisms for anyone's use.

Sabarth showed Sims chromatogram pictures, one of which illustrated how the material from a cranberry bog, though it contained an incredible 18 percent organic matter, was actually inert. Standard chemical analysis would not have revealed its biological valuelessness. A picture of adobe soil from California revealed that analysis of the minerals within it meant little because it had no well-developed microflora, and thus was infertile. When soils have only minerals but no organic matter, said Sabarth, the plants in them are like people forced to eat salty foods. They are driven to drink water and more water. Plants absorbing an excess of mineral salts take in an excess of moisture. Though they look lush to the eye, they are no longer in balance, and therefore no longer resistant to disease.

To his amazement Sims learned that with Pfeiffer's chromatograms Sabarth had been able to establish scientific proof that certain plants, beans and cucumbers, for instance, grow better if planted in conjunction with each other, and that other plants, such as beans and fennel, seem to fare badly together. Furthermore, the storage together of such crops as apples and potatoes mysteriously robs each of its most life-giving properties.

Pfeiffer came to realize that it is only our human egotistical point of view that labels a weed a weed, and that if they were viewed as a functioning part of nature, weeds would have much to teach. Pfeiffer proved that a whole group of weeds, including sorrels, docks, and horsetails, are sure indicators that the soil is becoming too acidic. Dandelions, which lawn owners so feverishly dig up, actually heal the soil by transporting minerals, especially calcium, upward from deep layers, even from underneath hardpan. The dandelion is thus warning the lawn owner that something is wrong with the life of his soil.

Pfeiffer showed that daisies play the same role, in that analyses of their incinerated ashes show them to be rich in calcium, the most important constituent of lime. Pfeiffer doubted whether the orthodox view, holding that the daisies have selectively "fixed" lime, was correct, since they could grow in limeless soil providing there is enough silicon present together with microorganisms. Pfeiffer came to the conclusion that, when soil lacks lime, silicon-loving plants such as daisies move onto it. When they die, they bring to the soil the missing calcium he had found in his analyses. But he could not answer the question "How does the calcium get into the daisies?"

Pfeiffer performed experiments on plant symbiosis to show that in some way camomile stimulates heavier growth of wheat, with fuller ears, but only when the ratio of camomile to wheat plants is no more than one to one hundred. Thus his latter-day research confirms the age-old wisdom of the Russian peasantry about cornflowers and rye.

Sims came to the realization that the prospects of Pfeiffer's unique tests seemed endless. He was fascinated that two chromatograms of wheat, one grown with inert chemicals, the other biologically, looked so different.

Sims took back with him to Texas a supply of the Biodynamic starter composed of some fifty different microorganisms, many coming from the outstanding soils of the world and each with its particular mission to fulfill, both in the compost as it is being made and in the soil onto which it is distributed. What makes the starter so inscrutable to the average scientist is the fact that there are homeopathic quantities of vital elements, enzymes, and other growth substances which work at dilutions of up to 1,000,000,000 to 1.

Applying the Biodynamic process to what may have been the first commercial compost operation using the Pfeiffer starter, Sims took raw manure which he could get free from the feedlots and treated it in such a way that microorganisms disassembled compounds in the waste and assembled them into new and beneficial ones. At the same time, disease organisms and seeds from weeds or grains are automatically destroyed and harmful chemicals are biologically degraded when the temperature in the piles reaches 140 degrees Fahrenheit. Laying out piles of compost in windrows, Sims turned them from time to time, using a machine of his own design with a capacity of six hundred tons per hour.

Within one month, his compost, having never been subjected either to grinding or screening, became a fine, dark brown, friable, earthy material, wholly devoid of manure odor. The cow dung was transformed, miraculously as it were, by *biological* action. As the farmers began to buy Sims's products and apply it to their land, startling results were not long in coming. John Wieck of nearby Umbarger, after only two years' treatment of his soil with half a ton of Biodynamic compost per acre and no other fertilizer or insecticides, and only two irrigations to supplement some three inches of rain, was able to harvest a fantastic 172½ bushels per acre of corn, or more than double the maximum crop achieved on the artificially nitrogenized lands of Illinois.

In the northern part of the Panhandle ten miles from Oklahoma's Cherokee Strip, another Texan, Don Hart, whose irrigated land had begun to tighten up from the use of commercial fertilizers, realized that he and his neighbors might soon be sitting on wasteland. Hearing of Sims's success, he not only began to compost his acres but soon started a composting business of his own to supply other farmers. Within a short time he found that his soil felt like a plush, moisture-laden carpet underfoot. A reporter visiting his acreage in late 1971 wrote that anyone who wanted to convince himself of the advantage of Biodynamic compost had only to drive along a road where from the car he could see on one side a beautiful crop of healthy corn plants coming up on Hart's field and on the other, planted two weeks before Hart's, a virtual nightmare: a few sickly plants starting out of hard-packed and cracked ground.

Southeastward across the enormous state of Texas, Warren Vincent has been encouraging farmers to grow rice organically in order to combat the rice growers' main nemesis, barnyard or water grass, on which herbicides of the kind used so devastatingly to defoliate the jungles of Vietnam have been extensively applied. Vincent encourages his neighbors to rotate rice with Bahaia grass, which turns the land back to sod, controls weeds, and makes an excellent pasturage for animals. Now that consumers are beginning to discover that organically grown brown rice is nutritionally far better than that grown with artificial fertilizer, other pioneering rice farmers have dared to go organic.

In northern California, 120 miles south of the towering Mount Shasta, which looks like Japan's Fuji, four Lundberg brothers, owners of Wewah Farm, have begun to grow brown rice organically. Though converting to organic methods involved additional costs, they remembered that their father had taught them that any farmer worth his salt has an obligation to improve the land he uses and, if possible, leave it to the next generation in a better condition than when he took it over, a philosophy which, applied worldwide, could make of this planet a Garden of Eden.

Despite generalized warnings against giving up the extended family of chemical products, the Lundberg brothers located a source of manure and composted it before working it into an initial seventy-six acres. Their first crop averaged thirty-seven hundred pounds per acre, low when compared to chemically treated rice, but high enough to be economically feasible, given the premium prices paid for organic rice. Their initial experiment convinced them to go all the way and convert the whole of Wewah's three thousand acres to organics. The Lundbergs next imported special milling equipment from Japan and established their own organic processing plant. This would not remove the rice's protective outer shell, the nutritious portion of the grain and to some the tastiest.

There are now indications from not only the public but also notables in California's government and even in its universities that the Lund-

bergs may be on the right trail. Floyd Allen, a reporter for *Organic Gardening and Farming,* visiting the state legislature in Sacramento, heard one assemblyman declare that the organic way was "a good mother philosophy." Allen was surprised to sit in the office of an eminent pesticide specialist at the University of California at Riverside and hear the man announce: "I wish someone would do something about the quality and taste of food. I'd like to eat a tomato that tastes like tomatoes used to taste."

The organic approach has also been adopted in the Middle West by dairy farmers who wish to sell their milk to such producers as Eldore Hanni, president of the Wisconsin River Valley Cheese company north of Wausau, who has been making organic cheese since 1962. When the Grade A raw milk arrives at the company it is pumped directly into the cheesemaking vat, completely by-passing pasteurization. No preservative or color is added and no imitation ingredients are used. To preserve the natural enzymes of raw milk, heating temperatures during manufacture of the cheese are not allowed to exceed 102 degrees Fahrenheit. Hanni's partner, Eldred Thiel, claims his cheese has the old-time flavor—"like my Dad used to make." The cheesemakers' suppliers are certified by the firm as "natural farmers," who take up to five years to make sure that no trace of chemicals remain on their land.

Among fruit growers who have seen the light is Ernest Halbleib, owner of Halbleib's Orchard and Organic Farm at McNabb, Illinois, who refutes the almost universal assertion that apple growers cannot get along without chemicals. Halbleib states that insects arrive in orchards just to point out the very mistakes that man is making. Producers who are fogging their orchards with deadly chemicals are finding that the single application sufficient ten years ago now has to be repeated many times in the growing season as bugs become resistant to instant death.

More than twenty years ago Halbleib went to Washington, where he testified to the FDA against poison sprays, poison fertilizers, and poison seed treatment, not a word of which he would take back today. Since that time, he has watched his colleagues administer over five hundred new chemicals to their trees. Today, says Halbleib, there is not one apple grower in his fruit belt that is not in distress. They have used so much poison on their soil that the manager of the USDA chemallurgical plant in Peoria, Illinois, told him that 100,000 acres in his area alone have been so toxified that they won't grow grass or even weeds and that the same is true for huge portions of once-rich potato land in the state of Maine.

"What do we want?" asks Halbleib. "To have children making their blood with poisoned food? Have you looked into the reason for such large enrollment in insane asylums and hospitals? Instead of pouring out funds to build more of them, why doesn't someone study the *cause* of disease?"

Lee Fryer, an agricultural and nutritional consultant who runs Earth Foods in Washington, D.C., states that in 1968 the figure spent on commercial fertilizers in the United States exceeded $2 billion. This sum would buy more than 100 million tons of Fletcher Sims's Biodynamic compost, which, if applied at the rate of one ton per acre would cover the whole state of California with enough left over for an area as large as the six New England states. For the cost of only a few days of the Vietnam war, the whole of the United States of America's soil could be given an annual treatment.

Fryer pointed to the successful use of seaweed as a natural fertilizer and soil improver as developed in the British Isles by a former chartered accountant, W. A. Stephenson, author of *Seaweed in Agriculture and Horticulture,* who quit his Birmingham job at forty and moved to the country, at the suggestion of a biochemist friend, to build a business which distributes seaweed fertilizer in liquid form all over the world.

One of the first to use seaweed successfully on a commercial operation in the United States is Glenn Graber of Hartville, Ohio, who farms four hundred acres of the blackest, richest peat soil to be found anywhere in the United States, on which he raises carloads of radishes; Bibb, Boston, iceberg, romaine, and leaf lettuces; and some fifty other vegetables. Six days a week for half the year an average of four huge trailer loads of produce leave Graber's farm for the market.

About 1955 Graber noticed that a destructive species of nematode or "roundworm" was appearing on his land and that "bluebottom" was wilting a large percentage of his crops as well as those of his neighbors.

Because the plague hit at a certain time of year, blame was universally put on the weather. Graber also found from analysis that his soil indicated a lack of trace minerals. Raised on the NPK concept which he had been following to the letter, Graber wondered what he could do to improve matters. He learned that marvelous things had been accomplished with seaweed at the Clemson College of Agriculture in South Carolina, where researchers had used seaweed meal and a liquid seaweed extract manufactured in Kristiansand, Norway, to achieve gains in sweet peppers, tomatoes, soya and lima beans, and peas.

On the basis of the little-heeded Clemson research, Graber decided to act, and ever since he has been applying kelp, imported from Norway in granulated form, to his land at the annual rate of two hundred pounds to the acre. Toward the end of the first season he noticed that healthy green mold was forming in the tracks of his farm equipment, his nematode infestation was dramatically reduced, and the bluebottom eradicated. Since then he has never put a pound of artificial fertilizer on his land, relying completely on seaweed, rock phosphate from Florida, and ground granite from Georgia, and on bacterial action and cover crops to produce nitrogen.

As his soil improved, Graber next realized that he was wasting money on pesticides, and abandoned their use, turning instead to a spray made of liquefied kelp applied at the rate of three gallons per acre over crops throughout the season. Graber is not sure how the liquid seaweed acts as a pesticide and says no research has yet been done to find out. Though he does not entirely escape infestations of pests from his neighbors' fields, Graber believes that when he incurs a 10 percent drop in his onion crop due to maggot flies, his neighbors are losing over half their crop, in spite of every insecticide they try. He is convinced that healthy plants on healthy soil resist pests naturally. To prove it he walked one visitor through a field of parsley swarming with leafhoppers, which brushed against their pants legs but were apparently not feasting on the best-looking and best-tasting parsley the visitor had ever tried.

Since his abandonment of commercial fertilizers, Graber has been able to give up a plow requiring two tractors to haul it. By simply cover-cropping his land with barley and rye, he not only adds humus and nutrients to the soil but allows it to be aerated by the plants' strong roots and by earthworms and microorganisms which flourish in it. The hardpan problem he once had disappeared as if by magic.

Another dividend to Graber is frost resistance. In one particularly unseasonable cold spell, when the mercury dipped to a chilly twenty degrees Fahrenheit, all of his freshly transplanted tomatoes and peppers withstood the cold with not a single loss, though he remembered that under the same conditions they all expired when artificially fertilized.

Graber thinks the problem of getting organically grown vegetables to the consumer is compounded because the present organic outlets do not have enough volume to warrant low-cost distribution in any one area. He thinks the only road to travel is to work through large food chains, which must find a means to isolate organically grown produce on their shelves from the conventional supplies.

Such an approach has recently been pioneered in West Germany by Latscha Filialbetriebe of Frankfort, a fast-growing family-owned supermarket chain of 123 stores with a bent for innovation. Latscha has introduced chickens, eggs, fruit juices, apples, and frozen green vegetables which are guaranteed to have only minimal quantities of "residuals" such as antibiotics, hormones, lead, and the full spectrum of pesticides. All plant products come from farms cultivated along organic gardening lines as developed by the German State Institution for Plant Protection in Stuttgart.

Latscha says that none of its controlled products costs more than 15 percent more than ordinary equivalents and that its juices and deep-frozen items can be offered at prices under those charged for standard brands. Though the premium it pays to a cooperative dairy to produce milk without such additives as chlorinated hydrocarbons and DDT is passed on to the customer, the certified milk has climbed to 10 percent of Latscha's sales and the chain's overall revenues have increased despite a generally falling market demand.

In Cambridge, Massachusetts, the Star Markets are beginning to act somewhat like Latscha. They take a trailerload a week of mixed vegetables that have been grown organically by Glenn Graber and market them in separate bins.

Oliver Popenoe, founder of Yes! Inc., one of the dozen natural-food outlets in the metropolitan area of Washington, D.C., applauding the Star Markets' effort, puts his finger on the reason why their example has not yet been widely followed: "The problem with most food chains is that their management and staffs lack commitment to organic principles," says Popenoe. "This makes it very difficult for them to market organically grown produce which *looks* about the same, or even worse to the eye, than chemicalized produce, and costs more. They suffer from a credibility gap. Credibility is everything when it comes to buying organic produce. There is no way I know of *knowing* it is organic unless you subject it to a gas chromatograph test for pesticide residues. Since such proof costs twenty-five to thirty dollars for each item tested, even the most purist of grocers use them sparingly. I think this is the main reason why the market for organic produce is so thin. Unless one knows one's farmer personally, or has great faith in the honesty of one's grocer, one hesitates to pay more for an uncertain benefit."

When Graber was asked how his fields compare with those of his neighbors, he replied candidly: "In ideal weather conditions they can beat me in yield and also in time but in adverse conditions it's the reverse." More important to Graber is the fact that he is confident that he is improving his soil as he goes along. Graber has recently begun to have a look at Biodynamic compost. At the beginning of the 1973 season he ordered enough of the product from Zook and Ranck in Gap, Pennsylvania, to treat his soil for vegetable crops at the rate of fifteen hundred pounds per acre. By running comparative tests over the next two years, Graber thinks he will be able to determine whether the compost will additionally help his soil and crops. What convinced him to begin trying the compost was his impression at an agricultural fair in Pennsylvania that not one of the farmers who visited Zook and Ranck's booth had an adverse comment about Biodynamic compost. All of them had good results and were full of praise. "You can well believe that if a farmer had spent his money for nothing," says Graber, "he would be raising the very devil."

In Switzerland a farmer working one hectare of land next to the Theological Faculty of the University of Fribourg grows enough vegetables during an eight-month season using the biodynamic method and the help of only one assistant to feed the two hundred theological students in the faculty's dormitories and send a large overflow to the public market. "I could teach this method to anyone," says the farmer, "as long as he has a natural or artificial supply of water. Just think what this could do for Third World countries with their rising population and food shortages."

For all their success in organic farming, some farmers like Glenn Graber feel that many organic proponents tend to be too "purist" and, as such, have alienated the chemical interests who might well change their closed thinking if met halfway. "It's about time the two camps got together to determine what's right and what's wrong," says Graber. This is also the opinion of Dr. John Whittaker, a veterinarian in Springfield, Missouri, who is animal health editor for the remarkable new monthly, *Acres USA*. Published in Kansas City by Charles Walters, Jr., the magazine calls itself a voice not for organic farming but for what Walters thinks is a better term: Eco-Agriculture.

Whittaker is nevertheless not at war with the chemists. He says that what is needed is to create common ground on which organic-minded farmers can meet with farmers who honestly have accepted the pronouncements of the chemical establishment. "On the one hand," he states, "the chemists have got to stop viewing the natural movement as a group of little old ladies working in geranium beds. The truth is there can be no sudden death of the technology now extant. There has to be a phasing down, a buffering process, a marriage. We have to learn from each other."

Asked how technology might harmonize with nature, Whittaker points to the development of metal proteinates, a process which takes minerals and "chelates" or hooks them to organic matter such as protein. One of the clearest statements about how proteinates work is that of Whittaker's fellow veterinarian, Phillip M. Hinze, who looks upon the physical body not only as a compilation of chemicals but as an electric complex as well.

"The animal body," says Hinze, "may be thought of as a very complex battery that not only receives, stores, and uses electricity for chemical

purposes, but also maintains itself by assimilating vitamins, minerals, amino acids and other products. The body recognizes these substances when they come along. Every organic substance has an electromotive property which determines whether it can be assimilated. When an animal needs nutrients, a signal is sent out to capture that nutrient from food that has been ingested. If there is no sickness, and the needed ingredients are present, they will be assimilated. Unfortunately the needed ingredients don't always correspond with substances considered suitable for food. For instance, the requirements of the animal body for metals are often met by feeding rations containing inorganic forms of these metals. But it happens that inorganic forms of nutritionally essential metals have different electromotive properties than the same metals complexed with organic materials such as amino acids. A pig can't eat a nail. It needs organic iron."

So does the soil; overharvested, overirrigated and overgrazed, it no longer contains the necessary organic minerals to produce good food in the form of plants.

This truth has been recognized by Dr. Mason Rose, Director of the Pacific Institute for Advanced Studies, one of the first educational institutions in Los Angeles to break away from the standard university compartmentalization of knowledge and to teach the manufacture of soil humus and the breeding of bacteria.

Other groups, aware that man, having fouled his nest, must now clean it, have been experimenting with ecological farming techniques. A salient example is the New Alchemy Institute, which projects a host of activities, including backyard fish-farming, in climates as varied as those of the Canadian Maritime Provinces, New Mexico, California, and Costa Rica. The New Alchemists say their trio of goals are "To Restore the Lands, Protect the Seas, and Inform the Earth's Stewards." This is what the planet's vegetal covering on *terra firma* has been doing since long before the advent of man to his stewardship. In that sense, plants are the oldest alchemists.

CHAPTER 17

Alchemists in the Garden

The medieval alchemist, whose dream of transmuting one element into another was maliciously ridiculed for centuries, may now be vindicated —thanks to the efforts of living plants.

Early in this century a young Breton schoolboy who was preparing himself for a scientific career began to notice a strange fact about the hens in his father's poultry yard. As they scratched the soil they constantly seemed to be pecking at specks of mica, a siliceous material dotting the ground. No one could explain to Louis Kervran why the chickens selected the mica, or why each time a bird was killed for the family cooking pot no trace of the mica could be found in its gizzard, or why each day the flock produced eggs with calcareous shells though they apparently had not ingested any calcium from land which was entirely lacking in limestone. It took Kervran many years to establish that the chickens were transmuting one element into another.

Reading a novel by Gustave Flaubert called *Bouvard et Pécuchet,* young Kervran came across a reference to Louis Nicolas Vauquelin, a celebrated French chemist, who, "having calculated all the lime in oats fed to a hen, found still more in the shells of its eggs. Therefore, there is a creation of matter. In what way, no one knows."

It seemed to Kervran that, if the hen had somehow been able to manufacture calcium in its own body, everything he was taught in his chemistry class needed reviewing. Ever since the end of the eighteenth century, when Vauquelin's contemporary Antoine Laurent Lavoisier, known as the "father of modern chemistry," had laid down the principle that in the universe "nothing is lost, nothing is created, everything is transformed," it had been believed that elements could be shifted about in different combinations but could not be transmuted one to another; millions of experiments appeared to verify Lavoisier's contention.

The first crack in this seemingly unshatterable wall around the atom came at the start of the twentieth century with the discovery of radioactivity, which showed that some twenty elements could indeed change into something different, apparently no longer obeying the law of the conservation of matter. Radium, for instance, disintegrates into electricity, warmth, light, and various substances such as lead, helium and other elements. With the advent of nuclear physics, man was even able to create certain elements which had been missing on the famous chart drawn by the Russian peasant genius Dmitri Mendeleyev, because they were thought either to have vanished radioactively in former times or to have never existed in a natural state.

Ernest Rutherford, the British physicist who first theorized the existence of the atom's nucleus, showed in 1919 that one could transmute elements by bombarding them with alpha particles—identical to helium atoms less their electrons—a practice which has continued to the present time, with increasingly "heavier artillery." But even these breakthroughs did not shatter Lavoisier's dictum about the eighty or more nonradioactive elements. Chemists still hold that it is impossible to create another element by chemical reaction, and even maintain that all reactions occurring in living matter are solely chemical. In their view chemistry can and must explain life.

As a young graduate engineer and biologist, Kervran remembered Vauquelin's experiment and decided to repeat it. He fed a chicken on oats alone, the calcium content of which he had carefully measured. He then checked the calcium content in both the eggs and feces issuing from the chicken and found the bird had produced four times as much calcium as it had ingested. When Kervran asked his biochemist colleagues how the extra calcium originated, they replied it had come from the chicken's skeleton. This, Kervran realized, might do in an emergency, but if a chicken were required to make shells very long its skeleton would soon be reduced to pulp. In fact, a chicken deprived of calcium lays soft-shelled eggs within four or five days. However, if fed potassium, the chicken's next egg has a hard shell composed of calcium. The chicken is evidently capable of transmuting the element potassium—which is found in high concentrations in oats—into the element calcium.

Kervran also learned that about the time of Vauquelin's retirement, an Englishman, William Prout, made a systematic study of the variations in calcium in incubating chicken eggs and found that when chicks hatched they contained four times more lime than was originally present in the egg and that, furthermore, the lime content of the shell had not changed. He concluded that there had to be an endogenous formation of lime from within the egg. This was long before scientists knew anything about the atom, says Kervran, so it was too early to talk about atomistic transmutation.

One of Kervran's friends pointed out to him that as far back as 1600 a Flemish chemist, Jan Baptista Helmont, had planted a willow sapling in a clay pot containing two hundred pounds of oven-dried soils and for five years had given the tree nothing but rain or distilled water. When Helmont removed the tree and weighed it he found it had gained 164 pounds whereas the weight of the soil remained approximately the same. Helmont wondered if the plant had not been able to turn water into wood, bark, and roots.

Another vegetal anomaly which interested Kervran was that of *Tillandsia*, or Spanish moss, which can grow on copper wires without any contact with the soil. When burnt there was no copper residue in its ash, but iron oxides and other elements, all apparently supplied simply by the atmosphere.

Henri Spindler, another French scientist, became fascinated with how *Laminaria*, a variety of algae, seemed to be able to manufacture iodine. Searching for answers in half-forgotten literature on the dusty shelves of libraries, Spindler found that a German researcher by the name of Vogel had planted cress seeds in a container covered by a glass bell jar and fed them nothing but distilled water. A few months later when Vogel burned the adult plants, he found they contained twice the amount of sulfur which had been present in their seeds. Spindler also uncovered the fact that, soon after Vogel, two Britishers by the names of Lawes and Gilbert discovered at the famous Agricultural Research Institute at Rothamsted, England, that plants seemed to extract from the soil more elements than it contained.

For seventeen years the Rothamsted researchers cropped a clover field, mowing it two or three times a year, and sowing it only every fourth year, without adding any fertilizer at all. This piece of land gave cuttings so abundant that it was estimated that if one had to add what had been removed in the period between the arrival of one swarm of seventeen-year locusts and another, it would be necessary to dump on the field over 5,700 pounds of lime, 2,700 pounds of magnesia, 4,700 pounds of potash, 2,700 pounds of phosphoric acid, and 5,700 pounds of nitrogen, or more than ten tons of the products combined. Where had all these minerals come from?

Delving deeper into the mystery, Spindler came across the work of a Hanoverian baron, Albrecht von Herzeele, who, in 1873, brought out a revolutionary new book, *The Origin of Inorganic Substances*, which offered proof that, far from simply absorbing matter from the soil and the air, living plants are continuously creating matter. During his lifetime von Herzeele made hundreds of analyses indicating that, in seeds sprouting in distilled water, the original content of potash, phosphorus, magnesium, calcium, and sulfur quite inexplicably increased. Though the law of the conservation of matter held that exactly the same mineral content in plants grown in distilled water would be found as in the seeds from which they spring, von Herzeele's analyses proved also that not only mineral ash but every one of the plants' components increased, such as the nitrogen which burned off during incineration of the seeds.

Von Herzeele also discovered that plants seemed to be able to *transmute*, in alchemical fashion, phosphorus into sulfur, calcium into phosphorus, magnesium into calcium, carbonic acid into magnesium, and nitrogen into potassium.

One of the many odd facts in scientific history is that von Herzeele's writings, published between 1876 and 1883, were given the silent treatment by official academia, which was supporting the fashion that biological phenomena could be explained atomistically according to chemical laws. Indeed, most of Herzeele's works never found their way onto library shelves.

Spindler drew the attention of some of his colleagues to von Herzeele's experimentation. One of them was Pierre Baranger, a professor and director of the laboratory of organic chemistry at the famous Ecole Polytechnique in Paris, which, since its establishment in 1794, has trained the best scientific and engineering minds in France. To check von Herzeele's work, Baranger began a series of experiments which were to last the best part of a decade.

These experiments amply confirmed von Herzeele's work and indicated that atomic science might be faced with a veritable revolution.

When Baranger announced his discoveries to the scientific world in January, 1958, before a distinguished audience of chemists, biologists, physicists, and mathematicians at Switzerland's Institut Genevois, he noted that if his investigations were further developed a certain number of theories which did not seem to have the benefit of a sufficiently experimental basis might have to be modified.

This cautious approach dictated by scientific mores was made more explicit by Baranger in an interview for *Science et Vie* in 1959. "My results look impossible," said Baranger, "but there they are. I have taken every precaution. I have repeated the experiments many times. I have made thousands of analyses for years. I have had the results verified by third parties who did not know what I was about. I have used several

methods. I changed my experimenters. But there's no way out; we have to submit to the evidence: plants know the old secret of the alchemists. *Every day under our very gaze they are transmuting elements.*"

By 1963 Baranger had incontestably proven that in the germinations of leguminous seeds in a manganese salt solution, manganese disappeared and iron appeared in its place. Trying to shed more light on the mechanisms involved, he discovered a whole web of complexities related to the transmutations of elements in seeds, including the time of their germination, the type of light involved, even the exact phase of the moon.

To understand the enormity of Baranger's work one has to realize that nuclear science asserts that in order to form the stability of elements such gigantic "energies of fixation" are needed that the alchemists, unable to produce and direct such energy, could never have transmuted one element into another as they claimed. Yet plants are constantly transmuting elements in a manner completely unknown to science without having to resort to enormous modern atom smashers. The tiniest blade of grass and the frailest crocus or petunia is able to achieve what modern-day alchemists known as nuclear physicists have heretofore found impossible.

In speaking of his new research, the quiet, courteous Baranger said: "I have been teaching chemistry at the Ecole Polytechnique for twenty years, and believe me, the laboratory which I direct is no den of false science. But I have never confused respect for science with the taboos imposed by intellectual conformism. For me, any meticulously performed experiment is a homage to science even if it shocks our ingrained habits. Von Herzeele's experiments were too few to be absolutely convincing. But their results inspired me to control them with all the precaution possible in a modern lab and to repeat them enough times so that they would be statistically irrefutable. That's what I've done."

Baranger established that seeds of Cerdagne vetch growing in distilled water showed no change in phosphorus or potassium content. But seeds growing in a calcium salt solution varied their phosphorus and potassium content by the enormous factor of 10 percent, and that calcium increased in both groups. "I understand perfectly well," Baranger told the science writers, who grilled him with every possible objection during the course of their interview, "that you are astonished by these results. For they are astonishing. I understand perfectly well that you are seeking the error which could make nonsense of these experiments. But so far no such error has been found. The phenomenon stands: plants can transmute elements."

As upsetting and contradictory as Baranger's experiments seemed, it was pointed out by *Science et Vie* that nuclear physics itself has reached a stage wherein its practitioners use four separate and quite contradictory theories about the atomic nucleus. Moreover, they add, the very secret of life has not yet been found, perhaps because no one has yet looked for it in the atomic nucleus. So far, they went on, life has been considered to be mainly a chemical and molecular phenomenon, but perhaps its roots are to be located in the most remote sub-basements and cellars of atomic physics.

The practical consequences of Baranger's findings cannot be overestimated. One of these is that certain plants can bring to the soil elements useful for the growth of other plants, which could lead to many changes in received doctrines about fallows, rotations, mixed crops, fertilizers, or, as Friend Sykes found out through actual trials on his Wiltshire land, the manuring of infertile soils. Moreover, as Baranger opines, nothing prevents us from thinking that certain plants are capable of producing rare elements of industrial importance. They appear to supply us with an example of subatomic transformation which we are not capable of performing in the laboratory without bringing into action particles of high energy in exactly the same way we are not capable of bringing about at ordinary temperatures the syntheses of innumerable products, either alkaloids or others, which are extracted from plants.

Kervran, a man with continuing ties to the land despite his urban academic duties, began to be fascinated by another phenomenon of a global nature which has long been known to agricultural specialists. He read in Didier Bertrand's *Magnesium and Life*, published in French in 1960, that each time wheat, maize, potatoes, or any other crop is harvested, elements in the earth used by plants in their growth process are taken out. Since virgin arable soil contains from 30 to 120 kilograms of

magnesium per hectare, Bertrand stressed that most of the earth's arable land should long since have been exhausted of this element. Not only is this not the case, but in various parts of the world, such as Egypt, China, and the Po Valley in Italy, soils continue to remain highly fertile in spite of the enormous quantities of magnesium taken from them through harvests of crops over thousands of years. Is it because plant life is able to upset the periodic table of the elements, to make magnesium from calcium or carbon from nitrogen, for instance, that lands have been able to replace the products they need, wondered Kervran.

With the Celtic directness of a Breton, Kervran published his *Biological Transmutations* in 1962, the first of a series of books which offered a whole new perspective on living creatures. It made clear that those who believe in a system of farming which takes into account chemistry alone are in for a rude shock and that man and animals nourished on diets formulated by chemists will not long survive. Kervran freely accepted the notion that Lavoisier was right as far as chemical reactions were concerned. The mistake made by science, he said, is to contend that *all* reactions in living organisms are chemical in nature and that, consequently, life should be interpreted in chemical terms. Kervran suggests that the biological properties of a substance are only inadequately determined by chemical analysis.

Kervran wrote that one of the main purposes of his book was "to show that matter has a property heretofore unseen, a property which is neither in chemistry nor in nuclear physics in its present state. In other words the laws of chemistry are not on trial here. The error of numerous chemists and biochemists lies in their desire to apply the laws of chemistry at any cost, with unverified assertions in a field where chemistry is not always applicable. In the final phase the results might be chemistry, but only as a consequence of the unperceived phenomenon of transmutation."

Rudolf Hauschka in his brilliant book *The Nature of Substance* carries Kervran and Heerzele's ideas even further, saying that life cannot possibly be interpreted in chemical terms because life is not the result of the combination of elements but something which precedes the elements. Matter, says Hauschka, is the precipitate of life. "Is it not more reasonable," he asks, "to suppose that life existed long before matter and was the product of a pre-existent spiritual cosmos?"

Supporter of Rudolf Steiner's "spiritual science," Hauschka is lapidary in his approach when he states that the elements as we know them are already corpses, the residue of life forms. Though chemists can derive oxygen, hydrogen and carbon from a plant, they cannot derive a plant from any combination of these or other elements. "What lives," says Hauschka, "may die; but nothing is created dead."

Hauschka, who also duplicated many of Heerzele's experiments, found that plants could not only generate matter out of a nonmaterial sphere, but could "etherealize" it once more, noting an emergence and disappearance of matter in rhythmic sequence, often in conjunction with phases of the moon.

In Paris, Kervran, a pleasant and forthrightly cooperative man of seventy with a prodigious memory for detail, told the authors that powerful energies are at work in the germination process of seeds which synthesize enzymes, probably by transmuting matter within them. His experiments have also convinced him that lunar forces are extremely important in germination, though botanists have long asserted that only warmth and water are required.

"We cannot deny the existence of something just because we don't know about it," said Kervran. "The kind of energies to which the great Austrian natural scientist and clairvoyant Rudolf Steiner refers as cosmic etheric forces must exist if only from the fact that certain plants will only germinate in springtime no matter what amounts of heat and water are administered to them during other parts of the year. There are varieties of wheat said to germinate only as the days lengthen, but, when days are artificially lengthened, the wheat does not always germinate."

We do not know what *matter* really is, says Kervran. We do not know what a proton or an electron is *made of*, and the words serve only to cloak our ignorance. He suggests that inside atomic nuclei may lie forces and energies of a totally unexpected nature and that a physical theory to explain the low energy transmutations with which he deals must be sought, not in the hypotheses of classical nuclear physics based on powerful interactions, but in the field of hyperweak interactions in

which there is no assurance of the operation of the established lawsof conservationof energy or even the existence of a mass/energy equivalent.

Physicists, says Kervran, are mistaken in claiming that physical laws are the same for the living as for inanimate matter. Many physicists declare, for instance, that a negative entropy, a force which in biology would build up matter, is an impossibility, since the second principle of thermodynamics of Carnot-Clausius, regarding the breakdown of energy, states that there is only positive entropy, i.e., that the natural state of matter is chaos and that all things run down and become random, losing heat and not acquiring it.

In contradiction to the physicists, Wilhelm Reich held that the accumulators he built to collect an energy, which he named "orgone," permanently raised the temperature inside their tops, thus making nonsense of the second law of thermodynamics. Despite the fact that he demonstrated the phenomenon to Albert Einstein in his house in Princeton, and that Einstein confirmed the phenomenon, though he could not account for it, Reich was considered mad.

Reich maintained that matter is created from orgone energy, that under appropriate conditions matter arises from mass-free orgone, and that these conditions are neither rare nor unusual. All of this further suggests that in living nature there exists, below the level of Lavoisier's classical molecular chemistry, a deeper level of nuclear chemistry which associates and dissociates nucleons, the components of atomic nuclei. In molecular combinations heat energy is produced. At the nuclear level a much more powerful energy, that of fission or fusion as in A or H bombs, must be added. What remains unexplained is why these fantastic energies are not released in biological transmutations.

Science et Vie has postulated that if plasma-type nuclear reactions take place in bombs, in nuclear reactors and in stars, then there must be a wholly different type of reaction, specifically utilized by life, which brings about fusion in a strangely quiet way. The magazine suggests the analogy of a strongbox which can be opened by dynamite or by a combination lock. Like the lock, the atomic nucleus can prove stubborn when confronted with blind violence but pliable to skillful manipulation. The secret of life, so long suspected by vitalists, is as much a secret as the locksmith's combination. The cleavage between the animate and the inanimate is to be found at the level of manipulation of the nuclear lock. It appears that, whereas man has to use dynamite, plants and other living organisms know the combination.

Kervran also wonders whether microorganisms can even take sand and make it fecund. After all, he maintains, humus comes today from organic matter but at one time there was no organic matter on earth.

This raises the question of whether Dr. Wilhelm Reich was not on the track of the discovery of the century when he purported that he had observed at the microscope energetic vesicles or "bions" which are not alive but "carry biological energy." Exposed to sufficiently high temperatures and made to swell, all matter, even sand, undergoes vesicular disintegration, wrote Reich, and the resulting vesicles can later develop into bacteria.

Kervran, who has now retired from his duties as one of France's more eminent professors in order to embark on the career of a determined alchemist, asks why chemically pure reactions such as the combination of one atom of nitrogen and one atom of oxygen can be realized in a test tube only at extremely high temperatures and pressures whereas living organisms can perform the same feat at room temperature. He feels that the biological catalysts known as enzymes are in some way responsible.

In a yearbook entitled *Alchemy: Dream or Reality?* published in 1973 in Rouen by the students of the prestigious Institut Nationale Superieur de Chimie Industrielle, Kervran writes that microorganisms are a concentration of enzymes. Their ability to transmute elements is not a mere hooking of peripheral electrons to form bonds as in classical chemistry but involves a fundamental alteration of the nucleus of elements.

Most transmutations have been observed to take place within the first twenty elements of the periodic table. They further always seem to involve hydrogen or oxygen. Thus the transmutation of potassium to calcium is accomplished through the addition of a hydrogen proton.

Kervran expects the phenomena he describes, and the data he supplies, to irritate chemists because it involves, not the displacement of electrons in the peripheral atomic layers and the chemical bonding in

molecules which lie at the heart of their discipline, but the alteration in structural arrangements of atoms induced by enzyme activities in living matter. Since this takes place within atomic nuclei, a new science distinct from chemistry is involved. Though strange at first sight, the new language is so simple that the average high school student can easily follow it. Thus, if one has sodium with eleven protons written ${}_{11}Na$ and oxygen with eight protons written ${}_{8}O$ one need only add the protons together to get nineteen, the number which exists in potassium written ${}_{19}K$.

Following this reasoning, calcium (Ca) can come from potassium (K) with the interaction of hydrogen (H) according to the formula ${}_{1}H$ plus ${}_{19}K$ equals ${}_{20}Ca$, or from magnesium with the interaction of oxygen in ${}_{12}Mg$ plus ${}_{8}O$ equals ${}_{20}Ca$, or from silicon with the interaction of carbon in ${}_{14}Si$ plus ${}_{6}C$ equals ${}_{20}Ca$.

Since nature's atom smashing, according to Kervran, is performed by biotic life, microorganisms are thus nature's prime mover in maintaining balance in soils.

In Kervran's view some transmutations are biologically beneficial, others dangerous. Since the harmful ones can be countered, the whole problem of deficiencies in the soil remains to be reassessed. Indiscriminate application of NPK fertilizers to the land can alter the content in plants of just those elements necessary to healthful nutrition. In this connection, Kervran cites the work of an American researcher, who, knowing nothing of Kervran's theory of biological transmutations, found that in hybrid corn too rich in potassium the content of molybdenum decreases. "What *are* the optimal quantities of these two elements in plants?" asks Kervran, then continues: "This does not appear to have been studied, and there is not only one answer, since values differ not only between species but between varieties of the same species."

Even if potassium fertilizers were no longer available to agriculturalists, Kervran says, this would represent no catastrophe since microorganisms could produce potassium from calcium. If yeasts and molds for penicillin are already being produced on an industrial scale, why not factories for growing microorganisms for the transmutation of elements? Already in the late 1960s Dr. Howard Worne started Enzymes, Inc., at

Cherry Hill, New Jersey, where microorganisms bombarded with strontium 90 were being mutated so as to produce enzymes that would transmute waste carbon into usable carbon simply by having microorganisms ingest one material and excrete a new one. Dr. Worne is now in New Mexico using microorganisms to transform solid waste from garbage and stockyards into humus for the compost-hungry Western states and methane gas for the energy-hungry Eastern states.

The understanding of the phenomena of biological transmutation, though as yet unrecognized by the majority of the world's agriculturalists, seems to have been anticipated by the advocates of biological cultivation, who, above all, realized that a price must be paid for *reliance on chemistry in a biological context.* Cultivation based on classical chemistry alone, stresses Kervran, fails wherever intensive and abusive methods are employed. The marked crop increases, such as those for the Illinois corn, can thus last only a certain time.

Though not applied as abusively as in America, where huge areas have been lost to cultivation because of a surfeit, even the more limited European use of artificial fertilizers has led, says Kervran, to a mounting lack of resistance in plants to pests. The increase of infestation is no more than a consequence of biological imbalance.

"Classical soil scientists and agronomists attached to the dogma that biology equals chemistry," writes Kervran, "cannot conceive that all that is in plants has not been put into the soil. They are not the people to advise farmers; farmers should be guided by the enlightened and intelligent agriculturalists who have long recognized the division between a purely chemical and biological agriculture. They might then achieve their own conversion, and carry out some of the experiments described in this book for themselves. If they are men of good faith, they will admit their past errors, but one doesn't ask that much—only that they act."

Pointing out that the great English astromomical physicist Fred Hoyle gave up the theory of the steady state universe which he utilized for nearly a quarter of a century and which made him famous, Kervran notes that Hoyle himself has recognized that if future observations confirm that physics has taken a wrong direction then "the properties of matter, the laws of chemistry, for example, would be completely changed."

It is in bulletins such as that of the British Soil Association that Kervran sees articles confirming his ideas of biological transmutation in the soil. In the French analog of this bulletin, *Nature et Progrès,* one researcher reports that, after analyzing month by month for one year the phosphorus content of identical soils, one benefited by fermented compost containing no phosphorus and the other by phosphorus-rich farmyard manure, the first sample had 314 milligrams of phosphorus at the year's end as against only 205 milligrams for the second. The researcher concluded: "Therefore the soil containing the greater amount of phosphorus was the one without any external supply of this mineral. A miracle of the living soil."

If Dr. Barry Commoner sees the buyers of artificial fertilizer becoming "hooked" on their product, Kervran says the same thing for plants. Offering them chemicals, he writes, is simply drugging them to achieve higher yields—for a time. He compares this process to stimulating human appetites with an *apéritif* and then not following it up with a meal.

Louis-Victor de Broglie, winner of the Nobel Prize for his prediction of the wave properties of the electron, has said: "It is premature to want to assess vital processes according to the very insufficient physio-chemical concepts of the nineteenth or even the twentieth centuries." Kervran, who puts this quotation at the start of the British edition of his book, adds: "Who is to say in which present-day branch of physics 'mental energy,' the strength of will or character, should be placed? One can associate memory with information and negative entropy with cybernetics (or should it be chemistry?) but nothing tells us if intelligence itself will not someday be expressed by a physical or chemical law."

Jean Lombard, a geologist, in a preface to Kervran's second book, *Natural Transmutations,* published in 1963, stated that Kervran had opened up a wide field, which in itself could lead to clarification of confusions in geological theory. Lombard also wrote: "The true workers of science, who are always ready to welcome new suggestions, sometimes ask themselves if the greatest obstacle to the progress of science is not bad memory on the part of scholars; they wish to remind the latter that some of their predecessors were burnt at the stake because of proposed 'interpretations' which have now become foremost truths. If pioneers of science were still being burnt, I would not give much for Louis Kervran's skin."

Reviewing Kervran's third book, *Low Energy Transmutations*, published in 1964, Professor René Furon, of the Faculty of Sciences at Paris University, wrote: "This book completes the two previous ones. It can no longer be denied that nature makes magnesium out of calcium (in some cases the reverse takes place); that potassium can come from sodium; and that carbon monoxide poisoning can occur without inhalation of CO gas."

It appears that outside France, not Western, but Japanese scientists have been the first to take Kervran's work seriously. When Hisatoki Komaki, a professor of science, read a Japanese translation of Kervran's book *Biological Transmutations*, he tied Kervran's findings into ancient Eastern cosmology and wrote to Kervran to say that the transmutation of sodium, a *yang* element, into potassium, a *yin* element, was of far-reaching interest, more especially since Japan has a paucity of potash deposits but ample supplies of sea salt.

Komaki abandoned his teaching to become head of a biological research laboratory at the Matsushita Electric Company and informed Kervran that he would try to confirm the sodium-to-potassium reaction and interest his collaborators in applying it on an industrial scale. Komaki's research proved to him that various microorganisms, including certain bacteria and two species each of molds and yeasts, were capable of transmuting sodium into potassium and that the yield of bacteria themselves was enormously raised when only a small amount of potassium was added to the cultures. Komaki has placed on the market a product made of brewer's yeast which, applied to composts, raises the potassium content in them. How this process relates to the action of Biodynamic sprays as conceived by Rudolf Steiner and developed by Ehrenfried Pfeiffer remains to be determined.

Kervran's work is also attracting important notice in the Soviet Union. Professor A. P. Dubrov of the Institute of Earth Physics of the USSR Academy of Sciences, who has been working on the links between radiosensitivity in animals and the geomagnetic field, wrote to Kervran at the end of 1971 to suggest that the magnetic field of the earth itself

might well play an important role in biological transmutation, and that elements might be affected depending on whether biological forms are oriented north-south.

In 1971, a Russian book, *Problems of Transmutations in Nature*, was published in a limited edition in Yerevan, capital of the Armenian Republic. Its editor, V. B. Neiman, notes in a lead article, "Transmutations in Nature: The Present Status of the Problem and Objects for Further Study," that the fundamental problems of entropy and negentropy must be re-examined, and maintains that the diversity of elements on earth is due to a series of nuclear transmutations with analogous processes applied to biological phenomena.

Neiman dug out the most extraordinary quotation from Lenin's *Materialism and Empirocriticism*, proving that the father of the Soviet Union tried to incorporate in his materialistic philosophy a notion more palatable to vitalists and mystics than to hard-core Communist pragmatists. "However miraculous, from the viewpoint of common sense," wrote Lenin, "the conversion of imponderable ether to ponderable matter may seem, it is but a further confirmation of dialectic materialism."

In the same collection, P. A. Korol'kov contributed an essay on the "Spontaneous Metamorphism of Minerals and Rocks," in which he shows how silicon can be converted to aluminum. In his summary of a conference held in July, 1972, devoted to chrome deposition in the Urals, Siberia, Kazakhstan, and the Soviet Far East, Korol'kov comes to the conclusion that the traditional geological views on the genesis of chromite and associated ores do not accord with new data presented at the conference.

"The fact is," writes Korol'kov, "that we are witnesses and participants in a scientific-technological revolution, that is, we are living in a time in which we are being subjected to a radical revision, not of minutiae, but of the basic status of an inherited natural science. The time has come to recognize that any chemical element can turn into another, under natural conditions. And I am not alone in maintaining this. I know a dozen persons in the USSR who hold the same views."

If Soviet scientists are coming around to a whole new view of matter

—and even citing Lenin on the possibility of its manufacture by the ether itself—it would seem that the ecological revolution so necessary to safeguard the future of humanity, and pleaded for in the United States since Fairfield Osborn wrote *Our Plundered Planet* shortly after World War II, may have a chance of taking place despite the host of adversaries who see in it the demise of their personal fortunes.

In a review of the American edition of Kervran's book for the International College of Applied Nutrition, V. Michael Walczak, M.D., an internist practicing in Studio City, California, said of Kervran's work: "It offers a totally different approach to our understanding of nutritional supplementation of the elements and how it functions in the physiologic and biochemical pathways of our bodies. It attempts to prove that our concepts of simple supplementation for deficiencies is not only questionable, but in serious error."

Though many nutritionists untrained even in simple chemistry are giving people huge and unnecessary doses of calcium because it is the mineral in largest quantity in the body, Walczak, who is now limiting his practice to internal metabolism and nutrition, states that his own research shows that 80 percent of his patients—with diets supplemented or unsupplemented—have *too much* calcium and too few trace minerals with respect to calcium. The lack of trace elements in soils, and in foods, Walczak maintains, leads to an imbalance in enzyme function.

Walczak says he is preventing disease by administering the right amounts of enzymes, hormones, vitamins, and minerals, which together he calls "the key to life," and also curing a host of degenerative diseases. He concludes that the "gold" which the medieval alchemists tried for centuries to derive from lead may very well turn out to be the secret for obtaining good health and long life.

Walczak's views are supported by Richard Barmakian, a nutritionist in nearby Pasadena, who wrote to Kervran's American publishers that the U.S. version of *Biological Transmutations* should prove to be "the most significant work of this century, scientifically and possibly otherwise." It was only after he had read the book that Barmakian thought he might at last get to the core of the problem of calcium-metabolism abnormalities and deficiencies which he says are "so tragically prevalent

in pseudo-civilized countries of the world today and especially in the U.S.A."

This view was echoed by *Organic Gardening and Farming*, now published by J. I. Rodale's son, Robert, which stated that Kervran had showed that current chemical treatment of the soil is totally wrong and is rapidly destroying the quality of the soil worldwide: "We're sure that as our understanding of the life processes involved in organic farming grows, the scientific community will be in for many surprises." The economist Charles Walters, Jr., publisher of *Acres USA*, also concurs: "Louis Kervran has opened a door. His works have received important recognition from Russians, Japanese, French and Chinese who don't have to ask the United States Department of Agriculture and the petrochemical firms what to think, as is the case with too many extension agents, land grant colleges and farmers under the thumb of bank examiners."

If doctors, nutritionists, editors, and economists in the United States are now beginning to see in Kervran the herald of a new age, as are professional scientists abroad, it may be that a revolution is at hand. Perhaps the time is near when the dictators of nutritional and agricultural policies, who have forced upon all natural life, from the smallest microorganisms to human beings, a drenching of chemicals to the point where the only recourse against adulterated food products is the growing of one's own private garden under natural conditions, will have to listen to the prophets who have warned against the chemification of the soil since the beginning of this century.

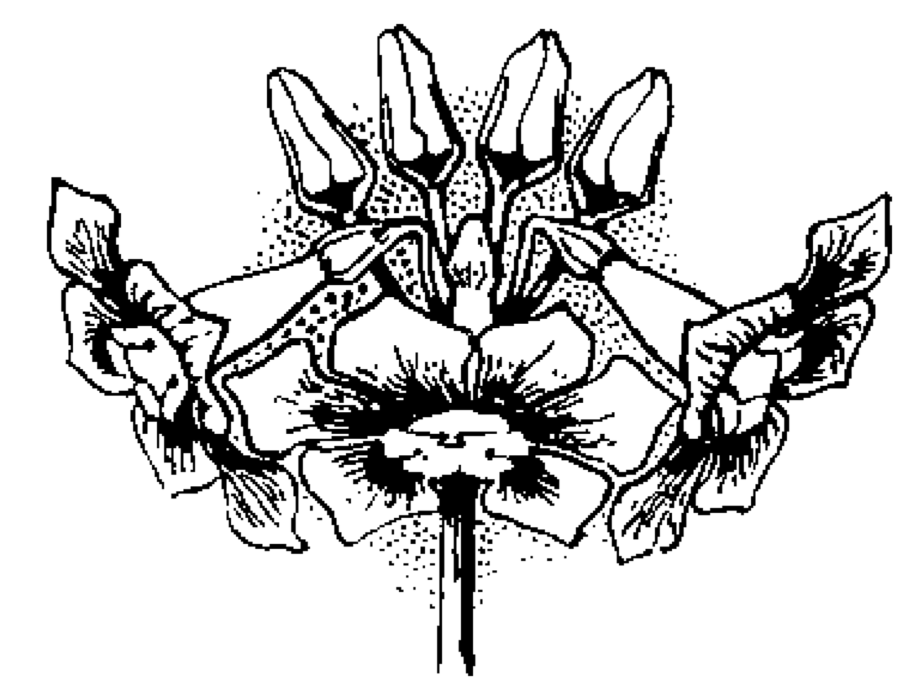
In an age in which science itself has become so specialized and the science of life, or biology, so molecular that our technological society seems to be producing a crowd of white-coated "idiot savants" who plead lack of competency in all but their own narrow divisions of knowledge, the broad outlooks of Goethe, Pfeiffer, Howard, Commoner and Voisin and the new discoveries by Louis Kervran may be the one antidote to catastrophe.

PART V

THE RADIANCE OF LIFE

CHAPTER 18

Dowsing Plants for Health



On the brighter side of life, a French engineer, André Simoneton, has found a straw which may keep the population of the planet from going under; his device, usable by man, woman, or child, is designed to make it possible to select healthy food from bad before ingesting it: it is a simple pendulum attached to a short piece of string used by diviners of water, lost objects, or the future.

For millennia the art or science of dowsing with forked stick or pendulum has been practiced by Chinese, Hindus, Egyptians, Persians, Medes, Etruscans, Greeks, and Romans. In the Renaissance it was revived by such notables as Goethe's predecessor as Director of Mines in Saxony, Christopher von Schenberg, who had his portrait painted holding a dowsing rod, a custom emulated in modern time by Lloyd George, who had himself photographed in the same pose.

Though dowsing has not yet been accepted as a science in America, in France it is no longer relegated to the domain of the witch and warlock—despite the fact that over the centuries many a French dowser has paid with his life for practicing "sorcery." Among the more celebrated victims were Jean du Chatelet, Baron de Beausoleil, and his dowser wife Marine de Bertereau, who, working under the protection of Maréchal d'Effiat, Louis XIV's superintendent of mines, discovered several hundred profitable mines in France only to be arrested for sorcery and succumb in prison, she in Vincennes, he in the Bastille. The persecution has continued in France mostly against doctors who find themselves dragged before tribunals for perpetrating dowsing cures on patients officially declared uncurable.

That dowsing is no longer considered anathema by the Church is thanks largely to the efforts of a long series of French abbés such as Mermet, Bouly, Vallemont, Richard, Carrie, Descosse, and Ferran, and the recent intercession in Rome of such an eminent churchman as Cardinal Tisserant.

In the scientific community the art is now on the fringe of recognition thanks to professors such as Yves Rocard of the Collège de France, head of the physics department of the prestigious Ecole Normale Supérieure, who is recognized not only as a brilliant physicist but as an admirable dowser. His book on the science of dowsing, *Le Signal du Sourcier,* as yet unpublished in English, has been translated in the Soviet Union where geologists have recently been dowsing for minerals from airplanes and helicopters, and also locating underground archeological artifacts.

The Mecca for dowsers in Europe is located in a small Parisian side street, now lost between the luxury of the Faubourg Saint Honoré and the tourist-ridden arcades of the rue de Rivoli, appropriately named for Saint Roch, canonized for protecting the populace against various pestilences. The actual Kaaba is an old curiosity shop called the Maison de Radiesthesie, "*radiesthesie*" being generic for dowsing and for the search for radiations beyond the electromagnetic spectrum, an appellative given to the art by the Abbé Bouly, who coined it from the Greek for "sensitivity" and the Latin for "radiance."

On the shelves of this now venerable institution, run for the last half century by Alfred Lambert and his wife, are scores of books on dowsing —dowsing for water, for objects, and for health. In addition to those written by Catholic clergymen, there are others by aristocrats such as Count Henry de France and Count André de Belizal and by several distinguished French physicians.

There are also brass and mahogany showcases protecting various exotic machines, some simple, some sophisticated, designed to tune in, amplify or shield radiations, healthy or toxic. The machines are used mostly by doctors from all over the world for diagnostic and curative purposes, though the fundamental instrument in each case is the simple pendulum. These lie in stacked drawers on velvet cushions designed in many shapes and sizes from various materials, including ivory, jade, and octagonal quartz or crystal, though any weight on any string or chain is said to be effective.

In the United States, Dr. Zaboj V. Harvalik, a professional physicist recently retired from his post as scientific adviser to the U.S. Army's Advanced Material Concepts Agency to devote himself to private research, has turned his attention to the dowsing phenomenon and to how physical theory might help to explain it. As chief of the research committee of the American Society of Dowsers, Harvalik is helping to break down fifty years of prejudice in official circles against dowsing as a "quack art."

At his home on the banks of the Potomac River in Lorton, Virginia, Harvalik has made meticulous tests to reveal for the first time that dowsers react with varying degrees of sensitivity to polarized electromagnetic radiation, artificial alternating magnetic fields in a frequency range from one to one million cycles per second and to DC magnetic fields. Harvalik is convinced that dowsers pick up magnetic field gradients whether they are trying to find water, underground pipes, wires, tunnels, or geological anomalies.

Dowsing, however, appears to extend far beyond the detection of flowing water or the magnetic field gradients thought to be associated with water currents. In its broadest definition it is simply *searching*—for anything. The former president of the American Society of Dowsers, John Shelley, before his premature death in 1972, amazed his fellow naval reserve officers when at the end of a training session at the Pensacola, Florida, Naval Air Station he was able, by using only a small dowsing rod, to locate his government salary check, which his colleagues had conspired with the help of the paymaster to hide somewhere in a huge two-story naval building with dozens of rooms branching out of its corridors.

Gordon MacLean, a research chemist for Pine State By-Products in Portland, Maine, who still works full time despite his eighty-odd years, will take any visitor out to the Coast Guard lighthouse at Portland Head and with his "divining" rod accurately predict when the next oil tanker on its way into Portland harbor will appear on the horizon and where.

Perhaps the most celebrated American dowser is Henry Gross, also of Maine, to whose feats Kenneth Roberts, the American historical novelist, devoted three books in the 1950s. Like the French abbots, Gross is an expert at dowsing from maps. Sitting at his kitchen table, he pinpointed on a map of the British-governed island of Bermuda, on which no source of water had been found, just those spots where he said drilling would produce it. To everyone's amazement, Gross was correct.

To physicists like Harvalik the forces at work in *map* dowsing, which do not appear to be related to the magnetic gradients operative in *field* dowsing, are totally inscrutable. Obviously a dowser is contacting some source of information which can provide accurate data on areas—or parts of space—far removed from his own physical location. Rexford Daniels, whose Interference Consultants Company of Concord, Massachusetts, has been pioneering the study for twenty-five years of how proliferating electromagnetic emissions interfere with one another and may work harmful environmental effects on man, states that he has become convinced that some overall force exists in the universe which is itself intelligent and provides answers. Daniels theorizes that this force operates through a whole spectrum of frequencies not necessarily linked to the electromagnetic spectrum and that human beings can mentally interact with it. To Daniels dowsing is simply an as yet imperfectly

defined though exceedingly useful communications system. In his eyes an important task confronting man now is to check out the system in all of its aspects.

The specific technique of dowsing food for freshness and vitality was learned by engineer Simoneton, now also in his eighties—though he looks like a successful French businessman in his sixties—from another extraordinary Frenchman, André Bovis, a fragile tinker who died in his native Nice during the Second World War. Bovis is most widely known for his experiments with pyramids built to the dimensions of the Great Pyramid of Cheops, which he found would mysteriously dehydrate and mummify dead animals without decomposing them, especially if they were placed in a pyramid at the relative height of the King's Chamber, or one third of the way from the base to the summit.

Basic to Bovis' theory is that the earth has positive magnetic currents running north to south, negative magnetic currents running east to west. He says that these currents are picked up by all bodies on the surface of the earth, and that *any* body placed in a north-south position will be more or less polarized, depending on its shape and consistency. In human bodies these telluric currents, both positive and negative, enter through one leg and go out through the opposite hand. At the same time cosmic currents from beyond the earth enter through the head and go out through the other hand and foot. The currents also go out through the open eyes.

All bodies containing water, says Bovis, accumulate these currents and can radiate them slowly. As the currents go out and act and react against other magnetic forces in objects, they affect the pendulum held by the dowser. Thus the human body, as a variable condenser, acts as a detector, selector and amplifier of short and ultra-short waves; it is a go-between for the animal electricity of Galvani and the inanimate electricity of Volta.

At the same time the pendulum, says Bovis, acts as a perfect lie detector in that if a person is frankly saying what he thinks about some subject, it will not affect the radiations and thus not affect the pendulum; but anyone saying something different from what he is thinking changes the wavelengths, making them shorter and negative.

Bovis developed a pendulum from a similar device which he says was used by the ancient Egyptians, made from crystal with a fixed metal point suspended on a double strand of red and violet silk. He called it "paradiamagnétique" because it is sensitive to objects which are either attracted or repelled by a magnet. Bodies which are attracted, such as iron, cobalt, nickel, magnesium, chrome, or titanium, he called paramagnetic; those which are repelled, such as copper, zinc, tin, lead, sulfur and bismuth, he called diamagnetic. By placing a small magnetic field in the form of a solenoid between the dowser and the pendulum he claimed to be able to pick up very faint currents such as those emanating from a nonfecundated egg. He explained the use of red and violet strands as increasing the sensitivity of his pendulum on the grounds that red light vibrations are the same as the atomic vibrations of iron, which are paramagnetic, and those of violet being the same as copper, which are diamagnetic.

Bovis found that with his pendulum he could tell the intrinsic vitality and relative freshness of different foods within their protective skins because of the power of their radiations. To measure with his pendulum the varying radiant frequencies produced by foods Bovis developed a *biomètre,* or simple ruler arbitrarily graduated in centimeters to indicate microns, which are thousandths of a millimeter, and angstroms, which are a hundred times smaller, covering a band between zero and ten thousand angstroms.

By placing a piece of fruit or vegetable, or any kind of food, at one end of the ruler, Bovis could watch his swinging pendulum change directions at a certain distance along the ruler, which gave him an indication of the degree of the food's vitality. According to Bovis the limit of any object's radiance is overcome at some point by the general telluric field surrounding it, and can thus be measured. Dowsers maintain that any two objects of the same material and size placed a yard or so apart will create two fields which will repel each other at a halfway mark easily noted with a pendulum. Increasing the size of one of the objects will cause its field to move closer to the smaller object.

Simoneton found that food which radiates 8,000 to 10,000 angstroms on Bovis' biomètre would also cause a pendulum to turn at the remarkable speed of 400 to 500 revolutions per minute in a radius of 80 millimeters. Foods which radiate between 6,000 and 8,000 spun it at a rate of 300 to 400, with a radius of 60 millimeters. Meats, pasteurized milk, and overcooked vegetables, which radiate less than 2,000 angstroms, have not sufficient energy to make the pendulum spin.

For those who might complain about the arbitrary selection of angstroms for measuring the relative radiant vitality of objects, Louis Kervran, in a preface to Simoneton's book, *Radiations des Aliments,* points out that the angstrom is no more arbitrary than the calorie used in nutrition—a calorie being the quantity of heat required to raise the temperature of one gram of water one degree centigrade. All systems of measurement, says Kervran, are conventional; Bovis' angstrom merely made it easy to distinguish between the radiant value of fermented cheese, which reads at 1,500, and that of fresh olive oil, which reads at 8,500. In any case, Kervran adds, the wavelengths emitted by fruits and vegetables and other biochemical foodstuffs which are picked up with the pendulum are of totally unknown nature, apparently outside the electromagnetic spectrum. It is simply the fact that they are measurable by dowsing methods which remains of great practical value.

According to Bovis, wavelengths broadcast by an object are picked up by the nerves in a human arm and then amplified by means of a pendulum swinging at the end of a string. Impressive proof of this has been established in Montreal by Jan Merta, whose laboratory experiments clearly indicate that a minute muscular movement occurs in the area of the wrist a fraction of a second after a change in the encephalograph has been registered. Merta has also designed a dowsing device, which can be placed not only in the hands but on the arms, shoulders, head, legs, or feet, or any other part of the body where it can be balanced.

In line with Bovis and Lakhovsky, Simoneton reasoned that if human nerve cells can receive wavelengths they must also be transmitters: senders and receivers must be able to enter into resonant vibration with each other in order to pick up a transmission. Lakhovsky likened the system to two well-tuned pianos: when a note is struck on one it will cause the same note to vibrate on the other.

Some dowsers say that the prime sensor in the human body may be located in the area of the solar plexus. This appears to be borne out by Harvalik's most recent research. To shield parts of the human body from the effects of the ocean of magnetic forces surrounding it, Harvalik took an eight-foot-by-ten-inch strip of highly effective magnetic shielding (made from a Co-Netic AA Perfection Annealed sheet 0.025 inches thick, produced by the Magnetic Shield Division of the Perfection Mica Company) and rolled it into a two-layered cylinder which could be lowered around the body to shield head, shoulders, torso, or pelvic area.

With the shield covering his head, Harvalik walked blindfolded across a level area known to produce dowsing signals and obtained a strong reaction over each of three dowsing zones. The same reactions were obtained with his head exposed but his shoulders shielded. Gradually lowering the shield, Harvalik found that he could pick up dowsing signals until he reached an area between the 7th and 12th rib, that is to say from sternum to navel.

"These measurements," says Harvalik, "suggest that dowsing sensors must be located in the region of the solar plexus and that perhaps there are additional sensors in the head or brain."

Dr. J. A. Kopp of Ebikon, Switzerland, who for years has been working with dowsing techniques to locate geopathogenic zones that seem to be related to high incidences of cancer, reported in 1972 that a German engineer, in an experiment analogous to those of Harvalik, had himself carried horizontally on a stretcher over a dowsing zone. As his head passed the dowsing zone, the rod was undisturbed; when his solar plexus was above the same zone, the dowsing rod immediately reacted.

Using a pendulum to establish the relative radiance of different foods was a technique developed by Simoneton as a matter of life or death. During the First World War he underwent five operations. One dark night lying on a stretcher by a hospital train he overheard two medics whispering in the shadows cast by a kerosene lantern that he was so severely tubercular there was no chance of his recovery. A forced diet of rich food ruined his liver and gave him other unpleasant side effects. Barely surviving the ministrations of the medics, Simoneton discovered Bovis' system of selecting fresh and vital foods from poisonous fare. In

a short time he rid himself not only of the TB but of its side effects and became so healthy that years later, at sixty-six and sixty-eight he still fathered children, and at seventy was still playing tennis.

As a young engineer Simoneton had been drafted into the French army to work on the new science of radio, which, says Simoneton, was in those days at about the level that dowsing is today. During World War I Simoneton worked alongside such electrical luminaries as physicist Louis de Broglie, who was to establish that every particle, down to a photon of light, is associated with a specific wavelength.

With this background Simoneton had enough electrical engineering and radio knowledge not to dismiss Bovis as a quack, and was able to establish empirically that with Bovis' system he could measure specific wavelengths from foods that indicated both vitality and freshness. Milk, which he measured at 6.5 thousand angstroms when fresh, lost 40 percent of its radiation by the end of twelve hours and 90 percent by the end of twenty-four. As for pasteurization, Simoneton found that it killed the wavelengths dead. The same he found true of pasteurized fruit and vegetable juices. Garlic juice, when pasteurized, coagulated like dead human blood and its vibrations dropped from around eight thousand angstroms to zero.

On the other hand freezing fresh fruit and vegetables has the effect of prolonging their life; on defrosting they resume their radiance at almost the same level as when they were iced. Food placed in a refrigerator will deteriorate, but at a much slower pace. Unripe fruits and vegetables in a refrigerator may actually increase in radiance as they slowly mature.

Dehydrated fruit was found by experiment to retain its vitality; if soaked in "vitalized" water for twenty-four hours, even several months after drying, it would reradiate almost as strongly as when freshly picked. Canned fruits remained perfectly dead. Water turned out to be a very strange medium: normally unradiant, it was capable of being "vitalized" by association with minerals, human beings, or plants. Some waters, such as those at Lourdes, Bovis found, in 1926, to radiate as high as 156,000 angstroms. Eight years later some of the same water still registered 78,000 angstroms. The Czech-born psychic Jan Merta holds that the rind from apples, pears, and other fruits and vegetables, when left to soak in a glass of water overnight, releases healthful vibrations into the water which can then be drunk to provide better nourishment than the rind itself, which has little or no effect on Simoneton's pendulum.

To simplify life for readers of his book, Simoneton divided foods into four general classes. In the first he placed those foods whose radiant wavelength he found higher than the basic human wavelength of 6,500 angstroms, going up to 10,000 or higher. These include most fruits, which run between 8,000 and 10,000 at the peak of their maturity, and vegetables if eaten fresh from the garden. Simoneton noted that by the time most vegetables get to the market in town they have lost one-third of their potency; by the time they have been subjected to cooking, they have lost another third.

Simoneton says fruits are filled with solar radiation in the healthful light spectrum between the bands of infrared and ultraviolet, and that their radiance rises slowly to a peak while ripening, then gradually decreases to zero at putrefaction. The banana, which is healthily edible for about eight days out of a span of twenty-four between the time it is picked and when it starts to rot, gives off optimum vibrations when it is yellow, not so good when green, and very low when black.

Anyone who has lived in pineapple-growing areas of the world such as the Hawaiian islands knows that a pineapple picked and eaten at the precise time of its ripening—a period lasting no longer than a few hours—has a delicious taste which amazes people who have only eaten store-bought fruit picked long before they come to maturity.

Vegetables are most radiant if eaten raw, two raw carrots being better than a plateful of cooked ones. The potato, which has a radiance of only 2,000 angstroms when raw (perhaps because it grows underground hidden from the sun), mysteriously rises to 7,000 angstroms when boiled and all the way to a very healthy 9,000 when baked. The same applies to other tubers.

Legumes, such as peas, beans, lentils, or chickpeas, rate 7,000 to 8,000 when fresh. Dried they lose most of their radiance. They become heavy, indigestible, and hard on the liver, says Simoneton. To benefit from legumes they too should be eaten raw and freshly picked. Optimum

results, says Simoneton, come from their juices, especially if drunk at 10 A.M. and 5 P.M. when they are easily digested and do not tire the system but nourish it.

On Simoneton's scale wheat has a radiance of 8,500 angstroms; when cooked this rises to 9,000. He says wheat can and should be eaten in a variety of ways rather than simply in bread. Whole-wheat flour should be mixed into pies, tarts, and other pastries with butter, eggs, milk, fruits, and vegetables. Baked in a wood-burning oven, bread gives off even better radiations than if cooked with coal or gas.

Olive oil was found by Simoneton to have a high radiance of 8,500, and to be extremely long-lasting. Six years after pressing it still gives off around 7,500. Butter, which radiates about 8,000, is good for about ten days before it starts to fall off, reaching bottom in about twenty days.

Ocean fish and shellfish are good foods with a bright radiance from 8,500 to 9,000 especially if caught fresh and eaten raw. This includes crabs, oysters, clams, and other shellfish. Lobsters, says Simoneton, are best cut in half while live and broiled on a wood fire. Fresh water fish is much less radiant.

In Simoneton's second category he places foods radiating from 6,500 down to 3,000 angstroms. These include eggs, peanut oil, wine, boiled vegetables, cane sugar, and cooked fish. He rates a good red wine between 4,000 and 5,000, and says it is a better drink than devitalized city water, and certainly better than coffee, chocolate, liquor, or pasteurized fruit juices, which have virtually no radiance.

Echoing Nichols, Simoneton says that, whereas the juice of a fresh sugar beet gives 8,500 angstroms, refined beet sugar can fall as low as 1,000, and the white lumps that get wrapped in papers are down to zero.

Of meats, the only one that makes Simoneton's list of edible foods is freshly smoked ham. Freshly killed pork radiates at 6,500, as does all animal meat; but once it has been soaked in salt and hung over a wood fire its radiance rises to 9,500 or 10,000 angstroms. Other meats are almost pointless to eat; they are an exercise in tough digestion, which wears out rather than vitalizes the eater, requiring him to drink coffee to keep from falling asleep.

Cooked meats, sausages, and other innards are all in Simoneton's third category along with coffee, tea, chocolate, jams, fermented cheeses, and white bread. Because of their low radiation they do one little or no good, says Simoneton.

In his fourth category are margarines, preserves, alcohols, liquors, refined white sugar, and bleached white flour: all dead as far as radiations are concerned.

Applying his technique for measuring wavelengths directly to human beings, Simoneton found that the normal healthy person gives off a radiance of about 6,500 or a little higher, whereas the radiations given off by tobacco smokers, alcohol imbibers, and carrion eaters are uniformly lower. Bovis claimed that cancer patients give off a wavelength of 4,875, which, he noted, was the same wavelength as that of overrefined white French bread before the Second World War.

However, because a cancer victim will radiate this low level long before any overt symptom of his disease is in evidence, Bovis pointed out that it is possible to take remedial steps well before the ailment has made serious inroads into the body's cellular tissue.

It is Bovis and Simoneton's thesis that human beings should eat fruit, vegetables, nuts, and fresh fish that give off radiations higher than their own normal 6,500, if they wish to energize themselves and feel healthy. They believe that low-radiance foods, such as meats and bad bread, instead of bringing vitality to the body, sap the body of its existing vitality and that that is why one can feel heavy and devitalized from a meal one expected to replenish one's energy.

From the fact that most microbes read well below 6.5 thousand angstroms, Simoneton, like Lakhovsky, deduces that they can only affect a human being whose vitality has been lowered to a point where cells resonate at their wavelength, whereas a body with a healthy vitality remains immune to attack by microbes. This gives a *raison d'être* for deadly microbes in an ordered universe. The same principle, no doubt, explains why plants whose radiance has been reduced by chemical fertilizers are subject to attack by pests.

It struck Simoneton that the therapeutic marvels attributed since the dawn of history to herbs, flowers, roots, and barks might not be due simply to their chemical content, but the healthy wavelengths they radiate. Though the apothecary's shelves are still stocked with chemical

derivatives from plants and herbs, their curative powers no longer appear so miraculous. The secret of their potency seems to have been lost.

Old wives and hermits are still reputed to know and understand the mysterious healing powers of plants, but they must have acquired their knowledge by some extra sense, or the woods would be strewn with the corpses of accidented sages, poisoned by belladonna, deadly nightshade and a host of other noxious weeds.

Simoneton believes the day will soon come when vaccines are made not from the bodies or carcasses of animals but from the radiant juice of plants. To set the world right Simoneton envisages doctors with headphones like radio operators, able to diagnose by the frequencies they receive from patients just what ails them, able to broadcast to them just the frequencies required to set things right.

Perhaps the most informed doctor in the healing power of plants was Paracelsus, who acquired his lore from old European herbalists, from wise men of the East, but primarily from the direct study of nature. According to his "doctrine of sympathetic resemblances" all growing things reveal through their structure, form, color, and aroma, their peculiar usefulness to man. Paracelsus recommended that a physician sit quietly in a meadow, relax and soon notice "how the blossoms follow the motion of the planets, opening their petals according to the phases of the moon, by the cycle of the sun, or in response to distant stars."

A modern follower of Paracelsus who turned out to be an extraordinary wizard with herbs and plants was a young London doctor, Edward Bach, who gave up a handsome practice as a physician on Harley Street in the 1930s to take to the woods and fields in search of a better cure for his fellow human beings. Like Paracelsus who sought to restore health by natural means so that it would not be necessary for the sick first to recover from their ailment and then have to recover from the cure, Bach rebelled against the idea that medicine should be painful and unpleasant. Noting that in most hospitals in England the so-called remedies gave the patient great pain and often did him more harm than good, he was determined to find remedies in nature that would neither be harmful nor unpleasant. He sought a remedy that would be gentle, sure, and would result in healing of both mind and body.

Like Paracelsus and Goethe, Bach was convinced that true knowledge was to be gained not through man's intellect, but through his ability to see and accept the natural, simple truths of life. Paracelsus had asserted that the further you search the greater you will realize the simplicity of all creation, and advised physicians to search within themselves for the spiritual insight that would lead them to sense and recognize the energies of plants.

In the summer of 1930 Bach turned the key on his lucrative practice and took to the highway, wandering through the English countryside and into the wild mountains of Wales in search of the wildflowers he was convinced contained the secret to healing both the spiritual and physical ailments of aberrant mankind. Like Paracelsus he was convinced that disease of the body is due not primarily to physical causes, but to disturbing moods or states of mind which interfere with the normal happiness of the individual, moods which if allowed to continue lead to a disturbance of the functions of the bodily organs and tissues with resulting ill health.

With Paracelsus, Bach believed that everything that lives radiates, and with Simoneton, he realized that plants with high vibrations were able to raise the lowered vibrations of human beings. As he put it, "herbal remedies have the power to elevate our vibrations, and thus draw down spiritual power, which cleanses mind and body, and heals." Bach compared his remedies to that of beautiful music or arrangements of color, or any gloriously uplifting medium that gives inspiration; his cure was not to attack the disease, but to flood the body with beautiful vibrations from wild herbs and flowers, in the presence of which "disease would melt away as snow in the sunshine."

Myrna I. Lewis, coauthor with Robert N. Butler, M.D., of a new book, *Aging and Mental Health,* was amazed when recently taken by the Soviets on a visit to several sanitariums in the Black Sea city of Sochi to find aging Soviet citizens, afflicted with a variety of ills, both physical and mental, being treated not with drugs but with vibrations from flowers in greenhouses where they were led to smell specific blooms so many minutes a day. They were also being treated with music played in their rooms and the sound of the sea recorded on tapes.

Fundamentally, Bach maintains that it is up to the sick person to change his mind about his own illness, but that healthy aesthetic vibrations help him recover his desire to be well. Bach felt that a long bout of fear or worry could deplete an individual's vitality to the point where his body lost its natural resistance to disease, and was thus in a state to become the prey of any infection and any form of illness. "It is not the disease which needs the treatment," said Bach. "There are no diseases; only sick people."

Although he was convinced that plants with the right medical properties were to be found among the simple wildflowers of the countryside, Bach was out to find those with the greatest power, capable of being more than palliatives, actually able to restore health to mind and body.

The first flower he tested for its medicinal properties was the yellow-spired agrimony *(Agrimonia eupatoria),* a common wildflower which grows in abundance on the grassy verges of country roads and fields throughout England. Its small blooms are golden with many stamens of the same hue. Bach found an infusion of it to be a great remedy for worry, for the restless tormented state of mind so often hidden behind outward cheerfulness. Next he experimented with the striking blue flower of chicory, which he found a remedy for overconcern, especially for others, and discovered that it brought calmness and serenity. Bach's remedy for extreme fear was the administration of a dose of the elixir of rockrose. As his discoveries and ministrations progressed, Bach felt he was on the verge of discovering an entirely new system of medicine. On impulse or instinct he went to the Welsh wilderness, where he found two beautiful plants: the pale mauve impatiens, and the golden-flowered mimulus, growing in profusion near a mountain stream. Both turned out to be powerful medicines.

During his months in Wales, Bach felt his senses quickening, becoming more developed. Through a finely developed sense of touch he was able to feel the vibrations and power emitted by any plant he wished to test. Like Paracelsus, if he held a petal or bloom in the palm of his hand or placed it on his tongue he could feel in his body the effects of the properties within that plant. Some had a strengthening, vitalizing effect on his mind and body; others would give him pain, vomiting, fevers, rashes, and the like. His instinct told him that the best plants would be found blooming in the middle of the year, when the days are longest and the sun at the height of its power and strength. The plants he chose were the most perfect of their kind, their bloom beautiful in shape and hue, growing in profusion.

Perhaps Bach had read that Paracelsus on his estate at Hohenheim had captured dew on plates of glass, gathering the dew under various configurations of the heavenly bodies, believing the water to carry within it the energy of these planetary combinations, or perhaps he had a flash of intuition. At any rate, early one morning as he walked through a field upon which the dew still lay heavy, it struck Bach that each dewdrop must contain some of the properties of the plant upon which it rested; the heat of the sun, acting through the fluid, would serve to draw out these properties until each drop was magnetized with power. He realized that if he could obtain the medicinal properties of the plants he was seeking in this way, the resulting remedies would contain the full, perfect, and uncontaminated power of the plants, and they might heal as no medical preparations had been known to heal before. Collecting the dew from certain flowers before the sun had caused evaporation, he tried it on himself, shaking the drops from various flowering plants into small bottles, filling some with the dew from flowers which had been in full sunlight, some from those still in shade, although the latter never seemed as potent as the ones in the sun.

Though many of the flowers did not contain the healing properties he sought, Bach found the dew from each plant held a definite power of some kind, and deduced that the sun's radiation was essential to the process of extraction. As collecting sufficient dew from individual flowers could be laborious he decided to pick a few blooms from a chosen plant and place them in a glass bowl filled with water from a clear stream, leaving them standing in the field in the sunlight for several hours. To his delight he found that the water became impregnated with the vibrations and power of the plant and was very potent. To potentize his water Bach would choose a summer day with no clouds to obscure the sun's light and heat. Taking three small plain glass bowls filled with fresh water, he set them in a field where the flowering plants were growing, then selected the most perfect blossoms and placed them on the surface

of the water. To lift the blooms from the water without touching the fluid with his fingers he used two blades of grass. The water was then transferred by means of a small lipped phial to bottles. When half-full the rest of the bottle was filled with brandy designed to preserve the mixture. Before the next experiment Bach would destroy both bowls and phials.

Altogether Bach produced thirty-eight remedies and wrote a philosophic booklet to go with them. Thousands of patients throughout England and the world were to vouch for their efficacy, and many thousands still depend on this elixir of flowers to cure them of innumerable ailments.

The work of Maurice Mességué, a sophisticated Frenchman born of peasant stock in a remote section of Gascony known as the Gers, parallels that of Bach. Taught by his father, who took him as a child on herb-collecting trips all over the countryside, Mességué went on to become a famous herbal healer successfully treating hundreds of patients including such notables as the president of the French Republic, Edouard Herriot, and artist Jean Cocteau. Among the afflictions he cured were such baffling ones as a withered arm on a beautiful young girl and the apparent inability to talk in a child of twelve. Most of Mességué's cures were effected by having his patients soak their extremities in infusions of wild plants. Hounded into court on many occasions for practicing medicine without a medical degree, Mességué fought back because he felt he could not abandon the thousands of sufferers who pleaded for his assistance. An account of his life with many anecdotes about his encounters with world figures appears in three best-selling books he has written on the subject of plants.

Another sensitive who can feel the radiations from flowers has gone Bach and Mességué one better, saying he can transfer radiations direct from a blooming flower into a bowl of water without in any way harming the plant on which it grows.

A ruddy-cheeked Scotsman, very independent, Alick McInnes was born and lives on a sheep farm in the shadow of the castle of the Thane of Cawdor, surrounded by gently rolling hills and a fortune in peat bog —which he cannot dig or burn because by Scottish tradition it all belongs to the Thane. Blindfolded, McInnes can put his hand over a ripe bloom and tell from the wavelength of its radiation just what plant it is and what its medical properties may be. In India, where he spent thirty years working for the British Raj, McInnes got his first introduction to the fact that plants not only give off radiations which are sensible to humans, but are themselves sensitive to the radiations given off by humans; this he discovered when he visited the Bose Institute near Calcutta.

By the entrance to the Institute stands a luxuriant *Mimosa pudica*. Visitors are requested to pick a small frond from this compliant horticultural guinea pig and place it in one of Bose's complicated machines, which provides a schematic pattern of the vibrations of the plant on a sheet of paper. A visitor is then asked to place his wrist inside the machine and watch as a duplicate of the pattern is produced, demonstrating that mimosa is so sensitive it can pick up and faultlessly reflect individual human radiations.

As McInnes interprets the phenomenon of human and plant radiations, each individual member of either kingdom modifies or qualifies with his own wavelength the fundamental energy radiating through him. The same applies, says McInnes, down to the finest particle of matter: "Everything radiates wavelengths which can be identified as sound, color, form, movement, perfume, temperature and intelligence."

McInnes says the radiations from some flowers are circular, others go from left to right, others from right to left. Some go up and down; others down and up; some go diagonally from left to right; others in the opposite direction. Some feel cold; others warm. But the same flower species always gives off the same radiation. McInnes says he has found it possible to transfer flower radiations to water, where the radiations will stay more or less indefinitely. He has some bottles with radiations still effective after twenty years. Each flower species has a time when its radiations can best be transferred to water, usually, though not always, when the flowers are at the peak of their maturity, which is also usually near a full moon.

Potencies, as McInnes calls the radiations which are transferred to water, can be taken from the rose around midsummer, or June 21, and

from the dandelion around the Easter full moon. When conditions are right, transfer of the radiations is instantaneous, and McInnes, wrinkling his weatherbeaten lips into a wise smile, says the water can actually be seen to change, "an awe-inspiring experience never to be forgotten." Far from damaging the plant, McInnes says that just at that moment when its potency is transferred to water, other members of the same species for miles around brighten up and appear to grow more vigorously than before. The resulting potentized water McInnes calls an Exultation of Flowers, which he says is not a specific for the treatment of any diagnosable disease, but operates in a subtle way on the radiations coming through the human body, on animal or the soil, and in so doing raises the vitality of the person, animal, or soil concerned. When vitality is raised to the necessary level, says McInnes, illness disappears.

McInnes prescribes his Exultation to be taken by mouth, so many drops at a time for varying conditions, as a salve for cuts and burns and other problems of the skin, and as a tonic diluted in one's bath. He says that although he has been asked to do so he has never attempted to find individual flowers, or groups, that would be helpful in the treatment of a particular disease. He figures it more worthwhile to work on the concept that all illness has a common cause, and strives for a preparation that will, ultimately, bring results to every illness, no matter what the diagnosis. The decision as to whether potencies from any particular flower should be included in the forty-odd varieties in his Exultation has been made by McInnes by feeling the radiations emanating from the particular potency concerned. He finds that not all can be mixed successfully. Some seem to cancel each other out; others disturb the mixture; others upset the temper of the radiations already in the preparation. McInnes is amazed at how many differing radiations he has managed to combine in a harmonious whole.

As the radiations in Exultation of Flowers are not identifiable by ordinary methods of analysis based on the identification of chemical ingredients, and as so far the impulses cannot be identified by any measuring instrument available in Britain, McInnes has been obliged by a court action instituted by the Scottish health authorities to label his bottles "Guaranteed Chemical Composition—100% water, without herbal or chemical ingredients." Pointing out that magnetized steel and ordinary steel show the same chemical ingredients but are obviously quite different from each other, McInnes still hopes some new method will be devised to identify the radiations.

McInnes says his Exultation is just as good for a cow with milk fever in Scotland as it is for a man with asthma in California or a woman stung by a wasp in New Zealand. It can be used on a baby with a stomach ache, on a hive of bees with "foul brood," on strawberry plants with "June yellows" or on hens which have eaten poisoned grain. Sprayed onto the soil McInnes says it increases the activity and quality of soil bacteria. But he warns that gardens which have been treated with chemical fertilizers will take longer to respond "because the whole polarity of the soil has been geared to decay." He says the vibrations of his Exultation channel fresh energy into the soil which counteracts disease, blight, and pests.

In the more than sixteen years since Exultation of Flowers was first offered to the public, many thousands of letters have been received reporting success in the treatment of pretty well every diagnosable disease. Philosophically McInnes believes that all forms of life are created to live in harmony, but mankind has so misused this dominion over created things that there is now disharmony everywhere, which is expressed in physical disease in human, animal, and plant life, the life forces coming from the Source of Creation becoming more and more distorted. Believing that in the Golden Age the lion would lie down with the lamb, he describes how, when he lived in Uganda, he would watch hundreds of animals making tracks through the elephant grass toward the salt licks, with carnivores such as leopards and panthers trotting alongside tiny timorous deer that in other circumstances would tremble and run away.

In South India, where McInnes spent a couple of weeks as the guest of Ramana Mohan Maharshi at his ashram at the foot of the holy hill Arunachalam, famed in Hindu mythology for many centuries, every evening when the Maharshi would go out for a walk, within seconds of his crossing the threshold of his residence, cattle tied up in stalls in the nearby village, about half a mile away, would struggle to get out of their

bonds. Released by the villagers they careered along the road to accompany the old man on his walk, followed by all the dogs and children of the village.

Before the procession had gone very far wild animals, says McInnes, joined it from the jungle, including several varieties of snakes. Thousands of birds appeared, almost blotting out the sky, including tiny tits, huge kites and other birds of prey, heavy-winged vultures, all flying in harmony around the Maharshi on his walk. When he returned to his room, said McInnes, all the birds, animals, and children would quietly disappear. To achieve such an atmosphere worldwide, McInnes realizes, would be quite a feat. His Exultation would have to help produce vegetation of such an improved nutritive quality that the lion could feed on it before he would happily lie down with the lamb. McInnes sees no reason such a food plant could not be encouraged by some new Burbank to grow in abundance.

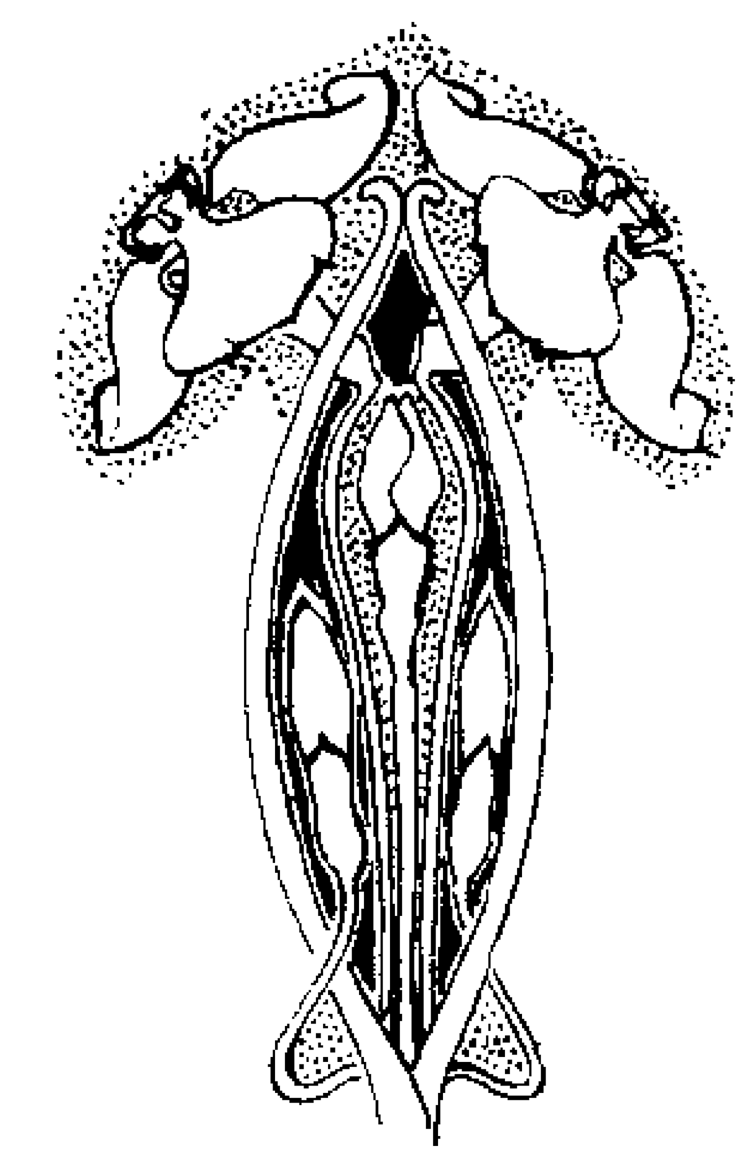
There will also have to be an increase in the sensitivity of humanity, says McInnes, to the point where the sacrifice of animals to sport becomes wholly intolerable, as well as the mass slaughter of animals in total terror in abattoirs. Better food must be more easily obtainable in such abundance that half-starved and semi-brutalized men no longer need to eat meat or demand work of half-dead, diseased, and suffering animals; in other words, we must cease to be a planet of jailors and chain-gang drivers.

As everything created is interdependent, says McInnes, it follows that what affects one form of life must affect all other forms as well. "If we deliberately cause suffering and disease in other lives, we increase our own suffering and disease." All creation, says McInnes, is affected by the disease inflicted on laboratory animals in what he believes to be a futile and foredoomed attempt to combat illness. All creation is tormented through the ghastly agonies which the vivisectionist inflicts on helpless creatures. Any relief of illness supposed to be removed by knowledge gained at the expense of such agonies will, says McInnes, be paid for many times over in increased suffering in some other part of the Whole. All creation suffers when plants in their millions are burnt by chemical weed killers.

Just as every created thing takes a knock for every victim of war or every inmate tortured in a concentration camp, so every created thing takes a knock when a rabbit dies of human-induced myxomatosis, or a plant dies in agony, deliberately diseased with toxic chemicals. "All of life," says McInnes, "is one. There is no exception."

CHAPTER 19

Radionic Pesticides



Simoneton's dream that doctors with earphones would one day diagnose patients simply by tuning in to the frequencies given off by their ailing organs and then be able to cure them by broadcasting to the organs more healthful vibrations has turned out to be closer to fact than fiction. However, because the mechanism appears to be as explosive as TNT and as amenable to the spread of death and disease as it is to the spread of life, the findings have been discreetly scotched by both the political and scientific establishments.

At the end of the nineteenth century Dr. Albert Abrams, the son of a successful San Francisco merchant from whom he had inherited a vast fortune, traveled to Heidelberg to study advanced medicine. In Naples young Abrams watched the famous Italian tenor Enrico Caruso flick a wine glass with his finger to produce a pure tone, then step back and by singing the same note shatter the glass. This impressive feat awoke in Abrams the idea that he might have stumbled on a fundamental principle which could be tied into medical diagnosis and healing.

At the University of Heidelberg's medical school, from which he was to receive top honors and the gold medal, Abrams met a Professor de Sauer, who was engaged—many years before Gurwitsch had happened on "mitogenetic radiation"—in a bizarre series of experiments with plants. De Sauer told Abrams that, while transplanting onion seedlings, he had inadvertently left some of the uprooted onions next to those still growing in one of several flats. Two days later he noticed that the seedlings growing on the side of the flat next to the dying plants were different in appearance from those on the opposite side. De Sauer could not explain the reason for the difference but Abrams was convinced that the onion roots were emitting some strange form of radiation and linked this in his mind with the resonance phenomenon behind Caruso's voice-shattered glass.

Abrams returned to the United States to teach pathology at Stanford University's medical school, of which he was later to become director of medical studies. A superb diagnostician and master of the art of percussion, he would tap the body of a patient to produce resonating sounds, which became clues to whatever ills might be afflicting the patient. One day Abrams noticed that when a nearby X-ray apparatus was switched on without warning it dulled the resonant note he was getting from his tapping. Perplexed, Abrams rotated his patient and discovered that the strange dulling occurred only while the man faced east and west, but that when he was aligned north and south the percussion note was continuously resonant. There seemed to be a relationship between the geomagnetic field and—as with the grains researched by Pittman in Alberta—the electromagnetic fields of individuals. Abrams later discovered a similar effect was produced by a man with a cancerous ulcer of the lip, even when the X-ray machine was not operating.

After several months of experimentation with persons afflicted with various maladies, Abrams concluded that nerve fibers in the epigastric region not only react by contracting to the stimulus of X-rays generated from a machine several yards distant, but appear to be in a state of permanent contraction in the case of a patient suffering from cancer, except when the patient is oriented in a north-south direction. Because of this similarity, Abrams concluded that the contractions, due in the first case to radiant energy rippling from an X-ray instrument, were in the second case taking place in response to vibrating molecules which were collectively forming the cancerous growth.

Abrams asked his houseboy, Ivor, who had accompanied him to class, to step onto the lecture platform, strip to the waist, and face west. As he tapped the boy just above the navel, Abrams told his students to listen carefully to the hollow, resonant quality of the note he was obtaining. He then asked one young doctor to hold a specimen of cancerous tissue in light contact with Ivor's forehead, applying it for a few seconds, removing it, and applying it again. As Abrams continuously percussed the abdomen, the class was amazed to hear the note change from resonance to dullness each time the specimen was placed on Ivor's forehead, apparently because of a contraction of muscle fibers. When Abrams substituted a tuberculous specimen for the cancerous one, the resonance of the note did not change. But when he began tapping an area just below the navel, the same effect was produced. Abrams was forced to the conclusion that unknown waves from diseased specimens could be received and recorded by a healthy human body and that they somehow altered the character of its tissues.

After months of work, Abrams was able to show that a series of what he called "electronic reactions," varying from cancerous and tuberculer to malarial and streptococcal, could be pinpointed on different areas of the trunk of a healthy person like Ivor. This led him to proclaim that the time-honored idea that disease was of cellular origin was out of date and must be discarded. Instead, he maintained it was because the molecular constituents of cells undergo a structural alteration, specifically a change in the number and arrangement of their electrons, that they develop characteristics which only later become visible at the microscope. Exactly what caused the alteration Abrams did not know, nor does anyone today. He nevertheless suspected that forces could be discovered for correcting what he considered to be intramolecular aberrations, and even for preventing their occurrence.

Abrams next found that the radiation from a pathological specimen could be transmitted, like electricity, over a six-foot wire. When a skeptical doctor challenged Abrams to find the exact location of a tuberculosis infection in his lung for which he had been receiving treatment in a sanitarium, Abrams immediately had the man hold one disc against his forehead and got another student to pass the second disc over the subject's chest until the percussing note changed in tone. The baffled man admitted Abrams had located the infection within centimeters.

Since one spot on the trunk of a healthy subject reacted to not just one but several pathological specimens, Abrams next began to conceive of an instrument which might differentiate between the wavelengths of all specifically diseased tissues. After months of research, he worked out what he called a "reflexophone," an instrument very much like the rheostat—a continuously variable electrical resistor used to regulate current—that could emit sounds varying in pitch and thus obviate the necessity of having to tap a specific point on a body.

Different diseases could now be read from the dial: 55 for a syphilitic specimen, 58 for sarcomatous tissue, and so on. Abrams asked his assistant to mix up the specimens and found he could infallibly select or "diagnose," by checking the readings on his indicator.

Abrams' developments to this point ran not only decades ahead of, but directly counter to, the prevailing medical philosophy of his day. His statement that "as physicians we dare not stand aloof from the progress made in physical science and segregate the human entity from other entities of the physical universe" was as incomprehensible to most of his medical colleagues as were the later pronouncements of Lakhovsky and Crile.

An even more fantastic revelation came when Abrams found he could diagnose the ills of the human body with his instrument from a single drop of the body's blood. Furthermore, by apparently inducting the

effect from one reflexophone to another which contained three rheostats calibrated in units of 10, 1 and 1/25, he was able to determine not only from what disease a person was suffering but *to what stage it had advanced.*

Even more fantastic, Abrams found that if a woman was afflicted with a breast cancer, he could determine from her blood spot alone in which breast the cancer was located, merely by having a healthy percussed subject point with his fingertips to his own breasts. In exactly the same way, Abrams could reveal the exact site of tubercular or any other diseased condition whether focused in the lungs, bowel, bladder, one of the vertebrae; in fact, wherever in the body.

One day while Abrams was demonstrating to a class the reaction induced by the blood of a malarial patient, he suddenly turned and said, "Well, there are upwards of forty of you physicians present, and probably all of you would prescribe quinine to a patient suffering from this disease, but can any one of you offer any scientific reason for so doing?" There being no reply, Abrams took out a few grains of sulfate of quinine and put them where the blood drop had been in the device. It produced exactly the same percussion note as malaria. He then placed the malarial material in the container *together* with a grain or so of quinine wrapped in tissue paper. Now the percussion which had produced a dull sound indicating malaria gave a resonant sound. To his amazed class Abrams put forward the suggestion that radiations emitted by quinine molecules *exactly canceled* those from malarial molecules, that the effect on malaria of quinine was due to an unsuspected electrical law which should become the subject of intensive research. Various other known antidotes behaved similarly—mercury against syphilis, to cite but one example.

Abrams knew that if he could devise a wave-emitting instrument, similar to a wireless broadcasting station, which could alter the character of the waves transmitted by malarial or syphilitic tissue, he might cancel them out as effectively as did quinine or mercury.

Though at first he believed "this was beyond the wit of man," he eventually built an "oscilloclast" with the help of a friend, Samuel O. Hoffman, a distinguished radio research engineer who had achieved fame in World War I by devising a unique method for detecting German zeppelins approaching the U.S. coast even at a great distance. This oscilloclast or "wave breaker" could emit specific waves capable of curing human afflictions by apparently altering or canceling out radiations emitted by various diseases. By 1919 Abrams began teaching its use to physicians, who, because neither they nor Abrams could exactly explain how it effected cures, regarded it as nothing short of miraculous.

In 1922, Abrams reported in the *Physico-Clinical Journal* that for the first time he had effected over telephone wires the diagnosis of a patient miles away from his office, using nothing more than a drop of blood from the patient and analysis of its vibratory rates by his instruments. This somewhat eerie claim finally aroused the ire of the AMA, which published a defamatory article impugning Abrams in its journal as a quack, an article which was parroted in England in the *British Medical Journal.* This caused Sir James Barr, past president of the British Medical Association, who had been successfully using Abrams' methods in his own practice, to write in reply: "You very seldom quote from the *Journal of the American Medical Association* and one might have expected that when you did you would have chosen a more serious subject than an ignorant tirade against an eminent medical man, against, in my opinion, the greatest genius in the medical profession." Barr concluded that one day "medical editors and medical men will begin to perceive that there was more to Abrams' vibrations than was dreamt of in their philosophy."

Abrams' greatest discoveries were that all matter is radioactive and that the generated waves can be picked up across space by using human reflexes as detectors; also, that in many conditions of disease dull patches are consistently found at specific spots on afflicted patients' bodies.

When Abrams died in 1924, the vilification against him continued in the United States in eighteen separate and consecutive issues of *Scientific American.* One of the worst insinuations was that the "Abrams box" had been devised for no other purpose than to make a financial killing by selling it to naïve physicians and an unsuspecting public. No one noted that Abrams, a millionaire in his own right, had written to Upton Sinclair, one of his American defenders, that he would donate his devices to, and work unremunerated for, any institute which would develop the "Abrams box" in the interests of humanity.

The sanctions against Abrams and his work scared off all but a small minority of American doctors, most of whom were independent-minded chiropractors or, as they like to be called, "drugless physicians."

But a generation after Abrams' death one of these, living in the San Francisco Bay area, was visited by Curtis P. Upton, a Princeton-trained civil engineer whose father was a partner of Thomas Alva Edison. Upton's engineering mind led him to wonder whether the strange device used to cure human affliction might not be applied to pest control for agriculture. In the summer of 1951 he and his Princeton classmate William J. Knuth, an electronics expert from Corpus Christi, Texas, drove into the cotton fields of the thirty-thousand-acre Cortaro-Marana tract near Tucson, Arizona. Together they unloaded from the back of their truck a mysterious boxlike instrument about the size of a portable radio, complete with dials and a stick antenna. Only this time they went one better than Simoneton and McInnes. They would attempt to affect the field not directly but through the medium of photographs.

An aerial photograph of the field was placed on a "collector plate" attached to the base of the instrument, together with a reagent known to be poisonous to cotton pests. The dials were set in a specific manner. The object of the exercise was to clear the field of pests without recourse to chemical insecticides. The theory behind the system—as "way out" as anything so far reported on the nature of plants—held that the molecular and atomic makeup of the emulsion on the photograph would be resonating at the identical frequencies of the objects they represented pictorially. Though the American engineers did not know it, the same discovery had been made by Bovis in the 1930s. By affecting the photograph with a reagent known to be poisonous to cotton pests the Americans believed the cotton plants in the field could be immunized against the pests. Because the amount of poisonous reagent used was infinitesimal compared to the number of acres photographed, the reagent was thought to act in the same way that trace dosages of dilution function in Homeopathic Medicine.

Homeopathy is a method of treatment founded by Christian Samuel Hahnemann, a physician of note born in Meissen in Saxony in 1755. Hahnemann, who was also a chemist, a linguist, a translator of medical works, and the author of a comprehensive apothecaries' lexicon, got himself into serious trouble with the then equivalent of the FDA by his discovery that small doses of what can cause the symptoms of a disease in human beings can also cure them. The original discovery was made by chance when the Countess of Cinchon, wife of the Spanish Viceroy to Peru, was relieved of malaria with an infusion of bark from a local tree which produced symptoms in her identical with those of malaria. Thereafter known as "cinchon bark," the remedy was sold by monks in Spain to the rich for its weight in gold and given to the poor for nothing.

Spurred by this novel approach to medicine, Hahnemann made a methodical search for plants, herbs, barks, or any substance, including snake venom, which could produce symptoms similar to those of a known disease, and by administering them in small doses produced some near miracle cures. He found belladonna to be a remedy against scarlet fever, pulsatilla against measles, and gelsemium against influenza. Quite as extraordinary as Hahnemann's cures was his next discovery, that the more he diluted a remedy the more potent and effective it became, even if diluted to an infinitesimal one million to one. Rudolf Hauschka explains the phenomenon by suggesting that if matter is a condensation or a crystallization of cosmic forces, these forces would naturally revert to being more powerful as they were liberated from their material casing like jinns from a bottle.

A careful chemist, Hahnemann would start by diluting the tincture of some bark, root, resin, seed, or gum with ninety-nine parts of pure alcohol. This would give him what he called a one-centesimal potency. He would then dilute one part of this liquid into ninety-nine parts of a diluent. The third time round he would have a tincture that was only one millionth part of the diluent. The result, for some even to him mysterious reason, was far more potent. Hauschka explains part of Hahnemann's secret as being in the rhythmic, mathematical fashion in which he shook his dilutions, rhythm having the same effect it has on humans of freeing the spirit from the clutches of the body.

But the authorities made short shrift of Hahnemann. Already in bad odor with his fellow physicians because he considered bleeding and cupping his patients to be a crime, Hahnemann next incurred the wrath

of his fellow apothecaries when they saw the threat to their profits from the sale of drugs in such minute quantities. The moment Hahnemann's discovery was given to the public in the journal of Goethe's personal physician, Dr. Hufeland, the Guild of Apothecaries (forerunners of today's pharmacists and the "detail men" who each year press hundreds of new pills on doctors) saw to it that Hahnemann was brought before a court, found guilty, forbidden to dispense medicine, and compelled to leave town.

In Tucson in 1951, it would have been hard to find a scientist who would bet the small change in his pocket that Upton and Knuth's protective process could offer them any safeguards against marauding pests. Yet the two engineers pursued their course, repeating the process with aerial photographs covering the entire four thousand acres owned by the Cortaro Management Company, one of Arizona's biggest cotton growers. The company executives were gambling that, if the twelve varieties of pests that normally attacked their million-dollar crop could be kept at bay with so simple a device, they could save up to $30,000 a year in operating costs by eliminating the use of insecticide sprays.

In the fall, the Tucson *Weekend-Reporter* ran an illustrated two-page spread headlined: "Million Dollar Gamble Pays Off for Cotton Man." The article stated that a "Buck Rogers type of electronic pest control" had allowed Cortaro to achieve an almost 25 percent increase in per-acre yield of cotton over the state average. W. S. Nichols, president of the Cortaro Management Company, stated in an affidavit that the treated cotton also seemed to have approximately 20 percent more seed: "This may possibly be the result of not destroying the bees, upon which the radionic process seems to have no effect." Nichols further remarked that his hoe hands had noted an almost complete absence of snakes in the areas subjected to the strange treatment.

On the East Coast of the United States, one of Upton's Princeton classmates, Howard Armstrong, who had become an industrial chemist with many inventions to his credit, decided to try his friend's method in Pennsylvania. After taking an aerial photograph of a cornfield under attack by Japanese beetles, he cut one corner off the photo with a pair of scissors and laid the remainder together with a small amount of rotenone, a beetle poison, extracted from the roots of a woody Asian vine which the Japanese call "roten," on the collector plate of one of Upton's radionic devices.

After several five- to ten-minute treatments with the machine's dials set to specific readings, a meticulous count of beetles revealed that 80–90 percent of them had died or disappeared from the corn plants treated through the photo. The untreated plants in the corner cut away from the photo remained 100 percent infested.

After witnessing this experiment, B. A. Rockwell, director of research for the Pennsylvania Farm Bureau Cooperative Association in Harrisburg, wrote: "To control insect pests at a distance of thirty miles with no danger to man, plants or animals would perhaps be an accomplishment heretofore unrivaled in the scientific control of insects injurious to vegetation. To an individual with 19 years experience in the research field this feat appeared unreal, impossible, fantastic, and crazy. Yet careful counts by the writer of the treated corn plants and untreated corn plants indicated definitely that the kill ratio was 10 to 1 in favor of the treated plants."

Upton, Knuth, and Armstrong combined their talents and the first letters of their names to form UKACO, Inc. The new company's goal was to relieve farmers of unwanted pests by the new method, as scientifically inexplicable as it was simple and inexpensive. The company received the backing of General Henry M. Gross, one of Harrisburg's most distinguished citizens, head of the Selective Service Board for the State of Pennsylvania.

In the West, Upton and Knuth contracted with forty-four artichoke growers to treat their crop against plume moths. The contracts were written on the basis of "no control—no pay." All the growers paid the service charge of one dollar an acre, a tiny fraction of the costs of conventional spraying. In Pennsylvania Rockwell stated: "Since farmers usually do not pay for a service unless there is value received, this is the best testimonial for the UKACO process which has come to my attention."

Convinced that a radical new development for controlling pests was in the offing, Rockwell arranged contracts with his fellow farmers to run

a long series of experiments under his supervision. In 1949 at the cooperative's "Camp Potato" in Potter County, and at the Fairview farmstead in Easton, potato crops treated by the UKACO process yielded 30 percent more than those fields sprayed seven times with conventional insecticides, the saving in chemicals also greatly adding to the value of the crop.

The following year the Farm Bureau's research division operatives, having learned to operate the UKACO equipment themselves, got yields 22 percent greater than in the insecticide-treated fields. In tests at Hershey Estates Farm No. 40, and the bureau's own poultry farm, a pair of cornfields showed, by actual count of cornstalks, 65 percent control of second-brood European corn borer, an efficiency never approached with any other treatment.

In Eatonville, Florida, the director of agriculture for the Hungerford School for Boys, a graduate in agriculture from Tallahassee University, also successfully used the UKACO method to eliminate pestilent worms from the school's cabbage patch and flea beetles from its turnip plants.

At this point, the new insecticideless method of treating crops piqued the curiosity of the United States Department of Agriculture's research station at Beltsville, Maryland, one of whose officials, Dr. Truman Hienton, called General Gross to say that he would like to find out exactly how UKACO was achieving its results. When Hienton and two of his Ph.D. colleagues arrived in Harrisburg, they were informed that the principle behind the machine seemed somehow to be related to that of radio broadcasting. But when UKACO's Howard Armstrong was asked at what wavelength he was broadcasting his treatments, he could only say he did not know. The mystified scientists shook their heads dubiously and returned to Beltsville.

In the summer of 1951 Armstrong traveled through the Cumberland Valley treating corn and anything else the farmers wanted him to treat. He was so successful that when insecticide salesmen visited the farms under treatment they were informed their products were no longer needed. The farmers themselves operated many of the treating devices which were left by Armstrong on their farms. This evidently raised the hackles of the American insecticide industry, which responded that winter to UKACO's new technology in the same way that the British fertilizer industry had to Sir Albert Howard's recommendations. *Agricultural Chemicals*, the industry's mouthpiece, printed an article in its January, 1952, issue, panning the UKACO process as fraudulent. When asked about the article's claim that his test results could not be duplicated by "disinterested agencies," the Pennsylvania farm bureau's Rockwell replied: "I've studied enough science to know a dead Japanese beetle when I see one."

In March of 1952, fifty York County agricultural leaders assembled, with a skeptical glint in their eyes, to hear R. M. Benjamin, executive secretary of the Pennsylvania Farm Bureau, tell them during a two-hour meeting how they could kill or chase away various insect pests by what seemed to be remote electronic control. Benjamin supplied testimonials to back up his story, one of them signed by the Secretary of Agriculture for Pennsylvania, Miles Horst, who reported highly effective results on a rose-of-Sharon bush in his garden which had been infested by Japanese beetles. Though many in the audience at first heckled Benjamin, and one jeeringly remarked that perhaps the cornfields should be injected with "a dose of faith," before the end of the meeting all present became convinced that the new methods should be given a trial the following summer.

When the York *Dispatch*, which had printed an account of the meeting, requested an opinion on the UKACO process from the U.S. Department of Agriculture in Washington, it was surprised to learn that the department put no faith in the process. F. C. Bishopp, assistant chief of the Agricultural Research Administration's Bureau of Entomology and Plant Quarantine, claimed in a letter that one of the bureau's field men had observed the experiments run by Knuth and Upton in the Southwest and found that the insects were *not controlled*. Bishopp added that "though we have not had an opportunity to carefully examine the device, or conduct any properly designed tests of it . . . a number of adverse reports on tests set up by the company have also reached us." He cited an article in the *Arizona Farmer* headlined "Electronic De-Bugger Flops—Promoter of Magic Black Box Leaves Texas Panhandle When Cotton Farmers Find It Didn't Work."

A week later, Bishopp, realizing that tests planned for the summer of 1952 were to proceed as scheduled and, evidently feeling that he had not made his point convincingly, wrote a second letter to the York *Dispatch*, in which he stated in part: "From our limited knowledge of the use of radiation in control of insects we frankly feel that the claims of this company are exaggerated. The question naturally arises as to why the company should proceed with large-scale tests without having competent authorities evaluate the method. We are anxious that unsound methods not be permitted to divert the farmer's attention, at this critical time, from recognized sound insect control practices." Bishopp's aim was evidently to use his authoritative position to prejudge and condemn a process of which he admitted he had no firsthand knowledge.

Rockwell never denied that the radionic process was *not always* successful. He himself stated plainly to the newspaper that certain tests could fail because of interference from standing irrigation pipes, high-tension wires, leaky transformers, wire fences, radar, plant pots, and various soil conditions, and added that, because the patents for UKACO devices had not yet been granted, he was not at liberty to turn one over to the Beltsville research center.

The same spring, the three UKACO partners and General Gross organized a nonprofit foundation to carry on their pest-control work. Because of the homeopathic quality of the reagents used, the nonprofit entity was called the Homeotronic Foundation, at the suggestion of Dr. William J. Hale, former chief of research in organic chemistry for the Dow Chemical Corporation.

In the meantime, despite Bishopp's statements, the USDA's Dr. Hienton again called General Gross to say that he had heard extremely favorable reports on Armstrong's work in the Cumberland Valley the previous year and wondered what his Beltsville agricultural research station could do to assist UKACO's further efforts. Gross suggested that the government research body send five representatives to work all summer with five UKACO operatives, each one of whom was to treat fields in a separate Pennsylvania county. By constant observation of the method of treatment and results obtained, they should be able to determine firsthand whether the UKACO work was all that it claimed to be.

Instead of accepting Gross's offer, Hienton decided to commission a USDA field worker in New Jersey, Dr. E. W. Seigler, and an assistant to oversee the UKACO operations on a sporadic basis.

During the 1952 growing season field corn was treated on 1,420 acres belonging to 61 farmers on 81 separate holdings in five counties; 78,360 individual corn stalks were examined. Officers of the new Homeotronic Foundation worked with several Pennsylvania Farm Bureau officials and one from the Farm Bureau Association of the State of Ohio.

The USDA officials finally put in an appearance on August 7. Dr. Seigler randomly selected one cornfield in York County owned by the Bittinger Cannery and checked the treated corn against the untreated. In four rows totaling 400 plants he found 346 silks damaged by beetles in the untreated section but only 65 silks damaged in the treated section. In another field, owned by the Pennsylvania Farm Bureau poultry farm cooperative, results were 339 and 64. Checks in other areas also testified to the success of the new methods, with the exception of one field where the process inexplicably did not seem to work. Overall results indicated that 92 percent success in the control of Japanese beetles, and 58 percent for corn borers was achieved.

The UKACO team was happy that the results had now been checked by the United States agricultural authorities. But the USDA's Dr. Seigler asked UKACO to refrain from publishing any results in the *Pennsylvania Farm Bureau Journal* until Beltsville had had time to issue their own report. When, after a number of weeks, no report was forthcoming from the USDA research station, General Gross called Beltsville to ask for thirty copies. Instead of mailing them, Bishopp sent a curt letter to Rockwell stating that, since no count had been made *before* the treatment had begun, the reports sent back from Pennsylvania by his own research men were valueless.

As the Pennsylvanians knew that Beltsville was well aware that the pictures had been taken and treatment started long before there was any appearance of either corn ears or Japanese beetles, they found the attitude of the USDA surprising. It seemed that the USDA was intent on killing the UKACO process in the bud. When several very large prospective customers called Beltsville for an opinion about it, they were

informed that the whole thing was a fake that had produced no results whatsoever.

Armstrong next learned from the West Coast that representatives of insecticide companies in concert with USDA employees had been visiting farmers who used the UKACO process and telling them it was an outright fraud. The UKACO team came to the conclusion that Beltsville was directly and intentionally preventing them from proceeding with their work and that lobbyists of the insecticide industry in Washington were putting extreme pressure on the government to stamp out the new pest-control methods which were so dangerously threatening to put them out of business. So effective was the campaign that UKACO had difficulty soliciting new clients among farmers, who were becoming convinced by an army of USDA agents that there was nothing to the Upton-Knuth-Armstrong treatments.

Meanwhile Upton, whose patent application had been rejected for "lack of convincing evidence in the record from qualified experts with scientific backgrounds," submitted a twenty-two-page addendum to support his claim. The addendum pleaded that "it is difficult to precisely define the nature and mechanism of the novel methods" and postulated that the process "comprehends the study and use of certain fundamental energy sources capable of affecting molecules, atoms and electrons through their characteristic harmonic potency resonance frequencies in which every particle of matter exhibits its own characteristic frequency under a controlled polarity in a magnetic field of motion."

In support of their allegations, the inventors cited the work of Dr. Edward Purcell, co-winner with Dr. Felix Bloch of a 1952 Nobel Prize in physics, who published an article in the November 15 issue of *Science News Letter* on the characteristic resonant frequency of elements when resonated in selected magnetic fields, and a report on the work of Dr. Bloch, wherein he succeeded, by a process he designated "nuclear induction," in turning atomic particles into what, in effect, were infinitesimal radio transmitters, whose broadcasts, if highly amplified, could be detected in loudspeakers. There was little doubt in Upton's mind that his "radiotonic treatment," as he called it, made use of the type of energy involved in the Bloch study, which, as Upton wrote, had "not heretofore been recognized by science—particularly in its applications to molecular structures of the complex nature of plant and animal life."

Holding that the work of electronic experts and the detection of potentials by means of delicate apparatus had long since proven the existence and the measurability of various amplitudes of electrical potentials in living creatures, Upton referred to the writings of Drs. George Washington Crile and Harold Saxton Burr.

When all this failed to get the patent accepted, General Gross brought into play his contacts on the boards of some of the nation's largest industrial companies and was able to introduce the process to the consideration of important scientists in the U.S Government, including Vannevar Bush, science adviser to President Eisenhower. When Gross explained to them UKACO's accomplishments and said they were based on the idea that every particle has its own generic frequency, as Dr. Crile had so stoutly maintained, the scientists responded heatedly that the UKACO-obtained results were impossible.

Though Gross politely suggested that the scientists come to Harrisburg and talk with Rockwell and the farmers whose crops had been "radiotonically" protected and see the results for themselves, they declined his invitation. Gross had no more success with the director of the Carnegie Institution in Washington, who flatly told him that there was nothing in the science of electronics to suggest that the UKACO process could work.

Dr. Willard F. Libby, who devised the carbon-14 dating technique, and who was soon to win the Nobel Prize in chemistry, after hearing Gross out, discouragingly yet perhaps accurately told him that it would take more than a million dollars to research the "box."

What also may have alarmed the government was the idea that if a host of insects could be affected, even killed, simply by radiating a poison at them via a picture of the plants which they were attacking, then the same technique could be militarily applied to concentrations of troops or even the populations of whole cities in wartime. All this discouragement, added to the studied and seemingly successful efforts of governmental and industrial moguls to wean farmers away from the new approach to insect control, finally forced UKACO to close its doors. But the story of what came to be called "radionics" was only beginning.

Thirty years before the demise of the UKACO enterprise, a young engineer for the Kansas City Power and Light Company, T. Galen Hieronymus, who was one of the first to be granted an amateur radio operator's license before World War I, was asked by one of his neighbors, a Dr. Planck, to machine various parts for some instrumentation which required precise components, such as strips of silver plate, cut to exact proportions down to the millimeter, and carefully wound coils. Beyond referring to a mysterious medical genius in San Francisco with whom he had studied fantastic new techniques to treat disease, Planck did not enlighten his young machinist as to the purpose of the new instruments he was helping to build. It was only after Planck died and his wife asked Hieronymus to come to the house to look over a workroom full of strange equipment and, because she had no use for it, select whatever he wanted, that Hieronymus learned the real purpose of the equipment he had been machining, and that the name of the unknown surgeon was Albert Abrams.

Meanwhile a vivacious young Los Angeles chiropractor, Dr. Ruth Drown, was also making refinements on Abrams' devices. Drown's most startling accomplishment was her development of a camera which could be used to take pictures of organs and tissues of patients using nothing but a drop of their blood, even when the patients were hundreds or thousands of miles from her office. Even more startling, she could take pictures in "cross-section," which cannot be done with X-rays. Though she received a British patent for this twenty-first-century apparatus, Dr. Drown's claim was relegated by FDA authorities to the realm of science fiction and her equipment was confiscated in the early 1940s. To make sure that her plight was suitably publicized, the same authorities saw to it that reporters from *Life* magazine were on the scene. After the *Life* story presented her as a charlatan, Dr. Ruth Drown died of grief—an unrecognized genius.

While Drown was working in California, still another of Abrams' followers, a Chicago doctor, G. W. Wiggelsworth, with the help of his brother, an electronics engineer who at first looked upon the oscilloclast as an outright fraud but finally became convinced of its efficacy, went on to improve the "Abrams box" by substituting for resistance coils variable condensers, a change which he found vastly improved the tuning. Wiggelsworth christened his new device a "pathoclast" or disease breaker, the users of which banded together into a Pathometric Association.

In the 1930s Glen Wills, an Arkansas chiropractor, successful businessman, and promoter, who pioneered the method of raising broiling chickens in cages or "batteries," heard Hieronymus lecture on electronic theory before the Pathometric Association. Wills bought out Wiggelsworth's Pathometric Association and asked Hieronymus if he could build a modified and more complex version of the pathoclast.

Hieronymus had earlier made a detailed study of his own of strange energies emitted, not from healthy or diseased tissues, but from metals. Working on his theory, he took sterling-silver objects, such as broken spoons, pepper-and-salt shakers, and anything else he could steal from his wife, and buried them in the Kansas prairie.

Knowing the location of the hidden silver, Hieronymus then "worked backward," as he says, trying to find the emanations from it. To his surprise, he discovered that every so often he could find *no energy* emanating from the silver, and wondered if someone might have dug up his hoard. A few hours later the energy would be radiating as strongly as ever.

Hieronymus' eclectic mind next wondered whether the energy was undetectable at given times because it was radiating not upward out of the earth but downward toward the earth's center. To find out, he took an eight-foot copper-clad steel ground rod and sledge-hammered it at an angle into the ground so that it would extend below the silver hoard. When the rod was at the level of the silver or below it, his device, to which the rod was attached, indicated a surge of energy; when he pulled the rod some distance above the silver, no energy was registered.

By repeatedly taking measurements over weeks, Hieronymus found that the energy from the silver seemed to be diverted downward for a few hours every two and a half days. Checking in an almanac he discovered that the cycle of diversions in some ways correlated with phases of the moon. What Pfeiffer had discovered about lunar influence with respect to plants seemed also to be applicable to metals.

Further work with buried metal also convinced Hieronymus that

these energies were, like those in Abrams' experiments, strongly influenced by magnetic attraction. Thus, at least two twentieth-century researchers, one a medical man, like Mesmer, the other a laboratory researcher, like Reichenbach, appeared to have rediscovered the link between mineral magnetism on the one hand and "animal magnetism" on the other.

Hieronymus suspected that the unknown energy emitted from metals might be somehow linked to sunlight; since it could be transmitted over wires, it might have an effect on the growth of plants.

To find out, Hieronymus placed some aluminum-lined boxes in the pitch-dark cellar of his Kansas City house. Some boxes he grounded to a water pipe and connected by separate copper wires to metal plates on the outside of the house exposed to full sunlight. Other boxes were left unconnected. In all of them Hieronymus planted seed grain. In the connected boxes the seeds grew into sturdy green plants. The seeds in the unconnected boxes had no trace of green and were anemic and drooping.

This brought Hieronymus to the revolutionary conclusion that whatever caused the development of chlorophyll in plants could not be sunlight itself but something associated with it, which, unlike light, was transmittable over wires. He had no idea at what frequency this energy might be located on the electromagnetic spectrum, or even if it was related to it.

As Hieronymus continued to build instruments for the doctors, and to experiment with them, he grew more and more convinced that the energy being modulated by the devices had little to do with electromagnetism. This notion became a certainty when he found the device itself was short-circuited if bathed in light rays from the sun just as electrical circuits in a radio are shorted by being plunged into a bath of water.

Hieronymus next designed a special analyzer, first with lenses, finally with a prism, by means of which he could identify, from the radiations they emitted, many of the elements on Mendeleyev's periodic chart. He found that the energy, when refracted through a prism, behaved in the same manner as light, except that the angles of refraction were much more acute, and that the energy from various elements came through at angles of refraction in the same order as the contents of their nuclei. His ability to detect a substance from its radiation alone convinced Hieronymus that disease was destroyed by the Abrams device and its descendants "through a radiative attack on the binding energy which holds molecular structures together."

The frequency of emanation, or angle of refraction, is in exact proportion to the number of particles in the nucleus of an element, says Hieronymus. The range of frequencies or angles of refraction from complex substances can thus be used to disclose what they contain. The energy emitted does not, like electromagnetic energy, attenuate inversely as the square of the distance from its source. It radiates out only a certain distance depending on the object from which it is emitted, on the direction it takes, and even on the time of day of its measurement. Something varies the amount of radiation emitted in the same way that fog, smoke or other materials altering the density of the air in our atmosphere vary the intensity of light from whatever source.

Trying to describe this radiation Hieronymus first came up with the cumbersome explanation: "Energy obeying some of the laws of *electricity* but not all of them, and some of the laws of *optics*, but not all of them." To obviate the repetition he finally coined the term *"eloptic energy."*

This energy, he concluded, though independent of, was somehow affiliated with, electromagnetic energy. Because of the difference, Hieronymus inferred that their spectra of frequencies were necessarily related. He decided to refer to eloptic energy in all its wavelengths as a *fine medium* which, as he wrote, "might be the same as that which used to be described by electronic engineers and physicists as 'the ether' put in action at higher harmonics than so far experienced."

In the early 1940s Hieronymus applied for a patent. The invention to which he put claim was basically a method and an apparatus "relating to the art of detecting the presence of, and measuring the intensity or quantity of, any known element of material matter, singly or in combination, whether in solid, fluid or gaseous form." For those who might rush to duplicate his idea, there was an important qualification in the application which stated that the *"apparatus preferably relies upon the element of touch and, therefore, the skill of the operator."*

This was because the operator had to stroke a detector which, substituting for the abdomen of Abrams' subject, was, in the abstruse language required by the patent office: "preferably an electrical conductor coated with a material having such characteristics that under influence of energy flowing through the conducting portion, the coating will change its surface tension or viscosity, or in some manner give evidence of the presence of the energy flowing through the conducting portion by producing a greater drag or resistance to the movement of any part of the body of the operators thereover, such as the hand or fingers."

What actually happened at the detector, to increase and decrease its drag at the touch of the operator, was not understood, but, as the text lamely explained, "the apparatus functions . . . and, therefore, a positively acting analyzer for atomic radiations is produced even though the principle upon which it is based is not fully known."

When he was invited in 1946, less than a year after Hiroshima and Nagasaki had been blasted, to describe his new process over Kansas City's radio station WHAM, Hieronymus paid full tribute to Abrams. "About twenty years ago a discovery was made by a California man," he said, "that was so hard to believe and more especially by those who did not wish to believe it, that the world was set back by their disbelief for many years. There were a few of those following along who took the original idea to the point where today it is as important, in fact, more important to mankind than the atomic bomb because the latter means destruction of humanity and the other idea means the lengthening of life and the alleviation of disease."

The bacteriologist Otto Rahn, whose book on radiation from living things had so puzzled his colleagues ten years before, after examining Hieronymus' process and experiments, wrote to the inventor: "Since those radiations hold the secret of life, they also hold the secret of death. At present, very few people know about the possibilities, and very few know *all* the facts. It seems imperative that those few keep their knowledge to themselves, and divulge only as much as is necessary to perform the immediate applications to cure disease. Your discoveries open up great possibilities, as tremendous as those of the atom bomb, and just like atomic energy, these radiations may be used for the bad as well as for the good of humanity." In the meantime, the *Saturday Evening Post* published a rehash of the more than twenty-year-old *Scientific American* series in a snide article "The Wondrous Box of Dr. Abrams," authored by a Robert M. Yoder, who falsely claimed that Abrams had risen to "fame and fortune selling a sealed box."

Part of the motive for this hatchet job was revealed by Hieronymus in his answering letter to the *Post's* editor, Ben Hibbs. "This is a controversial subject," wrote Hieronymus, "only because it involves the pocketbook of a large group of people who might be harmed financially should the truth of the present day status of the little black box be made generally known to the public. The unfortunate part of the situation at the moment is that a large pressure group is still fighting tooth and nail to keep the known facts from being presented and I just wonder if the article in the *Saturday Evening Post* wasn't instigated by that group."

The letter appeared in a booklet, *The Truth about Radionics and Some of the Criticism made about it by its Enemies*, published by a group which, because it applied the new term "Radionics" to the therapies being practiced on the basis of Abrams' finding, called itself the International Radionics Association.

In 1949 Hieronymus was awarded United States patent number 2,482,773 for the "Detection of Emanations from Materials and Measurement of the Volumes Thereof." Other patents were later issued in the United Kingdom and Canada.

The story of UKACO and the Homeotronic Foundation is further complicated by the fact that, at one point during the work, Hieronymus went to Harrisburg to consult with and assist Armstrong and his collaborators. Hieronymus told the authors that the device incorporating the amplifier which he had built for Wills was used in Pennsylvania with almost 100 percent success. However, according to Hieronymus, the UKACO group could not understand his notion that a new "eloptic energy" might be involved and preferred to proceed on the theory that the device worked solely on electromagnetic or electronic principles.

When they made further adaptations on his device, says Hieronymus, they began to get less than perfect results. The lack of a perfect record, however, was more than overshadowed in Hieronymus' eyes by observations which shook him profoundly. At the Hershey farms, together with

a UKACO representative he selected three ears of corn on each of which a corn worm was munching.

Isolating the ears so that the worms could not escape, Hieronymus began to treat them with his radionic broadcaster. He states that, after three days of treatment for ten minutes per hour round the clock, two of the corn worms were reduced to mush but the third was still wobblily intact. Another twenty-four hours of the same treatment and the stubborn worm was also mush. All that remained of the others was just "wet places" on the corn ears.

Hieronymus was so stunned by the lethal potential of the tuned radiation that he resolved never to reveal everything about the makeup of his devices or their operation until he could one day find serious researchers of impeccable character to help him elucidate the exact potentials of his discoveries.

Having for years measured the states of the human body and its organs radionically, Hieronymus and his wife, Louise, operator of the device, decided in 1968 to check the ongoing conditions of the first men ever to go on a trip to the moon.

They ordered photographs of the three astronauts from Washington and, after inserting them one at a time in their instrument, claimed they were not only able to track and monitor all physiological functions of the astronauts from the earth to the moon and back, but to determine that the transmitting energy could neither be shielded by the metal shell of the capsule nor affected by the great distance from Mother Earth or her satellite. They said they were also able to measure the effects of high "G" stress on the astronauts during take-off and re-entry as well as the effects of living in a weightless—zero "G"—environment for an extended period.

The Hieronymuses' most startling claim was the discovery of what they term a *lethal radiation belt round the moon*, which during the landing of Apollo 11 apparently extended from an altitude of roughly sixty-five miles down to approximately fifteen feet above the moon's surface. While the astronauts were traveling through or within this belt, Hieronymus noted a drop in the vitality as measured by his wife on the "box." But when two of the astronauts got out of the capsule and climbed down the ladder onto *luna firma,* he says the trends showed a spectacular turnaround.

In following later flights of the Apollo series, Hieronymus found that the lower level of the mysterious lethal atmosphere was as high as two miles above the moon's surface. Hieronymus believes further that its altitude may alter depending on a given time period or on its exact position above various spots on the moon's surface, or both, but states that extensive observations will be required to confirm this.

No less interesting was Hieronymus' confirmation that the energy he was picking up from the spacemen appeared not to be related to any of those on the electromagnetic spectrum. When the capsule was on the far side of the moon relative to the earth, no radio or other telemetered signals could be transmitted back to the Houston base. The astronauts were thus out of contact with their earthbound guides. Not so with Hieronymus, who says he was able to monitor them during this period on his analyzer. On the other hand, when the capsule was on the far side of the moon relative to the sun, i.e., in the moon's shadow, radio signals were easily sent to and received from earth, whereas Hieronymus' analyzer went "dead" and could pick up nothing. This seemed to confirm the idea, hit upon by Hieronymus when he was growing plants in his cellar, that the energy received by his analyzer was in close association, if not carried on, sunlight rays.

A German-born engineer, Rolf Schaffranke, working as a propulsion expert for American corporations contracting with NASA in Huntsville, Alabama, who as a young student watched the launching of the first man-made rocket, the V-2, from the secret German base at Peenemünde, wrote of Hieronymus' experiment: "Sounds absolutely crazy. Yet it really happened. Numerous observers are firmly convinced that the experiment is repeatable. Repeatable anywhere, any time, with as many witnesses present as desired."

Wondering whether eloptic energy could be carried not only on light rays from our sun but on those from all cosmic bodies including planets, Hieronymus took a ten-power telescope from an ordinary navigational sextant onto the roof of his house in Lakemont, Georgia, and fixed it so that it could be constantly directed at any spot in the heavens.

After focusing on Venus, he replaced the telescope's eyepiece with a metal disc penetrated by a hole, and soldered a wire to the edge of the disc to conduct what he believed was eloptic energy down into the house to the radionic device operated by his wife. Mrs. Hieronymus began to run tests similar to those which had measured the vitality rates of the astronauts' bodily parts and systems so as to see if there was anything that gave a similar response on the Venusian surface. Of the thirty-five wavelengths received from astronauts' organs and systems, half seemed to be tunable from Venus, the others not at all.

Perplexed by these findings, the Hieronymuses were suddenly struck that they might be receiving energies from parts, not of animals, but of plants. So they began running analyses on the organs of earthly plants *as if they were human beings.*

Checking three trees, a mango, a willow, and a pine, Hieronymus found that while they all had what appeared to be the equivalent of lungs, pineal, thymus, and pituitary glands, adrenals, thyroids, stomachs, a colon wall, a prostate, ovaries, and a nervous system, there were strange differences among them. The mango alone, for instance, seemed to have something akin to a lymphatic system, but, unlike both the willow and the pine, no duodenum or spleen.

Hieronymus next checked Bermuda grass, which he knew does not propagate by seeding itself but extends endlessly underground. Sure enough, no sex organs could be detected for the grass according to his readings, though a weed registered ovaries even when he had removed its seeds. Strangely, the Bermuda grass seemed to have the analog of an appendix.

The readings from Venus set on the tunings for each organ or system, for analog thereof, clearly indicated some structure on Venus similar to that of earthly plants. Hieronymus concludes that there may well be a form of Venusian plant life, though he has no idea what kind, or why the vitality of its organs seems to be more than twice that of the earth plants he has tested; nor has he any idea whether such "plants" may have no more than what occultists call etheric or astral bodies.

By the summer of 1973, as a result of the publication of a series of articles about him and his work in U.S. magazines devoted to the unexplained, Hieronymus began to attract wider interest; his correspondence mushroomed with letters and calls asking for further information.

Still keenly aware of Rahn's post-Hiroshima warning, and remembering with awe the corn borers reduced to no more than "wet spots," Hieronymus is still leery of revealing all he knows. As he stated to the authors: "While we are not intending to hold back scientific investigation, we are not going to broadcast complete information on our technology to the general public so that people can play around with it irresponsibly any more than we would advocate giving dynamite and matches to small children. If a group of responsible people will help us to run a proper and broad investigation of eloptic energy for the good of mankind, I will be glad to cooperate and tell them all I know."

CHAPTER 20

Mind Over Matter

About two decades before UKACO's efforts to help the farmers of Pennsylvania were put to rout by the chemical manufacturers and the USDA, a book appeared in the United Kingdom called *The Chain of Life* by the British surgeon Guyon Richards, who had built up wide experience in medical problems as physician in charge of an entire district for the Indian medical service.

He was stimulated by the theories of a colleague, Captain Sandes, who introduced him to the little-known benefits of ionization and its remarkable effects on the treatment of disease, a branch of science later developed in Germany and more particularly in the USSR, but almost wholly neglected in other countries. Richards became, as he put it, "electrically-minded," and proceeded to make detailed galvanometric studies of plants and people in health and disease. Of Abrams, Richards said it was a pity that the very invention of the oscilloclast had, because its curative properties could not be exactly explained, obscured from the medical profession the important issues which Abrams had raised.

Richards' book restimulated interest in radionics among a small coterie of imaginative British doctors who wanted to experiment with the new healing process. Looking for an engineer who could help them build the strange new equipment, they sought out an "English Hieronymus" and found him in the person of an Oxonian, George De La Warr, a psychically-gifted civil engineer.

Having built a series of instruments covered in black leather, which came to be known as "black boxes," about a year following the demise of UKACO, the work of which they had no inkling, De La Warr and his osteopath wife, Marjorie, found that they could affect the growth of diseased or undernourished plants by focusing "radionic" energy straight at them through a lens system, thus substantiating the claim of Hieronymus, of whom they were also unaware, that it was optically refractable. Like the UKACO partners, the De La Warrs found that they could obtain equally successful results either by directly radiating a plant or by beaming energy to it through one of its leaves or even its photograph. Why this should be so remained a mystery to the De La Warrs, who could only state: "It is still problematical whether it is the apparatus, the photographic emulsion or the presence of a specific operator that produces the effects—or a combination of all these factors."

De La Warr further theorized that in addition to radiations of light the emulsion on the negative receives from the subject other radiations, the precise nature of which was unknown. There was also evidence that a relationship perdured between a plant and a leaf detached from it, or the expressed juice of that plant, just as it existed between one of Abrams' patients and his blood spot.

"It would appear," wrote De La Warr, "that each molecule of matter is capable of producing a tiny electrical voltage that is specific to itself, and which 'transmits' rather like a tiny radio transmitter-receiver. A

collection of molecules, therefore, is capable of transmitting a generic pattern. This means that the signal from a plant or human is quite individual, and that each plant or person will receive a transmission on their own generic pattern. It is here that the photograph plays its part, as it is thought that the emulsion on the negative retains the generic pattern of the object photographed and can be induced to re-radiate as a carrier. Thus, with a photograph of a plant in circuit it is possible to affect that plant at a distance."

The theory was in no way airtight, but the results obtained by radionics were fantastic. Realizing that the presence of living organisms in the soil is a prerequisite to good husbandry, the De La Warrs wondered if they could treat the soil itself through the cells living within it by radiating energy patterns effectively equivalent to plant nutrients. To attempt this they determined to photograph the soil of garden plots, treat the photos radionically, then plant vegetables in the treated soil to see how they would fare.

They began with cabbages. Selecting two sites eighty feet apart, in the curtilage of their laboratory, they removed all the topsoil. This they thoroughly sieved and mixed to eliminate any possibility of soil variation, then spread it back on the sites, allowing it to settle for a week.

On the 27th of March, 1954, they began a month-long treatment of one site by radiating its photograph daily in their darkroom, leaving the other site untreated. This treatment accomplished, they planted four young cabbages, selected for their similarity, into the soil of each site. For two weeks no difference in the rate of growth was observable, causing them to have doubts about the procedure. Thenceforth to the end of June, the cabbages in the treated soil continued to grow larger than those left to grow normally. Photographs taken some four weeks before maturity revealed that the plants in the treated site were *three times larger* than those left to grow normally.

Encouraged by this success, the De La Warrs decided to repeat the experiment on a larger scale. They noticed that in one strip of garden three rows of peas thirty-seven feet long were growing so uniformly as to leave little doubt that the soil was of equal consistency throughout. The peas were uprooted and the site prepared for fresh planting. The strip was divided into fifteen plots, six of which were photographed from a bird's eye view and treated radionically every day for one month. Two plots were left untreated; seven others were used as buffers.

At the beginning of August, ninety-six Early English winter-resisting broccoli plants, all seven inches high, were set out, six to a plot. The radionically treated plots were rephotographed with the plants in them and irradiated daily until the experiment was concluded in mid-January, 1955, after snow and ice had apparently stopped all growth. Accurate weighing of the plants under the scrutiny of an expert from Oxford University's Department of Agriculture, Dr. E. W. Russell, who observed the experiment from beginning to end, revealed that an average 81 percent increase in total crop yield had been obtained for the treated plants compared to the nontreated controls.

After successfully experimenting with lettuces, suggested by Russell because they were fast-growing, the De La Warrs next decided to broadcast treatment from their laboratories to a garden at Old Boars Hill, two miles from Oxford. They laid out an equilateral plot, divided it into four squares, and planted broad-leaf beans in each square. A single square was photographed and irradiated from the beginning of May to the beginning of August, 1955. At the end of the test, the height of the bean plants grown in the treated square was 9½ inches greater than in any of the other squares, and the number of pods greater than for all the other plants combined.

Further to extend the distance between the soil treated and the laboratory, the De La Warrs cooperated with a carrot grower in Scotland. Soil samples taken from seventeen acres of a twenty-two-acre field were irradiated at Oxford each day throughout the growing season. When the carrots were pulled from the earth, those treated weighed out 20 percent heavier than the ones which were left alone. Pleased as they were with the astonishing results they were obtaining, the De La Warrs still had no idea why the radiation from their equipment affected the growth of various vegetables so favorably.

During the next growing season in 1956, they decided to ascertain whether an inert substance, if irradiated and mixed with soil, could reradiate the nutritive energy patterns to the seeds during germination

and growth. The substance they selected was "vermiculite," a micaceous silica sold by the building industry as an insulator, which was both chemically inert and insoluble in water. To treat it they blew it into the air for seven hours in front of a radionic apparatus normally used for therapeutic purposes on humans.

They then mixed the treated vermiculite with a grass-seed mixture containing rye, cocksfoot, and other varieties. The proportions were two parts vermiculite to one part grass seed by weight. The mix was sown in two boxes; an identical mixture, containing untreated vermiculite, was sown in two similar boxes. The soil was the same throughout. The results, as confirmed by a leading agricultural firm, showed that the treated vermiculite produced a crop 186 percent heavier in moist weight, with a protein content 270 percent higher, an extraordinary gain for any farmer.

Milford oats, seeded with treated vermiculite in a yard-square plot at a rate equivalent to 252 pounds to the acre, when harvested five months later produced at an estimated rate of *two tons to the acre* or a crop *270 percent larger* than that obtained from an untreated square. More uncannily, oat seeds grown in a beaker of nothing but distilled water containing not a single nutrient nevertheless grew luxuriously if treated vermiculite was added to the water.

At this point a nationally known plant-breeding establishment requested to perform tests with the treated vermiculite on various types of seed. Under the firm's rigid test conditions, the phenomenal increases in growth obtained by the De La Warrs were no longer apparent.

Instead of dejection, this news brought the De La Warrs to a stunning realization: perhaps the plants had been responding all along *not* to the radiations from their machines but indirectly to the human beings involved in the experiments!

To test this idea they called up the plant-breeding firm and obtained permission to run the very same tests the firm had performed on exactly the same plots. To the amazement of the establishment's horticultural staff, the De La Warrs were successful in increasing growth with treated vermiculite to a significant degree but, try as they would, the professional plant growers could not repeat the De La Warrs' success.

After three years of intense labor with plants, and out-of-pocket costs of some $20,000, the De La Warrs had at last stumbled onto the crux of the problem. A human factor of immense importance was confusing the issue. To determine the extent of this factor they again mixed vermiculite into the soil of potted oats. Their assistants, who daily poured measured quantities of water onto the seeds, were told which pots contained the treated substance, which the untreated. What they were *not* told was that none of the vermiculite used had in any way been irradiated and was as inert as when brought from the supplier.

Though every one of the oat seeds had received no nutrient energy other than that provided by the soil itself, the De La Warrs were excited to note that the seedlings in those pots which the assistants *believed* to contain treated vermiculite were coming up faster than the others. Human belief that a plant might grow faster was apparently acting as a nutrient to actually produce faster growth. Thought was a food!

De La Warr, who considered this experiment the most important he had ever run, found himself face to face with a shattering new reality with the most far-reaching implications: *the mind of a human being could affect cell formation!*

When De La Warr described this experiment to one of Great Britain's leading physicists and suggested that a universal energy could be evoked by the proper attunement of one's thoughts, he was told curtly: "I do not believe you, Mr. De La Warr. If you can affect the number of atoms in a growing plant by your thought process, we must revise our concept of what constitutes matter."

"Indeed we must," said De La Warr, "even if such revision poses a whole overhaul of existing knowledge. How, for instance, could this energy be incorporated into mathematical equations? What would happen to the law of the conservation of energy?"

When De La Warr realized that the real key to getting plants to flourish was simply asking them to do so, he published an article in his journal, *Mind and Matter,* entitled "Blessing Plants to Increase their Growth," asking readers to produce evidence to support his own experimental results, which were so at variance with accepted and current materialistic atomic theory.

One of the most crucial steps in a fifteen-step procedure outlined in the article was that in which the experimenter was to hold bean seeds in his hands and invoke a blessing, varying according to his faith or denomination, in a reverent and purposeful manner. Though warmly received by readers, the article evoked a harsh reply from officials of the Roman Catholic Church, who took umbrage because, as they pointed out, it was inadmissible for anyone below the rank of deacon to perform any act of blessing. Laymen were supposed only to ask the Creator to perform a blessing. To still the waters of protest, the De La Warrs renamed their experiment "Increasing the Rate of Plant Growth by the Mental Projection of an Undefined Energy."

Many of their readers reported success similar to that attained in America by the Reverend Franklin Loehr, whose 700 experiments on the effect of prayer on plants, conducted by 150 persons, using 27,000 seeds, under the auspices of Loehr's Religious Research Foundation in Los Angeles, are reported in his book *The Power of Prayer on Plants.* Loehr showed that the growth rate of plants could be accelerated as much as 20 percent when individuals singly or in concert visualized the plants as thriving under ideal conditions. Though their experiments seemed to be acceptable from the evidence and pictures presented, the results were ignored by scientists on the basis that Loehr and his assistants had no scientific training and used relatively crude methods to measure growth.

However, Dr. Robert N. Miller, an industrial research scientist and former professor of chemical engineering at Georgia Tech, began a series of experiments in 1967 with Ambrose and Olga Worrall, whose feats of healing have become celebrated in the United States. Using an extremely accurate method of measuring plant growth rates developed by Dr. H. H. Kleuter of the United States Department of Agriculture, with accuracies up to one thousandth of an inch per hour, Miller, working in Atlanta, Georgia, asked the Worralls to direct their thoughts at rye seedlings from Baltimore, some 600 miles away.

Whereas the growth rate of a new blade of rye grass had been observed by Miller to stabilize at 0.00625 inch per hour, after he asked the Worralls to think of the seedling at exactly 9 P.M., the trace on a graph indicating growth rate began immediately to deviate upward and by 8 A.M. the following morning the grass was growing at a rate 84 percent faster. Instead of growing the expected 1/16 inch in the interval, the seedling had sprouted more than ½ inch. Miller reported that the dramatic results of his experiment suggest that the sensitive experimental technique could be used to measure accurately the effect of mind over matter.

The mysteries of how the human mind may act through radionic devices such as those of UKACO, Hieronymus, or De La Warr are yet to be explained. In an amazing development, the late John Campbell, editor of *Astounding Science Fiction*—since become *Analog Science Fiction/Science Fact*—determined in the 1950s that a circuit diagram of Hieronymus' machine drawn in India ink worked as well as the machine itself. "Your electronic circuit," he wrote to Hieronymus, "represents a *pattern of relationships*. The electrical characteristics are unimportant and can be dropped out completely."

Voysey, an English dowser, corroborated the evidence by pointing out that if he traces a line with pencil on paper, thinking strongly that this mark will represent a certain metal, his pendulum will react to the drawn line exactly as if it were the metal.

After a prolonged study of radionic devices sponsored by the Foundation for the Study of Consciousness set up by Arthur M. Young, inventor of the Bell helicopter, Frances Farrelly, who ran her own college for medical laboratory technicians, also came to the conclusion that the devices were not necessary to achieve effects. While working in England with a Harley Street physician, she found she could walk toward a patient with her hands outstretched and feel within her own body where the patient had trouble. As she says: "I was beginning to run the instrument in my head, or mentally only." Since then, Farrelly has been able to make diagnoses of ills of individuals not only without a radionics device but without a blood spot or a photograph or anything at all. The mental image of a patient held in her mind is sufficient. She calls this a "resonating reflex phenomenon."

In the summer of 1973 Farrelly's talents were put to test in Prague when one of the participants in the First International Conference on

Psychotronics—a Czech logism for the effects of mental energy on matter—lost a wallet in the cavernous four-story Railway Workers' Building, site of the conference. Within minutes, Farrelly tracked it down, pinpointing its exact location inside a box at the back of a dark closet where a cleaning woman had placed it for safekeeping.

The following day she was confronted by a professor from the Czechoslovak Academy of Sciences who gave her a chip of mineralized rock and asked her before a large audience if she could state its origin and age. Rubbing the table before her to get a radionic type "stick," Farrelly, after putting a dozen questions to herself, stated that the mineral in question came from a meteor and was about 3,200,000 years old, answers which exactly matched the most considered conclusions of expert Czech minerologists.

During her stay in England, Farrelly was intrigued that the De La Warrs seemed to have radionically detected that every living plant has a critical rotational position (CRP), which is apparently established by the earth's magnetic field as the seed sprouts out of the ground. If the seedling is transplanted in such a way that it continues to grow in its CRP, it will thrive better than plants which have been transplanted out of that orientation. This phenomenon was also independently discovered by Hieronymus, who found that a reading on the dials of his radionic device was maximum when the plant was rotated in a given position with respect to a compass rose.

The De La Warrs had also found that, because of this apparent relationship with the geomagnetic field, a plant has a pattern of radiation around it. Nodal points within this pattern or web which seem to concentrate the field of radiation can be located by a portable detector with a probe and a rubbing plate similar to that on their radionics device.

In England Frances Farrelly found that with a simple dowsing pendulum she could locate on a tree and in the domelike geometric pattern around it nodal points of energy which could expose X-ray film.

This field of energy may be related in some way to a magnetic field, since both can be detected with dowsing methods. In Lorton, Virginia, the authors witnessed the incredible sensitivity to a magnetic field as displayed by Wilhelm de Boer, a *Rutenmeister*, or master dowser, who lives in the Hanseatic city of Bremen, West Germany. When Dr. Zaboj Harvalik asked de Boer to walk through a magnetic field which could be switched on or off, each time the field was on de Boer's tiny dowsing rod delicately held in his fingertips would revolve. When the field was off, the rod would not move.

With the same rod de Boer measures the auras of trees and people. First backing off from a large oak, he then advanced toward it until he was about twenty feet away, at which point the rod flipped downward. On a smaller tree de Boer had to approach more closely before there was any reaction from the rod.

"This energy coming out of a large oak can temporarily increase the strength of a human aura, or a person's vitality," said de Boer, demonstrating that it extended some nine to ten feet outward from Harvalik's chest but was double that length after Harvalik hugged a big oak for two minutes. De Boer related how the "Iron Chancellor" of Germany, Bismarck, at the advice of his personal physician, would put his arms around a tree for up to half an hour to recover from the fatigue of pressing duties.

Harvalik stated that the aura de Boer was measuring might not be the same as that seen around human beings by sensitives, to which the Britishers, Dr. Walter Kilner and Oscar Bagnall, devoted much attention, since it seemed to extend further from the body. As Harvalik put it: "We don't really know exactly what this extended aura is and we certainly have no way to analyze it in a physics laboratory, at least not yet."

Whether the auric field as measured by de Boer is the same as the one which contains the "nodal points" as revealed on film by Frances Farrelly is also as yet unanswerable. It appears that when the material substance with which the field is associated is broken up, the field goes with the individual parts which remain in contact even at a distance. This led the De La Warrs to wonder if a slip cut from a plant and rooted would benefit from the radiations emitted by its "mother" or pine away in the absence of such radiation. Incinerating a mother plant, roots and all, they found that its motherless children did not thrive as well as similar shoots taken from a mother which was permitted to continue growing.

Most incredible to J. I. Rodale, who successfully repeated the De La Warrs' experiment, was the allegation that the mother plant did not necessarily have to be growing near her children for them to benefit from her "protection." The mother could apparently be in the next city, the next country, across the ocean, or anywhere on earth. If so, suggested Rodale, it would tend to indicate that all living things, including human babies, get protective radiations from their mothers, that radiations might underlie "love at first sight" and that people with "green thumbs" are emitting radiations beneficial to their plants.

That an energy comes from the hands of a healer—as was claimed of Jesus Christ—and that this energy can increase the growth of plants seems to have been proved in a scientific experiment on sprouting seeds by Dr. Bernard Grad, a research biochemist at Allan Memorial Institute of Psychiatry of McGill University in Montreal. Taking the "healing controversy" into his laboratory, he performed some careful experiments with the cooperation of a retired Hungarian Army colonel, Oskar Estebany, who became aware of his own extraordinary healing powers during the Hungarian revolt against the Soviet occupation of his country in 1956.

Grad's meticulous experiments, written up in the *Journal of the Society for Psychical Research* and the *International Journal of Parapsychology*, indicated that the sprouting of grains and the total amount of green plant issuing therefrom could be significantly increased when compared to controls, by watering them with a solution sealed in bottles and exposed only to the healing energy of Estebany's hands.

In his first rigidly controlled experiments Grad convinced himself that by holding the cages of wounded mice, but not actually touching the animals themselves, Estebany could heal their wounds faster than if the mice were exposed to heat or left untreated. Estebany also could retard the growth of goiters produced in the mice by iodine-deficient diets and goitrogens and hasten their disappearance when the mice were returned to a normal diet.

Grad wondered what results might be obtained from subjects other than Estebany. From the many patients available at the institute he chose a twenty-six-year-old woman with a depressive neurotic reaction and a thirty-seven-year-old man with a psychotic depression. He also selected a psychiatrically normal man of fifty-two. What Grad sought to ascertain was whether a solution held for thirty minutes in the hands of a normal individual would cause plants to grow at a faster rate than a solution held for the same amount of time by neurotics and psychotics.

After the threesome had held sealed bottles of saline solution, their contents were poured on barley seeds embedded in soil. Grad found that the little plants watered by the saline solution held by the normal human being grew significantly faster than those held by the psychiatric patients, or by a control group left untreated. The plants treated by the psychotic grew the slowest. Contrary to Grad's expectations, the plants treated by the neurotic grew at a slightly higher rate than the controls.

Grad noticed that when the psychotic was given the sealed bottle to hold he expressed not the slightest reaction or emotion, whereas the neurotic immediately inquired about the reason for the procedure and, when told, responded with an expression of interest and what Grad termed a "brightening of mood." Grad also observed that she lovingly cradled the bottle in her lap as a mother would a child. Grad reached the conclusion that "the important fact for the purpose of the experiment was not the state of her general diagnosis but of her mood *at the time* she was holding the bottle." In his detailed account of the experiment Grad reported to the American Society for Psychical Research that it would seem that a negative mood, such as depression, anxiety, or hostility while treating the solutions would result in an inhibition of cell growth when plants were watered with that solution.

Grad saw the implications of his experiment to be far-reaching. If a person's mood could influence a saline solution held in the hands, it seemed natural to assume that a cook's or housewife's mood could influence the quality of food prepared for a meal. He recalled that in various countries menstruating milkmaids were not permitted in that part of the dairy where cheese was being prepared because of a presumed unfavorable effect on the bacterial cultures, and that during their menstrual periods women have been held to influence negatively the canning of perishables, the stiffening of egg white, and the survival of cut flowers. If Grad's experiments were correct, it was not the menstruation but the depression created by it in certain women that had the effect, a discovery

which removes from the realm of prejudice to the realm of science the biblical injunction against "unclean" women.

The whole subject of radionics and the part played by the action of the human mind—and whether it interacts with various radionics devices designed by De La Warr, Hieronymus, Drown, Abrams and others —stands on the very frontier of physics and metaphysics and the no-man's land which lies between them.

As Galen Hieronymus said to the authors: "Is the force and its manipulation basically in the realm of the psychic? We know that powerful psychics such as Frances Farrelly can produce results with no help whatsoever from a device. But others seem to be helped by a radionics instrument even when, like the De La Warrs, they have well-developed psychic powers."

Hieronymus has tried his best to separate the action of the human mind from whatever the various "boxes" do to interact with it. "I can take an ordinary empty cigar box and mount a tuning dial on top of it," he says. "By properly setting the dial at a given tuning, some psychics have been able to cure a given disease. I think they do this because they *believe* that they are *using* the box when, in reality, they are using only psychic ability.

"On the other hand, we are able without question to run analyses of ill persons and, having made our diagnoses, give information to third parties on how to set dials on healing instruments when those persons know nothing about radionics and are merely following instructions. The proper setting of the dials seems to have important effects. So there are two sides to the question which await resolution." Hieronymus says that a good friend, an Episcopal minister in Florida, received a hand-carved ebony cross from the family of an old Scottish vicar who had died in Great Britain. Touched, he replaced the metal cross which he normally wore around his neck with the ebony cross each time he offered holy services. A short time later he told Hieronymus that he felt exhaustingly depleted after each church service.

As a long-time "radionic detective," Hieronymus questioned his friend whether he had not done something different during the services which seemed so to fatigue him. When the clergyman remembered the substitution of crosses, Hieronymus tested his friend's vitality with and without the ebony rood around his neck. Whenever the black cross was worn, the minister's vitality dropped almost to the zero point on the device's dials.

Hieronymus suggested to his friend that he exorcise the gift cross. This accomplished, the minister no longer felt any debilitating effects. The two friends concluded that negative thoughts from the old vicar had lodged in the ebony cross and the energy therefrom was affecting its new owner.

The experiments run on certain strange figurines made of baked clay, stone, and bone discovered at Acámbaro in the Mexican state of Guanajuato by Waldemar Julsrud offer impressive evidence that matter can receive malevolent energy and store it for long periods of time, perhaps thousands of years.

Professor Charles H. Hapgood in his manuscript, *Reports from Acámbaro,* says of the huge Julsrud collection, numbering over 33,000 artifacts, that it cannot be identified with any of the known cultures of Mexico but suggests relationships not only with specific Indian tribes of the Western Hemisphere but also with peoples of the south Pacific and Africa. Researchers sponsored by Arthur M. Young's foundation selected a few examples which appeared to the eye as most evilly weird. After putting them individually in cages together with mice, they found that the tails of some of the mice turned black and fell off and that other animals died after only a night's exposure to the objects. There was evidently a malevolent energy—of a kind usually associated with voodoo—present in the evil-looking artifacts which was capable of destroying a mouse.

If mental intercession can act malevolently to destroy life, it is also clear, as the radionic process proves, that it can act benevolently to enhance life. In his unique paper, "Radionics, Radiesthesia and Physics," published by the Academy of Parapsychology and Medicine, Professor William A. Tiller, chairman of the Department of Material Science at Stanford University, who devoted part of a year-long stay in England to the study of radionics at the De La Warr laboratories, presents a model to explain how the process works.

> The basic idea in radionics [writes Tiller] is that each individual, organism, or material radiates and absorbs energy via a unique wave field which exhibits certain geometrical, frequency and radiation-type characteristics. This is an extended force field that exists around all forms of matter whether animate or inanimate. A useful analogy here is the physical atom that is continually radiating electromagnetic energy in the form of waves because of its oscillating electrical dipole movement and its thermal vibrations. The more complex the material, the more complex the wave form. Living things, like humans, emit a very complex wave spectrum of which parts are associated with the various organs and systems of the body.

Tiller holds that if the millions of new cells born in our bodies each day come into being in the presence of fields polarized by the radionic process, they tend to grow in a healthier configuration, which weakens the original field of an abnormal or diseased structure. Continued treatment eventually molds the healthy organ structure and the condition is healed.

Following Hindu Yoga philosophy, Tiller postulates further that there are seven principles operating in man, each of which constitutes a different type of substance that obeys a unique set of natural laws. These he lists as the *physical,* which most of us simply call the "body"; the *etheric,* or what the Russians have termed the "bioplasmic"; the *astral,* or emotional body, followed by three separate intuitive, intellectual, and spiritual *minds;* and finally *pure spirit* or divine mind.

"These substances are presumed to exist everywhere in nature and to interpenetrate with the human body, i.e., they all exist within the physical atom and organize themselves within the body," writes Tiller, who adds that if one thinks of seven transparent sheets containing seven different circuit patterns, each of a different color, and then overlays them, one can thus visualize the complete organization of the different levels of substance in the body. Although the different energy fields perturb each other only in a small way, they can be influenced to do so in a strong way, says Tiller, *by the agency of mind.*

Tiller points out that the seven endocrine centers of the physical body—the gonads, cells of Lydig, adrenals, thymus, thyroid, pineal, and pituitary—are paralleled in Hindu philosophy by seven energy vortices, or *chakras,* which are linked in the etheric body by a current of vitality. This current, says Tiller, is associated with the meridians of acupuncture and the points on them which, though known to the Chinese millennia ago, have only recently been detected with an instrument that measures electrical resistance.

> One of our goals [continues Tiller] is to arrange our etheric/physical system so as to deliver maximum power to the physical body from the environmental energy stream. One reason for wanting to tune the chakra/endocrine system relates to the transmitting of spiritual and healing qualities into the earth environment. These seven endocrine centers have been called our sacred centers and through them we radiate transmitting information of a quality (frequency) associated with that center.

Tiller offers the example of the thymus gland, the center supposed to control the quality of love in all its spectral range. He postulates that an entity radiates from this gland a field that is broadcast through space and is absorbed in the corresponding gland by another entity. This stimulates the gland and generates some biological activity within the organism. If the second entity radiates an in-phase vibration back to the first, then the love consciousness can form a bond between them. Most of us, in Tiller's view, are confined to expressing love in so limited a way that it is radiated at small power and has a restricted range of expression such that only a few individuals will receive the radiation and be aware of it. But, as Tiller puts it, "if the entity has built himself to radiate at large power and over a very broad band of the spectral distribution, then many, many entities will receive this radiation, be aware of this love and be nourished by it." Tiller's statement fits well with Rexford Daniels' idea that altruism has a higher, and perhaps more powerful, set of frequencies than egotism.

It also echoes the latest conclusions of Marcel Vogel:

> A thought is an act of creation. It is what we are here for, to create, to bring into being ourself by means of thinking. The way a thought can be observed and measured by a simple life form, a plant, shows a wonderful relationship between man and plant. When we love, we release our thought energy and transpose it to the recipient of our love. Our primary responsibility is to love.

Another researcher to accept the power of the mind is a neurologist and medical electronics expert, Dr. Andrija Puharich, who has recently reported some of the most awe-inspiring feats of psychic, or mental, power yet to confront physicists, psychologists, and other academicians. Author of *The Sacred Mushroom* (Doubleday, New York, 1959), which dealt with the effects of hallucinogenic plants, such as peyote, a decade before the world's younger generation became absorbed with mind-bending drugs, from marijuana to LSD, and of *Beyond Telepathy* (Darton, Longman and Todd, London, 1962) a decade before studies of direct idea transference from one human mind to another were considered anything but crazy by the "responsible" scientific community, Puharich has now discovered a truly remarkable psychic in the body of a young Israeli, Uri Geller, whose abilities have startled hundreds of audiences and left most open-minded scientists aghast at their implications.

Under rigorous test conditions, Geller has been able to unfailingly locate an iron ball or water hidden in one of ten identical sealed metal cans without touching the cans, to move solid objects at a distance without the use of any energy known to physics, to bend at a distance dense metal objects, such as a solid silver Mexican coin, as if they were plastic in his hands, to repair broken watches and get them running without having ever opened their cases, to shatter a set of watchmaker's screwdrivers made of a special alloyed steel, and even to cause objects to vanish from their locations and reappear somewhere else. Geller can also affect at will the material recorded on a magnetic tape, such as that used in television.

Puharich has now organized a multi-disciplinary international group of scientists to assess the abilities of Geller and of perhaps thousands of other people who would reveal similar gifts if they were taken seriously rather than considered freaks. A theoretical group which will take the results of the experiments and seek to mathematically provide physical constructs for them is being led by physicist Dr. Edward Bastin, member of the "Epiphany Philosophers" at Cambridge University in England and originator of the most advanced quantum theory.

The group will be asking such fundamental questions as: How can a coin disappear? What kind of space, or lack of it, is involved? What are the energetics which operate during Geller's transformations and vanishings?

As Puharich told Connie Best, author of an article on Geller, "The Man Who Bends Science":

> We're trying to develop a model to explain how all these atoms can be taken apart. There are theories of annihilation and so on in microphysics, but there is no theory in the world that can explain this on a macroscopic scale. How can you take all these atoms apart or infinitely compress them to the point where they are so tiny they are invisible, have the thing parked in some unknown space, and then get the atoms back reassembled?

Geller not only can miraculously affect the so-called inanimate world but the world of living things as well. Before reliable witnesses he has placed his hands over a rosebud for slightly longer than a quarter of a minute, then opened them to reveal the rose in full and radiant bloom. As Connie Best comments:

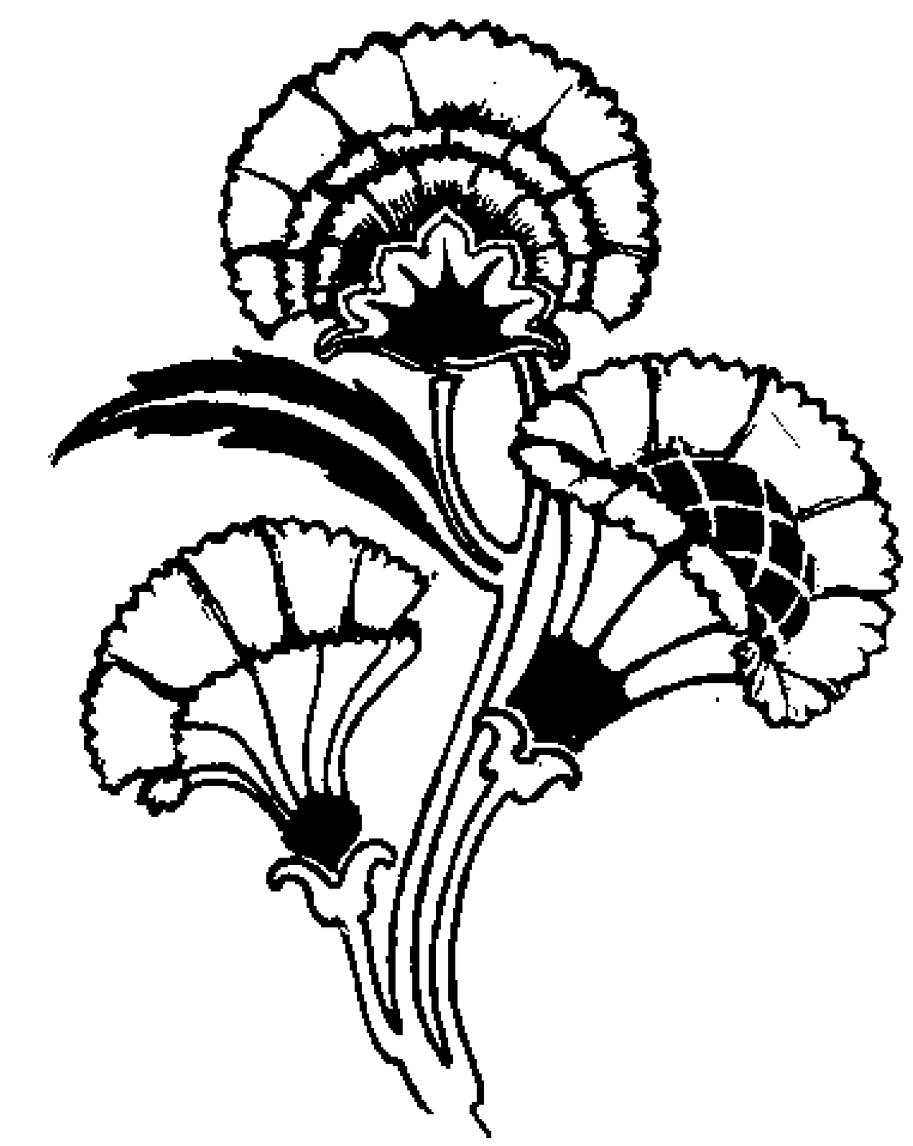
> Physics is precise, unbending. Yet Uri Geller is finding loopholes in science wide enough to pluck a rose out of. Uri Geller is bending physics, forcing it to take account of the so-called 'paranormal' powers of the mind. How much will physics have to change? If the readings of meters reflect the wishes of lab assistants, if the presence of an experimenter is enough to embarrass sub-atomic particles, how are we to know where we stand?

As the Serbian-born American inventor and genius, Nikola Tesla, stated before his death: "The day science begins to study nonphysical phenomena, it will make more progress in one decade than in all the previous centuries of its existence."

Perhaps that decade is upon us.

CHAPTER 21

Findhorn and the Garden of Eden



The most advanced experiment involving communication with plants has now developed in a remote corner of northern Scotland, with results more radiant than have been achieved by any other means. On a barren, wind-blown patch of gorse and sand overlooking the Firth of Moray, a seedling community has taken root which may flourish into a marvel of the Aquarian Age.

Three miles as the raven croaks from the battlements of Duncan's castle at Forres, and just south of the heath where the three witches prophesied to Macbeth that he would be Thane of Glamis and Cawdor, an ex-RAF squadron leader turned hotelkeeper decided to take up residence with his wife and three young sons in the derelict corner of a caravan park on Findhorn Bay—a rubbish heap of old tin cans, broken bottles, brambles, and gorse bushes.

Tall, ruddy, with the gentle manner of an English headmaster and the dress of a country squire, Peter Caddy, who once walked two thousand miles through the Himalayas, crossing Kashmir deep into Tibet, has been a follower since young manhood of a school of adepts whose object is to bring back beauty and wonder to this planet. Illumined by the dictates of his conscience, or as he chose to call it, the will of an all-powerful creative force revealed to him by his clairvoyant wife, Eileen, Caddy pulled up roots and moved to Findhorn one snowy November day in 1962. Accompanying the Caddys was another sensitive, Dorothy Maclean, who had left the Canadian Foreign Office to study Sufism.

For some time the Caddys had been intent upon radically changing their lives by turning away from mundane occupations and materialist pursuits in order to enter upon what Caddy calls a long period of training and preparation. During this period they planned to surrender everything, including all personal volition, to a being they term "Unlimited Power and Love," whose will is manifest to them through the guidance of a deceased Rosicrucian master whom they recognized in the flesh as Dr. G. A. Sullivan, and in the spirit as Aureolus, or St. Germain, or the Master of the Seventh Ray.

To be fair, the place in which the Caddys least expected to settle was the unsightly, overcrowded encampment of mobile houses known as Findhorn Caravan Park. For years they had hurried past it on their way to and from Forres. Now some mysterious force was overriding their aversion. Following what appeared to be crystal guidance, they wheeled an old caravan onto the site of their new home—less than half an acre in a hollow not far from the main cluster of trailers, a patch of land composed mainly of sand and gravel, constantly swept by gale-force winds, protected only partially by tufts of broom and quitch grass which kept the sand from blowing away, and shaded by a belt of spiny fir trees.

With winter coming it was a dismal prospect. Following the concept of the monks who used to build their monasteries by hand, putting love

and light into the fabric of the building with every stone they laid, the Caddys cleaned their rickety trailer from top to bottom and polished all the furniture, pouring in vibrations of love to cancel out the negative vibrations they considered to be inevitable in structures built by people interested only in money. Cleansing and hand painting the caravan was a first step toward the creation of their own center of light.

As none of the Findhorn pioneers was employed, and their meager resources would carry them through only one dark and clammy Scottish winter, they dreamed of springtime and establishing a garden, partly to increase the protective shield of light round them and partly as a source of healthy nourishment.

Short days and long nights Caddy pored over gardening books, which he found contradictory in their recommendations. Written for horticultural enthusiasts living mostly on the mild southern coast of England, they were irritatingly irrelevant. When Easter rolled around to herald a renaissance of the land, the arid, all but lifeless soil surrounding their caravan seemed hopeless for growing anything comestible. Caddy, who had never sown a vegetable seed in his life, felt like Noah when guided to build an ark where there was no water; but he dutifully persisted. Either guidance was to be followed to the letter or they might as well return to the world of business. His Rosicrucian masters had taught him one prime rule of life: "To love where I was, love whom I was with, and love what I was doing."

To receive the arcane guidance on which the infant community planned its every move, Eileen would rise regularly at midnight and meditate for several hours, bundling herself in an overcoat against the chill of the Scottish nights, taking refuge in the only place that could afford her absolute tranquillity, the trailer park's frigid toilet. Eileen had read in a book that everyone receives his spiritual name at some point in life and that only then can he begin his spiritual work in earnest. In 1953 she had felt the word Elixir branded on her forehead; so she adopted the name, and from then on her guidance was constant.

In her clairvoyant vision Elixir saw seven cedarwood bungalows clustered together, in the midst of a splendid garden, all trim and neat. How this vision was to materialize in the constricted squalor of the caravan site remained a mystery. Yet all were prepared to put their faith in her clairvoyance.

The prospect of creating a garden seemed a superhuman task. The ground was made of fine, dusty sand and gravel in which nothing grew but tough pointed grass. Elixir received guidance that each time you put a spade into the ground you put in your own vibrations, that the right vibrations acted as a magnet to draw in like vibrations. Peter Caddy cheerfully dug a strip of quitch turf three feet wide by nine feet long and laid it to one side. He then dug down eighteen inches, accumulating a pile of sand and gravel. In the clean trench he placed the strip of quitch turf upside down and broke it up with his spade. This was to insure that the turf would not sprout its way back up to the surface, but provide nourishment as it disintegrated.

Repeating the operation with two more trenches, Caddy had a garden nine feet by nine. His problem was to get water into the soil, a far more difficult job than he imagined. The sand was so fine the water poured onto it simply went into globules like quicksilver. Only by dint of the most assiduous patience, by spraying the surface over long periods with a very fine spray, was it possible to impregnate the soil sufficiently for it to hold the moisture. More stones and gravel had to be raked out; finally the plot was ready for seeding. According to the local agricultural experts and the available textbooks on gardening, nothing could be grown in the Findhorn soil except perhaps a few lettuces and radishes. Scanty fare for a family which had become accustomed at their hotel to daily steak or duck washed down with good red wine.

Fortunately Elixir had been warned by her guidance that man is eating the wrong food, drinking the wrong drink, thinking the wrong thoughts, and making his body gross instead of a body of light. They were to eat less dense food and begin to concentrate on making a real garden, the fruit and vegetables of which, combined with honey and wheat germ, would constitute the fare in the new age of refined bodies.

Conscientiously Caddy planted his lettuce seeds in an inch-deep furrow made with the handle of his spade, placing the seeds a foot apart, then raked them over. To sit in the sun and watch their garden grow the Findhorners needed a fence, to fend off the ever-present winds

blowing across the Moray Firth, and a level concrete patio. Sand they had in abundance, but no cement, nor any money for its purchase.

Lumber for a slatted fence appeared as if by miracle from a man who was dismantling his garage. As soon as the fence was up a neighbor ran over to say that some barely damaged bags of cement had fallen from a truck across the road. In a short while they had a fenced patio from which to admire—not thriving young lettuce, but stunted apparitions, attacked by wireworms.

What to do? Caddy had been warned by Elixir's guidance not to use chemical insecticides. A neighbor chanced to pass and informed him of a pile of seasoned soot just outside the entrance to the caravan park, an admirable antidote to wireworms.

Caddy spread it carefully, without taking into account the wind which that night blew it through the caravan, into hair, books, and clothing. Luckily it rained and the soot was washed into the soil. By the end of May they were eating luscious lettuces and radishes.

As Elixir's guidance informed them that chemical fertilizers were toxic to the human body, a compost heap was essential if they were to grow a greater variety of vegetables. Only, where to obtain the ingredients? A pile of rotting grass was donated by a neighbor. A nearby farmer, grateful for a rescued sheep, gave Caddy a large load of cow manure. A friend who owned a riding stable allowed them to follow his horses with bucket and shovel. A nearby distillery supplied them with free peat dross and cummings, a natural barley-germ fertilizer. Seaweed they gathered free from the beach. A bale of hay, dropped from a passing truck almost at the gate of the park as if from heaven, served to cover the piles of compost.

Relying on such "supermundane assistance," the Findhorners acted as if they were endowed. As one of them wrote: "We could have been negative and said the soil was useless—as it was. Instead we put hard work and positive thought into everything we did." Caddy began working from morning till night, putting sweat and radiations into the soil, his object to grow sufficient vegetables and salads to provide a large part of their diet in the months to come. Along with pure air, sunlight, sea bathing, and plenty of cold, pure water, they hoped gradually to purify their bodies and endow them with energy, on the theory that the more refined their bodies became the more they would be able to absorb cosmic energies and the less solid food they would need.

The Findhorners planted watercress, tomatoes, cucumbers, spinach, parsley, squash, and asparagus. As a living wall against an unruly Dalmatian they planted hedges of blackberries and raspberries round their garden, which began to spread beyond the caravan till it covered two acres of ground, every bit of soil of which had to be manufactured from old turf and new compost, every square inch manhandled several times in the process.

Within two months the results were stunning the neighbors, who, not knowing of the spirit in which the Caddys were going about their gardening, could not understand what was happening, especially when the Caddys' cabbages and Brussels sprouts were the only ones in the area to survive a plague of cabbage-root grubs which eat away at the roots of the plants, and their harvest of black currants grew healthily by the bushel, whereas the crop largely failed in the rest of the county.

Findhorn lunches began to consist of salads with over twenty ingredients; surplus quantities of lettuce, radishes, spinach, and parsley were disposed of round the county, which was suffering a shortage. Their evening meals included two or three vegetables from the garden, grown without fertilizer or insecticides, freshly picked and freshly cooked. Stews from garden vegetables consisted of onions, leeks, garlic, carrots, parsnips, rutabagas, turnips, artichokes, kohlrabi, celery, squash, potatoes, flavored with all kinds of herbs.

Elixir was told to let her mind dwell on each ingredient when making a salad, or a ratatouille, that her thoughts and feelings were important in the continuing cycle of life. She was to appreciate whatever she was doing, whether peeling a carrot or podding a pea, and to consider each pea or bean a living thing in her hands. Of the peelings and garbage nothing was to be wasted. All was to go back into the compost and the soil, constantly increasing the live vibrations. The only drawback to this life was that when they were obliged to go into town, or on a short holiday, they found it very difficult to support normal food. Elixir became so sensitive it was painful for her to go near the noxious vibrations of so-called civilization.

When midsummer came they were ready to preserve quantities of raspberries, blackberries, and strawberries, putting up altogether a hundred pounds of jam. They pickled fifteen pounds of red cabbage, and large quantities of cucumbers. In a newly built garage they stored potatoes, carrots, beets, and shelves full of shallots, garlic, and onions. During the winter they prepared the earth for the following season and planted more fruits, altogether some twenty species, including apples, pears, plums, greengages, cherries, apricots, loganberries, and boysenberries. By May of 1964 the fruit trees and bushes were bursting into bud.

When estimating the number of red cabbages the Findhorners would need for the following season Caddy calculated that with an average weight of three or four pounds they would require no more than eight. To the Findhorners' amazement, when the cabbages matured one of them weighed thirty-eight pounds and another forty-two. A sprouting broccoli, mistakenly planted as a cauliflower, grew to such enormous proportions that it provided vegetables for weeks; when eventually pulled out of the ground it was nearly too heavy to be lifted.

It began to dawn on Caddy that there might be some greater underlying purpose behind what was happening at Findhorn, that they must be involved in some mysterious pioneering venture, some larger experiment in group living, that the garden might be the nucleus of some larger experiment in New Age living, a sort of training course in the realization that Life is a Whole.

In June of 1964 when the county horticultural adviser came to take a sample of the soil for analysis, his first comment on arrival was that the soil would require a dressing of at least two ounces of sulfate of potash per square yard. Caddy replied that he did not believe in artificial fertilizers, that he was happy using compost and wood ash. The adviser said that would be totally inadequate.

Six weeks later, when the adviser returned bringing the results of the analysis which had been carried out in Aberdeen, he acknowledged with some bewilderment that the analysis had found no deficiencies in the soil sample. All necessary elements, including rare trace elements, were present. The adviser was so astonished by the results that he asked Caddy to take part in a broadcast about the garden in which the adviser would take the chair and an experienced gardener using conventional methods with chemical fertilizers would debate with Caddy. Caddy says that at the time he still did not feel it appropriate to expound to the public on the subject of the spiritual side of their endeavor and again he attributed the success solely to organic manure and compost.

By now they were growing sixty-five different kinds of vegetables, twenty-one fruits, and over forty herbs, both culinary and medicinal. For some time Dorothy Maclean had also been receiving extraordinary spiritual guidance of her own and had adopted the spiritual name of Divina. She learned from the aromatic plants in the garden that their unique wavelengths could serve special functions for humans, affecting different parts of human anatomy as well as the human psyche, some plants being good for wounds, others for eyesight, others for human emotions. She realized that by raising the quality of her own vibrations she might eventually open the doors to a whole new spiritual realm of plant life. It became clear to her that human thinking, human passion, human anger, human kindliness and affection, all have far-reaching effects on the world of plants, that they are most susceptible to human thoughts and emotions, which affect their energy. Poisonous and bad-tempered moods have as depressing an effect on plants as happy, uplifting frequencies have a beneficial effect. It occurred to her also that bad effects could come back to humans as they ate the produce they had infected with bad vibrations. Thus the whole cycle could become viciously descending, leading to more and more misery, pain, and disease, or hopefully ascending, leading to greater joy and greater light.

Divina says she realized that the most important contribution that man can make to a garden—even more important than water or compost—is the radiation he puts into the soil while cultivating it, such as love, and that every member of a group has something to contribute in the way of radiations—strength, happiness, and so on. Everything that comes into a human being through inspiration of one sort or another goes out again modified in wavelength, tone, and timber by the will of the person involved; he or she can improve the quality of what is sent out and increase the brilliance of its wavelength.

At the same time Divina realized that the soil and plants are constantly being affected by radiations from the earth itself and from the

cosmos, each of which contributes to its fertility, without which both soil and plants would be sterile; these radiations, she realized, were more fundamental than chemical elements or microbiotic organisms, radiations that are subject fundamentally to the mind of man. Man appeared to have the role of a demi-god; by cooperating with nature he might find no limit to what could be achieved on this planet.

In the spring of 1967 Elixir—who still received the overall policy guidance for the venture—was told that the garden was to be extended even further and made into a place of beauty with the planting of many kinds of flowers. The center was to be expanded and new bungalows built. The vision she had first received on arriving at Findhorn was now beginning to materialize. Money for neat cedarstrip bungalows turned up as if by miracle, and the bungalows were soon surrounded by impeccable flower gardens.

In 1968, when Findhorn was visited by a number of accomplished gardeners and agricultural experts, they were amazed at what they found, remarking they had never seen such a uniformly high standard in all sections of a garden. The growth and color of the flowers in the new herbaceous borders were so remarkable that the visitors were at a loss to explain the phenomena, considering the poverty of the soil and the rigorous northern climate. When Sir George Trevelyan, who for twenty-four years had run the famed Adult Education Foundation at Attingham, dropped in at Easter he was amazed by the quality of the daffodils and narcissi growing in beds crowded with shorter flowers, all as beautiful and large as he had ever seen, their brilliant colors of a scintillating quality. He found the root vegetables the best he had ever tasted, and was surprised to find fruit trees of all sorts in blossom, as well as a vigorous young chestnut standing eight feet high among broad-leaved trees and shrubs thriving on the landward slope of windswept dunes.

As a member of the Soil Association, with an interest in the organic method, Sir George said he had seen enough to know that compost and straw mulch alone mixed with poor and sandy soil were not enough to account for such a garden. There must, said he, be some Factor X to be taken into consideration, adding that if so much could be accomplished at Findhorn in such a short time the Sahara could be made to blossom.

In June of 1968, Miss Armine Wodehouse, of the Radionic Association, who ran a commercial truck garden in Wales for twenty years, visited Findhorn and was amazed at the lush crops she found, especially when she noted the pure sand thinly spread with compost and the powerful winds that swept uninterruptedly across the garden. She felt the strawberry plants would arouse the admiration of any gardener, and was surprised to find moisture-loving asters and primulas, which are notoriously thirsty, thriving in such soil.

Mrs. Elizabeth Murray, an independent organic gardener and member of the Soil Association, who visited Findhorn in July of 1968, felt that the radiant health of the trees, flowers, fruit, and vegetables was far beyond the ordinary. She felt the compost was of such poor quality when mixed with sand that it could not explain the superb produce, which for size, quality, and flavor was superior to anything she had ever seen anywhere. She too was sure that such results could not have been attained on such barren soil simply by good husbandry and compost.

Lady Mary Balfour, sister of Lady Eve, who describes herself as an "ordinary gardener of the organic school," spent twenty-four hours at Findhorn in September of 1968 and wrote: "The weather throughout was grey and at times wet. Yet in retrospect I can see that garden in brilliant sunshine without a cloud in the sky, which must be due to the extraordinary brilliance of the blooming flowers I saw there. The flower beds were all a compact mass of color."

Lady Cynthia Chance, a follower of Rudolf Steiner's Biodynamic farming methods, was astounded when Peter Caddy told her he did not need to apply Steiner's methods, that he had a more direct spiritual way of obtaining the same results. A United Nations agricultural expert and professor of agriculture at various universities, Professor R. Lindsay Robb, when he visited Findhorn just before Christmas went on record to say that "the vigor, health and bloom of the plants in the garden at midwinter on land which is almost a barren powdery sand cannot be explained by the moderate dressings of compost, nor indeed by the application of any known cultural methods of organic husbandry. There are other factors and they are vital ones."

At which point Peter Caddy broke down and let out to Sir George Trevelyan the secret of their success at Findhorn. He said that Dorothy Maclean, or Divina, had managed to get into direct contact with the devas or angelic creatures who control the nature spirits that are said by clairvoyants to be everywhere at work nurturing plant life. Sir George, an advanced student of the arcane, of astrology and the hermetic sciences, admitted he was aware that a number of sensitives claimed to be in touch with the devic world and to be working with it, that Rudolf Steiner had founded his Biodynamic methods on such knowledge. Far from scoffing at Caddy's explanation, he was prepared to give it credence and to validate it by suggesting that conscious investigation of such worlds is of the utmost importance to our understanding of life, and especially our understanding of the life of plants.

In short order Peter Caddy put out a series of pamphlets describing the true nature of the experiments at Findhorn. Divina contributed detailed descriptions of the messages she said she received directly from the devas, of which she described whole hierarchies responsible for every fruit and vegetable, for every flower and weed. Here was a Pandora's box more phenomenal than the one opened in New York by Backster.

Findhorn quickly developed into a community of over a hundred disciples. Young spiritual leaders turned up to preach the gospel of a New Age, and a college was founded in the community to teach the tenets of this New Age. What had started as a miraculous little garden appeared to be turning into a true center of light for the Aquarian Age, visited annually from every continent of the globe.

Parting the veil into other worlds and other vibrations beyond the limits of the electromagnetic spectrum may well go a long way to explain the mysteries which are incomprehensible to physicists who limit their looking to what they can see with their physical eyes and their instruments. In the more ethereal world of the clairvoyant, who claims to have mastered the art of etheric and astral vision, a whole new series of vistas opens up around plants and their relation to man, to the earth, and to the cosmos. The growth of seeds and plants, as Paracelsus intimated, may indeed be affected very strongly by the position of the moon, the positions of the planets, their relation to the sun and to the other stars of the firmament.

Fechner's animistic vision of plants being ensouled becomes less of a wild conceit, as does Goethe's concept of a prototype plant. Burbank's knowledge that whatever man wishes he can produce with the aid of nature or Carver's insistence that nature spirits abound in the woods and take part in the growth of plants may have to be reviewed in the light of the discoveries of the Theosophists and especially of such extraordinary seers of nature spirits as Geoffrey Hodson. The ancient wisdom, as detailed by seers like Mesdames Helena P. Blavatsky and Alice A. Bailey, throws quite another light on the energy of bodies, both of humans and of plants, as well as the relation of individual cells to the entire cosmos.

The secret behind Pfeiffer's Biodynamic compost, which has been proved so highly effective scientifically, turns out to be a homeopathic wonder based on a fairyland creation of Rudolf Steiner's organic brews made by burying cow horns filled with cow dung and deer bladders filled with nettles and camomile leaves. Steiner's anthroposophy, or Spiritual Science, throws such a light on plant life and agriculture as to make scientists root in their tracks.

Aesthetically, the world of the devas and the nature spirits turns out to be even more full of color and sound and perfume than the creations of Scriabin and Wagner, their gnomes, nymphs, and undines, their fire, water, earth, and air spirits closer to reality than the Holy Grail and the eternal quest it engendered. As Dr. Aubrey Westlake, author of *Pattern of Health,* describes our imprisoned state, we are locked in a "valley of materialistic concepts, refusing to believe there is anything other than the physical-material world of our five senses. For we, like the inhabitants of the country of the blind, reject those who claim to have 'seen' with their spiritual vision the greater supersensible world in which we are immersed, dismissing such claims as 'idle fancies' and advancing far 'saner' scientific explanations."

The attraction of the seer's supersensible world, or worlds within worlds, is too great to forgo, and the stakes too high, for they may include survival for the planet. Where the modern scientist is baffled by the secrets of the life of plants, the seer offers solutions which, however

incredible, make more sense than the dusty mouthings of academicians; what is more, they give philosophic meaning to the totality of life. This supersensible world of plants and man, only touched on in this volume, will be explored in another, *The Cosmic Life of Plants.*

The Secret Life of Plants

Tompkins and Bird

Harper
Collins

Occult / New Age

Exploring the world of plants and its relation to mankind as revealed by the latest discoveries of scientists, *The Secret Life of Plants* includes remarkable information about plants as lie detectors and plants as ecological sentinels; it describes their ability to adapt to human wishes, their response to music, their curative powers, and their ability to communicate with man. Authors Peter Tompkins and Christopher Bird suggest that the most far-reaching revolution of the twentieth century-one that could save or destroy the planet-may come from the bottom of your garden.

“Almost incredible ... bristles with plenty of hard facts and astounding scientific and practical lore.”
-S.K. Oberbeck, *Newsweek*

“This fascinating book roams ... over that marvelous no man's land of mystical glimmerings into the nature of science and life itself.”
- Henry Mitchell, *Washington Post Book World*

“In can't ‘get inside a plant’ or ‘feel emanations’ from a plant and don't know anyone else who can, that doesn't detract one whit from the possibility that some people can and do ....
According to *The Secret Life of Plants*, plants and men do interrelate, with plants exhibiting empathetic and spiritual relationships and showing reactions interpreted as demonstrating physical force connections with men. As my students say, 'hey, wow!' ”
-Richard M. Klein, Professor of Botany,
University of Vermont (in Smithsonian)

To Henry B. Tompkins, whose avuncular support made possible a quarter century of cosmopolitan research; to my friends Alan C. Collins, John Newhouse and Carlo and Nicola Caracciolo, in whose hospitable houses this book was largely written; to my wife, who, though she would rather it had been a novel, was a constant help.

CONTENTS

ACKNOWLEDGMENTS

My first debt is to the courteous and efficient staff of the Library of Congress, whose institution—along with those of other helpful librarians round the world—made the research for this book a delight instead of an ordeal; they are a better and cheaper investment for our future than more weapons of destruction.

To Geraldine Dent, of Hopewell, New Jersey, and to Edward O. Mitchell, of McLean, Virginia, I wish to express my gratitude for painstaking help in reproducing the pictures which adorn this volume; to Diagram Ltd. of London for the streamlined drawings which illustrate the text.

Father Francis J. Heyden, S.J., Director of Georgetown College Observatory, I wish to thank for his cheerful encouragement in the face of monumental problems: and Monsignor Patrick W. Skehan for his kind assistance with the weighty tomes of the Semitics Library of Catholic University.

For a careful checking of the mathematical properties incorporated in the Great Pyramid I am indebted to Philippe Dennery, author of *Mathematics for Physicists*. His mathematical analysis of the secret geometric structure of the Great Pyramid as discovered by the Danish engineer Tons Brunés, made it possible to resolve the problem of the geodetic and geographic functions of the pyramid.

Most grateful I am to Livio Catullo Stecchini, Professor of the History of Science (characterized by Professor Giorgio de Santillana of MIT as "a Copernicus of the twentieth century"), for permission to quote from numerous unpublished monographs, the fruit of thirty years research into the advanced science of geography, geodesy and astronomy developed by the ancient Egyptians and Sumerians, several of which appear for the first time in the appendix to this volume.

This is indeed a cumulative effort, and I hope that my successors in pyramidal quests will be as lively and entertaining as have been my predecessors.

I have taken the book's 350 illustrations from the most disparate Medieval, Renaissance, Romantic, and Modern sources, from the 400 engravers of Napoleon's 20-volume *Description de l'Egypte* to the most recent archeological journals.

I am indebted to the Royal Society of Edinburgh for the original plates of the first photographs ever taken inside the Great Pyramid, by Professor Piazzi Smyth in 1865.

In particular I wish to thank Manly P. Hall for permission to reproduce the illustrations on pages 4 and 257 from his *Encyclopedic Outline of Masonic, Hermetic, Qabalistic and Rosicrucian Symbolical Philosophy;* Mlle. Lucy Lamy for permission to reproduce from the works of R. A. Schwaller de Lubicz, published in Paris by Flammarion and Caractères; Charles E. Jeanneret-Gris, better known as Le Corbusier, for the illustrations on page 192, from his *The Modulor,* published by Harvard University Press; Albert Champdor for the illustration on page 259, from his *Le Livre des Morts,* published by Albin Michel; C. Funk-Hellet for illustrations from his *La Bible et la Grande Pyramide,* published by Vincent Fréal; David Davidson for several plates from his *The Great Pyramid: Its Divine Message,* published by Williams & Norgate; Morton Edgar for plates from his *The Great Pyramid, Its Scientific Features,* published by Bone & Hulley; Howard B. Rand for the intricate interior of the Pyramid on page 28, from his *The Challenge of the Great Pyramid,* published by Destiny Publishers; Ludwig Borchardt for line drawings from his various works listed in the bibliography; Georges Goyon for the illustrations on pages 252 and 254 from *Revue Archéologique;* Leonard Cottrell for the portrait of Flinders Petrie from his book *The Mountains of Pharaoh,* published by J. Hale; and Sir Flinders Petrie for the illustrations on pages 98 and 99 from his *70 Years in Archeology,* published by S. Low, Marston in London. The jacket and the extraordinary interiors of the Grand Gallery and the King's Chamber on pages 14 and 16 are from Ludwig Mayer's *Views of Egypt from the Original Drawings in the Possession of Sir Robert Ainsley During his Embassy in Constantinople,* published in London in 1804.

INTRODUCTION

Does the Great Pyramid of Cheops enshrine a lost science? Was this last remaining of the Seven Wonders of the World, often described as the most sublime landmark in history, designed by mysterious architects who had a deeper knowledge of the secrets of this universe than those who followed them?

For centuries a debate has been waged between supporters of such a theory and its opponents, with eminent scientists and academicians lining up on either side. Though all agree that the Great Pyramid is at least four thousand years old, none can say for certain just when it was built, by whom, or why.

Till recently there was no proof that the inhabitants of Egypt of five thousand years ago were capable of the precise astronomical calculations and mathematical solutions required to locate, orient and build the pyramid where it stands.

It was attributed to chance that the foundations were almost perfectly oriented to true north, that its structure incorporated a value for π (the constant by which the diameter of a circle may be multiplied to give its true circumference) accurate to several decimals and in several distinct and unmistakable ways; that its main chamber incorporated the "sacred" 3–4–5 and 2–$\sqrt{5}$–3 triangles ($a^2 + b^2 = c^2$) which were to make Pythagoras famous, and which Plato in his *Timaeus* claimed as the building blocks of the cosmos. Chance was said to be responsible for the fact that the Pyramid's angles and slopes display an advanced understanding of trigonometric values, that its shape quite precisely incorporates the fundamental proportions of the "Golden Section," known today by the Greek letter φ (pronounced *phi*), revered equally by masters of the *çinquecento* and luminaries of modern architecture.

According to modern academicians the first rough use of π in Egypt was not till about 1700 B.C.—at least a millennium after the Pyramid; Pythagoras' theorem is attributed to the fifth century B.C.; and the development of trigonometry to Hipparchus in the second century before Christ. That is what the Egyptologists say, and that is what they put in their textbooks.

Now the whole subject has had to be reviewed.

Recent studies of ancient Egyptian hieroglyphs and the cuneiform mathematical tablets of the Babylonians and Sumerians have established that an advanced science did flourish in the Middle East at least three thousand years before Christ, and that Pythagoras, Eratosthenes, Hipparchus and other Greeks reputed to have originated mathematics on this planet merely picked up fragments of an ancient science evolved by remote and unknown predecessors.

The Great Pyramid, like most of the great temples of antiquity, was designed on the basis of a hermetic geometry known only to a restricted group of initiates, mere traces of which percolated to the Classical and Alexandrian Greeks.

These and other recent discoveries have made it possible to reanalyze the entire history of the Great Pyramid with a whole new set of references: the results are explosive. The common—and indeed authoritative—assumption that the Pyramid was just another tomb built to memorialize some vainglorious Pharaoh is proved to be false.

For a thousand years men from many occupations and many stations have labored to establish the true purpose of the Pyramid. Each in his own way has discovered some facet, each in its own way valid. Like Stonehenge and other megalithic calendars, the Pyramid has been shown to be an almanac by means of which the length of the year including its awkward .2422 fraction of a day could be measured as accurately as with a modern telescope. It has been shown to be a theodolite, or instrument for the surveyor, of great precision and simplicity, virtually indestructible. It is still a compass so finely oriented that modern compasses are adjusted to it, not vice versa.

It has also been established that the Great Pyramid is a carefully located geodetic marker, or fixed landmark, on which the geography of the ancient world was brilliantly constructed; that it served as a celestial observatory from which maps and tables of the stellar hemisphere could be accurately drawn; and that it incorporates in its sides and angles the means for creating a highly sophisticated map projection of the northern hemisphere. It is, in fact, a scale model of the hemisphere, correctly incorporating the geographical degrees of latitude and longitude.

The Pyramid may well be the repository of an ancient and possibly universal system of weights and measures, the model for the most sensible system of linear and temporal measurements available on earth, based on the polar axis of rotation, a system first postulated in modern times a century ago by the British astronomer Sir John Herschel, whose accuracy is now confirmed by the mensuration of orbiting satellites.

Whoever built the Great Pyramid, it is now quite clear, knew the precise circumference of the planet, and the length of the year to several decimals—data which were not rediscovered till the seventeenth century. Its architects may well have known the mean length of the earth's orbit round the sun, the specific density of the planet, the 26,000-year cycle of the equinoxes, the acceleration of gravity and the speed of light.

But to disentangle the authentic from the phony in what has been attributed to the builders of the Great Pyramid has required the technique of a Sherlock Holmes. To climax the story there is a mystery of detection to match the classic style of Sax Rohmer's Abu Hassan, complete with radiography by cosmic rays.

I. ANCIENT BACKGROUND

Ten miles west of the modern city of Cairo at the end of an acacia, tamarind and eucalyptus avenue stands a rocky plateau. A mile square, it dominates the luxuriant palm groves of the Nile Valley from a height of 130 feet. On this man-leveled plateau, called Giza* by the Arabs, stands the Great Pyramid of Cheops. To the west stretch the vast wastes of the Libyan desert.

The Pyramid's base covers 13 acres, or 7 midtown blocks of the city of New York. From this broad area, leveled to within a fraction of an inch, more than two-and-a-half *million* blocks of limestone and granite—weighing from 2 to 70 tons apiece—rise in 201 stepped tiers to the height of a modern forty-story building, etched against the cloudless blue of the Egyptian skies.

In terms of solid masonry, the structure contains more stone than all the cathedrals, churches and chapels built in England since the time of Christ; as a feat in masonry it was not to be matched till the construction of Boulder Dam. Modern engineers are astounded by both the enormity of the problems involved in the construction of the Pyramid and the optician's precision with which these problems were resolved. As originally designed, with its full mantle of polished limestone, the Pyramid must have been a dazzling sight. Unlike marble, which tends to become eroded with time and the weather, limestone becomes harder and more polished.

Near the Pyramid of Cheops stand two more pyramids, one, slightly smaller, attributed to Cheops' successor, Kephren, and another, smaller still, partly sheathed in red granite, attributed to Kephren's successor, Mykerinos. Together with six diminutive pyramids, supposedly built for Cheops' wives and daughters, they form what is known as the Giza complex. About a hundred more pyramidal structures of various sizes and in various stages of dilapidation follow the western bank of the Nile southward toward the Sudan, mostly within one degree of latitude, or 70 miles; but it is the Great Pyramid, unique in size and proportion, which is of paramount interest in this story.

The three large pyramids on the Giza plateau seen from across the Nile. The nearest of the three large pyramids is that of Cheops. Kephren's appears to be higher because it stands on higher ground. The third is that of Mykerinos. The two smallest pyramids are attributed to Cheops' wife and daughter.

* Most often spelt Giza, but transliterated by various authors as Djiseh or Jeeseh, the G is pronounced hard by the Egyptians and soft by other Arabs—as in *J* or *Dj*.

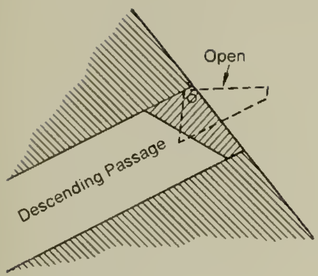
Reconstruction of a pyramid, showing the original polished limestone mantle which covered the entire structure.

What the Great Pyramid looked like when it was completed, or even for the first one or two millennia thereafter, is not recorded in history. No description of the Pyramid has survived in the Egyptian texts. Legends have it painted in various colors, marked with designs and inscribed with symbols. The thirteenth-century Arab historian, Abd-al-Latif, says the Pyramid was once inscribed with unintelligible characters in inscriptions so numerous they would fill ten thousand pages: his colleagues assumed them to be the graffiti of myriads of ancient tourists.

The first eyewitness descriptions from classical authors are pitifully sparse. Thales, the father of Greek geometry, who visited the Pyramid sometime in the sixth century B.C., is reputed to have astounded its Egyptian guardians with a correct computation of its height by measuring its shadow at the time of day when his own shadow was equal to his height. Unfortunately he left no detailed description of his visit.

The works of other classical authors known to have written about the Pyramid, such as Euhemerus, Duris of Samoa, Aristagoras, Antisthenes, Demetrius of Phaleron, Demoteles, Artemidorus of Ephesus, Dionysius of Halicarnassus, Alexander Polyhistor, Butoridas, and Apion are all lost, and survive only in fragmented quotation.

Herodotus, who saw the Pyramid about 440 B.C.—by which time it was as ancient to him as his period is to us—says that each of the structure's four perfectly triangular faces was still covered with a mantle of highly polished limestone, the joints so fine they could scarcely be seen. In his *History,* which contains the first comprehensive account of Egypt to have survived intact, Herodotus



Though no remains of a swivel door have been found at the Great Pyramid, Strabo's description fits the conditions; and a similar swivel door was found at the south pyramid of Dashur.

deals with other aspects of the Pyramid, but not all his information can be taken at face value.

Diodorus Siculus, the Greek historian who lived soon after the time of Christ, described the Great Pyramid's 22 acres of polished casing stones as being "complete and without the least decay." The Roman naturalist Pliny gives a report of natives gamboling up the polished sides to the delight of Roman tourists.

A man who may have had a lot to say about the Pyramids, in the forty-seven books of his *History,* was Strabo, the Pontine geographer who took a trip up the Nile in 24 B.C., but his history is lost: in the geographical appendix which survives he does little more than describe an entrance on the north face of the Great Pyramid made of a hinged stone which could be raised but which was indistinguishable from the surrounding masonry when it lay flush.

Strabo reports that this small opening gave onto a narrow and low passage, less than 4 feet by 4, which descended 374 feet into a damp, vermin-infested pit dug from the live bedrock 150 feet below the base of the Pyramid. That this pit was visited in Roman times was deduced from initials supposedly written with smoking torches on the rough ceilings by wealthy Greek and Roman tourists.

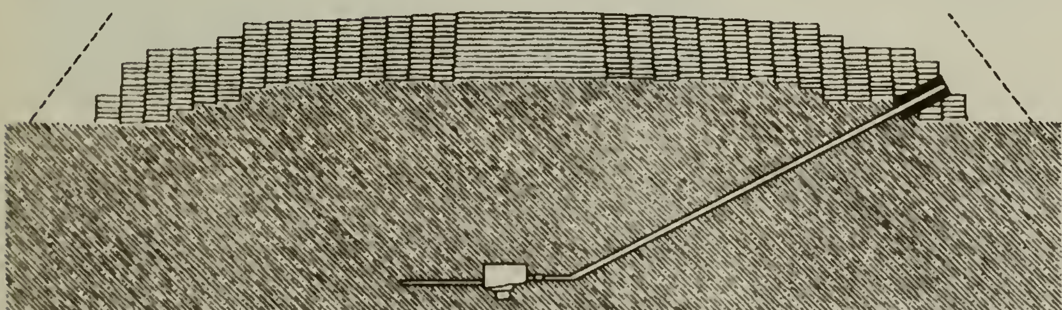
Sometime during the early centuries of the Christian era, the precise location of the movable door was lost. It was a period when information of all sorts began to grow scarce, when worldly learning came to be despised and denigrated. Christianized Egyptians were forbidden access to the ancient temples, which were either seized or razed by the Catholics; thousands of statues and inscriptions were disfigured; the hieroglyphs, whose meaning was already lost to most, became dead letters to the world to remain so for the next fifteen hundred years.

The great library of Alexandria, accidentally damaged by Julius Caesar and restored by Mark Anthony, was intentionally destroyed by a Christian mob on orders of the Christian emperor Theodosius in A.D. 389. All that was

From the original entrance a long passage descends into the heart of the Great Pyramid at an angle of 26 1/2°, or a slope of about 1 in 2. The passage is 3 feet 5 inches wide and 3 feet 11 1/2 inches high.

For the first 130 feet down, the passage is built into the masonry with beautifully finished sides of white limestone, perfectly straight and smooth. Thereafter it is cut equally smoothly through the bedrock of limestone on which the Pyramid is founded.

At 345 feet from the entrance, the passage levels out for 25 feet, then enters a roughly cut pit.



ancient was pagan, and therefore sinful. Those interested in mathematics and astronomy were persecuted and put to death for their inquisitiveness. Even women weren't spared, as with the lovely Hypatia, who was seized by an angry mob (incited by the monks under the control of St. Cyril, then Bishop of Alexandria), dragged into a church, stripped naked, and scraped to death with oyster shells. Her crime was to have been the daughter of the celebrated Alexandrian mathematician Theon, to have edited her father's works, taught mathematics, and become a leading philosopher in her own right, renowned for her beauty, modesty and learning.*

As the Dark Ages continued, little or nothing more was heard of the Great Pyramid of Cheops.

* Though her writings perished with the burning of the library of Alexandria, Hypatia is known from contemporary writings to have produced a commentary on the *Arithmetic* of Diophantus, one on the *Astronomical Canon* of Ptolemy, and one on the *Comics* of Appolonius of Perga. Synesius, Bishop of Ptolemais requested her assistance in the construction of an astrolabe and a hydroscope.

II. MEDIEVAL EXPLORATION

The first dawn of a renaissance came with the Arabs. When the followers of Mohammed swept into power in the Near East in the seventh century and captured Alexandria in A.D. 640, they found no library of any importance, but a city of four thousand palaces, four thousand baths and four hundred theaters. Impressed by the opulence of the city and the size of the Christian fleet, they decided to emulate both.

The Mohammedans' delight in navigation engendered a need for geography, which required astronomy and mathematics. The search for such data was to lead them to the secrets of the Pyramid. To broaden their knowledge, the Arabs set about translating into Arabic all they could lay hands on of ancient Greek and Sanskrit material, ransacking monasteries for rare copies of Euclid, Galen, Plato, Aristotle, and the Hindu sages. In the midst of otherwise Dark Ages, Mohammed's religious successors, the caliphs of Baghdad, were soon the most enlightened as well as the most powerful potentates. Under caliph Harun Al-Rashid, whose feats were to be celebrated in the *Arabian Nights,* translators were paid in gold by the weight of each manuscript.

Harun's young son Abdullah Al Mamun, who came to the throne in A.D. 813, founded universities, patronized literature and science, and turned Baghdad—known as Dar-al-Salam, or City of Peace—into a seat of academic learning, with its own library and astronomical observatory.

Described by Gibbon as "a prince of rare learning who could assist with pleasure and modesty at the assemblies and disputations of the learned," young Al Mamun was responsible for the translation into Arabic of Ptolemy's great astronomical treatise, the *Almagest.* This work contained astronomical and geographical data, including the earliest star catalogue which has survived, all of which knowledge had been lost to the West for centuries but was of great value to the Arabs in their growing empire.

Claiming that Aristotle had appeared to him in a dream, Al Mamun commissioned seventy scholars to produce an "image of the earth" and the first "stellar map in the world of Islam." (Though they have since disappeared, these maps were consulted by the Arab historian Al Masudi in the first half of the tenth century.) To check Ptolemy's

In the *Arabian Nights* the Great Pyramid was reputed to have magical qualities and to contain extraordinary treasures. E. W. Lane's picture illustrates his nineteenth-century translation of *The Thousand and One Nights*.

statement that the circumference of the earth was 18,000 miles, Al Mamun ordered his astronomers to measure the actual overland length of a degree of latitude across the adjacent plain of Palmyra, north of the Euphrates. From a central point the observers moved north and south till they noted by astronomical observation that the latitude had changed 1°; with wooden rods they measured across the sandy plain and obtained a degree of 56 2/3 Arabic miles, the equivalent of 64.39 English statute miles. This figure, which gave a circumference of 23,180 miles, was more precise than Ptolemy's, but the Arabs had no way of checking it: no one had yet circumnavigated the globe; indeed, most still argued that the world was flat!

Al Mamun, who ran an up-to-date intelligence service under the direction of his postmaster-general employing as many as seventeen hundred old women as intelligence agents in Baghdad alone, was informed that the Great Pyramid was reputed to contain a secret chamber with maps and tables of the celestial and terrestrial spheres. Although they were said to have been made in the remote past, they were supposed to be of great accuracy. The chamber was also reported to contain vast treasures and such strange articles as "arms which would not rust" and "glass which might be bended and not break."

Arab historians, including one with the imposing name of Abu Abd Allah Mohammed ben Abdurakin Alkaisi, have recounted the tale of Al Mamun's attempts to enter the Pyramid. In 820 the young caliph collected a vast conglomeration of engineers, architects, builders and stonemasons to attack the Pyramid; for days they searched the steep polished surface of the northern slope for its secret entrance, but could find no trace of it.

Not to be thwarted, so the story goes, Al Mamun decided to burrow straight into the solid rock of the structure in the hope of running across some passage within the interior. Hammer and chisel would not dent the huge blocks of limestone, no matter how many blacksmiths stood ready to sharpen them; so a more primitive but effective system was used: fires were built close to the blocks of masonry, and when these became red hot they were doused with cold vinegar until they cracked. Battering rams knocked out the fragmented stone.

Al Mamun forced his way into the Pyramid to the west of the main axis of the northern face, at the level of the seventh course of masonry. He misjudged the level of the original entrance by starting ten courses too low, and too far to the west.

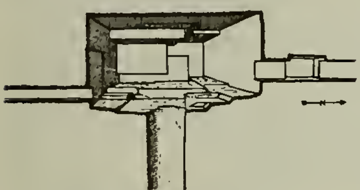
Entrance to Descending Passage.



The subterranean pit cut deep into the bedrock is almost 600 feet directly below the apex of the Pyramid. It is 31 feet in the east-west direction but only 27 feet north-south.

Though its ceiling is relatively smooth, its floor is cut in several rough levels, the lowest being 11 feet 6 inches from the ceiling.

In the south wall, opposite the entrance, is a low passage which runs another 53 feet southward before coming to a blind end.

In the center of the floor is a square hole, which was 12 feet deep in 1838, but was dug deeper by the English explorer Howard-Vyse in the vain hope of finding an outlet for a further hidden chamber.

For over 100 feet Al Mamun's men tunneled into the solid core of the Pyramid, excavating a narrow passage that became hotter, dustier and more constricted. Illumination by candle or flare consumed oxygen and poisoned the air.

Al Mamun was on the point of giving up when a workman heard a muffled sound of something heavy falling somewhere within the Pyramid, east of the tunnel. Renewing their efforts and altering the direction of the bore, the workers broke into a hollow way "exceeding dark, dreadful to look at, and difficult to pass." It was a passage 3 1/2 feet wide by 3 feet 11 inches high, which sloped at a steep angle of 26°. On the floor lay a large prismatic stone which had been dislodged from the ceiling of the passage.

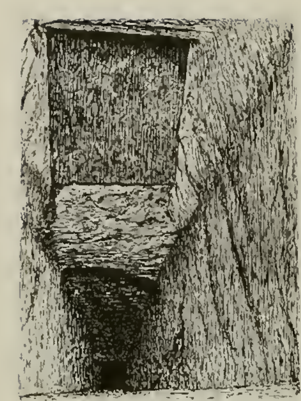
Struggling up the passage on all fours, the Arabs discovered the original secret entrance about 90 feet to the north. It had been placed 49 feet above the base of the Pyramid, ten courses higher than Al Mamun had guessed, and 24 feet east of the main axis of the north face of the Pyramid.

Retracing their steps, Al Mamun and his men groped down the low, slippery, Descending Passage, cut deep into the rock of the plateau. At the bottom they were disappointed to find nothing but the unfinished, roughly hewn chamber, or "pit," with an uneven floor, containing nothing but debris and dust. On the far side of it, an even narrower horizontal passage led 50 feet to a blank wall; in the floor a well shaft appeared to have been carved to a depth of 30 feet, leading nowhere.

From the torch marks on the ceiling, the Arabs deduced that the "pit" had been visited in classical times and that anything of interest it may have contained had long since been removed.

What now intrigued the Arabs was the large prismatic stone that had fallen from the ceiling of the Descending Passage. It had evidently covered the end of a large rectangular red-and-black granite plug which completely filled what looked like another passage sloping *up* into the body of the Pyramid. Of such a passage there had been no mention in the writings of Strabo or other classical authors; Al Mamun figured he might have stumbled onto a secret which had been kept since the original construction of the building.

The Arabs tried to chip or dislodge the granite plug, but it was tightly wedged, of indeterminate length, and it evidently weighed several tons. Spurred by the prospect of a new passage leading to some hidden treasure chamber, Al Mamun ordered his men to cut around the plug through

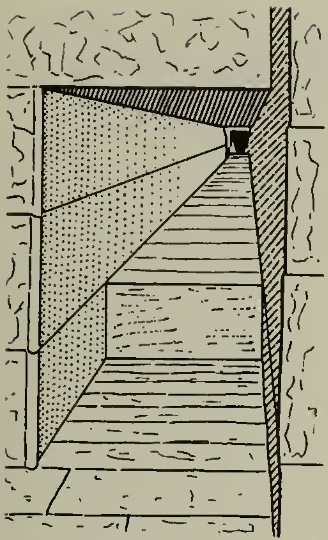


The granite plug in the ceiling, halfway down the descending passage, was of very hard quartz, mica and feldspar, which blunted the Arabs' chisels.

The Arabs dug a large cavity into the softer limestone blocks of the body of the Great Pyramid to the west of the Descending Passage. By means of this hole Al Mamun was able to circumvent the three impenetrable granite monoliths which barred his way to what appeared to be a passage leading upward into the Pyramid.

the softer limestone blocks of the surrounding walls. Even this turned out to be more of a job than expected. When the Arabs had bored beyond the first granite plug for over 6 feet, they encountered another granite plug, equally hard and equally tightly wedged. Beyond it lay yet a third. By now the Arabs had tunneled more than 16 feet. Beyond the third granite plug they came upon a passage filled with a limestone plug which could be cracked with chisels and removed piece by piece.

It is not recorded how many such plugs the Arabs encountered, but they may have had to clear a score or more before they could force their way into a narrow ascending passage, again less than 4 feet high and equally narrow. On their hands and knees, holding their torches low, Al Mamun and his men were obliged to scramble up 150 feet of dark, slippery passageway, at the same steep



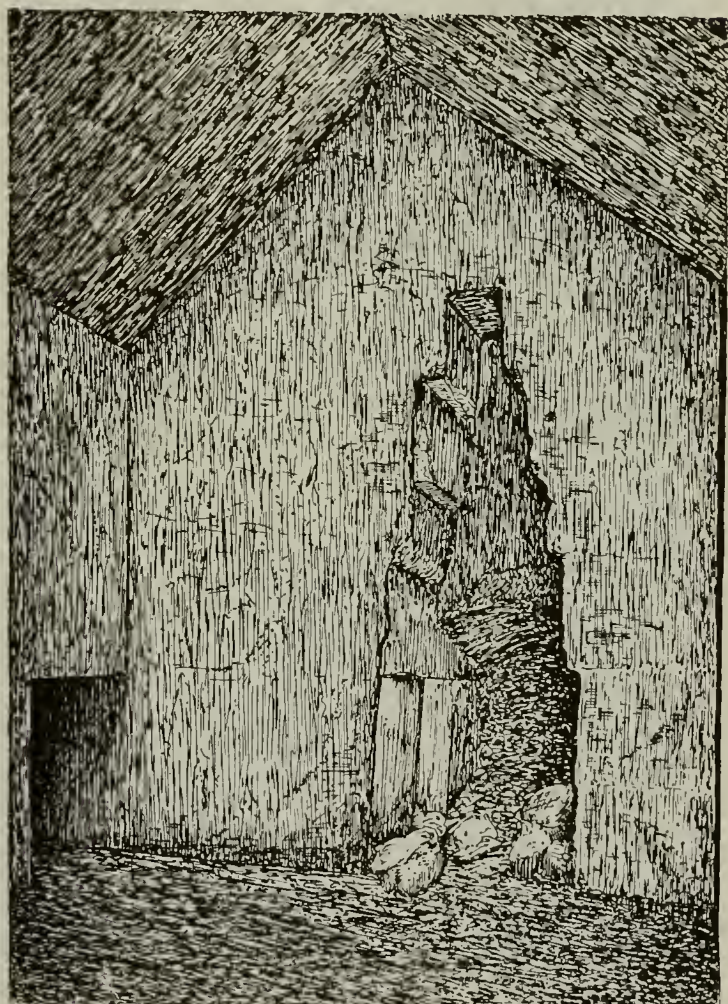
The first-level passage, at the top of the first long incline, is 127 feet long, 3 feet 9 inches high, and 3 feet 5 inches wide.
A sudden drop of 2 feet mysteriously appears in the passage.

slope of 26°, before they could raise their heads and stand on a level spot.

In front of them stretched another low horizontal passage, no higher than the one they had painfully ascended.

Inching their way to the end of this passage, they found themselves in a rectangular limestone room with a rough floor and a gabled limestone roof. Because of the custom among the Arabs of placing their women in tombs with gabled ceilings (as opposed to flat ones for men), this room came to be known as the "Queen's Chamber."

The bare room, 18 feet long, and almost square, had an empty niche in the east wall large enough to have contained an overlifesize statue. Thinking the niche might conceal the entrance to a second chamber, the Arabs hacked their way into its solid masonry for another yard before giving up.



Queen's Chamber, with niche, excavated by Arabs.

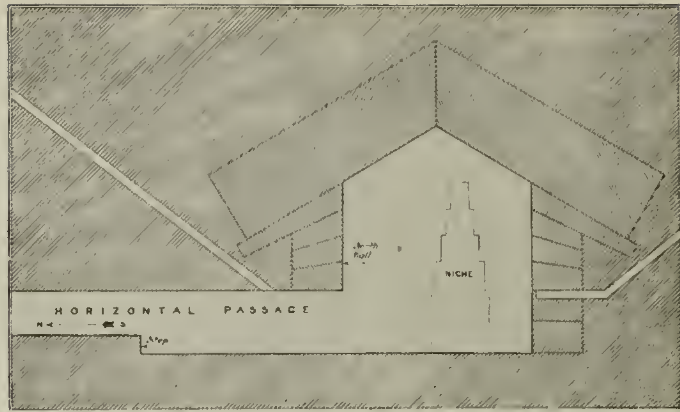
The name "Queen's Chamber" is considered a misnomer by Egyptologists, who claim that the Egyptians placed no queens in the pyramids of the Pharaohs.

The walls of the chamber are unblemished limestone blocks, beautifully finished, but early explorers found them mysteriously encrusted with salt as much as 1/2 inch thick.

Originally the niche was 3 feet 5 inches deep, but treasure seekers have hacked a passage through the back for several yards. The niche is just over 16 feet high. The sides have four corbeled courses, and are 61 3/4 inches (3 cubits) apart at the base and 20 1/4 inches (1 cubit) apart at the top.

The chamber, placed directly beneath the apex of the Pyramid, is almost square: 18 feet 10 inches from east to west and 17 feet 2 inches from north to south. It has a double-pitched ceiling, 20 feet 5 inches at its highest, formed by huge blocks of polished limestone at a slope of 30° 26′, which extend 10 feet beyond the supporting walls; there is no pressure, or arch thrust, at the apex, the center of gravity of each block being well behind the wall face.

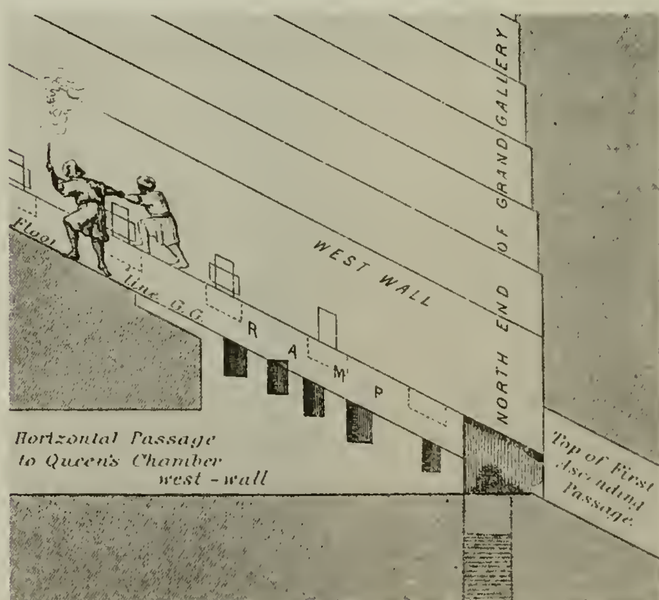
The floor of the chamber is of roughly dressed stones, and appears never to have been finished, as if another layer of polished stones were to be laid.



Retracing their steps to where they had left the low Ascending Passage, the Arabs raised their torches into an ominous void above them. In the side walls joist holes indicated that the floor of the Ascending Passage had once continued upwards, blocking and hiding the low passage to the Queen's Chamber.

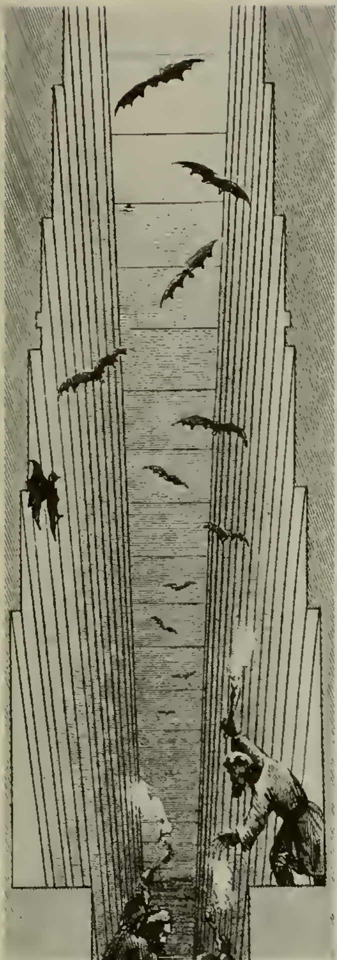
Climbing on each others' shoulders and raising their torches, the Arabs now saw that they were at the bottom of a narrow but grand gallery, about 28 feet high, which appeared to stretch upward at the same steep slope as the Ascending Passage into the black and mysterious heart of the Pyramid.

The center of this new passage was very slippery, but to either side of it were two narrow ramps slotted at regular intervals; they afforded a better foothold.



Holding their torches high, the Arabs proceeded to escalade these ramps. At the end of another 150-foot climb, they came upon a huge solid stone, raised 3 feet from the floor, which they had to clamber up in order to stand at the top of the gallery on a 6 × 8 foot platform.

Beyond this platform the floor continued level, but the



The overall length of the Grand Gallery, shown here, is 157 feet. It is inclined 26°, as is the Ascending Passage.

The walls are 28 feet high, rising vertically in seven courses of polished limestone, each corbeled 3 inches toward the center, making the gallery narrow from 62 inches at the base to 41 inches at the top. The first corbeling is 7 feet high.

On either side of the central 2-foot passage are two ramps 18 inches wide and 2 feet high; along the walls is a series of notches.

The gallery is considered an architectural masterpiece. Egyptologists have differed as to its function, and that of its ramps and notched holes.

At the top of the Grand Gallery lies a huge stone step, 6 feet wide, 3 feet high, which blocks the Ascending Passage and forms a platform 8 feet deep, now badly chipped and worn.

Beyond the Great Step there stretches another low, level passage 41 inches (or 2 cubits) square. A third of the way along this passage, it rises and widens into a sort of antechamber, the south, east and west walls of which are no longer of polished limestone but of polished red granite.

ceiling fell to a mere 41 inches, forming a sort of portcullis entrance to a small antechamber.

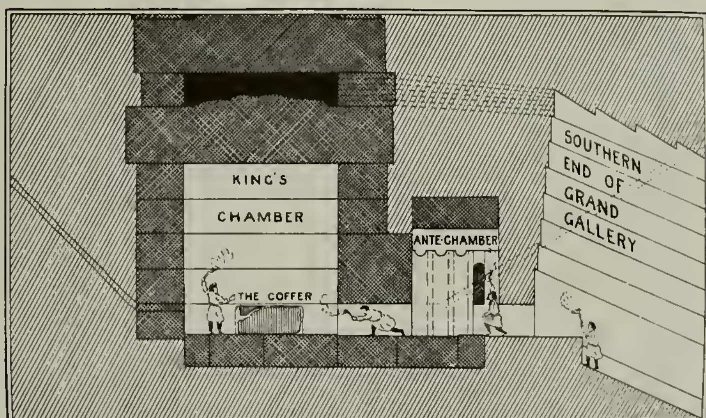
Past the portcullis, Al Mamun's men were again obliged to stoop along a short passage which led to yet another chamber.

Their torches revealed a great and well-proportioned room; the walls, floor and ceiling were all of beautifully wrought and polished red-granite blocks, squared and extremely finely jointed: "a right noble apartment, thirty-four feet long, seventeen broad, and nineteen high." Because of its flat ceiling, the Arabs named it the "King's Chamber."

Al Mamun's men frantically searched every cranny of the chamber but could find nothing of interest or value—there was no sign of any treasure, only a large lidless "sarcophagus" of highly polished, dark chocolate-colored granite.

Some Arabian authors have reported that Al Mamun found in the sarcophagus a stone statue in the shape of a man. They say that within the statue lay a body wearing a breastplate of gold set with precious stones, an invaluable sword on his chest, and a carbuncle ruby on his head the size of an egg, which shone as with the light of day. According to the storytellers the statue was inscribed with a mysterious writing that no one could decipher; but there is no historical evidence to support the tale.

To Al Mamun it appeared that either the vast mausoleum had been built about nothing but a single empty chest, or the whole place had previously been looted; though how and by whom it was hard to imagine, considering the enormous number of stone plugs the Arabs had been obliged to break up in order to make their entrance.



VERTICAL SECTION (LOOKING WEST) OF KINGS CHAMBER; ALSO OF ANTE-CHAMBER, AND SOUTH END OF GRAND GALLERY CROSSED LINES INDICATE GRANITE

The sole item within the King's Chamber is a lidless coffer cut from a solid block of chocolate-colored granite, whose granules of feldspar, quartz and mica are even harder than those of the chamber walls. They were fabled to have come not from the Egyptian quarries up the Nile at Syene but from the mythical Atlantis or even from America.

Because the coffer is 6 feet 6 inches long, 2 feet 3 inches wide and 3 feet deep and could comfortably accommodate a human body, it has been called a sarcophagus and is believed by Egyptologists to have been the tomb of the Pharaoh Cheops.

A ridge along the top edge of the coffer indicates it may have once had a sliding lid, though no trace of the lid has been found.

As the Arabs removed 22 acres of 100-inch-thick pure-limestone covering from the Great Pyramid, vast mounds of chips and refuse built up as high as 50 feet around the base.

In a fury of disappointment, the Arabs ripped up part of the floor and hacked at the beautiful granite walls, even burrowing a short tunnel into a corner of the room, all to no avail.

Legend has it that to pacify his disappointed men Al Mamun had a treasure of gold secreted in the Pyramid at night, amounting to just the wages due his men, and palmed off the coincidence on the wisdom and prescience of Allah.

For another four centuries the great pile lay undisturbed on the desert's edge, its outer casing virtually intact, its geometric shadows lengthening and shortening with the revolutions of each year. An Arab historian who saw the Pyramid in the early thirteenth century compared it to a great female breast rising from the bosom of Egypt. He remarked that it was still perfect except for the entrance carved in it by Al Mamun.

Subsequently a series of earthquakes demolished large parts of northern Egypt, and the descendents of Al Mamun's workers wreaked their revenge on the treasureless Pyramid by stripping it of its precious limestone casing to rebuild their new capital city El Kaherah, "The Victorious." In the course of several generations they managed to remove the entire 22 acres of 100-inch-thick covering of the Pyramid, and even built two bridges especially to drag the heavier stones across the river on camel trains to Cairo for the construction of a series of mosques and palaces.

The Mosque of Sultun Hasan in Cairo, built in 1356 with limestone blocks removed from the covering of the Great Pyramid.

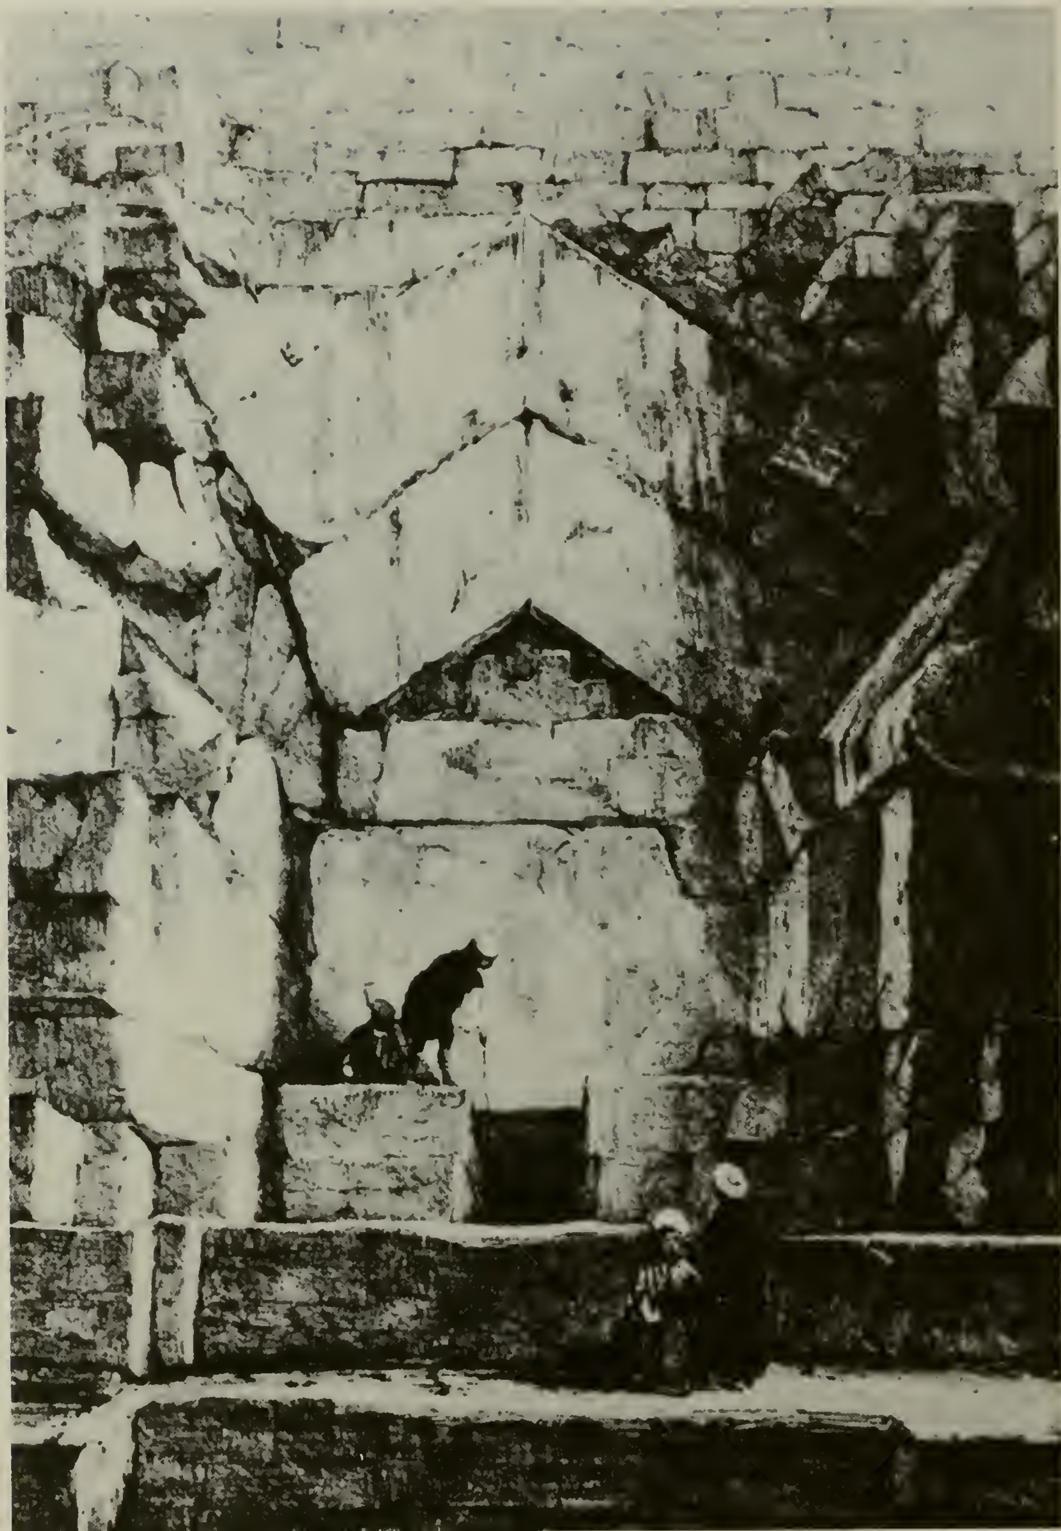
One of the more renowned of the several hundred minareted mosques in what came to be known as "Grand" Cairo was built in 1356 by Sultan Hasan almost entirely with stones removed from the Pyramid. Forty years later, in the reign of his successor Barluk, when the French Baron d'Anglure traveled to Egypt, he was able to see and report on the continued dismantling of casing stones by Arab stonemasons. D'Anglure was naïve enough to fall for the historical canard that the pyramids had been built as granaries by the biblical Joseph to store Pharaoh's grain in years of plenty; but his old French gives a vivid picture of the despoilers tumbling the massive blocks from the summit: ". . . *certain ouvriers massons qui à force desmuroient les grosses pierres taillés qui font la couverture de desdits greniers, et les laissoient devaller à val.*" ("Certain masons demolished the course of great casing stones which covered these granaries, and tumbled them into the valley.")

The stripping of the limestone left the core masonry exposed in a series of gradually ascending and receding steps to be weathered and worn by wind, sand and rain. Some of the underlying core blocks proved to be of pure limestone, others of nummulitic limestone containing large quantities of fossil shells resembling coins.

Around the stripped Pyramid, fragments of limestone and rubble were piled so high that they finally obliterated the entrance which Al Mamun had forced in the north face.

But the removal of the outer casing brought to light two huge transoms embedded in the masonry which formed a protective gable over the tiny gaping original entrance to the Descending Passage.

Only now, no one cared to reenter the Pyramid.



III. RENAISSANCE AND REVIVAL OF INTEREST

Superstition shrouded the ancient structure. It was said to be haunted by ghosts and to be alive with venomous vermin. According to the Arabs the Great Pyramid was haunted at noon and sunset by a naked woman with large teeth who seduced people into her power and then drove them insane.

When Rabbi Benjamin ben Jonah of Navarre, an adventurous twelfth-century traveler, reached the Giza plateau from Abyssinia he noted that "the Pyramids which are seen here are constructed by witchcraft."

Abd-al-Latif, who taught medicine as well as history in Baghdad, summoned the courage to enter the Great Pyramid shortly after Benjamin's visit but admitted that within its stifling interior he fainted from fear and came out more dead than alive.

The Pyramid's bad reputation spread so far afield that when the fabulous English explorer Sir John Mandeville is supposed to have visited Egypt in the fourteenth century, he is said to have complained he dared not enter the Pyramid because it was filled with serpents: but the serpents turned out to be as fabulous as his *Travels* which were produced by a notary in Liège who had never even left his native country.

Not till the Renaissance had swept away some of the cobwebs of medieval obscurantism, and revived man's interest in science, was there enough motive for Europeans to enter the Pyramid and rationally examine its interior.

In 1638 John Greaves, a 36-year-old mathematician and astronomer who had studied at Oxford and taught geometry in London, decided to set off for Egypt. His was no idle curiosity: like Al Mamun, he hoped to find in the Great Pyramid a datum that might help to establish the dimensions of the planet. Although the preceding century had spawned the great voyages of exploration, and Magellan's crew had circumnavigated the earth, the sciences of geography and astronomy were still so much in their infancy—to all appearances—that no one had improved on Ptolemy's or Al Mamun's geographical degree and hence no one knew the true circumference of the earth.

The Giza pyramids and Sphinx as depicted in 1610, showing European travelers.

A clue to a possible solution had been postulated by Girolamo Cardano, an astonishing Milanese physician and mathematician of the early sixteenth century and a close friend of Leonardo da Vinci's, who maintained that a body of exact science must have preexisted the Greeks. Cardano suspected that a degree of meridian (far more exact than that of Eratosthenes, Ptolemy or Al Mamum) must have been in existence hundreds if not thousands of years before the Alexandrians and that to find it one must search in Egypt. Pythagoras was said to have claimed that the measures of antiquity were derived from Egyptian standards, themselves copied from an invariable prototype taken from nature. It followed that the pyramids might have been built to record the dimensions of the earth and furnish an imperishable standard of linear measure.

Greaves had already traveled to Italy to measure its ancient buildings and statues in an attempt to establish the original standard of measure used by the Romans—which he concluded to be a foot somewhat shorter than a British foot by 28 thousandths.

John Greaves.

Statue of young Roman architect, Statilius Aper, in Vatican gardens, from which Greaves measured a Roman foot which was related to the circumference of the earth.

In the Vatican gardens Greaves found a statue commemorating a young architect of the first century A.D., T. Statilius Vol Aper, who had died in his twenty-third year. Portrayed in relief were Aper's architectural instruments, including a Roman foot. Greaves copied this foot and compared it to an English foot made of brass which he had divided in 2,000 parts. "I spent at least two hours," wrote

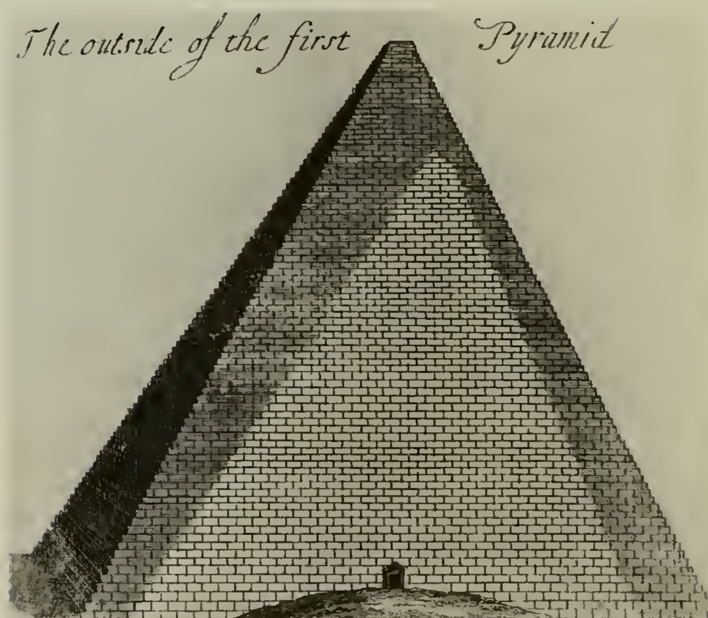
Greaves, explaining the diligence with which he performed the operation, "so often comparing the several divisions and digits of it respectively one with another, that I think more circumspection could not have been used."

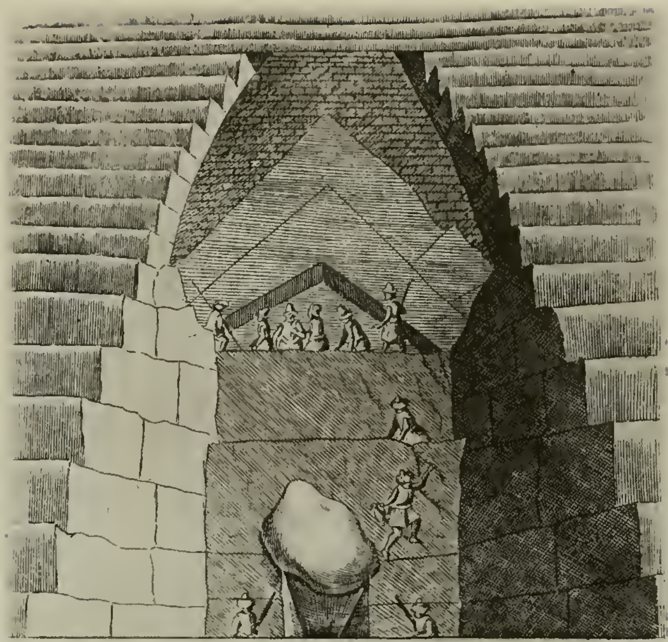
Greaves found that the Roman foot contained "1,944 such parts as the English foot contains 2,000." The interesting result of this measurement was the fact that it confirmed a Roman foot to be exactly 24/25ths of the Greek foot derived from the Parthenon—a foot of which there are 100 in the width and 225 in the length of the building.

Greaves's next problem was to establish the basic unit on which the Pyramid had been built—whether foot, pace, cubit (an arm's length), or palm.

To help defray his expenses, Greaves applied for the patronage and assistance of the magistrates of the City of London, but they turned him down. Luckily the Archbishop of Canterbury thought enough of Greaves, and was sufficiently interested in rare Arabic and Persian manuscripts which might be discovered in the East, to patronize him. Greaves was able to equip himself with instruments for measuring the inside and the outside of the Pyramid and for obtaining the declination and right ascension of the stars above it, and have enough money left over to spend a few weeks in Cairo.

Though a bookish mathematician and an ingrained antiquarian, Greaves was not without courage as an explorer. At the Pyramid he climbed onto the mound of rubbish 38 feet high which surrounded it and gingerly let himself into the Descending Passage, "creeping like a serpent," horrified to





Entrance to the Great Pyramid as depicted by John Greaves.

find himself in a storm of bats "so ugly and so large, exceeding a foot in length," such as he had never imagined.

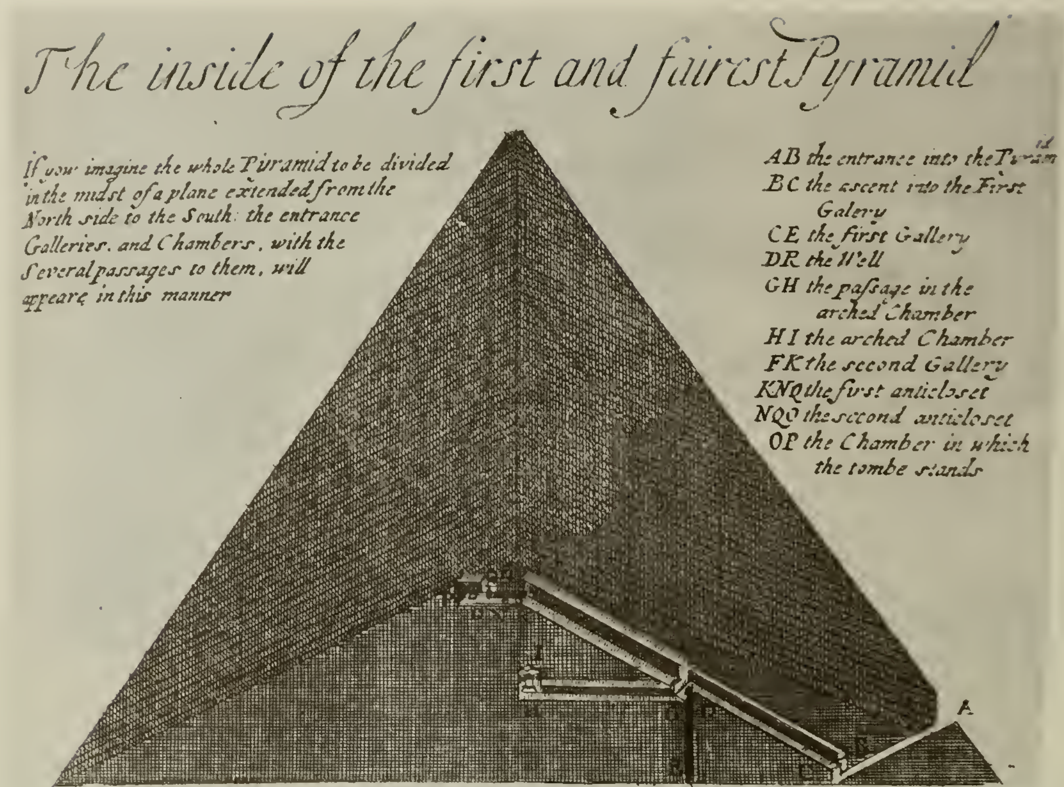
To scare off the bats and clear the air, Greaves resorted to firing his pistols; the explosions reverberated like cannon shots in the restricted passage of the Pyramid.

Working his way downward, Greaves reached the point where Al Mamun's original tunnel joined the Descending Passage, but was unable to proceed in a downward direction because of the debris left behind by Al Mamun's men when they had broken up the series of limestone plugs that had filled the upper passage.

Following in the Arabs' footsteps, Greaves climbed around the massive granite plugs and up into the low Ascending Passage. Having scrambled to the top, Greaves retraced Al Mamun's course along the short Horizontal Passage to the Queen's Chamber, where he found the stench of vermin so offensive he could not linger.

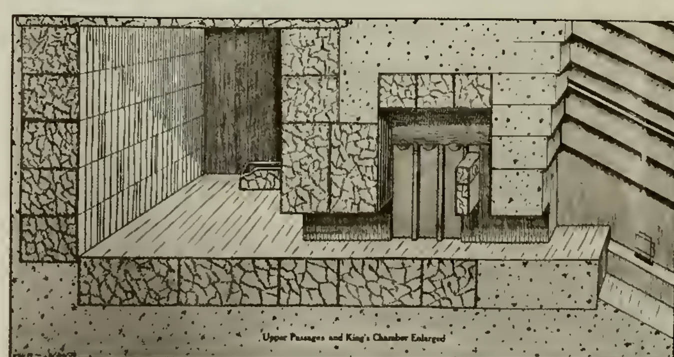
Everything Greaves came across was a puzzle to him. The steepness of the Grand Gallery seemed to preclude its having been designed as a chamber: the difficulty of scaling its polished slope made it impractical as a stairway. Also, it was accessible only through the preceding very low passage.

He admitted nevertheless that the Pyramid was "a very stately piece of work, and not inferior, either in respect of the curiosity of art or richness of materials, to the most sumptuous and magnificent buildings." He noted that it was built of polished limestone "very evenly cut in spacious



squares or tables"; and he found that the "coagmentation or knitting" of the joints was so close it was scarcely discernible with the naked eye.

Making his way to the King's Chamber, Greaves was puzzled that so incredibly imposing a structure as the Pyramid should be built around a single chamber with a single empty coffer. He could see no apparent reason for its portcullis entrance or for the complexity of its antechamber where the walls changed mysteriously from limestone to granite. But being a scientist by nature, Greaves set to collecting and noting data about the building.



How the King's Chamber and its Antechamber with its portcullis are entirely cased by granite blocks within the limestone body of the Pyramid.

Entrance to the "well."

In the west wall of the Grand Gallery, not far from the north wall, a small part of the ramp is missing, allowing entry into a shallow pit. At the bottom of this pit a short passage leads westward to an opening in the floor which becomes a shaft.

This shaft descends through the nucleus masonry of the Pyramid and penetrates a rocky core which was left by the builders as an anchor for the Pyramid *above* the level of the foundation pavement.

A grotto opens off the shaft and the shaft passes through several natural fissures in the bedrock.

For many centuries the shaft's terminus was a mystery, as was its purpose.

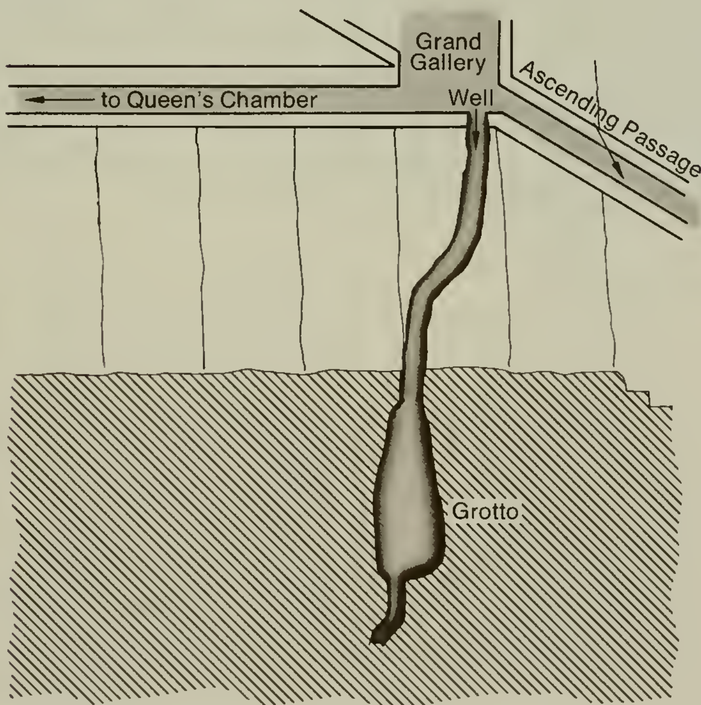
Shaft entrance to the grotto.

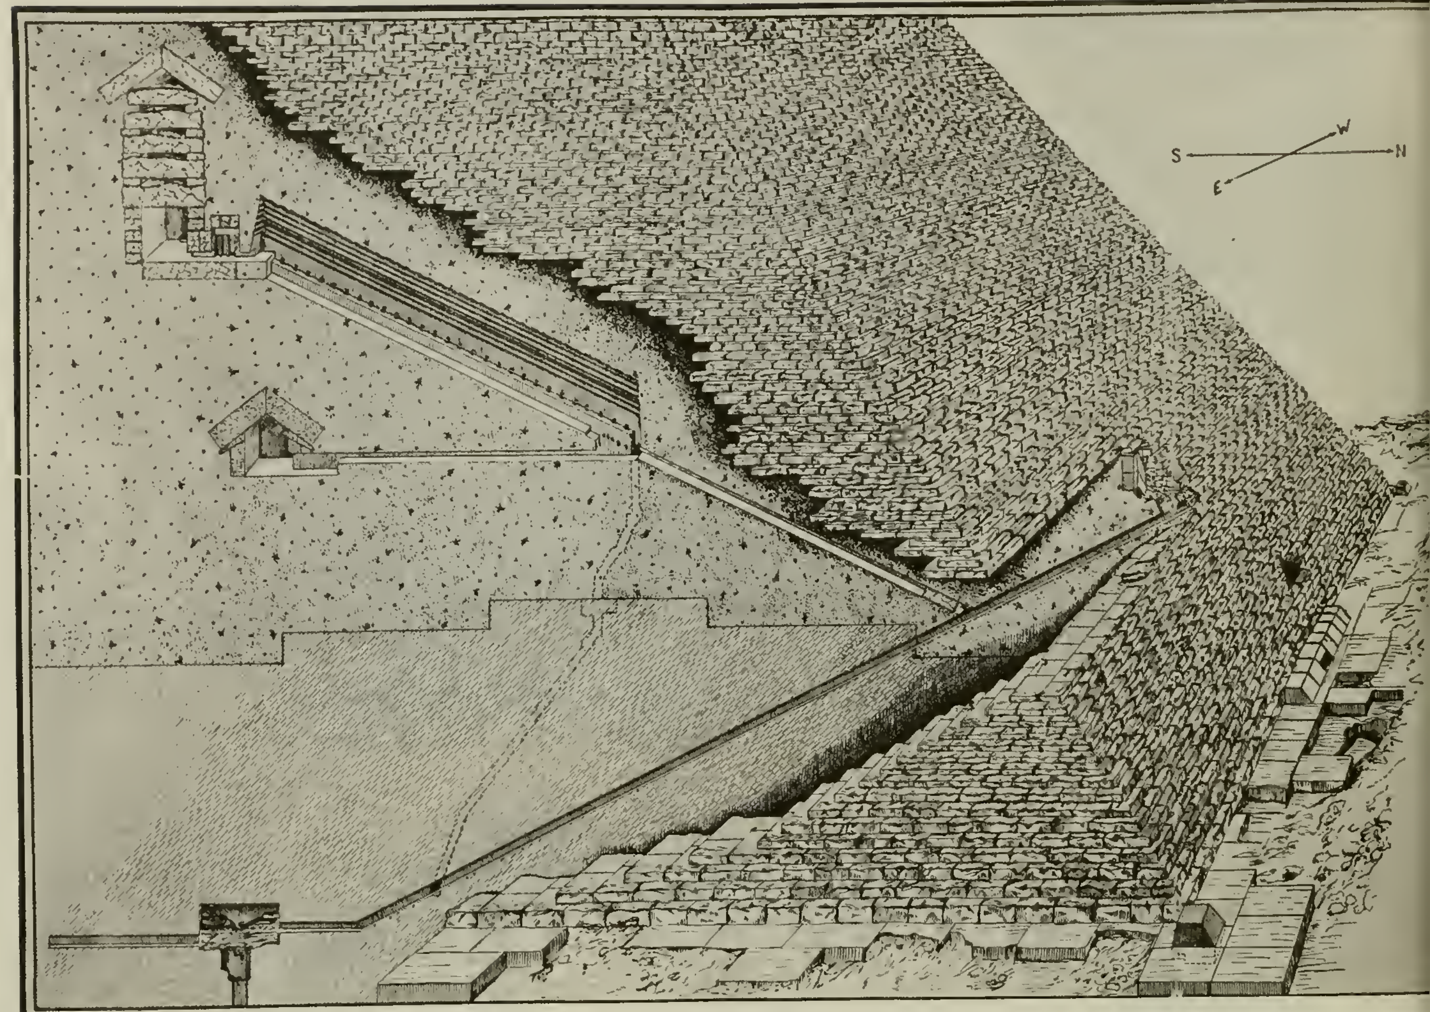
In London Greaves had furnished himself with a special 10-foot measuring rod based on a standard English foot deposited in Guild Hall, finely divided into 10,000 equal parts. With great care he measured the length, breadth and width of the King's Chamber, commenting that "the structure of it hath been the labour of an exquisite hand." He counted its tiers of granite, measured their length and breadth, and did likewise to the empty coffer, "even to the thousandth part of a foot," finding it to be 6.488 English feet.

Picking his way back to the foot of the Grand Gallery, Greaves made a new and startling discovery. From the ramp at one side, a stone block had been forcibly removed and a passage appeared to have been dug straight down into the bowels of the Pyramid.

The aperture was a little over 3 feet wide; but as notches had been carved opposite one another on the sides of this "well," Greaves lowered himself into it and descended about 60 feet, to where the shaft had been enlarged into a small chamber, or "grotto." Below him the shaft continued into the murky darkness, but the air was so foul, and the bats so thick, that Greaves decided to climb back up the way he had entered, puzzled by this strange feature of the Pyramid.

That the well shaft was not bottomless he established by dropping a lighted flare which continued to flicker from its depths.





Chambers and passages in the Great Pyramid.

Outside, Greaves climbed to the top of the Pyramid. From this high point he could admire the minarets of Cairo, the range of Mokattam hills across the Nile, and the silhouettes of the pyramids of Abusir, Saqqara and Dashur to the south.

On his way down Greaves was the first to make a reasonable count of the Pyramid's visible tiers of chiseled blocks, which he figured to be 207, estimating the total height of the structure to be 481 feet, or 499 with the missing capstone. This was within a dozen feet of being correct.

As a length for the base, Greaves estimated 693 feet, which was short of the mark by some 70 feet: but the base was so littered with rubbish that he had no way of telling where the first tier might rise from the hidden base.

Back in England Greaves was rewarded for his efforts at the Pyramid by being appointed Savilian Professor of

Pyramidographia:

O R, A

DESCRIPTION

OF THE

PYRAMIDS

IN

Æ G Y P T.

By JOHN GREAVES, *Profeſſor of Aſtronomy in the Univerſity of* Oxford.

Romanorum Fabricæ & antiqua opera (cum veniâ id dictum ſit) nihil accedunt ad Pyramidum ſplendorem, & ſuperbiam.
Bellon. lib. II. Obſerv. cap. 42.

Astronomy at Oxford. All the facts and figures Greaves had accumulated he meticulously wrote up in a scholarly booklet entitled *Pyramidographia.*

His conclusions led to a very lively discussion—with as much con as pro—in which even the celebrated Dr. William Harvey, discoverer of the circulation of blood, took part. Harvey was surprised that Greaves had not described, or apparently even discovered, any conduits by means of which the central chambers in the Pyramid could be ventilated from the exterior. According to Harvey such conduits were bound to have existed, or the air in the King's Chamber would have become extremely foul—"Seeing we never breathe the same air twice, but still new air is required to a new inspiration (the succus alibilis of it being spent in every expiration)." Harvey's surmise turned out to be true, but was not established for another two generations.

Greaves had indeed noted "two inlets or spaces, in the south and north sides of the chamber, just opposite from one another," but attributed the blackness within them to their being receptacles for burning lamps.

Before returning to England, Greaves had left his instruments, including the special 10-foot rod, to a young Venetian whom he had met in Egypt and who had accompanied him to the Pyramid, Tito Livio Burattini, who who was as anxious as Greaves to find out not only the exact measurements of the Pyramid, but the unit—whether cubit, foot or palm—on which it had originally been designed.

Burattini's trip to Egypt had been subsidized by the Jesuit Father Athanasius Kircher of Cracow, Poland, who had moved to Rome and entered into correspondence with Galileo Galilei on the subject of a universal standard of measure.

At that time Galileo was living in seclusion near Florence, having been tried and imprisoned by the Inquisition for supporting the Copernican belief that the earth and the planets revolved round the sun, and the equally heretical conceit that the earth and the sun spun on their own axes.

As a young man Galileo had timed the oscillations of a lamp swinging in the Duomo of Pisa by means of his pulse beats and found the time for each swing to be the same, no matter what the amplitude of the oscillation, thus discovering what is known as the isochronism of the pendulum.

Developing Galileo's idea, Burattini had tried to obtain a universal standard of measure by using the length of a pendulum that would vibrate exactly 3600 times in one hour, or once every second, but the gold-ball pendulum he devised proved impractical because it was found that its swing varied with temperature, location, and altitude above sea level.

Burattini lingered four years in Egypt taking careful measurements with Greaves's instruments, and he sent reports of the results to Father Kircher by letter, which was lucky for the scientific world: on Burattini's journey through the Balkans back to his adopted Poland he was set upon by bandits and deprived of not only his cash but all his notes on the Pyramid which he intended to have printed as a book in Italy.

There remained the data which he had sent to Father Kircher; but it was from Greaves's data that Sir Isaac Newton deduced that the Great Pyramid had been built on the basis of two different cubits, one of which he called "profane" and the other which he called "sacred." From Greaves's and Burattini's measurements of the King's

Sir Isaac Newton is described by Giorgio de Santillana, of MIT, as "the last of the magicians, the last of the Babylonians and Sumerians, the last great mind which looked on the visible world with the same eyes as those who began to build our intellectual world rather less than 10,000 years ago."

Chamber, Newton computed that a cubit of 20.63 British inches produced a room with an even length of cubits: 20×10. This cubit Newton called the "profane," or Memphis, cubit; whereas a longer, more arcane cubit appeared to measure about 25 British inches.

This longer, or "sacred," cubit Newton derived from the Jewish historian Josephus's description of the circumference of the pillars of the Temple at Jerusalem. Newton estimated this cubit to be between 24.80 and 25.02 English inches, but believed the figure could be refined through further measurement of the Great Pyramid and other ancient buildings.

All of this Newton wrote up in a small and now hard-to-find paper called *A Dissertation upon the Sacred Cubit of the Jews and the Cubits of several Nations: in which, from the Dimensions of the Greatest Pyramid, as taken by Mr. John Greaves, the ancient Cubit of Memphis is determined.*

Newton's preoccupation with establishing the cubit of the ancient Egyptians was no idle curiosity, nor just a desire to find a universal standard of measure; his general theory of gravitation, which he had not yet announced, was dependent on an accurate knowledge of the circumference of the earth. All he had to go on were the old figures of Eratosthenes and his followers, and on their figures his theory did not work out accurately.

By establishing the cubit of the ancient Egyptians, Newton hoped to find the exact length of their stadium, reputed by classical authors to bear a relation to a geographical degree, and this he believed to be somehow enshrined in the proportions of the Great Pyramid.

Unfortunately Greaves's and Burattini's measurements of the *base* of the Pyramid were incorrect because of the accumulated debris, and though Newton's figure for the cubit was very close to perfect, the false measurements of the base failed to give him the answer he was searching.

To resolve Newton's problem, Burattini suggested taking the actual measure of two or three degrees of latitude across the flat countryside of Poland; but the operation proved too costly. Unfortunately, neither Newton nor Burattini knew that in 1635 Richard Norwood, author of *Sea-Man's Practice,* had made an observation of the sun at noon at York using a sextant more than 5 feet in radius, and a similar observation in London near the Tower; the distance between the two points was 9149 chains, and he thus obtained a figure of 69.5 English statute miles for 1° of latitude. This figure would have solved Newton's problem, but because of the political unrest in Cromwellian England he did not hear of it; so he put away his theory of gravitation for several more years, or until the French astronomer Jean Picard repeated Norwood's feat with rather more fanfare.

In 1671 Picard measured a degree of latitude between Amiens and Malvoisine. His method was to measure a base line at Amiens very meticulously with wooden rods, then measure the angles formed by this base line with a point on the horizon and deduce its distance by trigonometry. Selecting a series of points on hilltops easily distinguished with a telescope and measuring only the angles between their sides, he was able to string out a series of thirteen large triangles across the countryside and obtain a very accurate degree of 69.1 English statute miles.

On the basis of this computation Newton was able to announce his general theory of gravitation—that all bodies in the universe attract each other in proportion to the product of their mass and inversely as the square of their distance apart—and so launch a new era of physics.

As the English poet Alfred Noyes summed up the event:

> . . . Newton withheld his hope
> Until that day when light was brought from France,
> New light, new hope, in one small glistening fact . . .
> Picard in France—all glory to her name—
> Had measured earth's diameter once more
> With exquisite precision . . .

But all this Anglo-Gallic dalliance was short-lived because an argument developed between Newton and a French family of astronomers, map makers, and surveyors called Cassini. Newton figured that the centrifugal force of the globe spinning on its north-south axis would cause the earth to bulge at the equator and be slightly flattened at the poles.

In his *Principia* Newton estimated that this would have the effect of making a degree of latitude longer nearer the poles and shorter nearer the equator.

The theory was heatedly opposed by the Cassinis, who had extended Picard's triangulation survey north to Dunkirk and south to Perpignan on the Spanish border, and maintained that the earth was elongated like an egg, as depicted in Ptolemaic Egypt: that the degree of latitude was *shorter* north of Paris.

To settle the argument the French Academy of Sciences sent out two expeditions, one to Lapland to measure an actual degree near the Arctic Circle and another to Peru to measure a degree near the equator.

After 18 months of being frozen in winter and devoured by mosquitoes in summer, the expedition to Lapland returned with a figure that showed a degree of latitude was *longer* near the flattened Pole. The Peruvian expedition suffered

The Great Sphinx lies about twelve hundred feet southeast of the Pyramid of Cheops near the valley building of Kephren. Carved from a single sandstone knoll, the colossus is 240 feet long, 66 feet high, and 13 feet 8 inches at its widest.

The headdress and the cobra on the forehead are said to have been symbols of royalty; the features are thought to resemble those of Kephren.

At one time the Sphinx may have been coated with plaster and painted in various colors.

A rational explanation of the mystery of the Sphinx was produced by the British astronomer Sir Norman Lockyer, who said that its being half lion, half virgin symbolizes the junction of the constellations Leo and Virgo which occurred at a summer solstice in the fourth millennium B.C.

even worse conditions, measuring from mountaintop to mountaintop in the Andean highlands, but after ten years of misery, came back with a similar conclusion that the degree was shorter at the equator, vindicating Newton: the Peruvian degree measured 56,734 French *toises,* the Paris degree was 226 *toises* longer, and the Lapland degree 362 *toises* longer still.*

Cassini, who very sensibly proposed the adoption of a geodetic foot representing 1/6000th part of a terrestrial minute of arc, would have been astounded had he known that just such a foot had been in existence for several millennia and that the Sphinx, which could be used as a geodetic marker to indicate the equinox, also once had an obelisk between its paws whose shadow could be used to compute not only the correct circumference of the earth but the variance in the degree of latitude.

But in all this geodetic enterprise the Pyramid's geodetic values were forgotten; its secrets remained as enigmatic as those of its neighbor the Sphinx, which by this time was almost obliterated in the accumulation of wind-blown sand from the Libyan desert.

* The *toise,* or double arm's length, was the standard of measure used by the French before the development of the meter.

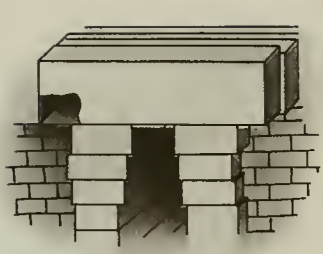
IV. THE AGE OF ENLIGHTENMENT

Travel to the Giza plateau became a dangerous undertaking in the eighteenth century. Though Egypt was still nominally under the suzerainty of the Ottoman Turks, the traveler was likely to be robbed or killed by gangs of bandit Arabs unless protected by a bodyguard of friendly Janissaries such as had accompanied Greaves.

Not until the time of the American Revolution was any further discovery of importance made at the Pyramid. In 1765, Nathaniel Davison, who was later British Consul General in Algeria, was able to spend a vacation in Egypt in the company of Edward Wortley Montagu, former British ambassador to the Sublime Porte, and carefully explore the Pyramid.

More intrepid than Greaves, Davison lowered a lamp into the "well," tied a rope round his waist, and had himself carefully lowered into its ominous darkness, about a hundred feet farther than Greaves, only to find the bottom blocked with sand and rubbish. To Davison it appeared strange that anyone should go to such an enormous amount of effort to dig a shaft almost 200 feet into the heart of the Pyramid and simply come to a dead end. But there was nothing more he could do. It was extremely close and filthy at the bottom of the "well," and his candle soon burnt up what little air was available. Also, an immense number of huge bats made it difficult for Davison to keep his candle alight; so he laboriously made his way back to the surface.

Abandoning this quest, Davison set about finding any other secret features within the interior of the Pyramid. At the top of the Grand Gallery he noted that his voice was answered in a curious way by repeated echoes which appeared to resonate from somewhere above him.



Davison's hole at the top of the Grand Gallery.

Placing a candle at the end of two long canes, Davison was able to spot a small rectangular hole about 2 feet wide at the very top of the Grand Gallery, where its wall joined the ceiling.

To reach this hole was a precarious ordeal: the walls of the gallery were polished and slippery; the perch upon which he had to place his ladder was extremely small and stood high above a yawning drop of 150 feet, all the way down the Grand Gallery. Nevertheless Davison managed to raise seven short ladders till the topmost reached the small rectangular hole.

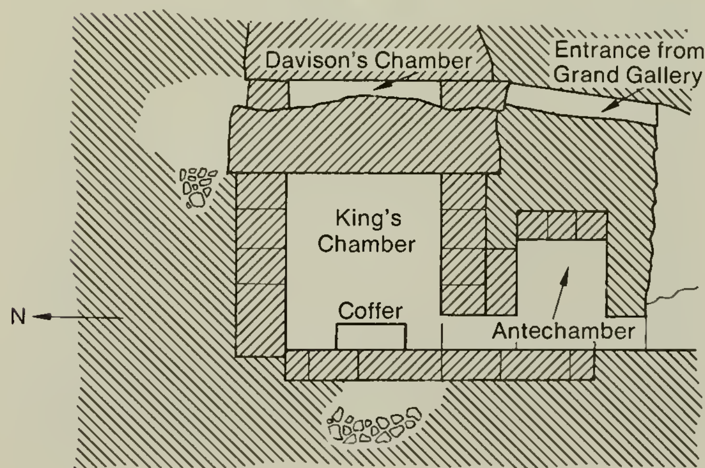
Davison climbed this rickety echeloning with difficulty. At the top he found that he was prevented from entering the 2-foot hole by some 16 inches of bat dung, which had accumulated through the centuries.

Masking his face with a kerchief, Davison managed to wedge himself into the stifling passage and crawl 25 feet to a chamber not high enough to stand in, but every bit as wide and as long as the King's Chamber below it.

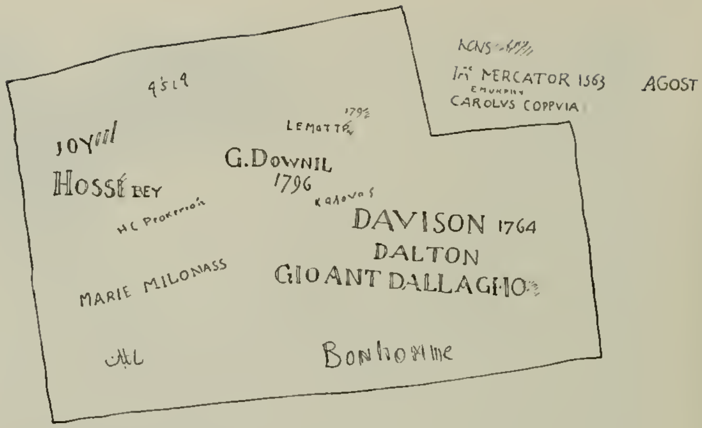
Beneath the bat dung Davison was able to make out a floor consisting of the tops of nine rough-hewn monolithic granite slabs, each weighing up to 70 tons, or as much as a modern railway engine. The under sides of these slabs formed the ceiling of the King's Chamber. To Davison's amazement, the low flat ceiling of the chamber was also constructed of another similar row of granite monoliths.

Otherwise, Davison could find nothing of either historical or architectural interest: no treasure, no inscription, no sign of any further passage. His sole reward was to carve his

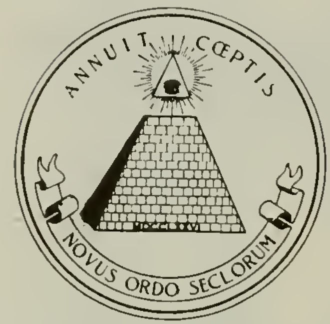
Three distinct types of Egyptian bats as depicted in the eighteenth century. The bats found by Greaves in the Great Pyramid were over a foot long, with an even greater wingspread. Of the more than a thousand known varieties of these curious nocturnal mammals the "flying foxes" of Australia have a wing-spread of up to 5 feet.



Davison's Chamber above the King's Chamber.



Davison's and other graffiti in the Great Pyramid, including that of Mercator, the Flemish cartographer.



Reverse of the seal of the United States of America. According to Manly P. Hall, an expert on Masonic lore, not only were many of the founders of the U.S. government Masons, but they received aid from a secret and august body existing in Europe, which helped them to establish the United States for "a peculiar and particular purpose known only to the initiated few." The Great Seal, says Hall, was the signature of this exalted body, and the unfinished pyramid on its reverse side "is a trestleboard setting forth symbolically the task to the accomplishment of which the U.S. Government was dedicated from the day of its inception." The eagle was apparently intended to represent a phoenix, or symbol of the immortality of the human soul. Great currency has been given to the pyramid and phoenix symbols by placing them upon a one dollar bill.

graffito on the wall and to have the newly discovered chamber named Davison's Chamber in his honor.

When the American Revolution was followed by the French, and Napoleon set out to spread his political doctrines of Free Masonry, interest was rekindled in the Pyramid.

The American revolutionaries had already gone so far as to adopt the ancient Masonic symbol of the Pyramid for the reverse of the Great Seal of the United States.

In their own revolutionary housecleaning, the French outlawed the biblical seven-day week and reverted to the decades of the ancient Egyptians. The *sans-culottes* replaced the old holidays with feast days celebrating Nature and the Supreme Being, the Human Race, the Martyrs of Liberty, Truth, Justice, Paternal Tenderness, Conjugal Faith and even Misfortune. To replace the archaic *toise* made up of six *pied de roi,* the new academicians remeasured the arc from Dunkirk to Perpignan and adopted as a decimal unit the meter, which they computed to be exactly one ten-millionth of the Paris meridian from pole to equator.

On the last day of the month of Floreal in the IXth year of the revolution—our May 19, 1798—General Bonaparte, a sallow little man of 29, set sail from Toulon with a force of 35,000 soldiers crammed into 328 vessels, to conquer Egypt as a steppingstone to India and world domination. Bored by the company of his fellow officers, Napoleon spent most of his time with an extraordinary collection of erudite French civilians classified as "savants." He had brought them along because they were reputed to have acquired a profound knowledge of Egyptian antiquities despite the fact that no one had yet deciphered Egyptian hieroglyphics, so that very little was known of Egypt's remote antiquity.

These savants, a hundred and seventy-five of whom were scattered throughout the fleet, were treated with something less than respect by Napoleon's lower ranks, who were convinced that the "graybeards" had been brought along solely to help locate and dig up hidden treasure. Once the learned gentlemen had landed in Egypt, where their function was to "civilize the natives," they were issued no rations or billets, and whenever the French came under attack from the Mameluke forces of Murad Bey, Napoleon's soldiers would form their famous squares and shout "savants and asses to the center."

Not that the savants ran any real risk. When the French reached the Great Pyramid and were attacked by 10,000 Mameluke horsemen armed with glittering yagatans under the command of Murad himself, in a brilliant green turban astride a snow-white charger, the slaughter consisted entirely of the intrepid Mamelukes. Renowned for having withstood the hordes of Genghis Khan, they were no match for the French sharpshooters and cannoneers.

In two hours two thousand Mamelukes were killed for two score Frenchmen.

Mameluke Beys and their horsemen were mostly converted Christian slaves like the Janissaries and Pages of the Sublime Porte, trained to police, tax, and control Egypt under the nominal suzerainty of the Ottoman Sultan.

In 1811 the Mamelukes were destroyed in one of the foulest but most successful ambushes in history. May 1 they were invited to a feast by Mohammed Ali, the Greek-born adventurer who governed Egypt for the Turks. Dressed in their finery, on richly caparisoned horses, 420 Mameluke Beys arrived at the citadel. Once they were crowded into the narrow street, Mohammed Ali's Albanian mercenaries opened fire from rooftops and windows with rifle and cannon. The Mamelukes screamed, their horses neighed, the street ran with blood. In half an hour all the Mamelukes were dead with the exception of Amir-bey whose horse is reputed to have leapt from the battlements and carried him safely to Syria.

Bonaparte's general staff arriving at the Great Pyramid.

Napoleon Bonaparte before the Battle of the Pyramids.

Murad Bey, whose Mameluke forces were defeated.

July 12, 1798, in the shadow of the pyramids of Giza, some 25,000 Frenchmen, demoralized, hungry, and sleepy from a ten-hour march, were ordered by Napoleon to face what he overestimated to be 78,000 Egyptians, including 12,000 mounted Mamelukes in multicolored turbans and gold-embroidered caftans that floated like gauze. The French formed into squares, ten soldiers deep, their cannons (and savants) in the center. With remarkable discipline the French held their fire till Murad Bey's cavalry were upon them. The Mamelukes outdid themselves in bravery, slashing through the barrels of the Frenchmen's rifles with their scimitars, but in vain. In two hours the squares were surrounded by corpses, the Battle of the Pyramids was over, and Napoleon was master of Egypt. As the flames from the Egyptian fleet illumined Cairo's minarets, Napoleon's men feasted on hoards of captured sweetmeats and looted the gold-laden bodies of the Mamelukes, dumping them into the Nile to float seaward the news of the Egyptian defeat.

Jomard, Coutelle and Le Père exploring the Grand Gallery.

The discoveries of the savants within the Pyramid were not sensational, mostly because of the hindrance of bats, which had greatly increased since the time of Davison.

Edmé-François Jomard, one of the younger but more astute of the savants, described the painful process of moving through the passages bent double, seared by the heat of the torches, stifled by lack of air, and sweating profusely from the effort.

Colonel Jean Marie Joseph Coutelle, a military member of the expedition, made another exploration of the well, but complained of being attacked by clouds of infuriated bats, "who scratched with their claws and stifled with the acrid stench of their bodies."

Discharging their pistols at the top of the Grand Gallery, the French were astonished at the repeated echo which sounded like thunder moving away into the distance.

In Davison's Chamber the accumulation of bat dung had risen to 28 centimeters. The savants retired without further contribution to the problem of the Pyramid's interior.

Outside, the savants were more successful. Jomard dogtrotted round the Pyramid, appalled by the amount of sand and debris which had accumulated on its flanks.

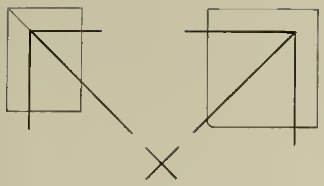
With the help of 150 Ottoman Turks, the French were able to clear the northeast and northwest corners of the building and make an important discovery.

They found the "esplanade" on which the Pyramid had originally been established, as well as two shallow rectangular "encastrements," or sockets, 10 feet by 12, hollowed some 20 inches into the base rock, quite level with each other, where the original cornerstones had once been laid.

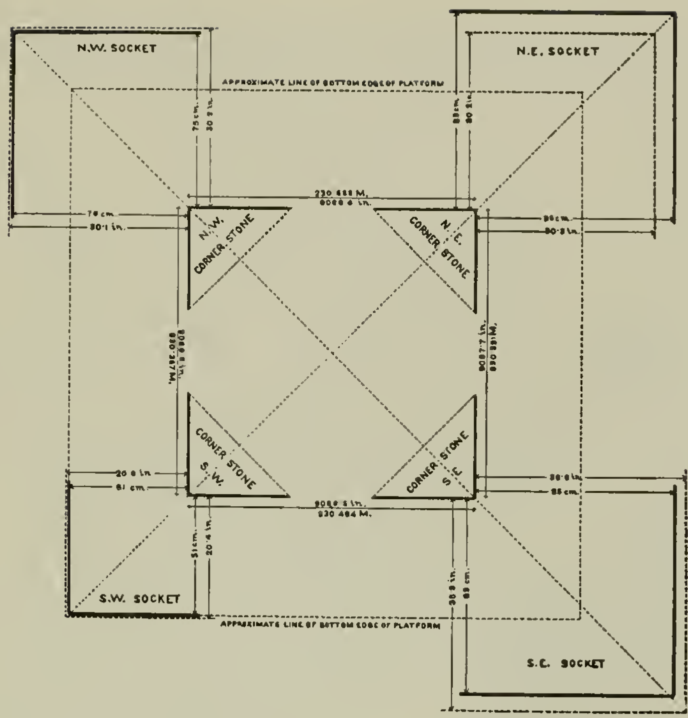
These gave the savants two firm points from which to measure the base of the Pyramid. Though the huge mounds of debris all along the north face of the structure still impeded their efforts, Jomard was able to make a series of measurements up and down and around. These gave a length for the base of 230.902 meters, or 757.5 English feet. The French now needed to know the height.

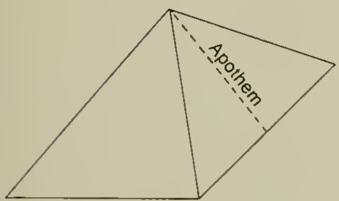
Jomard took almost an hour to climb the Pyramid, stopping on the way for breath. Once he reached the summit, his imagination was exalted by the view of the green Delta to the north, the black strip of fertile earth along the Nile, the wavelike dunes to the west. Arab villages looked like anthills on the horizon; men at the base of the Pyramid were barely distinguishable.

With a slingshot Jomard tried to hurl a stone far enough to clear the base, but in vain. Not even the Arabs had been able to shoot an arrow from the summit that would clear the footing.



The positions of the sockets.





To obtain a height of the Pyramid, Jomard measured down each step, for a total of 144 meters, or 481 feet. By elemental trigonometry this gave him an angle for the slope of 51° 19′ 14″ and an apothem of 184.722 meters.

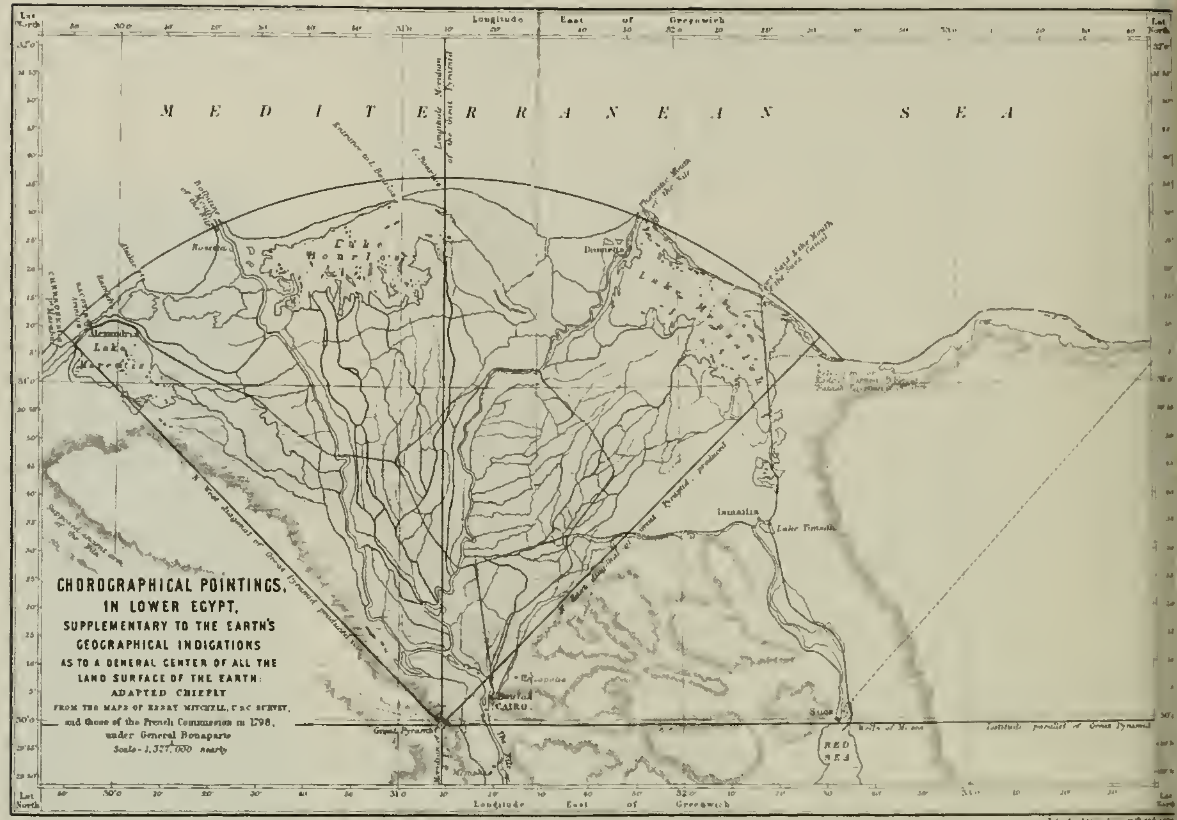
The apothem is the slant height of the Pyramid, or line from apex to center of each base, down which a raindrop would run as the shortest distance to the ground.

Because the outer casing was entirely missing there was no way to know just how thick it had been: so the measure for the apothem had to be an estimate; but the figure of 184.722 meters was to open up a whole new vista for Jomard, who was a very well-read young man.

Jomard remembered that according to Diodorus Siculus and Strabo, the apothem of the Pyramid was supposed to be one stadium long. He also knew that an Olympic stadium of 600 Greek feet—from which our modern stadium is derived —was a basic unit of land measure in the ancient world, one which was said to be related to the size of the earth.

Searching further through the trunks full of classics which the savants had brought to Egypt, Jomard found that the stadium of the Alexandrine Greeks (of Eratosthenes and Hipparchus) had been the equivalent of 185.5 meters—which was within a meter of what he had found for the apothem.

To reinforce the point, Jomard discovered that the



Bonaparte's surveyors found that the Pyramid was accurately oriented to the four cardinal points of the compass and therefore used the meridian running through its apex as the base line for their measurements.

Having mapped Lower Egypt, they were surprised to find that this meridian neatly cut the Delta region into two equal portions, and were even more surprised when they found that the diagonals drawn through the Pyramid, at right angles to each other, completely enclosed the entire Delta.

Evidently a structure which could serve as such a perfect geodetic benchmark could not have been located at random, and without considerable proficiency in astronomy, as well as a developed understanding of the configuration of the planet.

distance between the Egyptian localities as measured by Napoleon's surveyors also coincided with the classical distances between these localities computed in stadia, if the stadium was taken to be 185 meters.

Finally, Jomard learnt from his perusal of the classics that a stadium of 600 feet was considered to be 1/600 of a geographical degree.

Jomard calculated that a geographical degree at the mean latitude of Egypt was 110,827.68 meters. Dividing this figure by 600 resulted in a measure of 184.712 meters. This was within 10 centimeters of his value for the apothem.*

Could the Egyptians, Jomard wondered, have been capable of working out their basic units of measure—such as the stadium, the cubit, and the foot—from the size of the earth and then built this knowledge into the Pyramid?

To reinforce this exciting hypothesis Jomard found that several Greek authors reported that the perimeter of the base

* At Seyne the degree of longitude is 110,791.11. At Alexandria it is 110,892.66. The mean for the whole planet is 111,111.9. Jomard took the mean for Egypt.

of the Pyramid was intended to measure half a minute of longitude. In other words, 480 times the base of the Pyramid was equal to a geographical degree.

Jomard took the 110,827-meter degree and divided it by 480. The result was 230.8 meters, or again within 10 centimeters of his measured length of the base.

To find the length of the cubit that would fit these measures, Jomard again consulted the classics. According to Herodotus 400 cubits made a stadium of 600 ft. Jomard divided the apothem of the Pyramid by 400 and obtained a cubit of .4618 meter. To his surprise this turned out to be the common cubit of the modern Egyptians.

According to other Greek sources the base of the Pyramid was said to be 500 cubits. Multiplying his .4618 meter cubit by 500, Jomard got 230.90 meters—which was just what he had measured for the base.

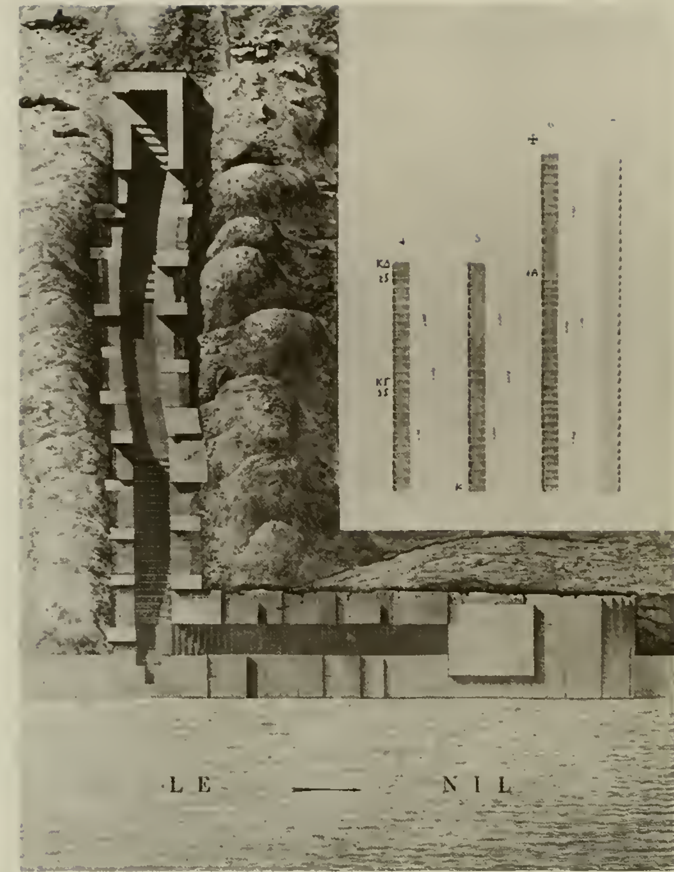
Jomard's theory was impressive to his colleagues; but when Gratien Le Père and Colonel Coutelle *re*-measured the base of the Pyramid, they found it to be 2 meters longer. They also *re*-measured the height with a specially designed instrument, step by step, and the results showed Jomard's angle of incline to have been too low, and his apothem consequently too short.

In vain Jomard argued that he had found an even more surprising coincidence in that the four-hundredth part of his base of the Pyramid gave a figure of .5773 meter, which was exactly the length of a longer modern Egyptian cubit called the *pyk belady*.

Jomard's colleagues insisted there was no evidence in any other ancient Egyptian building of the use of such odd cubits and that the only adequate cubit they had found was the one marked on the nilometer of Elephantine, which was nearly the same as the "royal" cubit of Memphis of .524 meter, or 20.63 inches, which Newton had derived from the dimensions of the King's Chamber.

Unperturbed, Jomard continued his observations. It seemed to him that from the bottom of the Descending Passage, the ancients might have been able to see the transit across the meridian of some circumpolar star, and thus have previously established true north and correctly oriented the building. Because of the length and narrowness of the passage, he said, they might even have been able to see such a star by daylight. His colleagues argued that the trap door would have prevented any such observation.

Jomard suggested that the King's Chamber, with its empty sarcophagus, might not necessarily have been a tomb but a metric monument, designed to embody, and perpetuate, a system of measures.



Nilometer discovered by the French at Elephantine, near Syene, used by the Egyptians for measuring the rise of the Nile at flood time, and marked in cubits very close to the royal cubit of Memphis.

To the end, Jomard remained convinced that the builders of the Pyramid had the necessary astronomical know-how to measure a geographical degree and thus the true circumference of the earth, and had developed an advanced science of geography and geodesy which they had immortalized in the geometry of the Great Pyramid.

Jomard pointed out that Herodotus, Plato, Diodorus and many others had all named Egypt as the birthplace of geometry, that Solon as well as Plato had come to Egypt to study geometry, and that Pythagoras had learnt from the Egyptians his theorems of geometry, his art of calculation, and his doctrine of metempsychosis.

Jomard's classically indoctrinated colleagues could not stomach the idea that their cherished Greeks might not be the founders of geometry; so the pursuit was dropped.

One last boost to Jomard's theory was given by one of Napoleon's favorite generals, Louis Charles Antoine Desaix: on his way up the Nile to conquer Upper Egypt, the 29-year-old general found a gorgeous temple near Thebes half

Edmé-François Jomard.

buried in the sand. On its ceiling was a circular zodiac. Because the zodiac clearly depicted the skies over Egypt and showed the recognizable constellations in quite different positions, the savants deduced that it must have represented the skies many centuries in the past and that the ancient Egyptians must have been acquainted with the zodiacal constellations in remote antiquity.

Unfortunately, an inscription also found in the temple appeared to date it from Ptolemaic times, shortly before our era; so another of Jomard's balloons was pricked.

Meanwhile Napoleon, whose logistical mind enabled him to figure that the Great Pyramid and its Giza neighbors contained enough stone to build a wall 3 meters high and one meter thick all around France, had become attracted by the arcane qualities of the King's Chamber.

On the twenty-fifth of Thermidor (the Revolutionaries' August 12, 1799) the General-in-Chief visited the Pyramid with the Imam Muhammed as his guide; at a certain point Bonaparte asked to be left alone in the King's Chamber,

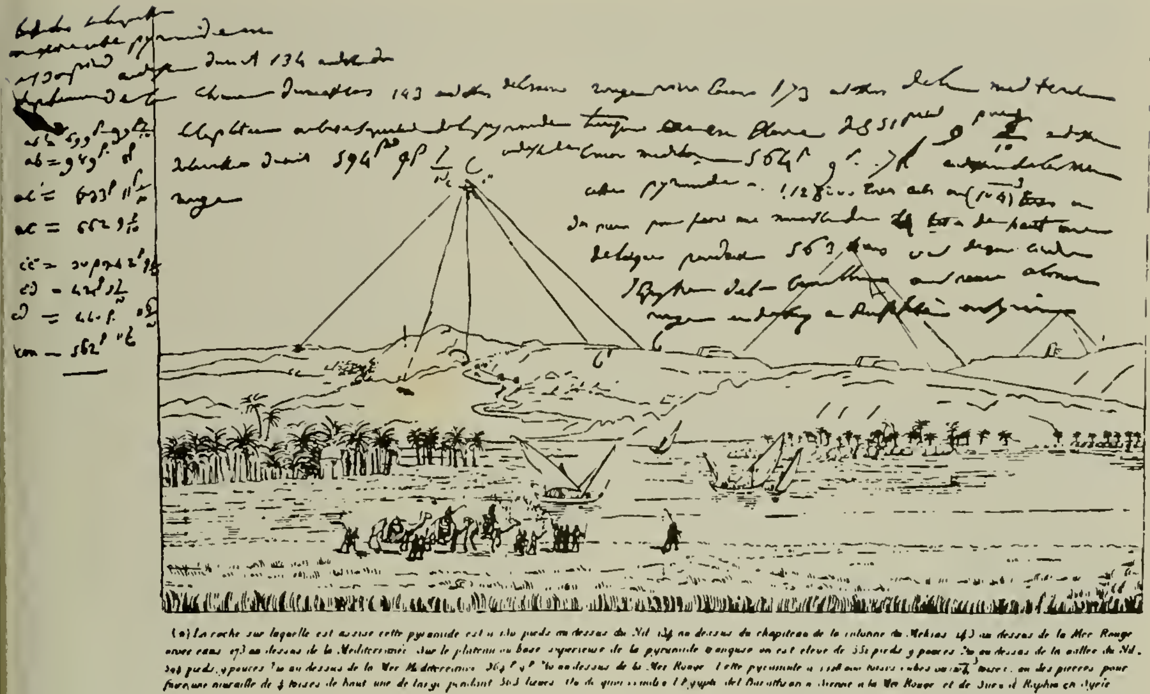
Napoleon in the King's Chamber.

as Alexander the Great was reported to have done before him.

Coming out, the general is said to have been very pale and impressed. When an aide asked him in a jocular tone if he had witnessed anything mysterious, Bonaparte replied abruptly that he had no comment, adding in a gentler voice that he never wanted the incident mentioned again.

Many years later, when he was emperor, Napoleon continued to refuse to speak of this strange occurrence in the Pyramid, merely hinting that he had received some presage of his destiny. At St. Helena, just before the end, he seems to have been on the point of confiding to Las Cases, but instead shook his head, saying, "No. What's the use. You'd never believe me."

When military and political priorities obliged Napoleon to pull out of Egypt, he abandoned his savants to be captured by the British. Chivalrously treated as civilians, they were allowed to return to France with their notes and drawings. By the time they got home Napoleon had gained sufficient power as First Consul to order them to produce a truly monumental work on all they had discovered about the sites, buildings, inscriptions, life, language and manners of the ancient and modern Egyptians. With the help of an army of painters, typographers and four hundred engravers, the study was completed and published over a period of 25 years



Napoleon's notes on his sketch of the Pyramid.

with the title, *Description de l'Egypte ou Recueil des observations et des recherches qui ont été faites en Egypte pendant l'expédition de l'armée française.*

The work ran to nine folio volumes of text and twelve of plates, and was described as "the most immortal conception and glorious performance of a book ever realized by man." Jomard contributed to it brilliantly, but his perspicacious thesis received little credit.

The savants were scooped by the wily Baron Vivant Denon, who brought out two volumes of the etchings he had made during the campaign in Egypt. His *Voyage dans la basse et la haute Egypte* became an instant best seller, stunning Europe with incredible sights of an unknown world of Egypt both ancient and modern, and launching a great vogue for the style known as *Empire.*

Denon's publication and the *Description de l'Egypte* which followed it piecemeal were to turn what had been a French military disaster into a cultural triumph. They also shattered once and for all the figment that before the Homeric Greeks there had been nothing but primitive barbarism.

Scientifically the most sensational discovery made by the French in Egypt proved to be a 3-foot diorite slab engraved with hieroglyphics found by a Captain Bouchard in a branch of the Delta near Rosetta. Hijacked by the British, the

Dominique Vivant Denon accompanied Napoleon on his expedition to Egypt and produced a series of drawings and etchings of the land of the Pharaohs which revealed a whole new world to an amazed Europe.

Born an aristocrat and renowned mostly for a series of pornographic etchings, Denon managed to ingratiate himself with the revolutionaries and escape execution. Hypnotically attractive to women, Denon was befriended by such notables as Madame de Pompadour and Catherine II of Russia. He was introduced to Napoleon by his wife Josephine.

In Egypt Denon would ride ahead of the French columns, sometimes under fire, to catch the vivid scenes of action. Sketching directly from the saddle, in which he had been for as many as sixteen hours, his eyelids ripped by the windblown sand, and seeing through a veil of blood, Denon managed to reproduce the most evocative scenes of Egypt, ancient and modern, full of verve and an exquisite sense of composition.

Brought up to think that Greek architecture of the best period was *the* standard of beauty, he was seized by the extraordinary beauty of the Egyptian works "with no extraneous ornaments or superfluity of lines." His two-volume illustrated description of Bonaparte's campaign in Egypt was an instant bestseller in Europe.

Denon was made a baron by his emperor and became superintendent of the Louvre and director of the Beaux Arts.

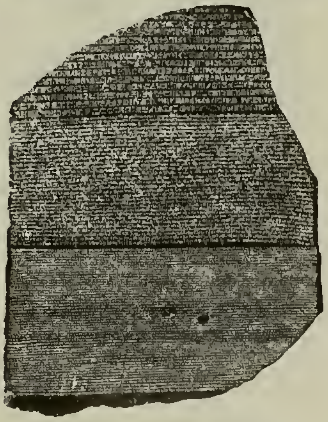
J. F. Champollion.



The Rosetta Stone, found in 1799, was ordered by Napoleon to be placed in the French Institute in Cairo. By an article of the treaty of capitulation it was surrendered to the British in 1801. Major General Turner sailed with it to Portsmouth in 1802 and deposited it with the Society of Antiquarians in London who turned it over to the British Museum.

A plaster of paris cast of its inscription in hieroglyphs, demotic Egyptian, and Greek, enabled Champollion to decipher the hieroglyphic language of the ancient Egyptians and formulate a system for their grammar; this made it possible for archeologists and Egyptologists to read the millennial inscriptions found throughout Egypt.

trophy ended up in the Egyptian Gallery of the British Museum. It lay there undeciphered for twenty years, until another young Frenchman, Jean-François Champollion, was to crack the mystery of its ancient hieroglyphs and throw the first real light on several millennia of Egypt's mysterious past.

As Napoleon had somewhat pompously remarked when elected a member of the National Institute, "the only true conquests are those gained by knowledge over ignorance."

V. EXPLORING WITH CHISEL AND GUNPOWDER

After Wellington's victory at Waterloo, the efforts of the French savants at the Pyramid were forgotten and the sockets they had cleaned were covered once more with the sands of the desert.

It remained for an obscure Italian to make the next impressive discovery within the Pyramid. While Napoleon was languishing on St. Helena, an exophthalmic Genoese merchant, Captain G. B. Caviglia, arrived in Egypt as the master of a Maltese vessel flying the British flag. Seized by the mystery of the Great Pyramid, he gave up the sea and settled down to exploring the Pyramid and its neighbors on the Giza plateau, financing himself by helping rich Europeans scavenge the surrounding tombs to assuage their taste for original Egyptian antiquities—a taste which ran to anything from scarab rings to thousand-ton obelisks.

Described by a contemporary as an "enthusiastic devotee at the shrine of antiquarian learning, who sacrificed country, home, friends and fortune for the indulgence of the refined though eccentric taste of exploring the hidden mysteries of the Pyramids and Tombs of Egypt," Caviglia cleared out the bat excrement from Davison's Chamber and set up housekeeping within it, turning "the gloomy recess into a residential apartment"—though how this was accomplished under a 3-foot ceiling is not explained.

Alexander William Crawford (later Lord Lindsay), who encountered Caviglia in Cairo, found the Italian to be a deeply religious man, well versed in the Bible, which he constantly quoted, but also a man with some pretty strange ideas about what he would find in the Pyramid. To England Crawford wrote: "Caviglia told me that he had pushed his studies in magic, animal magnetism, etc., to an extent which nearly killed him . . . to the very verge, he said, of what is forbidden man to know, and it was only the purity of his intentions which saved him."

Caviglia was convinced that if he dug into the Pyramid he would eventually encounter a secret room. To find it he hired a gang of Arab workmen to dig a tunnel leading off from Davison's Chamber. But no matter how far they dug, they found nothing but solid masonry.

Caviglia cleared the sand from the base of the Sphinx and revealed the footing for a missing obelisk between its paws.

At last Caviglia was obliged to give up the job; to console himself he set about analyzing the mystery of the "well." Lowering himself down the shaft, Caviglia got as far as 125 feet below the grotto only to find, as Davison had before him, that the bottom was completely stopped, and that the air was so scarce his candle spluttered, making it difficult for him to breathe.

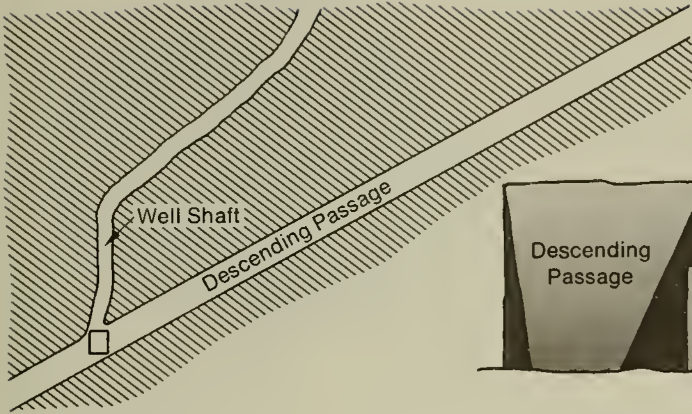
However, as the bottom appeared to be mostly sand and loose rocks, Caviglia was determined to unplug it and see where it led. For a while he managed to impress a gang of Arabs into raising basketfuls of the sand all the way up to the top of the well; but the shaft was so tight, the air so fetid with bat dung, and the dust so suffocating, that the Arabs began to faint and refused to work further. Caviglia attempted to clear the air at the bottom of the well by burning chunks of sulfur, but it was still impossible to breathe that far down for any length of time, and the Arabs would not resume their digging.

Lower end of the well shaft.

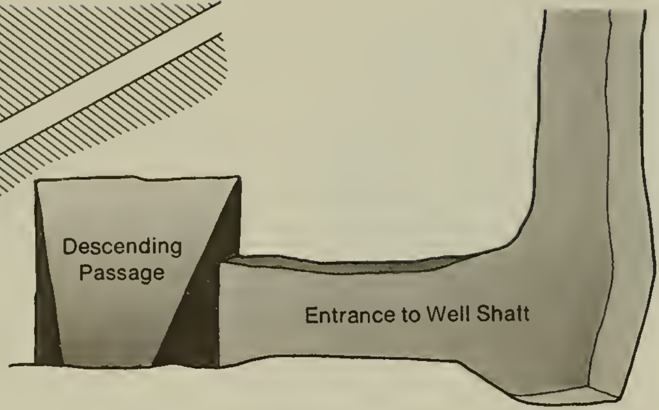
Caviglia decided to attack the problem from a different angle. He would attempt to clear the main Descending Passage to the subterranean pit which had been filled since Al Mamun's time with the refuse of the plugs they had broken out of the Ascending Passage. Caviglia had the refuse carried up and out of the Pyramid, and was able to push his way on hands and knees down the passage for 150 feet; then the air became so impure and the heat so great that he started to spit up blood. Still, he would not give up. At the end of another 50 feet he made a discovery which seemed to indicate he might be on the right track. On the west side of the passage he found a low doorway leading into a hole. As the Arabs began to dig upward into this hole, Caviglia noted a strong smell of sulfur. It occurred to him that he might have hit upon the solution to his previous problem: the smell of sulfur might be coming from the bottom of the well, which must therefore be very close.

Digging harder, the Arab workmen dislodged some loose earth. A pile of dust and rubbish fell onto them, including a basket and ropes which had been left at the bottom of the well. There was also a sudden gush of air up the tunnel, and those in the passage were able to breathe with ease. Caviglia had discovered the end of the well. But a greater mystery remained. Why had it been dug there, when, and by whom?

As Caviglia set about resolving this mystery, another



Where the well joins the Descending Passage.



strange figure joined in the Pyramid research, one quite the opposite of the romantic, uncommunicative Caviglia. Richard Howard-Vyse, a British Guards officer, at first collaborated heartily with Caviglia, but they soon grew angry at each other and came to a heated parting.

Colonel (afterward General) Howard-Vyse in 1830.

Colonel Howard-Vyse, son of General Richard Vyse and grandson of the Earl of Stafford, was a martinet with little humor who had been equerry to the Duke of Cumberland (later first king of Hanover) and had stood unsuccessfully for Parliament in the borough of Windsor. He has been described as thoroughgoing and as artless as Wellington, under whom he served.

A trial to his family, who were pleased to have him away from the county seat in Buckinghamshire, even if it cost them some of the family patrimony, Howard-Vyse was to spend over 10,000 pounds sterling on exploration of the Pyramid site.

Howard-Vyse first saw the pyramids on a moonlit ride from across the Nile at Turah in November of 1836, during a trip to Egypt as "a fashionable amusement seeker." In his own words he was attracted by "the remote antiquity and uncertainty of their origin, and . . . the peculiarity of their mysterious construction." He was curious about "the purpose for which the passages and chambers already discovered were originally intended, but in much greater degree respecting any other passage or apartments which might reasonably be supposed to exist in the enormous structures."

Impressed by Caviglia's theories about the mysterious and hermetic purposes for which the Great Pyramid had originally been constructed, Howard-Vyse hired the services of a professional civil engineer, John Shae Perring, who had been an assistant to Mohammed Ali, the khedive of Egypt. Perring was to take measurements of all the pyramids and tombs which had thus far been discovered on the Giza plateau, as well as many of those farther south.

In his *La Pyramide de Cheops ât-elle livré son secret* Fernand Ihek says that the shape of the Great Pyramid was such that it enabled bodies (either animal or vegetable) to become naturally mummified when placed within the King's Chamber. He says the end result was a desiccation or dehydration of the body with no sign of putrefaction. Experiments revealed that an uncleaned trout became mummified in thirteen days, a radish in fifteen days, and the heart of a sheep in forty days.

Ancient Egyptians removed the brain and entrails of a body to be mummified without scarring it by pulling the brain out through the nose and the viscera through the anal aperture.

The body was then soaked in brine for a month; aromatic plugs, often perfumed with onion, were placed in the nostrils and other orifices.

According to Manly P. Hall, there is every reason to suppose that originally only those who had received some grade of hermetic initiation were mummified; for "it is certain that, in the eyes of the Egyptians, mummification effectually prevented reincarnation."

Reincarnation was considered necessary to imperfect souls, or those who had failed to pass the tests of initiation. "The body of the Initiate," says Hall, "was preserved after death as a species of Talisman or material basis for the manifestation of the soul upon earth." When the body of a "god-like" Pharaoh was mummified it could serve as a medium through which survivors could communicate and plead their cause with "the beyond." At first only Pharaohs appear to have been mummified; later it was done to persons of royal rank, and to anyone who could afford it; eventually even animals were mummified.

Howard-Vyse set up his headquarters in an empty tomb near the Great Pyramid and was soon employing a larger number of workmen than anyone since the time of Al Mamun, often as many as seven hundred, using Captain Caviglia as superintendent of works.

All went well till the colonel chose to take an extended tour up the Nile to inspect a further series of pyramids. When he returned he was outraged to find that Captain Caviglia had almost entirely neglected the Great Pyramid and was using the men hired by Howard-Vyse to search for mummies and little green idols in the neighboring burial pits.*

Caviglia became equally outraged at the colonel's reprimands, and gesticulated abusively declaring that "he alone had the head to conduct excavations and to understand the value of 'curios' and '*anticos*,' the colonel having nothing but money."

When the colonel asked for the return of his money, Caviglia disdainfully appeared at breakfast in the colonel's tent and threw on the table the money wrapped in an old stocking.

It was the end of Caviglia's exploring in Egypt. He retired to Paris, where he was sporadically supported by another great scavenger of antiquities, the former British ambassador to the Sublime Porte, Lord Elgin.

Howard-Vyse took over Caviglia's duties. In the words of a Victorian lady admirer, the colonel "sat down before the Great Pyramid as a fortress to be besieged, and through winter and spring and the burning summer of Egypt, long after all travelers had left the country, became the sole director of operations, clerk of the works and paymaster of his hundreds of workmen, day after day, month after month, until they had wrought out his own ideas of pyramidical exploration to the full. For not only was he one of those men who was never known to turn back after having put his hand to the plow, but he was a religiously [*sic*] minded man, a devout Christian, who felt that he was in this case called to a certain work for the Master, and though in the first instance he had distrusted himself in a new field of labor

* Mummy flesh was in great demand in Europe during the sixteenth and seventeenth centuries as a medicinal; it was a common drug to be found in all apothecaries. Mistaken for Persian *moma*, or pitch, which was used to heal cuts and bruises, mummy flesh was believed to make fractures unite in a few minutes and to be good for all kinds of internal ailments. When mummies became scarce traders used the bodies of executed Christians, or the bodies removed from hospitals, many of which had died of loathsome diseases. The bodies were stuffed with bitumen, wrapped in bandages and baked.

so that he had thought it better to use the purchased help of the Italian professional, yet when that failed he became a most admirable example to all kinds of men, rich and poor alike, of giving himself to the work, putting his own shoulder to the wheel, and never quitting it until the end was gained, during all the time, too, preserving the utmost urbanity, but dealing out the strictest justice in a manner that made a most honorable and lasting impression on the tawny Arabs around him."

In the Queen's Chamber Colonel Howard-Vyse had relays of men work day and night digging up the floor in front of the niche, but all they found was an old basket: so they refilled the hole.

In Davison's Chamber they found a crack in the ceiling through which they could run a reed about 3 feet long. Believing this to be an indication of a similar chamber above, Howard-Vyse had the workmen chisel their way into the granite over their heads. But the stone was too hard, and again the Arabs could not stand the heat in the restricted space of Davison's low-ceilinged chamber.

Special quarrymen were imported from the Mokattam hills across the valley. When even they could not manage the job, the colonel resorted to gunpowder to blast his way upward. To handle the charges he found a workman called Daued who lived mostly on hashish and alcohol. Daued successfully set off the blasts—a job that was particularly dangerous as the splintered granite flew about like shrapnel.

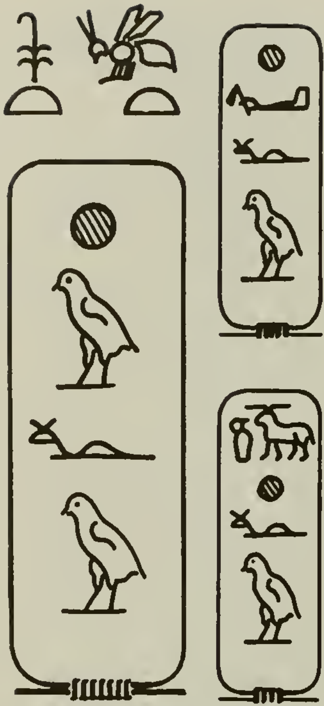
When the dust subsided Howard-Vyse found that they had indeed broken through to another chamber, which he chauvinistically named after Wellington. Its floor was the top of the nine monolithic blocks of granite which formed the rough-hewn ceiling of Davison's Chamber, each block weighing over 50 tons. About a yard above them lay another flat ceiling made of eight blocks of granite.

The new chamber had a strange effect on those who entered; it turned them black. Instead of bat dung, the floor was covered with a thin black powder which when analyzed turned out to be exuviae, or the cast-off shells and skins of insects. Of living insects there were none to be found.

Convinced that the monoliths of the ceiling were in turn the floor of a third chamber, Howard-Vyse ordered the blasting resumed. The colonel's excavations above the King's Chamber became more and more difficult as they rose vertically to a height of 40 feet and took three and a half months to accomplish.

One by one, three more chambers were found above the two already discovered, the uppermost being gabled with huge blocks of sloping limestone. These chambers

Construction chambers above the King's Chamber.



As some of the quarry marks found in the chambers are hieroglyphs signifying "year 17," Egyptologists deduced that the building had reached that stage in the seventeenth year of the king's reign. Most of the marks were roughly daubed in red paint and appeared upside down, indicating they were quarry marks and not decorations.

Similar marks, mostly red, but occasionally black, were also found on the first five or six courses of the Pyramid, behind the casing blocks.

Howard-Vyse sent copies of the crayon marks to Samuel Birch of the British Museum who identified one of the ovals as belonging to King Suphis, or Shofo, or Khufu.

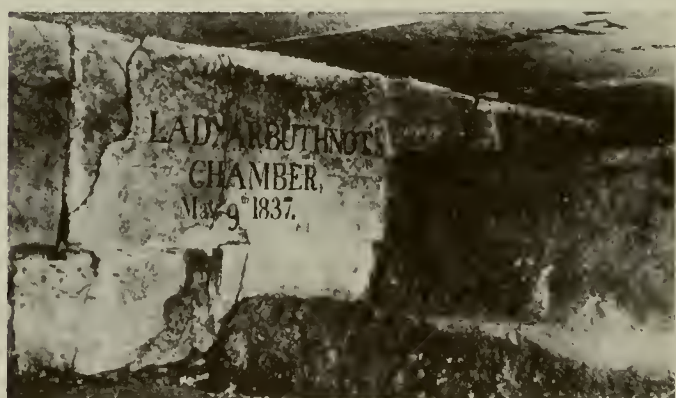
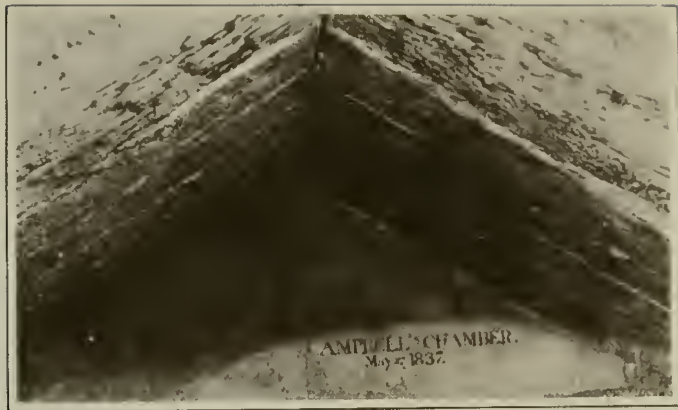
Lady Arbuthnot's Chamber, discovered by Howard-Vyse.





Ceiling construction above Campbell's Chamber.

Howard-Vyse named in turn for Admiral Nelson, for Lady Ann Arbuthnot, wife of Lt. General Sir Robert Arbuthnot, who happened to visit the Pyramid shortly after the room was discovered, and for Colonel Campbell, Her Brittanic Majesty's Consul in Cairo.

The most interesting discovery was not so much the chambers themselves but some red-paint cartouches daubed on the inner walls of the upper chambers. Thanks to the Rosetta Stone and Champollion's successors, one of these cartouches was recognized by Egyptologists as belonging to Khufu, believed to be the second Pharaoh of the Fourth Dynasty, called Cheops by the Greeks, whose reign was thought to have occurred in the third millennium before our era.

There was, of course, no way to prove that this Khufu was indeed the Cheops who had reigned in Egypt. But the fact that similar cartouches had been found in the quarries of the Wadi Magharah hills, from which much of the stone for the Pyramid was derived, added weight to the assumption.

One thing seemed clear. Whoever had daubed the cartouches on the inner walls of the upper chambers must have done so *before* the chamber was sealed and the Pyramid completed; there appeared to be no entrance or exit other than the one blasted by the colonel.

Doubt still lingered that there might have been a far earlier king with a similar cartouche, quite unknown to Egyptologists; but until further evidence could be adduced, it seemed hard to go against the theory of the Pyramid having been built in the reign of the historic Cheops, as reported by Herodotus and other classic authors.

As for the reason for the five superimposed chambers, it was the conclusion of Howard-Vyse, and many who came after him, that they had been designed to relieve the flat

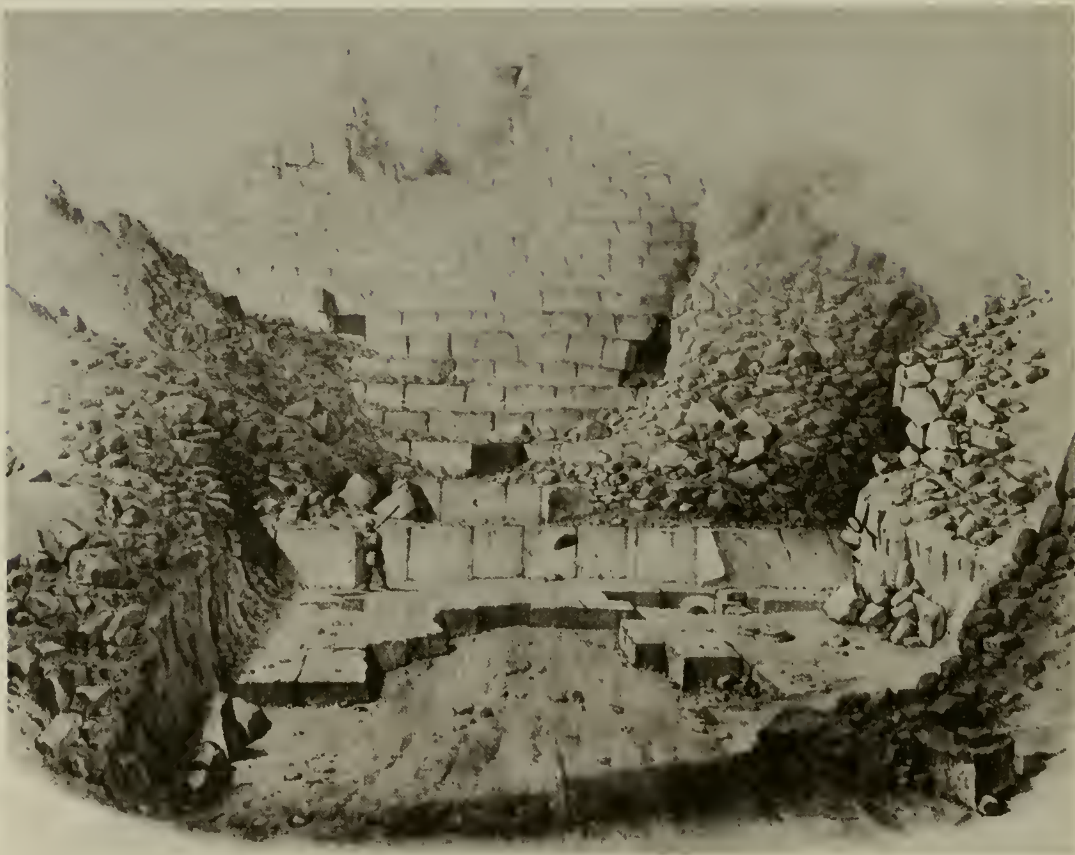
Casing stones and pavement as exposed by Howard-Vyse. Both entrances can be seen, Al Mamun's on the sixth course, and the original entrance ten courses higher.



ceiling of the King's Chamber from the pressure of the 200 more feet of solid masonry piled above it.

Another remarkable discovery made by the colonel in the walls of the King's Chamber was to vindicate the hypothesis of Dr. Harvey. Greaves had found the two 9-inch-wide openings in the side walls of the King's Chamber, but it was not till Mr. Hill, one of Howard-Vyse's assistants, who ran a hotel in Cairo, climbed high up on the outer surface of the Pyramid and found two similar outlets that it was established they were connected for over 200 feet right through the solid masonry to the holes in the King's Chamber. The colonel's engineer, Perring, was nearly decapitated when a stone dislodged by Hill came crashing all the way down one of these conduits.

When the conduit was cleared, an immediate rush of cool air entered the King's Chamber. Thus ventilated, the temperature of this chamber in the center of the Pyramid was to remain at an even and pleasant 68 degrees, irrespective of the weather or season outside, a prehistoric system of air conditioning. This added substance to Jomard's theory that the chamber might have been the repository for weights and measures which require an even temperature and constant barometric pressure, such as the Paris observatory for measurements of standards 85 feet below ground.

Even more sensational for those who were bent on unraveling the secrets of the Pyramid was the next discovery of Howard-Vyse. Ever since the Middle Ages, when the Arabs had despoiled the outer casing, the whole perimeter of the base of the Pyramid had been heaped high with fragments of limestone, and sand and debris, often in piles as high as 50 feet. The two northern corners uncovered several years earlier by the French had already been buried again. This time Howard-Vyse decided to clear away a patch of debris in the center of the north façade to see if he could get down to the very base and bedrock of the Pyramid. In doing so, he was to make a great discovery: two of the original polished-limestone casing stones on the lowest level of the Pyramid were still in the spot where they had been originally placed.

This ended the argument about the casing; it silenced forever those who had continued to consider it a fiction that the whole of the Pyramid had once been covered with a fine mantle of limestone. The original limestone was there, and so finely carved that it was now possible to correctly measure the angle of the slope on which the Pyramid had originally been constructed. The blocks, 5 feet high, 12 feet long, and 8 wide, showed an angle of about 51° 51′, a little sharper than the one estimated by the French.

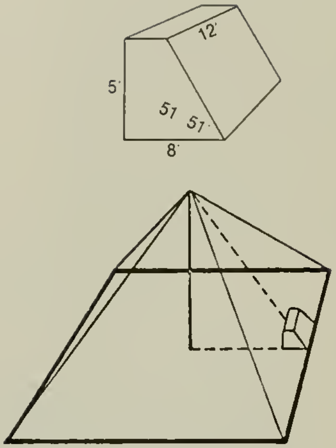
Hewn to the correct angle and polished to a uniform surface, they were quite perfect, in the words of Howard-Vyse, "in a sloping plane as correct and true almost as modern work by optical instrument makers. The joints were scarcely perceptible, not wider than the thickness of silver paper."

The colonel also managed to uncover part of the original pavement on which the building rested, and which appeared to stretch away to the north. "It was well laid and beautifully finished," noted Howard-Vyse, "but beneath the edifice it was worked with even greater exactness, and to the most perfect level."

Though the reason for this astounding accuracy on the northern side was not to become apparent for some years, Howard-Vyse summed up his discoveries thus: "I consider the workmanship displayed in the King's Chamber, in the pavement and the casing stones, is perfectly unrivaled."

The colonel had the casing stones quickly covered up pending permission to take them to the British Museum, but he was not able to prevent the infuriated local Moslems from uncovering them again and smashing the fine edges with hammers, jealous that Christians might obtain and dispose of something of value in their country.

With the angle of 51° 51′ of the casing stones and the base length of 763.62 feet measured by the Frenchmen Coutelle and Le Père, it was now possible to obtain by trigonometry a new dimension of the Pyramid. Its perpendicular height to where the missing capstone was presumed to have come to a point was figured to be 485.5 feet, or 147.9 meters, above the center of the base.



Relation of the casing stones to the slope of the Pyramid.

The base circuit of the Pyramid rests on a platform of finely finished limestone blocks which project beyond the end of the casing stones for an average of 2 feet on the south, east and west sides, and are still in place some 33 feet from the north edge.

This platform is so finely leveled that the official survey of the Egyptian government found it does not exceed 7/8 inch from dead level, and this variation may be due to subsidence.

At present it is not possible to say how far the platform extends under the building; but where the platform stones have been removed, the bed-rock is found to have been cut and leveled to receive each individual stone, sometimes as deep as 2 inches.

On the north side the platform stones have been deliberately laid at irregular angles, each corner being carefully cut out to receive the next irregularly angled stone.

Stone sarcophagus found by Howard-Vyse in the pyramid of Mykerinos, which was lost at sea en route to the British Museum.

In 1840 Colonel Howard-Vyse sailed for England with his accumulated notes. Back home, at his own expense, or his family's, he produced two elegant volumes crammed with detailed but patronizingly Victorian descriptions of his exploits in Egypt, called *Operations Carried on at the Pyramids of Gizeh in 1837*. The book had the merit of including quotations from the works of 71 Europeans and 32 Asiatic authors who had written about the Pyramid from the fifth century B.C. to the nineteenth century.

The colonel's assistant John Perring also produced a handsome volume with some lovely copperplate etchings, *The Pyramids of Gizeh from Actual Survey and Measurement on the Spot*.

Unfortunately, Howard-Vyse was to lose his best trophy, the sarcophagus of Mykerinos, which he had found in the subterranean chamber of the Third Pyramid; the ship carrying it foundered in a storm off the coast of Spain and was sunk in deep water.

But the general measurements taken by Howard-Vyse and Perring were to open a whole new phase in the study of the Great Pyramid, now to be ennobled by the appellative "pyramidology."

VI. FIRST SCIENTIFIC THEORIES

A poet and essayist who had never set eyes on the Pyramid was to take the measurements of Howard-Vyse and those of the French savants and draw from them a set of conclusions, the most far-reaching thus far about the origin and purpose of the Pyramid.

John Taylor, the son of a London bookseller, whose regular job was editing the *London Observer,* already in his fifties when Howard-Vyse returned from Egypt, was to spend the next thirty years collecting and comparing accounts of travelers who had visited the Pyramid.

A gifted mathematician and amateur astronomer, Taylor made models to scale of the Pyramid and began to analyze the results from a mathematician's point of view. To account for the discrepancies in the length of the base reported by successive travelers—which increased progressively from the 693 feet of Greaves to the 763.62 feet of the French—it occurred to Taylor that as each measurer had arrived on the scene, more sand and rubble had been cleared from the base. Each had measured accurately, but at a constantly deeper layer of masonry.

Taylor set about drawing and redrawing every feature of the Pyramid on the basis of the measurements reported by Howard-Vyse, so as to see what geometrical or mathematical formulas might be derived from the structure.

Taylor was puzzled as to why the builders of the Pyramid should have chosen the particular angle of 51° 51′ for the Pyramid's faces instead of the regular equilateral triangle of 60°.

Analyzing Herodotus' report of what the Egyptian priests had told him about the surface of each face of the Pyramid, Taylor concluded they had been designed to be equal in area to the square of the Pyramid's height. If so, this meant the building was of a particular if not unique geometric construction; no other pyramid has these proportions.

Taylor then discovered that if he divided the perimeter of the Pyramid by twice its height, it gave him a quotient of 3.144, remarkably close to the value of π, which is computed as 3.14159+. In other words, the height of the Pyramid appeared to be in relation to the perimeter of its base as the radius of a circle is to its circumference.

John Taylor.

This seemed to Taylor far too extraordinary to attribute to chance, and he deduced that the Pyramid might have been specifically intended by its builders to incorporate the incommensurable value of π. If so, this was a demonstration of the advanced knowledge of the builders.* Still today the oldest known document which indicates that the Egyp-

* Not till the sixth century was π correctly worked out to the fourth decimal point by the Hindu sage Arya-Bhata. It took another thousand years before the Dutchman Pierre Metius calculated π to six decimals by means of the fraction 335/113. In 1593 François Viete carried the computation to eleven figures, and a generation later Rudolph Van Ceulin, just before he died, took π to 127 figures by postulating a circle with 36,893,488,147,419,103,232 sides. In 1813 the English mathematician William Shanks developed π to 707 decimals. Modern computers have carried the operation to 10,000 points of decimal, but with no solution to this apparently incommensurable number.

tians had a knowledge of the value of π is the Rhind Papyrus, dated about 1700 B.C., and therefore much later than the Pyramid. Found in the wrappings of a mummy in 1855 by a young Scottish archeologist, Henry Alexander Rhind, the rare papyrus is now in the British Museum. It gives a very rough value for π of 3.16.

Searching for a reason for such a π proportion in the Pyramid, Taylor concluded that the perimeter might have been intended to represent the circumference of the earth at the equator while the height represented the distance from the earth's center to the pole.

Perhaps Jomard had been right: perhaps the ancient designers *had* measured the length of a geographical degree, multiplied it by 360° for the circumference of the globe, and by the π relation had deduced the polar radius of the earth, immortalizing their knowledge by making the circumference to scale with the perimeter and the radius to scale with the height of the Pyramid.

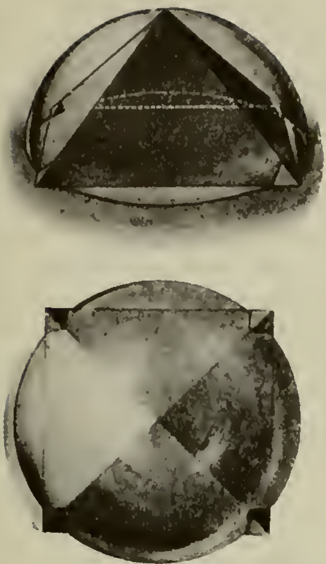
Taylor underlined his thesis: "It was *to make a record of the measure of the Earth* that it was built." He then elaborated: "They knew the Earth was a sphere; and by observing the motion of the heavenly bodies over the earth's surface, had ascertained its circumference, and were desirous of leaving behind them a record of the circumference as correct and imperishable as it was possible for them to construct."

But it was evident to Taylor that the builders of the Pyramid could not have used for their calculations such a unit as the British foot, which fitted neither the height nor the base exactly; he therefore looked for a unit that would retain the π proportion and fit the Pyramid in whole numbers.

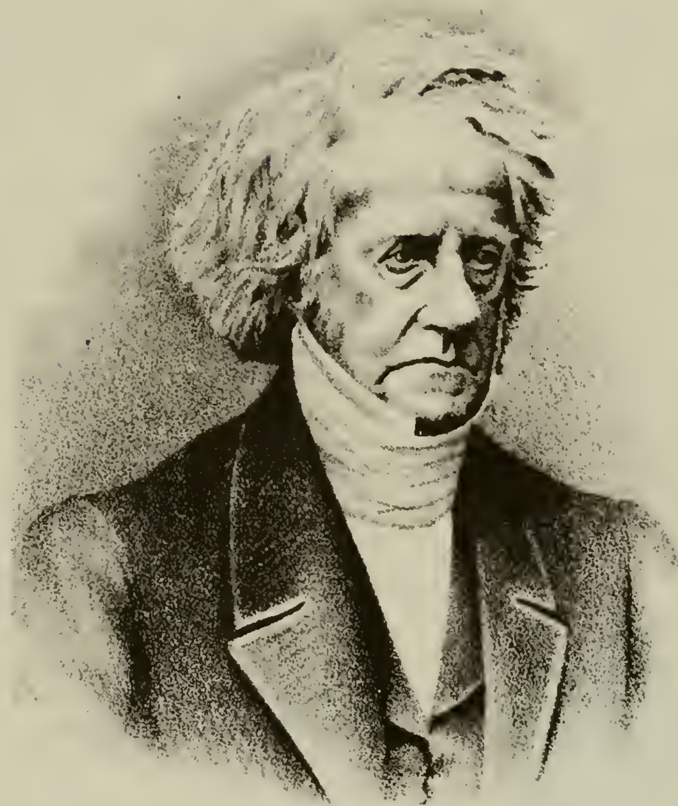
When he came to 366:116.5 he was struck by the similarity of 366 to the number of days in the year and wondered if the Egyptians might have intentionally divided the perimeter of the Pyramid into units of the solar year.

He then noticed that if he converted the perimeter into inches, it came to very nearly 100 times 366. Also he was surprised to see that if he divided the base by 25 inches, he obtained the same 366 result. Could the ancient Egyptians have used a unit so close to the British inch? And a cubit of 25 such inches?

By coincidence, Sir John Herschel, one of Britain's most eminent astronomers at the beginning of the nineteenth century, had just postulated a unit half a human hair's breadth longer than a British inch as the only sensible earth-commensurable unit, or unit based on the actual size of the earth.



Relation of a hemisphere to the Pyramid.



Sir John F. W. Herschel.

Herschel criticized the French meter derived from a curved meridian of the earth as being erratic and variable from country to country because the earth is not a true sphere, and each meridian of longitude would therefore be different. (What's more the French had erred, and produced a meter that was .0002 too short.)

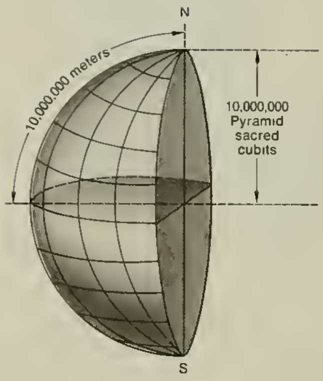
According to Herschel the only really reliable basis for a standard of measure was the polar axis of the earth— the straight line from pole to pole—which a recent British Ordnance Survey had fixed at 7898.78 miles (by taking the mean of all the available meridians measured). This translated into 500,500,000 British inches, or an even five hundred million inches if the British inch were half a human hair's breadth longer.

Herschel suggested that the regular British inch— which was officially computed as the length of three grains of barley taken from the middle ear and placed end to end— be arbitrarily lengthened by a mere one-thousandth part in order to obtain a truly scientific, earth-commensurable unit exactly one fifty-millionth part of the polar axis of the earth.

Fifty such inches, said Herschel, would make a yard that was exactly one ten-millionth of the polar axis, and half that measure, or 25 inches, would make a very useful cubit.

By coincidence these were the cubit and the inch which Taylor had found to fit the Great Pyramid in multiples of 366.*

Another unexpected piece of evidence astounded Taylor. He discovered that recent maps produced by the British Ordnance, the largest and most expensive yet undertaken, had been done on a scale of 1:2500. This scale turned out to bear no relation to the standard British mile of 5280 feet, which had varied through the ages, but almost miraculously fitted the "sacred" cubit as postulated by Newton, as well as the British acre, one side of which was equal to 100 cubits of 25 inches. It appeared that the British inch must have been an ancient unit of measure which had lost a thousandth part as it was handed down from generation to generation.†



To Taylor the inference was clear: the ancient Egyptians must have had a system of measurements based on the true spherical dimensions of the planet, which used a unit which was within a thousandth part of being equal to a British inch.

Fired by what he considered a stunning discovery, Taylor launched into a monumental study of the cubits, feet, spans, inches and stadia, not only of the ancient Egyptians, but of the Babylonians, Hebrews, Greeks and Romans. He found that all kinds of cubits had been used in the past, some of which appeared to have mathematical relations to each other. He also analyzed the ancient measures of cubic capacity along with the modern gallons, firkins, kilderkins,
