BUREAUCRACY. The idea of bureaucracy formally begins with Max Weber (1864–1920); indeed, the *idea* of bureaucracy ends with Weber as well. Prior to Weber's explication of the "ideal type" of rational, efficient organization of public or private business as a bureaucracy, the idea was simply a commonsense, practical method for the organization of economic or government action. While the original idea of bureaucracy was a prescription for social organization for both public and private organizations, the contemporary usage of the term is limited nearly exclusively to public organizations.

The association between Weber and the concept of bureaucracy is readily apparent; however, Weber himself did not explicate a definition of bureaucracy as such. Rather, he simply elaborated on a form of social organization according to specific characteristics and suggested that these were the elements of what would become bureaucracy. It is important to note that Weber was a sociologist committed to explaining the organizational forms within the world around him; bureaucratic forms of social organization were certainly in existence before Weber's ideal typology came to light.

The Practical Form of Social Organization Later Known as Bureaucracy

Prior to the coinage of the term *bureaucracy* in the nineteenth century, organizations that functioned essentially as bureaucracies had long existed throughout the world. As early as the Han Dynasty (206 B.C.E.–220 C.E.), Chinese bureaucracy was taking on the form of a merit-based, centralized administrative apparatus of the state. Other early civilizations, including the Egyptians and the Greeks, included active administrative arms, but unlike the Chinese, were not selected primarily on criteria of merit. The early practice of bureaucracy was nominally a system of individuals employed (often permanently) in court advisership, tax collection, and the implementation of imperial/monarchical policy. This form of bureaucratic social organization dates back to the early Chinese dynasties as well as the early Egyptians, Phoenicians, Romans, Greeks, and other ancient societies, all of whom employed a designated body of loyal officials to implement the various policies of the ruling classes. Throughout the early common era, bureaucracy remained an arm of the ruling powers and the aristocracy; imperial, monarchical, and feudal systems employed bureaucratic-type organizations primarily to implement taxation and land-use policies.

The Middle Ages saw the expansion of another form of public bureaucracy. The ecclesiastic bureaucracy was designed

to implement policies and maintain the hierarchy of the Catholic Church. The church was certainly not alone in its use of formal hierarchical structures for the purpose of efficient implementation of policy: early Protestant faiths and the Islamic faith also employed bureaucratized structures for the coordination of their ever-growing populations of clerics and faithful. The bureaucratization of modern life is intimately tied to religion, in Weber's case, Protestantism. The alliance between ecclesiastic and secular bureaucracies would dominate the greater part of the millennium. For example, the Crusades to the Holy Land were in many ways marvels of imperialist-expansionist uses of both bureaucratic structures. The use of the two bureaucratic forms in the foreign occupation and domination of foreign lands would be an important idea in the late-twentieth-century rejection of colonialism. As Rodney argues, the church was also a colonizing force, "[meant] primarily to preserve the social relations of colonialism . . ." (p. 253), and had to be dealt with as a colonizing bureaucratic power.

The key elements of the early practical bureaucracies (from the early Han Dynasty bureaucracy to the nascent Prussian state administration) included significant loyalty to the court, (very) limited policy discretion, frequent abuses of government power for organizational and individual gain, and the erection and maintenance of significant barriers to entry into the public service. The earliest practicing bureaucrats were rightfully accused of coveting and vehemently defending their titles as well as unduly influencing court decisions in favor of maintenance of the bureaucratic structure. This tendency of bureaucratic officials would be a perennial argument against the use of bureaucracy, particularly for the organization of government business. Later, within the early modern era (particularly the time of the prerevolutionary French administration) bureaucracy was used primarily as an aristocratic tool of domination of the many by the few. However, the inefficiencies and graft of rational-legal and formalistic bureaucratic systems are unlikely to be noted as particularly heinous compared to earlier, traditional forms of imperial and aristocratic abuses.

Max Weber and the Idea of Bureaucracy

What is notable about the very idea of bureaucracy is its severe rational modernism. Political modernity and bureaucracy are largely symbiotic; the rise of the state paralleled the rise of the bureaucracy. One of the philosophers of the modern economizing state and the modern bureaucratic idea is Adam Smith (1723–1790), whose defense of the division of labor promoted the bureaucratization of the early Westphalian state. Indeed, Smith's ideas are elemental to Weber's core tenets of bureaucracy: the rigid division of responsibilities and tasks and the economization of organizational forms. Whereas Smith advocated the division of labor in order to promote efficient economic growth, Weber suggests the division of labor for the efficient production of goods or services. Inevitably, bureaucracy was conceived as, and has become, an economizing tool for the rationalization of complex and ambiguous environments.

The rationality of bureaucracy is a central idea within Weber's ideal type. In fact, Weber himself suggests that bureaucracy be a rational-legal form designed to promote the rationalization of organizational tasks and goals. The rational-

izing tendency of bureaucracy, while being one of the elements most open to contemporary criticism, was also its most attractive quality for the architects of Enlightenment-guided governance, who sought alternatives to earlier forms of despotic and aristocratic dominance. The adoption of the bureaucratic form by theorists of liberal government has its roots in the legal protection of natural (rational) rights for all. In fact, embedded in the rationalization structure of bureaucracy is the elimination of particularism—the diminishment of universal individual rights for the sake of traditional forms of class or ethnic domination. Those responsible for the French Revolution pined, within their writings, for the rational nonexceptionalism of the bureaucratic form. Indeed, as Maximilien de Robespierre (1758–1794) and later Alexis de Tocqueville (1805–1859) identified, the *ancien régime* was epitomized by the irrational occupation of power by a centralized bureaucracy of the ruling class.

The products of mid-modern European thought on the liberalizing and economizing role of government produced the context in which Weber penned his essay "Bureaucracy." Within the essay he establishes the criteria elemental to the ideal bureaucracy. Foremost, he recommends that bureaucracy be the instrument of rational-legal authority, which he defines as that manner of authority "resting on a belief in the 'legality' of patterns of normative rules and the right of those elevated to authority under such rules to issue commands" (Scott, p. 44). This supplanted traditional forms of authority such as the sanctity of hereditary rule or charismatic authority such as the leadership of Napoleon. The bureaucratic organization of rational-legal authority involves the following necessary criteria: the specification of jurisdictional areas, the hierarchical organization of roles, a clear and intentionally established system of decision-making rules, the restriction of bureau property to use by the bureau, the compensation by salary (not spoils) of appointed officials, and the professionalization of the bureaucratic role into a tenured lifelong career. The idea of bureaucracy suggests that rules, norms, merit, regulations, and stability are paramount to the operation of government. The rule-bound nature of bureaucracy has been widely critiqued in modern political and sociological analyses; however, the number of alternative forms of organization that have received as much consideration is limited.

Criticism of and Advancements in the Idea of Bureaucracy

Critics primarily attack the practice of bureaucracy, but a few notable scholars attack or enhance the very idea of a bureaucracy and/or a bureaucratic state. Oddly, Georg Wilhelm Friedrich Hegel (1770–1831) was a reformer of the idea of bureaucracy without being an outright critic of the form. The Hegelian notion of the neutral universalizing civil service devoted to the common good contradicts Weber's notion of the bureaucracy that unquestioningly serves the rational-legal authority of the state. Hegel expands the role of bureaucracy beyond simply the implementation of rules to a universalizing and constitutive, productive artifact of modern society. This notion of the constitutive and productive bureaucracy is picked up by later political scientists such as Brian J. Cook. Despite the positive contribution that Hegelian philosophy has upon the idea of bureaucracy, followers of Hegel, such as Karl Marx and

Hannah Arendt, have damned the practice of bureaucracy as a dominating instrument of rationalized capitalist will. However, they have not notably expanded upon the idea of bureaucracy but have rather simply recast the rules already understood to be elemental to the idea and defined them as ills of modernity.

One avenue of expansion upon the idea comes from the criticism that postcolonial and postmodern theorists have directed toward bureaucracy. Weber initially argued for bureaucracy to be a tool for internal organization of offices that served to legitimate the power of the organization's authority through rationalization and rules. What postcolonial and postmodern theorists have charged is that bureaucracy is also designed for domination of the organization by those external to it. Weber's idea was, according to later critics, formed within a social vacuum and neglected the role of environment and context upon bureaucratic behavior. However, Weber likely did not intend to explicate a form of social organization void of social context; rather, he espoused one that could potentially work within a multitude of situations with or without being extensively tailored to individual societies. As such, Weber's original idea is decidedly impersonal and lacks space for exceptionalism. Consequently the organizational form is also ideal for discipline and domination; as an organizational tool within the public, bureaucracy has, as Hegel suspected, a tendency toward projection of a universal standard (of rationality, in this case). As Robert K. Merton suggests, the "formalism, even ritualism [of bureaucracy], ensues with an unchallenged insistence upon punctilious adherence to formalized procedures" (p. 106). The bureaucratic insistence upon rule-based formality codifies conformance, the primary tool of bureaucratic dominance.

Bureaucracies, particularly in modern democratic societies, have significant roles to play as channels of representation. Theorists of representative bureaucracy have expanded upon the idea itself to suggest that the practice be a conduit of effective and well-rounded governance. Similarly, as suggested by Michael Lipsky, lower-level bureaucrats can serve as advocates for citizen needs within their official capacities. Theorists of representative or advocative bureaucracy clearly reject the Weberian characteristic of neutral servants of authority and by doing so expand the idea of bureaucracy from a micro-level instrument of social organization to a macro-level system of social responsibility.

Criticisms of the Practice of Bureaucracy

The speculation that bureaucracy will bear bad fruit within society began with criticisms of government practice across history. These criticisms came from various philosophical schools as well as from the rapidly decolonized nations, particularly following World War II. However, many of the philosophical criticisms of bureaucracy are leveled against the practice rather than the idea. As Charles T. Goodsell notes, there are three broad typologies of antibureaucratic criticism within academia. These are a focus on unacceptable performance, the fear of bureaucracies serving elite interests over the interests of the entire polity, and the fear of bureaucratic oppression through formalism and a general lack of concern for particular needs of clientele. Of these criticisms, the focus on the unacceptable

performance and antihumanitarianism of bureaucracies seems to dominate the majority of the literature. For example, Thorstein Veblen, James Dewey, and D. Warnotte identify ills in bureaucratic practice that include, respectively, "trained incapacity," "occupational psychosis," and "professional deformation" (Merton, p. 104). However, each of these criticisms is lodged against practical states of bureaucratic employment rather than the idea of bureaucracy itself. Additional critical thought on the practice comes largely from contemporary organization theorists who have concerned themselves with the impact of bureaucratic structure on employees' motivation and attitudes. Additionally, theorists of public administration have speculated upon the role of bureaucracy within other organizational forms such as democratic governance. While these criticisms are decidedly useful as a pedagogical tool for understanding the nature of bureaucracy, they represent neither a critical reflection upon nor notable additions to the idea itself.

Goodsell's third typology has been largely taken up by postmodernists, critical theorists, and postcolonial critics of bureaucracy. The use of government bureaucratic domination as well as ecclesiastic bureaucratic domination was highly effective in the overtaking of colonial properties. However, bureaucratization was an ineffective tool for the reformation of decolonized states. Perhaps Weber was correct in his assertion that "bureaucracy, thus understood, is fully developed in political and ecclesiastical communities only in the modern state, and, in the private economy, only in the most advanced institutions of capitalism" (p. 73). The bureaucratization of juridical states and the rise of capitalist economy are inextricably related; the bureaucratic form is unnatural in societies where charismatic or traditional authority still dominates. The modernist preference for rational-legal authority suggests that bureaucracy should be the natural form of organization, but for decolonizing states in a situation of authoritative flux, bureaucracy may be an unnatural and in many cases falsely dominating form of organization.

Another form of critique against the practice of bureaucracy has come from scholars of gender relations. These critiques center primarily upon the rejection of the rationalist-modern form of organization as decidedly male-centered. Feminist scholars have argued that bureaucratic structures privilege male forms of communication, deemphasize intuitive and experiential knowledge, diminish the creative capacities of employees, and encourage conformity with historically male institutions, such as government. Again, while these critiques address some structures of bureaucracy as suggested by Weber, the idea itself is not augmented in the address.

Contrary to the thesis that bureaucratic organizations are consistently dominating is the thesis that bureaucracies (as Hegel supposes) can be neutral civil services devoted to the benefit of all in the society. Particularly because of its rational character and nonparticularistic method of organizing client needs, the bureaucracy can ideally serve all within a given community at an equally efficient level. However, according to some critical theorists, Jürgen Habermas being the most notable, the current conditions of social interaction within society are prohibitive of appreciative discourse between equal parties capable of reaching mutually acceptable and operable conclusions. Whether the bu-

reaucracy offers itself as a neutral public servant or not, the social structure of government in capitalist societies in particular unconsciously promotes unequal dialogue and domination by bureaucracies.

Summary of the History of the Idea of Bureaucracy

The history of the idea of bureaucracy is also marked by changes in the public perception of the term. Prior to Weber's defining the idea of bureaucracy, the practice of rational organization of government services according to neutral merit-based qualifications was viewed as a positive antidote to the nepotism and hereditary domination of traditional monarchical or ethnocentric forms of government. However, across most of the globe, the recent history of the term suggests that it has had a largely negative influence upon society. Indeed, the term *bureaucracy* now evokes epithetical connotations that refer exclusively to perceived inadequacies in government policy implementation.

One final characteristic of the history of the idea of bureaucracy is the multitude of synonyms that have evolved to describe the practice or the idea of bureaucracy in more neutral or passive terms, particularly within the past century. These synonyms include public administration, public management, public service, and governance or policy implementation. In fact, within much of the contemporary literature on bureaucracy, or public administration in particular, the two concepts are used coterminously. This tendency to conflate the idea of bureaucracy with the idea of public service, management, or administration demonstrates that the term has expanded from its original sociological implications. However, this is not to suggest that the idea of bureaucracy as the social organization of complex tasks according to rational-legal authority has lost any of its original appeal. It merely suggests that changing public preferences have altered the disciplinary significance of historical ideas and distorted them to reflect current social contexts, even if it leads to the incorrect hijacking of what once was a neutral academic term.

BUSHIDO. Literally translated as "way of the warrior," Bushido evolved into a clearly defined ethical system of the *bushi*, or warrior class of Japan, during the seventeenth and eighteenth centuries; the term first appeared in the *Kōyō gunkan* in about 1625. In his 1899 *Bushido: The Soul of Japan*, Nitobe Inazō, the first to articulate the concept in English, enumerated seven essential values of the warrior class: justice, courage, benevolence, politeness, veracity and sincerity, honor, and loyalty. cently, Bushido has been credited with fueling Japanese atrocities in World War II, through “the unassailable rule that death is preferable to dishonour” (Edwards, p. 5). In fact, neither of these popular conceptions accurately represents the codes of warrior behavior that developed over the course of six centuries.

The Warrior Governments of Japan

In 1192 Minamoto Yoritomo established the first *bakufu*, or “tent government,” to counter the growing inability of the imperial family and aristocracy to control the provinces. From that time until the Meiji Restoration of 1868 Japan was governed by its warrior class.

Yoritomo’s Kamakura government was later idealized as the warrior’s “Golden Age,” when “selfless loyalty unto death” characterized relations between warlords and their samurai retainers. Modern scholarship has uncovered a different picture, however. According to Dr. Karl Friday, “From the beginnings of the samurai class and the lord/vassal bond in the eighth century to at least the onset of the early modern age in the seventeenth, the ties between master and retainer were contractual, based on mutual interest and advantage, and were heavily conditioned by the demands of self-interest” (p. 342). There was no single prescriptive code of behavior; instead each warrior clan had its own behavioral norms, sometimes listed in formal “house pre-

cepts,” or *kakun*, or in admonitory epistles to a lord’s heirs and retainers.

These early warrior documents varied considerably—some had a decidedly Buddhist cast, others insisted on a thorough education in the arts, while still others advised a single-minded focus on strategy and skills for battle. Some were written in a highly stylized Chinese form; others were composed in a more natural Japanese manner. The Chinese-influenced theme of balance between *bun* (literature) and *bu* (martial skills), *bunbu ryōdō*, appears frequently. So do the reciprocal admonitions of loyalty to the lord and benevolence toward retainers. Maintaining martial skills is so important that Shiba Yoshimasa writes, “Insofar as martial arts are concerned, it goes without saying that one should practice . . .” (Hurst, p. 218).

From War to Peace

Prior to the Edo period (1600–1868), the primary function of a warrior was to fight. Writing about how to behave as warriors was of less immediate concern than actual battlefield skills. Tokugawa Ieyasu changed all that, through the unification of the country and his establishment of the third and final bakufu in 1603. Suddenly the *bushi*, who had been engaged in almost continual warfare for one hundred years, were left without any battles to fight. By the eighteenth century, the gap between name and role had widened to the point that the *bushi* experienced a full-fledged identity crisis. The samurai were now primarily administrators and bureaucrats searching for an understanding of their proper role in a warless age.

Unlike their predecessors, who had been writing for fighting men and clan leaders, thinkers such as Yamaga Sokō and his student Daidōji Yūzan wrote about Bushido in an attempt to define and encourage behaviors that would distinguish warriors from the other classes of farmers, artisans, and merchants. Incorporating a more traditional Confucianism than the state-favored Neo-Confucianism, Yamaga argued that the primary duty of the warrior was to serve as an exemplar for the rest of society, through deeply cultivated sincerity of action.

Yamamoto Tsunetomo, in the *Hagakure*, saw a very different purpose for the eighteenth-century warrior—“The Way of the Samurai is found in death” (p. 17). This anachronistic view—warriors had not died in battle for more than a century—is frequently misunderstood. In order to control the armed warriors, Tokugawa Ieyasu established a series of inviolable laws; these at times came into conflict with the warrior’s individual loyalties or sense of honor. In particular, both parties in any conflict between samurai were to be punished equally; in this context, Yamamoto urged that if warriors were forced to break the Shogun’s law they might as well fight to the death.

Modern Legacy

The values of the *bushi*, both actual and idealized, have permeated all levels of Japanese society. In the Edo period, members of the merchant class deliberately adopted samurai standards of behavior to identify themselves more closely with

the ruling class. After the Meiji Restoration, unemployed samurai became doctors and educators, and brought their written codes with them. The *Imagawa kabegaki*, by the fourteenth-century poet-warlord Imagawa Ryōshun, was even used as a textbook in Edo-period schools. During the years prior to the Meiji Restoration, the samurai's spirit of sincerity in action, loyalty, and self-sacrifice allowed them to take leadership in the revolt that would lead to the abolition of their class.

Bushido's most tragic legacy is the warped version ultranationalists used in formulating propaganda to encourage and sustain the Japanese soldier before and during World War II. The spirit of the *Hagakure* incited young Japanese men to become kamikaze suicide pilots; death was promoted as preferable to surrender.

In the early twenty-first century the term *Bushido* appeared more frequently in English-language martial arts publications than it ever did in early warrior texts. And even though Nitobe's list of virtues was not directly derived from actual warrior codes, it did reflect romanticized warrior ideals that the rapidly modernized Japanese recognized as noble and found comforting to call their own.

CALCULATION AND COMPUTATION. Words containing the roots *calcul-* and *comput-* have existed since antiquity. The study of concepts used to indicate actions, professions, and (mental and material) artifacts suggests that *calculation* and *computation* have not been, as canonically assumed, an exclusive concern of modern times. The mere existence of both word clusters throughout the decades (and centuries) prior to World War II also suggests that it may be problematic to assume that the relationship between calculation and computation has been simple—that is, computation existing as an exclusive postwar phenomenon brought about by a technical revolution that left calculation behind. For both Charles Steinmetz (1865–1923) and Vannevar Bush (1890–1974), celebrated pioneers of the prewar and interwar generation of electrical engineering, respectively, both calculation and computation were of constitutional importance to all their technical work. Their writings indicate a belief that the computing revolution started long before the 1940s. Steinmetz and Bush employed both concepts contemporaneously in their pervasive engineering textbooks in order to differentiate between high-skill analysis and low-skill application, between creative mental design and routine manual implementation, between that which was subject to the least and to the most of mechanization.

Steinmetz and Bush perceived themselves as analysts, in the tradition of Gottfried Wilhelm von Leibnitz (1646–1716) and Isaac Newton (1642–1727), the early modern founders of calculus. With the dynamic expansion of the division of labor that has been part and parcel of the expanding capitalist mode of production, the progress of calculation was a prerequisite for the advance of computation. Successful calculation from the top by the well-paid few would, first, routinize the work performed by the multitudes in the base of the pyramid; second, it would minimize the skill required by them; third, it would subject their work to mechanization; and fourth, it would lower their salary expectations. Computation was the job for a low-paid clerk known as the “computer” or “computor.” These human computers were usually women, who produced computations for the state and the military, for insurance companies and other businesses, and for analysts within the engineering and scientific community. While human computers worked with a rich variety of artifacts, it was the mass employment of mechanical desktop “calculating machines” that determined their history. By contrast, the engineering graduate, almost exclusively a male, was trying to distance himself from the ranks of the human computers by passionately defending the accuracy of his inexpensive slide rule, which he could own individually and skillfully use to “calculate.”

After the 1950s, amid popular expectation that full mechanization had finally arrived, the concept of “computer” connoted a machine rather than a human, thereby signifying the ideological hegemony that pointed to full separation of production from skilled labor, of accumulated (or dead) labor from living labor, and of fixed from variable capital. Instead of disappearing, the dated engineering differentiation between “analysts” and “computors” resurfaced in the system analysts versus coders struggle that marked the emergence of the programmers, computation’s new professionals. The difference between computation and calculation resonates throughout the fierce competition between the digital and analog computer (1940s–1950s), followed by the juxtaposition of digital computer hardware to software (1960s–1970s), which, in turn, was succeeded by the contrast between digital computer software operating systems from software for special purposes (i.e., application software) in the 1980s and 1990s.

Premodern, Early Modern, Non-Western

The difference in the meaning of “calculation” and “computation” that are found in Steinmetz and Bush seems to have been built on the precapitalist use of terms formed by the roots *calcul-* and *comput-*, respectively. Historiographically, the late medieval period offers an example when one compares the interest shown in quantifying the heterogeneity of motion by the Merton College theorists known as the “Oxford calculatores” to the practice shown by the ecclesiastical community toward homogenizing the standardization of time through a technique known as *computus*. During the late medieval and early modern period, the attack by the algorists upon the abacists—that is, the promoters of computing who relied upon previous and private memorization of tables of numerical relationships versus the defenders of the ancient tradition who placed emphasis on live calculations performed in public by moving pebbles (that is, calculi) along designated lines—compares favorably to the conflict between the digital (programming) and the analog (living labor) of the recent decades.

The physical embodiment of complex numerical relationships through interconnected mechanical parts that were concealed by a case, hence masking the motion of the gears, displayed only the input and output numbers. Some celebrated early modern examples were Blaise Pascal’s (1623–1662) adding machine (1642) and Leibniz’s adding and multiplication machine (1685). Earlier in the same century (1623), the German mathematician and linguist Wilhelm Schickard (1592–1635) had mechanized the set of numbered sliding rods that John Napier (1550–1617) had devised in 1617 to simplify astronomical calculations. Both Pascal and Leibniz sought to

profit selling their machines to merchants and natural philosophers. Galileo Galilei (1564–1642) tried the same with his improved computing dividers. Many of the early modern natural philosophers were heavily involved in calculating innovations. Additional contributions include “calculation by analysis” to the coordinates of René Descartes (1596–1650), by differentiation and integration in the calculus tradition that prefigures in Simon Stevin (1548–1620) and materializes in Newton and Leibniz, and by the analysis of multiplication and division into addition and subtraction through the logarithms that Napier introduced in 1614.

As with the method of algorists, the speed in calculation by logarithms assumed the availability of relevant tables. The transformation of these tables into scales inscribed in, first, circles sharing a fixed center and, soon after, scales that slid beside each other while sharing a fixed framework, found its ultimate presentation in the logarithmic slide rule, configured by William Oughtred (1574–1660) as early as 1621. The interactive proliferation of both tables of logarithms and logarithmic slide rules determined the history of calculation from the early modern period until the very recent decades. The dilemmas of computation in the recent decades have prefigured in the construction and worldwide use of tens (if not hundreds) of millions of slide rules, linear, circular, cylindrical, or hybrid, wooden, metal, or plastic, handmade or mass produced, cheap or expensive, with accessories such as cursors and magnifying glasses to increase the accuracy without increasing the size. The recent debates over special versus general purpose software and over competing software operating systems was long rehearsed in debates over choice of general or special purpose slide rule scales and scale system standards. Moreover, as scales of all sorts slid beside each other or within each other, the logarithmic slide rule turned out to be only one of innumerable versions of slide rules. Material culture scholars see no end to collection of calculation wheels devised to compute phenomena ranging from a menstrual cycle to a baseball season.

The coevolution of logarithmic slide rules and tables of logarithms is no different from the codevelopment of Leibniz’s “calculus” and his “calculating machine.” Taken together they point to the paired constitution of the scientific and the technical since earlier modernity. If Leibniz sought to sell his machine to merchants, Charles Babbage (1792–1871), a Cambridge mathematics professor, was interested in a calculating engine organized internally according to the symbolic efficiency and rationality of the nascent industrial order emerging within the first half of the nineteenth century in Great Britain. Partially funded by the government, Babbage failed for economic reasons to have his “difference engine” constructed because he was forced to depend on one of the most skillful workers of the period, Joseph Clement (1779–1844), in the workshop of whom the engine to calculate as if powered by “steam” was to be constructed. While the construction of the difference engine encountered the problem of skilled labor, Babbage realized that the use of the engine itself would be limited to special purposes, which would not eliminate calculation’s dependence on skilled labor. In 1833, he started drafting sketches of a second engine, the “analytical engine,” which he sought to be

independent of labor skill. He kept making modifications to the plans until his death in 1871 without ever managing to advance beyond programmatic descriptions of such an engine.

In Babbage’s *The Exposition of 1851; or, Views of Industry, the Science and the Government of England*, published in London in 1851 following his review of the panorama of industrial capitalism staged at the Crystal Palace World Fair, he repeatedly touched on the ideal of an engine that would render laborers mere “attendants,” unable to influence the production of calculation. Although Babbage’s calculating engines matched his promotion of a version of continental analysis that he thought to be more appropriate to a calculation to sustain further industrial growth, he became known for his emphasis on the mechanization rather than the organization of work. The organization of work has been the pursuit of the division-of-labor scheme that the French engineer Gaspard Clair Prony (1755–1839) devised in 1792 to have a new set of logarithmic and trigonometric tables produced as a monument to the new French Republic. Six eminent mathematicians who selected the appropriate equations formed the peak of his pyramid, a layer of ten mathematicians below them advanced the analysis to the point where everything was converted to simple arithmetic, and a group of one hundred humans, recruited even from hairdressers, performed simple operations on a part of a problem before passing it to the next person.

The expansive reproduction of this scheme by setting smaller or larger groups during the nineteenth and the twentieth century, after taking advantage of sources available both within and outside the Western society, resulted in the formation of an army of “computers.” By the introduction of commercial calculating machines such as Thomas de Colmar’s (1785–1870) Arithmometer, exhibited at the 1855 Paris Exposition, references to “human computers” are found from as near as a British male scientist’s environment of female friends and as far as male Indians working in British engineering initiatives in their country. The relative continuity between Leibniz’s calculating machine and the Arithmometer—the most widely available calculating machine based on improvements on Leibniz’s machine by 1871—is an index of the relative continuity between merchant and industrial capitalism. Leibniz had promoted his machine to a society marked by the dynamic appearance of merchants by stating that “it is unworthy of excellent men to lose hours like slaves in the labor of calculation, which could safely be relegated to anyone else if the machine were used” (Leibniz, quoted in David Eugene Smith, *A Source Book in Mathematics* [1929], pp. 180–181). Babbage’s “attendants” were the industrial version of Leibniz’s slaves. Babbage wanted his calculating engines used for the production of general and special purpose tables, including tables for the navigational pursuits of the British empire. Batteries of human computers—along with other implements such as calculating machines and slide rules—produced numerous tables and charts for an assortment of military and civilian purposes (scientific, engineering, and commercial).

The lack of a synthesis of scholarly studies limits scholars’ ability to compare the modern European experience with calculation and computation to those of non-European societies. What is known about the Inca knotted strings known as *quipu*

and the Chinese knotted cords suggests that societies paradigmatic of civilization in other continents relied heavily on what is now identified as calculation and computation. Ongoing historical interpretation of archaeological findings from ancient Mesopotamia point to the few who knew how to connect computations routinely produced by the many to a calculating coefficient that could make the abstract concrete. Projecting Western conceptual demarcations to non-Western societies may prove problematic, especially considering the parallel dead ends from having projected late modern Western demarcations to ancient and early modern histories. Interpretation, for example, of the Hellenistic Antikythera mechanism as “analog,” and accordingly, a technically inferior computer, has blocked historians from taking into account the digitalization introduced by the complicated geared structure underneath the disk representing analogically the universe. As a result, the search for how the technical accuracy of the artifact matched with social interests of the period has been replaced by the assumption of limits in the accuracy due to inferiority from belonging to an essentialist inaccurate technical genre. Similarly, a historiography aiming at interpreting the analog motion of the pebbles on ancient and early modern abacuses has been blocked by the late modern emphasis on the resting pebbles—that is, on the perception of pebbles as digits. The tradition of the Chinese and the Western abacus, therefore, has been flatly situated under the “digital,” thereby making it impossible to acknowledge differences in the employment of abacus analogies between and within traditions.

Late Modern Period

Abacuses and artifacts from the associated tradition of counting boards with pebbles or beads share the honor of being ancestors of the digital computer along with the various mechanical and electromechanical desktop calculating machines produced from 1850 to 1950. They are joined by an ensemble of mechanical and (later) electromechanical tools and machines used for punching holes into cards, which represent computable variables, for sorting these cards according to the variable to be computed, and for tabulating and printing the results. They are best known as punched card machines, based on the part of the process that was least subjected to mechanization. Going back to the end of the nineteenth century, punched card machines were rented by companies that were ancestors to IBM (International Business Machines) to, first, the United States Census Bureau, and, subsequently, censuses for nations around the world. Calculating and punched card machines were extensively used for filing, accounting, and related activities that involved the processing of large amounts of data in larger enterprises, which have ranged from railroads to insurance companies. The U.S. Social Security Administration also used hundreds of punched card mechanisms and machines to implement a social security system that, in 1935, had to handle information about the wages paid by three million employers to their twenty-six million employees.

In addition to the slide rule, the list of what has been a posteriori placed under analog computers includes calendars, sundials, orreries, astrolabes, planetariums, material models of all kinds (including scale models), mathematical and other

mental models, graphs that could be as complex as the nomograms of Maurice D’Ocagne (1862–1938) and his followers (used from the late nineteenth century until the recent decades), computing linkages, artifacts with mechanical integrators and differentiators, curve tracers and kinematic mechanisms in the tradition of planimeters and associated artifacts, harmonic analyzers and synthesizers like the one that Lord Kelvin had built as a tide predictor, mechanical, electromechanical, and electrical analyzers for general (e.g., Bush’s differential analyzer) and special purposes (e.g., Bush’s electric power network analyzers), electrolytic tanks, resistive papers and elastic membranes used as models, and countless mechanisms and machines produced and used in fire control (internal, external, and terminal ballistics). Case studies have retrieved the histories of many other cases of unique tools and machines, including those used for crucial tidal calculations in the Netherlands.

Changes in calculating machinery were coupled with changes to make the calculus correspondingly operational. Remembered more as the author of the state-of-the-art calculating machines during the interwar period, Bush was also the author of influential writings on the “operational calculus,” which capitalized on a tradition of modifications of the calculus that adjusted it to the ever-changing needs of engineers who thought of themselves as equal to any scientist. In the 1930s and in the 1940s, punched card machines were reconfigured to be useful in scientific calculations. Bush’s differential and network analyzers were also used in the scientific calculations of the period immediately before and after World War II. Calculating machines were used in scientific calculations even earlier and so were slide rules.

The various branches of the state have had an organic role in fostering technological change. To the examples of the extensive use of digital punched card machinery by civilian apparatuses such as the census should be added the involvement by the military in purchasing analog fire control mechanisms and machines; of the state’s exclusive involvement in cryptography-related calculation and computation even less is known, with the exception of the celebrated Colossus machine during World War II. Using the Colossus machine, a British team that included in its members the mathematician Alan Turing (1912–1954) broke the code produced by a German machine known as the Enigma. The military had actually used hundreds of punched card machines in World War I for materiel inventory and for medical record keeping. Interwar support for military needs changed so remarkably that the computing bombsight and the anti-aircraft director were by World War II extremely complex artifacts with thousands of mechanical, electrical, and electronic parts. The competing development of the computing bombsight, which increased the target reach for a bomber, and the anti-aircraft director, which increased the reach of ground-based fire targeting the bomber itself, has formed a vicious circle that exemplifies the contradiction of modern technology. In the United States, the development of accurate bombsights during World War II was a secret second only to the construction of the atomic bomb. The extreme technological contradiction to date may have been that the most accurate computing bombsight was used

to drop the first atomic bomb, a lethal weapon like none before it, the efficient release of which required the least accuracy.

Contemporary Period

The demand for ballistics tables beyond what available human computers could supply in World War II resulted in the construction of ENIAC (Electronic Numerical Integrator and Computer), considered by many to have been the first digital electronic computer. It was constructed by employing 18,000 vacuum tubes between 1943 and 1945 at the Moore School of Pennsylvania by a team led by John Mauchly (1907–1980) and J. Presper Eckert (1919–1995) with funds from the U.S. Army's Ballistics Research Laboratory. Under the direction of Howard Aiken (1900–1973), a physics instructor at Harvard University, IBM completed in 1944 the construction of the Automatic Sequence Controlled Calculator (Harvard Mark I), used to produce the U.S. Navy's ballistic tables. A wealth of detail exists about the 1940s and the 1950s, the period of the heroes of electronic computation, which has attracted the disproportionate attention of historians. At the very least, this attention has made it clear that the electronic computer was a "multiple invention," which means that it came by a social cause, not an individual genius.

The construction of ENIAC was roughly contemporaneous to several other projects. Aiken's efforts at reconfiguring IBM's accounting machines for the purpose of solving nonlinear differential equations went back to 1937. The Bell Labs employee George Stibitz constructed a series of machines based on relays and other telephonic equipment, including the Complex Number Calculator, which was used successfully by the military between 1940 and 1949. In Germany, starting in 1938 and continuing through the war, Conrad Zuse (1910–1995) constructed a series of machines that were also based on electromechanical relays. Iowa State College physics professor John Atanasoff (1903–1995) and his graduate student Clifford Berry (1918–1963) built a special purpose electronic computer, the ABC (Atanasoff-Berry Computer) between 1939 and 1942. Ranging from the big to the gigantic, these machines inaugurated experimentation with correspondence between electronic circuitry and numerical computational relationships, in the decimal or the binary system. Claude Shannon is the most recognizable of those who were arguing for such correspondence theoretically by showing that the design of electronic circuits and the reduction of reasoning to a series of simple algebraic operations (as proposed by the Boolean algebra) could be used to push each other forward.

Having been a participant of the Moore School team, the Princeton mathematician John von Neumann (1903–1957) shaped the following generation of electronic computers by setting the standard of a computer architecture based on an internal division of labor between a control unit that interacted with the memory to check the flow of data between the memory and the arithmetic unit while controlling the input and output. His division between an arithmetic unit, which is where any future calculation was to take place (by taking into account selected past computations from a stock accumulated in the memory) imported the living-dead labor dynamic balance of the whole of the capitalist economy into the

workings of the machine—the balance during the dynamic self-accumulation of past computations in the memory was to be provided by the control unit. The accumulation of data and instructions in the memory unit became known as the "stored program technique." It represented an economy of flexible allocation of resources that was opposite to the brute-force approach of the previous generation of electronic computers. Von Neumann presented his architecture in a 1945 report on EDVAC, a computer to follow ENIAC. The architecture was rehearsed in the construction of the IAS (named after Princeton's Institute for Advanced Study) by a team led by von Neumann at Princeton. It was completed in 1952. Like most experimental computers of the period, IAS was funded by sources such as the military and the Atomic Energy Commission. Similar machines were constructed at seventeen other research centers in the United States and several more in various other countries.

Interested in commercial rather than scientific computers, Eckert and Mauchly tried a series of intermediate computer configurations and business schemes before authorizing the production of the Remington-Rand UNIVAC (Universal Automatic Computer), the first of which was delivered to the Census Bureau in 1951. The first UNIVAC for business use was installed at the General Electric Appliance Division, for payroll computations in 1954. By 1957, the number of UNIVACs sold was up to forty-six. Along with several other manufacturers, IBM entered the electronic computer business in the early 1950s. It started with the 1951 IAS-type Defense Calculator, which was renamed IBM 701. IBM constructed and rented nineteen such machines. By 1960, IBM had dominated the market with machines such as the IBM 650, usually rented to universities under attractive terms, which subsequently tied university computations to IBM. IBM's dominance was solidified by its introduction in the mid-1960s of the standard-setting System/360 family of computers.

By then, the analog-digital debate, which has started in the late 1940s and escalated in the early 1950s, was practically over. The evolution of the MIT Project Whirlwind between 1945 and 1953, under the direction of Jay Forrester, captured the emergence of the analog-digital demarcation. Intended to be used in real-time aircraft flight simulation, it started as an analog machine. Upon learning about the EDVAC, Forrester decided to attempt to construct a digital computer. His costly change was supported, initially, by the U.S. Office of Naval Research with approximately one million dollars per year. When the Navy gave up, the Air Force stepped into the void hoping that the digital Whirlwind computer could lead into a machine suitable to the needs of SAGE (Semi-Automatic Ground Environment), a system to coordinate the detection of and response to the Soviet Union's strategic bombers. The pursuit of SAGE brought about enormous demands for programming, thereby revealing the dependence on computer software. It started to become apparent that the analog-digital contrast was succeeded by a contrast between software and hardware.

There is no record of thinkers who foresaw a market for more than a few mainframes in the 1940s. There is also no record of thinkers who predicted that the future of computation was not

in the formation of computer utilities, according to the direction suggested by the time-sharing of mainframes during the 1960s. Patented in 1959 by Jack Kilby of Texas Instruments, the integrated circuit contained all the elements of an electronic circuit in a chip of silicon. The microprocessor appeared a decade later as a general-purpose programmable integrated circuit. The cheapening of the hardware and the miniaturization of electronic components made possible the decrease of the size of the mainframes to that of minicomputers. The potential of reducing the size of the computer further to that of a home appliance was realized in the subsequent decades, resulting in the mass production and use of personal computers during the 1980s and the mass interconnection of personal computers that led to the formation of the Internet and the World Wide Web during the 1990s. In the meantime, microprocessors have been installed everywhere from home appliances to automobiles.

The decrease of the value of hardware accentuated the increase in the value of software. What concluded as a “software crisis” started as a problem of “programmer shortage.” Generations of general and special-purpose programming languages, and, by now, software operating systems have yet to provide a stable solution. Attempts at computer-aided programming (machine self-programming) and software engineering (mass production of software) have met with limited success if not complete failure. From eliminating the “programming bugs” that clogged the early electronic computers to blocking the so-called spam that plugs contemporary e-mailing, computation seemed to have increased rather than decreased the dependence on skilled labor. In its absence, all sorts of computer viruses threaten the contemporary world with catastrophe. Many of the world’s habitants anxiously anticipated living through the completion of a millennium in the transition from year 1999 to year 2000, which became known as Y2K. Their recollection of the event is marked by the memory of anxiety surrounding Y2K, a concern that stemmed from decades of labor-saving yet short-sighted use of two digits for the purpose of making electronic computations economical.

CALENDAR. A calendar is a system of reckoning and ordering time beyond the period of a day in a repetitive, usually annual, cycle. A calendar’s primary function is regulating and organizing human activities; the word derives from the Latin *calendarium* or *calendra*, “account book,” and *kalendae* or “calends,” the new moon and first day of the Roman month, when Romans paid their debts. Calendars may have derived from the human penchant for imposing order; however, the most efficient exploitation of natural resources implies synchronizing productive efforts with nature’s cycles. Sensitivity to such

cycles is biologically programmed into humans as circadian rhythms, including the twenty-four-hour cycle of sleep and wakefulness and fluctuating body temperature; and in the female menstrual cycle, which approximates a lunar period.

Calendric periodicities are traced ultimately to the Sun and the Moon. The daily apparent rising and setting of the Sun is due to the rotation of the Earth, while the annual cycle of the seasons is related to the revolution of the Earth around the Sun, and the tilt of the Earth relevant to its plane of revolution. The most commonly reckoned calendrical period beyond day and night is the synodical lunar month (the cycle of lunar phases) of 29.5 days. Incommensurability between this period and the seasonal cycle based on the solar year of 365.24 days and the need to process fractions of days in the astronomical cycles with whole-day counts have been among the most difficult challenges for calendar specialists.

Early, Nonliterate, and Folk Calendars

Alexander Marshack sees in the scorings and tally marks on Paleolithic fossils and artifacts the beginnings of time recording. With Neolithic domestication, systematic time reckoning allowed farming practices to fit local moisture and temperature patterns. Such concerns and efforts are suggested at Stonehenge in England, where, beginning about five thousand years ago, massive stones were arranged in geometric patterns. While interpretations of the site vary, its main axis includes an alignment to the June solstice sunrise, the day of longest sunlight.

Small-scale and nonliterate societies such as the Nuer of Africa emphasize a sensitivity and responsiveness to seasonal cycles that E. E. Evans-Pritchard calls “ecological time.” Such calendars are characterized by:

1. space-time (the fusing of concepts of time with the space accessed and occupied in that time);
2. fuzzy-bordered seasons (increasing rains gradually transform dry season to wet);
3. “layered” observations of synchronous events at different ecological levels (for example, the bloom of plant species coincident with the movement of fish or game); and
4. diachronic sequences, such as episodic faunal or floral changes or consecutive astronomical observations (for example, advancing stellar positions, changes in the Moon’s position and shape, or the movement of the Sun on the horizon).

Calendar Codification and Civilization

Awareness of the astronomical significance behind seasonal phenomena allowed human communities to coordinate their activities seasonally for strategic and productive ends. Once a reliable system of recording such information was devised, calendar refinement and codification were possible. Calendar codification and the enhanced utilization of energy and other resources that this enabled are a significant factor in the process of civilization—a topic deserving additional study. The earliest centers of civilization in Mesopotamia, the Indus and Nile

valleys, eastern China, Mesoamerica, and the Andes all have information recording systems and codified calendars, which were probably overseen by high-ranking astronomer-priests who also likely oversaw timely rituals relating human endeavors to cosmic powers.

Varieties of Calendars

The prominence of the Moon in premodern societies with limited lighting and the regularity of its phases resulted in the synodical lunar month being basic to many traditional calendars. In the Muslim calendar, twelve lunar months of twenty-nine or thirty days are reckoned in a year of 354 days, or a leap year of 355, in a thirty-year cycle. The approximately eleven-day difference between such a synodical lunar calendar and the solar year, however, results in a slippage of months through the seasons. In order to maintain synchrony between lunar months and the seasons, an intercalated month is necessary, a strategy employed in the Jewish calendar with influence from Babylonia: seven leap years intersperse with twelve common years in a nineteen-year cycle.

Ancient Egyptians used the annual heliacal rise (predawn reappearance) of Sirius to help coordinate their lunar months with the seasons and solar year. While maintaining this system for religious observance, they later developed a civil year of 365 days comprising twelve fixed months of thirty days with five additional days. The ancient Maya had a similar five-day end-of-year, but divided the other 360 days into eighteen named periods of twenty days. This yearly calendar intermeshed every fifty-two years with a divinatory cycle of 260 days. Maintaining separate calendars for civic and religious (and/or regional and ethnic) functions is a common practice, useful in the twenty-first century for the retention of local traditions amidst the spread of the Gregorian calendar.

The Gregorian Calendar and Globalization

The Gregorian calendar spread through European colonialism and later through international relations, exchange, and commerce. It developed from the first-century B.C.E. Julian calendar, named after Julius Caesar, who commissioned its development and approved the reckoning of months no longer determined by lunar observations in a year that averaged 365.25 days. The Gregorian gets its name from Pope Gregory XIII, by whose election in the year 1572 C.E. the day marking the vernal equinox had strayed ten days from its occurrence. His papal bull in 1582 set out the mechanisms by which:

1. the spring equinox would occur on its actual date;
2. Easter—which depends on calculations from the vernal equinox—would be determined; and
3. a leap year system would be implemented, allowing for prolonged congruency between the calendar and its astronomical underpinnings.

Since the sixteenth century, countries around the world have adopted the Gregorian calendar, including its twelve fixed months, seven-day weeks, and beginning date. However, day and month names usually occur in the vernacular, and

traditional reckonings may be kept for local, ethnic, and religious observances.

Through calendars, humans impose culturally significant rhythms on the perception of time. Across human cultures two primary perceptions of the character of time predominate:

1. time as recursive or cyclic, observed in the recurrence of day and night, lunar waxing and waning, and the return of the seasons; and
2. time as linear, an ongoing process, observed in the maturation of vegetation, decay, and the transition of a human life from birth to death.

Specially marked dates and periodicities are the human, cultural cadence in the infinitude of time. While unable to control the passage of time, humans with calendars have increasingly ordered their relationship to and utilization of it.

CANNIBALISM. The possibility of cannibalism has been an object of thought and imagination in virtually every society. The idea of consuming human body substance as food or for symbolic purposes invokes emotionally charged cultural and psychological concerns with boundaries between self and other, persons and nonpersons, the meanings of food and ingestion, and the limits of a moral community. Many societies, both Western and non-Western, have seen cannibalism as a marker of negative difference between peoples, a quintessential symbol of otherness, savagery, and subhumanity. Others have treated it as a form of exchange or as a mechanism of transformation, regeneration, or reproduction through transactions between ontological categories such as kin and enemy, mortals and deities, human and animal.

In Western thought, two uses of the idea of cannibalism have been recurring themes: as a negative stereotype of exotic "others," and as a metaphor for reflexive questioning, critique,

and parody of Western culture. Especially in the politics of colonialism, accusations of cannibalism have been deployed to denigrate non-Western peoples, assert colonizers' moral superiority, and legitimize the takeover of native lives and lands. Only recently have scholars called attention to socially approved cannibal practices in Western history, such as the tradition of using human body substances as medicines, which flourished in Europe until the eighteenth century.

The stigma associated with cannibalism in Western thought makes any assertion that certain people engaged in it politically sensitive. Since the 1970s, especially in the United States, anthropologists and historians have debated where and to what extent cannibalism was an institutionalized, socially accepted practice (as distinguished from its occurrence as an aberrant, individual act motivated by starvation or psychological deviance). These arguments mostly involved historical and retrospective evidence, since under the impact of colonialism and modernity, any former practices of institutionalized flesh-eating had largely disappeared by the 1970s. Major controversies focused on Michael Harner's and Marvin Harris's interpretation of human sacrifice as a response to dietary shortages among the Aztecs of fifteenth-century Mexico; the role of funerary cannibalism in epidemics of the neurological disease *kuru* in the New Guinea highlands; the ongoing debate between Marshall Sahlins and Gananath Obeyesekere over allegations of cannibalism among South Pacific islanders and after the death of Captain James Cook; and the interpretation of archaeological finds from Europe and the southwestern United States that show dismemberment, mutilation, and cooking of body parts.

A major impetus to debates over the reality of cannibalism came from William Arens's *The Man-Eating Myth* (1979), which examined selected accounts from some non-Western societies. Finding a lack of hard evidence and no credible eyewitness accounts by Western experts, Arens expressed doubt that cannibalism ever existed anywhere as a socially approved practice. He argued that cannibalism is best understood not as a cultural practice but as a projection of Western fantasies, racism, and political propaganda. Although presented as a critique of Orientalist prejudices, the argument reified negative colonial stereotypes with its implicit assumption that the act of ingesting human substance is in all cases repulsive and morally indefensible. Arens's critique of the supposed bias and credulity of those who have written about cannibalism as social practice found some scholarly receptivity, particularly within cultural studies.

In anthropology, Arens's book drew criticism for its methodology, sensational rhetoric, and unreasonable and inconsistent empirical standards. The controversy had the positive effect of stimulating ethnographers and historians to reassess historical and ethnographic evidence. While debates continue over the evidence in specific cases, most anthropologists accept the idea that normative, institutionalized practices of consuming human body substances did occur in some times and places in the past.

Recent anthropological work has sought to contextualize local cultural practices by elucidating their social, symbolic,

religious, and ritual significance. A few scholars, such as Eli Sagan and I. M. Lewis, have proposed universal explanations interpreting flesh-eating in all contexts, from warfare to funeral rites, as expressions of similar impulses such as hostility, ambivalence, or desires for dominance. The stronger trend has been to recognize diversity and the many different kinds of practices with distinctive cultural meanings that have been lumped together under the rubric of “cannibalism.” Ethnographies from Melanesia and the South Pacific have highlighted how cannibalism, as practice or idea, was linked to cultural ideas about ethnicity and gender, the uses of flesh and food to define spheres of morality and exchange, and human reproduction and the circulation of vital energies or substances contained in the body. Lowland South American ethnography has emphasized cannibalism’s role in the production of personhood and alterity and indigenous notions of its role in metaphysical transformations and exchanges between enemies and between the living and the dead, humans and animal, mortals and immortals. There has also been new attention directed to native peoples’ images of Europeans or other foreigners and their descendants as “white cannibals.” An implicit agenda in much recent scholarship is to undermine negative stereotypes and deexoticize the subject of cannibalism by expanding humanistic understandings of how, within local systems of cultural meaning, some peoples may have felt that consuming human flesh or bones was a positive, morally acceptable thing to do.

Over the past five centuries, numerous writers, from Michel de Montaigne to Jonathan Swift and Ruth Benedict, have used cannibal imagery to express critical perspectives on Western culture and as a rhetorical device for inverting conventional boundaries of civilization and morality. In Brazil in 1928, Oswald de Andrade’s “Cannibal Manifesto” launched the avant-garde Antropofagia movement, which reclaimed cannibal imagery from native Brazilians’ early encounters with Europeans and asserted that the key principle of Brazilian modernity is assimilation of foreign influences. Latin American artists and intellectuals continue to find cannibalism a fertile metaphor for Euro-American culture and exploitative political economic relations.

Since the 1970s, there has been a trend among scholars, artists, and culture critics in the United States and elsewhere to deploy cannibalism as a metaphor for Western civilization itself. Globalization, capitalist consumer culture, and cross-cultural appropriation in tourism, art, media, and museums have been portrayed as forms of cannibalism. Richard King criticizes the Occidentalism in analyses that treat “the West” as a single, undifferentiated entity while perpetuating negative stereotypes, trivializing cannibalism as a real experience and embodied cultural practice, and deflecting attention from its meanings in specific social-historical contexts. As one of the last real taboos in contemporary cosmopolitan society, cannibalism’s attention-getting power to shock ensures that it will continue to be a theme and source of fascination in popular culture and scholarship.

CAPITALISM.

OVERVIEW

Capitalism has been the dominant economic system in the West since the nineteenth century and has increasingly spread across the globe. Characterized by unfettered markets in labor and natural resources, commodity production, and the reinvestment of profit, capitalism must be distinguished from other forms of commercial society that existed in early times or outside of the West, in which market-oriented activity remained ultimately subservient to political or moral goals. (Examples of such non-capitalist market society include the so-called mercantilism that preceded full-fledged capitalism in Europe and the city-state empires of the ancient Mediterranean world, which actively engaged in commerce yet did not generate capitalist socioeconomic relations.) Throughout its history—even before it took

root—capitalism was a controversial idea that posed serious issues for philosophers, moralists, and social scientists alike.

Early Advocates

Perhaps the best-known and most important early exponent of capitalism was the Scottish economist Adam Smith (1723–1790). Smith employed the term *capital* in technical economic discussions contained in *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), but he did not describe his economic system as “capitalism.” Rather, the latter term seems to have arisen only in the nineteenth century. Smith preferred to speak about natural liberty, by which he meant simply that if everyone acts freely as they see fit in their own interests, then the welfare of the whole society will be best served. For Smith, the system of natural liberty constitutes a sort of automatic or homeostatic mechanism of self-adjustment (which he sometimes calls the “invisible hand”), so that any attempt (on the part of government or some other agent) to interfere in its operation will lead to greater inefficiency and hence less total welfare. The doctrine of natural liberty thus yields the founding principles of capitalism as an economic system. In turn, Smith applied this discovery not only to the operation of the marketplace but also to all aspects of society, including its educational, religious, and judicial institutions. He narrowly confines the role of government to those functions consistent with natural liberty: foreign defense, regulation of criminal activity, and provision of “public goods” too expensive for any single segment of the private economy to undertake.

The sources for Smith’s insight about maximized individual liberty, unconstrained by coercive externalities, have been debated. Certainly, an earlier group of French economic theorists, known collectively as the Physiocrats, may have played a role in the formulation of this idea. Perhaps more importantly, as Albert O. Hirschman and others have argued, many influential political and moral theorists writing in the seventeenth and eighteenth centuries had promoted doctrines of human psychology and action that comported well with Smithian natural liberty. So-called heroic virtues were replaced with more mundane values in the writings of a wide range of early modern thinkers, including Niccolò Machiavelli (1469–1527), Thomas Hobbes (1588–1679), François de La Rochefoucauld (1613–1680), Anthony Ashley Cooper, third earl of Shaftesbury (1671–1713), and Bernard Mandeville (c.1670–1733).

The work of Smith inspired a school of thought known broadly as classical political economy. Its leading members in the nineteenth century, such as David Ricardo (1772–1823) and Thomas Malthus (1766–1834), extended and refined Smith’s insights, often drawing in addition on the work of the utilitarian philosopher and social reformer Jeremy Bentham (1748–1832). In its most ruthless form, this position was combined with a reading of Darwinian biology to make the argument that capitalism, as a system of the survival of the fittest, was sanctioned by evolution, as in the Social Darwinism of Herbert Spencer (1820–1903). Nor were devotees of unlimited capitalism limited to the earliest stages of capitalist development. The neoclassical school of economic theory, exemplified

by the work of Friedrich von Hayek (1899–1992) and Milton Friedman (b. 1912), continues to exercise considerable influence on all dimensions of social thought into the twenty-first century. The so-called rational choice or public choice economists persist in their belief that the free market relations realized only under capitalism constitute the single legitimate model of all social order.

Foes

Capitalism has by no means lacked for criticism from many different quarters. Communitarians, such as Henri de Saint-Simon (1760–1825), asserted that capitalists’ concentration on competition and individual self-interest at the expense of social solidarity would ultimately corrupt and corrode communal order. Utopians, such as Charles Fourier (1772–1837), sought to replace capitalism’s exploitation of labor with a free and creative socioeconomic system in which human potential could flourish. The anarchist Pierre-Joseph Proudhon (1809–1865), proclaiming that “private property is theft,” denounced the collusion of state and capitalist enterprise and proposed to level the unequal distribution of the material benefits of work and to liberate workers to collaborate freely in their chosen activities. What all of these essentially left-wing responses to capitalism shared was a belief that cooperation rather than competition was the key to the improvement of human society and the amelioration of psychological as well as material misery.

The most famous nineteenth-century opponent of capitalism was Karl Marx (1818–1883), who, with his collaborator Friedrich Engels (1820–1895), offered far-reaching and systematic criticism based on a careful study of the inner operations of the capitalist economy. It is too seldom acknowledged that Marx shared more with the classical political economists than with capitalism’s moralistic antagonists. In his unfinished masterwork, *Capital* (volume 1 published in 1867), Marx viewed himself as engaging in the “scientific” analysis of capitalism, borrowing heavily from Smith and his successors, while pointing out the structural weaknesses and limitations that the capitalist apologists had overlooked. In particular, Marx believed that the intense conflicts between capitalists and workers, as well as among capitalists themselves, would produce recurrent and ever-deepening economic, social, and political crises. Eventually the growing body of exploited industrial laborers, whom Marx labeled the proletariat, would recognize the source of its exploitation in the market-engendered condition of “wage slavery” and would revolt against the capitalist system as a whole.

Yet Marx did not dismiss lightly the accomplishments of capitalism. He maintained, instead, that the technological achievement of capitalism in constantly revolutionizing the means of production should be harnessed by any future communist society. Indeed, one of the inherent contradictions of capitalism was its inability to utilize fully its own productive capacity, a situation that would be rectified under communism. In sum, what singled out Marx’s criticism of capitalism was its immanent character, in comparison to communitarians, utopians, and anarchists, whose critiques were based on standards external to capitalist economics.

Origins

One of the central issues in the conceptualization of capitalism has been the explanation of its emergence in the first place. Both classical political economists and orthodox Marxists provide essentially materialistic accounts rooted internally in the economic realm, whether arising from technological innovation, class conflict, urbanization, or demographic pressures. In the late nineteenth century, the endogenous position was challenged by the German sociologist Max Weber (1864–1920), who, in a series of studies ultimately published as *The Protestant Ethic and the Spirit of Capitalism*, argued against the validity of all such internal explanations for the growth of capitalism. Rather, Weber proposed that the emergence of a Calvinist version of Reformed Christian theology during the sixteenth and seventeenth centuries constituted the necessary and sufficient condition for capitalism's origins. According to Weber, the Calvinist Protestant was impelled to demonstrate to his community his worthiness for salvation (the certainty of which was by no means earned by external merit, as in Catholicism) by working hard and leading an ascetic life. Such hard work, however, produced economic gains and the temptation for leisure and luxury. What was the Calvinist to do with the deserved profits of his labors? The answer was to rid himself of his riches by investing them in further economic enterprises, which in turn yielded additional wealth. As an unintended consequence of the Calvinist renunciation of worldliness, the circulation of capital was born and with it the pattern of capitalist development. Weber's antimaterialistic explanation of capitalism directly challenged the primacy of the economic realm upheld by classical political economists and Marxists alike.

The response to Weber's thesis was loud and shrill on all sides, and there is good reason to believe that in its initial statement it misrepresents history. Yet the question of why capitalism emerged when and where it did—or indeed at all—remains a widely debated topic. One dimension of this discussion has been a debate raging since the 1940s, centered mainly within differing schools of economic history, concerning the transition from feudalism to capitalism. Scholars such as Paul Sweezy and Immanuel Wallerstein, elaborating on the earlier work of Henri Pirenne (1862–1935), postulated that a commercially stimulated push toward exchange relations, centered in the growing late medieval towns, undermined feudalism and introduced the basic principles of economic rationality. Other historians, such as J. A. Raftis, considering the radical depopulation of Europe at the end of the Middle Ages caused by recurrent and severe plagues, point to purely demographic factors among the laboring masses to account for disruptions in long-established patterns of land tenure that occasioned the decline of feudalism. Still another body of literature, represented by the research of R. H. Hilton and Robert Brenner, places local political factors arising from conflicts between peasant producers and seigniorial appropriators at the center of the transition to capitalist social relations. All of these views, however, share the conviction that material factors endogenous to economic life are adequate to explain the decline of feudalism and the emergence of capitalism.

By contrast, some later scholars, mindful of the pitfalls of the Weberian analysis, have nonetheless sought to proffer an

“exogamous” account of the origins of capitalism. For example, Liah Greenfeld has posited a certain version of “nationalism” as the explanatory metric for the spread of the “spirit of capitalism.” According to Greenfeld, England in the sixteenth and seventeenth centuries generated a form of nationalism that promoted the common wealth through the pursuit of individual profit, hence leading to the accumulation and circulation of private capital. In turn, the initial success of this nationalism pushed other European countries and regions to pursue similar nationalistic programs, with varied rates of success. As with Weber, Greenfeld maintains that “cultural” or “ideological” factors are required to explain the expansion of the capitalist economy.

Globalization

With the demise of communism as an economic and ideological alternative to capitalism, many thinkers have proclaimed the final and ultimate victory of the capitalist system and its supposedly attendant sociopolitical values of democratic rights and individual liberty. According to Francis Fukuyama, for instance, history has proven that capitalism constitutes the best way of arranging the basic production and distribution of human goods. The global spread of capitalism signals an end to the contention between the fundamentally incommensurable economic ideas and doctrines; all that remains to be done is a fine-tuning of the balance between the private profit economy and those public goods that government is better qualified to provide. The process of capitalist globalization, then, represents nothing less than the civilizing of the human species.

Yet critics of capitalism persist, even in the face of optimism that capitalism will bring prosperity and well-being around the globe “in the long run.” (The economist John Maynard Keynes [1883–1946] once famously quipped that “of course, in the long run, we're all dead.”) Feminists point out that capitalism has done little to erase the economic and social disparities that exist between men and women. Authors concerned with race relations make a similar point about the market's failure to break down inequalities between people of differing skin colors and ethnicities. Environmentalists charge that capitalism's emphasis on unlimited growth as the only sustainable form of economy has led and will continue to lead to the ruin of the planet and, eventually, to the extinction of the human species. Latter-day communitarians and republicans hold that contempt for legal authority and civic virtue stems from the capitalist-inspired glorification of leisure and luxury. And religious authorities worldwide (including leaders of major Western churches, such as Pope John Paul II) have sternly criticized capitalism for eroding spiritual and moral values in favor of unrestrained accumulation and consumption. Capitalist ideas appear destined to remain controversial even, or perhaps especially, in the age of economic globalization.

AFRICA

Debates over capitalism in Africa revolve around the best means to rescue the continent from a prolonged period of stagnation and decline. Observers agree that the program, in the absence of a socialist alternative, must focus on capitalist development. There is disagreement, however, over the role of the African state in this process, as well as over whether to make raw materials exports or industrialization the main engines of growth. On the one side stand the Bretton Woods Institutions (the World Bank and International Monetary Fund, hereinafter the BWIs), who advocate a neoliberal approach based on freeing up markets for cash crop exports and reducing the state's control over national development. On the other side stand African scholars, mainly those representing the United Nations Economic Commission for Africa (UNECA), who argue for more industrialization and a much stronger role for the state. As the debate has continued, African leaders have moved closer to the BWI position with the establishment of the New Partnership for Africa's Development (NEPAD). Still, NEPAD has its critics, and the debate persists over the relative roles of the state and the market.

The Colonial Legacy and Uneven Capitalist Development

These debates have not unfolded in a vacuum; they are rooted in the colonial legacy and the response to that legacy by the first generation of African leaders. The Atlantic slave trade and colonialism blocked the conditions for the development of capitalism in Africa. In dwarfing all other commerce, the slave trade interrupted the accumulation process necessary for capitalist development. Its abolition reversed this trend by creating an opening for "legitimate" commerce, which African producers pursued by increasing their production of raw materials (such as gum, hides, and palm oil) for expanding European markets. Most of the production, however, was based on noncapitalist

labor regimes such as family and household labor or forced labor of various kinds. Colonialism did not alter this structure appreciably, because the colonial powers tended to block the development of private property and of wage labor—with the exception of migrant labor in the mining and plantation sectors. Although African industries appeared in the major cities, especially after World War II, the absence of land markets and the predominance of migrant labor ensured that capitalism did not develop fully during the colonial period. To make matters worse, the colonial powers discriminated against African capitalists in favor of nonindigenous entrepreneurs, and against women, the main agricultural producers. In sum, capitalism did take root during the colonial era, but its development was uneven, halting, and incomplete.

Independence, State-Led Development, and Import-Substitution Industrialization

Between 1960 and 1975, the new African leaders pursued industrialization in order to overcome the colonial inheritance. Rooted in the anticolonial struggle, some of their programs were socialist (as in Ghana and Algeria), some more explicitly capitalist (as in Kenya). Others, such as that in Ethiopia, were more difficult to define. In practice, however, most African countries shared a commitment to modernization and industrialization. Many followed the model of Import-Substitution Industrialization (ISI), in which governments took control over national industrialization by protecting domestic industries from foreign competition. Rooted in modernization theory, the goal was for the state to mobilize enough investment in domestic industry to achieve the "big push" thought necessary for self-sustaining economic growth. State-led development became the norm in the 1960s.

Ghana and Algeria provide two examples of the socialist variant of ISI, with a high percentage of state-owned enterprises and a professed commitment to labor rather than capital. In Ghana, Kwame Nkrumah implemented a Seven-Year Development Plan (1957–1966) designed to develop domestic industry, infrastructure, and social welfare. Nkrumah mobilized investment capital export taxes, foreign borrowing, and the sale of electricity produced by the new Volta hydroelectric dam. Nkrumah's government took control of the country's major industries as well as the agricultural sector, but he also provided state-sponsored social services such as education and health care. In Algeria, after a nationalist revolution between 1954 and 1962, the country's first leader, Ahmed Ben Bella, pursued an orthodox Marxist program, setting out to smash the middle-class traders and bureaucrats. A military coup in 1965 brought a new leader (Houari Boumédiène), who declared a fusion of socialism, Islam, and Arabic culture. Although Boumédiène left education and cultural matters in the hands of politicians who emphasized Algeria's Islamic heritage, his economic vision was secular, technocratic, and socialist. Between 1966 and 1971, the state nationalized 90 percent of the country's industries, beginning with oil and gas and then extending to industrial production. The idea was to nationalize Algeria's natural resources and use the profits to develop state-owned industrial enterprises. Ultimately this vision failed to achieve its goals, and Boumédiène's socialist program gave way to the increasing "Islamicization" of Algeria.

Kenya and South Africa provide illustrations of a more capitalist road to national development. In Kenya between 1963 and 1978, President Jomo Kenyatta supported the African bourgeoisie with government intervention into agriculture, trade, and production. This program was not uncontested; a number of prominent trade unionists, including Bildad Kaggia and Fred Kubai, argued for a radical socialist alternative. Kenyatta purged these elements from the ruling party (the Kenyan African National Union, or KANU) and pushed ahead with a program of state-managed capitalism, although one of its most famous architects, Tom Mboya, referred to it as “African socialism.” While there was an element of redistribution, the core of the Kenyatta-Mboya program is better understood as corporate capitalism, under which the state partnered with labor and capital (domestic and foreign) in the pursuit of capital formation and industrialization. Import-Substitution Industrialization provided the model, with protected home markets for consumer goods and agreements with foreign firms to import essential capital-goods inputs. By the late 1970s, Kenyatta had built up strong agricultural and industrial sectors. South Africa pursued capitalist development through ISI from an early date (the 1940s), with impressive economic results. Industrialization there, however, was racialized, and the post-1948 apartheid state ruthlessly exploited the black population, stripping them of the most basic human and political rights. This strategy worked economically until the 1970s, when the economy faltered and African resistance intensified. International sanctions exacerbated the downward trend in the 1980s, and apartheid finally met its end in 1994, when national elections brought the African National Congress to power under Nelson Mandela. Thirty years after Kenyatta had set out to Africanize the Kenyan economy, South Africa’s black majority government faced pressures for similar Africanization, but the state-led option was no longer on the table.

In Ethiopia, the emperor Haile Selassie presided after 1935 over the conversion of feudal lands into private holdings, especially in the southern part of the country. Land sales accelerated between 1960 and 1974, producing concentration in the south, with farms as big as 200,000 acres. Using ISI as a model, the state invested in agricultural commercialization along capitalist lines; in industry the government attempted to develop textile and beverage production. These policies triggered the development of an agrarian bourgeoisie during the 1960s, as well as a small industrial sector, but these were dependent on foreign capital and insignificant in relation to subsistence agriculture, which remained under the domination of the big landlords. Peasant and student resistance to the landlords emerged during the 1970s under the slogan “land to the tiller.” Grievances paralleled a wave of army mutinies, resulting in a revolution that swept away the emperor’s government in favor of a Soviet-backed regime that ruled between 1974 and 1977. In the end, the ruling military council gave way to an authoritarian regime under Haile Meriam Mengistu, which allied with the Soviets in 1977 and pushed through a collectivization program in the countryside. This program succeeded in revolutionizing the social basis of power in the rural areas, but Mengistu’s authoritarianism produced widespread resistance, and the regime finally fell in 1991.

Selassie’s state-led development programs produced some significant successes during the 1960s, with growth in gross domestic product and comprehensive social welfare programs. As the decade progressed, however, it became clear that the gains would not be sustainable and that Africa had entered a period of economic stagnation. The oil shocks of 1973 and 1979, and a wave of drought in 1975 and 1976, worsened the crisis considerably. Flagging economic performance fed into a wave of unrest and military coups, including those in Algeria (1965), Ghana (1966), and Ethiopia (1974). As the 1970s progressed, stagnation worsened and African governments became less democratic; the decade witnessed the rise of one-party states presiding over a deteriorating economic climate.

During the 1970s, it seemed that “the African state had not been up to its ‘historic mission’ of ensuring capitalist accumulation”; as Thandika Mkandwire noted, the question for African analysts was whether this was a temporary phenomenon, which could be solved while retaining Africa’s links to the world economy, or a permanent structural problem solvable only by delinking from the global system. In the 1970s several prominent dependency theorists, including Egypt’s Samir Amin and Nigeria’s Bade Onimode, took up the latter position in arguing for a radical program of African autonomy and self-sufficiency.

In the late 1970s the dependency school lost ground to a more reform-minded version of structuralism, which argued that developing nations could achieve capitalist development while retaining their links to a reformed world economy. UNECA exemplified this stance with its 1976 report entitled the *Revised Framework for the Implementation of the New International Order for Africa*. The *Revised Framework* led to the Lagos Plan of Action (LPA) of 1980, which emphasized external factors—especially the continent’s reliance on raw materials exports—as the main causes of Africa’s economic stagnation. On this issue the LPA agreed with the dependency argument that declining terms of trade, which reflected the neocolonialist exploitation of the continent, posed a serious threat to African economic development. As a result, the LPA’s goals for Africa emphasized regional and continental self-reliance and self-sustaining development, to be achieved through a greater focus on industrialization and economic cooperation. Exports would be pursued, but they would be subordinated to domestic industrial development.

The Lagos Plan of Action also placed gender on the development agenda, arguing that women were central to the development process and that their interests had to be considered in the design and implementation of development programs. This stance provided a welcome corrective to modernization theory, which insisted that women were impediments to development and should be confined to the domestic sphere. This view had been challenged in the 1970s by the Women in Development (WID) paradigm and the proclamation of the UN’s International Decade for Women (1975–1985). In 1976, the Association of African Women for Development called for the integration of women into development programs. The LPA took up this call by demanding more support for women in agriculture and industry. Although they praised the LPA’s stance as a step in the right direction, critics argued that the

plan did little to facilitate a significant shift in African women's economic and political power. This criticism formed part of a larger movement during the 1980s to recognize issues of gender inequality in the design and implementation of development programs. This approach argued that development must address issues such as the sexual division of labor and power over reproduction if African women were to benefit from economic growth.

Neoliberalism, Structural Adjustment, and the African Reaction

African recommendations between 1976 and 1980 set the scene for a protracted debate between African intellectuals and the Bretton Woods Institutions over the terms of capitalist development on the continent. In 1981, the World Bank rejected the LPA in its famous Berg Report (*Towards Accelerated Development in Sub-Saharan Africa*), which attributed economic stagnation to poor government policies rather than external factors. In pursuing Import-Substitution Industrialization, Africa's leaders had turned their backs on the continent's comparative advantage in raw materials, in favor of propping up inefficient domestic industries and a bloated public sector. The Berg Report recommended returning to an outward-oriented program of raw materials exports, to be accomplished by rolling back state intervention and freeing up market forces. Specific recommendations promoted under the rubric of Structural Adjustment Programs (SAPs) included eliminating subsidies and controls (on imports, wages, and prices), devaluing local currencies, and letting the market determine the prices for raw materials exports.

In 1989 UNECA responded to the Berg Report by reaffirming the Lagos Plan through the African Alternative Framework to Structural Adjustment (AAF-SAP). This rejected the outward-oriented, market-based strategy of structural adjustment in favor of an inward-looking, state-led program of African self-reliance. The report also recommended subsidies for exports, bilateral and multilateral trade agreements, and debt forgiveness. Finally, the AAF-SAP stressed the importance of human development, especially the provision of basic social services and education. In short, it advocated a modified version of ISI, with a greater emphasis on the export sector.

The World Bank accepted the need for human-centered development in its 1989 report, *Sub-Saharan Africa: From Crisis to Sustainable Growth*. Citing the LPA and UNECA, this accepted the need to consider human-centered development in creating an environment to enable sustainable economic growth in Africa. The report, however, clung to the bank's commitment to structural adjustment and export-led development. A subsequent bank report emphasized SAPs even more strongly, claiming that "adjustment is working" in countries that followed its prescriptions, in agriculture as well as industry. In 1999, African critics countered once again with a systematic critique of structural adjustment entitled *Our Continent, Our Future: African Perspectives on Structural Adjustment*, which modified earlier calls for African self-reliance by accepting the need to compete in the global economy on the basis of comparative advantage. This was not to be achieved, however, through SAPs and raw materials exports; instead, the

study recommended a modified version of ISI in which African governments would nurture high-value-added, labor-intensive industries producing manufactured exports for the world market. Thandika Mkandawire, coeditor of *Our Continent, Our Future*, subsequently argued for the creation of developmental states in Africa—along Asian lines—which he believed could be socially engineered by political actors and civil society within the context of African democratization.

The World Bank has not accepted ISI in the early twenty-first century, but recent bank initiatives have made more concessions to African participation and social development, particularly through the new Comprehensive Development Framework (CDF). This moves beyond structural adjustment to focus on poverty reduction and social development; it also emphasizes local ownership of the development process. African leaders have responded to this shift by creating the New Partnership for Africa's Development (NEPAD), led by Thabo Mbeki of South Africa. NEPAD accepts the BWIs' neoliberal program for capitalist development as well as the need for peace, security, and good governance. To guarantee that Africa will benefit from globalization, however, NEPAD also seeks to reform the rules of globalization to guarantee equity as well as economic growth, by reducing Western protectionism and providing for African social needs. Separating itself from UNECA, the OAU (now reconstituted as the African Union) came out in support of NEPAD in 2001.

Several prominent African scholars have criticized NEPAD for rejecting the programs proposed by UNECA in favor of the neoliberal model of the Bretton Woods Institutions. This acceptance of neoliberalism threatens to reproduce African dependence on Western donors, which is especially dangerous in an age of shrinking Official Development Assistance. African critics of NEPAD argue that any concessions to Western donors must not compromise the principles of the LPA. Some of these critics call for a return of the developmental state. Other African scholars, such as Claude Ake, have tried to find a middle ground between this position and the neoliberal program. Ake proposes a populist alternative, drawing on "the energy of ordinary people" and geared toward the development of smallholder agriculture underwritten by popular democracy. Driven by farmer participation, this approach would increase the efficiency and productivity of small farmers and provide the basis for rural industries such as food processing and packaging. The result would be a bottom-up process of endogenous economic and human development. This process would have to involve African women, who appear to have been left out of the NEPAD blueprint, in what some critics consider a step backward from the LPA on the issue of gender and development.

Claude Ake's work illustrates that the debate over capitalism in Africa in the early 2000s revolves around three poles—the market, the state, and the community—rather than two. It remains an open question, however, which of these will emerge as the preferred trustee over African capitalism in the twenty-first century.

CARTESIANISM. When René Descartes died in 1650, his work had already attracted both critics and followers. In 1632 Cartesian philosophy was being taught in the Netherlands by his disciple Henri Reneri (1593–1639), and by the mid-1630s

the far more independently minded Henri Regius (1598–1679) was setting out his own version of Cartesianism in a less guarded and more polemical way than had Descartes himself. Indeed it was Regius who attracted the first condemnation of Cartesianism, from the Dutch theologian Gisbert Voetius (1589–1676), in 1641, and in 1642 Voetius turned on Descartes himself, drawing him into a very public controversy. Cartesianism first flourished as a movement in the Netherlands, being established as early as the 1650s at Leiden and Utrecht—where there was a Cartesian club, the College der Savanten—as well as at other Dutch universities. It was through a member of one of these Dutch groups, Johannes Clauberg (1622–1665), that Cartesianism came to be established in Germany: he took up the chair of theology and philosophy at the University of Duisberg in 1651, a new university set up by the cousin of Princess Elizabeth, Descartes's correspondent and staunch defender.

Responses to Descartes

In England there was less enthusiasm. In 1644 Kenelm Digby (1603–1665) set out his own eclectic version of Descartes's philosophy (and invited Descartes to come and live in England), and later in the decade Henry More (1614–1687), the Cambridge Platonist, explored various features of Cartesianism in his correspondence with Descartes. But Cartesianism soon developed a reputation for heterodoxy in England, above all because of his rejection of any aims or ends acting in nature, and his writings were widely attacked in the second half of the seventeenth century. In France, Louis XIV banned the teaching of Cartesian philosophy, and Cartesians were excluded from the Académie des Sciences. While these attacks were directed at the perceived radical nature of Cartesianism, others such as Daniel Huet (1630–1721), a patron of the Jesuits, were charging him with plagiarism: Huet claimed he took his epistemology from the Greek skeptics, the *cogito* from Augustine, and the ontological argument from Anselm.

However, Descartes had disciples in France, including Claude Clerselier (1614–1684), who oversaw the publication of his letters and other hitherto unpublished works (a laborious undertaking, which included retrieving the trunk containing them from the sea and drying them out), establishing a vital resource for scholars all over Europe and in the New World. Moreover, there was a strong French Cartesian movement in natural philosophy, centered on Jacques Rohault (1620–1672) and Pierre-Sylvain Régis (1632–1707), in the second half of the century, and by the 1670s there was a movement applying the Cartesian principle of "clear and distinct ideas" to social and political questions, with radical consequences: François Poulain de la Barre (1647–1723) was defending the equality of the sexes on this basis, and Descartes's niece, Catherine, was proposing Cartesianism as an alternative (with women particularly in mind) to the philosophy of the universities. The peculiar political circumstances in France—Louis in effect brought a delayed Counter-Reformation to France—resulted in a radicalization of Cartesianism in the late seventeenth century. By the early decades of the eighteenth century, there were Cartesians in painting (Charles Le Brun), architecture (the Perrault brothers), and music (Jean-Philippe

Rameau), and Descartes had become almost an establishment figure in France, as the famous attack on him by Voltaire indicates, where he was castigated for being out of date in comparison with developments in English philosophy. Yet by the 1770s he was radicalized again, as the Enlightenment *philosophes* claimed him as a corevolutionary.

Descartes had a deep concern for orthodoxy—even his advocacy of mechanism, in the form of the doctrine of the inertness of nature, can be seen as a response to the heterodox naturalism of the Renaissance, where the powers attributed to nature leave little room for a divine role—and had written his *Principles of Philosophy* with a view to having it adopted as a textbook in Jesuit colleges. Nevertheless, much of his work was bitterly condemned by the Catholic Church after his death. His writings were placed on the *Index of Prohibited Books* in 1663, primarily it would seem because of his heterodox account of transubstantiation, but his view that ours is not the only solar system also elicited explicit condemnations from religious authorities throughout the remainder of the seventeenth century.

Aspects of Cartesianism

In some areas, Descartes's work was accepted as pathbreaking: above all his geometrical optics and his algebra (Isaac Newton learned his advanced mathematics in the first instance from Descartes's *Geometry*). But other areas attracted a more partisan response. We can distinguish three different kinds of concern in the Cartesian corpus in this respect: epistemology and metaphysics, cosmology, and physiology.

Although the *Meditations* is for modern readers the canonical text by Descartes, this focus is really a nineteenth-century development, and the most widely read and discussed of his works in the eighteenth century were the *Discourse on Method*, *Principles of Philosophy*, and the posthumously published *Treatise on Man*. Moreover, Descartes himself had played down the epistemological and metaphysical concerns that characterize the *Meditations*. Two themes dominate the *Meditations*—a skeptically driven epistemology and the mind/body problem—and the fortunes of these differ radically among later philosophers. Neither Baruch Spinoza (1632–1677) nor Gottfried Wilhelm von Leibniz (1646–1716) could see any value or legitimacy in beginning epistemology by answering radical skeptical problems (and Blaise Pascal [1623–1662] referred to Descartes's philosophy as “useless and uncertain”), and they abandoned the idea of a skeptically driven epistemology. Nicolas Malebranche (1638–1715) was a little closer to Descartes, although still at variance with him on key doctrines, and he was not so dismissive of skeptical beginnings for epistemology, but they work in a rather different way in his philosophy than they do in Descartes. Malebranche's philosophy vied with that of John Locke (1632–1794) at the end of the seventeenth century, and his influence on George Berkeley (1685–1753) and David Hume (1711–1776) was at least as great as that of Locke, putting skeptical issues to the fore. On the mind/body question, no one was satisfied with Cartesian dualism. Spinoza, Malebranche, and Leibniz each saw the question as being the key to success, and each offered their own distinctive solution to the question: neutral monism, occasionalism, and preestablished harmony, respectively. By the eighteenth century,

epistemologically oriented issues of mind had receded from the philosophical arena to some extent, and Cartesianism was less associated with dualism.

Two natural-philosophical topics on which Descartes's views had caused immense controversy were his account of the solar system in book 3 of the *Principles of Philosophy* and his account of the formation of the earth in book 4. Descartes's response to the Copernicanism problem was not to make the sun the center of the cosmos, as Copernicus had done, but to make the sun one of an indefinite (perhaps infinite) number of solar systems, each containing planets like ours that may harbor beings with souls. The idea that our sun was simply one star among many and could not be held to be the center of the cosmos gained credence in the course of the later seventeenth century (for those who held that the universe was infinite there was no issue, of course, since something infinite cannot have a center since every point is equidistant from an infinitely remote boundary). Even more radical was his view of the formation of the earth. The Bible had presented a creation story in which the fabric of the earth, plants, and animals, had a function in a unique, highly designed system. Descartes, by contrast, has a general theory of planet formation: planets derive from stars that have formed a coating of hard matter around their periphery and are squeezed out by surrounding solar systems, in effect becoming massive pieces of refuse that find a home in other solar systems in orbits that depend on their size and speed. No exception is made for the Earth in Descartes's account, which completely robs the formation of earth of any teleology. The account was the first nonmythological treatment of the formation of the earth and was of great influence in the eighteenth century, not least in Georges-Louis Buffon's (1707–1778) account.

More generally, Descartes's cosmology—in which planets were carried around their suns by means of the vortical motion of a swiftly circulating medium in which they were immersed—was taken very seriously, and was the dominant cosmological system before Newton's *Principia*. Indeed, in continental Europe, it was not abandoned in favor of Newtonianism for some time, primarily because it did not involve any appeal to action at a distance, which was universally perceived to be the most problematic general feature of Newton's system. Moreover, Descartes's system was far more comprehensive than Newton's, tying his vortex theory of planetary motion in with phenomena such as magnetism and static electricity.

Descartes's rejection of teleology was also manifest in his account of embryology, set out in the *Treatise on Man* and in more detail in *The Description of the Human Body*. There he insists on a radically mechanistic approach, denying that the fetus strives to realize an end or goal in the development process. The inert and initially undifferentiated matter making up the horse fetus, for example, develops into a horse not because it somehow contains “horseness” or because it is able to shape itself into a horse but because the distinctive mechanical and physio-chemical processes in the womb of a horse cause the matter to develop in a certain way. In this way, Descartes opened up the question of the physiology of fetal development. Embryology is in fact just one topic in Descartes's comprehensive attempt to mechanize physiology, and in the

Treatise on Man a variety of physiological processes are construed in such a way that we need only postulate inert matter being acted upon by mechanical forces. From this derives his infamous doctrine of *bêtes machines* (animal machines), whereby the behavior of animals, who lack minds (in the sense of awareness of their “cognitive” states) in Descartes’s account, can be accounted for fully in terms of the mechanically describable interaction between their constituent parts. In 1747 Julien Offray de La Mettrie (1709–1751) published his *Man Machine*, in which he purported to apply the Cartesian theory of animal machines to human beings (actually his materialism was different from Cartesian mechanism), claiming that this could be done successfully, so that it was unnecessary to postulate a human soul to account for human thoughts and behavior. This solidified the image of Descartes as a dangerous materialist, and it was only in the nineteenth century that the idea of Descartes as a dualist was generally revived.

By the twentieth century, interest in Descartes in Anglophone philosophy was largely confined to his skeptically driven epistemology and his dualist account of mind. The revival of interest in empiricist epistemology, helped by the rise of positivism, resulted in skepticism being taken much more seriously as a philosophical problem (for example, in A. J. Ayer). In the philosophy of mind, various alternatives to dualism—such as epiphenomenalism, behaviorism, and materialism—were devised, with the effect that Cartesian dualism was often set up as a straw man by which to contrast one’s own theory (as in Gilbert Ryle’s defense of behaviorism). By contrast, in French and German philosophy, interest centered rather on Descartes’s idea of a self as independent of the world in which it finds itself, as a locus of subjectivity that is given prior to any interactions that it has with other subjects. The ethical and political aspects of this understanding have been explored either in their own right (by Jean-Paul Sartre, for example) or in combination with a Kantian account of ethical autonomy (such as by Jürgen Habermas).

CASUISTRY. From the Latin *casūs* (cases), casuistry is a method of practical reasoning that aims to identify the scope and force of moral obligations in the varied contexts of human action. While the golden era of casuistry belongs to the period 1450–1660, its origins as an intellectual outlook on moral decision-making can be traced back to ancient philosophy and to the legal traditions of medieval Europe. Aristotle, for instance, stressed the importance of an irreducibly practical method of moral reasoning that would be attentive to “the particulars” (*ta kath’ hekasta*) of cases. The Stoics also sought to provide detailed reasons as to how universal principles could be applied to particular cases. In addition to this, they bequeathed the idea of a natural law and a set of stock “casuistical examples,” such as “Murderer at the Door” and “the Merchant of Rhodes,” which would command the attention of European moralists for many centuries.

The development of a casuistical ethics would await the emergence of medieval canon law as set down by Gratian of Bologna (d. before 1159) and his interpreters, as well as the analysis by Scholastic theologians of the problems of human life as they affected the Christian conscience. Alongside canon lawyers, Scholastic thinkers considered cases of conscience (*casūs conscientiae*) that required a sensitive analysis of their conflicting options. The casuistical tendencies inherent in medieval theology and law were further fortified by the stipulation of the Fourth Lateran Council (1215) that all members of the faithful undergo auricular confession before a priest at least once a year. As a result of this development, medieval thought witnessed the advancement of a new genre of theological writing: the *summa confessorum*. These tracts were written for pastors hearing confession and contain detailed recommendations on the types of sin as well as their appropriate penitential tariffs. Well-known fifteenth-century manuals written by Angelo Carletti di Chivasso (1411–1495) and Sylvester Mazzolini (1460–1523) helped to condition the method adopted by later casuistical treatises.

Casuistry came of age in the sixteenth century. Building on the legacy of medieval moral thought, it sought to address the complexities of early modern life by means of restating the verities of the Christian tradition, while developing new theories of moral decision-making. There is a great diversity among the varieties of casuistical writing. On the one hand, there are speculative treatments of the practical problems of natural law and moral theology. An example of this tendency can be witnessed in the writings of Jesuit theologians Gabriel Vásquez (1549 or 1551–1604), Francisco Suárez (1548–1617), and Leonardus Lessius (1554–1623). This, however, might be said to contrast with other types of casuistical writing, where the intention of the author is wholly pastoral. Here the aim was to provide pithy and more accessible treatments of the basic problems of conscience, either for the benefit of those involved in the training of priests—a need that became pressing with the establishment of seminaries after the Council of Trent (1545–1563)—or else for priests engaged in parochial work or missionary activity. Examples of this type of manual can be found in the writings of the Jesuits Franciscus Toletus (1534–1596) and Antonio Escobar y Mendoza (1589–1669).

Probabilism

A distinctive innovation of early modern casuistry was probabilism. Originally advanced by a Dominican theologian, Bartolomé de Medina (1527 or 1528–1580), the theory was later taken up by an assortment of Jesuit theologians. Put briefly, probabilism states that in a case of conscience, provided that both options for a course of action are “probable”—that is, they can be justified by right reason, good argument, and sound authority—and that one alternative is more probable than the other, one is permitted to choose the “least probable” (*minus probabilis*) alternative and is not required to act on the more probable option. Although upheld by many luminaries of early modern Scholastic theology, probabilism failed to convince the vast majority of sixteenth- and seventeenth-century thinkers that it could avoid laxism. Later confessions of probabilism, especially those developed by the Cistercian Juan Caramuel Lobkowitz (1606–1682) and the Theatine cleric Antonino Diana (1586–1663), were held to be reprehensible theories that served to endow immoral acts with the token appearance of morality.

The close association of the Jesuit order with probabilism and a residual anti-Jesuit feeling in many quarters of Catholicism and Protestantism conspired to make the terms *Jesuit*, *probabilist*, and *casuist* synonymous in the European mind from the mid-seventeenth century onward. It was, however, powerful critiques of Jesuit moral theology that did most to alter the fortunes of casuistry and condemn it to years of decline. One of the best-known broadsides was advanced by Blaise Pascal (1623–1662), whose merciless *Les lettres provinciales* (1656–1657) dealt a near fatal blow to casuistry. Pascal’s brilliant yet highly rhetorical tirade against the Jesuits sought to expose the putative inconsistencies and errors in their probabilistic method and its application to a wide range of moral questions.

Although Pascal’s critique was largely judged to have been a success, it would be wrong to think that the production of works of casuistical ethics or an interest in its issues abruptly terminated after 1657. Even when attacked by an impressive array of detractors, ranging from Dominican supporters of “probabiliorism” (the view that one should always choose the more probable alternative in a case of conscience), Jansenist rigorists, and a hodgepodge of Anglican theologians and Puritan divines to secular moral philosophers, casuistry was still a noticeable feature of the eighteenth-century intellectual landscape, especially in Roman Catholic countries. During a time when European culture and philosophy were being changed as a result of the Enlightenment, the old casuistical methods were similarly refreshed and refashioned by thinkers such as St. Alfonso Maria de’ Liguori (1696–1787), who sought to recast theories such as probabilism in order to take account of the preceding century of debate. Liguori’s efforts ensured the continuation of vestiges of the casuistical tradition in Roman Catholic moral theology up to the Second Vatican Council (1962–1965).

Decline

While a case-method approach to moral theology can be found in some Anglican writers like Robert Sanderson (1587–1663) and Jeremy Taylor (1613–1667), it is noticeable that most

philosophers and theologians in English-speaking countries eschewed probabilism and other theories of Roman Catholic casuistry. Their hostility to these ideas, however, did not prevent them from developing a Christian ethics that addressed its own understanding of cases of conscience. Puritan moralists like William Ames (1576–1633), William Perkins (1558–1602), and Richard Baxter (1615–1691) discussed the vagaries of conscience as they pertained to the practices of piety, while the aforementioned Anglicans, Sanderson and Taylor, and Joseph Hall (1574–1656), were at pains to stress the gulf that separated their treatment of the problems of morality from “papists” and other such undesirables. The effect of these developments was to sideline casuistical ethics within English-speaking moral theology for most of the late seventeenth and eighteenth centuries, with the consequence that it had become invisible by the advent of the nineteenth.

The continuing decline of casuistry can also be witnessed in modern moral philosophy. As they began to express their independence from religion and theology, moral philosophers began to doubt the relevance of a theory of practical conduct indebted to religious values and principles. Further to this, the appeal to authority inherent in a theory like probabilism was now deemed to be authoritarian in an age smitten with ideas of individual autonomy and inalienable rights. For these reasons, traditional casuistry found little favor among philosophers. Thinkers such as Adam Smith (1723–1790) expressed their hostility with aplomb, while Immanuel Kant’s (1724–1804) treatment of certain “Casuistical Questions” at the end of his *Metaphysik der Sitten* (1797) reveals the extent of the changes that had occurred within the discussion of casuistry from the mid-seventeenth century onward. For Kant, casuistry could only mean “applied ethics”; the method of the theologians had been debunked and abandoned.

This more neutral sense of casuistry as the “application of moral principles to particular cases” persisted up until the early 2000s, as can be witnessed in the isolated remarks on the subject by William Paley (1743–1805), Henry Sidgwick (1838–1900), and George Edward Moore (1873–1958). Apart from several historical studies that invariably upheld the critique of Pascal, twentieth-century thinkers were rarely inclined to study the claims of the casuistical tradition. This changed, however, with the publication in 1988 of the *Abuse of Casuistry* by Albert Jonsen and Stephen Toulmin. They argued that, notwithstanding its colorful past, the old casuistical methods of the theologians could be transposed with great benefit to ongoing debates in bioethics. Jonsen and Toulmin offered a redescription of casuistry in terms of reasoning about “paradigm cases,” a method that they deemed sufficient to fashion a viable notion of moral consensus. If not in moral philosophy, certainly in bioethics their work has been favorably received and continues to stimulate further work on a host of practical issues. Here, “casuistry” is deemed to be an important tool for making decisions of principle while respecting the requirements of particular cases. While Jonsen and Toulmin’s portrayal of the casuistical tradition is controversial—not least in its eschewal of probabilism and readiness to concur with the basic ingredients of Pascal’s questionable critique—it is interesting that as a new century begins, the much maligned

method of the theologians is enjoying something of a modest revival.

CAUSALITY. The causality debate has been centered on two issues, one metaphysical, the other epistemic. The metaphysical issue concerns the nature of the connection between cause and effect: How and in virtue of what does the cause bring about the effect? The epistemic issue concerns the possibility of causal knowledge: How, if at all, can causal knowledge be obtained?

Aristotle

Aristotle (384–322 B.C.E.) claimed a sharp distinction between understanding the fact and understanding the reason why (*dioti; aitia*). Though both types of understanding proceed via deductive syllogism, only the latter is characteristic of science because only the latter is tied to the knowledge of causes. In his *Posterior Analytics*, Aristotle contrasted the following two instances of deductive syllogism:

- A. Planets do not twinkle; what does not twinkle is near; therefore, planets are near.
- B. Planets are near; what is near does not twinkle; therefore, planets do not twinkle.

Syllogism A demonstrates the fact that planets are near but does not explain it because it does not state its causes. On the contrary, syllogism B is explanatory because it gives the reason why planets do not twinkle: because they are near. Explanatory syllogisms like B are formally similar to nonexplanatory syllogisms like A. Both are demonstrative arguments of the form: all Fs are Gs; all Gs are Hs; therefore, all Fs are Hs. The difference between them lies in the “middle term” G. In B, but not in A, the middle term states a cause. As Aristotle said: “The middle term is the cause, and in all cases it is the cause that is being sought” (90a5–10). To ask why F is H is to look for a causal link joining F and H. Aristotle’s key observation was that, besides being demonstrative, explanatory arguments should also be asymmetric: the asymmetric relation between causes and effects should be reflected in an explanatory asymmetry between the premises and the conclusion of

the explanatory arguments—the premises should explain the conclusion and not the other way around.

Aristotle took scientific knowledge to form a tight deductive-axiomatic system whose axioms are first principles, being “true and primary and immediate, and more known than and prior to and causes of the conclusion” (71b20–25). Being an empiricist, he thought that knowledge of causes has experience as its source. But experience on its own cannot lead, through induction, to the first principles: these are universal and necessary and state the ultimate causes. On pain of either circularity or infinite regress, the first principles cannot be demonstrated either. So, something besides experience and demonstration is necessary for the knowledge of first principles. This is a process of abstraction based on intuition, a process that reveals the essences of things—that is, the properties by virtue of which the thing is what it is. In the example B above, it is of the essence of something’s being near that it does not twinkle. In the rich Aristotelian ontology, causes are essential properties of their subjects and necessitate their effects. He thought that the logical necessity by which the conclusion follows from the premises of an explanatory argument mirrors the physical necessity by which causes produce their effects.

In his *Physics*, Aristotle distinguishes between four types of causes. The material cause is “that out of which a thing comes to be”; the formal cause is “the definition of its essence”; the efficient cause is “the primary source of the change or rest”; and the final cause is “that for the sake of which a thing is done” (194b23–195a3). For instance, the material cause of a statue is its material; its formal cause is its form or shape; its efficient cause is its maker; and its final cause is the purpose for which the statue was made. Aristotle thought that a complete causal explanation has to cite all four causes: the efficient cause is the active agent that puts the form on matter for a purpose.

Aristotle’s Legacy

Most of Aristotle’s views were accepted by the Scholastics. Aristotle thought that the chains of efficient causes must stop at some “unmoved movers”—that is, things that are themselves unmoved but produce motion to other things. The Scholastics thought that the only proper efficient cause was God, being the ultimate unmoved mover. Later thinkers revolted against all but efficient causality. Efficient causality, what Aristotle called “the source of motion” (195a10), was taken to be the only type of causality by all those who advocated, in one form or another, the mechanical philosophy: in their hands, efficient causality became tantamount to pushings and pullings. Final causes, in particular, were cast to the winds. Where Aristotle saw goals and purposes in nature, mechanical philosophers either excised purpose from nature (Hobbes, Hume) or placed it firmly in the hands of God (Descartes, Leibniz). The moderns also revolted, to varying degrees, against the rich ontological landscape that Aristotle had painted: essences, substantial forms, activities, and so on. However, two key Aristotelian ideas, that there is necessity in nature and that this necessity is the same as the logical necessity of a demonstrative argument, were to become part of the mainstream philosophical thinking about causality until David Hume (1711–1776) subjected them to severe criticism and undermined them.

Descartes

René Descartes (1596–1650) distinguished all substances into two sorts: thinking things (*res cogitans*) and extended things (*res extensa*). He took the essence of mind to be thought and that of matter extension. Unlike Aristotle, he thought that matter was inert (since its essence is that it occupies space). Yet, there are causal connections between bodies (bits of matter) and between minds and bodies (bits of different substances). So, two big questions emerge within Cartesianism. The first is: how is body-body interaction possible? The second is: how is mind-matter interaction possible? Descartes's answer to the first question is the so-called transference model of causality: when x causes y , a property of x is communicated to y . He thought that this view is an obvious consequence of the principle "Nothing comes from nothing." As he put it: "For if we admit that there is something in the effect that was not previously present in the cause, we shall also have to admit that this something was produced by nothing" (vol. 1, p. 97). But Descartes failed to explain how this communication is possible. Indeed, by taking matter to be an inert extended substance, he had to retreat to some external cause of motion and change. Descartes treated forces with suspicion since they did not quite fit within his tight scheme of the two distinct substances and their two essential attributes. So in his *Principles of Philosophy* (1644) he retreated to God, whom he took to be "the efficient cause of all things" (vol. 1, p. 202). But this retreat to God cannot save the transference model. Besides, the transference model of causality makes an answer to the second question above (how do mind and matter interact?) metaphysically impossible. Being distinct substances, they have nothing in common that can be communicated between them. Descartes was a rationalist. He thought that Reason alone can, by a priori reflection, discover the basic casual laws of nature, which, Descartes thought, stem directly from God.

Descartes's Successors

Descartes's successors were divided into two groups: the occasionalists and those who reintroduced activity into nature. Occasionalism is the view that the only real cause of everything is God and that all causal talk that refers to worldly substances is a sham. Nicolas Malebranche (1638–1715) drew a distinction between real causes and natural causes (or occasions). As he put it: "A true cause as I understand it is one such that the mind perceives a necessary connection between it and its effect. Now the mind perceives a necessary connection between the will of an infinite being and its effect. Therefore, it is only God who is the true cause and who truly has the power to move bodies" (1997, p. 450). Natural causes are then merely the occasions on which God causes something to happen. Malebranche pushed Cartesianism to its extremes: since a body's nature is exhausted by its extension, bodies cannot have the power to move anything, and hence to cause anything to happen. What Malebranche also added was that since causality involves a necessary connection between the cause and the effect (a view that Descartes accepted too), and since no such necessary connection is perceived in cases of alleged worldly causality (where, for instance, it is said that a billiard ball causes another one to move), there is no worldly causality: all there is in the world is regular sequences of events, which strictly

speaking are not causal. Gottfried Wilhelm Leibniz (1646–1716), on the other hand, aimed to reintroduce forces and active powers into nature. As he said: "activity is the essence of substance" (1981, p. 65). Each substance is sustained by an internal "primitive active force," which causes its subsequent states. Yet, in a rather puzzling move, he also thought that there is no real causality in nature, since Leibnizian substances (what he called "the monads") do not interact. Rather, they are coordinated with each other by God's act of preestablished harmony, which confers on them the natural agreement of exact clocks.

There is an irony to be noted at this point. Most early modern philosophers tried to solve the metaphysical issue of causality. They devised elaborate theories to explain how the cause brings about the effect. But in the end, they excised causality from nature. More mildly put, insofar as there was causality in nature it was taken to be the product of divine impulse (Descartes) or of mysterious primitive forces (Leibniz).

Hume

In his ground-breaking *A Treatise of Human Nature* (1739–1740), David Hume made the scientific hunt for causes possible, by freeing the concept of causality from the metaphysical chains that his predecessors had used to pin it down. For Hume, causality, as it is in the world, is a regular succession of event-types: one thing invariably following another. His famous first definition of causality runs as follows: "We may define a CAUSE to be 'An object precedent and contiguous to another, and where all the objects resembling the former are plac'd in like relations of precedency and contiguity to those objects, that resemble the latter'" (1978 ed., p. 170).

Taking a cue from Malebranche, Hume argued that there was no perception of the supposed necessary connection between the cause and the effect. When a sequence of events that is considered causal is observed—for example, two billiard balls hitting each other and flying apart—there are impressions of the two balls, of their motions, of their collision, and of their flying apart, but there is no impression of any alleged necessity by which the cause brings about the effect. Hume went one step further. He found worthless his predecessors' appeals to the power of God to cause things to happen, since, as he said, such claims give us "no insight into the nature of this power or connection" (p. 249). So, Hume secularized completely the notion of causality. He also found inadequate, because circular, his predecessors' attempts to explain the link between causes and effects in terms of powers, active forces, and so on. As he put it: "[T]he terms *efficacy*, *agency*, *power*, *force*, *energy*, *necessity*, *connexion*, and *productive quality*, are all nearly synonymous; and therefore 'tis an absurdity to employ any of them in defining the rest" (p. 157).

Yet Hume faced a puzzle. According to his empiricist theory of ideas, there are no ideas in the mind unless there were prior impressions (perceptions). He did, however, recognize that the concept of causality involved the idea of necessary connection. Where does this idea come from, if there is no perception of necessity in causal sequences? Hume argued that the source of this idea is the perception of "a new relation

betwixt cause and effect”: a “constant conjunction” such that “like objects have always been plac’d in like relations of contiguity and succession” (p. 88). The perception of this constant conjunction leads the mind to form a certain habit or custom: to make a “customary transition” from cause to effect. It is this felt determination of the mind that affords us the idea of necessity.

So instead of ascribing the idea of necessity to a feature of the natural world, Hume took it to arise from within the human mind, when the latter is conditioned by the observation of a regularity in nature to form an expectation of the effect, when the cause is present. Indeed, Hume offered a second definition of causality: “A CAUSE is an object precedent and contiguous to another, and so united with it, that the idea of the one determines the mind to form the idea of the other, and the impression of the one to form a more lively idea of the other” (p. 170). Hume thought that he had unpacked the “essence of necessity”: it “is something that exists in the mind, not in the objects” (p. 165). He claimed that the supposed objective necessity in nature is spread by the mind onto the world. Hume can be seen as offering an objective theory of causality in the world (since causation amounts to regular succession), which was however accompanied by a mind-dependent view of necessity. This dual aspect of Hume’s account of causality is reflected in his two definitions.

Being an empiricist, Hume argued that all causal knowledge stems from experience. He revolted against the traditional view that the necessity that links cause and effect is the same as the logical necessity of a demonstrative argument. He argued that there can be no a priori demonstration of any causal connection, since the cause can be conceived without its effect and conversely. His far-reaching observation was that the alleged necessity of causal connection cannot be proved empirically either. As he famously argued, any attempt to show, based on experience, that a regularity that has held in the past will or must continue to hold in the future will be circular and question-begging. It will presuppose a principle of uniformity of nature. But this principle is not a priori true. Nor can it be proved empirically without circularity. For any attempt to prove it empirically will have to assume what needs to be proved—namely, that since nature has been uniform in the past it will or must continue to be uniform in the future. This Humean challenge to any attempt to establish the necessity of causal connections on empirical grounds has become known as his skepticism about induction. But it should be noted that Hume never doubted that people think and reason inductively. He just took this to be a fundamental psychological fact about human beings that cannot be accommodated within the confines of the traditional conception of Reason. Indeed, Hume went on to describe in detail some basic “rules by which to judge of causes and effects” (p. 173).

Kant

It was Hume’s critique of necessity in nature that awoke Immanuel Kant (1724–1804) from his “dogmatic slumber,” as he himself famously stated. In his *Critique of Pure Reason* (1787), Kant tried to demonstrate that the principle of causality—namely, “everything that happens, that is, begins to

be, presupposes something upon which it follows by rule,” (1965 ed., p. 218)—is a precondition for the very possibility of objective experience. He took the principle of causality to be required for the mind to make sense of the temporal irreversibility that there is in certain sequences of impressions. So, whereas we can have the sequence of impressions that correspond to the sides of a house in any order we please, the sequence of impressions that correspond to a ship going downstream cannot be reversed: it exhibits a certain temporal order (or direction). This temporal order by which certain impressions appear can be taken to constitute an objective happening only if the later event is taken to be necessarily determined by the earlier one (i.e., to follow by rule from its cause). For Kant, objective events are not “given”: they are constituted by the organizing activity of the mind and in particular by the imposition of the principle of causality on the phenomena. Consequently, the principle of causality is, for Kant, a synthetic a priori principle.

Ingenious though Kant’s answer to Hume was, it was ironic in three respects. Firstly, Kant safeguarded the concept of causality but at the price of making it applicable only to the phenomena and not to the unknowable things-in-themselves (noumena). Secondly, recall that Hume argued that the supposed necessity of causal sequences cannot be observed in the sequences themselves, but is projected by the mind onto the world. Kant agreed with all this, but took this projection by the mind onto the world to be presupposed for the distinction between causal and noncausal sequences. Thirdly, Kant identified causality with the rule of natural law: causal sequences of events are lawful sequences of events. This became the main plank of the Humean philosophical tradition. Stripped from objective necessity, natural laws boil down to worldly regularities.

The Regularity View of Causality

Arthur Schopenhauer (1788–1860) charged Kant with showing the absurd result that all sequence is consequence. As he noted, the tones of a musical composition follow each other in a certain objective order and yet it would be absurd to say that they follow each other according to the law of causality. This has also been a major objection to Hume’s views. Hume left the metaphysics of causality behind, but like Kant, he ended up with a loose notion of causality. On the one hand, it seems that there can be causality without regularity. This is the case of the so-called singular causality, where one event causes another to happen without this particular (singular) sequence of events falling under a regularity. On the other hand, there can be regularity without causality. There are cases in which events regularly follow each other (like the night always follows the day) without being the cause of each other. Once more, the metaphysical and the epistemological issues of causality come to the fore. We might not be able to know that a sequence of events is causal unless we see it repeat itself many times. But this does not imply that, metaphysically speaking, causality consists in regular sequence. On the Humean view, whether or not a sequence of events is causal depends on things that happen elsewhere and elsewhere in the universe, and in particular on whether or not this particular sequence instantiates a regularity. The Humean

view may be entitled the Regularity View of Causality. But an opposite view that became prominent in the twentieth century, due mostly to the work of Curt John Ducasse (1881–1969), is that what makes a sequence of events causal is something that happens there and then: a local tie between the cause and the effect, or an intrinsic feature of the particular sequence. Ducasse's (1968) single-difference account, roughly that an event *c* causes an event *e* if and only if *c* was the last—or, the only—difference in *e*'s environment before *e* occurred, takes causality to link individual events independently of any regular association that there may or may not be between events like the cause and events like the effect. Causality, non-Humeans argue, is essentially singular: a matter of this causing that.

Most advocates of singular causation argue that, contra Hume, causality is observable. A central claim is that causal relations are embodied in language by causal verbs, such as “to bend,” “to corrode,” “to push,” “to break,” and so on. So, we are told, when one asserts that, for instance, the vase broke after being struck with a hammer, by the very use of the verb “to break,” one makes a causal claim, and one has thereby directly perceived the vase being caused to break. Elizabeth Anscombe (b. 1919) argued that since our language is infested with causal verbs, there is no mystery in the claim that we directly perceive causings: when we learn to report such things as pushings, pullings, breakings, and the like from having observed them, we have thereby learned to report causings from having observed them.

Mill

In his monumental *A System of Logic Ratiocinative and Inductive* (1843), John Stuart Mill (1806–1873) defended the Regularity View of Causality, with the sophisticated addition that in claiming that an effect invariably follows from the cause, the cause should be taken to be the whole conjunction of the conditions that are sufficient and necessary for the effect. For Mill, regular association is not, on its own, enough for causality. A regular association of events is causal only if it is “unconditional”—that is, only if its occurrence does not depend on the presence of further factors which are such that, given their presence, the effect would occur even if its putative cause was not present. A clear case in which unconditionality fails is when the events that are invariably conjoined are effects of a common cause. Ultimately, Mill took to be causal those invariable successions that constitute laws of nature.

Mill is also famous for his methods by which causes can be discovered. These are known as the Method of Agreement and the Method of Difference. According to the first, the cause is the common factor in a number of otherwise different cases in which the effect occurs. According to the second, the cause is the factor that is different in two cases, which are similar except that in the one the effect occurs, while in the other it does not. In effect, Mill's methods encapsulate what is going on in controlled experiments: we find causes by creating circumstances in which the presence (or the absence) of a factor makes the only difference to the production (or the absence) of an effect. Mill, however, was adamant that his methods work only if certain metaphysical assumptions are in place. It must be

the case that: (a) events have causes; (b) events have a limited number of possible causes; and (c) same causes have same effects, and conversely.

Logical Positivism

Bertrand Russell (1872–1970), in his “On the Notion of Cause” (1918), argued that the concept of causality was incoherent. But this was just as well for him, since, as he claimed, physics has stopped looking for causes: for “there are no such things.” Here is his famous dictum: “The law of causality, I believe, like much that passes muster among philosophers, is a relic of a bygone age, surviving, like the monarchy, only because it is erroneously supposed to do no harm” (1918, p. 180). His suspicion of the concept of causality was inherited by the movement of logical positivism (the Vienna Circle), which set the agenda for most of the philosophy of science in the twentieth century. They took to heart Hume's critique of the supposed necessary connection between cause and effect. The twist they gave to this critique was based on their verificationist criterion of meaning. As the leader of the Circle, Moritz Schlick (1882–1936), stressed, positing a “linkage” between two events would be tantamount to “committing a kind of nonsense” since all attempts to verify it would be necessarily futile (1979, p. 245). Rudolf Carnap (1891–1970) thought that insofar as the concept of causality is useful to science, it should be understood by reference to the notion of laws of nature. He insisted that the only meaningful content that causal talk can have is when we call “cause” the event, or the physical magnitude, or the physical state, which temporally precedes another one nomologically dependent on the former. The logical positivists took the laws to be exceptionless regularities that are expressed by true universal statements of the form “all Fs are Gs” (e.g., all planets move in ellipses).

Deductive-Nomological Explanation

A central element of the empiricist project was to legitimize—and demystify—the concept of causality by subsuming it under the concept of lawful explanation, which, in turn, was modeled on deductive arguments. This project culminated in Carl Hempel (1905–1977) and Paul Oppenheim's Deductive-Nomological model of explanation. According to this, to offer an explanation of an event *e* is to construct a valid deductive argument of the following form:

Antecedent/Initial Conditions

Statements of Laws

Therefore, *e* (event/fact to be explained)

So, when the claim is made that event *c* causes event *e* (e.g., that the sugar cube dissolved because it was immersed in water), it should be understood as follows: there are relevant laws in virtue of which the occurrence of the antecedent condition *c* (putting the sugar in water) is nomologically sufficient for the occurrence of the event *e* (the dissolving of the sugar). It has been a standard criticism of the Deductive-Nomological (DN) model that, insofar as it aims to offer sufficient and necessary conditions for an argument to count as a bona fide explanation, it fails. For, there are arguments that satisfy the

There are some philosophers who assert that secondary causes act through their matter, figure, and motion . . . others assert that they do so through a substantial form; others through accidents or qualities, and some through matter and form; of these some through form and accidents, others through certain virtues or faculties different from the above. . . . Philosophers do not even agree about the action by which secondary causes produce their effects. Some of them claim that causality must not be produced, for it is what produces. Others would have them truly act through their action; but they find such great difficulty in explaining precisely what this action is, and there are so many different views on the matter that I cannot bring myself to relate to them.

structure of the DN-model, and yet fail to be bona fide explanations of a certain event. For instance, one can construct a deductive-nomological “explanation” of the height of a flagpole having as premises (a statement of) the length of its shadow and (statements of) relevant laws of optics, but this is not an explanation of why the flagpole has the height it does. In a sense, this counterexample repeats a point that we saw already made by Aristotle—namely, that good explanations are asymmetric: they explain effects in terms of causes and not conversely. Conversely, there are bona fide explanations that fail to instantiate the DN-model. For instance, one can construct an explanation of why there was a car crash (by telling a causal story of how it happened) without referring to any law at all. The joined message of these counterexamples is that the DN-model fails precisely because it ignores the role of causality in explanation. In other words, the moral of the counterexamples is there is more to the concept of causality than what can be captured by DN-explanations.

Laws of Nature

Be that as it may, the Deductive-Nomological model, as well as any attempt to tie causality to laws, faces a rather central conceptual difficulty: the problem of how to characterize the laws of nature. Most Humeans have come to adopt the Regularity View of Laws: laws of nature are regularities. Yet, they have a hurdle to jump: not all regularities are causal. Nor can all regularities be deemed laws of nature. The night always follows the day, but it is not caused by the day. And, though a regularity, it is not a law of nature that all coins in my pocket are euros. So, the Humeans have to draw a distinction between the good regularities (those that constitute the laws of nature) and the bad ones—that is, those that are, as Mill put it, “conjunctions in some sense accidental.” Only the former can underpin causality and play a role in explanation. Among the many attempts to distinguish between laws and accidents, the most promising is what may be called the web of laws view. According to this, the regularities that constitute the laws of nature are those that are expressed by the axioms and

theorems of an ideal deductive system of our knowledge of the world, which strikes the best balance between simplicity and strength. Whatever regularity is not part of this best system is merely accidental: it fails to be a genuine law of nature. The gist of this approach, which has been advocated by Mill, Frank Ramsey (1903–1930), and David Lewis (1941–2001), is that no regularity, taken in isolation, can be deemed a law of nature. The regularities that constitute laws of nature are determined in a kind of holistic fashion by being parts of a structure. But despite its many attractions, this view does not offer a purely objective account of laws of nature.

A contrary view that has been defended by David Armstrong (b. 1926) is that lawhood cannot be reduced to regularity. Lawhood is said to be a certain necessitating relation among natural properties. An attraction of this view is that it makes clear how laws can cause anything to happen: they do so because they embody causal relations among properties. But the central concept of nomic necessitation is still not sufficiently clear.

Inus Conditions

Among the more recent attempts to develop more defensible versions of the Regularity View of Causality, J. L. Mackie’s (1917–1981) inus-conditions approach stands out. Mackie stressed that effects have, typically, a “plurality of causes” (p. 61). That is, a certain effect can be brought about by a number of distinct clusters of factors. Each cluster is sufficient to bring about the effect, but none of them is necessary. So, he takes the regularities in nature to have a complex form $(A \& B \& C \text{ or } D \& E \& F \text{ or } G \& H \& I) \leftrightarrow E$, which should be read as: all $(A \& B \& C \text{ or } D \& E \& F \text{ or } G \& H \& I)$ are followed by E , and all E are preceded by $(A \& B \& C \text{ or } D \& E \& F \text{ or } G \& H \& I)$. How do we pick out the cause of an event in this setting? Each single factor of $A \& B \& C$ (e.g., A) is related to the effect E in an important way. It is an *insufficient* but *nonredundant* part of an *unnecessary* but *sufficient* condition for E . Using the first letters of the italicized words, Mackie has called

such a factor an inus condition. Causes, then, are inus conditions. So to say that short circuits cause house fires is to say that the short circuit is an inus condition for house fires. It is an insufficient part because it cannot cause the fire on its own (other conditions such as oxygen, inflammable material, etc. should be present). It is, nonetheless, a nonredundant part because, without it, the rest of the conditions are not sufficient for the fire. It is just a part, and not the whole, of a sufficient condition (which includes oxygen, the presence of inflammable material, etc.), but this whole sufficient condition is not necessary, since some other cluster of conditions, for example, an arsonist with gasoline, can produce the fire.

Counterfactual Dependence

In his *Enquiry Concerning Human Understanding* (1748) Hume stated briefly another way to view causality. He said that an object is the cause of another when “if the first object had not been, the second never had existed” (1975 ed., p. 146). This view has been articulated into a theory of causality by David Lewis. Lewis (1986) defined causality in terms of the counterfactual dependence of the effect on the cause: the cause is rendered counterfactually necessary for the effect. For instance, to say that the short-circuit caused the fire is to say that if the short-circuit had not happened, the fire would not have ensued. To be more precise, Lewis defined causality by reference to a *causal chain* of counterfactually dependent events, where a sequence of events (C, E, E', \dots) is a chain of counterfactual dependence if and only if E counterfactually depends on C , E' counterfactually depends on E , and so on. This move is meant to enforce that causation is a transitive relation among events (that is, if C causes E and E causes E' , then C causes E'). As Lewis put it: “one event is a cause of another if and only if there exists a causal chain leading from the first to second” (p. 167). Statements such as “if C had happened, then E would have happened” are called counterfactual conditionals (another example, “if this sugar cube had been in water, it would have dissolved”) for they state what could or could not have happened, under certain circumstances. But it has been notoriously difficult to specify the conditions under which counterfactual conditionals are true or false. Lewis articulated a rather complicated logic of counterfactual conditionals, which was based on the idea that, besides the actual world, there are also other possible worlds, which can be deemed more or less similar to the actual. A chief but not inviolable criterion for judging the similarity among worlds was taken to be whether the same laws of nature govern the worlds under comparison.

Though it is still one of the main contestants, this view of causality faces important difficulties. A chief among them comes from cases of causal overdetermination, where there are two factors each of which is sufficient to bring about the effect, but none of them is necessary, since even if the one was not present, the other factor would ensure the occurrence of the effect. For instance, two rocks are simultaneously thrown at a bottle and they shatter it. They both caused the shattering, but the effect is not counterfactually dependent on either of them, since if the first rock had missed the bottle, the other would have still shattered it. So there is causality without the cause being counterfactually dependent on the effect.

Here is a billiard-ball lying on the table, and another ball moving towards it with rapidity. They strike; and the ball, which was formerly at rest, now acquires a motion. This is as perfect an instance of the relation of cause and effect as any which we know, either by sensation or by reflection. Let us therefore examine it. 'Tis evident, that the two balls touched one another before the motion was communicated, and that there was no interval betwixt the shock and the motion. *Contiguity* in time and place is therefore a requisite circumstance to the operation of all causes. 'Tis evident likewise, that the motion, which was the cause, is prior to the motion, which was the effect. *Priority* in time, is therefore another requisite circumstance in every cause. But this is not all. Let us try any other balls of the same kind in a like situation, and we shall always find, that the impulse of the one produces motion in the other. Here therefore is a *third* circumstance, viz., that is a constant conjunction betwixt the cause and effect. Every object like the cause, produces always some object like the effect. Beyond these three circumstances of contiguity, priority, and *constant conjunction*, I can discover nothing in this cause. The first ball is in motion; touches the second; immediately the second is in motion: and when I try the experiment with the same or like balls, in the same or like circumstances, I find that upon the motion and touch of the one ball, motion always follows in the other. In whatever shape I turn this matter, and however I examine it, I can find nothing farther. (pp. 649–650)

Probabilistic Causality

No matter how one thinks about causality, there are certain platitudes that this concept should satisfy. One of them may be called the difference platitude: causes make a difference—namely, things would be different if the causes of some effects were absent. This platitude is normally cast in two ways. We

[W]e derived the principle that everything that happens has a cause from the condition under which alone a concept of happening in general is objectively possible—namely, by showing that the determination of an event in time, and therefore the event as belonging to experience, would be impossible save as standing under such a dynamical rule.

have already seen the first, the counterfactual way: if the cause had not been, the effect would not have been either. The other is a probabilistic way: causes raise the chances of their effects—namely, the probability that a certain event happens is higher if we take into account its cause than if we do not. This thought has led to the development of theories of probabilistic causality. We do rightly claim that smoking causes lung cancer, even though there is no regular association (or deterministic connection) between smoking and lung cancer. Some philosophers, most notably Patrick Suppes (1984) and Nancy Cartwright (1983), think that this is already a good argument against the view that causality is connected with invariable sequences or regularities. They then analyze causal claims in terms of probabilistic relations among magnitudes, capitalizing on the intuition that causes (mostly, but not invariably) raise the probabilities of their effects. Some think that there are good empirical reasons to jettison determinism (roughly, that each and every event has a fully sufficient set of causes) in favor of indeterminism (roughly, that there are genuinely chancy events). They then try to show that indeterminism and causality mix well, given the thought that a certain event can be caused to happen even though its cause made only a difference to its chance to happen. Interestingly, these ideas are extended to deterministic causality as well, with the prime thought being that an effect is deterministically caused to happen if its probability, given its cause, is unity.

Causes as Recipes

Another central platitude of the concept of causality may be called the recipe platitude: causes are recipes for producing or preventing their effects. This platitude is normally cast in terms of manipulability: causes can be manipulated to bring about certain effects. G. H. von Wright (1906–2003) developed this thought into a full-blown theory of causality. He took it that what confers on a sequence of events the character of causal connection is “the possibility of subjecting cause-factors to experimental test by interfering with the ‘natural’ course of events” (1993, p. 117). Since manipulation is a distinctively human action, he concluded that the causal relation is dependent upon the concept of human action. But his views were

taken to be too anthropomorphic. For, do we not think that there would be causal relations, even if there would not be any humans around capable of manipulating anything? Yet, recently, there have been important attempts to give a more objective gloss to the idea of manipulation. James Woodward (2003) introduces a notion of intervention that is not restricted to human action and argues that a relationship among some magnitudes X and Y is causal if, were one to intervene to change the value of X appropriately, the relationship between X and Y would remain invariant but the value of Y would change, as a result of the intervention on X . This interventionist account has been developed by Judea Pearl (2001) into a rather powerful mathematical tool, known as Bayesian probabilistic networks, for discovering and establishing causal relations from relations of probabilistic dependence among variables. An attraction of the interventionist approach is that it is not so much concerned with the metaphysics of causality as with the epistemological and methodological circumstances under which causal facts can be ascertained.

Physical Causality

Lately, there have been a number of attempts to show that there is more to causality than regular succession by positing a physical mechanism that links cause and effect. In his *Scientific Explanation and the Causal Structure of the World* (1984), Wesley Salmon (1925–2001) advanced a mechanistic approach, roughly that an event c causes an event e if and only if there is a causal process that connects c and e . Borrowing an idea of Hans Reichenbach's (1956), Salmon characterized “causal” those processes that are capable of transmitting a mark, where a mark is a modification of the structure of a process. Later on, Salmon (1997) and Phil Dowe (2000) took causality to consist in the exchange or transfer of some conserved quantity, such as energy-momentum or charge. Such accounts may be called transference models because they claim that causality consists in the transfer of something (some physical quantity) between the cause and its effect. They claim that causality need not involve regularities or laws. Rather, it consists in a local physical tie between cause and effect. But there is a drawback. Even if it is granted that these models offer neat accounts of causality at the level of physical events or processes, they can be generalized as accounts of causality *simpliciter* only if they are married to strong reductionistic views that all worldly phenomena (be they social or psychological or biological) are, ultimately, reducible to physical phenomena. We saw earlier that Descartes, too, advanced a transference model of causality and that he stumbled on the issue of mental causality: how can the mental cause anything physical to happen, as it manifestly does? The irony is that the very same hurdle might have to be jumped by the advocates of the modern transference models.

Neo-Aristotelianism

Hume found any appeal to causal powers suspect, since he thought there were no impressions of them. Hume's views were dominant until the last quarter of the twentieth century, when there was a resurgence of Aristotelianism. A few contemporary philosophers think that causation should be best understood in terms of causal powers—that is, powers, dispositions, and

capacities things have to cause other things to happen. These powers are supposed to stem from the nature or essence of a thing and they determine what a thing is and what it can do. The causal laws that govern the world are supposed to stem from these causal powers. According to Brian Ellis (2001), a chief defender of this view, causal laws state necessary truths about how things are intrinsically disposed to behave. But many philosophers find these views unappealing, not least because they fail to explain the fundamental notion of causal power.

CAUSATION. Philosophers have theorized about causation since well before Aristotle, who distinguished several types of causation: efficient, material, final, and formal. For example, a wood carving is made by an artist (the efficient cause) by chiseling a piece of wood (the material cause) for the purpose of creating a beautiful object (the final cause), arriving at something that has the properties of a wood carving (the formal cause).

Although Aristotle's typology framed discussions of causation until the scientific revolution and in some circles even until David Hume, the focus settled onto analyzing efficient causation and in particular on understanding the kinds of substances that might interact causally. René Descartes, for example, separated material and mental substances and wrote extensively on how cross-substance causation might happen. Discussions of causation thus became entangled with the metaphysics of substance, and positions ranged all the way from Baruch Spinoza, who claimed there is only one type of substance, to Gottfried Wilhelm Leibniz, who claimed there was an infinity of unique substances, one per monad. Everyone wanted to understand causation as involving some "power" to produce change, and different substances possess different sorts of powers over their own and other substances. For example, the empiricist Bishop George Berkeley argued that our ideas (sensations) cannot be caused by other ideas or matter, because ideas and matter are "inert" and do not have the sort of causal "power" necessary for efficient causation. Only an agent like God or a willful person possesses such power. John Locke, in *An Essay concerning Human Understanding*, wrote voluminously trying to explicate the idea of causal power in empiricist terms. David Hume, the brilliant eighteenth-century Scottish philosopher, finally rejected the notion of causal power as being beyond direct observation, and he recast the problem of understanding the connection between a cause and its effect as another version of the problem of induction. Although causes always seem to be followed by their effects, the bond between them might well be nothing more than a psychological habit we develop as a result of regularly perceiving the idea of one type of object or event (e.g., thunder) just after the idea of another (e.g., lightning). Hume's challenge was to find compelling reasons for believing that when an object similar to one we have seen previously occurs, then the effect must necessarily occur. No one has succeeded in answering Hume's challenge, but his effect on the debate was as powerful as Aristotle's. All modern theories of causation begin with something like Hume's story: there are objects or events that we can group as similar, like the events of walking in the rain with no coat and developing a cold. They all ask what does it mean to assert that the relation between these events is causal.

Modern Theories of Causation

Practically, causation matters. Juries must decide, for example, whether a pregnant mother's refusal to give birth by cesarean section was the cause of the death of one of her twins. Policy makers must decide whether violence on TV causes violence in life. Neither question can be coherently debated without some theory of causation. Fortunately (or not, depending on where one sits), a virtual plethora of theories of causation have been championed in the third of a century between 1970 and 2004.

Before the sketch of a few of the major theories, however, consider what one might want out of a theory of causation. First, although one can agree that causation is a relation, what are the relata? Are causes and effects *objects*, like moving billiard balls? Are they *particular events*, like the *Titanic* hitting an iceberg in 1912? Or are they *kinds of events*, like smoking cigarettes and getting lung cancer? As it turns out, trying to understand causation as a relation between particular objects or events is quite a different task than trying to understand it as relation between *kinds* of occurrences or events.

Second, one wants a theory to clarify, explain, or illuminate those properties of causation that one can agree are central. For example, whatever causation is, it has a direction. Warm weather causes people to wear lighter clothing, but wearing lighter clothing does not cause warm weather. A theory that fails to capture the *asymmetry of causation* will be unsatisfying.

Third, one knows that in many cases one thing can occur regularly *before* another, and thus appear to be related as cause and effect, but is in fact the effect of a common cause, a phenomenon called *spurious causation*. For example, flashes of lightning appear just before and seem to cause the thunderclaps that follow them, but in reality both are effects of a common cause: the superheating of air molecules from the massive static electric discharge between the earth and the atmosphere. A good theory of causation ought to successfully separate cases of real from spurious causation.

The history of thinking on causation from 1970 to 2004 can be organized in many ways, but the one that separates matters best, both temporally and conceptually, is captured eloquently by Clark Glymour:

Philosophical theories come chiefly in two flavors, Socratic and Euclidean. Socratic philosophical theories, whose paradigm is *The Meno*, advance an analysis (sometimes called an "explication"), a set of purportedly necessary and sufficient conditions for some concept, giving its meaning; in justification they consider examples, putative counterexamples, alternative analyses and relations to other concepts. Euclidean philosophical theories, whose paradigm is *The Elements*, advance assumptions, considerations taken to warrant them, and investigate the consequences of the assumptions. Socratic theories have the form of definitions. Analyses of "virtue," "cause," "knowledge," "confirmation," "explanation," are ancient and recent examples. Euclidian theories have the form of formal or informal axiomatic systems and are often essentially mathematical: Euclid's geometry, Frege's

EVENT CAUSATION VERSUS CAUSAL GENERALIZATIONS

Legal cases and accident investigations usually deal with a particular event and ask what caused it. For example, when in February 2003 the space shuttle *Columbia* burned up during reentry, investigators looked for the cause of the disaster. In the end, they concluded that a chunk of foam insulation that had broken off and hit the wing during launch was the cause of a rupture in the insulating tiles, which was the cause of the shuttle's demise during reentry. Philosophers call this *event causation*, or *actual causation*, or *token-causation*.

Policy makers, statisticians, and social scientists usually deal with *kinds* of events, like graduating from college, or becoming a smoker, or playing lots of violent video games. For example, epidemiologists in the 1950s and 1960s looked for the kind of event that was causing a large number of people to get lung cancer, and they identified smoking as a primary cause. Philosophers call this *type-causation*, or *causal generalization*, or *causation among variables*.

The properties of causal relationships are different for actual causation and for causal generalizations. Actual causation is typically considered transitive, antisymmetrical, and irreflexive. If we are willing to say that one event A, say the *Titanic* hitting an iceberg on 12 April 1912,

caused another event B, its hull ripping open below the water line and taking on water moments later, which in turn caused a third event C, its sinking a few hours later, then surely we should be willing to say that event A (hitting the iceberg) caused event C (sinking). So actual causation is transitive. (Plenty of philosophers disagree, for example, see the work of Christopher Hitchcock.) It is antisymmetrical because of how we view time. If a particular event A caused a later event B, then B did not cause A. Finally, single events do not cause themselves, so causation between particular events is irreflexive.

Causal generalizations, however, are usually but not always transitive, definitely not antisymmetrical, and definitely not irreflexive. In some cases causal generalizations *are* symmetrical, for example, confidence causes success, and success causes confidence, but in others they are not, for example, warm weather causes people to wear less clothing, but wearing less clothing does not cause the weather to warm. So causal generalizations are *asymmetrical*, not antisymmetrical, like actual causation. When they are symmetrical, causal generalizations are reflexive. Success breeds more success and so forth.

logic, Kolmogorov's probabilities, That of course does not mean that Euclidean theories do not also contain definitions, but their definitions are not philosophical analyses of concepts. Nor does it mean that the work of Euclidean theories is confined to theorem proving: axioms may be reformulated to separate and illuminate their contents or to provide justifications (n.p.).

For causation, Socratic-style analyses dominated from approximately 1970 to the mid-1980s. By then, it had become apparent that all such theories either invoked noncausal primitives that were more metaphysically mysterious than causation itself, or were circular, or were simply unable to account for the asymmetry of causation or to separate spurious from real causation. Slowly, Euclidean style theories replaced Socratic ones, and by the early 1990s a rich axiomatic theory of causation had emerged that combined insights from statisticians, computer scientists, philosophers, economists, psychologists, social scientists, biologists, and even epidemiologists.

The 1970s and Early 1980s: The Age of Causal Analyses

Several different analyses of causation were given serious attention in the 1970s. One school gave an account based on counterfactuals, another used Hume's idea of regularity or constant conjunction, still another attempted to reduce causation to probabilistic relations and another to physical processes interacting spatiotemporally, and yet another was founded on the idea of manipulability.

The counterfactual theory. In the late 1960s Robert Stalnaker began the rigorous study of sentences that assert what are called *contrary-to-fact conditionals*. For example, "If the September 11, 2001, terrorist attacks on the United States had not happened, then the United States would not have invaded Afghanistan shortly thereafter." In his classic 1973 book *Counterfactuals*, David Lewis produced what has become the most popular account of such statements. Lewis's theory rests on two ideas: the existence of alternative "possible worlds" and a similarity metric over these worlds. For example, it is intuitive

OVERDETERMINATION AND PREEMPTION

A spy, setting out to cross the desert with some key intelligence, fills his canteen with just enough water for the crossing and settles down for a quick nap. While he is asleep, Enemy A sneaks into his tent and pokes a very small hole in the canteen, and a short while later enemy B sneaks in and adds a tasteless poison. The spy awakes, forges ahead into the desert, and when he goes to drink from his canteen discovers it is empty and dies of thirst before he can get water. What was the cause of the spy's death? According to the counterfactual theory, neither enemy's action caused the death. If enemy A had not poked a hole in the canteen, then the spy still would have died by poison. If enemy B had not put poison into the canteen, then he still would have died from thirst. Their actions overdetermined the spy's death, and the pinprick from enemy A preempted the poison from enemy B.

In the beginning of the movie *Magnolia*, a classic causal conundrum is dramatized. A

fifteen-year-old boy goes up to the roof of his ten-story apartment building, ponders the abyss, and jumps to his death. Did he commit suicide? It turns out that construction workers had installed netting the day before that would have saved him from the fall, but as he is falling past the fifth story, a gun is shot from inside the building by his mother, and the bullet kills the boy instantly. Did his mother murder her son? As it turns out, his mother fired the family rifle at his drunk stepfather but missed and shot her son by mistake. She fired the gun every week at approximately that time after their horrific regular argument, which the boy cited as his reason for attempting suicide, but the gun was usually not loaded. This week the boy secretly loaded the gun without telling his parents, presumably with the intent of causing the death of his stepfather. Did he, then, in fact commit suicide, albeit unintentionally?

that the possible world identical to our own in all details except for the spelling of my wife's middle name ("Anne" instead of "Ann") is closer to the actual world than one in which the asteroid that killed the dinosaurs missed the earth and primates never evolved from mammals.

For Lewis, the meaning and truth of counterfactuals depend on our similarity metric over possible worlds. When we say "if A had not happened, then B would not have happened either," we mean that for each possible world W_1 in which A did not happen and B did happen, there is at least one world W_2 in which A did not happen and B did not happen that is closer to the actual world than W_1 . Lewis represents counterfactual dependence with the symbol: $\square \rightarrow$, so $P \square \rightarrow Q$ means that, among all the worlds in which P happens, there is a world in which Q also happens that is closer to the actual world than all the worlds in which Q does not.

That there is some connection between counterfactuals and causation seems obvious. We see one event A followed by another B. What do we mean when we say A caused B? We might well mean that if A had not happened, then B would not have happened either. If the *Titanic* had not hit an iceberg, it would not have sunk. Formalizing this intuition in 1973, Lewis analyzed causation as a relation between two events A and B that both occurred such that two counterfactuals hold:

1. $A \square \rightarrow B$, and
2. $\sim A \square \rightarrow \sim B$

Because both A and B already occurred, the first is trivially true, so we need only assess the second in order to assess whether A caused B.

Is this analysis satisfactory? Even if possible worlds and a similarity metric among them are clearer and less metaphysically mysterious than causal claims, which many dispute, there are two major problems with this account of causation. First, in its original version it just misses cases of overdetermination or preemption, that is, cases in which more than one cause was present and could in fact have produced the effect.

Even more importantly, Lewis's counterfactual theory has a very hard time with the asymmetry of causality and only a slightly better time with the problem of spurious causation. Consider a man George who jumps off the Brooklyn Bridge and plunges into the East River. (This example is originally from Horacio Arlo-Costa and is discussed in Hausman, 1998, pp. 116–117.) On Lewis's theory, it is clear that it was jumping that caused George to plunge into the river, because had George not jumped, the world in which he did not plunge is closer to the actual one than any in which he just happened to plunge for some other reason at approximately the same time. Fair enough. But consider the opposite direction: if George had not plunged, then he would not have jumped. Should we assent to this counterfactual? Is a world in which George did not plunge into the river and did not jump closer to the real one than any in which he did not plunge but did jump? Most everyone except Lewis and his followers would

say yes. Thus on Lewis's account jumping off the bridge caused George to plunge into the river, but plunging into the river (as distinct from the idea or goal of plunging into the river) also caused George to jump. (Lewis and many others have amended the counterfactual account of causation to handle problems of overdetermination and preemption, but no account has yet satisfactorily handled the asymmetry of causality.)

For the problem of spurious causation, consider Johnny, who gets infected with the measles virus, runs a fever, and shortly thereafter gets a rash. Is it reasonable to assert that if Johnny had not gotten a fever, he would not have gotten a rash? Yes, but it was not the fever that caused the rash, it was the measles virus. Lewis later responded to this problem by prohibiting "backtracking" and to the problem of overdetermination and preemption with an analysis of "influence," but the details are beyond our scope.

Mackie's regularity account. Where David Lewis tried to base causation on counterfactuals, John Mackie tried to extend Hume's idea that causes and effects are "constantly conjoined" and to use the logical idea of necessary and sufficient conditions to make things clear. In 1974 Mackie published an analysis of causation in some part aimed at solving the problems that plagued Lewis's counterfactual analysis, namely overdetermination and preemption. Mackie realized that *many* factors combine to produce an effect, and it is only our idiosyncratic sense of what is "normal" that draws our attention to one particular feature of the situation, such as hitting the iceberg. It is a set of factors, for example, A: air with sufficient oxygen, B: a dry pile of combustible newspaper and kindling, and C: a lit match that *combine* to cause D: a fire. Together the *set* of factors A, B, and C are *sufficient* for D, but there might be other sets that would work just as well, for example A, B, and F: a bolt of lightning. If there were a fire caused by a lit match, but a bolt of lightning occurred that also would have started the fire, then Lewis's account has trouble saying that the lit match caused the fire, because the fire would have started without the lit match; or put another way, the match was not necessary for starting the fire. Mackie embraces this idea and says that X is a cause of Y just in case X is an Insufficient but Necessary part of an Unnecessary but Sufficient *set* of conditions for Y, that is, an INUS condition. The set of conditions that produced Y need not be the only sufficient set, thus the set is not necessary, but X should be an essential part of a set that is sufficient for Y.

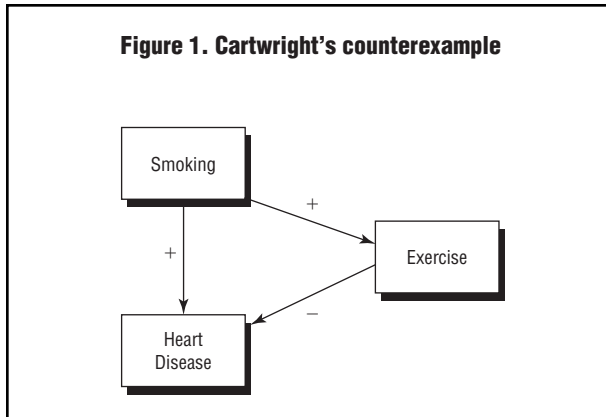

Again, however, the asymmetry of causality and the problem of spurious causation wreak havoc with Mackie's INUS account of causation. Before penicillin, approximately 10 percent of those people who contracted syphilis eventually developed a debilitating disease called paresis, and nothing doctors could measure seemed to tell them anything about which syphilitics developed paresis and which did not. As far as is known, paresis can result only from syphilis, so having paresis is by itself sufficient for having syphilis. Consider applying Mackie's account to this case. Paresis *is* an INUS condition of syphilis, because it is sufficient by itself for having syphilis, but it is surely not a cause of it.

Consider the measles. If we suppose that when people are infected they either show both symptoms (the fever and rash) or their immune system controls it and they show neither, then the INUS theory gets things wrong. The fever is a necessary part of a set that is sufficient for the rash: {fever, infected with measles virus}, and for that matter the rash is a necessary part of a set that is sufficient for fever: {rash, infected with measles virus}. So, unfortunately, on this analysis fever is an INUS cause of rash and rash is also a cause of fever.

Probabilistic causality. Twentieth-century physics had a profound effect on a wide range of ideas, including theories of causation. In the years between about 1930 and 1970 the astounding and unabated success of quantum mechanics forced most physicists to accept the idea that, at bedrock, the material universe unfolds probabilistically. Past states of subatomic particles, no matter how finely described, do not determine their future states, they merely determine the probability of such future states. Embracing this brave new world in 1970, Patrick Suppes published a theory of causality that attempted to reduce causation to probability. Whereas electrons have only a propensity, that is, an objective physical probability to be measured at a particular location at a particular time, perhaps macroscopic events like developing lung cancer have only a probability as well. We observe that some events seem to quite dramatically change the probability of other events, however, so perhaps causes *change the probability* of their effects. If $\Pr(E)$, the probability of an event E, changes given that another event C has occurred, notated $\Pr(E | C)$, then we say E and C are *associated*. If not, then we say they are *independent*. Suppes was quite familiar with the problem of asymmetry, and he was well aware that association and independence are perfectly symmetrical, that is, $\Pr(E) = \Pr(E | C) \Leftrightarrow \Pr(C) = \Pr(C | E)$. He was also familiar with the problem of spurious causation and knew that two effects of a common cause could appear associated. To handle asymmetry and spurious causation, he used time and the idea of *conditional* independence. His theory of probabilistic causation is simple and elegant:

1. C is a *prima facie* cause of E if C occurs before E in time, and C and E are associated, that is, $\Pr(E) < \Pr(E | C)$.
2. C is a *genuine cause* of E if C is a *prima facie* cause of E, and there is *no* event Z prior to C such that C and E are independent conditional on Z, that is, there is *no* Z such that $\Pr(E | Z) = \Pr(E | Z, C)$.

Without doubt, the idea of handling the problem of spurious causation by looking for other events Z that *screen off* C and E, although anticipated by Hans Reichenbach, Irving John Good, and others, was a real breakthrough and remains a key feature of any metaphysical or epistemological account that connects causation to probability. Many other writers have elaborated a probabilistic theory of causation with metaphysical aspirations, for example, Ellery Eells, David Papineau, Brian Skyrms, and Wolfgang Spohn.

Probabilistic accounts have drawn criticism on several fronts. First, defining causation in terms of probability just replaces one mystery with another. Although we have managed to produce a mathematically rigorous theory of probability, the core of which is now widely accepted, we have not managed to produce a reductive metaphysics of probability. It is still as much a mystery as causation. Second, there is something unsatisfying about using time explicitly to handle the asymmetry of causation and at least part of the problem of spurious causation (we can only screen off spurious causes with a *Z* that is prior in time to *C*).

Third, as Nancy Cartwright persuasively argued in 1979, we cannot define causation with probabilities alone, we need causal concepts in the definiens (definition) as well as the definiendum (expression being defined). Consider her famous (even if implausible) hypothetical example, shown in Figure 1: smoking might cause more heart disease, but it might also cause exercise, which in turn might cause *less* heart disease. If the negative effect of exercise on heart disease is stronger than the positive effect of smoking and the association between smoking and exercise is high enough, then the probability of heart disease given smoking could be *lower* than the probability of heart disease given not smoking, making it appear as though smoking prevents heart disease instead of causing it.

The two effects could also exactly cancel, making smoking and heart disease look independent. Cartwright's solution is to look at the relationship between smoking and heart disease within groups that are doing the same amount of exercise, that is, to look at the relationship between smoking and heart disease *conditional* on exercise, even though exercise does not in this example come before smoking, as Suppes insists it should. Why does Suppes not allow *Z*s that are prior to *E* but after *C* in time? Because that would allow situations in which although *C* really does cause *E*, its influence was entirely mediated by *Z*, and by conditioning on *Z* it appears as if *C* is *not* a genuine cause of *E*, even though it is (Fig. 2).

In Cartwright's language: Smoking should increase the probability of heart disease in *all causally homogeneous situations* for heart disease. The problem is circularity. By

referring to the causally homogeneous situations, we invoke causation in our definition. The moral Cartwright drew, and one that is now widely accepted, is that causation is *connected* to probability but cannot be *defined* in terms of it.

Salmon's physical process theory. A wholly different account of causation comes from Wes Salmon, one of the pre-eminent philosophers of science in the later half of the twentieth century. In the 1970s Salmon developed a theory of scientific explanation that foundered partly on an asymmetry very similar to the asymmetry of causation. Realizing that causes explain their effects but not vice versa, Salmon made the connection between explanation and causation explicit. He then went on to characterize causation as an interaction between two *physical processes*, not a probabilistic or logical or counterfactual relationship between events. A *causal interaction*, according to Salmon, is the intersection of two *causal processes* and the exchange of some invariant quantity, like momentum. For example, two pool balls that collide each change direction (and perhaps speed), but their total momentum after the collision is (ideally) no different than before. An interaction has taken place, but momentum is conserved. Explaining the features of a causal process is beyond the scope of such a short review article, but Phil Dowe has made them quite accessible and extremely clear in a 2000 review article in the *British Journal for Philosophy of Science*.

It turns out to be very difficult to distinguish real causal processes from pseudo-processes, but even accepting Salmon's and Dowe's criteria, the theory uses time to handle the asymmetry of causation and has big trouble with the problem of spurious causation. Again, see Dowe's excellent review article for details.

Manipulability theories. Perhaps the most tempting strategy for understanding causation is to conceive of it as how the world responds to an intervention or manipulation. Consider a well-insulated, closed room containing two people. The room temperature is 58 degrees Fahrenheit, and each person has a sweater on. Later the room temperature is 78 degrees Fahrenheit and each person has taken his or her sweater off. If we ask whether it was the rise in room temperature that caused the people to peel off their sweaters or the peeling off of sweaters that caused the room temperature to rise, then unless there was some strange signal between the taking off of sweaters and turning up a thermostat somewhere, the answer is obvious. Manipulating the room temperature from 58 to 78 degrees will cause people to take off their sweaters, but manipulating them to take off their sweaters will not make the room heat up.

In general, causes can be used to control their effects, but effects cannot be used to control their causes. Further, there is an invariance between a cause and its effects that does not hold between an effect and its causes. It does not seem to matter *how* we change the temperature in the room from 58 to 78 degrees or from 78 to 58, the co-occurrence between room temperature and sweaters remains. When the temperature is 58, people have sweaters on. When the temperature is 78, they do not. The opposite is not true for the relationship between the effect and its causes. It *does* matter how they come to have their sweaters on. If we let them decide for themselves naturally, then the co-occurrence between sweaters and temperature will remain, but if we intervene to make them take their sweaters off or put them on, then we will annihilate any co-occurrence between wearing sweaters and the room temperature precisely because the room temperature will not *respond* to whether or not people are wearing sweaters. Thus manipulability accounts handle the asymmetry problem.

They do the same for the problem of spurious causation. Tar-stained fingers and lung cancer are both effects of a common cause—smoking. Intervening to remove the stains from one’s fingers will not in any way change the probability of getting lung cancer, however.

The philosophical problem with manipulability accounts is circularity, for what is it to “intervene” and “manipulate” other than to “cause”? Intervening to set the thermostat to 78 is just to cause it to be set at 78. Manipulation is causation, so defining causation in terms of manipulation is, at least on the surface of it, circular.

Perhaps we can escape from this circularity by separating human actions from natural ones. Perhaps forming an intention and then acting to execute it *is* special, and *could* be used as a noncausal primitive in a reductive theory of causation. Writers like George Henrik von Wright have pursued this line. Others, like Paul Holland, have gone so far as to say that we have no causation without human manipulation. But is this reasonable or desirable? Virtually all physicists would agree that it is the moon’s gravity that causes the tides. Yet we cannot manipulate the moon’s position or its gravity. Are we to abandon all instances of causation where human manipulation was not involved? If a painting falls off the wall and hits the thermostat, bumping it up from 58 to 78 degrees, and a half hour later sweaters come off, are we satisfied saying that the sequence: thermostat goes up, room temperature goes up, sweaters come off was not causal?

Because they failed as reductive theories of causation, manipulability theories drew much less attention than perhaps they should have. As James Woodward elegantly puts it:

Philosophical discussion has been unsympathetic to manipulability theories: it is claimed both that they are unilluminatingly circular and that they lead to an implausibly anthropocentric and subjectivist conception of causation. This negative assessment among philosophers contrasts sharply with the widespread view among statisticians, theorists of experimental design, and many social and natural scientists that an appreciation of the

connection between causation and manipulation can play an important role in clarifying the meaning of causal claims and understanding their distinctive features. (p. 25)

The Axiomatic and Epistemological Turn: 1985–2004

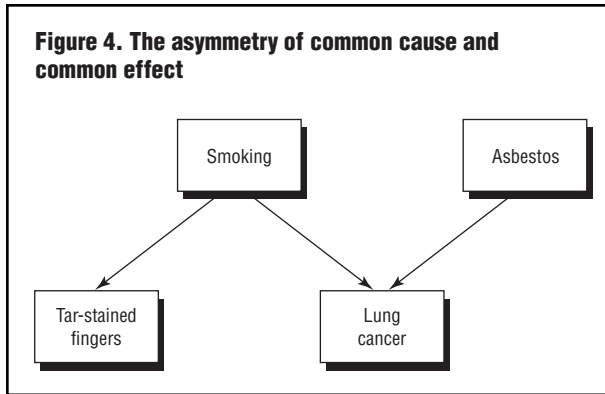

Although there will always be those unwilling to give up on a reductive analysis of causation, by the mid-1980s it was reasonably clear that such an account was not forthcoming. What has emerged as an alternative, however, is a rich axiomatic theory that clarifies the role of manipulation in much the way Woodward wants and connects rather than reduces causation to probabilistic independence, as Nancy Cartwright insisted. The modern theory of causation is truly interdisciplinary and fundamentally epistemological in focus. That is, it allows a rigorous and systematic investigation of what can and cannot be learned about causation from statistical evidence. Its intellectual beginnings go back to at least the early twentieth century.

Path analysis. Sometime around 1920 the brilliant geneticist Sewall Wright realized that standard statistical tools were too thin to represent the causal mechanisms he wanted to model. He invented “path analysis” to fill the gap. Path analytic models are causal graphs (like those shown in Figs. 1 and 2) that quantify the strength of each arrow, or direct cause, which allowed Wright to quantify and estimate from data the relative strength of two or more mechanisms by which one quantity might affect another. By midcentury prominent economists (e.g., Herbert Simon and Herman Wold) and sociologists (e.g., Hubert Blalock and Otis Dudley Duncan) had adopted this representation. In several instances they made important contributions, either by expanding the representational power of path models or by articulating how one might distinguish one causal model from another with statistical evidence.

Path models, however, did nothing much to help model the asymmetry of causation.

In the simplest possible path model representing that X is a cause of Y (Fig. 3), we write Y as a linear function of X and an “error” term (that represents all other unobserved causes of Y besides X. The real-valued coefficient β quantifies X’s effect on Y. Nothing save convention, however, prevents us from inverting the equation and rewriting the statistical model as:

$$X = \alpha Y + \delta, \text{ where } \alpha = 1/\beta \text{ and } \delta = -1/\beta \varepsilon$$

This algebraically equivalent model makes it appear as if Y is the cause of X instead of vice versa. Equations are symmetrical, but causation is not.

Philosophy. In the early 1980s two philosophers of causation, David Papineau and Daniel Hausman, paying no real attention to path analysis, nevertheless provided major insights into how to incorporate causal asymmetry into path models and probabilistic accounts of causation. Papineau, in a 1985 article titled “Causal Asymmetry,” considered the difference between (1) two effects of a common cause and (2) two causes of a common effect (Fig. 4). He argued that two effects of a common cause (tar-stained fingers and lung cancer) are *associated* in virtue of having a common cause (smoking) but that two causes of a common effect (smoking and asbestos) are not associated in virtue of having a common effect (lung cancer). In fact he could have argued that the two effects of a common cause C are associated in virtue of C , but are *independent* conditional on C , whereas the two causes of a common effect E are *not* associated in virtue of E but are *associated* conditional on E .

Daniel Hausman, in a 1984 article (and more fully in a 1998 book *Causal Asymmetries*), generalized this insight still further by developing a theory of causal asymmetry based on “causal connection.” X and Y are *causally connected* if and only if X is a cause of Y , Y a cause of X , or there is some common cause of both X and Y . Hausman connects causation to probability by assuming that two quantities are associated if they are causally connected and independent if they are not. How does he get the asymmetry of causation? By showing that when X is a cause of Y , anything else causally connected to X is also connected to Y but not vice versa.

Papineau and Hausman handle the asymmetry of causation by considering not just the relationship between the cause and effect but rather by considering the way a cause and effect relate to other quantities in an expanded system. How does this help locate the asymmetry in the path analytic representation of causation? First, consider the apparent symmetry in the statistical model in Figure 3. X and ε are not causally connected and have Y as a common effect. Thus following both Papineau and Hausman, we will assume that X and ε are independent and that in any path model properly representing

a direct causal relation $C \rightarrow E$, C and the error term for E will be independent. But now consider the equation $X = \alpha Y + \delta$, which we used to make it appear that $Y \rightarrow X$. Because of the way δ is defined, Y and δ will be associated, except for extremely rare cases.

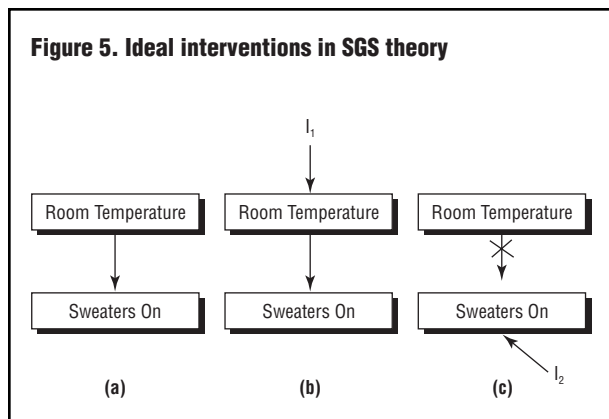

Statistics and computer science. Path analytic models have two parts, a path diagram and a statistical model. A path diagram is just a directed graph, a mathematical object very familiar to computer scientists and somewhat familiar to statisticians. As we have seen, association and independence are intimately connected to causation, and they happen to be one of the fundamental topics in probability and statistics.

Paying little attention to causation, in the 1970s and early 1980s the statisticians Phil Dawid, David Spiegelhalter, Nanny Wermuth, David Cox, Steffen Lauritzen, and others developed a branch of statistics called *graphical models* that represented the independence relationships among a set of random variables with undirected and directed graphs. Computer scientists interested in studying how robots might learn began to use graphical models to represent and selectively update their uncertainty about the world, especially Judea Pearl and his colleagues at the University of California, Los Angeles (UCLA). By the late 1980s Pearl had developed a very powerful theory of reasoning with uncertainty using Bayesian Networks and the Directed Acyclic Graphs (DAGs) attached to them. Although in 1988 he eschewed interpreting Bayesian Networks causally, Pearl made a major epistemological breakthrough by beginning the study of indistinguishability. He and Thomas Verma characterized when two Bayesian Networks with different DAGs entail the same independencies and are thus empirically indistinguishable on evidence consisting of independence relations.

Philosophy again. In the mid-1980s Peter Spirtes, Clark Glymour, and Richard Scheines (SGS hereafter), philosophers working at Carnegie Mellon, recognized that path analysis was a special case of Pearl’s theory of DAGs. Following Hausman, Papineau, Cartwright, and others trying to connect rather than reduce causation to probabilistic independence, they explicitly axiomatized the connection between causation and probabilistic independence in accord with Pearl’s theory and work by the statisticians Harry Kiiveri and Terrence Speed. Their theory of causation is explicitly nonreductionist. Instead of trying to define causation in terms of probability, counterfactuals, or some other relation, they are intentionally agnostic about the metaphysics of the subject. Instead, their focus is on the epistemology of causation, in particular on exploring what can and cannot be learned about causal structure from statistics concerning independence and association. SGS formulate several axioms connecting causal structure to probability, but one is central:

Causal Markov Axiom: Every variable is probabilistically independent of all of its noneffects (direct or indirect), conditional on its immediate causes.

The axiom has been the source of a vigorous debate (see the *British Journal for the Philosophy of Science* between 1999

and 2002), but it is only half of the SGS theory. The second half involves explicitly modeling the idea of a manipulation or intervention. All manipulability theories conceive of interventions as coming from outside the system. SGS model an intervention by adding a new variable external to the system that

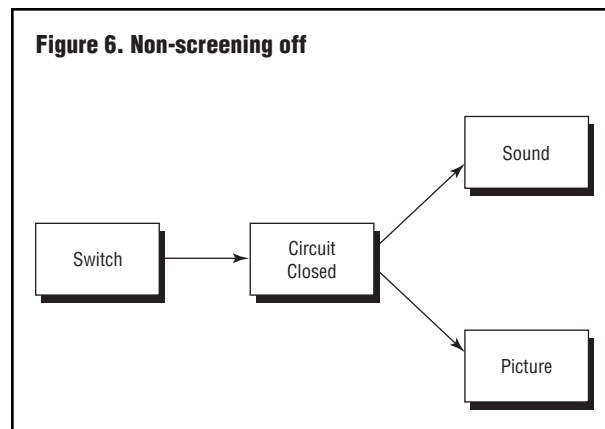

1. is a direct cause of exactly the variable it targets and
2. is the effect of no variable in the system

and by assuming that the resulting system still satisfies the Causal Markov Axiom.

If the intervention completely determines the variable it targets, then the intervention is *ideal*. Since an ideal intervention determines its target and thus overrides any influence the variable might have gotten from its other causes, SGS model the intervened system by “x-ing out” the arrows into the variable ideally intervened upon. In Figure 5a, for example, we show the causal graph relating room temperature and wearing sweaters. In Figure 5b we show the system in which we have intervened upon room temperature with I_1 and in Figure 5c the system after an ideal intervention I_2 on sweaters on.

This basic perspective on causation, elaborated powerfully and presented elegantly by Judea Pearl (2000), has also been adopted by other prominent computer scientists (David Heckerman and Greg Cooper), psychologists (Alison Gopnik and Patricia Cheng), economists (David Bessler, Clive Granger, and Kevin Hoover), epidemiologists (Sander Greenland and Jamie Robins), biologists (William Shipley), statisticians (Steffen Lauritzen, Thomas Richardson, and Larry Wasserman), and philosophers (James Woodward and Daniel Hausman).

How is the theory epistemological? Researchers have been able to characterize precisely, for many different sets of assumptions above and beyond the Causal Markov Axiom, the class of causal systems that is empirically indistinguishable, and they have also been able to automate discovery procedures that can efficiently search for such indistinguishable classes of models, including models with hidden common causes. Even in

such cases, we can still sometimes tell just from the independencies and associations among the variables measured that one variable is not a cause of another, that two variables are effects of an unmeasured common cause, or that one variable is a definite cause of another. We even have an algorithm for deciding, from data and the class of models that are indistinguishable on these data, when the effect of an intervention *can* be predicted and when it cannot.

Like anything new, the theory has its detractors. The philosopher Nancy Cartwright, although having herself contributed heavily to the axiomatic theory, has been a vocal critic of its core axiom, the Causal Markov Axiom. Cartwright maintains that common causes do not always screen off their effects. Her chief counterexample involves a chemical factory, but the example is formally identical to another that is easier to understand. Consider a TV with a balky on/off switch. When turned to “on,” the switch does not always make the picture and sound come on, but whenever it makes the sound come on, it also makes the picture come on (Fig. 6). The problem is this: knowing the state of the switch does not make the sound and the picture independent. Even having been told that the switch is on, for example, also being told that the sound is on adds information about whether the picture is also on.

The response of SGS and many others (e.g., Hausman and Woodward) is that it only appears as if we do not have screening off because we are not conditioning on *all* the common causes, especially those more proximate to the effects in question. They argue that we must condition on the Circuit Closed, and not just on the Switch, in order to screen off Sound and Picture.

A deeper puzzle along these same lines arises from quantum mechanics. A famous thought experiment, called the Einstein-Podolsky-Rosen experiment, considered a coupled system of quantum particles that are separated gently and allowed to diverge. Each particle is in superposition, that is, it *has no definite spin until it is measured*. J. S. Bell’s famous inequality shows that no matter how far apart we allow them to drift, the measurements on one particle will be highly correlated with

THE ASYMMETRY OF CAUSATION THROUGH CAUSAL CONNECTION

Two variables A and B are “causally connected” if either A is a cause of B, B a cause of A, or a third variable causes them both. If causation is transitive, then it turns out that everything causally connected to X is connected to its effects, but not everything connected to Y is connected to its causes. When $X \rightarrow Y$, everything causally connected to X is causally connected to Y (Fig. 7a), but something causally connected to Y is *not* necessarily causally connected to X (Fig. 7b).

Figure 7. The asymmetry in the transitivity of causal connection

the other, even after we condition on the state of the original coupled system. There are no extra hidden variables (common causes) we could introduce to screen off the measurements of the distant particles. Although the details are quite important and nothing if not controversial, it looks as if the Causal Markov Axiom might not hold in quantum mechanical systems. Why it should hold in macroscopic systems when it might not hold for their constituents is a mystery.

The SGS model of an intervention incorporates many controversial assumptions. In a 2003 tour de force, however, James Woodward works through all the philosophical reasons why the basic model of intervention adopted by the interdisciplinary view is reasonable. For example, Woodward considers why a manipulation must be modeled as a direct cause of only the variable it targets. Not just *any* manipulation of our roomful of sweater-wearing people will settle the question of whether sweater wearing causes the room temperature. If we make people take off their sweaters by blowing super-hot air on them—sufficient to also heat the room—then we have not *independently* manipulated just the sweaters. Similarly, if we are testing to see if confidence improves athletic performance, we cannot intervene to improve confidence with a muscle relaxant that also reduces motor coordination. These manipula-

tions are “fat hand”—they directly cause more than they should.

Woodward covers many issues like this one and develops a rich philosophical theory of intervention that is not reductive but is illuminating and rigorously connects the wide range of ideas that have been associated with causation. For example, the idea of an independent manipulation illuminates and solves the problems we pointed out earlier when discussing the counterfactual theory of causation. Instead of assessing counterfactuals like (1) George would not have plunged into the East River had he not jumped off the Brooklyn Bridge and (2) George would not have jumped off the bridge had he not plunged into the East River, we should assess counterfactuals about manipulations: (1') George would not have plunged into the East River had he been independently manipulated to not jump off the Brooklyn Bridge and (2') George would not have jumped off the bridge had he been independently manipulated not to have plunged into the East River. The difference is in how we interpret “independently manipulated.” In the case of 2' we mean if we assign George to not plunging but leave everything else as it was, for example, if we catch George just before he dunks. In this way of conceiving of the counterfactual, George *would* have jumped off the bridge, and so we can recover the asymmetry of causation once we augment the counterfactual theory with the idea of an independent manipulation, as Woodward argues.

Conclusion

Although the whirlwind tour in this short article is woefully inadequate, the references below (and especially their bibliographies) should be sufficient to point interested readers to the voluminous literature on causation produced in the late twentieth century and early twenty-first century. Although the literature is vast and somewhat inchoate, it is safe to say that no reductive analysis of causation has emerged still afloat and basically seaworthy. What has been described here as the interdisciplinary theory of causation takes direct causation as a primitive, defines intervention from direct causation, and then connects causal systems to probabilities and statistical evidence through axioms, including the Causal Markov Axiom. Although it provides little comfort for those hoping to analyze causation Socratically, the theory does open the topic of causal epistemology in a way that has affected statistical and scientific practice, hopefully for the better. Surely that is some progress.

CAUSATION IN EAST ASIAN AND SOUTHEAST ASIAN PHILOSOPHY. Causation is defined most commonly as a relationship between two events or two states of

affairs in which the first brings about the second. The idea of causation has long existed among the peoples in South and East Asia, but as a historical notion, it has taken different forms of expression in these regions.

The Influence of Buddhism in South Asia

In South Asia, where the belief in reincarnation constituted an important philosophical base for both Hinduism and Buddhism, the concept of causation played a vital role in shaping one's outlook on life and history. According to Buddhism, all forms of existence are related one way or another in an infinite and endless causal web. Thus the creation theory, which is crucial to some religions, finds no place in Buddhism. Drawing on the incarnation belief, Buddhism also connects the life of this world to the next, in which the rise or fall of one's status leading to either salvation or condemnation is dependent on the karma one accumulates in this life. Ironically, however, this causal connection between this world and the next is not necessarily conducive to the development of historical consciousness because it dwells on the mutability, fluidity, and temporality of life, which breeds an extreme relativism that negates the meaning of life itself. Indeed, while Buddhism urges one to improve one's karma in life, it also stresses, extending the broad-based belief in eschatology in South Asia, that life is merely a fleeting bubble and that the world is extinguishable ablaze. Moreover, because everything is causally related in an infinite and endless web, nothing is constant or specifically consequential to anything else. Explanation for change also becomes unnecessary.

In its later development, however, Buddhism began to value life and history, which in turn translated its idea of causation into an important contribution to the development of historical thinking. In Theravada Buddhism, hagiological need led to the development of a scholastic trend. The same need also gave rise to a new concept of time, in which the birth of Buddha became a watershed in the otherwise completely cyclical flow of time. More important, the appearance of Buddha was not considered an accidental event, but a result of the work of an inexorable, omnipresent rule or norm. All this renders the Buddhist theory of causation germane to the study of history. Buddhists continue to situate the change of history in an infinite causal relation, or an "iron chain of causality," which leads them to a multilateral and simultaneous consideration of historical causation. In the meantime, they also seek to identify the specific causes for each event. They argue that even if the result is the same, the causal relation between the result and its causes remains unique. Historical change thus is regarded as an outcome of the concatenation of a number of divergent factors coming together in a unique circumstance and relationship.

The Influence of Confucianism in East Asia

In East Asia, the conception of causation was also characterized by relativism, or by a correlative way of thinking that, in both ontology and cosmology, took what Joseph Needham called "an organicist" approach to describing the relationship between humans and their environment. This correlative thought originated from speculations on the possible impact

of what happened in nature, or in Heaven, on human lives on Earth. But in its later development, particularly in the theoretical formations of yin and yang and the Five Elements/Phases (*wuxing*), it exerted a fundamental and pervasive influence on shaping the notion of causality in ancient China. Instead of searching for a linear, particulate cause, ancient Chinese approached causation in a circumambient (all-encompassing) manner, which allowed them to note an organic web of causal connection.

Out of its worldly interest and moral concerns, Confucianism appears more assertive in defining causal relations in human affairs, although it was by no means immune to the idea of a Heaven–humanity correlation in developing historical explanations. Confucius (551–479 B.C.E.), for example, believed that the rise and fall of political powers depended on the Mandate of Heaven. But dismayed by the decline of central government of his time, he nevertheless set out, after seeing the unicorn that to him suggested a mission charged by Heaven, to revise the *Spring and Autumn Annals*, hoping to bring about a punitive consequence for the unruly behaviors of officials and princes. Mencius (c. 371–c. 289 B.C.E.), devout follower of Confucius, claimed that Confucius’s effort was not in vain, indicating a belief in historical causation among the Confucians in that immoral behavior is to be condemned through the course of history. Throughout early imperial China, the idea of a Heaven–humanity correlation represented a major expression of historical causation, subscribed to by Dong Zhongshu (c. 194–c. 114 B.C.E.), a political theorist, as well as by Sima Qian (c. 145–86 B.C.E.), a court historian. Dong used it to forge a theory on dynastic succession for legitimizing the reigning Han dynasty (206 B.C.E.–220 C.E.), whereas Sima used it to help structure his interpretative framework of history. While a main framework, the correlative idea did not stop Sima from searching for other temporal and coincidental causes in explaining historical change. In fact, Sima was both commended and chided for demonstrating great curiosity for the “wonders” of history in his *Shiji* (The records of history). By comparison, Ban Gu (32–92 C.E.), also a Han historian, was narrower in his interest and more rigid in his method in seeking causal explanations for history, focusing on the bond between morality and history.

Diversifying Tradition in Post-Han Era

After the fall of the Han dynasty, China’s cultural tradition diversified as a result of the entrance of Buddhism, which gave rise to the expansion of Daoism and the resurgence of Confucianism. The theories of historical causation also flourished. Yet a general tendency remained identifiable, marked by the decline of the notion of a Heaven–humanity correlation. This decline was shown in the tradition, established in the seventh century, of writing official dynastic histories, which, following Ban Gu’s model, purported to draw analogies from the history of previous dynasties for the benefit of the reigning dynasty. Hence the writing of dynastic historiography amounted to a serious effort to find specific causal relations in history, rather than to apply the mysterious and superstitious correlative idea. In his *Zizhi tongjian* (A comprehensive mirror of aid for government), Sima Guang (1019–1086) made a valiant at-

tempt to generalize the causes for the successes and failures of the previous rulers. Of the important ones identified by him, few were attributed to the will of Heaven.

Yet the notion of Heaven remained important. Influenced by the metaphysics of Buddhism, the Neo-Confucians of the Song period (960–1279), such as Zhu Xi (1130–1200), averred that *li* (principle), or *tianli* (heavenly principle), was the ultimate cause for the change of history, commanding the ebb and flow of good and evil times. At the same time, they searched for *tianli*’s various worldly manifestations in order to demonstrate and explain the mutability and temporality of life and history. This effort was continued by Wang Fuzhi (1619–1692) in late imperial China and Arai Hakuseki (1657–1725) of Tokugawa Japan (1603–1867). Wang and Arai discussed the concept *shi* (circumstance), which they used to underscore the uniqueness of the causal relations of historical events, an emphasis also readily identifiable in the Buddhist construction of historical causation.

CENSORSHIP. Censorship comprises many methods of preventing the publication or dissemination of speech, printed matter, art, theater, music, electronic media, or other forms of expression. The most common subjects that are censored are religion, politics, and sex. The usual justification is that such expression is subversive, blasphemous, heretical, obscene, pornographic, or otherwise offensive or harmful. Censorship can take place before publication, known as prior restraint, in the form of requirements such as licensing and prior review. It can also take place after publication in such forms as banning, burning, or boycotting of the published product and fining, imprisonment, or the death penalty for the author or publisher.

The English term is derived from the ancient Roman institution of the censors, two elected magistrates responsible for overseeing the morals of the Roman people and who could warn or ban certain people or behavior at will. In later times censorship has often been carried out by individuals or committees appointed by religious or political authorities, but it can also be carried out by self-appointed vigilantes. The term has been expanded to include self-censorship, in which one does not express something for fear of the consequences, and market censorship, in which suppression of a publication is caused by the refusal of advertisers to advertise in it or of the public to buy it.

The political ideology of modern liberalism is generally against censorship on the ground that it limits freedom unnecessarily. By far the largest body of reflection on censorship has been written by its opponents. Those who are in a position to impose censorship have usually done it without articulating their reasons in any depth. Communitarian and autocratic ideologies such as socialism, national socialism, communism, absolute monarchism, and theocracy have generally done little more than assert that censorship protects the community and its leaders against perceived threats. In the late twentieth and early twenty-first centuries, there has been an upsurge in articulation of justifications for censorship. Radical feminists and spokespersons for ethnic, religious, or formerly colonized groups have supported censorship of pornography, “hate speech,” and criticism of themselves, pointing to the harm that uncensored expression can do.

Sex has been the target of much censorship. Objectionable sexual material is variously labeled obscene, pornographic, indecent, or degrading. Obscenity has been defined as having a tendency to deprave or corrupt; as appealing to prurient interest; or as being offensive to prevailing moral standards. Pornography has been defined as explicit depiction of sexual behavior intended to cause arousal. Censorship of these matters is sometimes limited to shielding younger age-groups, and it is sometimes claimed that this type of censorship should only be applied if there is no redeeming scientific, artistic, or political value to sexual materials. Since the 1980s, censorship has been justified by the argument that pornography is equivalent to rape.

Almost no one believes in absolute freedom of expression. Libel, slander, and defamation are prohibited by nearly every legal code. These prohibitions are not usually considered to be censorship, but rather a part of tort law.

It is widely accepted that prior restraint is more effective at preventing expression than postpublication censorship. The requirement to submit items for approval may intimidate someone into not submitting something that might actually be approved or that might not attract negative attention if it were published. Postpublication punishment is rarely fully effective: the censors might miss a few items entirely, and when books or recordings that have already been published are destroyed, a few copies can often be saved surreptitiously.

Blasphemy, Heresy, and Atheism

Socrates (c. 470–399 B.C.E.) was put to death in ancient Greece for introducing new gods, among other charges. Later, the main religions introduced doctrines of blasphemy and heresy as justifications for censorship. For the Jews blasphemy meant insult to God and was closely related to idolatry. The Christians expanded the meaning to include insult to Christ, and they tended to confuse blasphemy with heresy, or theological error. There is little evidence that blasphemy was a major concern in early Islam, but in 1989 a *fatwa* in Iran called for the death penalty against the author Salman Rushdie (1947–) for blasphemy. The same year, Hindu fundamentalists issued a death threat against the historian M. M. Kalburgi for blasphemy.

In the widest meaning of heresy, the beliefs of every sect are heresies to every other sect, but it is usually the dominant orthodoxy that gets to define the heretical for practical purposes. Censorship of heresies can begin with prohibition of expression and develop through excommunication and punishment up to the death penalty. Atheism is a heresy to most religions and is sometimes considered worse than mere adherence to a mistaken religion. In ancient Greece, Anaxagoras (c. 500–c. 428 B.C.E.) was prosecuted for denying the existence of the gods.

The Catholic Church developed the most sophisticated early censoring apparatus in the form of the Inquisitions and *Index*. In 1231 the Dominican and Franciscan orders were charged with inquiry into the spread of heresy, an undertaking later known as the Inquisition. The Spanish Inquisition was instituted in 1478, and after various experiments with local inquisitions, a centralized Roman Inquisition was set up in 1542 to root out heresy. Lists of banned books were published in Paris (1544), Lucca (1545), Louvain (1546), and Venice (1549). In 1559 the first *Index of Prohibited Books* was issued at the Council of Trent, and a separate papal Congregation of the Index, set up in 1571, continued to issue an *Index* every few decades until it was abolished in 1966. Enforcement of such efforts at censorship depends in part on the climate of public opinion: in the eighteenth century, for example, sale of the *Index* was banned in Austria because people were buying it to use as a guide to reading.

Political Subversion

Because his pupils were closely allied to the oligarchy, it is arguable that the real reason for the persecution of Socrates was his political stance. Plato's *Laws* (c. 350 B.C.E.) makes the case for wide powers of censorship in order to prevent innovation: If no new songs and books are allowed and few people are allowed to travel, there will be no new ideas and no pressure for harmful political change.

In the Roman Empire, censorship of writers was often provoked by political satires of the emperors. In later times, political authorities have often censored expressions that they perceived to be threatening to their power and social stability, even claiming that any opposition to their persons or policies is treason.

The Netherlands and England

The first two countries to have substantial freedom from censorship were the Netherlands and England. At the time of the Dutch Revolt (1568–1648), the chaos of civil war, an extreme federalism consisting of numerous jurisdictions, and the growing economic importance of the commercial book market meant that the Dutch civil authorities were too exhausted to initiate effective censorship, that what was banned in one jurisdiction could be published in another, and that economic interests opposed censorship in the Netherlands. Protestant criticism of the Catholic Inquisition and *Index* also made it difficult to justify Protestant censorship. Similar reasons encouraged effective limits on censorship during the English Civil War and Commonwealth (1642–1660).

The English philosopher Thomas Hobbes articulated the case for censorship in his *Leviathan* (1651). A philosophical nominalist, Hobbes believed very much in the importance of words and even claimed that the English Civil War was caused by too much reading of ancient republican authors. Therefore, he argued, the prince should have control over all forms of expression, a position frequently emulated by political authorities elsewhere. But even Hobbes did not articulate a full case for censorship with no exceptions. He warned princes against wasting valuable power trying to control people's minds when unnecessary.

The first major articulation of opposition to censorship was John Milton's (1608–1674) *Areopagitica* of 1644. He associated licensing with the infamous Inquisition of the Catholic Church and argued that knowledge of errors helps confirm the truth. Also among his arguments were that books cannot be suppressed without great harm to learning, and most people do not learn their evil ways from books. The censors

are not infallible, he said, and the attempt to regulate all forms of expression would be both exhausting and futile. Furthermore, he said, criticism of magistrates helps keep them informed. As usual, there were limits to Milton's tolerance: he approved of suppression of Catholics and the impious as threats to society. In the same period, Henry Robinson argued in *Liberty of Conscience* (1644) for liberty of the press on the ground that it was good for business.

The Dutch writer Benedictus de Spinoza (1632–1677) wrote provocative historical criticism of the Bible in his *Theological-Political Treatise* (1670), which also called for the freedom of every person to think what he wanted and to say what he thought. Spinoza's posthumously published *Ethics* (1677) argued for materialism, which was widely interpreted as atheism, and also asserted that part of the definition of a free man is one who can say what he thinks. Even though he wrote in Latin to avoid attention from anybody but the most educated, Spinoza's work was widely banned, and his followers were persecuted and censored throughout the following century.

Charles Blount (1654–1693) published *A Just Vindication of Learning* in 1679, and in *Miracles, No Violation of the Laws of Nature* (1683), he offered the first translation of part of Spinoza's work into English. His *Reasons Humbly Offered for the Liberty of Unlicens'd Printing* (1693) retailed Milton's reasoning and may have influenced Parliament's decision not to renew the Licensing Act in 1695. Like Milton, the English philosopher John Locke (1632–1704) opposed toleration of atheists and Catholics, and he also wrote several memoranda in the 1690s against the renewal of the Licensing Act. "I know not why a man should not have liberty to print what ever he would speake, and to be answerable for the one just as he is for the other if he transgresses the law in either," he wrote. When the Licensing Act expired in 1695 without renewal, England had de facto press freedom.

The deist John Toland (1670–1722) was responsible for the widespread distribution of Milton's *Areopagitica* in his 1698 edition of Milton's complete works, and he attacked censorship in several later publications. Other English deists from Anthony Collins to Matthew Tindal also defended freedom of expression. Both Spinoza and the deists are examples of radical philosophers in opposition to censorship.

James Mill (1773–1836) and his son John Stuart Mill (1806–1873) updated many of the arguments against censorship that had circulated in English, French, and German before them. James Mill argued that true statements about individuals should never be censored and that only direct obstruction of government operations should be censored, not general objections to policy. John Stuart Mill insisted that we do not really know anything unless we have considered the alternatives to it and that there is some truth in every opinion.

From Bayle to Constant

In the francophone world, the Huguenot refugee Pierre Bayle (1647–1706) penned the first general justification of the publication of obscenity. His "An Explanation Concerning Obscenities" (1702) argued that outright recommendation of lewdness and debauchery should be punished, but anything less than that should be left to the people to judge for themselves. The works of great authors such as Giovanni Boccaccio are protected by a "right" of the republic of letters, he argued, and even the Bible contains accounts of lewdness. Finally, he said that historians can report obscene things as mere facts of history, and no one is forced to read them. Bayle also wrote against censorship of atheists.

In 1747 Elie Luzac (1723–1796) published the atheistic *Man a Machine* by J. O. de La Mettrie, which resulted in much scandal. He was forced to turn over most copies for burning. Luzac then wrote his *Essay on Freedom of Expression* (1749) in order to defend freedom of the press. He relied on the tradition of natural law and claimed that the expression of ideas can never be harmful to society: false ideas will be refuted, and even true ideas will not be fully convincing unless we have seen the false alternatives. Luzac also pointed out that prohibited books will circulate underground anyway. He was no social or political radical, and his work demonstrates that conservatives can oppose censorship.

When her work was attacked in the press, Germaine de Staël (1766–1817) wrote in favor of censorship. Her intellectual companion, Benjamin Constant (1767–1830), countered with the case against censorship in many writings, including *Principles of Government Applicable to All Representative Governments* (1815). He agreed that writers who preach murder, theft, and pillage should be punished, but he argued that most pamphlets are harmless.

From Schmidt to Bahrtd

In the German-speaking world, substantial freedom of the press emerged from the multiple jurisdictions in the region, but authors were still imprisoned for their publications. Johann Lorenz Schmidt's (1702–1749) rationalist translation of the Bible in 1735 was outlawed in 1737, and he was imprisoned but escaped. The introduction to his German translation (1741) of Matthew Tindal's *Christianity as Old as the Creation* included a 130-page prefatory essay on freedom of the press, which may have been the first extended critique of censorship in German. Schmidt also translated Spinoza's *Ethics* into German in 1744.

Joseph II (1741–1790) relaxed press controls in the Habsburg Empire, and Frederick II of Prussia (1712–1786) generally limited censorship to political matters, not attacks on religion. In the decades of ferment after about 1770, many German writers called for press freedom. Christoph Martin Wieland's periodical *German Mercury* called press freedom the palladium of humanity in 1784; August Ludwig von Schlözer's *Letters to Eichstädt in Vindication of Publicity* (1785) rejected a bishop's censorship; and Johannes Kern's *Letters on Freedom of Thought, Belief, Speech, and the Press* (1786) based such freedoms on the social nature of mankind. The philosopher Immanuel Kant (1724–1804) elevated press freedom into the transcendental principle of public law.

Carl Friedrich Bahrtd's *On Freedom of the Press and Its Limits* (1787) consolidated much of the foregoing German material into an extended critique of censorship. He labeled freedom of the press a human right and argued that people only really believe truths they have found for ourselves. He opposed suppression of atheism and claimed that all human progress depends on mutual communication. Bahrtd was willing to condone censorship of state secrets and private matters and spelled out what later became known as the public figure doctrine. His satire of the Prussian king Frederick William II, *The Edict of Religion* (1788), landed him in prison for more than a year.

Pushkin and Solzhenitsyn

In the nineteenth and twentieth centuries, two Russian writers penned brilliant critiques of censorship. Aleksandr Pushkin's (1799–1837) long poems "Epistle to the Censor" (1822) and "Second Epistle to the Censor" (1824) could not be published in his lifetime. They described censors as gloomy, "meddling eunuchs." Aleksandr Solzhenitsyn's (1918–) "Letter to the Fourth Writers Congress" (1967) called censorship a survival from the Middle Ages and complained about the power of ignorant censors over literature.

Legal Declarations

In 1767 Sweden became the first country in the world to declare official freedom of the press, although a number of countries already had de facto freedom from censorship by then. However, Sweden's law specifically excepted matters of religion, one of the most common matters censored. In 1770 Denmark became the first to end censorship of all subjects. The decree was the work of Prime Minister Johann Friedrich Struensee (1737–1772), whose publications had been censored in Hamburg a decade before. He was overthrown and executed in 1772, but prior restraint of the press was not reimposed.

The fledgling United States was the site of several declarations of freedom of the press. The Virginia Declaration of Rights (1776) asserted that freedom of the press is one of the bulwarks of freedom itself, and declarations and constitutions in Pennsylvania (1776), Delaware (1776), North Carolina (1776), Vermont (1777), South Carolina (1778), and other states contained similar provisions. These provisions were precedents for the First Amendment to the United States Constitution (1791), which holds that "Congress shall make no law . . . abridging the freedom of speech, or of the press." How these words would be interpreted, of course, would have a great effect on censorship in the United States. Thomas Jefferson, for example, was highly in favor of freedom of the press until he became president, when he prosecuted newspapers that criticized his policies.

Article 11 of the French Declaration of the Rights of Man of 1789 provided that "Every citizen may freely speak, write, and print, subject to accountability for abuse of this freedom."

Many European constitutions of the nineteenth century abolished censorship. Article 19 of the United Nations Universal Declaration of Human Rights (1948) provides that "Everyone has the right to freedom of opinion and expression; this right includes freedom to . . . seek, receive and impart information and ideas through any media."

Sites of Censorship

Public libraries, museums, and schools are common sites of efforts to censor. The financing of libraries and museums by the public is alleged to confer a different standard than the open market, and protection of children from harmful materials is the usual justification for censorship of schoolbooks.

The development of each new medium of communication has brought with it efforts to censor that medium. Internet censorship is the latest in that line, with authorities around the world trying more or less effectively to limit access to certain Web sites and information.

Another late-twentieth-century phenomenon is the spread of "hate speech" codes on academic campuses. Intended to protect the vulnerable against speech that is alleged to express hate, the codes are open to wide-ranging interpretation and amount to imposition of judgments by whomever controls the censoring apparatus. Wherever anyone alleges that the expressions of others are insulting, offensive, or degrading, presumably those others could assert that the former's allegations are insulting, offensive, or degrading to them.

China has been a particularly active site for censorship and protests against it since the 1990s, but few observers from other countries can indulge in complacency. Derek Jones's *Censorship* (2001) details numerous cases of censorship of writers, directors, and artists on every continent and in almost every country in the twentieth century.

Censorship is not always an unmitigated bane for writers, artists, and publishers. One advantage is that it draws attention to works and causes. Authors have actively sought book burnings for the publicity value, and some books that have been taken off prohibited lists have seen their sales drop. Artistic careers have been made from the martyr value of censorship.

CHAIN OF BEING. See **Hierarchy and Order.**

CHANGE. “Cold things warm up, the hot cools off, wet becomes dry, dry becomes wet,” observes Heraclitus (fr. 126), as if to state an obvious fact. Yet this fact became highly troublesome to early philosophers.

Antiquity

Although his predecessors had theories to account for natural changes, Heraclitus (c. 540–c. 480 b.c.e.) seems to be the first Western thinker to raise philosophical questions about change itself. According to Plato, Heraclitus held that (1) all things are changing, and (2) comparing life to a river, he claimed that one could not step twice into the same river (Cratylus 402a). On the basis of these two theses Plato draws the conclusion that (3) Heraclitus maintained that contradictory propositions were true (Theaetetus 182–183). In fact, Heraclitus seems to have held a more defensible, if still radical, view. Plato probably derives (1) and (2) directly from Heraclitus fr. 12: “On those stepping into the same rivers, other and other waters flow.” Instead of saying the rivers are different, Heraclitus says they are the same—in contrast to the waters that comprise them. From this and other fragments we can extract a theory that although there is constant change in the materials of the world, stable structures supervene on them. Indeed, Heraclitus seems to imply that if there were not constant exchanges of matter, the structures would not exist; for instance, if the water ceased to flow, the river would cease to be.

The Eleatic challenge. In contrast to Heraclitus, Parmenides (b. c. 515 B.C.E.) of Elea (possibly reacting to Heraclitus, though this is controversial) denies the possibility of change. Rejecting the way “that it is not” because what-is-not could not be uttered (fr. 2), Parmenides rules out whatever properties rely on not-being. Since coming to be or perishing presuppose a time when something is not, they are not allowed, and similarly motion (in place?) is to be rejected (fr. 8). Parmenides enumerates several kinds of change: “coming to be and perishing, being and not being, changing place and exchanging bright color” (fr. 8.40–41). He seems to reject all of these as impossible. Parmenides’ argument presents a problem often called the “Eleatic challenge”: how can what-is come from what-is-not? The challenge poses a direct threat to cosmogony, the standard kind of pre-Socratic theory. After Parmenides, most cosmological theories posited the existence of a plurality of continuing materials that were individually supposed to be everlasting, for instance the four elements of

Empedocles (c. 490–c. 430 B.C.E.): earth, water, air, and fire. Thus cosmologists could claim that they did not allow coming to be or perishing of the ultimate realities, but only a harmless rearrangement of them. Nonetheless, Parmenides’ argument seems to rule out not only coming to be and perishing, but all other kinds of change as well, and also to preclude a plurality of existences. Reinforced and sharpened by Zeno of Elea (c. 495–c. 430 B.C.E.) and Melissus of Samos (5th c. B.C.E.), the Eleatic challenge seems to have gone unanswered for more than a century.

Plato’s response. Perhaps influenced by the lectures of Cratylus (a follower of Heraclitus), Plato (c. 428–348 or 347 B.C.E.) attributes a radical flux to the world of sensible things: they are always changing and never completely stable. If sensible things were the only existing things, knowledge and even discourse about the world would be impossible. But there is another world of changeless realities, the Forms, which provide a stable structure for sensible things, referents for language, and objects for knowledge. Forms, such as Justice and Equality, and perhaps *Being*, have Parmenidean properties but no Heraclitean properties. Thus Plato creates a two-world theory, in which Heraclitean change of sensible things is tempered by Parmenidean constancy of ideal things. In his later work, Plato even posits a Form of Motion and another of Rest as ultimate kinds in which all sensible things participate (*Sophist* 254d). Unfortunately, a Form of Motion does not allow for any analysis of different kinds of motion or of different stages within a motion. Plato claims that the ultimate source of orderly motion is soul, which is immortal and self-moving (*Phaedrus* 245c–e).

Aristotle. Aristotle (384–322 B.C.E.) provides the first systematic study of change. He maintains that only primary substances can survive a change of one property to its opposite, implying that changes are variations in properties over time (*Categories* 5). He distinguishes several types of change by the kind of entity involved: coming-to-be and its opposite perishing (change in the category of substance), alteration (change of quality), increase and decrease (change of quantity), and locomotion (change of place) (*ibid.* 14). In *Physics* I, he sets out to answer the Eleatic challenge. Observing that changes always involve a subject changing from one opposite state to another, he generalizes this scheme to the most problematic case: that of change in substance. Even in this case there is some continuing subject for a change from one state to its opposite, as in the case of bronze, which goes from being unformed to being formed (in a statue). Similarly, there is some continuing substratum for something going from being not-human to human; the substratum for substantial change can be called matter (e.g., bronze), the negative state the privation (e.g., not-formed), the positive state the form (e.g., formed). On this model, though the final object comes from what-is-not, it does not come from nothing: the negative state is not nonexistence, but characterizes something that is, e.g., the bronze. “What-is-not” is seen to pick out not-*F*, and to presuppose a matter *m*, and not to refer to nothing at all. The Eleatic challenge rests on a mistake.

Aristotle sets out the circumstances of change as follows: a cause of motion *M* causes an object *O* to change from condition

(place, property, etc.) C_1 to C_2 between times t_1 and t_2 (*Physics* V 1). In those cases in which O does not come to be or perish (undergo change of substance), the change is a *motion*. We may identify the circumstances with identity conditions: two changes are the same just in case they have the same mover, object, initial and final conditions, and beginning and ending times.

Not satisfied with a general definition and defense of change, Aristotle seeks to identify its place in the cosmos. Some things are always in motion (e.g., the heavenly bodies), some always at rest (e.g., the earth), and some things are at different times in motion and at rest (e.g., animals). Because there can be no beginning of time, but time is only the measure of regular motion, there must always have been cosmic motion. The only kind of motion that can be everlasting is locomotion in a circle (seen in the heavenly bodies). Such everlasting motion is only possible if there is some unmoved entity that causes the motion (*Physics* VIII). This is the first unmoved mover, which acts as a final cause, so that the heavenly bodies try to imitate its perfect (but motionless) actuality. Aristotle assumes that motion needs some sort of explanation, and everlasting motion needs an everlasting cause.

Christian Platonism. Throughout late antiquity and the Middle Ages, Platonic and Aristotelian concepts of change continued to provide the standard account. There is, however, one important departure from classical theories that early Christian thinkers made: beginning in the second century C.E. they began to claim that God created the world *ex nihilo* (out of nothing), contrary to the classical notion expressed by Parmenides that what-is could not come from what-is-not. The Creation was a miraculous event caused by an omnipotent God.

Later Platonists interpreted Plato as saying that there was a simple and perfect One from which Mind (including the Platonic Forms) emanated; from Mind, Soul emanated, and from Soul, matter. Emanation was a kind of ontological overflowing according to which one being gave of its fullness to produce a lower-level being; the lower being proceeds from the higher in a timeless way such that the lower is always in existence, but dependent on the higher. Temporal distinctions are found only in the lower beings, so that the One and Mind are not in time and hence not subject to change.

In Christian Platonism, both *ex nihilo* creation and a changeless deity are combined with a historical account of God's interaction with the world, as in St. Augustine of Hippo's (354–430) *City of God*. Paradoxically, a changeless God interacts with changeable mortals to produce the drama of human salvation.

Modern Era

In the modern era a fundamental reorientation in the theory of motion occurred when the principle of inertia was recognized. Put forth first by René Descartes (1596–1650) and Pierre Gassendi (1592–1655), and canonized by Isaac Newton (1642–1727) as his first law, the principle stated that a body in uniform straight motion tends to stay in motion, and a body at rest tends to stay at rest. Thus the physicist did not need to explain continued motion. Moreover, since Newton's

law of gravity could account for elliptical motions of satellites around a massive body, there was no longer any need for an unmoved mover to maintain the cosmic order. The kind of kinetic change that needed to be explained was acceleration, which depended on the application of a force to the moving body. John Locke (1632–1704) identified motion and rest as primary qualities whose ideas resembled the originals; colors and the like were secondary qualities whose ideas did not resemble the originals. Increasingly, motion in place came to be seen as the fundamental kind of change, which accounted for all other kinds.

History and physics. Up until the nineteenth century, the study of history had been of little interest to philosophers. Aristotle had said that history was less philosophical than poetry, because it dealt with the particular rather than the universal. But when Georg Wilhelm Friedrich Hegel (1770–1831) explained the development of consciousness as a dialectical progression leading to ever more comprehensive concepts, he made history vitally important to philosophy. In particular the history of thought seemed to reflect the growth of spirit, exemplifying the realization of freedom and self-consciousness. An understanding of the development of culture and human institutions was now indispensable for philosophy. Historical change was essential to human self-realization. Becoming was the fulfillment of the concepts of *being* and *not-being*.

Although the historicist idealism launched by Hegel was highly influential, it eventually occasioned a strong reaction in England. One of the leading critics of idealism, Bertrand Russell (1872–1970), argued against “internal relations” by which every event was necessarily connected with every other. Instead, he proposed that the world consisted of a set of independent facts. Change itself could be defined in terms of propositions: “Change is the difference, in respect of truth or falsehood, between a proposition concerning an entity and a time T , and a proposition concerning the same entity and another time T' , provided that the two propositions differ only by the fact that T occurs in one where T' occurs in the other” (sec. 442). Thus if “Socrates is literate at T ” is false and “Socrates is literate at T' ” is true for the times 465 B.C.E. and 450 B.C.E., respectively, we can infer a change. Against Russell, John M. E. McTaggart (1866–1925) has argued that we should distinguish between an “A series” of events ordered with respect to past, present, and future, and a “B series” ordered with respect to before and after; only the former entails the existence (the flow) of time, since the latter involves only a fixed sequence of determinate events. But the A series produces contradiction, since every event is allegedly past, present, and future, that is, has incompatible predicates. Thus the A series is incoherent, and consequently there is no time and hence no change. Yet one can reply that the B series provides an adequate basis for time and change, and that the predicates *past*, *present*, and *future* are no more incompatible than *taller* and *shorter*: they are incomplete predicates, which, when properly completed for a given subject, would not produce a contradiction: “past with respect to time T_3 [or event E_3 , etc.],” “present with respect to T_2 ,” “future with respect to T_1 .” The kinds of changes described by Russell's and McTaggart's accounts (sometimes called “Cambridge changes”) have been criticized

as too weak: a statement about a subject can change truth value with the subject's undergoing any alteration. For instance, I become shorter than my son when he grows taller than I, even though my stature does not change. Russell could reply that his account is meant only to identify some change in the world, not to analyze the subject of that change. In any case, we seem to need a richer account than Russell's to analyze the structure of change itself.

Advances in physics have affected views of the place of change in the world. Whereas Newtonian physics saw motion and rest as interchangeable phenomena seen from different frames of reference, the Theory of Relativity puts a limit on speed (the speed of light) and makes time a fourth dimension on a par with the three dimensions of space. Space, time, and mass all became relative quantities, and acceleration ceased to provide a necessary condition of change. At a quantum level, some particles have properties of both bodies and waves, and subatomic particles seem to be packets of energy. New theories such as String Theory suggest that subatomic particles are states of multidimensional strings of energy. Alfred North Whitehead (1861–1947) drew on early-twentieth-century physics to develop a speculative metaphysics positing processes rather than things as the ultimate realities. His style of philosophy, however, has gone out of favor, and in the late twentieth century philosophers tended to study change in trying to specify identity conditions for events.

CHARACTER. The word *character*, when applied to persons, has two sources, distinguished lexically in ancient Greek by the terms *êthos* and *charaktêr*. *Êthos*, originally referring to a disposition or custom, from Aristotle on refers to the stable dispositions that guide a person's actions and that are suitable objects of moral praise and blame. The earliest uses of *charaktêr* in Greek, like the earliest uses of *character* in English, refer to an impression such as would be carved or stamped onto a coin or tablet; metaphorically, "characters" are signs (actions, facial features, social positions) that reveal something about a person's soul. Dur-

ing the seventeenth century, the sense of "character" in English came to include a person's psychological traits themselves.

Aristotle and Virtue Ethics

The fourth-century B.C.E. philosopher Aristotle, in *Nicomachean Ethics*, understands character (*êthos*, or *hexis êthikê*, "moral disposition") to be a disposition of the appetitive and emotional faculties, which leads its possessor to act and feel in particular ways. This disposition is acquired through habituation, a process that develops the intellectual as well as the appetitive and emotional faculties. Aristotelian virtues are such dispositions informed by practical wisdom—a capacity for judgment developed through experience and reflection, which guides conduct where technical knowledge cannot. This is one point of convergence between Aristotle's ethics and the thinking of contemporary virtue theorists, for as Aristotle rejects the claims of his teacher Plato (c. 428–348 or 347 B.C.E.) and Sophists such as Protagoras (c. 485–410 B.C.E.) that there is some art or science that can guide conduct, contemporary virtue theorists reject the claims of deontological ethics that conduct is well-guided by rules, such as "maximize utility" or "act only upon a maxim you could without contradiction will to be a universal maxim." Aristotle and contemporary virtue theorists also share the view that characters are appropriate objects of moral praise and blame; Aristotle reasons that this requires that our characters be voluntary, and argues that this is so on the grounds that our actions are voluntary and our characters are the products of our actions.

Aristotle's *Ethics* focuses on the cultivation (or acquisition or promotion in others) of virtuous character. When Aristotle describes the courageous or liberal person, he does so from the inside, showing us the person's concerns so that we see how, given the person's values, it makes sense for him to do as he does. But Aristotle's *Rhetoric* uses characterization to dispose audiences to trust a speaker, and his *Poetics*, to effect an appropriate fit between a person and his words and deeds; here, words and actions are signs by which we may know someone's character. Subsequently, Aristotle's student Theophrastus (c. 372–c. 287 B.C.E.) sketched representative vicious types by enumerating their typical words and deeds, in a work that came to be known as the *Êthikoi Charaktêres* (English trans. *Characters of Theophrastus*, or Moral signs), which was much imitated in English literature from the seventeenth century on. In *Characters of Vertues and Vices* (1608), by the English prelate Joseph Hall (1574–1656), "character" for the first time refers to a type of person, rather than just to the signs that reveal that type. A "character" genre evolved in various directions in the seventeenth and eighteenth centuries, adding to moral types, types of men and women in various stations of life (perhaps influenced by the Stoic notion that human beings are given *personae*, or roles to play in this world), and using their sketches to satirize individuals and societies. Although this literature interacts richly with popular ideas about character, it has generally not been taken up in philosophical ethics.

Kantian Ethics

An ancient tradition in natural philosophy, and particularly medicine, sought to explain an individual's character (*êthos*) in

terms of the four humors, or bodily fluids—namely the melancholy, phlegmatic, sanguine, and choleric. In his *Anthropology from a Pragmatic Point of View*, the eighteenth-century philosopher Immanuel Kant (1724–1804) sweeps such speculation to one side by distinguishing character from temperament: Temperament is given one by nature or habituation. People may vary in their temperaments, and indeed be classified by their dominant humors; however, character, which one either has or lacks, is the property of the will by which one binds oneself to self-prescribed rational practical principles. Kant's most influential ethical work, *The Groundwork for the Metaphysics of Morals*, identifies character with the good will, a will motivated solely by duty or principles of practical reason that it legislates to itself; Kant gives character the role of making use of such qualities as courage, resolution, and perseverance—which belong to temperament and might be bad if not in the control of a good will, the only thing good without qualification. In the *Metaphysics of Morals*, Kant likewise describes virtue as self-constraint, a power to withstand those of our inclinations that oppose morality—not merely some habit of morally good actions, virtue requires acting on “considered, firm and continually purified principles.”

Neo-Aristotelian critics have charged that Kant's emphasis on acting on principle results in his neglecting the roles character and virtue play in both a good ethical life and morally praiseworthy action, and Kantian defenders often reply by pointing to Kant's doctrine of virtue. But the criticism can be raised anew with respect to Kant's conception of character and virtue itself, for these replace appropriate feeling and the sensitivity it affords with a commitment to acting on principle. One source of apparent disagreement between Kant and Aristotle is terminological: Aristotle defines moral character as a disposition of appetite and emotion, but he insists that it cannot exist without practical wisdom. So Aristotle does not consider an act or person guided solely by appetite and emotion, however well trained these may be, to be virtuous or praiseworthy. For Aristotle, practical wisdom is necessary for appetitive and emotional dispositions to be good (this is what distinguishes virtue proper from natural virtue), just as for Kant, the good will is necessary for courage, resolution, and perseverance to be good. Still, principle is not practical wisdom, and Kant has less faith in the ability of developed capacities of judgment and feeling to result in right action, and more faith in the ability of principles to do so, than does Aristotle. This may be one reason for Kant's restriction of character to one's commitment to the ends that practical reason prescribes itself; presumably another is that, to the extent that character is the appropriate object of praise and blame, it ought to be voluntary, and Kant takes only our resolutions, but not our natural and habituated inclinations, to be voluntary.

Utilitarianism

Not himself a utilitarian, the eighteenth-century philosopher David Hume (1711–1776) characterizes virtuous character traits as those that tend to the good, of mankind or at least of their possessor, and vicious ones as those that tend to the bad. Hume thus shares with utilitarians the view that the moral value of a character trait depends on its nonmoral value for

people. Given its first widely influential formulation by Jeremy Bentham (1748–1832) in the nineteenth century in *The Principles of Morals and Legislation*, utilitarianism focuses on the rightness or wrongness of actions: the principle of utility deems that action right that, of the available alternatives in any given situation, tends to maximize the happiness of those affected. Utilitarianism's critics fault it for being insensitive to the importance of character evaluation for moral evaluation, but John Stuart Mill (1806–1873), a second-generation utilitarian, already stresses that acts ought to be evaluated for their consequences on character and character formation and includes as ingredients of happiness or utility such diverse intrinsic goods as friendship and virtue. A utilitarian may also subject character-traits and rules, and not only acts, to utilitarian assessment.

Challenges

In the twentieth and twenty-first centuries, questions have been raised about whether there is such a thing as character at all. The existentialist philosopher Jean-Paul Sartre (1905–1980) charged that to explain a person's (one's own or someone else's) action in terms of his or her character is to assimilate the action to an event in the natural world (for which the character is an ad hoc explanation), denying the person's freedom and refusing the rational understanding that human action demands. In a separate development, a research tradition in experimental social psychology, “situationism,” holds that people's behavior is not distinctive or consistent across a range of situations. These criticisms may apply more to the conception of character as revealed in signs than to the conception put forth in philosophical ethics.

CHEMISTRY. Where and when did chemistry originate? Some chemists would identify ancient Egypt as the birthplace of chemistry because of that culture’s glassworks, cosmetics, and mummification techniques. Advocates of this theory might also refer to a possible etymology of the word *chemistry* from the Egyptian word for *black*. Other historians place the origins of chemistry amid ancient Greek theories of matter that formulated the basic concepts—principles, elements, and atoms—for understanding the individuality of material substances and their transformations. Others would argue that chemistry emerged in medieval alchemy: alchemists invented the laboratory that is still the site for the production of chemical knowledge, and they established and transmitted techniques and instruments that are still at work in many chemical processes. Meanwhile, historians of institutional life would assert that chemistry emerged in seventeenth-century Europe when public lectures and chairs of chemistry were created.

The variety of answers to the question of origins points to the multiple identities of chemistry. A posteriori it seems natural to consider chemistry as an autonomous academic science with technological applications in a variety of domains. However, this is only one face of chemistry. Whether we consider chemistry as a set of technological practices—such as metal reduction, dyeing, glass-making—or as a theory of matter transformations, or as a teachable and public knowledge enjoying an academic status, the chronological marks change dramatically.

The question of origin cannot be settled not only because chemistry is multifaceted, but also because the answer depends heavily on the image of chemistry one wants to convey. For instance, eighteenth-century chemists strongly denied any connection between chemistry and alchemy. The kind of useful and reliable discipline they wanted to promote on the academic stage was contrasted with the obscurity and fraudulent practices of alchemists, although this is a discontinuity seriously questioned by historians of alchemy at the turn of the twenty-first century.

Alchemy in the Scientific Revolution

First, historians of alchemy note that there was no linguistic distinction between chemistry and alchemy in the seventeenth century—both disciplines being named “chymistry.” Second,

against the popular view of alchemy as a spiritual quest based on religious symbolism, historians such as Lawrence Principe and William Newman claim that “chymists” did actually manipulate and transform matter. While the religious interpretation of alchemy served to distance it from chemistry, they emphasize the continuity and argue that medieval alchemists already had developed experimental methods often considered as chief characteristics of modern science. They established a number of tests to identify substances; they used analysis and synthesis in order to demonstrate the similarity between substances extracted from nature and substances artificially produced in the laboratory; and they used weight measurements and the balance-sheet method traditionally credited to Antoine-Laurent de Lavoisier (1743–1794) to determine the identity of substances.

Early modern “chymistry” also questions the grand narrative of the scientific revolution, with Galileo Galilei’s (1564–1642) and Robert Boyle’s (1627–1691) mechanical philosophy whisking away the alchemical tradition. Boyle’s view of material phenomena as being produced by the interaction of small particles that have only primary qualities (size, shape, and motion) by no means implied a rejection of the alchemical tradition. Since Jabir ibn Hayyan (c. 721–c. 851), whose work was spread and discussed in the West in the thirteenth century, the discipline of alchemy had fostered a corpuscular view of matter that was later developed by Daniel Sennert (1572–1657), an early seventeenth-century chemist. Sennert managed to reconfigure the Aristotelian theory of matter by combining the

four principles with Democritean atomism. In order to provide experimental demonstration that matter at the microlevel is made by the juxtaposition of atoms, he performed a *reductio in pristinum statum* (reduction into the pristine state). Although Boyle positioned himself as a “natural philosopher” against “chymical philosophers, he was in debt to Sennert, since he tacitly used his experiments and his theoretical framework in his early essays as well as in *The Sceptical Chymist* (1680).

In addition, Boyle’s skepticism did not apply to alchemical transmutations. Until his death, he kept seeking the philosopher’s stone, using the knowledge he had learned in his youth from the American chymist George Starkey (1627–1665), who also initiated Sir Isaac Newton (1642–1727). Boyle, the advocate of public knowledge at the Royal Society, concealed his transmutational processes in secret language.

Thus, two of the celebrated founding fathers of modern science, Boyle and Newton, were dedicated believers in alchemical transmutation. Since Betty Dobbs’s 1975 work, *The Foundations of Newton’s Alchemy: or, “The Hunting of the Greene Lyon,”* historians of chemistry have reconsidered the impact of Newton’s bold chemical hypothesis at the end of his *Opticks* (1704). In the famous Query 31, Newton ventured an interpretation of chemical reactions in terms of attraction between the smallest particles of matter. A uniform attractive force allowed the smallest particles to cohere and form aggregates whose “virtue” gradually decreased as the aggregates became bigger and bigger. Whereas this hypothesis has been read as an extrapolation of gravitational physics to chemistry, it is possible to view it as a way to rationalize chemical practices that was impossible in Cartesian mechanism. Newton allowed chemists to understand and measure affinities in purely chemical terms.

Eighteenth-Century Cultures of Chemistry

Such was the program initiated by Etienne-François Geoffroy (Geoffroy the Elder; 1672–1731), who published a “Table des rapports” (table of affinities) in 1718. The substance at the head of a column is followed by all the substances that could combine with it in order of decreasing affinity—the degree of affinity being indicated by the place in the column. A substance C that displaces B from a combination AB to form AC will be located above B in the column because of its stronger affinity for A. Displacement reactions thus provided a qualitative measure of affinities and allowed predicting the outcome of reactions. Thus, chemistry came to be seen as a predictive and useful science in the eighteenth century.

It is important to stress that long before Lavoisier, chemistry had conquered the status of an autonomous academic discipline. A chemistry class had been established at the Paris Academy of Science in the late seventeenth century, whereas the physics class was only created in 1785. The chemistry class conducted systematic research programs in plant analysis and mineralogy. Not only were chemistry chairs established in a number of European universities, but also innumerable public and private courses of chemistry opened up with experimental demonstrations. They were attended by a variety of

audiences: pharmacists, metallurgists, as well as gentlemen and “philosophes” who practiced chemistry as enlightened amateurs. Chemistry was promoted alongside Enlightenment values as a rational and useful knowledge that would be of benefit to economy and society. A key strategy for winning political support was the introduction of the distinction between “pure” and “applied” chemistry by Johan Gottschalk Wallerius (1709–1785), who took the chair of chemistry in Uppsala in 1753. This distinction asserted the dignity of pure chemistry while transforming the chronological priority of chemical arts into a logical dependence upon “pure” knowledge. Chemistry could thus be perceived as a legitimate academic discipline in university curricula and highly valued for its usefulness in various applications. At the same time in France, chemistry was celebrated in the context of the *Encyclopédie* as a model science based on empirical data rather than on a priori speculations, a science requiring craft and labor, cultivated by skilled “artists” working hard in their laboratories unlike those lazy philosophers who never took off the academic gown.

However, chemistry was more than a fashionable science. So decisive was the success of Lavoisier’s revolution in the 1780s that most chemists and historians of science, according to Frederic Holmes, “viewed eighteenth-century chemistry as the stage on which the drama of the chemical revolution was performed” (Holmes, 1989, p. 3). They once described it as an obscure and inconsistent set of practical rules based on the erroneous phlogiston theory. This theory, shaped by Georg-Ernst Stahl in the early eighteenth century, explained a number of phenomena such as combustion, as well as properties such as metals or acids, by the action of an invisible principle or fire named phlogistan (from the Greek term for “burnt”). The canonical story thus culminated in Lavoisier’s questioning the existence of phlogiston and its alleged presence in metals, in acids, in combustion and respiration, and consequently overthrowing the old paradigm.

When historians resist the temptation to read eighteenth-century chemistry backward, waiting for Lavoisier to arrive on the stage, they quickly realize that this standard picture was only one aspect among numerous diverse cultures of chemistry in the eighteenth century, many of which were extremely innovative. In workshops and firms, the invention of continuous processes led to what historians of industry described as “the chemical revolution.” In more academic spaces, laboratory practices were also deeply changed by the study of salt solutions when wet analysis was added to the traditional fire analysis and color indicators were systematically applied to acids and alkalis. This change, especially visible in the research program conducted at the Paris Academy of Science on plant and mineral analysis, had a theoretical impact: chemists gave up the old concept of salt as a universal principle, in favor of the notion of middle salt—a substance resulting from the combination of volatile and nonvolatile salts or of alkali and acid. This redefinition subverted the traditional notion of principles as material entities as bearers of properties. Substances could present similar properties and belong to the same class despite their different constituent principles. The idea of interchangeability was reinforced by the displacement reactions that

allowed the construction of affinity tables. Affinity tables favored the view that the behavior of a “mixt” (compound) depends less upon the nature of its constituent principles than on its relations with other substances. The relational identity of chemical substances minimized the importance of principles—whether they be three, four, or five—that chemists used to oppose to the mechanistic view of a “catholic matter.” Moreover in a number of eighteenth-century chemistry courses—for instance in Hermann Boerhaave’s (1668–1738) textbook and Guillaume-François Rouelle’s (1703–1770) lectures—elements were often redefined as “agents” of chemical reactions rather than as constituent principles. Elements were consequently presented as “natural instruments” together with “artificial instruments” such as laboratory vessels, furnaces, and alembics. This pragmatic notion of elements accompanied their redefinition in operational terms as substances that could not be further decomposed by available analytic techniques.

From Phlogiston to Oxygen

In addition, the phlogiston theory was neither an overarching nor a rigid framework. The notion, which was first forged by Georg Ernst Stahl (c. 1660–1734) around 1700, was most often mixed either with Newton’s views of matter that inspired salt and affinity chemistry or with various notions inspired by local mining or pharmaceutical traditions. It is therefore difficult to identify a unitary phlogiston theory that would define eighteenth-century chemistry. Rather, two distinct phlogiston theories prevailed in two different contexts. In mid-eighteenth-century France, Stahl was considered as the founder of chemistry when Rouelle and his pupils redefined Stahl’s “inflammable earth” as fire. The fire principle, always invisible because it circulated from one combination to another one, imparted combustibility or metallic properties when it was “fixed.” It was released during combustion and metals calcination. Indeed, there was a difficulty here: if phlogiston was released when metals calcinated, how would one explain their increase of weight? The anomaly had been known for decades and had not prevented the success of this powerful theoretical framework since, as Immanuel Kant and Lavoisier himself acknowledged, it was Stahl’s merit to realize that combustion and reduction were two inverse reactions and that calcination and combustion were one and the same process despite their phenomenological dissimilarities. Lavoisier cast doubts on phlogiston when he addressed the question of weight increase in 1772. After conducting experiments of combustion of phosphorus and lead calcination with careful weighing of each ingredient and each piece of apparatus before and after the reaction took place, he concluded that the weight gain could be due to a combination with part of the air contained under the flask. Although Lavoisier was convinced that his discovery was about to cause a revolutionary change in physics and chemistry, he could not yet refute that combustion released phlogiston. Unsurprisingly many contemporary chemists adopted a compromise between the two interpretations, and Pierre-Joseph Macquer (1718–1784) redefined phlogiston as the principle of light distinct from heat. Meanwhile an “English phlogiston” emerged from pneumatic studies that gained a sound phenomenological reality through its assimilation with hydrogen.

The study of gases so much changed the landscape of chemistry in the 1770s that some contemporary chemists used the phrase “the pneumatic revolution.” Although air had been considered as one of the four elements, it was considered as a mechanical agent rather than as a chemical reactant until Stephen Hales (1677–1761), a British plant physiologist, built a “pneumatic chest” for collecting gases released by physiological processes. With this apparatus chemists were able to collect the gases given off by chemical reactions, to measure their volume, and to submit them to various tests. Joseph Black (1728–1799) identified “fixed air” (carbon dioxide) in 1756; in 1766, Henry Cavendish (1731–1810) isolated “inflammable air” (hydrogen); in 1772 Joseph Priestley (1733–1804) described a dozen new airs in his *Experiments and Observations on Different Kinds of Air*. In 1774 Karl Wilhelm Scheele (1742–1786), a Swedish pharmacist, isolated and described a new air that made a candle flame brighter and facilitated respiration. By the same time, Priestley had also produced a similar air by the reduction of the “red precipitate of mercury,” a result that he communicated to Lavoisier when he visited him in Paris in October 1774.

Lavoisier was a latecomer in the crowd of chemists “hunting” airs, his earlier interest in chemistry being related to geology. His attention was drawn to the mechanisms of fixation and release of gases when he discovered the role of air in combustion. He consequently became aware of the British works—with the help of his wife Marie-Anne-Pierrette Paulze-Lavoisier (1758–1836), who translated foreign publications for him. He conducted systematic experiments on “elastic fluids” that were published in his *Opuscules physiques et chimiques* in 1774. He repeated Priestley’s reduction of the red precipitate of mercury and performed the reverse operation of calcining mercury. Whereas Priestley characterized the gas released as “dephlogisticated air” Lavoisier concluded in 1778 that this gas was “the purest part of the air.”

Two alternative views of gases were in competition. For the British pneumatists, the various gases isolated were composed of one single air differentiated according to the proportion of phlogiston they contained. In other terms, they fit nicely into the phlogiston paradigm. They even reinforced it because a pneumatic science, whose unquestioned leader was Priestley and which allowed a better understanding of physiological processes in plants and animals as well as medical applications, emerged. By contrast, Lavoisier came to see atmospheric air as a compound and developed a theory of gaseous state. All solid or liquid substances could be in a gaseous state depending on the quantity of caloric (or heat) they fix. Thanks to his caloric theory of gases, Lavoisier was in a better position to refute the phlogiston theory of combustion. He could account for the release of heat once he admitted that combustion consisted in a combination with a portion of atmospheric air that released its caloric. This portion of air that he first named “vital air”—later renamed oxygen—would play a key role in Lavoisier’s chemistry. Not only did it explain combustion and calcinations but it was also the principle of acidity. Therefore, during the controversy that followed, Lavoisier’s theory was referred to as “oxygen theory” or sometimes “antiphlogistic

theory.” Phlogiston was condemned as a useless chimerical entity, only to be replaced by another enigmatic principle of heat, “caloric,” while the omnipresent element oxygen’s being a bearer of properties was an echo of the older chemistry.

Revolution or Foundation?

Lavoisier’s revolution did not condemn the old notion of elements common to all substances, although he destroyed three of the traditional four elements, fire, air, and water. The demonstration that water was not an element but a compound of two gases was made in a solemn experiment of analysis and synthesis of water set up in February 1785. It required heavy and expensive equipment designed with the help of a military engineer and with the support of an academic Commission of Study for the Improvement of Balloons. With this spectacular experiment Lavoisier won his first allies. Together they were able to take advantage of the opportunity to reform the chemical language as outlined by Louis Bernard Guyton de Morveau (1737–1816) and build up a new “Method of Chymical Nomenclature” that reflected Lavoisier’s theory and eliminated phlogiston. The new system, published in 1777, was seen as a coup d’état and sparked a fierce controversy. The anti-phlogisticians mobilized all resources, including the creation of a new journal, *Annales de chimie*, in order to convince European chemists. Moreover, to defeat the last and attractive British version of phlogiston as inflammable air (hydrogen), which was articulated by Richard Kirwan (1732–1812), Madame Lavoisier translated into French his *Essai sur le phlogistique* (1788; Essay on phlogiston), while the anti-phlogisticians criticized the author’s view in footnotes. Beyond the issue of phlogiston, numerous objections to the new language were raised by contemporary chemists concerning the choice of terms, such as “oxygen” (an acid generator according to Lavoisier’s theory of acids) and “azote” (improper for animal life and a property of many other gases). Although the French “nomenclators” did not change any term, their system was finally adopted throughout Europe by 1800. But this victory did not always mean conversion to all facets of Lavoisier’s chemistry. The reform of language fulfilled a long-felt need among the chemical community and it came at the right moment: textbooks were needed to train pharmacists as well as chemists for burgeoning industries. The new systematic language and Lavoisier’s *Elements of Chemistry* (1789) facilitated the teaching of chemistry.

In the context of the French Revolution, which resulted in Lavoisier’s death on the guillotine and the creation of a new educational system, Lavoisier’s revolution has been perceived as the destruction of premodern chemistry and the foundation of modern chemistry on a tabula rasa. However, the celebration of the founding hero overemphasizes the impact of his contribution to chemistry. Lavoisier did not overthrow the whole of chemistry. The tradition of salt and affinity chemistry remained untouched. Rather, the latter was revised and integrated in a grandiose “Newtonian dream” by Claude-Louis Berthollet (1748–1822) in his *Essai de statique chimique* (1803). Lavoisier invented neither the “law of conservation of matter”—a kind of axiomatic principle tacitly assumed by all natural scientists long before him—nor the laws of chemical

proportions that inspired the chemical atomism developed by the next generation of chemists.

Nineteenth-Century Chemical Atoms

Nineteenth-century chemistry has often been described as a smooth sequence of discoveries that gradually established modern chemistry. Positivist historians were content with reporting landmark events such as John Dalton’s atomic theory, Amedeo Avogadro’s law, Dmitry Ivanovich Mendeleev’s periodic system, and so on. In thus conveying a cumulative process, they not only distorted history but also tended to deprive past scientists of inner consistency because they failed to accept many of these “great discoveries.”

One major feature of nineteenth-century chemistry is that the history of ideas did not follow the pathway that seems logical from a present-day perspective. For instance, the laws of chemical proportions did not follow from Lavoisier’s program. Instead, they emerged from salt chemistry, more precisely from attempts to determine the weight or ponderous quantity of a base that could neutralize a definite quantity of acid. While the chemical revolution was drawing all attention toward Paris, two German chemists, Karl Friedrich Wenzel (1740–1793) and Jeremias Richter (1762–1807), were initiating a quantitative chemistry that they named *stöichiometrie* or stoichiometry (from the Greek *stoicheion*, or element). The main assumption that the properties of any substance depend upon the nature and proportion of its constituent elements opened up a research program for chemists whose key words were *analysis* and *quantification* (titration or dosage).

The field of stoichiometry was extended in 1802 when Joseph Louis Proust (1754–1826) applied Richter’s notion of “equivalent,” so far limited to reactions between acids and bases, to all combinations and formulated a general law: the relationships of the masses according to which two or several elements combine are fixed and not susceptible of continuous variations. While Berthollet questioned the generality of Proust’s law of definite proportions, John Dalton (1766–1844), a professor at Manchester, made it the basis for his atomic hypothesis. He assumed that chemical combinations take place unit by unit, or atom by atom. He added a law of multiple proportions: when two elements form more than one compound, the weight proportions of the element that combines with a fixed proportion of another one are in a simple numerical ratio. Dalton’s hypothesis rested on the assumption that atoms were solid and indivisible, that they were surrounded by an atmosphere of heat, that there were as many kinds of atoms as there were elements. Dalton’s atoms were not the uniform and minute discrete units that structured all material bodies of ancient atomism. Rather, they were minimum and discrete units of chemical combination. And Dalton assumed that atoms would combine in the simplest way, that is, two atoms formed a binary compound. The main advantage of Dalton’s hypothesis was that it allowed simple formulas. Instead of determining the composition of a body by percentages, chemists could express it in terms of constituent atoms thanks to the determination of atomic weights. Of course it was impossible to weigh individual atoms. Since Dalton could not determine this weight

by using the neutrality of the compound like Richter, he elected a conventional standard. He chose hydrogen as the unit of reference. For instance, hydrogen and oxygen were known to form water, whose analysis gave the ratio 87.4 parts by weight of oxygen for 12.6 of hydrogen. If hydrogen has a weight equal to 1, the relative atomic weight of an atom of oxygen will be roughly 7. Shortly after Dalton's *New System of Chemical Philosophy* (1808), Joseph Gay-Lussac (1778–1850) announced that volumes of gas that combine with each other were in direct proportion and that the volume of the compound thus formed was also in direct proportion with the volume of the constituent gases. The volumetric proportions thus seemed to confirm Dalton's weight ratios.

To explain the convergence, both Amedeo Avogadro (1776–1856) in 1811 and André-Marie Ampère (1775–1836) in 1814 suggested that in the same conditions of temperature and pressure, equal volumes of gases contain the same number of molecules. In order to admit this simple hypothesis, however, both men had to admit a second hypothesis: that when two gases joined to form a compound, the integrating molecules should divide into two parts.

From a modern perspective this hypothesis was a big step forward because it suggested the distinction between atoms and molecules. Why, then, was it rejected in the 1830s and for several decades afterward by the most prominent chemists? The rejection of Avogadro's law is a classical topos for illustrating the opposition between presentist and historicist approaches. The alleged "blindness" of nineteenth-century chemists appears as a perfectly consistent attitude once one considers that Avogadro's hypothesis of molecules formed of two atoms of the same element stood in contradiction to the theoretical framework of chemical atomism. In Dalton's theory, such diatomic molecules were physically impossible because of the repulsion between the atmospheres of heat of two identical atoms, and they were theoretically impossible in the new electrochemical paradigm set up by Jöns Jacob Berzelius (1779–1848) on the basis of his experiments on electrolytic decomposition. Elements were defined by their electric polarity, and the intensity of the positive or negative charge determined the affinity between them. Molecules of two atoms of the same element were impossible because of the repulsion between two identical electrical charges.

The distinction between atom and molecule did not directly follow from Avogadro's law. Rather it was formulated by a young chemist, Auguste Laurent (1807–1853), trained in mineralogy and crystallography. He challenged Berzelius's electrochemical view. For Berzelius all compounds resulted from the electric attraction between two elements. This dualistic view was extended to organic compounds thanks to the notion of radical—for instance the benzoyl radical discovered by Leibig—a group of atoms that, like elements, persisted through reactions. In the 1830s Jean-Baptiste-André Dumas (1800–1884) prepared trichloroacetic acid by the substitution of three atoms of chlorine to three atoms of hydrogen in acetic acid. His student Laurent noticed the similarity of properties between the two acids. Electronegative atoms of chlorine could replace electropositive atoms of hydrogen without changing

the properties too much. He consequently developed a unitary theory that Dumas called "type theory" in 1838: in organic compounds there exist types that persist when elements are changed. This suggested that the properties of compounds depended more on the architecture of molecules than on the nature of constituent atoms. Type theory applied to the increasing crowd of organic compounds while inorganic chemistry was still ruled by dualism.

Charles Frédéric Gerhardt (1816–1856) attempted to reunify chemistry by extending the type theory to all compounds, using analogy as a guide. Although he admitted that we do not know anything about the actual arrangement of atoms in a molecule, he defined three types—hydrogen, water, and ammonia—as an ideal taxonomic scheme. According to Gerhardt, all compounds derived from these three types.

The theory of type implicitly indicated that atoms of different elements had different combining powers or valences. Hydrogen, for example, has a valence of one, while oxygen has two and nitrogen three. It is worth emphasizing that although nineteenth-century organic chemists such as Gerhardt and August Kekulé (1829–1896) did not believe in the actual existence of atoms and molecules, they were able to invent structural formulas that allowed them to predict and create new compounds.

The Construction of the Periodic System

Gerhardt's unitary perspective also provided the foundation for the construction of the periodic system. Dmitry Ivanovich Mendeleev (1834–1907) was certainly not the first chemist who tried to classify elements on the basis of atomic weights. Van Spronsen reasonably argued that the periodic system was codiscovered by six chemists in the 1860s. However, Mendeleev adopted a different strategy. He pointed to the Karlsruhe Conference, held in 1860, as the first step toward the periodic law. This first international meeting of chemists adopted atomic weights based on Avogadro's and Gerhardt's views. From the general agreement on the distinction between atoms and molecules, Mendeleev derived another crucial distinction, between simple body and element. Since Lavoisier's famous definition of elements as nondecomposed bodies, most chemists did not distinguish between the two terms. Mendeleev, on the contrary, stressed the difference between the simple substances, empirical residues of decomposition characterized by their physical properties and molecular weights, and the abstract element defined as an invisible ingredient and characterized by its atomic weight. Mendeleev chose to classify elements rather than simple bodies because he considered them as responsible for the properties of simple and compound substances. Mendeleev was thus the first chemist who really worried about a clear definition of what was to be classified. Although abstract and unobservable, Mendeleev's elements were material entities and true individuals. Mendeleev was a staunch opponent of the hypothesis formulated by William Prout (1785–1850), which asserted that the multitude of simple substances derived from one single primary element, usually identified as hydrogen. Throughout the

nineteenth century this reductionist mainstream stimulated attempts at classifying elements. Classifications were mainly aimed at tracing genealogical relations or families by grouping analogous elements in triads or families according to the numerical ratios of their atomic weights. Starting from the assumption that elements would never be divided or transmuted into one another, Mendeleev took an opposite direction. He sought unity in a natural law ruling the multiple elements, rather than in matter itself. He compared the most dissimilar elements and firmly relied on the order of increasing atomic weights. Whereas grouping elements on the basis of valences always faced the difficulty of multiple valences, Mendeleev strictly relied on the order of increasing atomic weight, which he regarded as the constant criterion of the individuality of chemical elements.

Indeed, this criterion revealed some deficiencies. It sometimes blurred strong chemical analogies (for instance between Li and Mg, Be and Al, B and Si) or induced unexpected proximities (for example, in Mendeleev's eighth group). Mendeleev struggled with these difficulties and published thirty different tables in order to better suit his system with chemical analogies. However, his abstract notion of elements allowed predictions of unknown elements. Many of these elements were confirmed during Mendeleev's lifetime and served to validate his system while guarding it from further challenges. The discovery of a dozen rare earth elements in the late nineteenth century created difficulties because they lack individual properties and have strong mutual analogies. The inert gases were not welcomed either, first, because they had not been predicted, but mainly because they did not exhibit chemical properties. The atomic weights determined by William Ramsay (1852–1916) and Lord Rayleigh (John William Strutt; 1842–1919) for helium (4) and argon (40) would result in the placement of the latter between potassium and calcium according to its atomic weight. This was impossible, and the whole periodic system was in danger to collapse. Mendeleev raised doubts about the elemental nature of argon. Thanks to their sound belief in the periodic law, Ramsay and Rayleigh found a place for them at the cost of a new reversal of increasing atomic weight values and a new prediction of an intermediate element between neon and argon. A zero group was opened up that first undermined Mendeleev's notion of individual elements defined by their atomic weight. A second blow came from the discovery of electrons and radioactivity. Mendeleev desperately tried to explain this apparent anomaly with the hypothesis of confused movements of ether around heavy atoms. In this grandiose attempt to unify mechanics and chemistry, Mendeleev admitted ether in the periodic system in the 0 group. This error is instructive because it reveals the intellectual roots of Mendeleev's system. It is thus impossible to consider Mendeleev's system as a kind of precursor of quantum chemistry. Mendeleev dealt with elements and not with atoms.

Chemistry and Quantum Theory

The periodic system nevertheless served as a guide in the emergence of atomic physics, especially for Niels Bohr's (1885–1962) quantum model of the atom. Atoms of successive elements in the periodic system present an additional electron on the outermost shell. When a shell becomes full, a new shell

begins to fill. Exceptions to this rule are reflected in the uneven length of periods in the periodic system.

The autonomy of chemistry thus seemed to be deeply questioned in the mid-twentieth century. If individual properties of chemical elements can be deduced from quantum theory, the theoretical foundations of chemistry lie in physics. Chemistry would be a reduced science. Many chemistry teachers struggle against these reductionist tendencies and claim that all the properties of chemical elements and compounds cannot be predicted by quantum calculus, even with the help of computer simulation. The bottom-up approach that prevails in recent materials chemistry and pharmaceutical research places great expectations in the control of individual atoms. However, those nanotechnologies also reveal that the chemist's ability to synthesize new products relies on a good deal of know-how and astute rules as much as on the fundamental laws of nature. Furthermore, recent synthetic strategies are more and more inspired by living organisms. For instance, supramolecular chemistry aims to design chemical processes that mimic the selectivity of biological processes to obtain molecular recognition without the help of genetic code. Thus, chemistry is renewing its old alliance with life science.

CHICANO MOVEMENT. Between 1966 and 1977, members of the Mexican-American community engaged in a period of widespread political activism akin to other civil rights and antiwar movements of the 1960s. The resulting challenges and concurrent mentalities became the Chicano movement, or as it is now known in recognition of the equally important participation of Chicanas, the Chicana/o movement. During this period large-scale political organizing occurred among the Mexican-American community with a hitherto unprecedented urban energy. For those involved in the Chicana/o movement, the experience was characterized by a remarkable intensity at the personal and local collective levels. This rise in political engagement was the consequence of an interaction between a specific cultural context and contending, contentious social efforts, civic events, and ideological beliefs. It challenged the ineffectiveness of liberalism and the increasing economic and human cost of an armed interventionist foreign policy in the third world and this, combined with urban youth dissidence and ethnic protests, encouraged growing social and political militancy among Mexican-Americans.

A series of changes and continuities took place across Mexamerica in regard to the position and status of Mexican-Americans. Even though Mexicans slowly entered the skilled labor market, larger numbers remained poor due to discrimination and exploitation, and their social and educational possibilities were inhibited by social controls and economic immobility. At the same time, a very modest, educated, and political middle class burgeoned. During the 1950s and 1960s, the number of Mexican-Americans elected to office slowly increased, but electoral underrepresentation remained the rule. In comparison with the preceding periods, the number of

Mexican-American union participants slightly increased in industries accessible to unions. However, far more people were barred from, rather than included in, these unions. Basic workers and farm laborers remained the most visibly excluded.

While explicit anti-Mexican discrimination receded in some areas of employment and housing, overall discrimination continued. Mexicans held the least desirable and worst-paying jobs in the economy and lagged behind the income and schooling levels of both Anglos and blacks. Despite this, the Mexican community grew numerically, including both citizens and immigrants, and this was reflected in the increase of Mexican high school and college graduates. Growth continued into the following decades. Women's participative access to heretofore enclosed social and economic sectors was particularly noticeable, yet some exclusion persisted. The number of Mexican female college graduates increased relative to years past, as did female business ownership. Still, most Mexican women did not attend college and continued to figure prominently in the minimum-wage labor sectors. They were variously oppressed by diverse institutions including the state, their neighborhoods, and their family circles. Immigrant single mothers were most vulnerable to forms of brutality and violence, which included forced sterilizations. These multiple oppressions continued to limit the opportunities for Mexican women, as well as Mexican men and children, over generations.

Selecting chronological dates is always an arguable procedure, but there are two events that, because of their public resonance, could be used to chart the rise and decline of the national Chicana/o movement. The 1966 farmworkers' march to Sacramento, California, is often acknowledged as a visible sign of rising, proactive Mexican-American public sentiment. This could be considered the beginning of notable political ferment. Ten years or so later, the 1977 San Antonio, Texas, Immigrant Rights Conference, which was prefaced by growing anti-Mexican outlooks, signaled an acknowledged decline of Chicano militant effectiveness since the attempt at coordinated pro-immigrant rights failed on this occasion. This was soon followed by the anti-affirmative action backlash stimulated by the Supreme Court's "reverse discrimination" decision in *Bakke v. Regents of the University of California* (1978).

The view of some Chicana/o activists from the mid-1960s to the mid-1970s was that civic matters compelled a reevaluation of earlier ideological tenets (a trend emphasizing gradualism known as Mexican-Americanism), and required the development of a new "in your face" style of politics. There was much insistence upon democratic rights, and high-volume addresses were full of heightened cultural and ethnic references. These trends were effectively legitimated by relatively wide mobilizations. Advocacy reform practices previously local became increasingly regional and tentatively national. In short, the Chicana/o movement flourished as an ethnic revivalist movement of the 1960s and 1970s and was anchored in new, specifically charged politics. It involved thousands and spread from Galveston to Chicago, from Seattle to Brownsville.

Contents

Central to the movement phenomena, ad hoc organizations that focused on specific local crises or sector needs sprang up across the Southwest and Midwest. These groups centered on issues such as education reforms, service inequities, undesired urban changes, biases in war on poverty programs, drug impact, welfare rights, child care and ex-felon needs. Title II of the Economic Opportunity Act of 1964, which stipulates participation by the “client” (that is, the poor), encouraged local group mobilization either through a positive outreach facilitating participation or as a consequence of negative reactions to the perceived malfunctioning or exclusivity of certain programs. Self-help organizations advocating individual determination developed in many localities and placed stress on individual rights and access to services, particularly for women and children. Many urban Mexican-Americans increasingly came to participate in public civic activities that involved direct interaction with officials and program personnel. The youth and women stepped forward as the primary participants in these efforts. Although Chicana/o politics in the early 1960s remained overwhelmingly liberal and reformist in content, more radical currents insisted on civic equities and plural participation within areas often controlled by electoral or patronage cliques. However, the dynamic leadership initiators often voiced a distrust of known older electoral *políticos*. By the late 1960s, certain currents encompassed procommunity autonomy and pluralist tendencies vis-à-vis constituted civic arrangements that were perceived as exclusionary and manipulated. Importantly, movement spokespersons established relations with groups, organizations, educational institutions, and political leaders not only across the Mexican border but also in other countries.

Cultural Context

At times, Chicana/o political energy flowed from cultural circumstances. On other occasions, political conditions encouraged cultural happenings. Culture, history, and arts resonated in every discourse. Community affairs became increasingly varied and complex, reflecting nearly all hues of the social spectrum from center to left. To oppose the movement, its cultural rhetoric, professed priorities, or stressed styles could be interpreted as a confession of rightist sympathies. To be sure, older organizations and electoral politics continued as the new politics emerged. The origins of this energized cultural ideological activity lie in the demographic and material circumstances of the early 1960s as well as in subjective conditions. Certainly, contrasting opinions on politics and history—of complacency versus insurgency—contributed to ideological growth. Mexicans were increasingly recognized by the media as the nation’s second-largest minority, but their protest movement was not defined in the way that those of white and black dissidents were, and the media did not actively shape their leadership and rhetoric. The widespread social and economic conditions of laboring people heightened the political consciousness of Chicana/o activists. The movement drew inspirational and ideological reinforcements from a variety of sources, including those common to other social movements. But it also uniquely derived many of its beliefs from the historical heritage of Mexican-Americans themselves and in particular the ideological legacy of Mexico and Latin America. Significantly, Chicana/o activists also explored and deployed nativist

Mesoamerican heritages, and this was particularly evident in the arts. After politicized arts hammered on doors, commercially expressive cultural activities eventually flowed to the public domain.

Sharing the upheaval that grew out of changes in the ideological climate and material conditions of the early 1960s, individuals of Mexican descent engaged in a variegated burst of activity loosely identified as the “Chicano movement.” Among the seminal organizing and strategic forces were student organizations, defense groups, and artists’ coalitions; the United Farm Workers Union; the Alianza Federal de Mercedes, or land rights movement; the Crusade for Justice, a political rights organization; and eventually, La Raza Unida Party. These were followed by church associations and women’s and immigrants’ rights organizations. Most of these forces were comprised of working-class people, and women often provided the membership base. The movement had a range of concurrent fronts, which were noticeably secured in local bases where individuals chose priorities and the levels of their participation. Whatever the particular goals and methods of the political activism, the underlying motivation was always a general dissatisfaction over the Mexican’s political, economic, and social status in an Anglo-dominated society. Focus was increasingly placed on questions of exploitation, repression, exclusion, alienation, ethnicity, identity, class, gender, and chauvinism. History was privileged, perhaps more than in other social movements. Understanding the dynamics of the Mexican-American experience became a paramount motif, a voiced ideological necessity in the struggle to assess the present and envision a future for Mexican-Americans. These particular issues were sharply expressed in the arts; poets and muralists served as ideologues.

Ideology

Although *Chicanismo* often seemed a loosely expressed concept, in specific situations it could translate as a radical political and affirmative ethnic populism. The issue of identity linked to political demands jumped to the forefront. The term *Chicano* itself, used among the youth in particular regions, denoted the person and the group. *Chicanismo* referred to a set of beliefs and, more importantly, to a political practice. Its emphasis on dignity, self-worth, pride, uniqueness, and a feeling of cultural rebirth made the term attractive to many people of Mexican origin, as well as some of Latin American descent, in a way that cut across class, gender, regional, and generational lines. Negative past experiences regarding the denial of cultural heritage increased the appeal of *Chicanismo*, which emphasized Mexican cultural consciousness and social and linguistic tradition as well as economic and occupational opportunities. The Chicana/o movement became a challenge to the assumptions, politics, and principles of the established systems within and outside the community. However, even though it marked a progressive step in the struggle for identity by denying the grosser aspects of deculturalization, the designation also became a subterfuge for avoiding a critique of identity and Mexican “singularity.” The widespread appeal of *Chicanismo* without explicit ideological class content shows, in large part, how often heterogeneous political elements could identify with the “Chicano movement.” In practice, people expressed *Chicanismo* in a variety of ways.

In hindsight, one can ask whether *Chicanismo*, if seen through a militant conceptualization and in the context of its identity and ideological notions, was not simply one more effort to subsume Mexican identity and all of its implications in a dominant social context of covert anti-Mexicanism. Indeed, the term was a necessary referent for a distinct social group that could be differentiated from others in the United States by virtue of its ethnic and national roots. Other designations continued to be used, and the tension between *Chicano* and *Mexican* evolved rather than disappeared. In the initial cultural and political discourse, *Chicano* was clearly an abbreviated form for Mexicans north of the Rio Bravo, and *Chicanismo* meant a politically asserted *Mexicanidad*. Curiously, many middle-class people rejected the term as pejorative, while the lower classes preferred the appellation of *Mexicano*. Yet, to many of the young, *Chicano* was *the* term; for activists it was *the* litmus test for a political frame of mind. Furthermore, the *Chicano* denotation not only emphasized an unconventional “lifestyle” stressing *Chicanismo* but also stressed the more widely noted features of emphatic public cultural practices and radical personal values of the late 1960s embodied in the attitude, “*Soy Chicano y qué!*” (“*I am Chicano and what of it!*”).

Gender

The gender issue was sharply raised by individuals, organizations, and community activists in several Chicana/o movement areas starting in the late 1960s. Particularly noticeable were matters related to women in community settings and youth and student circles and on the perceived subordination of women and gender issues within the movement itself. Nonetheless, women obviously participated in all efforts associated with the Chicano movement. Any reference to its subsumed activities objectively implied female participation even as some pointed out that traditional gender roles were enforced, meaning that women could only occasionally assume leadership roles in many movement organizations. Inspired by militant women, Chicanas integrated Mexican and Latin American feminist heritages and drew from the contemporary radical feminist programs. Increasingly, women’s organizations grew out of community actions, political campaigns, union groups, campus activities, and inmate and ex-felon concerns. The late 1960s and the 1970s witnessed an increasing emphasis on full female participation in all aspects of community civic efforts as well as on the development of activities specific to women. At the same time, movement newspapers and journals increased their coverage on issues pertinent to gender issues.

Chicanas believed in Chicana solutions to Chicana problems the same way that Chicanos upheld Chicano solutions to Chicano problems. The initial impetus was for a critique of stereotypes impeding gender equality. This thrust grew organizationally, and its edge reflected the internal dynamics within movement organizations. Eventually a view of Chicanas as the victims of multiple oppressions (as women, ethnics, and workers) evolved. Female activity remained strongest in community arenas such as those of unionization and public services. The majority of Chicana activists participated in organizations that were not exclusively female, but gender issues arose in all groups and circumstances and were dealt with in one way or

another. Over time Chicana/o organizations have had prominent female members. In fact, MALDEF (Mexican American Legal Defense and Educational Fund), a highly visible civil rights organization, has had two long-term national women leaders. Women in higher education circles had advantaged access to forums from the 1980s onward and publicized their views and priorities. Despite resistance and controversy, veteran militants did not ultimately defer the feminist concerns, and eventually a persistent strain of efforts addressed the needs and concerns of lesbian and bisexual women.

Universalism

From the late 1960s through the 1970s, the tendencies of utopian indigenismo, cultural nationalism, and Saul Alinsky-style civil rights activism seemingly spread. These spoke only partially to the more structurally oriented economic critiques of the Mexican-American reality being raised. These criticisms were condensed into a modestly growing Marxist current within the Mexican-American community containing many of the various Marxist tendencies found in the United States. For some Marxism remained an intellectual fad, and a few considered it a philosophical critique of the capitalist society and capitalist “hegemonic culture” in particular. For others Marxism became a conceptual framework for examining the Mexican experience in a more specific and extensive manner, particularly as related to labor and gender. And some took it as an ideology combining analysis and guidance in political action and organizational structure. In this renovation, members of the 1960s and 1970s generations joined Marxists from the 1940s and 1950s. Despite the Chicana/o left wing’s ideological commonality, this sector’s social makeup was varied. Moreover, a substantial part of the Mexican Left had no specific organizational allegiance. And the part that did drew a distinction between those groups stemming from the community, such as CASA (Court Appointed Special Advocates), and those outside of it.

Problems and Achievements

As the events of the 1960s and 1970s unfolded, a presently unmeasurable element impacted political development, organization, and leadership. Police surveillance presumably occurred throughout the Southwest among Chicana/o efforts. Targets were determined, strategies devised, and tactics conducted to weaken militancy and political organizations of all types. This covert procedure was concurrent with the more visible and understood overt activities of incitements, arrests, and beatings. Police provocation to commit violent acts and, more frequently, display counterproductive behavior, was a fact. This of course led to dissension within or between groups, as well as among individuals. Police control remained constant throughout the 1970s, perhaps negatively affecting achievements.

By stressing self-determination, pride, and even aggression, the spokespersons of the Chicana/o movement achieved reasonable successes during the 1960s and 1970s: they made the larger social majority acknowledge the discrepancy between the democratic stance professed by the state and the reality in the barrios. Moreover, leaders undertook the strong actions needed to enable the more moderate elements to enter governmental,

academic, and labor institutions. Significantly, several movement thrusts continued: unionization, Chicano studies, civil rights litigation, and immigrant rights are some examples.

Clear limitations stand out when reviewing the accomplishments of the movement. Token reforms, limited representation, and personal mobility were often achieved. But Chicano self-determination, though espoused, was not accomplished. The problems confronting the movement were several: the lack of a coherent, broad, radical program for a convinced constituency; a lack of adequate material resources; and a lack of structured disciplined organizations with stable leadership mechanisms.

Conclusion

The Chicana/o movement reflected a broad and deep range of activities, most of which proved seminal to the debates, issues, and forms of later years. By the late 1970s, activists and goals diffused, and priorities and means were transformed. The intensity of the movement's momentum diminished somewhat, and activism too often became a consciously delimited activity for individuals. Mexican-American political players were no longer easily identifiable as stemming from two or three sectors within the community, nor did they share the same ethnic fervor or radical perspective as the militant Chicanas/os who had first created the context and opportunity for empowerment. Rather, spokespersons and leaders, women and men, became a complex amalgam of backgrounds, interests, ways, and goals. A growing number of professional politicians surfaced from a variety of Mexican communities, each of them espousing the concerns of a unique political constituency, and were increasingly acknowledged or tolerated as public "leadership." Many young Mexicans had explored the forbearance of the establishment and, in every way accessible, pursued what the system offered and accepted pragmatic ways of achieving reformist results. Almost bereft of resources, activists transmuted their energy into assets for their community. In that turnabout, young Chicanas/os motivated a large percentage of their community leaders to exhibit a stronger public image. In effect, they demanded that society at large receive a new message about what it meant to be of Mexican descent. They also generated support for educational, political, and economic advancements.

Public officials began addressing issues of concern to Mexican-Americans in a more considerate manner. Finally, and perhaps most importantly, the Chicana/o movement forced certain concessions from the Anglo institutional mainstream, and some of these concessions—voting and representational rights, partial bilingual education, meagerly funded Chicano studies programs and unenthusiastic affirmative-action employment practices—created a setting from which a viable Mexican middle class could expand to local prominence. The 1960s and 1970s activists also laid the groundwork for a series of economic advancements, so that by the 1980s a Mexican middle class had indeed effectively consolidated within the community. The short-term occupational gains of the 1970s were perhaps magnified by the economic setbacks of the 1980s and the consequences of 1990s globalism. Mexican-Americans suffered the effects of drastic federal policy changes lessening government support for affirmative action and civil rights affirmations. But as with other U.S. constituencies, some Mexican-American

analysts in the late 1980s totaled the score card. The score was short but the game was still on.

In retrospect, the late twentieth century looms as a time of cultural revitalization within the community. This was evident in the energies directed toward education, unions, the arts, the media, and religious institutions, as well as in a period of increased efforts at social integration. In a whip of that cultural whirlwind, the Chicana/o community remains tempered by a uniquely Mexican-American concern for both cultural continuity and political affirmation while testing how pluralistic the allegedly diverse system is. In the 1990s, dominant social elites put forth two overarching responses: promulgate the belief that civil rights gains had consolidated, and propagandize the notion that Mexican aliens subverted the society by their presence. In this context, the master narrative of the Chicana/o movement is still being elaborated.

CHILDHOOD AND CHILD REARING. During the last two centuries, even amid poverty and war, more children have had the opportunity for successful lives than ever before. The modern concern for child health, education, and well-being, however, emerged only after long millennia in which children's welfare was subordinated to the needs and goals of caretakers and communities—a pattern also encountered today in developing regions of the world. In recent decades, scholars have gained considerable understanding of the experience of children, as well as attitudes toward childhood in the premodern world.

The Child-Centered Modern Age

Since the nineteenth century, scholars, scientists, and writers, along with lawyers, statesmen, and philanthropists, have concerned themselves with the nature and welfare of the child as at no previous time. Triggering that interest were the ideas of John Locke (1632–1704), Jean-Jacques Rousseau (1712–1778), and later authors of the Romantic movement.

Elaborated in his *Essay on Human Understanding* (1690), Locke's notion that the human infant's brain is a tabula rasa, free of innate ideas but subject to the formative stresses of the environment, made the earliest stage of human development seem critical. In his *Émile* (1762), Rousseau understood the child as a noble savage, best able to gather knowledge as he pursued his natural interests and instincts long before he needed to master the artificial skills of the schoolroom. Soon afterwards, Romantic writers and artists idealized childhood innocence and empathized with childhood experience, as did William Blake (1757–1827) in his *Songs of Innocence* (1789) and William Wordsworth (1770–1850) in his *Ode: Intimations of Immortality from Recollections of Early Childhood* (1807).

The exploration of childhood proceeded as new “social sciences” of the human condition developed. Charles Darwin's (1809–1882) theory of evolution by the process of natural selection, described in his seminal works *The Origin of Species* (1859) and *The Descent of Man* (1871), envisioned the creation of new species as the product of individual acts of procreation by millions of genetically privileged individuals—a vision of biological change, that is, centered on the birth of new infant generations. In a series of works published from the 1890s through the 1930s, the Austrian psychoanalyst Sigmund Freud (1856–1939) explored the role of childhood trauma on later adulthood and mapped the struggles toward autonomy of the developing infant personality. In *The School and Society* (1899), among other works, the American philosopher John Dewey (1859–1952) redefined the purpose of education: its aim was not to instill the accumulation of adult learning but to prepare future citizens and workers.

Practitioners of the new science of anthropology traveled the globe to study pre-state human societies, including their child-rearing concepts and practices, an interest exhibited in, among others, Margaret Mead's (1901–1978) *Coming of Age in Samoa* (1928). Sociologists investigated the situation of youth in modern societies, looking at peer groups, youth gangs, adolescent drug use, and teen pregnancy, among many other topics. Psychologists explored early childhood learning and development, a topic they share more recently with biologists, philosophers, and linguists in the interdisciplinary pursuit of “cognitive science.”

Social reformers, philanthropists, and journalists, meanwhile, took up the cause of child welfare, as did Danish-born Jacob Riis (1849–1914) and Lewis Hine (1874–1940), for instance, who depicted in photographs and prose the condition of “street Arabs” and child workers at the turn of the twentieth century in America. While advocating women's civil rights, the early feminist movement highlighted women's maternal capacities and duties, an orientation that culminated in the publication in 1900 of the Swedish feminist Ellen Key's (1849–1926) influential book, *The Century of the Child*.

In the twentieth century, both communist and fascist governments targeted the child. Soviet Communism promoted collective childcare so as to free women to become workers, while Italian Fascists and German Nazis adopted maternalist and pro-natalist policies. Totalitarian states of both persuasions promoted youth societies that indoctrinated adolescents in official ideology. Reeling from the slaughter of World War I, meanwhile, democratic states instituted welfare policies that supported mothers, families, and children. Among the free and the unfree, twentieth century wars and genocidal projects resulted in the slaughter, starvation, displacement, and militarization of children. The United Nations Convention on the Rights of the Child (1989) addresses these, among other abuses of children that have survived in the modern world.

At the same time, the twentieth century has also seen great progress in the medical care of the child. The modern practice of childbirth put traditional midwives out of business by about 1900. Whereas vaccination for smallpox had been known since the eighteenth century, the twentieth century brought new vaccinations against diseases dangerous specifically for children, such as diphtheria. In addition, the availability of pasteurization, refrigeration, and devices for artificial feeding dramatically improved survival rates of abandoned and orphaned children. Funded by public and private monies, social workers tended to the needs of the children of the poor and immigrant populations. Experts on child rearing flooded the market with advice books for middle-class readers, a flood epitomized by the popular work of Dr. Benjamin Spock (1903–1998), whose *Common Sense Book of Baby and Child Care*, first published in 1946, reached its seventh edition before the author's death in 1998.

A generation before Spock's death, however, a new book appeared in France that shook the scholarly world: Philippe Ariès's *Centuries of Childhood* (1960; English trans., 1962). So careful of children had citizens of the modern West become that they had forgotten the lost world of not so very long ago:

the premodern world, where children perhaps counted not so much as in the present era, or at least not in the same way.

The Historicity of Childhood

Centuries of Childhood presents the thesis that the “concept of childhood” itself is modern: a creation of the seventeenth and eighteenth centuries. This thesis has been disputed and defended by later scholars. As a product of that controversy, the historicity of childhood has been established indisputably. The concept of childhood, along with childhood itself, is subject to change in changing historical circumstances.

In earlier times, Ariès argued, children were perceived as participants in adult society. They shared the same amusements as adults and did not have distinctive occupations or adornments. Even at school, children, adolescents, and adults intermingled, without distinction of age. The important boundary was not between child and elder, but dependent and master. Sentimental relations between parents and children were weakened, moreover, by the frequency of child death. Attitudes began to shift in the seventeenth century as smaller, coherent family groups supported the experience of individual children. Literary works evinced a newfound affection for children, while families willingly invested in child accessories and

education and grieved at child deaths. Ariès based his arguments mainly on literary texts and artistic representations, mostly from France and England between 1500 and 1750.

Ariès’s work evoked responses that critiqued and confirmed his hypotheses. In 1965 the British historian Peter Laslett published *The World We Have Lost* echoing some of Ariès’s conclusions. Laslett was reporting on the project of empirical research on the history of the family centered at Cambridge University, which studied such archival sources as baptismal records for evidence of family structure, ages of baptism, marriage, and death. Using different sources, Laslett, like Ariès, concluded that the experience of past childhood was unlike that in the modern age: such children lived in a world we have lost.

Also affirming Ariès’s hypothesis, Lawrence Stone’s massive *Family, Sex, and Marriage in England, 1500–1800* (1977) focused on elite households and utilized literary evidence such as diaries, autobiographies, and letters. Over three stages of development ranging from large, authoritarian households to smaller, more egalitarian ones, the family became increasingly “affective,” Stone argued, characterized by strong sentimental ties and abundant investment in child welfare.

The American psychohistorian Lloyd de Mause, agreeing with Ariès and Stone on the greater importance of the child in modern times, proposed a model of the history of childhood that unfolded in five stages from the horrors of antiquity to the enlightened childrearing practices of the present day. Declaring in his seminal 1973 essay “The Evolution of Childhood” that the history of childhood was a “nightmare from which we have just begun to awaken,” de Mause credited modern psychoanalytic theory with persuading adults to abandon age-old practices of abuse and consciously to further the child’s autonomy and creativity. Also highlighting recent shifts in child-rearing attitudes, Edward Shorter’s *Making of the Modern Family* (1975) argued that warmer, sentimental relations between men and women encouraged a stronger bond between mother and child.

Historians of the Italian Renaissance, examining a period (principally the fifteenth century) well before the kind of turning point in perceptions of children identified by Ariès, Stone, de Mause, or Shorter, found a trove of empirical data that permitted the mapping of household structures of Florence and its surrounding countryside. The work of David Herlihy and Christiane Klapisch-Zuber, first published in 1978, yielded important insights about family size and ethos in different social groups. In essays collected and republished in 1993, Richard Trexler further explored both the dependency of children in Florence and their capacity as innocents as agents of salvation. Turning from Florence, Margaret King studied childhood death and adult bereavement in a noble Venetian family (1994).

While not aligning themselves as supporters or opponents of Ariès, Renaissance historians added to the evidence pointing to the difference between modern and past childhoods. In the wake of Stone’s study, however, historians of England plunged into the controversy, generally to defend past parents and childhoods. Clarissa Atkinson’s study of medieval moth-

erhood, and Barbara Hanawalt's of children in fourteenth-century London, pointed to the complexity of past family relationships in contradiction to Ariès's notion of a premodern "indifference." More heatedly, Linda Pollock plowed through hundreds of diaries (mostly seventeenth century) to support her claim that parents cared deeply about their children. Alan Macfarlane, in studies of the origins of English individualism (1978) and of love and marriage in the early modern era (1986), proposed that familial relationships in England had long exhibited supposedly "modern" qualities of profound sentiment.

Examining Puritan communities in England and colonial Anglo-America, John Sommerville and John Demos each found attitudes toward children that were surprisingly modern. Examining family documents from Reformation-era Germany in several studies between 1983 and 2001, Steven Ozment argued (as had Macfarlane for England) that modern sentiments of family intimacy were well-established long before the modern age. Historians of ancient Greece and Rome such as Mark Golden and Suzanne Dixon, similarly, did not detect, as Ariès had suggested, any lack of a "concept" of childhood. Anthropologists note that in the Americas, early documents about the Aztec and Inca civilizations reveal a very structured picture of the life course, in which phases of childhood play an important role; in tribal societies of Africa and the Americas, too, initiation rituals divide a life into discrete phases associated with childhood, adolescence, parenthood, and grandparenthood. Hugh Cunningham, finally, focusing on children in the industrial era, placed the break between older and modern perceptions of children not in the early modern era, as had Ariès and Stone, but in the nineteenth century.

This brief overview shows that Ariès's pioneering hypothesis did not win universal acceptance from scholars. On one point agreement has been general: childhood is not the unchanging phenomenon contemporary experts often assume it is, but it varies according to time, setting, social context, gender, and culture. Ariès's great achievement was to establish the historicity of childhood as something no longer capable of refutation.

That established, it is clear that scholars have moved beyond the issues of the Ariès debate to explore a broader range of issues. These include issues concerning the child in the context of the mother-child relationship; those concerning the child in the context of the father-headed household; and those related to the training and education of children. This survey concludes with a consideration of the impact of industrialization on childhood, ushering us into the modern world.

Mother and Child: The First Dyad

Women alone give birth to children, although in the simplest band-level societies, child rearing is a more collective enterprise than among later agriculturalists, and even among agricultural peoples, social structures such as kin groups (clans and lineages) and polygynous marriages often lead to families in which children acknowledge multiple adults who raise them, and adults correspondingly recognize their responsibilities to-

ward children other than their own birth children. In history, those children who survived were reared by mothers or mother surrogates. Even in advanced societies, the most powerful of human bonds has been that between mother and child, and the metaphor of motherhood is often used by other adults in expressing their bond with a child, as Gracia Clark has shown in her studies of West African motherhood. The dependency of the child on the mother, and the implication of the mother in the life of the child, is expressed in artistic representations of the mother-child dyad that appear in many different cultural settings—most famously, for Western civilization, in the image of Mary, the virgin mother, and the child Jesus. In recent years, however, African-American and Chicana scholars, while emphasizing the significance of motherhood within their cultural traditions, have used concepts such as "Othermothering" to underscore that mothering is typically a task shared among kinswomen, in contrast to the isolated white mother of the middle-class Euro-American nuclear family.

The importance of motherhood is further expressed in mythologies and cult objects: mother goddesses, fierce and gentle, the consorts of their sons, the guarantors of the fertility of the fields or of safety in childbirth, conspirators at times against the power of men. The fantasies of maternal power are also expressed in fantasies of matriarchal societies—although scholars now generally agree that there were none truly such—such as that of the Amazons.

Although anthropologists, linguists, and literary critics have been the primary observers of the ancient figure of the mother, real and mythic, historians have also examined the circles of women who surround the mother. These were the women who, across cultures, gathered to assist mothers in childbirth—female kin, friends, servants, and neighbors—while the skilled expert among them, the midwife, took charge. (Male physicians retained control of the theoretical literature about childbirth until the eighteenth century, when they took on the obstetrical role as well.) The same communities of women gathered to mourn the dead, or to provide advice at times of crisis and illness. John Riddle has shown in his works on abortion and herbalism that these informal women’s groups wordlessly transmitted medical and physiological information across generations.

In some societies, such female communities lived in physical isolation within larger households, as in the *gynaecium* of the ancient Greeks, or the “inner quarters” of elite Chinese families. Here children of both sexes were raised until about age seven, and girls remained until they were wed. The harems of the Chinese emperors and Ottoman sultans constituted more formalized versions of such female communities. In these separate worlds, women gave birth, raised children, tended the sick, spun thread, and mourned the dead.

Supported by female networks, mothers faced that first essential task after childbirth itself: breastfeeding. The health and survival chances of all children before modern times depended on the availability of a lactating mother or mother-surrogate, as Valerie Fildes has shown in her comprehensive history of nursing. The alternatives that were attempted, including arti-

ficial feeding of nonhuman milk and nursing from animal teats, often resulted in infant death. In societies such as ancient Rome and the Americas, slave nurses nourished and reared the children of their masters. In the premodern West and later colonial and postcolonial settings, paid wetnurses were hired to feed the children of the nobility, and later of urban, colonial, and racial elites. Gilberto Freyre’s classic psychosocial analysis of Brazilian society, *The Masters and the Slaves* (English trans., 1947), dissects the effects of this infantile closeness with the black female body, and concomitant distance from the white mother, on the sexual development of Brazil’s upper classes. This practice was commonplace in premodern Europe despite the universal advice of expert physicians, theologians, and philosophers. In the West, as in China and the Islamic world, injunctions to mothers to nurse their children account for a large part of all advice literature pertaining to children.

Mothers regularly experienced the deaths of their offspring in childbirth, in infancy, and in early childhood, an experience that is still common today for the world’s poor, as documented in Nancy Scheper-Hughes’s penetrating analysis of motherhood in urban Brazil, *Death without Weeping* (1992). The toll of infant death prior to modernization was in the range of 20 to 50 percent of live births, statistics that remain all too common in impoverished areas of the developing world. In the near-absence of birth control, fertility was high, and women commonly gave birth to many children, with totals of more than twenty not uncommon; yet mothers often saw only a few children reach adulthood. The high rate of infant and child mortality is the single most important fact to be culled from the history of childhood; as Scheper-Hughes documents, childhood signifies differently when few children reach adulthood.

Most babies died of disease or malnutrition, from which perils their mothers could not protect them, as they still cannot today. Others died also from accidents, neglect, or infanticide, the last of these an act most often perpetrated by mothers—and sometimes by salaried or servile nurses. Impoverished mothers, often servants, slaves, or prostitutes, or others whose conception and parturition was deemed “illegitimate,” were often, and disproportionately, infanticidal. Enslaved Africans and American Indian mothers often chose to terminate their infants’ lives rather than see them grow up under the tragic circumstances in which their mothers lived; for slave women, this horror was compounded by the knowledge that the children belonged to the master, and not to their own parents.

Mothering varies, of course, according to economic status. Among working families, the labor of absent mothers earning cash to support their children counted as material symbols of maternal love, whereas in middle-class, mid-twentieth-century American families, it was the presence of the mother inside the home rather than in the workplace that demonstrated her commitment to her children. In wealthy households, mothers are often freed from the constant demands of children by the services provided by hired help—nannies, babysitters, and tutors. In contemporary American and European societies, this

labor is provided by immigrant women whose own children are often a continent away, cared for by grandparents or other female kin.

In Western society, the profound detestation of maternal, and more broadly female, endangerment of children is witnessed by the condemnation and, sporadically, prosecution of abortion and infanticide. The idea of the evil mother appears to have triggered profound passions expressed in the fantasies of the evil deeds done by witches (in Europe, especially the fifteenth to seventeenth centuries); by Christians (as perceived by the Romans during the late-ancient era of persecution); or by Jews (as perceived by Christians during anti-Semitic outbursts). All of these persecuted malefactors were believed to have sickened, killed, and cannibalized children.

The vulnerability of children was thus a source of great anxiety to the adults who, nevertheless, sacrificed children to divine forces in a practice that was once nearly universal—as Martin Bergmann, among others, informs us. Although mothers were not the only agents of child sacrifice, the connection already seen of women with death and mourning, with the often fatal event of childbirth, and with frequent child death, indicates that connection.

Successful mothers of child survivors were, in addition, the primary educators of children. Modern social science has established that mothers and mother substitutes are the first teachers of language—in the Western world, a fact reflected in the term used for the natal language as the “mother tongue” (*lingua materna*, *Muttersprache*). In the United States, the notion of “mother language” took on special poignancy for the young children of immigrants. Warm childhood memories of the smells and sounds of their monolingual mother’s kitchens contrasted with life at school and workplaces, where they struggled to master the language and customs of an alien and sometimes racially and ethnically hostile world. Throughout history, male suspicion of mothers and nurses as shapers of language also testifies to their important role: the ancient Roman statesman and author Cato the Elder (234–149 B.C.E.) would not have his children spoken to by nurses, and the Dutch humanist Desiderius Erasmus (1466?–1536) disdained the linguistic environment of the nursery and urged the swift conveyance of the child to a qualified tutor. In contrast, Chinese theorists celebrated those heroic mothers who prepared their sons from infancy to study for the civil service examinations.

The maternal role was probably more potent than these experts feared. Before written texts, the values and traditions of a culture were probably transmitted in story and, even more likely, in song, sung by mothers and nurses to generations of infants. In more developed societies, mothers and mother-surrogates were the first agents of religious instruction, a powerful welder of civilizational loyalties.

The Household: The Father’s Domain

In premodern times, a child’s chances of survival depended on her mother’s availability to nurture; but so, too, on her father’s benevolence. For once human beings joined together in sedentary communities to engage in agricultural production, the

father-headed household made an appearance. Fathers were the gatekeepers of households, and the guardians of the children he admitted to them. Those fortunate children were generally the offspring of approved women: those considered to be “legitimate.” A bright line divided the spheres of legitimacy and illegitimacy, with great consequence for the lives of children (even though, in many societies, the illegitimate children of concubines lived under the same roof as their preferred half-siblings).

In Greek and Roman society, the master of the household had the power to welcome or reject a newborn child. Children not so welcomed would be “exposed,” or placed outside the household in a place where they might perhaps perish, or possibly be retrieved by other families seeking a servant or by slavedealers interested in exploiting the child as a laborer or prostitute. As John Boswell carefully noted, exposure was not necessarily coterminous with infanticide; but certainly, a child’s destiny was more assured if he remained in the household into which he was born.

The “exposure,” abandonment, or killing of unwanted infants was commonplace in ancient civilizations, including China as well as those of the Mediterranean world. The aim was to limit population and conserve household resources, purposes achieved in modern times by contraception and abortion. Another form of abandonment practiced in medieval Europe, which may also have been caused by demographic factors, had at least superficially a religious motivation as well. Children given to a monastery, as “oblates” (offerings), would not only disburden a family of too many children, but would enhance their parents’ chances of salvation. Yet the oblation of a child had ancient roots as well and approaches the phenomenon of child sacrifice as much as that of abandonment.

When fathers kept or exposed children, gender issues came into play. Boys were generally preferred to girls, as skewed sex ratios in different communities of the ancient world inform us; indeed, they still do so inform us, as sex preference by abortion is widely practiced today in Asia. When girls were raised in the household, the status of males remained higher. In ancient Rome, for instance, when boys received distinctive personal names at birth, girls bore their fathers’ name with a feminine ending: the daughter of Julius, for instance, was Julia. In Italian Renaissance genealogies, daughters were often anonymous, designated only as “filia” (daughter). In contrast, in some pre-state societies, such as those of the American Iroquois or Hopi, the birth of a female child was celebrated.

In Western and Asian civilizations, boys were generally preferred to girls as heirs, whether they were valued as the keepers of the family rites, as in China and Rome, or as the inheritors of property, as they were nearly everywhere. The dowry was a common device—prevalent among the Hebrews and Babylonians, the Chinese and Indians, the Greeks and Romans, and premodern Europeans—used to give a limited portion of a patrimony to daughters upon marriage (or entry to a convent, in Christendom) so that the bulk of it was preserved for one or more sons.

The concern with inheritance, resulting in the devaluation of daughters relative to sons, characterizes societies organized

by father-dominated households. The organization of those households, however, varies enormously according to region, era, and social rank. In China, India, and Islamic society, the young tended to marry early and remain within or closely related to the bridegroom's male kin. In Islam, endogamous marriage, principally to first cousins, was and remains common, and polygamy, although never universal, is permitted. In China, young brides often suffered under the hand of their powerful mothers-in-law.

European society, in a pattern especially characteristic of northwestern Europe, tended toward late marriage and the establishment of autonomous households, and truly nuclear families, by the newly married. As Alan Macfarlane has argued (1978, and again in 1985), the latter pattern, which prevailed in England, was conducive to the development of behavioral autonomy and the sense of individualism that was to manifest itself in the theoretical products of the Renaissance and Enlightenment. Certainly, in monogamous, nuclear families, it may be assumed that individual children received greater parental attention, with a consequent enhancement of their life chances.

The iron reality of high mortality meant that, whether the family was more or less extended, all children in premodern times experienced a different type of household than is common in contemporary society. Women generally gave birth to children over the whole span of their fertile years. Their first-born children might be twenty or more years older than their last. Sibling relationships would be greatly complicated by this fact: late-born children would find themselves subject to the authority of early children, if those remained at home; or early-born children might be ejected early from the household in favor of late-born dependents. As women's lives were often cut short by death in childbirth, moreover, husbands tended to remarry, and more than once. Their second and subsequent wives continued to bear children, who were half-children of the first wife, occasioning even more intense sibling rivalries and the often-hostile presence of the stepmother.

When the father of the household died, patterns of widow remarriage differed. In China, India, and the West, the preference was that they should not remarry—and in traditional India, some widows died on their husbands' funeral pyres, in the Hindu custom of *suttee*. In Europe, although chaste widowhood was theoretically preferred, widow remarriage was common. Young widows who remarried might surrender their children to their husband's kin. Widows who did not remarry might continue to rear their children in the households of their husbands, or form one of the few woman-headed households.

A child's life chances in history depended even more than today on the nature of her mother, her father, and her household. So too did the kind of training or education that children received.

Training and Education: The Circulation of Children

Maternal rearing lasted until the age of seven, approximately, in most societies. Thereafter, although some girls continued under their mothers' care until marriage, most children learned

the tasks of adulthood elsewhere: from tutors, at work, in school, or by apprenticeship.

Almost universally, the age of seven (sometimes six or eight) is the point at which children were thought to reach an age of competence. At that point, they could perform tasks responsibly, understand religious instruction, or begin formal education. At this point, too, boys were generally transferred from maternal to paternal oversight. In some tribal societies, as in such settings as ancient Sparta, the Ottoman Janissary Corps, and the nineteenth-century English public school, boys have been removed from the care of their mothers at an early age and raised in exclusively male groups—a kind of collective extension of paternal care.

If there was general agreement on the approximate age of seven as demarcating a stage of childhood, other demarcations were variable. Weaning (around eighteen months to two years was typical in the Western world) marked for some the boundary between infancy and early childhood. Later childhood was often seen to begin somewhere after age ten, when children were seen working outside the home, although some did so as early as age eight or nine as well. Some societies, like the Jews and the Romans, ritually marked the entry of boys into adulthood at age thirteen or fourteen. Minimum ages of marriage for girls clustered around age twelve.

No consensus, therefore, existed on the stages of childhood after age seven, or about the length of childhood. The child who was trained to peasant labor, or apprenticed to a master, or sent into service, or swept up in the experience of war, had only a brief childhood. In those peasant societies where household structures were extended, as in China, sons lived in the natal household even after marriage, still subordinate to paternal authority, while girls often married young, to be raised by the parents of their young husbands. In Western society, where it was common for young couples to begin their own separate households, adulthood began with marriage.

After regional and cultural factors, the boundaries of childhood depended most on the social standing of the child. In Western society, many children were in a process of circulation from ages as young as eight or nine. The poor were sent from home to labor as servants; nobles to acquire the skills of knighthood (if male) or household management (if female); those of artisan origin to apprenticeships lasting five, seven, or even ten years. Children circulated for purposes other than work or training. Wealthy households took in the surplus or orphaned children of their kin, while the children of an unwed or widowed mother would follow her on a tedious journey in search of shelter or employment.

In contrast, those children privileged enough to remain at home, supported by their bourgeois or aristocratic parents, were the real prototype of modern children. Dressed in special clothing, and endowed with specialized objects—known to us as toys—to enhance their play, they would be perceived as uniquely innocent. They would be protected from exposure to adult sexuality and violence; they would be tended in illness and mourned in death; and they might be given tutors and teachers and provided a liberal educa-

tion. An interesting comparison is provided by Bronislaw Malinowski's famous description of childhood in the Trobriand Islands off the coast of Papua New Guinea, where children spent their days in a separate "nation of children," similarly freed from adult responsibility, but also from adult supervision to a degree unthinkable in the upper- and middle-class West.

Until recent times, schooling has been an opportunity limited to the fortunate few. One of the hallmarks of civilization, literacy was initially the property of an esoteric elite of priests and scribes. In Mesopotamia, Egypt, and China, writing consisted of numerous and intricate characters that were learned with difficulty and reproduced slowly. That pattern persisted in imperial China, where the literary arts were highly esteemed, and families sacrificed so that their sons could be educated and compete, and sometimes qualify for office, in strenuous state-run examinations. In tribal societies, sex-specific education could last for years, but usually took place in sex-segregated contexts and depended upon the oral and ritual transmission of knowledge.

Alphabetic writing systems made literacy easier to achieve. As merchants and artisans gained access to writing skills, schooling became more generalized. In Greek, Hellenistic, and Roman society, literacy was relatively widespread among urban elites. Islamic civilization, as well, esteemed literacy. Significant numbers of Muslims from the straits of Gibraltar into south Asia and Oceania learned to read Arabic, the language of the Koran.

In the wake of the Germanic invasions of the fifth and sixth centuries, the level of civilization in Europe dropped dramatically from Roman days. For centuries, literacy was limited to members of the Christian church hierarchy: priests and monks. Schools were appendages of monasteries and cathedrals, their prime purpose to supply the minimal knowledge of Latin necessary to perform the liturgy. As scholastic (school-based) learning developed in the twelfth and thirteenth century, stimulated by the incorporation of ancient Greek (especially Aristotelian) texts, universities took form. In these institutions of higher learning—the world's first—students in their teens and twenties gained degrees in philosophy, theology, medicine, and law. In the Americas, Aztec and Inca noble youth entered priest-run schools where they received education in the forms of knowledge; only among the Maya, however, would this include literacy in the Western sense.

The humanists of the Italian Renaissance created a form of schooling beyond the church-based system, whose purpose was to enlighten and develop the individual rather than to instill specific systems of knowledge. The Protestant and Catholic Reformations each adopted the Renaissance notion of elementary and secondary schools that now proliferated, serving to prepare not only a priestly class, but male elites from the middle classes and the nobility, and even girls at elementary levels. These educational initiatives, together with revolutions in economics and science that made backward Europe the dominant world power, greatly enhanced the chances children would have for their own advancement.

Schooling came at a cost for young students—the cost of corporal punishment. From antiquity, the symbol of a teacher was the rod that he wielded to "correct" the unruly or unresponsive student. In medieval Europe, it was understood that Latin was literally to be beaten into the young. Although humanist pedagogues deplored the use of the rod, corporal punishment remained a feature of the schoolroom into modern times. Such abuse was only an extension of norms outside the classroom. Those with power could visit physical chastisement on their dependents: masters over apprentices, householders over servants, the state over malefactors, and fathers over children. Perhaps the world has seen, over the last century, along with those consumed by Holocaust, world war, and state-sponsored famine, the first children to escape the rod.

The Advent of Modernity: School and Work

The twin processes of Enlightenment and industrialization mark the division between premodern and modern for childhood and concepts of childhood. Whereas the Enlightenment introduced the ideas with which this article began, leading to the modern disciplines that specialize in the condition and care of the child, industrialization introduced new forms of exploitation of children, but also, in time, new opportunities for family life as standards of living eventually rose. In the two areas of work and schooling, the lives of children changed most dramatically during the industrial era.

Industrialization meant, above all, the factory organization of labor. Children, notoriously, labored in the early factories, to the great detriment of their health and well-being. As industrialization progressed, an inquest into the welfare of children workers resulted in Britain's Factory Act of 1833, which set hour limits for child workdays. Following suit, most advanced nations introduced the regulation of child labor, beginning with France in 1841, and culminating in the first decades of the next century with Japan, Russia, and the United States. Today, child labor is found in developing regions of the world and is the subject of investigation and censure by many activists and policy-makers in the developed world.

As policy-makers, employers, and parents came to understand that children must not spend their lives in factory labor, they established instead the goal of sending all children to school. Beginning with France by 1878 and Britain by 1891, secular, free, and compulsory mass public education was the norm for the wealthiest nations of Europe and the Americas, as well as rapidly modernized Japan. At the same time, the kindergarten movement created by central European pedagogical theorists Johann Heinrich Pestalozzi (1746–1827) and Friedrich W. A. Froebel (1782–1852) swept the Western world, encouraging the establishment of kindergartens supported by fee-paying elite parents and charitable institutions. In the early twentieth century, Maria Montessori (1870–1952) introduced the concept of a nursery school for the very young, featuring child-friendly spaces and materials and a structured but individualized and child-appropriate curriculum. In the more privileged countries, these opportunities for young children have become increasingly commonplace. In poor countries, in contrast, even children over age seven, especially girls, lack the opportunity for a basic education.

Laslett's depiction of *The World We Have Lost* poignantly alerted modern readers to the unbridgeable distance between their own reality and that of children of premodern times. More recently, we have learned that the distance is not so very great. In the developing nations of the modern world, millions of children live in conditions strikingly like those of the times we thought we had left behind: among them, continual maternal childbearing without possibility of contraception; high rates of infant and child mortality; abandonment, infanticide, and abuse; absent or tyrannical fathers; child labor; and the cataclysm of war.

CHINESE THOUGHT. *Chinese thought* is a generic term, referring to the ideas produced, expanded, and transmitted in the history of China. First, these ideas are not simply general opinions, but the philosophical views of the world, life, and society that have been commonly accepted as concepts or systematic theories. These ideas or theories are the end-products of logical reasoning—in Chinese, the two characters *si xiang* (thought) both contain a radical *xin* (heart/mind), the faculty of which is defined as "thinking" (Mengzi, 6A:15, p. 168). Secondly, these concepts or theories are primarily transmitted through words or writings, conveyable to and understandable by the people of later generations, although other means can also be used to pass on ideas; for example, symbolic form and structure of excavated artifacts and architectures have been correctly "understood" or interpreted as the meaningful ideas that underlie, and are integrated with, the history and culture of China. Thirdly, these concepts or theories are "typical" of the Chinese, who have employed them as tools to explore the inner and the external world, and to recapture the interaction

between human activities and the natural and/or the supernatural realms. What is meant by “typical” here is in practice the formalization of philosophical opinions characteristic of the process of thinking by major Chinese philosophers.

The Origin

There is no consensus among modern scholars as to when Chinese thought started and whether or not the philosophical ideas of Chinese people originated from a single source. According to traditional beliefs, Chinese culture started with the invention of the diagrams or ideographical symbols by a legendary figure Fu Xi, and was continually shaped through the working of cultural heroes and legendary sage kings, particularly the Yellow Emperor (Huang di), Yao, Shun, and Yu, who are believed to have been the leaders of China in the fourth to third millennia B.C.E. It is traditionally believed that the period of cultural heroes was followed by the three dynasties—Xia (c. 2205–c. 1600 B.C.E.), Shang (c. 1600–c. 1045 B.C.E.), and Zhou (c. 1045–256 B.C.E.)—in which a reasonably comprehensive system of thought about the philosophical foundation of the world developed and that the earliest writings discovered so far as presented in “oracle bone inscriptions,” recording royal divinations and major natural and political events in the early part of the Shang dynasty, mark the beginning of systematic thinking concerning political, religious, and philosophical matters. Modern scholarship on ancient China and new findings of regional centers of civilization, however, have challenged the traditional convictions about the actual existence and functioning of the Xia dynasty and about a single line of development in early Chinese thought. Symbols and preliminary pictographs on potteries and jades discovered in East and South China (Longshan culture), and jade wares and bronze figures and masks found in Southwest China (Shu culture), have shed a new light on the multi-original sources of Chinese thought, and on the ways these sources were integrated into a single culture through a long and gradual process. Archaeological excavations of houses, cities, and sacrificial sites dated to the prehistorical period also prove that well before using characters to record their thinking of the world and life, the people who lived in the land of China had started to reflect on the physical and the metaphysical world, search for the harmonious interaction between the spiritual and the mundane, and implement these ideas in construction, decoration, and in a variety of economic, political, and religious activities.

The Rise of Rational Thinking

Having said this, we are fully aware of the importance of written language, without which it would be impossible to form abstract concepts, and to preserve and transmit systematic ideas. The ideas as presented in the oracle bones inscriptions of the Shang and the bronze inscriptions of the early Zhou represented an attempt to rationalize, albeit in a preliminary way, the Chinese understanding about cosmic change, the nature and function of social institutions, life and death, and so on. These ideas were later reflected and expanded upon in the *Book of Documents* (*Shu*), the *Book of Poetry* (*Shi*), and the *Book of Changes* (*Yi*), part of which can be dated to the western Zhou dynasty (1045?–771 B.C.E.). However, the rationalization of Chinese thought did not come into full play until

the Spring and Autumn period (770–476 B.C.E.), when the early theological view of the world was challenged, modified, and transformed by new thinkers. Since the moving of the capital to Luoyang in 770 B.C.E., the Zhou kings gradually lost control over the states, while the lords of large states became powerful and competed with each other for the domination of the smaller ones. Natural disasters and administrative abuses had fundamentally shaken the political and economic foundation of the feudal system, and society experienced dramatic change and transformation. Substantially weakened were the force of the beliefs that the power of the Zhou king was endowed in the name of the Mandate of Heaven (*tian ming*) and that the ritual (*li*) binding people and states to the king was part of the cosmic order. The official ideology under the royal patronage and control was gradually torn apart: “The arts of the Way in time comes to be rent and torn apart by the world” (Zhuangzi, p. 364), and Chinese thought came to the stage where several distinct ways of thinking were pioneered as responses to the social and political reality, either negatively deconstructing or positively reconstructing. These thinking streams led to the final formation of a number of major schools, the so-called “a hundred schools” (*bai jia*), during the Warring States period (475–221 B.C.E.), whose rational calling found representative voices in Confucianism (*Ru*), Daoism (*Dao*), Mohism (*Mo*), Legalism (*Fa*), Logicians (*Ming*), Yin-yang School, School of Military Strategies (*Bing*), School of Agriculture (*Nong*), and so on. The competition and mutual criticism between these schools was substantial and productive, in which they developed and extended the boundaries of their own thought. Of these schools Confucianism, Daoism, Mohism, and Legalism were of the greatest significance for the formation and development of Chinese thought.

Confucianism. The early *ru* tradition became a school of thought that bears the name of Confucianism in the West today, mainly through the educational efforts of Confucius (Kong fuzi, 551–479 B.C.E.), who, although claiming only to be a transmitter of ancient culture, attempted to rectify political chaos and social disruption by transmitting and transforming the ritual and learning of the past. Employing “controlling one’s selfish desires” (*ke ji*) and “re-establishing the ethical codes of conduct” (*fu li*) as two major tools, Confucius was devoted to the realization of a humane and righteous society in which people followed the good example of rulers and treated each other in accord with the rules of propriety or moral codes. Confucius trained his students to become conscious moral agents or “gentlemen” (*jun zi*), who sincerely upheld the Way (*dao*), were grounded firmly on virtues (*de*), behaved in accord with humaneness (*ren*), and took recreation in the arts (Confucius 7:6, p. 86). In practice he required them to be filial to their parents, respectful to the elders in community, earnest in action and trustful in words, and to love all the people, have the friendship of the good, and cultivate themselves through studying traditional culture (Confucius 1:6, pp. 59–60). The ideas and ideals Confucius illustrated in his conversations that were later compiled into a book entitled *Lun yu* (*The Analects*) and were further expanded by his followers during the Warring States period, among whom Mengzi (372?–289? B.C.E.) and Xunzi (330?–227? B.C.E.) took a lead. Mengzi believed in the religious, ethical, and political vision contained in the Confucian classics, and devel-

oped the Confucian doctrine in a religio-ethical direction, while Xunzi was inclined toward the naturalistic and ritualistic vision, and cultivated it in the spirit of humanistic rationalism. Both honored Confucius and believed that everybody was able to attain the ideal—that is, to become a sage (*sheng*) through learning and practicing—but Mengzi and Xunzi differed dramatically in their views of Heaven (*tian*) and human nature (*xing*): while the former held that Heaven is the supreme moral authority and humans are born with a good nature, the latter argued that Heaven is natural and human instincts would lead to evil and chaos if not checked by rituals, moral rules, and sagely teachings. New discoveries of writings on bamboo strips at Guodian and other parts of south China dating to about 300 B.C.E. provided certain evidence that between Confucius and Mengzi there were active a number of Confucian “sub-schools” that developed Confucius’s thinking about the Way of Heaven, human nature, and moral and political applications.

Daoism. In contrast to Confucian ideals, many Daoist ideas were propagated as an alternative route to social harmony, as evidenced in the following passage: “Exterminate the sage, discard the wise; and the people will benefit a hundredfold; exterminate benevolence, discard rectitude, and the people again will be filial” (Laozi, 1963 p. 75). A variety of sources have been identified showing the rise of the Daoist thought during the end of the Spring and Autumn period and the beginning of the Warring States period, but no definitive dates for the Daoist masters Laozi (traditional dates c. 571–c. 480 B.C.E.) and Zhuangzi (360?–280? B.C.E.) have been agreed on. The majority of modern scholars have refuted the traditional beliefs, arguing that the two most important Daoist philosophical books, *Daode jing* (or *Laozi*) and *Zhuangzi*, might not have come into existence until the fourth to third centuries B.C.E. However, the two silk texts of the *Laozi* discovered in 1973 at a Han tomb in Mawangdui dated to 168 B.C.E. and the bamboo version of part of the *Laozi* excavated in 1993 from a Chu tomb at Guodian were testimony that this Daoist work had already had different lines of textual transmission by the fourth century B.C.E. It is clear that the *Laozi* and the *Zhuangzi* were representative of the way of life for those people who withdrew themselves from social and political controversies. Central to them are the concepts of *dao*, the Way, and *de*, its power. As the mystic origin and principle of the world, we are told, *dao* cannot be known unless we have reduced our sensational experience and knowledge to the minimum, which is described either as a process of “polishing the mystic mirror” (Laozi, 1963, p. 66) and/or as “driving out perception and intellect” and “doing away with understanding” (*Zhuangzi*, p. 90). To live peacefully in a chaotic society, we are advised to take water as our guide: staying lower, withdrawing from politics, and not contending with others. In defining the nature of Dao as *yin* or yielding, the *Laozi* openly opted for a “feministic approach” and took “the mystic female” as the model for humanity. Withdrawing from the corrupted and chaotic society, the Daoist masters propagated a natural way of life in which there was no competition and purposeful action (*wu wei*). Apart from these philosophical collections, other strings of Daoist ideas and practices, such as the so-called Learning of Huang (the Yellow Emperor)-Lao (Laozi), also played an important part in the formation of Daoism.

Mohism. Mohism (also spelled Moism) was virtually created in the activities and thought of Mo Di or Mozi (Master Mo, 468?–376? B.C.E.). Differing from Confucians who presented a humanistic system that defined and redefined the moral-political-religious code by way of a “virtue ethic,” Mohists went for a utilitarian way to improve people’s material welfare, maintaining that a theory was good only if it was able to bring benefits to the people, order to society, and an increase in population to the state. For Mozi, what brought the greatest harm to the world was partiality (*bie*) that caused people to love their own parents, families, and states while hating and attacking the parents, families, and states of others. He called for the abandonment of partiality and replaced it with universal love (*jian ai*), regarding the states of others as our own, and loving the families of others as our own. By this, it was claimed, the ideal society of the great unity would be realized. Based on utilitarian principles, Mozi was strongly against all activities that did not contribute to the material welfare of the people, and called for the abandonment of Confucian ritual and music. Unlike Daoists who simply withdrew themselves, Mohists were constantly on peace missions, strongly condemning aggressive wars and selflessly aiding the defense of the state attacked. Against the tide of pragmatism, rationalism, and agnosticism, Mozi and his followers reconfirmed the authority of the spirits and spiritual powers, arguing that the righteous way we must follow was to worship Heaven above, to provide services to the spirits in the middle realm, and to bring benefits to the people below. In politics they called for “honoring the worthies”—namely, selecting and promoting the most qualified to governmental posts. In order to increase the welfare of the state and the people, they put forward as important policies “identifying with the superior” and exercising the control of thought as the tool for social order. Having a particular appeal to artisans, merchants, and small property owners, Mohism occupied a distinguished and influential position in the philosophical arena during that time, which can be seen from the fact that Mengzi listed the school of Mo as one of the two most dangerous rivals (Menzi, 3B:9, p. 114), while Han Fei (280?–233 B.C.E.), a Legalist thinker, described Mohism as one of the two most important schools (Han Fei, p. 118). After the death of Master Mo, however, Mohists disintegrated into three sub-schools, each claiming to be “true Mohism” and accusing others of being “false Mohism.” They developed Mohist thought in the areas of epistemology and formal logics, which together with many of earlier Mohist ideas and ideals had a lasting effect on the development of Chinese thought, although Mohism as a school had died out by the time of the Han dynasty.

Legalism. Listed under “Legalism” (*fa jia*) by later historians or catalogs are such politicians and thinkers as Guang Zhong or Guanzi (d. c. 645 B.C.E.), Shang Yang (390?–338 B.C.E.), Shen Buhai (401?–337 B.C.E.), Shen Dao (350?–275? B.C.E.), and Han Fei (280?–233 B.C.E.). According to the authors of *Han shu* (History of the former Han dynasty), Legalists originated with administrative officials (*li guan*), who put into practice realizable codes of rewards and penalties in order to support rites and institutions (Ban Gu, p. 1736). However, the formation of the so-called Legalism school followed a route quite different from that of other schools, since these men were

not united by loyalty to a master, nor by an organization, nor through their commitment to specific books. They were grouped together as a single school on the grounds that they all asserted that the only way to save the world from collapse and to strengthen the power of the state was to govern it by penal codes and restrain it with clearly defined law (*fǎ*). All Legalists attempted to justify the universality of law, and to identify law not only with the codes of punishment, but also with the “standardized” patterns of behavior, including administrative and military planning and statecraft. Taking law as the most important tool for governance, some Legalists deliberately associated law (*fǎ*) with the arts of rulership (*shù*) and the authoritative power (*shì*). Entwined with administrative techniques, Legalism demonstrated a tendency toward ideological authoritarianism, encouraging the ruler of the state to exercise control over people’s thinking, constantly disciplining as well as stimulating individuals to avoid punishment and to seek benefits. Differing from the other schools of the time that engaged in scholarly debates and argument as the way to prevail, some Legalists held a negative attitude towards the so-called “useless and harmful” philosophies and encouraged the ruler to suppress them if at all possible. Hostile to Confucians who took the past as the moral and political model for today, Legalists argued that the times had changed and the past must not be used to guide today’s activities, and some went even further to attack the so-called sage kings as the culprits of an immoral society. Despising the reclusive Daoists who refrained from engaging in politics, Legalists positively took part in the state administration; also, ignoring Mohists who opposed aggressive war and championed for peace, Legalists took war as a necessary tool to strengthen the power of the ruler, expand the state, and make the people strong, disciplined, and submissive. Effective means as many Legalist ideas were in increasing the power and wealth of a state, Legalism virtually elevated the state of Qin in West China above all other states and was instrumental to the final establishment of a unified empire in 221 B.C.E.

Heaven and Humans

Divergent as these schools are in terms of metaphysical views and political vision, they developed their ideas and theories around a certain number of key themes, such as Heaven and humans, the Way and changes, the past and today, knowledge and the criteria of truth, the internal and the external realms, and so on. Of these themes the relation between Heaven and humans stands at the center, underlying almost all the important ideas and ideals propagated by the major thinkers, and functioning as the core of Chinese thought in later history. Heaven is a convenient translation of *tian*, which, originally meaning “sky” above us, contains multidimensional meanings, such as the natural order, the religious ultimate (the Lord of Heaven), the source of the political order (the Mandate of Heaven), and the moral order. In search of the Way of Heaven and its relation to the way of humans, Chinese thinkers of the Axial era (800–200 B.C.E.) raised a number of questions such as whether or not Heaven or the Will of Heaven could be known, whether or not Heaven would intervene in human affairs, and what attitude humans should have toward Heaven.

The majority of the early philosophers came to the understanding that harmonious interaction between Heaven and humans was the key to the solving of all social, political, and philosophical problems.

In its metaphysical and physical connotation, Heaven refers to the cosmos, the material world, the Natural Law, or simply Nature, in which humans live, act, and regenerate, and to which humans conform. When asked why he did not speak, Confucius pointed out that silent Heaven ran its course by its law rather than by its words: “What does Heaven ever say? Yet there are the four seasons going round and there are the hundred things coming into being” (Confucius 17:19, p. 146). Major Daoist masters took Dao (the Way) as the original substance of Heaven, and regarded the returning to Heaven as a necessary step for the unity with Dao: “Humans follow the way of Earth; Earth follows the way of Heaven; Heaven follows Dao, and Dao follows its own nature” (*Laozi*, chapter 25; see Laozi, 1963, p. 82). Xunzi understood Heaven as the natural order operating according to unchanging principles, arguing that Heaven ran its courses constantly and did not change along with the events in the human society. Against the religious and moralist teaching that Heaven would bless the good and punish evil, Xunzi believed that Heaven did not intervene in human affairs but provided the environment in which all living things exist. Differing from the ideas that humans could do nothing in relation to the natural order, however, Xunzi defends the position of humans in the world that while performing their duties in accord with seasonal changes, humans should not simply glorify and obey Heaven, but rather must “regulate what Heaven has mandated and use it” (*Xunzi*, vol. 3, p. 21). The texts of *The Book of Changes (Yi jing)* provided many insights into the nature and function of the universal order (Heaven and Earth) that underlies the myriad phenomena and defines the natural law of Heaven as the foundation of human existence. Represented by the sage, humans are equipped with the power and intelligence to stay in tune with the natural order.

Applied in the spiritual realm, Heaven signifies an anthropomorphic Lord (*huang tian*) who presides above, and rules over or governs directly, the spiritual and material worlds, by which humans fulfill their destiny. In the Confucian classics, particularly the *Book of Poetry*, the *Book of Documents*, and the *Book of Rites*, Heaven and humans are locked in a mandate giver and receiver relation: while the king rules the world by the Mandate of Heaven (*tian ming*), he must be responsible to Heaven above him. It is a fundamental belief that as the spiritual power, Heaven awards virtuous people with the right to govern and punishes those who depart from the Way, which will definitively lead to the collapse of the dynasty. Succeeding to this tradition, Confucius claimed that “Heaven alone is great!” (Confucius 8:19, p. 94), believing that whether or not the Way prevailed in the world was predetermined by Heaven, and that his mission to transmit the ancient culture was endowed by the power of Heaven. However, Confucius admitted that it was not easy for ordinary people to understand the will of Heaven, and that the only path to this kind of knowledge was through learning and practice (Confucius 2:4, p. 63). This theme is further illustrated in the *Mengzi*, where humans

are required to know their heart/mind first: by extending the heart/mind, we are able to know the will of Heaven and to serve Heaven (*Mencius* 7 A:1, p. 182). The spiritual relationship between Heaven and humans is clearly explained in Mohism: Heaven is like the watchdog above us and nobody would be able to evade Heaven's eyes. For Mozi, Heaven desires righteousness and hates unrighteousness, and if we devote ourselves to righteousness then we are doing what Heaven desires, and if we disobey the will of Heaven then we are bringing misfortune and calamity upon ourselves (Mozi, p. 79).

For a majority of Confucian followers, Heaven is the source of virtues, the prototype of the moral order that guides humans in their social life, and the supreme sanction of human behavior. Confucius claimed that "Heaven has given birth to virtues that are in me" (Confucius 7:23, p. 89). Mengzi believed that there are two kinds of honors, the honors bestowed by Heaven (for example, humaneness, righteousness, sincerity, and the like) and the honors bestowed by humans (for example, positions and ranks in the government). He believed that the former should be sought after first and the latter would follow as a matter of course (Mengzi 6A:16, pp. 168–169). Even Xunzi, who attempted to separate the natural order and the moral order, defining the three roots of rituals as serving Heaven above and Earth below, paying honor to one's forebears and exalting rulers and teachers, drew much from the moral significance of Heaven (Xunzi, vol. 3, p. 58). Later Confucians in general took Heaven and Earth as the model of moral rules and principles; for example, just as Heaven is above and the earth below, so too the sovereign is placed over his ministers and subjects, parents over their children, and a husband over his wife. Although other schools did not emphasize as much the moral nature of Heaven as the Confucians did, they argued from different perspectives that the Way of Heaven was the foundation of moral virtues. Mozi drew upon his understanding that Heaven has its will, and argued that humans must follow Heaven's will, devoting themselves to the good fortune and prosperity of the people (Mozi, p. 79). Regarding Heaven as a natural process revolving ceaselessly, the *Zhuangzi* nevertheless requires the virtue of emperors and kings to take Heaven and Earth as its ancestor, the Way and its virtue as its master, and to take nonaction as its constant rule (Zhuangzi, p. 144). Han Fei believed that the Way was the beginning of all beings and the measures of right and wrong, although under Daoist influence he argued that only by being empty and still could the ruler hold fast to the Way (Han Fei, p. 16).

Syncretic Philosophies

The so-called philosophical schools were never clear-cut in their heritages and boundaries. It has been argued that diverse as they were, these schools actually sprang from the unified tradition of an earlier time and shared a common root in their teachings. The commonality in theoretical deliberation and the practical needs for communication between different schools paved the way for a philosophical syncretism. Toward the end of the Warring States period syncretic writings became dominant, in which mutual accommodation between seemingly divergent theories and inter-philosophical dialogue were enthusiastically engaged. Qin (221–206 B.C.E.) and Han (206

B.C.E.–220 C.E.) thinkers went even further by drawing upon a variety of cultural and literary lineages, and constructed or reconstructed a grand philosophy of cosmological, religious, political, and ethical theories, which is evidenced in such eclectic collections as *The Spring and Autumn Annals of Mr. Lü*, *The Book of Guan Zhong*, and *The Book of Master Huainan*. Yin-yang, the Five Elements or Five Agents (*wu xing*), the Way, Heaven, the spiritual realm and the mundane world, political ideals, and ethical norms were all woven into a structure in which Heaven, Earth, and humanity stood as the three interrelated pillars of the universe, and resonances between human society, government administration, and natural processes were intensively sought after. In the powerful current of syncretism, the earlier teachings of the philosophical schools were transformed and regenerated, and became constituent elements of a new phase in the development of Chinese thought.

Confucian ethics and the Confucian orthodoxy. Confucian thinkers and politicians led the way of syncretism and pushed the boundaries of their own teachings far beyond the recognition of early Confucian masters. Confucian ethics and the Confucian political blueprint were replanted in the rich soil of syncretic ideas and values, embodied in such popular texts as *Xiao jing* (The book of filial piety), as well as *Da xue* (The great learning), *Zhong yong* (The doctrine of the mean) and *Li yun* (The evolution of rites), three of the essays on ritual and rites in an anthology entitled *Li ji* (The book of rites). The transmission of the mainstream Confucian learning was focused on the commentary lineages of *Chun qiu* (The spring and autumn annals), a work believed to be composed by Confucius himself. Dong Zhongshu (195?–105? B.C.E.), a leading thinker of the Han period, drew upon the earlier resources, Confucian, Daoist, Legalist, and particularly that of Yin-yang and the Five Elements, and constructed Confucian doctrines in line with the new thinking of the Han. He reinterpreted the relationship between Heaven and humans into the backbone of a new integrated system of ethics, politics, religion, and education. Eclectic as he was in the book attributed to him, *The Luxurious Dew of the Spring and Autumn Annals* (*Chunqiu Fanlu*), Dong was nevertheless faithful to Confucian ideals, according to which harmony between the three realms, Heaven, Earth, and humans, is central to the peace of the world, while the king or emperor is described as the agent of Heaven who ruled over the world by the mandate from above. In holding the vital and immense responsibility for the moral guidance of the people, the ruler's authority must be spiritually disciplined and practically based on the advice of the enlightened scholar-officials and support by the people. It was this kind of Confucian thought that was eventually elevated to be the state orthodoxy during the reign of Emperor Wu (r. 141–87 B.C.E.), to which all other schools of thought were required to conform.

Daoist religion and Neo-Daoist philosophy. The wisdom in Lao-Zhuang Daoism was particularly appealing to thinkers with a creative mind, and its leaning to the concepts of *xuan* (mystery), *wu wei* (nonaction or no purposeful action), *wu* (nothingness), *kong* (emptiness), and *jing* (tranquil-

ity) opened up the imaginary vision of philosophers and religious practitioners as well. The other branch of the broadly defined Daoism, the teachings of the Yellow Emperor and Laozi (Huang-Lao) was also particularly popular at the time and penetrated all layers of social life through medical and shamanic practices that, extended and put into political practices, underlay the imperial policies during the first few decades of the Han dynasty. Through synthesizing Confucian ethics, Lao-Zhuang philosophy, and Huang-Lao teaching, Daoism developed in two directions: religio-political movements aimed at purifying the world, prolonging the life, and overthrowing the Han dynasty, and a kind of Mysterious Learning (*xuan xue*) emerging during the Wei-Jing period (256–420 C.E.). In the former, Dao was mystified as the divine source and Laozi the philosopher as the Savior of the world, while in the latter the heavily politicized relation between Heaven and humans was reinterpreted as that between social norms and human naturalness, and the philosophers Confucius and Laozi were transformed into the moral ideals who had embodied Dao and had reached very high stages in self-cultivation. Religious Daoism and Neo-Daoist philosophy were combined and integrated into the Daoist tradition that exercised a powerful influence over the way of life in Chinese history.

Buddhism and the interaction of “the three teachings.”

By the first century of the common era, if not earlier, Buddhism had been introduced to China via Central Asia. Different but innovative, Buddhist teachings on ignorance, suffering, and Buddhahood were met both with enthusiasm and suspicion, welcomed by those who were preoccupied with issues of longevity, metaphysical speculation, and superhuman achievements, while resisted by those who attempted to secure the integrity of Chinese culture in relation to the state and family. In debates with Confucians and Daoists, Buddhists skillfully accommodated their teachings to the cultural requirements and spiritual needs of Chinese society, soon seizing the minds of the people and becoming powerful in the reshaping of the political and religious landscape. Based on the study of particular texts and the synthesis of Indian and Chinese understandings, distinguished Buddhist thinkers and their followers created various schools of Buddhist doctrine, of which Tiantai, Huayan, Chan, and Pure Land were particularly important and influential. In search of harmony and unity between the three teachings, Confucian, Daoist, and Buddhist theorists and practitioners consciously explored and justified the rationality of the one body of the three teachings (*san jiao yi ti*). Confucius, Laozi, and the Buddha were recognized as the fountainheads of three religio-ethical traditions, distinctive from each other and yet being the same in essence. It was held that in their mutual supplementation, the three teachings were all needed to meet the political, ethical, personal, social, and spiritual needs of the society. The interaction between Confucianism, Daoism, and Buddhism became the major subject matter and the mainstream current in the later development of Chinese thought.

Neo-Confucianism. Well embedded in the integral development of the “three traditions,” the Confucians of the Song (906–1279) and Ming (1368–1644) dynasties revived the traditional Confucian teachings in response to the challenges

from a variety of philosophical lineages, particularly those of Buddhism and Daoism. Their works or commentaries on earlier Confucian texts revealed new horizons for Confucian philosophy, innovating its ethical understandings, and placing moral and political principles on the ground of metaphysical and metaethical rethinking about the Supreme Ultimate (*Tai ji*), Heaven (*tian*), Principles of Heaven (*Tian li*), material force (*qi*), and the heart/mind (*xin*). Of the seminal thinkers of this period, Cheng Yi (1033–1107) and Zhu Xi (1130–1200) led the way to a rational reasoning about the reality of Confucian principles and norms, while Lu Jiuyuan (1139–1193) and Wang Shouren (1472–1523) preferred an idealistic identification between human heart/mind and social virtues and between knowledge and action. Common to both types of Confucian learning, however, was the emphasis on humanity and self-cultivation, pointing to the direction of the attainability of sagehood by all. Reshaped as the new learning of the Confucian Way, known as Neo-Confucianism in the West, Confucian thought became the state ideology and the philosophical basis of Chinese life and thinking until the beginning of the nineteenth century.

However, Neo-Confucianism did not go without significant challenges. Dissatisfied with the stereotypes of Zhu Xi’s authoritarian scholarship, a number of independent thinkers in the Qing dynasty (1644–1911) branded Song scholars as “unfaithful followers” of the Confucian Way, proposing to return to the learning of the Han dynasty (*Han Xue*) and to take studies of Confucian classics rather than philosophical reinterpretations as the path to Confucian values. Other scholars engaged in “evidential studies” of ancient texts and commentaries (*Kao Zheng Xue*) against speculations, and explored new ways by which Confucian learning could be used to improve people’s lives and to strengthen the state. Although these currents did not change the overall landscape of Qing learning, they in one way or another prepared Confucian intellectuals for a new stage that was looming large with the incoming of “Western learning” (*Xi Xue*), in which the further development of Chinese thought would be fundamentally influenced by the conflict and interaction between the Chinese and the Western cultures.

CHINESE WARLORDISM. The term *junfa* became part of the Chinese vocabulary in the 1910s and gained popularity in the 1920s to describe the phenomenon of militarism that dominated the Chinese political scene between 1916 and 1928. While both characters, *jun* (military) and *fa* (as in *menfa*, prominent lineage), are ancient Chinese words, it was in Japan that *fa* as a suffix was paired with other words to mean “a clique of” or “a faction of.” *Zaibatsu*, for example, means financial combines (*caifa* in Chinese); and *gumbatsu*, meaning military clique, helped the Chinese define the emerging situation of militarism in China.

Before *junfa*, there were other Chinese terms to refer to individual military governors. *Zongdu*—viceroy, for example—was used in the Qing text. In the early twentieth century, the character *du*, “to supervise,” appeared in such compounds as *dudu*, *dujun*, and *duban*—all referring to a military governor.

Junfa, or its English equivalents *warlords* and *warlordism*, when used in the context of Chinese polity and society during the first part of the twentieth century, are pejorative expressions, evoking brutality, chaos, and the plundering of the civilian population. The warlord era was marked by constant warfare, thrusting China into perpetual economic and political instability. Typically, modern warlordism in China applies to the years between 1916 and 1928, but its impact and legacy, with its residual influence, lasted well into the 1940s. Official history in Beijing and Taipei denounces warlords and characterizes the era as reactionary to China's endeavor toward national unity and progress. Both Chinese and English scholarship describe the warlords as regional militarists, possessing personal armies that they constantly strove to expand and heavily relied on to advance their own interests in power and money. Backed by their military power, they maintained virtual territorial autonomy over the regions under their control. They relied heavily on taxes of the local population for revenue. While petty warlords depended more on local sources, including the domestic opium traffic, more significant ones had established ties with the foreign powers present in China from whom they gained financial and military support.

However, it would be a mistake to think of warlords as being under the thumb of the foreign powers. Between 1916 and 1928, when the warlords held sway in China, they numbered in the hundreds if not in the thousands. Their strengths varied tremendously, from a force composed of no more than a handful of men to well-armed troops of several hundred thousand strong. Numerous as they were, there were fewer than a dozen major factions, among which were three infamous cliques in North China. The Anhui clique (Wan) was headed by Duan Qirui, the premier of the Beijing government between 1912 and 1920. The Zhili (Zhi) faction was commanded by Feng Guozhang, who, after his death, was succeeded by Cao Kun. The Fengtian (Feng) clique was led by Zhang Zuolin. Members of all warlord coalitions, big and small, shifted their allegiance constantly as was the nature of the warlord alliances; but the three northern factions stood out and commanded more attention than the southern warlord groupings because they fought for national power represented by the Beijing government.

Warlordism in modern China had its origin in the last decades of the nineteenth century, when the Qing government was losing control of the empire under the pressure of domestic unrest and foreign intervention. Though not the hereditary descendants of the regionally originated Xiang and Huai armies that aided the imperial government in defeating the Taiping rebels in the mid-1800s, the later warlord troops were nourished by the same political crisis that had challenged the Qing's power. A more immediate model followed by the twentieth-century warlord system was the New Army that the Qing established in the 1890s as part of its attempt to revamp the imperial power. Unfortunately for the central government, the reform effort failed, and the New Army, comparatively modern in training and equipment, acquired the quality of a personal army loyal to its commander, Yuan Shikai.

With this army at his command, Yuan emerged as a power to be reckoned with at a time when China was undergoing its most fundamental historical transformation. Oscillating between the Qing and the anti-Qing forces, but finally leaning toward the latter, Yuan used his military power to gain the highest political position in the new government, becoming the first president of the Republic of China in 1912. During his reign, Yuan more than once resorted to force in implementing his policies. His opponents also turned to military power in their effort to block and defeat Yuan's political agenda, as in the anti-monarchical war in 1915, touched off by Yuan's scheme of putting himself on the dragon throne. Military force, thus politicized and empowered by political leaders, established its legitimate authority in political struggles.

China was well on the road toward rule by the gun during Yuan's presidency. But his regime was not a military regime; it represented a central authority supported by provincial leaders, a structure not fundamentally different from the Qing bureaucracy. However, more than the Qing monarchy, Yuan's government was plagued by the perennial tension between centralization and local autonomy. Yuan's death in 1916 left the weak and antiquated civil institutions in the hands of his less capable successors, plunging the country into complete fragmentation.

What also contributed to the rise of the system of warlords was the absence of an institutional passage to power. The civil service examination had long channeled the talented and ambitious to the service of the imperial bureaucracy. No longer in use, it left one with nothing to follow but one's own ability to survive. Consequently, military power became the assurance of success in a society without a clearly defined code of conduct.

Instead of an aberration, twentieth-century warlordism was a manifestation of a recurrent theme in Chinese history—a history that alternated between political integration and fragmentation and a history filled with struggles of local powers challenging the central authority. During times of disintegration, soldiers dominated politics. The backgrounds of the modern warlords were diverse: some were bandits with little education; others had training in Confucianist classics. A few

may even have received some Western education. While many deserved the reputation of being a breed of gross and unscrupulous men, there were also those who succeeded in presenting themselves as men of idealism and altruism, steeped in Confucianist morality and Christian benevolence. Provincial warlords such as those in Sichuan were notoriously corrupt and cruel; Yan Xishan, who overlorded Shanxi, was mostly noted for his effective control of the province. Nationally known figures such as Wu Peifu and Feng Yuxiang, on the other hand, maintained a façade of being honest and high-minded. Though some of them displayed modern attitudes and used rhetoric of patriotic nationalism, and in fact many of them adopted modern organization and technology to their forces, they were not men of ideology. Their political and military maneuvering at various levels, confusing and conflicting but ultimately in accordance with their own interests, only prolonged and deepened China's political crisis.

Though the warlords dominated Chinese politics during the early years of the Republic of China, they did not come to power suddenly in the wake of the fall of the Qing dynasty. The system evolved over a period of time. In contrast, the end of the warlords' rule came rather suddenly. After two years between 1926 and 1928, the Northern Expedition claimed victory over the warlords when its troops entered Beijing, signifying the reunification of the whole of China. The defeat of the warlords was more than a military victory. Built on the rising nationalistic desire for a strong and unified China and a strong antiwarlordist sentiment, the nationalist government was finally able to wage a successful war against the warlords.

However, this was not a complete victory, as political and military expediency forced the newly established nationalist government to negotiate with some of the warlords, allowing their troops to be absorbed en masse into its own army in exchange for their allegiance. These "residual warlords" continued to contest the central power and made China's unification only a nominal reality. The Communist victory in 1949 ultimately put an end to the influence of the warlords who had survived throughout the Republican era.

OVERVIEW

According to the writers of the Gospels, Jesus of Nazareth gathered a small group of disciples and went about for three years in first century Galilee, preaching a message of hope to the poor and healing the sick. John the “Baptist” had gone before him, calling people to repent and be baptized, promising the imminent coming of the Kingdom of Heaven. He recognized in Jesus a far greater preacher than himself, sent from God. Jesus and his disciples eventually set out for Jerusalem. He threw out those who were trading in the temple precincts. He prophesied that the temple would be destroyed. The Jewish leaders pressed for his punishment and the Roman authorities authorized his crucifixion, with a mocking title nailed to the Cross: “Jesus of Nazareth, King of the Jews.” Three days after Jesus’s body was buried it was discovered to be missing from the tomb where it had been laid. Some of the disciples said they had seen and spoken to the Risen Lord and later that they had seen him ascend into heaven. They began to declare him to be the Son of God.

The spread of Christianity toward the West, through the Roman Empire and eventually the whole world, began with the conversion of the Saul of Tarsus, known after his conversion as Paul. He had been determined to eradicate this new sect until he had a vision on the road to Damascus that took him from an energetic Judaism to missionary zeal for Christianity. It was he who persuaded Peter and the other disciples that it was God’s will that they should preach the gospel of Jesus to everyone and not just the Jews.

Jesus wrote nothing, and the lack of contemporary accounts of his ministry makes the “historical Jesus” hard to be sure of. The Holy Scriptures of the Christian faith were composed after his death. The four Gospels, accounts of the life of Jesus, the Acts of the Apostles (a history of the early church), a series of pastoral letters to young churches by Paul and others, and an Apocalypse describing the end of all things came to be accepted by the end of the fourth century as a divinely inspired “New Testament” to be added to the Old Testament of the Jewish Scriptures to form the Bible. The Bible has always been used as authority, taken literally by fundamentalists but in most centuries figuratively interpreted as a means of resolving apparent contradictions within it and using it to answer questions it does not directly address.

Christianity and Secular Thought

A series of Christian authors during the first centuries C.E., later known as “the Fathers,” defended the faith to contemporary philosophers. Roman imperial religion was syncretistic. Apart from the Christians only the Jews refused to mingle their God with the gods of the pagans. Christians claimed that Jesus of Nazareth was the Son of God and had promised to

send the Holy Spirit, or Paraclete, into the world to be “with” his people. Contemporary philosophy described a Trinity in descending order: a Supreme Being, a Logos, a “Soul of the World.” Christians insisted that the three “Persons” in one God in their Trinity were equal and coeternal. There were long-running debates about the manner in which God could have “become man.” The definitive creed of the council of the whole church held at Nicaea in 325 provided an “official” statement of the approved faith.

With the fall of the Roman Empire, the arena of debate changed. In the Eastern, Greek-speaking half of the old Roman Empire, Christian learning survived in deeply conservative monasteries and focused on a mystical spirituality colored by late Platonism. Christian thought and learning in the West moved into the new Christian monasteries, the cathedral schools, and eventually, from the end of the twelfth century, into the newly created universities. Islamic scholarship had preserved and developed Greek thought and was absorbed in its turn by the Christian scholars of the thirteenth century.

Thinkers of the Middle Ages such as Peter Lombard (c. 1095–1160) and Thomas Aquinas (c. 1224–1274) worked out a “systematic theology” covering the existence and nature of God, Unity, and Trinity; the way in which God became man and why; a doctrine of the church and the sacraments; and the relationship of human free will to the foreknowledge and predestination and grace of an omniscient and omnipotent God. For most of fifteen hundred years in the West the church dominated intellectual endeavor to the point where philosophy and science were subsumed in theology.

Division

Christians, despite their schismatic tendencies, always put a premium on unity of faith. Yet the Christological debates of the third to fifth centuries ultimately led to the separation of the Monophysite Churches after the Council of Chalcedon (451). In 1054 the Orthodox Church and the Western Roman Church divided, partly over the Western addition to the creed of the assertion that the Holy Spirit proceeded from both the Father and the Son.

The Reformation of the sixteenth century in western Europe divided the Roman Catholic Church from the Lutherans, Calvinists, Anglicans, and other “reforming” communities. In dispute at this period were the claims of the institutional church to provide the only route to salvation and the reformers’ claim that the individual needed only a justifying faith and the Bible to read, and the grace of the Holy Spirit would do the rest. In the eighteenth century the Methodist Church separated from the Church of England (Anglican) over the validity of its ministry and in due course itself became a worldwide “communion.”

Ecumenism

From the second half of the twentieth century there have been serious attempts to restore Christian unity. From 1948, the World Council of Churches, which influenced the whole of the twentieth century with its work on “faith and order” as

well as on “peace and justice,” excluded the Roman Catholic Church. The Second Vatican Council of the early 1960s put the Roman Catholic Church’s stamp of approval on the modern ecumenical movement and allowed it to enter into bilateral and multilateral dialogues with other Christian communities.

Christianity and Modern Thought

The eighteenth-century Age of Enlightenment returned to “natural” religion, those “truths” that can be arrived at by rational observation of the “created world.” This was a first step in allowing changes of fashion in modern secular philosophy and political assumption to drive new thinking in Christian theology. Theologians were prompted to fresh thinking by philosophers such as Immanuel Kant. Friedrich Schleiermacher continued the challenge into the nineteenth century. Søren Kierkegaard called for a move away from believing “propositions” to living the Christian life. Charles Darwin’s work on the *Origin of Species* forced Christians to think radically about the story of the Creation told in Genesis. Karl Barth, Rudolf Bultmann, Dietrich Bonhoeffer, Reinhold Niebuhr, Paul Tillich, and Karl Rahner are leading theologians of the twentieth century who have attempted modern restatements of the faith that allow for the changed philosophical infrastructure. “Process theology” (Alfred Whitehead and Charles Hartshorne) postulated that God is changeable and challengeable—a process, not a substance. Don Cupitt and others have experimented with the idea of the “death” of God. Postmodernism, a multiple and shapeless movement emerging after World War II, and the “deconstruction” of language and forms (Michel Foucault and Jacques Derrida) have undermined old certainties.

Christianity and Secular Politics

The Gospels say that Jesus taught his disciples to be compliant citizens, “rendering to Caesar” what the law required. The Roman Empire became officially Christian with the conversion of the emperor Constantine the Great in the early fourth century. Modern manifestations of the resulting long-term tension in relations of church and state include liberation theology in South America in the late twentieth century, which pressed for recognition of the dignity of the poor. Liberal feminism, especially vigorous in the United States in the late twentieth century, called for inclusiveness of language and an end to the assumption that God is a “he.” Women are ordained to the Anglican, though not the Roman Catholic or Orthodox, priesthood and episcopate in the early twenty-first century. The old debate about the relationship of science and religion has moved partly into the political arena and is now preoccupied with the ethics of the mapping of the human genome, genetically modified food, and the means now available to achieve live births of human children not conceived by ordinary sexual intercourse.

Mission and Interfaith Relations

The Gospels relate that Jesus charged his disciples with spreading the Gospel, and the first generations took it throughout the Roman Empire. Gregory the Great sent a mis-

sion of Augustine of Canterbury to England in 597, and from there Boniface in the eighth century took missions into continental Europe. Christianity was still spreading east and north in the tenth and eleventh centuries. The crusading period from the late eleventh to the thirteenth century brought Christianity into contact with Islam in the Middle East and the first translation of the Koran was made in the West in the mid-twelfth century. With world explorations and discovery of the Americas in the sixteenth century it was carried to the New World. There the Roman Catholic tradition dominated Latin America and the colonies established by the Spanish and French in North America, with the future United States predominantly colonized by Protestant exiles from Northern Europe. The nineteenth century saw a somewhat “imperialist” spreading of the faith into the Far East and Africa and the Pacific. Much of this later missionary endeavor has been “denominational”; American Baptist missionaries entered Orthodox Russia after the fall of communism. Throughout the Middle Ages and early modern period the Jews had lived in Europe alongside the Christian communities. During World War II the Roman Catholic Church did not protest about the Holocaust, and Pope John Paul II eventually apologized for the silence of the Church. Interfaith dialogue in the early twenty-first century seeks to establish a basis of mutual respect on which adherents of different faiths may live.

Conclusion

Christianity remains numerically probably the largest world religion, with Islam close behind. About a third of the population of the world was Christian in the 1990s, and the majority of the non-Christian population knew of Christianity or had some opportunity of contact with it. The largest number of Christians resided in Latin America, with Europe second and Africa third, then North America, then South Asia. Post-colonialism and globalization pose major challenges as to how far the faith can absorb local culture without itself being essentially changed. But paradoxically the loss of heritage makes for conservatism. The fastest-growing Christian community is in Africa, where the intellectual history of the patristic and medieval West is often unfamiliar. Conservative fundamentalism is making the ordination of homosexuals as priests and bishops in the West a church-dividing matter in parts of Africa. The altered balance of the Christian populations worldwide has begun to throw into question the continuance of an intellectual tradition now culturally remote from many Christians while it continues to privilege the Bible as the foundation text and ultimate authority.

ASIA

Since the 1970s, the study of Christianity in Asia has been transformed by new approaches in which the scholarly perspective has become less Eurocentric and more Asian. Particularly in regard to China, Western missionary sources have given way to Chinese sources while the meaning of Christianity has been broadened beyond a narrow religious content to include Asian cultural elements.

The history of Christianity in Asia begins with the unconfirmed legend that St. Thomas, one of the original Twelve Disciples, carried the teaching as a missionary to the southwest coast of India. By the third century, Nestorian Christians of the Syrian church were well established in the Malabar Coast region of India. When the Portuguese began landing in India in 1498, they encountered a group of approximately 100,000 St. Thomas Christians.

Christianity in East Asia dates from the arrival of the missionary Aluoben in the Tang capital of Changan in 635. This Nestorian church in China grew with imperial support until it peaked in 781 and then was destroyed in the anti-Buddhist persecution of 845. The period of continuous and sustained development of Christianity in China dates from the entry of Jesuit missionaries in 1580. It was the result of European global voyages, Catholic Reformation fervor, and Chinese receptivity in the syncretic cultural atmosphere of the Ming dynasty (1368–1644).

Jesuit Accommodation

The newly formed Society of Jesus led the way in missionizing Asia in the early modern period. The Jesuits cultivated regional Asian elites in an effort to accommodate Christianity with indigenous cultural elements. While Jesuit accommodation was criticized by other missionaries, it is clear that some process of inculturation (assimilation) was necessary for the long-term viability of Christianity in Asia.

In China, led by the pioneering Father Matteo Ricci (1552–1610), the Jesuits developed a mission strategy focusing on the scholar-officials. A number of prominent literati were converted in the early seventeenth century, including the famous Three Pillars of the Early Christian Church: Xu Guangqi (1562–1633), Li Zhizao (1565–1630), and Yang Tingyun (1557–1627). Instead of syncretizing the traditional Three Teachings (Buddhism, Confucianism, and Daoism), Xu proposed to “supplement Confucianism and displace Buddhism” by blending Confucianism and Christianity. This formula influenced later literati, such as Shang Huqing (b. 1619) and Zhang Xingyao (b. 1633). However, with the Manchu conquest of 1644, Chinese culture became more conservative and less open to creative synthesizing, causing the literati converts to decrease both in numbers and eminence.

In south India, a Jesuit named Robert de Nobili (1577–1656) studied the languages of ancient India (Sanskrit and classical Tamil) to develop a new and fruitful approach to inculturating Christianity into Tamil culture in the years 1605–1656. However, the Hindu and Muslim cultures of this region resisted Christianity, making South Asia far less fertile territory than East Asia. In southeast Asia, Buddhist cultures resisted the penetration of Christianity, with the notable exception of Vietnam. The French Jesuit Alexandre de Rhodes (1593–1660) developed a remarkably effective missionary method by creating a Vietnamese group of catechists who were trained in basic medicine and who lived as a celibate brotherhood. This led to the creation of a thriving Catholic Church. In more recent times, evangelical Protestants in Vietnam have grown to an estimated 700,000 in number.

In Japan, missionaries met with striking initial success followed by rejection. The Jesuit Francis Xavier arrived in 1549 while Japan was emerging from a period of warring feudal chaos, which provided a brief window of opportunity for the missionaries. Within sixty-five years, there were 300,000 Christians in a Japanese population of twenty million. However, fears of subversion by this foreign religion led to a harsh persecution of Christians that culminated in the death of 3,125 Christian martyrs in the years 1597–1660. Christianity was exterminated in Japan, except for a small group of underground Christians in the area of Nagasaki. Christianity never again rekindled the interest that it had in the late sixteenth century in spite of the extensive investment of American missionaries and church funds made in Japan in the aftermath of World War II.

The isolation of Korea, which was controlled by China, delayed the development of Christianity by denying access to missionaries. However, Jesuit publications in Chinese did reach China and these stimulated a young Korean named Lee Sung-hun (1751–1801) to travel to Beijing and be baptized in 1784. Lee returned to Korea and converted other Koreans. The first Protestant missionaries entered Korea in 1885 and in the twentieth century, Korea became a leading area of Christian growth in Asia.

The entire population of the Philippines was converted within one century after the arrival of Spanish missionaries in

1565. Protestant missionaries first entered the Philippines when the Americans replaced the Spaniards as colonizers in 1898. The Philippines remain today the only Asian country where Christianity is a majority religion, although there has been rapid growth in China, Indonesia, Singapore, and South Korea.

Asian Inculturation

In China, the acceptance of Christianity was made more difficult by the Rites Controversy and related Eurocentric rulings from Rome that were inflexible in dealing with rites to ancestors and to Confucius. This produced an untenable situation in which conversion to Christianity forced one to be unfilial to one's ancestors. Rome later reversed these rulings in 1939 in a case involving Japanese Shinto rites. With the Jesuits losing favor at the court in Beijing, most of the conversions made in the late seventeenth and eighteenth centuries were made by non-Jesuit missionaries working in the provincial cities and rural areas of China. Although magistrates were increasingly harsh in their treatment of Christians, the Catholic rural converts remained faithful.

The first Protestant missionary to work in China was Robert Morrison (1782–1834) of the London Missionary Society who served in Macau and Canton from 1807 to 1834. The missionaries working out of Canton distributed religious tracts that were instrumental in stimulating mystical visions in a frustrated examination candidate named Hong Xiuquan who became convinced that he was the younger brother of Jesus. The result was a powerful blending of Christian and native Chinese folk beliefs in a Taiping movement that nearly toppled the Qing dynasty in 1853–1864. Whereas Catholics emphasized the development of Chinese catechisms, Protestants concentrated on translating the Bible into Chinese. The Delegates Version appeared in 1852–1854 and the Union Version in 1919.

After the Treaty of Nanjing (1842), other treaty ports were opened up to Christian missionaries. However, the missionaries were tainted in the eyes of many Chinese by their association with foreign imperialist pressures. When the Communists took over in 1949 and expelled both the imperialists and the missionaries, there were three million Catholics and 1.5 million Protestants. Because the Chinese communist government and the Vatican refused to normalize relations, Catholic churches split into those registered with the government (Chinese Catholic Patriotic Association) and underground Catholic churches loyal to Rome. Distrust of the government caused a similar split of Protestants into registered churches (Three-Self Patriotic Movement) and unregistered house churches.

Many observers believed that Christian churches were nearly exterminated in China during the antireligious activities of the Cultural Revolution (1966–1976). Actually, religious persecution and in more recent times, the spiritual thirst generated by a rapidly changing society, have fostered strong growth in the numbers of Christians, particularly in native Chinese churches. The emergence of these indigenous movements indicates that Christianity is taking root in China, although it is likely to remain, like Buddhism, a minority religion. Estimates today place the number of Catholics at ten million and the number of Protestants at thirty million. This would

mean that 3 percent of the Chinese population is Christian. Of the three billion people in Asia today, 8 percent are estimated to be Christians.

CINEMA. The latter half of the twentieth century witnessed a swift decline in the popularity and significance of cinemagoing in the West, associated with suburbanization and the rise of competitor media like rock and roll and television. From the 1990s, cinema release was repositioned as a cornerstone of multimedia-themed product lines, including alternative forms of distribution and exhibition (in-flight entertainment, video, broadcast, DVD, and Webstreaming) and spin-offs such as soundtrack albums, novelizations, comic books, franchised toys, board and computer games, and fast-food branding. Moribund profit centers like celebrity gossip magazines were revived, and new ones like product placement inaugurated. Integration of print, TV, theme parks, and Internet companies into massive corporations allowed for an increasing cross-marketing of products in cycles of which film was only one instance. In this transition from mass spectacle to integrated media product, it might have been difficult to retain respect for cinema as “the seventh art.” Nonetheless, during this period and into the early twenty-first century, there has been vigorous interest in the medium of film.

The Language of Cinema

As a broad generalization, the development of cinema studies since 1970 has been shaped by a debate between the search for a medium-specific “language” of cinema and inquiries into the ways cinema reflects, reproduces, or otherwise expresses

Based on the best-selling novel of the twentieth century, the first major blockbuster of the twenty-first could base its innovations on a significant preexisting fan base. The trilogy format, already opened up as a possibility by the highly successful 1999 release of *The Matrix*, differed from the better established “franchise” model of comic-book superhero and horror cycles in the 1980s and 1990s by promising to tell a complete narrative, rather than an open-ended series of discrete tales. Though large, the production budget

was comparable to similarly ambitious blockbuster films of the period. The risk of spending such budgets on fantasy, a genre notoriously difficult to sell to mass audiences, was spread across the fame of the original “property,” J. R. R. Tolkien’s novel, the use of overseas labor, and an innovative marketing campaign.

The Lord of the Rings, though frequently marketed as a triumph of the New Zealand film industry, is an example of a “runaway” production—that is, a Hollywood project filmed in a foreign territory to benefit not only from location scenery but from tax breaks offered by national governments to entice high-spending studio productions, cheaper labor costs than the highly unionized U.S. industry, and flexible working arrangements often unavailable in the United States. Unusually for a big-budget production, the film employed relatively unknown actors at cheaper rates, concentrating spending instead on props, stunts, locations, and digital effects. Without a star, the film then needed to be sold on its look and its story. (The 1977 blockbuster *Star Wars* is a comparable example.)

During the 1990s, a low-budget student film achieved significant box-office success through judicious use of word-of-mouth advertising on the then-new Worldwide Web. The marketing of *The Lord of the Rings*, while also using the familiar channels for preselling blockbusters, used carefully leaked and later carefully timed releases of teasers, interviews, backstage footage, trailers, stills, and production details to fan sites, even inviting fan Webmasters to attend significant film festivals and to report on them. In contrast to the Disney Company, which had set lawyers onto fans running Harry Potter sites, New Line, the AOL–Time-Warner branch company responsible for the film, used the fans as a medium for publicity before, during, and after the release of the films.

The trilogy extended and systematized a number of developments in the blockbuster film

that may now be referred to as event movies. The theatrical release of the film is the trigger for a raft of related products including books, toys, computer games, soundtrack albums, and, very significantly, DVD release. Unusually, *The Lord of the Rings* could not benefit from the lucrative market in “product placement” (the sale of screen time within the film to automobile, computer, hotel and food companies, among others). Instead it capitalized on the very authenticity of a fantastic world without commercial products. The international touring exhibition of props from the films helped build this aura of authenticity. The planning and filming of substantial extra scenes so that the theatrical release of the film could be supplemented with up to an hour of extra storytime on the extended DVD release

allowed an innovative release pattern for the films stretching over a five- to six-year period. This in turn required a loyal fan base, whose interest could be maintained over the extended period of the release strategy.

The films’ budget also required that the movies, like *The Matrix* and *Crouching Tiger, Hidden Dragon* (2000), should be especially palatable to East Asian audiences. Action sequences quoting both Hong Kong fight films and Japanese anime graphic style have become key components in large-budget films destined for a cosmopolitan marketplace. Cinema theory now needs to undertake explorations of such global cultural phenomena, their relationship with both the United States and the country of production, and the future status of cultural specificity in the global circulation of audiovisual materials.

the cultures it derives from or seeks to change. Initial work of the later 1960s emphasized the linguistic structures that appeared to govern cinema. In the later 1970s, two backlashes came in the form first of a film-specific criticism antipathetic to the idea that “bourgeois” forms like the novel and the feature film shared similar structures, and second, of a move away from “theory” toward more traditional forms of humanistic and sociological scholarship. The 1980s witnessed a powerful burst of interest in the cultural dimensions of cinema as an expression of macro- and microcultures—African-American, queer, and third cinema theories privileging the role of cinema as communicator of distinct and differentiated cultural values. In the 1990s, additional emphases were placed on ostensibly marginalized techniques like sound and animation, while the struggle over theory was renewed in the arrival of new theoretical paradigms, notably from phenomenology and the philosophy of desire.

Earlier criticism (commonly referred to as “classical film theory”) often celebrated cinema’s capacity for realism (see Andrew, 1976). After 1968 the French journal *Cahiers du cinéma*, in common with much of French culture, was rapidly and radically politicized and began to critique the illusion of reality in cinema. In the person of Christian Metz, the new criticism articulated an influential mix of Marxism, psychoanalysis, and semiotics, the “science of signs.” In the 1970s, critics associated with the U.K. journal *Screen* began to translate much of this work, and to develop an indigenous theoretical practice, today often referred to as *Screen* theory. The addition of a powerful strand of feminist criticism was the most significant new development, especially as presented in Laura

Mulvey’s 1975 essay “Visual Pleasure and Narrative Cinema” and in the work of Stephen Heath, while Paul Willemen added political commitment and polemic. Rejecting the realist proposals of André Bazin and Siegfried Kracauer, the *Screen* critics proposed that cinema acted as an ideological apparatus, a term borrowed in part from the French Communist Party’s leading philosopher of the day, Louis Althusser. Rather than transmitting ideological messages, as earlier political critics had assumed, cinema’s technical apparatus of camera and projector lenses and screens recreated a model in which the audience member was constructed as the subject of ideology. Interpellated (or “hailed”) by the apparatus and positioned by it, the cinematic subject became a willing participant in the construction of illusion. (It is interesting to note that the two leading political theorists of working-class collusion in their own oppression, Louis Althusser and Antonio Gramsci, were both translated by editors of *Screen*.)

In Mulvey’s version, this process recapitulated the mirror phase of early childhood development proposed by the French psychoanalyst Jacques Lacan. For Lacan, the child’s first recognition of itself in the mirror was both a traumatic discovery of separation from the maternal body and the first identification with an ideal version of itself—more distinct, more capable than it feels itself to be. This dialectic between the loss and idealization of the self Mulvey holds to be the origin of identification with human figures on screen, a fundamental identification that is then articulated with the differing representations of men and women (the one typically looking, the other typically being looked at) to produce the effect of gendered subjectivity in the cinema apparatus. *Screen* critics prized especially the works

PRINCESS MONONOKE

Princess Mononoke (Mononoke-hime, 1997). A product of the Japanese animation industry, *Princess Mononoke* depicts the struggle between the natural world and technology. REUTERS NEWMEDIA INC./CORBIS

Princess Mononoke, directed by Hayao Miyazake, Tokuma Shoten/Nippon Television Network/Dentsu/Studio Ghibli/Miramax, Japan, 1999 (U.S. version), 128 mins.

Hayao Miyazake's *Mononoke-hime* (1997; released in the United States in 1999 as *Princess Mononoke*), the sixth feature film for his Studio Ghibli, built on the success of his child-oriented anime, extending back more than a decade. The Japanese animation industry, powered in part by its close relations with the export of television shows for children and the toys and games crazes of the 1980s, had turned in the late 1980s to themes more suited to young adults. The international success of Katsuhiro Otomo's *Akira* in 1988 and Mamoru Oshii and Masamune Shirow's *Ghost in the Shell* of 1995 had paved the way for higher production values, the assimilation of digital technologies into traditional hand-painted cel animation, and increasingly convoluted narrative lines.

Immensely successful in Japan, where it was only outgrossed by *Titanic*, the film raises special

challenges for the theory of cinema. The animation form has traditionally been seen as childish and has received proportionately little critical attention, while Japanese product aimed at television sales had acquired a reputation for shoddy technique, often due to the practice of farming large proportions of the handcraft out to overseas animation factories, notably in Thailand. Miyazake's film is extremely well crafted throughout, essential if the film was to succeed on the big screen. Several innovations helped, including the use of specially-written software to make three-dimensional digital animation look more like traditional cartoons.

Princess Mononoke's themes of struggle between environmental and mechanistic forces at a formative moment in Japanese history seem not only to have chimed with audiences, but to have echoed in the cartoon form the dialectics of technology and nature. Evoking the environmental ethics of first peoples, the film seeks to reconcile

technological progress with a mystical understanding of the forest as stronghold of nature. The very unnaturalness of the medium, including the necessity to invent sounds for the various cartoon creatures that inhabit the film, give the movie a greater depth and deeper conflicts than the wishful ending would suggest. And the success of the film challenges cinema theory to address two of its major weaknesses: the first being the audio component of audiovisual media and its articulation with the visual; the second,

the distance between photographic and graphic depiction.

Digital theorist Lev Manovich observes that the rise of digital cinema makes contemporary audiences aware that cinematography is a brief excursion in the history of animated pictures. From such specialized formal analyses, cinema studies can hope to derive new paradigms for understanding relations between recording, inventing, representing, and communicating in an increasingly global media society.

of the avant-garde, deploying the semiotic theory of signs to advance the theory that avant-garde cinema freed signifiers (the materials of light and shade for example) from their bondage to the signified (to the illusory representation of an always already ideological reality). At the same time, they sought out more popular films that exemplified the contradictory and dialectical tendencies within the dominant ideology, such as the 1950s melodramas of Douglas Sirk with their clash of wealthy lifestyles and emotional catastrophe. Technical work in film semiotics continues with the work of Warren Buckland, and *Screen* theory has retained its position since the 1970s, especially among feminist critics like Kaja Silverman, but it has never been uncontroversial.

The Specificity of Cinema

The most influential critic of the *Screen* agenda has been David Bordwell. Accusing the *Screen* critics of blindness to the specificity of film, Bordwell and his co-author Kristin Thompson developed a “neoformalist” analysis. Combining inspiration from Russian formalism with cognitive psychology, they proposed a rigorous film scholarship grounded in archive work and extensive as well as intensive film viewing. They also argued for what appeared to be a more commonsense approach to audience activity. Using cognitive theories, Bordwell argued that audiences were actively engaged in constructing meaning, guessing what will happen next, forming hypotheses and mental maps, and piecing together the action of the plot from the fragments of edited film narration. Criticized for their normative and apolitical account of the cinema experience, and despite the sometimes strident protestations of their later work, Thompson and Bordwell have been influential in establishing close analysis of filmic technique and high levels of historical scholarship as necessary prerequisites of film study.

New historicism (rather confusingly referred to as “revisionist” in some accounts) has been especially effective in the

renewal of film studies, focusing attention on the specificity of film’s evolution as technology, industry, and culture. In the 1980s and 1990s scholars such as Barry Salt, Tom Gunning, Roberta Pearson, Janet Staiger, Miriam Hansen, Kevin Brownlow, and Robert Allen and Douglas Gomery on U.S. cinema; Michael Chanan, Pam Cook, Andrew Higson, John Hill, and Robert Murphy on the United Kingdom; Thomas Elsaesser on Germany; Richard Abel on France; Yuri Tsivian on Russia; and others have radically rewritten the glib accounts of journalistic film history. The new cinema historicism diminishes the importance of individuals and denies the apparent linear progress from silent to sound, monochrome to color. Instead the new historicists emphasize the importance of institutional forces and economic trends in the innovation and dissemination of technologies and techniques, seeking reasons why certain promising technologies are delayed or abandoned, assessing the reactions of audiences and exhibitors to emerging technologies, focusing on the institutional histories of studios and government agencies, and tracing links between cinema and cognate industries. In the process some key beliefs of even recent film criticism have been undermined, as when Rick Altman argued, on evidence from D. W. Griffith’s involvement with the stage, that melodrama was a formative component of classical Hollywood, thus critiquing both the belief that U.S. cinema was realist in essence and that melodrama was an effective antidote to its dominance.

Since the 1990s film historians have turned to oral history and documentary accounts of audience activity in the cinema. A major element of television studies throughout its life, audience studies have had a weaker position in film studies, perhaps because of the relative difficulty and social impropriety of staring at audience members in the dark. Early accounts from the 1930s by participants in the British Mass Observation project, even Hugo Münsterberg’s pioneering psychological study of 1916, failed to establish a strong tradition of reception studies. THE RULES OF THE GAME

Scene from *La Règle du jeu* (*The Rules of the Game*), 1939. France has produced many films that have proven to possess cross-cultural appeal. One of these is Jean Renoir's classic *La Règle du jeu*. The original negative was damaged during the German occupation of World War II but was restored in 1956. NOUVELLE EDITION FRANCAISE / THE KOBAL COLLECTION

La Règle du jeu, directed by Jean Renoir, Nouvelle Editions Françaises, France, 1939, 110 mins.

Hated or ignored on its release in 1939, Jean Renoir's *La Règle du jeu* is one of the most consistently admired of all films. An ensemble cast in an upstairs-downstairs country weekend enact the rituals of a dying civilization on the brink of war. With its deep staging and deep-focus cinematography, its long takes, and a fluid camera that seems to track the actors (rather than construct the action for the camera), the film became a touchstone of realist criticism.

In a widely read essay, "S/Z and *Rules of the Game*" (in the film journal *Jump Cut*, nos. 12–13,

winter 1976–1977, pp. 45–51), Julia Lesage argued that in fact the film was constructed through the types of code identified by Roland Barthes and that its realism was merely the effect of cinematic and narrative technique. This formalist analysis would also inspire readings by, among others, Kristin Thompson, for whom the film is an elaborately constructed artifice. That Renoir appears in the film as the character Octave, caught between the aristocrats and the servants, inspired a number of *auteur* critics to single out the film as an account of the artist's role in society and in cinema. In his 1990s *His-*

toire du cinéma, the cinéaste Jean-Luc Godard returns many times to *The Rules of the Game* as if to an exemplary combination of formal innovation and political commitment.

Phenomenological and psychoanalytic critics have focused on the role of illusion in the film, the series of mistaken identities that propel the plot, and the ethos of “keeping up appearances” that leads to the final tragedy. Still baffling for

textual analysts is the charm and the comedy that have kept the film popular not only with critics but with film buffs for more than sixty years. Compellingly humanist in outlook—Renoir’s direction rarely if ever seems to dislike his characters—the film’s narrative nonetheless enacts a damning satire on a rigidly stratified society that prides itself on the appearances through which it lies to itself. This paradox of a realist cinema portraying an unreal society maintains the film’s interest long after that society has faded away.

research by their interest in emotional, inventive, ironic, and resistant attitudes, and in the extremities of fan culture, such studies of necessity emphasize the depth rather than the breadth of their findings, giving more attention to highly specific audiences than to the standard aggregate measure of film audience, box-office returns. At least one international project attempted to do both deep and broad research, investigating cross-cultural meanings of fantasy through an Internet-based survey of responses to the twenty-first century blockbuster *The Lord of the Rings*. Both historical and contemporary reception studies focus on the cultural construction of audiences, the determinations of race, class, gender, and other formations on the ways audiences read and react to movies, disputing both the *Screen* concept of an apparatus that determines response, and Bordwell’s idea of the audience’s work of textual reconstruction.

Cultures and Economies of Cinema

Cross-cultural dimensions of cinema, initially discussed mostly in terms of the textual properties and ideological concerns of national cinemas, are now the object of much work in reception, political economy, and postcolonial research. Summed up in Ella Shohat and Robert Stam’s 1994 title “Unthinking Eurocentrism,” cross-cultural studies result in several kinds of work that dispute the normative tendency of neoformalism and the blindness to cultural difference of the apparatus theory espoused by the *Screen* critics. Some scholars have been at pains to emphasize the creativity or political significance of previously marginalized cinemas and directors. Others apply rigorous theoretical critique to such art house favorites as the Chinese fifth-generation filmmakers. Still more radical was the movement in filmmaking and film theory known as *third cinema*, after an influential 1976 essay by Cuban cinéastes Fernando Solanas and Octavio Gettino, which argued that the first and second cinemas—mass entertainment and bourgeois psychodramas, respectively—had failed the revolution and that a third cinema based in popular forms and addressing popular struggles was the best way forward. This spirit was echoed across the world, in the films of Haile Gerima

in Ethiopia, Sembene Ousmane in Senegal, and Anand Patwardhan in India, and in the critical writings of Teshome Gabriel, Trinh Minh-Ha, and others (for example, Jim Pines, Paul Willemsen, Coco Fusco, and John Downing). Since a central tenet of third cinema was that cultural specificity was integral to a cinema that was genuinely popular in the sense of belonging to and acting with the people, the term acted as an umbrella for a wide range of practice. Another early Cuban proponent, Julio Garcia Espinoza, called for an imperfect cinema; in Brazil, Glauber Rocha called for a cinema of hunger. For some proponents, the third cinema demanded a break with the technical wealth as well as the techniques of the first and second cinemas, while for others the resultant formally challenging films were merely reversions to the self-important antics of art house cinema and of no interest or use to the oppressed. This debate became especially vibrant in North America and in Europe where a new and intensely articulate generation of filmmakers and critics from African- and Hispanic-American, black British, and British-Asian backgrounds began to give voice to their artistic and political demands.

A second effect of this global consciousness has been a reappraisal of the old Marxist political economy espoused by *Screen* theory, updating the analysis to take account of globalization on the film business, its working practices, and its use of international free trade agreements to maintain and develop monopolistic corporate cartels. Janet Wasko, Andrew Higson, and Richard Maltby, among others, have addressed the impact of information technologies and the increasing integration of entertainment industries in guiding the development of new industrial practices as well as strategic policy on global media flows, intellectual property rights legislation, and the potential impacts of North American dominance of film distribution on the cultural lives of smaller nations. Increasingly, studies of auteurs are articulating the creative process with the industrial, and the best of them are also informed by theoretical paradigms that explain the dependence of creation in film on industrial and technical processes over which an individual director has little control.

Such studies of the development of film industries merge with analytical concerns in the study of cinema's relationships with modernity. A number of scholars, among them Anne Friedberg and Friedrich Kittler, trace cinema's roots back to related developments of the late nineteenth century such as department stores, electric streetlights, railways, and advertising, and argue forward to the digital era that cinema has always integrated with a range of other media into a broad process of modernization. In this context the study of entertainment has developed rapidly, with increasing awareness of the cross-media appeal of stardom, movie soundtracks, and animation. Film sound has benefited especially from the work of Michel Chion, Rick Altman, and Philip Brophy, who listen not only to music but to sound effects, to the construction of off-screen space, thematic constructions of gender and race, and the shifting hierarchy of recorded sound and recorded image. Like stardom, which is governed by a dialectical relation between on-screen presence and real absence, the study of film sound reveals complex interactions of space and time, sometimes reinforcing and sometimes undermining the coherence of a film's imaginary world. The sense of modernity as a complex process of homogenization and fragmentation is also common to studies of popular genres like horror, action movies, and science fiction, genres that frequently evoke both utopian and dystopian alternatives to dominant conceptions of embodiment, agency, and the necessity of current social arrangements.

Technologies of Cinema

The arrival of digital technologies in cinema has provoked debate over the degree of continuity between this process of modernization in the predigital cinema and the potential postmodernity of digital film. Critics like Lev Manovich believe in the continuity of the two, and in cinema's powerful determination of such key factors of digital media as the use of screens. Others derive from digital media new paradigms for reviewing the historical data, rediscovering such typically digital techniques as motion capture in the pre-cinematic chronophotography of Étienne-Jules Marey, or digital compositing of layers in the trompe-l'oeil sets of Georges Méliès' early fantasy films. Scholars of special effects, such as Vivian Sobchack, Scott Bukatman, and Timothy Murray, have begun to analyze the diminishing dependence of cinema on what can be enacted in front of a camera, tracing, in Michelle Pearson's work, a transition from spectacle for its own sake to a more embedded expectation of near-photographic illusion seamlessly wedded to cinematographic imagery, as in James Cameron's *Titanic* (1997), a case argued by Angela Ndaliansis, for whom spectacle is, if anything, a more significant element of contemporary entertainment than at any time since the Baroque.

At certain points, this discussion of the transition from photo-mechanical to electronic cinema replicates the long-running debate between culturalist and medium-specific accounts of film. If such vast currents as modernity or globalization run through the transition to digital, then there will be continuity. But if the deep-seated alterations to cinematic technique take precedence, then the experience of

cinema, and to some extent of cultural activity at large, can be expected to change equally. This hypothesis has been tested especially by a generation of phenomenological critics like Vivian Sobchack and Laura U. Marks, for whom the object of inquiry is the physical embodiment of the spectator and the ways this relates to the richness of the felt experience of cinema. This type of work, instigated by Dudley Andrew, is extended in Marks's work into a consideration of the emulation of touching in certain modes of cinema practice. The theme of embodiment also runs through the rapid rise of interest in Gilles Deleuze's two-volume analysis of cinema, remarkable for its espousal of a philosophy of desire grounded in Henri Bergson (rather than the ubiquitous Heideggerianism, in themes of loss, lack, and the fading of reality, of poststructural criticism) and for its meticulous readings of individual films. Deleuze envisages a shift from the "movement-image" pre-1945 toward a "direct time image" in postwar cinema. Informed by the semiotic pragmatism of Charles Sanders Peirce, Deleuze deploys an idiosyncratic vocabulary to argue for cinema's gradual liberation from a mechanistic dependence on the image of the human body toward a more metaphysical engagement with the pure dimensionality of time and its flows.

Challenges of Cinema

The tumultuous history of cinema studies since the mid twentieth century has concentrated several core debates in the history of ideas. Should the study of film deploy traditional hermeneutic and humanistic techniques, or should it abandon them for a more rigorous analysis grounded in linguistics? Or was such grappling with continental theory an alibi for a failure to address the realities of political economy, actual rather than textually determined readers, and the operations of oppression and exploitation disguised or denied by filmic representations? Or was cinema in any case an entirely symbolic activity, a simulacrum with no relation to any reality, physical or social? In institutions where cinema has been taught, there have been the additional claims that the analysis of film is mere carping, all too often negative and destructive, and of no use to those who wish to move into filmmaking as a career. Such claims have led to the rise of major literatures in script analysis and structure, in the technical aspects of filmmaking, and in elements of creative industries literature devoted to film financing, marketing, and policy, many of which have been subsumed into the canon of cinema studies teaching.

Looking to cinema's specific contributions to the history of ideas, among the most significant has been its meticulous attention to the specificities of cultural difference and the contemporaneous splitting and differentiation of subjectivity, in the admission of transcultural cinemas and in queer cinema, for example. At its best, the affirmation of camp, for example in Richard Dyer's work on queer cinema, is valuable not only for film studies but for better understanding of the rich emotional life of the culture.

Indeed, if anything distinguishes the cinema theory among media studies, it is its readiness to engage with the emotional life. Alongside the cool analysis of finance, technique, and box office, it is difficult to sidestep the intense emotive power of

film, from haunting abstraction to political passion, and in physiological reactions of tears, shrieks, and laughter. While some advances have been made in the study of the erotic (by Linda Williams) and the horrific (by Barbara Creed), both comedy and tearjerkers have resisted analysis and remain in many ways the most difficult emotional technologies to account for, partially because they are among the least esteemed in intellectual circles.

There is too the contradictory fascination of cinema captured in the phrase *the dream factory*. Flagship of the consciousness industries, cinema figures as both escape and utopia, flight from oppression or flight toward its alternative. It is both a device for replenishing the exhausted with meaningless entertainment and a technology for demanding the impossible. Its illusions may be seen as lies and ideology, or as evocations of emotional and spiritual satisfactions denied and destroyed by consumerism. Its darkness, serried ranks of seating, and clockwork rhythms of projection can appear as both a continuation of factory discipline into leisure time and as an expression of solidarity, community, and sociability.

Meanwhile, despite (and, in some resistant political sense, perhaps because of) the dominance of Hollywood on world screens, cinema has proved remarkably successful at translating cultural difference across the world: one thinks of the mix of kung fu, spaghetti western, and U.S. gangster in Perry Henzell's Jamaican *The Harder They Come* (1973). The films of Rainer Werner Fassbinder, John Woo, Akira Kurosawa, and Satyajit Ray have reached far more people than equivalent literary or even musical creations. Nonetheless, there remain huge difficulties in securing distribution for non-Hollywood films, a challenge that film studies shows signs of addressing in the early twenty-first century, along with the issues of cross-cultural transmission, emotion, and identification, and the utopian as well as the industrial capabilities of the medium.

OVERVIEW

Citizenship consists in sharing a political community, and enjoying the benefits and assuming the political responsibilities that give effect to this experience of shared political community. If the purpose of political philosophy is to provide a principled account of the nature and appropriate boundaries of political community, then it makes sense to say that the tradition of political philosophy from Aristotle to the present is more or less defined by a tradition of reflection on the normative foundations of citizenship. In an important sense, then, the whole history of political philosophy offers a continuing reflection on and dialogue about the nature of citizenship, and it is not clear that one can give a full report on the history of reflection about citizenship with anything less than a thorough and comprehensive account of the history of political philosophy in its totality. This is impossible here, and therefore a short summary of basic themes in the tradition of political philosophy, and its relation to thinking concerning the meaning of citizenship, will have to suffice.

Citizenship in the History of Political Philosophy

Book three of *The Politics* by Aristotle (384–322 B.C.E.) is the first treatise on citizenship, and it remains an essential reference point for all subsequent reflection on what it means to be a citizen: "The citizen in an unqualified sense is defined by no other thing so much as by sharing in decision and office. . . . Whoever is entitled to participate in an office involving deliberation or decision is . . . a citizen in this city; and the city is the multitude of such persons that is adequate with a view to a self-sufficient life" (p. 87). Aristotle's definition of citizenship sounds modest enough, but in fact it encapsulates an awesomely ambitious account of what is required in order for human nature truly to flourish. Aristotle's account of what it means to be a citizen is intended to be a conceptualization of the experience of free, native-born males in the polis as a unique site for the development of properly human capacities. What the definition affirms is that only a very small number of human

beings in the history of humankind (and only a minority of the inhabitants of Athens even during the age of the polis) have been in a position to realize their full humanity because they happen to be members of the kind of political community that uniquely gives play to their properly human (political or polis-based) capacities.

In republican Rome the idea of citizen virtue was detached from the robust theory of moral development offered by Aristotle, and saw its crowning ideal in a practice of courageous military heroism in defense of the free state. Still, the Roman drive for glory, honor, and power to defend the liberties of collective, aristocratic self-rule was regarded as double-edged by one of the great Christian fathers, St. Augustine of Hippo (354–430). While praising the Romans in his *City of God* for such a long-lasting and glorious state, Augustine called upon Christian believers (and those who felt themselves to be future citizens of heaven) to recognize the pride residing in these Roman ideals of citizenship, and to see the ultimate futility of all earthly ambitions. Christians, as pilgrims in this world, should adopt a stance of submission, disengaging themselves from the ideals of active participation. Augustine saw in the ultimate failure of human enterprises an opportunity to cultivate humility and acceptance of God's will.

It has long been thought that, following Augustine, the ideals of citizenship were largely absent from medieval thinking and only reappeared in the Western tradition in the Italian Renaissance. However, more recent research has shown the deep historical roots of the links between the language of citizenship and the struggle for communal independence throughout Europe (see Höfert). The lingering presence of Roman law, along with the emergence of a class of burghers who sought new forms of political influence, gave rise to political struggles in which the language of citizenship became, once again, salient.

Niccolò Machiavelli (1469–1527), particularly in his *Discourses on Livy*, is regarded as the most famous—as well as the most controversial—defender of citizen liberties. Inspired by the ideal of civic virtue as practiced by the Romans, he called for a new ethos of devotion to the political community sealed by a practice of collective self-rule and self-defense. Needless to say, Machiavelli's conception of the citizen-body remains emphatically patriarchal, as is the case, with rare exceptions, for the entire political theory tradition until recent times. Understanding of the internal and external challenges to the survival of the free state led him to recognize that the duties of successful leadership of a free state would necessitate actions that would, at times, contravene the precepts of conventional morality. Nonetheless, he praised republics over principalities, for it was only through collective self-rule that the greatest number could guarantee their personal autonomy and independence and thereby achieve a more lasting and glorious state.

Post-Reformation religious struggles in Europe gave rise to new accounts of the proper relation between rulers and their peoples, especially in matters of religious practice. While these debates were initially more relevant to individuals as subjects of absolute rulers, they brought about broader reflection on

the concept of natural individual rights, which would later become a powerful tool in the struggle against absolutist rule. *The Second Treatise of Government*, by John Locke (1632–1704), is the best-known account, harnessing the idea of individual rights to a notion of collective sovereignty even though Locke does not reject monarchy. Still, with the advent of commercial society, the possibility of fusing the promotion of individual liberties with a form of government that would require very limited participation on the part of all citizens was increasingly regarded as an attractive alternative. It has meant that in the modern era the quality of citizenship has often been judged more by the accountability of liberal democratic governments toward their citizenry than by the actual forms and degrees of popular participation. But this new synthesis has not been without its critics: modern theorists, notably Jean-Jacques Rousseau (1712–1778), have drawn on more ancient accounts of citizen virtue to decry the lack of active participation in collective self-rule as an ongoing assault upon true popular liberties.

On the Social Contract, by Rousseau, and *The Philosophy of Right*, by Georg Wilhelm Friedrich Hegel (1770–1831), remain the two most important modern treatises on citizenship. At the core of Rousseau's political philosophy is the idea that modern human beings should be judged by the (suitably high) standard of the ancient experience of citizenship. When Rousseau claims, in a note to *Social Contract* (Book one, chap. 6), that modern men know only what it means to be bourgeois and have no notion of what it means to be a *citoyen* (citizen), he makes perfectly clear how deficient he regards modern human beings in relation to this standard. This celebration (mythicization?) of ancient citizenship has of course not gone uncontested within modern political thought: just as Rousseau challenged the Lockean synthesis outlined above, so Rousseau's account of citizenship in turn was challenged vigorously by subsequent liberals. Hence it has been one of the chief theoretical purposes defining liberal political theory going back to Charles de Montesquieu (1689–1755)—or perhaps going back to Thomas Hobbes (1588–1679) if one considers Hobbes part of the liberal tradition—precisely to challenge the normative superiority of classical republicanism. This has been nicely summarized by J. G. A. Pocock: “[Thinkers such as Montesquieu, David Hume (1711–1776), and Adam Smith (1723–1790)] argued that the virtuous man of antiquity was obliged by the lack of a free market to live off the labour of slaves who worked his land and gave him the leisure to serve the republic. His ‘virtue’ made him harsh and barbaric; even his moral personality was impoverished by his inability to exchange goods with his fellows. . . . [With the development of the market, the] rigid and fragile virtue of antique man was replaced by the greater flexibility of ‘manners’” (Pocock, p. xxi). Hegel, with his huge debt to the vindication of modernity contained in the classical political economy tradition (see Plant), represents perhaps the crowning expression of the thought that citizenship in the modern liberal state cannot be exhausted by the notion of citizens unwaveringly committed to the exertions of civic virtue. Hegel, in common with other liberals, believed that consciousness of rightful membership in the modern state must incorporate a clear acknowledgment of the legitimacy and, indeed, moral necessity of the energies that individuals invest in their private lives.

Reading Rousseau gives one the impression that the most powerful theorizing about citizenship is located outside of, and in polemical opposition to, the liberal tradition. But students of the history of political philosophy should never forget that there is at the same time a decisively important tradition of reflection about citizenship and civic virtue *within* liberalism. Alexis de Tocqueville (1805–1859) and John Stuart Mill (1806–1873) are two great exemplars of civic theorizing within the liberal tradition. For all Mill's apprehensions about an unrestricted franchise, and for all Tocqueville's anxieties about the unwelcome consequences of the culture of democracy, both of them were strongly committed to enhancing the civic dimension of liberalism, and in that sense, both are important modern theorists of citizenship.

Citizenship in Contemporary Debates

Not surprisingly, the problem of citizenship has continued to shape contemporary debates in political philosophy. Communitarianism, at least as expressed in the work of Charles Taylor and Michael Sandel, presented itself as a new vocabulary for articulating an old complaint about the attenuated character of liberal citizenship. (This is emphatically not the case with the communitarianism of Alasdair MacIntyre, who fundamentally rejects modern nation-state-based citizenship as a site for moral community.) In the case of Sandel, for example, the more he has continued to develop his theoretical concerns, the clearer it has become that his real concern is not with community per se, but rather with the eclipse of richer possibilities of civic engagement and civic identity in an age dominated by liberal-proceduralist conceptions of politics. This basically civic-republican critique of liberalism should be set within a broader resurgence of civic-republican theorizing. Civic republicanism has surged back to life, philosophically, in the influential work of Hannah Arendt and, in a more historical vein, in the work of John Pocock, Quentin Skinner, and Philip Pettit.

More recently, new challenges to liberal citizenship have arisen in the debates about feminism and multiculturalism. As regards the latter, important arguments have been mounted to the effect that civic norms defined within the horizon of liberalism cannot do justice to the profound forms of cultural diversity ("deep diversity") that characterize virtually all political communities today. The basic multiculturalist idea is that liberal societies cannot fully honor the citizenship of their members if essential aspects of the identity of those members are slighted or treated as irrelevant to citizenship. Like any doctrine in political theory, multiculturalism comes in strikingly different versions. In Iris Young's view, liberal citizenship must be radically reconstructed so as to acknowledge an emphatic "politics of difference." In Will Kymlicka's more moderate view, accommodations to cultural difference are themselves required by liberal justice, rightly understood. According to the latter view, multiculturalism is merely a more effective (and more just) vehicle for the integration of minorities into a liberal civic regime, whereas according to the former view, the liberal vision of citizenship is intrinsically flawed, since liberal universalism is simply a mask for the hegemony of a majority culture.

At the same time, one can say that the powerful challenges to liberal understandings of citizenship generated by communitarian, civic-republican, and multiculturalist theorists have provoked, in response, more robust and more philosophical theories of citizenship from the liberal side. Jürgen Habermas's theory of communicative action can be interpreted as a new liberal (or post-liberal) doctrine of citizenship, and John Rawls's ambitious meditation on the notion of "public reason" in the latter phase of his intellectual career offers another such doctrine. The fundamental issue is posed by Rawls in relation to what he calls "civic humanism" ("classical republicanism" he regards as a more modest doctrine): "[Civic humanists believe that] the activity in which human beings achieve their fullest realization, their greatest good, is in the activities of political life. . . . [Liberal justice as Rawls understands it] rejects any such declaration; and to make the good of civil society subordinate to that of public life it views as mistaken" (Rawls, pp. 420–421; cf. pp. 205–206).

The opposing side is represented by Hannah Arendt when, at the conclusion of *On Revolution*, she endorses the ancient Greek solution to the problem, posed by Sophocles, of how "to bear life's burden": "It was the polis, the space of men's free deeds and living words, which could endow life with splendor" (Arendt, p. 285). The issue here, as it was originally in Aristotle's doctrine of citizenship, is whether civic life constitutes a privileged location for the expression of our proper humanity, or whether it ought merely to furnish a procedural framework for more diverse, privately defined activities in which we express our humanity. So we see that one of the core debates that has animated political philosophy throughout its history—for instance, in the argument between Rousseau, with his uncompromising republicanism, and his liberal critics such as Adam Smith (see Ignatieff) and Benjamin Constant (1767–1830)—continues to be a living question in contemporary thought.

JUAN GÓMEZ-QUIÑONES

Born of Mexican parents in 1940 in Parral, Chihuahua, Juan Gómez-Quíñones has been active in the articulation and political negotiation of cultural citizenship since the 1960s. His experience in the United States' Chicano civil rights movement led to his authoring of foundational papers on the history and identity of Chicano peoples of the southwestern United States. Soon after, he expressed the importance of and developed an epistemology for Chicano studies as a new interdisciplinary field. Such efforts helped to establish Chicano studies in institutions of higher education throughout the nation. Among his published works are *Chicano Politics: Reality and Promise, 1940–1990* (1990); *Mexican American Labor, 1790–1990* (1994); and *Roots of Chicano Politics, 1600–1940* (1994). In 1971 he helped found *Aztlan: International Journal of Chicano Studies Research*, the United States' premier journal of Chicana and Chicano studies. He is professor of history at the University of California at Los Angeles (UCLA) and lives with his family in Santa Monica, California. In 2003 UCLA presented him with the Rosenfield Distinguished Community Partnership Prize for community service.

CULTURAL CITIZENSHIP

Cultural citizenship has been part of a broader discussion on cultural pluralism that began in the United States at the beginning of the twentieth century. Since then pluralism has undergone at least three noteworthy transformations, beginning with, during the first quarter of the twentieth century, attempts to preserve primarily European immigrant cultures vis-à-vis the state, followed by the integrationist civil rights movements of the 1960s and 1970s, and lastly, the mainstreaming of "difference" and a multiculturalism that began in the 1980s. Never intended to destabilize the authority of the nation-state or its ideology, these "politics of difference" have helped give voice to American democratic citizenship.

Cultural Citizenship and Latinos

The notion of cultural citizenship initially developed in the 1980s, in part to bring greater multicultural emphasis to dis-

courses of race in the United States that stressed black and white dichotomies. It is both a theoretical perspective and methodological approach with which to examine the socio-cultural identity, political will, and cultural creation of primarily Latino populations in the United States. Theoretically, the notion acknowledges the cultural resiliency, social reproduction (the class, cultural, and linguistic knowledge and skills that establish the cultural capital of social groups), and rights-claiming agency of ethnic communities and other marginalized groups as viable and worthy outcomes of social injustice and alienation. Methodologically, cultural citizenship requires that social scientists approach their studies from the perspective of subordinate groups in order to understand the latter's goals, perceptions, and purposes. The term appears to have been coined by the anthropologist Renato Rosaldo, who first used it in the late 1980s to make a case for the democratization of institutions of higher education through diversity in the classroom, curricula, decision making, and society at large; a call not unlike that made by Chicano civil rights leaders of a generation before. In the 1980s and 1990s a Latino cohort of social scientists, among them Rosaldo, used the concept to examine Latino civic participation in the voicing, claiming, and negotiating of cultural space. Importantly, these studies speak to cultural phenomena as the aesthetic and force behind the empowerment of groups to civic action. As such, cultural citizenship examines the colloquial meanings of alienation and belonging as they apply to marginalized groups with respect to the national community. In this context, claims to rights made against the state by subordinate communities arise as a consequence of degradation and exclusion in their daily environments but may also result from acts of self-definition, representation, affirmation, sensibility, and aesthetics. Specifically, these may be expressed as desires and aspirations for

equality, respect, and dignity. In the early years of the twenty-first century, cultural citizenship has been applied to modernizing efforts in an international context.

Sociocultural Agents of Citizenship

It is clear from the literature on cultural citizenship that cultural phenomena and issues of identity are privileged over theoretical considerations having to do with membership in the polity, except for its emphasis on the group. Unlike traditional concepts of citizenship in which the individual is the rights holder, the agents and subjects of cultural citizenship are undeniably the group. In concert with the literature on cultural pluralism, cultural citizenship too presents rights claiming as the prerogative of the group and, as such, calls attention to an ongoing broader debate between cultural pluralism and universal citizenship in the nation-state.

For much of the studies on Latino cultural citizenship, membership in the nation-state is implicitly ambiguous as if yet to be determined or in the process of becoming, as must be the case for illegal immigrant populations in the nation-state. Others describe a kind of citizenship practiced by Latino communities before the nation-state as “social citizenship,” specifically using T. H. Marshall’s meaning of *social* as entitlement to benefits deriving from the largesse of the welfare state. Similarly, social rights to citizenship have been used to describe a “citizenship without consent” practiced by communities of Mexican illegal immigrants in a postnational context inclusive of as well as beyond the nation-state.

Group-differentiated citizenship has been criticized on several counts, among them its reverting to premodern ways of using religious, ethnic, or class membership to determine the political status of people; its discouraging the integration of ethnoracial groups into mainstream society; and its undermining of a greater fraternity between all Americans and a common sense of purpose. The historian David Hollinger argues that group-differentiated citizenship is provincial and given to insularity when the need is for cosmopolitanism and “freedom of affiliation” embodied by the exceptional growth (compared with other nations) of mixed-raced people in the United States.

In response, cultural pluralists point out that citizenship rights as originally conceived by the nation’s founding fathers are oblivious to the needs and differences of multicultural groups. Indeed, the philosopher Iris M. Young argues, the American liberal concept of equal citizenship plays no part in the notion of universal citizenship, nor is it meant to, since the latter assumes and upholds a homogeneous collective community at the expense and suppression of group difference. For this reason, Juan Gómez-Quíñones believes, Chicano/Latino cultural identity is vital to membership in a political community precisely because citizenship rights and responsibilities do not encompass multicultural rights. “Though there has been a great stress on voting qua voting as a measure of political achievement and influence,” he writes, “the act of voting does not promise the achievement of full equities, much less direct and full democracy” (p. 211).

Defenders of differentiated group representation believe that citizenship should recognize and accommodate sociocultural difference to compensate for past injustices. For Young, any conception of equal citizenship must include historically excluded groups in the political community both as individuals and as members of the group. Young questions an ideal that in practice reinforces the power of the privileged in “this unified public” (of universal citizenship) while marginalizing others. An alternative approach to membership in the polity is “differentiated citizenship,” which allows for group-based claims or distinct group rights for what Young calls “social-cultural” groups but which the philosopher Will Kymlicka distinguishes as national and ethnic minorities and underrepresented groups. According to Kymlicka, some form of differentiated group rights for the latter comprise part of citizenship rights in most, if not all, modern democracies.

NATURALIZATION

Citizenship rests with territory at the heart of the definition of *nation-state*. If territory determines the geographical limits of state sovereignty, citizenship determines a state’s population. Beyond these limits one finds foreign land, foreign sovereignty, and foreigners. Drawing the boundary within which some human beings are included and others excluded as foreigners, permitting

some of them to acquire citizenship with certain conditions and others to lose citizenship, is a state prerogative that requires legal tools. In citizenship law, the two most important legal tools traditionally used to determine citizenship are:

1. *Birthplace*, or *jus soli*, the fact of being born in a territory over which the state maintains, has maintained, or wishes to extend its sovereignty.
2. *Bloodline*, or *jus sanguinis*, citizenship as a result of the nationality of one parent or of other, more distant ancestors.

All nations use *jus soli* and *jus sanguinis* in defining attribution of citizenship at birth. However, two other tools are used in citizenship law, attributing citizenship after birth through naturalization:

1. *Marital status*, in that marriage to a citizen of another country can lead to the acquisition of the spouse's citizenship.
2. Past, present, or future *residence* within the country's past, present, future, or intended borders (including colonial borders).

In eighteenth-century Europe, *jus soli* was the dominant criterion of nationality in the two most powerful kingdoms: France and the United Kingdom. The state simply inherited feudal tradition: human beings were linked to the lord who held the land where they were born. The French Revolution broke with this feudal tradition. Against Napoléon Bonaparte's wish, the new civil code of 1804 granted French nationality at birth only to a child born to a French father, either in France or abroad. This policy of *jus sanguinis*, representing a modern innovation, was not ethnically motivated; it simply reflected the fact that individual rights and family had become more important than subjecthood and state power. This French innovation was borrowed extensively and became the law in Austria (1811), Belgium (1831), Spain (1837), Prussia (1842), Russia (1864), Italy (1865), Netherlands (1888), Norway (1892), and Sweden (1894).

The British tradition of *jus soli*, on the contrary, was transplanted, unamended and unbroken, to Britain's colonies in North America (the United States and Canada), Europe (Ireland), Africa (South Africa), and Australia. It also influenced Portugal and Denmark until the Nordic countries adopted a common nationality regime in the 1920s.

Were a population and territory to match one another exactly, attributing citizenship on the basis of *jus sanguinis*, *jus soli* or residence would not make any difference. Citizenship law would concern the same population and would have the same juridical effects. Further, naturalization would be irrelevant. It is the case, of course, that the population and territory of a nation-state do not coincide. People migrate and, with respect to migration, one can distinguish broadly between two different types of countries:

1. "Countries of emigration" are countries where part of the core population resides outside the

national boundaries, a characteristic applying to the majority of European countries before World War II (with the exception of France), and Mexico since the 1930s.

2. "Countries of immigration" are those in which the majority of citizens are immigrants or descendants of immigrants, or whose foreign populations have settled as permanent residents alongside a majority population that is perceived to have existed since time immemorial and is not descended from immigrants. The United States, Canada, and Australia and countries of South America are examples of the former, while the latter category includes France since the mid-nineteenth century and all other western European countries since World War II.

The legal traditions of *jus soli* and *jus sanguinis* were maintained with consistency and relative ease in the majority of these different countries until World War II. In countries of immigration such as the United States, *jus soli* allows the children of immigrants to acquire citizenship automatically. For continental European countries that were countries of emigration, *jus sanguinis* allowed citizens abroad to maintain links until their descendants lost touch.

Since World War II, however, citizenship laws have converged across all democratic states, due to the large increase in the scale of migrations across the world. In many continental European states, large-scale postwar immigration led to legislative changes so as to permit increasingly large segments of the population born in their territories, namely second- and third-generation immigrants, to access citizenship more easily. Elements of *jus soli* have been included in their *jus sanguinis* tradition that extends citizenship automatically at birth to third-generation immigrants (France since 1889, the Netherlands since 1953, Spain since 1990, and Belgium since 1992). For the second generation, in many countries, children born to immigrants on national territory are entitled to citizenship if the child (Belgium, Denmark, Finland, France, Italy, Netherlands, Spain, Sweden) or one of the child's parents (Germany) has lawfully resided there for a period of years.

Countries with nationality laws based upon automatic *jus soli* often attracted a number of immigrants into their territory, encouraging these countries to become more restrictive. For example, the United Kingdom's imperial and expansive conception of territory, combined with its *jus soli* tradition, involuntarily encouraged immigration. Just after World War II, all subjects of the British Empire had access to British citizenship simply by residing in the territory of the United Kingdom proper. Since that time, British legislation on nationality has undergone a swift and silent revolution away from the extended and automatic *jus soli* to a 1981 law that attributes citizenship only to children born in U.K. territory to parents with legal residence status. The legal residence of parents has also been included as a requirement in the Portuguese and South African laws.

The trend toward convergence in nationality laws concerns almost all advanced industrial countries, insofar as they share

three basic characteristics: democratic values, stable borders, and a self-perception as countries of immigration rather than of emigration. The importance of these three conditions is confirmed when considering exceptions to this rule, such as Israel and Russia. In both countries, there is a dominant perception that many of their citizens reside outside their borders, and that the borders—indispensable for the definition of the *solī*—are not stable. *Jus sanguinis* thus remains at the center of both of their citizenship laws. But for all countries, regardless of their situation concerning migration or their level of development, there are two distinct lines of convergence in nationality laws. First, there has been a notable trend since the mid-twentieth century toward repealing provisions for the automatic acquisition of citizenship through marriage, a move motivated at the same time by the development of equal rights between men and women in nationality laws and by worries about fraudulent marriages with illegal aliens. Second, equal rights between men and women to transmit their citizenship to their children has produced the development of dual citizenship and more toleration of this phenomenon in many countries that formerly refused it (for example, Switzerland since 1990). What remains divergent are the rules for naturalization; that is, the processes by which foreign residents of the first generation access citizenship in a host country. States generally require a period of residence and knowledge of the language, and take into account a criminal record, but the details of these requirements still vary greatly, both in the formal requirements of nationality laws and in the practices through which these laws are enforced.

THE CITY AS CULTURAL CENTER

In the modern conception of the word *city*—characterized by the size, the aggregation of housing, differentiated division of labor, and the density of interaction—the first cities appeared in Mesopotamia around 10,000 B.C.E. and most clearly by 3,000 B.C.E. The great city of Babylon marked the coming of age of civilization, characterized by an urban culture that highlighted sophisticated arts and crafts, rare products, a multiplicity of material objects introduced through trade, the emergence of new ideas and modes of domination, and a more complex social structure.

From the early days of urbanization, several often competing conceptions of cities were evident:

- the material city of walls, squares, houses, roads, light, utilities, buildings, waste, and physical infrastructure;
- the cultural city in terms of imaginations, differences, representations, ideas, symbols, arts, texts, senses, religion, aesthetics;
- the politics and policies of the city in terms of domination, power, government, mobilization, public policies, welfare, education;
- the social city of riots, ethnic, economic, or gender inequalities, everyday life, and social movements;
- the economy of the city: division of labor, scale, production, consumption, and trade.

As a unit of analysis the city is often characterized through the emphasis on diversity, fragmentation, strangeness, encounters with strangers, the mosaic of variety, contingent interactions, moving borders, everyday life and events, and the multitude of interactions. However, another perspective focuses upon integration, domination, assimilation, social order, control, inequalities, unity, models, patterns of economic development, structures, and systems. From Babylon, Athens, Rome, and later Florence, to the present era's so-called global cities comes the idea that cities are places where culture flourishes, where civilization reaches its highest point of complexity and sophistication. The density and diversity of interactions are supposed to stimulate innovations in all sorts of ways, to free urban inhabitants from traditional cultural constraint. Cities are therefore presented by social scientists, historians, and writers in a progressive way as centers of innovation and culture even if civilizations first developed without or beyond cities, as, for instance, in the case of Egypt. By contrast, the city is also portrayed as the place of darkness, chaos, violence, riots, exploitation, marginal life and deviance, destruction, and oppression.

Those categories were for the most part derived from the division of labor between disciplines put forward at the end of the nineteenth century. The study of the city as a cultural center evoked passionate debates at the start of the twentieth century when the German sociologists Max Weber, Werner Sombart, and Georg Simmel discussed the relationship between cities, culture, arts, technological developments, and

domination. They asked questions about the influence of a particular set of structural social, economic, political, and cultural conditions such as capitalism on the effect of cities or on individual and collective behavior, modes of thinking, ways of life, cultural creation, and imagination.

The City as an Integrated Political and Social Structure

In the Western world, cities emerged at the turn of the first millennium, insinuating themselves into the gaps of the feudal system. In a section titled “The City” in his 1925 study, *Economy and Society*, Max Weber portrays the medieval Western city as having the following characteristic features: fortifications, a market, and a specifically urban economy of consumption, exchange, and production; a court of law and the ability to ordain a set of rules and laws; rules relating to landed property (since cities were not subject to the taxes and constraints of feudalism); a structure based on associations of guilds; and—at least partial—political autonomy, expressed in particular through the existence of an administrative body and the participation of the burghers in local government, and sometimes even through the existence of an army and an actual policy of foreign expansion; and a citizenship with relative freedom often associated with affiliation to a guild.

The medieval city was the crucible of European society, a place in which new cultural and political models developed, along with new social relations and cultural and organizational innovations, furthered by interactions between the various populations thus promoting mechanisms for learning a collective way of life, for innovation and spreading innovation, rapid accumulation, transformation of behaviors, interplay of competition and cooperation, and processes of social differentiation engendered by proximity. The Europe of cities was not just the Europe of early capitalism and of merchants, but also the Europe of intellectuals, universities, and culture that launched the Renaissance.

In analytical terms, this sketches out a research perspective in terms of local societies and governance that is crucial for the analysis of contemporary cities, in Europe in particular. The city is conceived as an integrated local society (most of

the time, incomplete), and as a complex social formation, sometimes a local society. Cities may be more or less structured in their economic and cultural exchanges, and the different actors may be related to each other in the same local context with long-term strategies, investing their resources in a coordinated way and adding to the social capital riches. In this case the urban society appears as well structured and visible, and one can detect forms of (relative) integration. If not, the city reveals itself as less structured and as such no longer a significant subject for study: somewhere where decisions are made externally by separate actors. Such an analysis examines the interplay and conflicts of social groups, interests, and institutions, and the way in which, to some extent, regulations have been put in place through conflicts and the logics of integration. Cities do not develop solely according to interactions and contingencies: groups, actors, and organizations oppose one another, enter into conflict, coordinate, produce representations in order to institutionalize collective forms of action, implement policies, structure inequalities, and defend their interests. This perspective on cities highlights the informal economy, the dynamism of localized family relations, the interplay of associations, reciprocity, culture and ways of life, the density of localized horizontal relations, and local social formations.

The Industrial City

The industrial revolution led to a new wave of urbanization. Concentration in great metropolises and large industrial areas lent a different dynamic to cities, changing them both socially and physically: a new type of industrial city emerged in the nineteenth century—most often around coal mining, textiles, or iron and steel, then later chemicals, electricity, and mechanical engineering—enjoying an extraordinarily rapid growth fueled by immigration and leading to the formation of dense industrial regions and centers as in Britain, the German Ruhr, or the northeast of France—“Coketowns” as Lewis Mumford put it. The “tyranny of fixed cost” (transport) also supported the rise of industrial ports and the pace of concentration in large industrial cities such as Calcutta and, most decisively, in large U.S. cities of the Northeast and Midwest—New York and Chicago in particular. Cities became places

where capital was tied up in major fixed assets, with labor forces that varied in composition and size, and with a high level of internal diversity.

The industrial city is first and foremost a place of social conflicts, inequalities, urban poverty, social segregation, and speculation. Karl Marx and his followers sketched a view of the city organized by capitalism, a place of class struggle determined to a large extent by the economy. The Marxist analysis was “urbanized” by David Harvey, who stressed the role of land and property for capital accumulation, investment together with the contradictions of capitalism in cities. He underlined both the role of the built environment in capitalism and the social struggle of social groups to prevent the disinvestment in industrial cities, which fed the dynamics of deindustrialization and urban crisis. Others have developed the role of class struggle to analyze the dynamics and culture of cities in different parts of the world. Changing forms of capitalism after 1945 gave rise to the analysis of the “Fordist city”—that is, the city organized around and for the needs of the large industry.

Industrial cities are characterized by their social structure and by their form and organization. Although U.S. cities had large firms and major entrepreneurs, they were above all workers’ cities, sites of immense poverty and exploitation, and crucibles for working-class organization. The industrial city took the form of this combination of industries, workers’ housing (slums, social housing, suburban houses), minimal communal amenities, transportation infrastructure, and, later, social democratic forms of urban government. Overpopulated working-class districts mixed with factories in city centers, driving out the bourgeoisie (in a configuration that reversed that of the old European cities, where industrial activities and working populations had most often been pushed out to the periphery) into what became the suburbs. Social surveys were initiated in Britain, France, and Germany to assess poverty and the terrible conditions of public health. Working-class culture was organized around work, clubs, cafés, dances, and sport, although with considerable variations from one city to another. Even beyond the structural opposition between the bourgeoisie and the newly forming working class, these industrial cities were socially diverse places: artisans continued to exist and to develop, and the number of shops increased, if only to feed the abundant populations of vagrants, prostitutes, and white-collar office workers.

After the 1960s, the most industrialized cities declined in the United States and Western Europe, leading to a postindustrial landscape, a mix of derelict land and buildings and new cultural or housing activities. By contrast, other cities in the world—for instance, in rapidly urbanizing China—have become the new workshops of the world, comprising a high concentration of the working class in the manufacturing sector.

The Rise of the Metropolis: Centers of Experiment for Modern Social Life

For observers of the late nineteenth and early twentieth century (Simmel in particular), the development of the large metropolis is a major phenomenon, both in Europe and in the United States.

Capital cities benefited from the consolidation of states, the shift of political life onto the national level, and the strengthening of the states’—and therefore the bureaucracies’ (including the army’s)—capacity for control, as well as from industrial development and colonization. These major cities absorbed a large part of the flow of migration, thus providing sizeable reserves of labor. They were the first beneficiaries of the transport revolution, from tramways to road and rail networks. Open to the world in an era that saw increasing numbers of different kinds of exchanges, discoveries, and technical innovations, they established their role by organizing universal exhibitions and great fairs. Concerned with public health and safety, governments organized major improvement works, created wide avenues, and constructed new public buildings: stations, squares, and monuments that symbolized their dynamism and technical progress. These cities were also places of speculation, of public and private investment in housing, and of financial capital. Their cultural influence changed scale because of more rapid diffusion, transports, and colonial empires. In particular, London, Paris, Berlin, and Vienna were the theaters of extraordinary physical and cultural transformations. As university cities and cultural centers, they were the focus of unrest and the sites of the political and social revolts that punctuated the nineteenth century. The great metropolis became the site of consumption, of department stores and wide avenues, of overstimulation that changed the urban cultural experience. This led also to physical transformation with the ever-increasing diffusion of urbanization around those large metropolises, hence the rise of suburbs, either working-class ones such as the red belt in Paris or bourgeois suburbs where the middle class abandoned the center.

The rise of the large metropolis became an American feature: New York and Chicago and later Los Angeles in particular gradually replaced European cities in the urban imagination of the modernist metropolis. They grew thanks to stunning economic development and massive immigration. In the 1920s both the American and European metropolis became a place of strong inequalities, anti-Semitism, violence against foreigners, racism, anticommunist movements, and flamboyant cultural creativity. The U.S. model is constructed around the industrial city with its low-income neighborhoods linked to manufacturing districts and close to commercial cores and its middle-income neighborhoods beyond. Out of the suburban migration of the middle classes accentuated after World War II emerged the prototypical metropolis with its central city ringed by suburban enclaves. In the best case, the commercial core became dominant. In the worst cases it, along with the manufacturing district, was in decline. The dynamics of development was horizontal, with activities deconcentrated and decentralized.

The metropolis and the neighborhood are associated with the Chicago school of urban sociology, which for several decades developed ethnographic studies on different ethnic communities and neighborhoods, and also—in research such as that by Robert Ezra Park, Ernest W. Burgess, and Roderick D. McKenzie—on groups such as hobos, gangs, and the like. Such work concentrates on interaction and on the density of

interactions within the city, leading to an ecological model of the urban process based upon the dynamics of competition and conflict between different groups and their evolution in terms of social and spatial mobility. The city is the place of dense interaction, of mobility, within a context of rapid social change, industrialization, and immigration, a “social laboratory” of modernity where more classic social structures are eroded.

The issue of immigration and the presence of ghettos became central, and racism was quickly established as the leading cultural divide within cities. The question of race and relations between ethnic groups, particularly in U.S. cities, became the cornerstone of American sociology and urban sociology. Ghetto formation, competition between ethnic and racial groups, and assimilation remain the main lenses through which cities are analyzed.

Related debates concerning the integration of diverse ethnic groups took place in European cities during the period of mass migration to industrial cities in the 1960s and 1970s, and the urban-ethnic issue also became central in the political and social dynamics of cities: suburbanization and the rise of xenophobic organizations.

Cities of Difference: Globalization in Progress

Urbanization was reaching new highs in the contemporary world with the rise of mega cities whose greater metropolitan populations exceeded 15 million, such as Calcutta, Cairo, Tokyo, Bombay, and Seoul. Beyond the modern metropolis, researchers try to make sense of those large urban areas with terms such as “postmetropolis,” “global cities,” and “global city-regions.” The processes of globalization, including transnational migration, architecture, financial transactions, transport flux, and dissemination of technological innovations contribute to the rise of mega cities in different parts of the globe.

In contrast to the modernist view of the metropolis, cities have been a major subject of the cultural turn in the social sciences suggesting that culture orients our behavior and shapes what we are able to know about the world. According to cultural studies that have taken place within cities, the question of identity and culture has become a central paradigm. Immigration and the pluralization of identity pave the way for the image of the city as fragmented mosaics. The city is about “the other,” and the risks associated with diversity.

The first impact of the cultural turn is about the questioning of classic Western categories such as cities, gender, ethnic, militarism, surveillance, and colonialism. A body of research has made visible issues of sexual, racial, age, religious, gender, and ethnic minorities, together with class, stressing the fluidity of cities, the role of informal organizations and social movements in social conflicts; it has raised issues of justice and the pluralization of identity formation beyond the state. The city is therefore analyzed through representation, discourse, objects, arts. Cultural studies scholars now take up goods as texts that signal the important social processes of their time and context. They look at cities as worked out through perception, memories, and imagination, everyday life and practices, interactions and events, a space simultaneously real and imagined,

material and metaphorical, ordered and disordered: from gay enclaves to fortress cities and postcolonial environments. The city is seen as a fluid process, constantly reshaped, chaotic and indeterminate, subject to rival and contradictory claims.

Culture is now a major determinant of migration and the dynamics of cities. From the studios of Los Angeles and Hong Kong to the old neighborhood of Istanbul or Bombay and the cultural clusters of Florence and Prague, all places have culture industries from museums to choirs, county fairs to religious buildings, galleries to theaters. Each city is unique, and its uniqueness relies both upon the interactions within the city, a place for spectacles, and upon interactions with other cities. Tourism, migration, economic development, and urban regeneration seem to rely now, at least in part, upon culture.

“Fantasy cities” are on the rise (as documented by John Hannigan) and one exemplar, Las Vegas, is the fastest growing city in the United States. Surveillance technologies, marketing, standardized entertainment, and culture give a new boost to cities as places of cultural consumption under strict surveillance, at the expense of local groups, social conflicts, and local culture.

The traditional ideas of the city, the modern metropolis or the industrial city, are now associated or replaced by contradictory images of those mega cities where one either emphasizes cultural diversity and the infinite range of interactions or the strength of control and capital accumulation by dominant groups. The rise of mobility and transnational flux within more globalized capitalist cities raise new issues about assimilation, social order, politics, and culture in cities. Cities are reshaped by local groups and culture interacting, adapting, or protesting against globalized flows.

THE CITY AS POLITICAL CENTER

In Western political thought, ideas about cities, citizenship, and democracy have always been inextricably linked. Since Socrates suggested in *The Republic* that his interlocutors help him to create a city in speech, the city has functioned as a real and metaphorical center for struggles over what it means to be political. Ideas about civilization and barbarism, egalitarianism and exclusion, virtue and vice, civic participation and social unrest, all find expression in discussions of the city. Yet the city is and has always been an ambiguous achievement; its success (or failure) as a form of political organization rests on its citizens' dubious abilities to govern themselves, deliberate with strangers, act on principles beyond narrow self-interest, and collectively determine their future. Thus the state of a nation's cities is often used as a barometer to judge the quality of its political life.

City as Democratic Ideal

In its most utopian incarnations, the city is common ground, a space where the democratic values of equality, heterogeneity, public life, and creative expression might be freely lived. In the United States the roots of its democratic heritage are routinely traced to ancient Greece, where in Athens in the fifth century B.C.E. the vision of the "good life" was concomitant with city life. As Pericles famously argued:

Our constitution is called a democracy because power is in the hands not of a minority but of the whole people.

When it is a question of settling private disputes, everyone is equal before the law. . . . [J]ust as our political life is free and open, so is our day-to-day life in our relations with each other. We do not get in a state with our next door neighbor if he enjoys himself in his own way. . . . We are free and tolerant in our private lives, but in public affairs we keep to the law. . . . Here each individual is interested not only in his own affairs but in the affairs of the state as well: even those who are mostly occupied with their own business are extremely well-informed on general politics—this is a peculiarity of ours: we do not say that a man who takes no interest in politics is a man who minds his own business; we say that he has no business here at all. (Pericles' Funeral Oration, in Thucydides, pp. 145–147)

Equality before the law, tolerance of difference, and civic participation—these are the qualities of city life that are found desirable and worthy of imitation.

In the modern context, the ideal of metropolitan democracy is grounded in the potential found in these three aspects of city life originally articulated in Pericles' speech. First, as Max Weber argued, modern city life—as characterized by economic and bureaucratic rationalization and autonomous law and administration—disrupted feudal and paternalistic forms of governance. Traditional and often immutable hierarchies (such as tribe, religion, or kinship) thus were replaced by more egalitarian political associations.

Second, democratic urbanists exalt the city's inherent heterogeneity as democracy's greatest good. The city is a place where citizens are required to negotiate many different axes of identity and difference (for example, race, class, gender, and sexual orientation), so city life cultivates an appreciation of diverse groups without necessarily assuming either assimilation or exclusion. While in ancient Athens the boundaries for demarcating "citizen" and "other" were considerably narrower than they are in the early twenty-first century, the principles of toleration and noninterference are cornerstones of democratic urbanism. The city functions as a place where persons unknown to each other and often without shared familial, religious, ethnic, or cultural ties have the opportunity to act in concert to achieve mutual good; a certain kind of cosmopolitanism (or an ability to "move comfortably in diversity") is intrinsic to discussions of democratic urbanism (Sennett, p. 17).

Third, because political life is not based on private relationships but on the whole body of citizens deliberating among themselves (the public's business is everyone's business), the presence of truly public spaces—boulevards, parks, and plazas—is a requirement for collective action. In fact such places serve as stages for political activity, facilitating interaction among diverse groups with different interests and creating the necessary conditions for collective decision-making. This very material public sphere both presupposes and cultivates political imagination by encouraging citizens to think and act in ways that transcend their particular experiences.

The City as Democratic Menace

From its inception, however, the city's equality and diversity have also signified its instability—the threat it poses to moral, social, and political order. The city has been regarded as the site of sinful excess and moral turpitude, where upstanding citizens may risk succumbing to the depravity of the mob. Despite (or because of) its status as the rationalized center of Western political and economic life, the city has also been the site of its revolutions; from Europe in 1848 to the United States and Paris in 1968, cities have been recognized as the epicenters of democratic upheaval.

Attempts to secure the city as a political and cultural center have historically often sought to contain, control, or eliminate many of the very elements urban democrats find so promising. Efforts to create meaningful, modern urban life have varied greatly, ranging from the reinvention of Paris by Baron Georges-Eugène Haussmann (1809–1891), the Garden City of Ebenezer Howard (1850–1928), the City Beautiful of Daniel Burnham (1846–1912), and the Radiant City of Le Corbusier (1887–1965), to numerous public housing projects across the United States and Europe. But as Elizabeth Wilson notes, what these efforts have in common is the desire to replace chaos with order, heterogeneity with uniformity, and the noise and commotion inevitable in lively public places with placidity and good behavior.

Contemporary Challenges to the City's Democratic Potential

One of the widely debated issues regarding cities in the early twenty-first century is how their democratic possibilities might be realized in practice. While (at least implicitly) remaining sympathetic to the ideal of the city as a democratic space, important contributions in critical urban thought examine the inequalities woven into the urban fabric that delimit the amount and quality of freedom allowed to citizens, especially through residential segregation and the privatization of public space.

Residential segregation is caused by any number of factors. In the American context, typical examples of these include the use of racially restrictive covenants and redlining up through the 1960s; the priority placed on the federal highway system rather than public transit; federal tax incentives offered to homeowners (via deductions for mortgage interest) rather than to renters; and the use of local property taxes to fund public schools. These practices are not accidental but institutional and political, and they work to create, sustain, and embed economic and racial inequalities in the urban landscape. All result in widely divergent experiences for living, working, and pursuing educational opportunities in the context of modern city life.

As a result of these practices the inner city and inner-ring suburban areas are increasingly racially segregated and economically isolated. The results of this are myriad. First, the economically privileged have less and less contact with working-class and poor people, especially persons of color. Second, geographic segregation often produces serious spatial mismatches, where jobs and workers move in opposite directions; as more companies move to areas outside the central city, low-

wage workers have more difficulty finding jobs and then commuting to them, since they often cannot afford to work, live, and find child care in the same areas. Finally, residents in poor and working-class neighborhoods often pay more for basic goods and services, such as groceries (Dreier et al., pp. 41–77).

These costs are not only directed at the economically underprivileged, however. Instead, what is commonly referred to as “urban sprawl” (low-density development at the edges of an existing city) is the other side of concentrated poverty and has its own burdens: complete car dependency and longer commutes, shrinking green space and loss of farmland, increased pollution and flooding, and higher taxes to support new infrastructure (roads, schools, water and sewer, and power lines). Furthermore, these sprawling, redundant netherworlds between city and suburb defy Kevin Lynch's (1960) aesthetic prescriptions for memorable, livable cities: a legible city, he suggested, would be one whose physical features and landmarks are easily identifiable. As a result of sprawl, urban peripheries look more and more similar (freeways and off-ramps, chain stores and traffic), while also looking less and less like traditional urban centers.

Intensifying residential segregation finds its apotheosis in gated communities, which not only include elite suburban housing developments but also increasingly many inner-city, middle-income apartment buildings. While scholars stress numerous reasons for Americans' affinity for living behind walls (ranging from fear of falling property values to craving privacy, security, and/or like-minded neighbors), they generally agree that such arrangements inhibit, rather than promote, democracy. In gated communities, typically public spaces such as streets, sidewalks, and green spaces are walled off and “forted up” (in Blakely and Snyder's evocative phrase), privatizing not only individual residences but community space as well. Gated communities also are often racially homogenous. According to the U.S. Census Bureau's 2001 American housing survey, while the white and Hispanic middle classes are embracing gated communities in greater numbers, African Americans are much less likely to live in such areas. Although gated communities take a variety of forms and serve myriad functions (from retirement communities to inner-city security zones), spaces that promote homogeneity and exclusivity can only have a chilling effect on democracy. Their net result, then, is division rather than diversification, thus “undermin[ing] the very concept of civitas, organized community life” (Blakely and Snyder in Ellin, ed., p. 85). Residential segregation—especially as exemplified in gated communities—thus undermines the city's potential to foster tolerance of and political alliances across class and racial differences.

In part gated communities are symptomatic of the second challenge to urban democracy: the rapid privatization of public space. In *City of Quartz*, Mike Davis observes that “the American city . . . is being systematically turned inside out—or, rather, outside in. The valorized spaces of the new megastructures and super-malls are concentrated in the center, street frontage is denuded, public activity is sorted into strictly functional compartments, and circulation is internalized in corridors under the gaze of private police” (p. 226). Boundaries between public and private spaces are consciously constructed through the use of walls, landscapes, and police or

private security guards, but they are also marked through less tangible (though no less real) obstructions: commodities some cannot purchase, real estate that some cannot afford, a history and traditions that are not commonly shared. Davis argues that while architectural critics (often members of the dominant racial group and economic class) are often oblivious to these sorts of spatial segregation, marginalized groups recognize these borders immediately (p. 226).

This is all to say that urban space is no longer exemplified by truly public places. Instead, urban space at the millennium is increasingly contained, sanitized, monitored and defended; its goal is not to promote democracy (as in the Athenian polis) but rather to provide safe spaces for (predominantly white) middle-class suburbanites to work, shop, and play (Davis, p. 227).

Whither the City Center?

Many predictions for the future of urban democracy are dire. As Elizabeth Wilson plainly states, “The result is that today in many cities we have the worst of all worlds: danger without pleasure, safety without stimulation, consumerism without choice, monumentality without diversity. At the same time, larger and larger numbers of people inhabit zones that are no longer really either town or countryside” (p. 9).

These indeterminate zones that are not “town or countryside” indicate a final challenge for the city as political center: a new kind of urbanism typified by exurbs or edge cities that are no longer economically dependent on an urban center and defy the “core-periphery” model of the twentieth-century city. In fact, some would argue, casting the “city as political center” at the new millennium is entirely misguided. Rather, as Robert Fishman contends, “the true centre of this new city is not in some downtown business district but in each residential unit. From that central starting point, the members of the household create their own city from the multitude of destinations that are within suitable driving distance” (p. 185).

The “city” as it exists for most people, then, no longer matches the traditional picture of centrally concentrated economic and cultural life but rather comprises travel routes and endpoints, transportation and communications networks that together form weblike metropolitan regions that often include more than one urban center and frequently span several states. Edge cities and exurbs, some commentators assert, are almost entirely disconnected from their nearest urban centers, containing within themselves all the necessities of life: opportunities not only to live (as in traditional suburbs) but also for commerce and leisure, functions previously delegated to cities. Faced with the dilution of urban public life, the “city on a hill” is replaced by the “dream home” as the site of utopian possibilities.

The diminishment of the city as political center raises the question of whether or not the city has declined in importance as an economic center. Some theorists of the global city argue that industrial restructuring and the development of sophisticated communications networks have rendered city space less crucial than what Manuel Castells calls “the space of flows,” or the continual movement of people, goods, technology, and information over large distances, and the material infrastructure

that makes this movement possible. For Castells, what is important is no longer centers but networks, which allows real-time interaction between dispersed actors. Others, most notably Saskia Sassen, contend that the past few decades have seen the emergence of truly global cities, which provide an immense telecommunications, design, and service infrastructure for transnational corporations. This has created an unprecedented concentration of wealth and labor power in these cities while at the same time forging even greater disparities of wealth.

Throughout history people have staked claims to better lives in better cities, knowing that this particular spatial form of organization carries with it the potential both for hegemony and equality, disenfranchisement and deliberation. The question for advocates of urban democracy is how to correct some of the egregious inequalities rendered by twenty-first-century urban planning practices and globalization and how to best modify governance systems to take into account the changing shape of metropolitan democracy. The shapes presently given to cities and towns, the lines drawn with concrete and steel or building codes and zoning ordinances—or the connections forged with digital communications networks—enable citizens to make material their ideas about assimilation, stratification, and segregation. Uncritically adopting the city as a normative ideal, however, ignores the ways in which the built environment can legitimate and perpetuate exclusion, inequality, and even disenfranchisement from the ranks of proper citizenship.

THE ISLAMIC AND BYZANTINE CITY

Islam first developed and spread in a region of the world where urban civilizations had originated. Caravan routes crisscrossed the Fertile Crescent and the Arabian peninsula several millennia prior to the birth of Christianity, linking the urban-centered civilizations of Mesopotamia, the Nile Valley, and the Indian subcontinent. Overland routes were supplemented by water transit via the Red Sea and the Persian (Arab) Gulf, with transshipping ports in what is now Yemen. Arabia was then more fertile than it is in the early 2000s, and its products (including frankincense and myrrh) were in much demand.

The lands through which the desert caravans passed were divided into the territories of seminomadic tribes that controlled and protected passage. The islands in the narrow gulfs harbored “pirates” who could block passage, pillage, and even sink sailing dhows. If there was not to be a war of all against

all, the neighboring communities, whether urban, transhumant, or nomadic, had to develop rules of trust, hospitality, and fair exchange of goods. And there needed to be centers of safety in which members of diverse tribes and communities could mingle without fear.

Mecca: A Place of Safety

Long before the message of Muhammad initiated the religion of Islam, the thriving city of Mecca was just such a place of safety. It was considered “sacred;” its Ka’ba (an enormous, cubicle black stone) was endowed with holy significance (Esin). In much the same way that the polytheism of Greek mythology derived from the unification of various city-states, each with its own deity, so the Ka’ba was host to the gods of various tribes and peoples who, at least there, could coexist. In this context, “sacred” meant safe. As early as the first millennium B.C.E., Mecca had been established as a place of pilgrimage, where traders could meet without fear. Greco-Roman influences and the monotheistic cults of Judaism and, later, Christianity, were already present in Mecca when Muhammad was born in Arabia in about 570 C.E. He eventually settled in Mecca where he lived with his first wife, Khadijah, serving as commercial agent for her long-distance caravan trade. When he was about forty years old, revelations began to appear to him, in which the text of the Koran was revealed in a series of retreats.

Thus began the formulation of a new monotheism called Islam, considered seditious by the residents of Mecca. In 622, when Muhammad was fifty-three and in declining health, he

was forced to escape with his followers to the city of Yathrib (later renamed Al-Medina, meaning “The City”) and gained the support of the local tribe there and his first converts to the new religion. The date of the Hegira (flight to Yathrib) is accepted as the founding date of Islam and the first year in the Muslim calendar. The first mosque, a simple unroofed walled square with the prayer direction oriented toward the Ka’ba in Mecca, was built in the desert outside Medina, to which followers were summoned to gather five times per day by a call to communal prayer. Resisting recurring attacks from Meccans, Muhammad finally returned to Mecca in 630 at the head of a powerful army of his followers, accepted the keys to the Ka’ba, destroyed the idols and other signs of polytheism, and dedicated the structure (and the city) to the worship of one God and as the destination of prayer and pilgrimage. Two years later the Messenger of God was dead.

The Rapid Spread of the New Religion

Within one century of the death of the Prophet, Islam had spread to a vast area that included, in addition to the Arabian peninsula, Sassanid Persia as far north as the Caucasus and including Mesopotamia, the Fertile Crescent, and a thin coastal layer along North Africa that stretched from northern Egypt up the Nile to Cairo and had reached the westernmost tip of Morocco. The Byzantine Empire, defenders of Orthodox Christianity, controlled much of the northern edge of the Mediterranean, from its base in Anatolia and its capital, the New Rome, in Constantinople. While it is impossible to estimate what proportion of the populations in these two juxtaposed “empires” actually lived in urban centers (and that would depend upon the demographic definition of a city one accepted), it must be acknowledged that, for its time, the region was, along with the Indian subcontinent and China, certainly one of the most “urbanized” in the world.

Over the ensuing centuries, the Arab Conquest increased the levels of urbanization in three ways: by establishing temporary encampments for its troops and their accompanying dependents, by founding new “princely” cities for the successive ruling dynasties that came to power in various subregions of western Islam, and by occupying preexisting cities that would grow larger under conditions of increased prosperity.

The New Garrison Towns

The early days of expansion saw the founding of armed camps, often outside existing settlements, where troops were quartered, mosques were constructed, captive populations administered, and conversions encouraged. Basra and Kufa were the first “garrison towns” (*amsar*) set up by the Arab conquerors in the Persian-ruled region of lower Mesopotamia. *Fustat*, which means “tent city,” was an army camp set up beyond the limits of an existing Greco-Roman bishopric seat of Babylon, near present-day Cairo, by the Arab general who in 640 C.E. conquered Egypt. Another variety was the *ribat* or fort. Rabat in Morocco began as just such a walled fortress in which the ruler and his troops were quartered. “The term *Amsar* . . . as later used . . . to designate those *fustats* and *ribats* that were selected as centers to manage the conquered territories and as bases from which further military campaigns could be launched” (Al-

Sayyad, p. 45). Their regular gridiron arrangements revealed their military origins, just as the bastide towns in Gaul revealed their origins in the Roman conquests. Gradually, as the lines between conquerors and converts grew more permeable, these army camps blended with existing settlements and were transformed into cities endowed with schools and mosques, palaces, and offices of the rulers, and took on unified commercial functions.

New Princely Capitals for Dynasties

Although fewer in number and developed later, these served significant symbolic purposes, since the “royal cities” established in the emerging Islamic world were often accompanied by regime changes: the movement of the caliphate or shifts between Sunni and Shiite sects. Two notable examples were the planned princely cities of Baghdad (properly *Madinat al-Salam*, the “City of Peace,” or *Madinat al-Mansur*, the “City of the [Caliph] Mansur”) founded during the second half of the eighth century by the Abbasids who displaced the Umayyad caliphate, formerly located in Damascus, and Cairo (*Al-Qahirah*, “the Victorious”), founded in 969 by the Fatimids, a Shiite dynasty coming from Tunisia that displaced the former Sunni rulers. Both were new cities, located on level and well-irrigated land some distance from existing settlements; they were carefully designed as walled protected enclaves for new rulers. But they differed radically in terms of conceptions and plans.

The royal city of Baghdad was a circular city on the opposite bank of the Tigris from the village of Baghdad, intended to house the newly victorious Abbasid caliphate. Surrounded by a pair of formidable walls and a moat, with entry restricted to four gateways and commoners forbidden admittance, the round city held at its center the palace of the caliph with its attached cathedral mosque. Around this most protected focus were the palaces for the princes and their armed defenders. Inside the peripheral walls were arranged governmental offices to administer the empire. Gradually, population gathered on the outskirts of this city, of which only archaeological traces remain. Within a short time Baghdad had grown into a large capital in which Islamic learning and scientific and intellectual development reached a medieval peak—at least until it was sacked by the Mongols in 1258.

Cairo, in contrast, would eventually grow from imperial enclave into the greatest capital in the Islamic world until Ottoman times, filled with architectural and artistic treasures, many of which are preserved to this day. Laid out in the form of a walled rectangle with a regular street pattern of two major streets intersecting at right angles and leading to four impressive gateways, it contained the palaces of Mu’izz al-Din, the newly installed Fatimid caliph, the major mosque, and quarters assigned to various ethnic groups that made up his army. The ordinary citizens of Fustat, by then grown into a prosperous commercial city to its south, were at first enjoined from entering. Only after Fustat was burned (in 1169) to protect the princely city from invading Crusaders, were the gates to Al-Qahirah opened to the “masses.” But this marked the rise of Salah al-Din Yusuf al-Ayyub (Saladin; 1137/8–1193),

the demise of the Fatimids, and the establishment of the Ayyubid dynasty. Thereafter, the history of the city's development approximated that of the third category.

Conversions of Existing Cities into Cities of the Dar al-Islam

Constantinople, the Christian capital of Byzantium until its conquest by Muslim forces in 1453 (officially renamed Istanbul in 1930), and the Roman-patterned cities of Aleppo and Damascus in Syria and of Tunis in North Africa, are noteworthy examples of existing cities whose plans were transformed by Islamic occupation. These walled cities had inherited from the pre-Islamic period regular streets and processions, churches, covered markets, and a clear division, according to principles of Roman property law, between public (both secular and religious) and private space. Over time, the major changes were to create, from those regular divisions, the narrow labyrinthian paths and dead-ends that are associated with the Islamic city.

Sauvaget, in his pathbreaking studies of the transformation of Damascus (1934) and Aleppo (1941), traced these changes, attributing them to the substitution of Islamic law for Roman law, a theory more fully explicated by Hakim (1986), who examined Islamic legal precedents as they developed primarily in the Maghreb (western North Africa). In Islamic property law, responsibilities to one's neighbors, including the protection of their visual privacy, took precedence over a priori protection of the public way. As a result, buildings began to infringe on the streets, unless neighbors objected in the courts, and the residential neighborhoods became honeycombed into cells of semipublic space. Given the greater segregation between male and female space in Islamic codes of modesty, markets and residential zones became more spatially differentiated, with markets, courts, mosques, and industrial districts more specialized. These changes, which occurred over time in both preexisting "Christian" cities and in formally planned army camps and princely towns, gave rise to many of the characteristics now associated with the Islamic city.

Relation of Islam to the Idea of the City

This brief history is sufficient to establish several principles of Islamic expansion and its urban and social roots.

1. First, cities and commerce were central to the new religion, and many of the developments in Islamic law and jurisprudence dealt with densely settled urban places.
2. Islam was initially tolerant of other religions but welcoming to converts, extending to them equality in the *umma* (community of believers).
3. Property laws differed substantially from Roman law.
4. The religion stressed rules to police business practices and ensure trust and credit in trade.
5. Laws reformed social relations, regularizing and liberalizing relations between masters and slaves,

husbands and wives, albeit while increasing gender separation.

6. Religious duties were incumbent on all members of the community of believers, including declaring belief in one God (Allah), accepting the prophetic message of Muhammad, praying five times daily, tithing to charity and sharing wealth with the poor, observing the dawn to dusk fast during the month of Ramadan, and make the pilgrimage to Mecca.

Common Consequences of these Distinguishing Features

The *amsar*, the *ribats*, the converted Greco-Roman settlements, and the new princely capitals, while differing in origins and original plans, eventually evolved into communities that had much in common. Most were walled. The center of the city usually contained the main mosque, next to which were linear market streets specializing in books, candles, and other religious items. Nearby were the hostels for long-distance merchants and high value, low bulk items such as gold, other precious metals and minerals, and the officer whose duties included policing honest trade in the markets. Another main thoroughfare held the workshops of artisans and their shops, other mosques, hospitals, and schools, with the judicial courts and other government offices nearby. Outside or just inside the major gates to the walls were the markets for live animals and bulk agricultural products, on which taxes were imposed. But what was particularly noticeable in developed towns of Islam, attributable to Islamic property law, was the tendency of regular plans to be transformed into cellular structures of what might be called "defensible space." Religious charitable endowments (called *awaqf*, sing., *waqf*) and the largesse of rulers provided material support for many of the "public" functions, such as hospitals, schools, mosques, and water fountains, that Westerners associate with municipal government. Unlike the West, however, private users were held collectively responsible for cleaning, sprinkling, and lighting the streets in their own neighborhoods, as well as for protecting the safety of their residents. It was a workable system of governance so long as the empires remained prosperous but, as in all cities, in times of economic, political, and epidemic troubles, urban decay could set in.

The Consequences of Ottoman Rule and Subsequent Colonialism

The conquest by the Ottoman Turks of Constantinople in the mid-fifteenth century and the expansion of the Ottoman Empire to the Arab provinces in the Fertile Crescent and North Africa in the sixteenth century led to a period when the wealth of empire was concentrated in their capital Konstantiniyee (Constantinople), known by its popular Turkish name as Istanbul. Istanbul grew to become one of the largest cities in the world, whereas former major metropolitan centers such as Cairo were demoted to mere provincial capitals, losing population and economic vigor. Severely weakened, province after province fell victim to European colonial incursions in the course of the nineteenth century, and the remaining remnants

of the Ottoman Empire, with the exception of Anatolia, were lost to the victorious Allies after World War I.

While twentieth-century decolonization movements, with few exceptions, succeeded in liberating the countries of western Islam, the region was fragmented into many small states, in contrast to the unities in religion and law the region had enjoyed during the heights of earlier empires, and the poor economic conditions due to subservience to the industrialized West left a heritage of underdevelopment. Although urban populations increased, from both higher rates of natural increase and immigration from the countryside (Istanbul in the early 2000s has a population of eleven million and the greater Cairo region houses perhaps sixteen million), economic development lagged behind, creating conditions typical in Third World cities. In most countries, although Islam remains the official religion, governing laws mostly derive from the Napoleonic Code. Many of the older forms of urban property law, charity, and personal behavior no longer sustain vital urban functions.

LATIN AMERICA

The history of the city in Latin America stretches over three thousand years and a vast geographic area. The cities vary considerably over space and time. Prior to the coming of the Spaniards, many pre-Columbian cities are thought to have been cosmograms or cosmologically conceived—the cities' buildings and plans emulated the cosmos as their leaders conceived of it. After the conquest, the Spanish Crown sought to impose order on the new lands in its possession and based planning on a grid that had a centrally located church fronting on a plaza. The checkerboard grid plan persisted throughout

the colonial period. After independence from Spain, Latin-American countries sought out new forms of city planning in Europe, especially France, that would make visible their status as newly formed republics.

Ancient Indigenous America: Mesoamerican and Andean Civilization

Ancient indigenous cities in the Western Hemisphere were prominent, complex centers of economic, cultural, political, and religious power and authority. As administrative centers, cities functioned variously as city-states, centers of regional states, and centers of empire. Political life and religious life were intertwined and overseen by divine and semidivine rulers or the ruling elite. At the heart of most cities were palaces, monumental civic-religious structures, and the ceremonial plazas where public rituals took place. Cities were also frequently cosmopolitan, with enclaves of resident foreigners who are identified as such by cultural practices and material goods consistent with their culture of origin.

The city as cosmogram. City plans are many and varied; in some regions, such as the central Mexican urban center at Teotihuacan, planners imposed a consistent grid plan on every structure, from central temples and palaces to small outlying barrios. In contrast, the Chimú capital of Chan Chan in Peru was comprised of large walled palatial compounds that loosely shared the same orientation. Elsewhere, notably in the clusters of buildings and temples organized around plazas among the Maya and the capital city of Cuzco (Peru), site plans are irregular in shape, their form dictated by the local topography and inherent processes of agglutination, yet still organized according to an internal logic, albeit a more organic one. The organizing plan of Cuzco has been the subject of lively debate, with some scholars suggesting that it represents a puma, while others note its grid plan tempered by topographic irregularities. Of particular interest are the forty-two sacred *ceque* (pathways) radiating from a central node outward, linking the sacred city to all corners of the Inka empire.

Regardless of these differences, common shared features among these pre-Columbian centers include the cosmological alignment of major buildings and of the city itself with the passage of the Sun, the movement of significant planets and stars, and the cardinal directions; the alignment of buildings with significant features of the surrounding topography such as sacred places, caves, and mountains; built statements of politico-religious power and authority such as large pyramids and walled precincts; as well as the pragmatic concerns of dense, urban life (workshops, urban housing of workers, water, food, and disposal of waste, for example). The indigenous city harmonized with its environment even as it shaped that environment and gave focus and significance to elements of the environment that were held to be important. Natural features of the landscape, such as the rivers at Teotihuacan and Cuzco, were even made to conform to the planning principles employed. As symbolic texts, indigenous cities gave visible form to collective belief and shared identity. Through the powerful intersection of cosmological time and space, the city functioned as both axis mundi and cosmogram.

Colonial Spanish America

From its inception, Spanish urban planning in the Western hemisphere was based on the grid plan, with its characteristic large central plaza dominated by a church. The earliest royal instructions (1513) and government decrees indicated that a geometric grid was to be used, but not until 1573 did King Philip II's ordinances explicitly direct that the grid be used in city planning, thereby codifying practices long in effect. Scholars have cited gridded prototypes ranging from indigenous city planning; the Roman *castrum*; the French *bastide*; the ideal city of the Renaissance architectural theorist, Leon Battista Alberti; Santa Fe (1491), the military encampment of Ferdinand and Isabella at the siege of Granada; and the apocalyptic New Jerusalem in the Book of Revelation. It is probable that some or all of these multiple indigenous and European urban sources were precursors to the colonial Spanish-American urban grid and converged to serve complementary economic, social, political, and religious goals.

The ordered city. In Mexico, the typical grid plan came into being in urban developments in the 1520s and 1530s as new towns were built and the destroyed Aztec capital Tenochtitlan, an indigenous gridded city, was rebuilt as the administrative capital of New Spain. These geometrically ordered, regularized towns met the needs of the army, church, and state bureaucracy as they provided a framework for administrative efficiency, political control, and Christian indoctrination. The urban landscape was radically altered as the multiple cultural expressions of prequest cities were supplanted by the uniformity of the grid extended across space and time in what had become Spanish America. The grid physically and symbolically established and confirmed the desired social order and clearly marked both the land and its people as being under the well-ordered, administrative, and Christian control of the Spanish.

Republican and Contemporary Latin America

Latin-American countries, with the exception of Cuba and Puerto Rico, won their political independence from Spain and Portugal between 1808 and 1826. As newly independent countries, they sought to express national identity, progress, and modernity and take their place among the metropolises of the Western world. To do so and to refashion its capital cities, Latin America looked to Paris, which was itself undergoing modern transformation under the direction of Georges-Eugène Haussmann. France's economic connections to Latin America and its position as a champion of independence and republicanism and a center of the arts and urbanity made it a natural model for the new Latin-American republics. Large public parks and grand, tree-lined, diagonal boulevards (such as the Paseo de la Reforma in Mexico City) followed the Haussmann model and reshaped Latin-American cities, freeing them from the colonial grid.

From metropolis to megalopolis. In the second half of the nineteenth century and the beginning of the twentieth, many urban populations grew exponentially as foreign investments and overseas immigrants poured into Latin America. Capitals were enlarged to accommodate their growing populations, and the ideas of the early-twentieth-century Swiss architect and planner, Charles-Édouard Jeanneret, known as Le Corbusier, and his followers in the Congrès International d'Architecture Mod-

erne (CIAM) became influential. Le Corbusier's ideas focused on high-rise buildings to increase living density and relieve overcrowding, new highways to relieve traffic congestion, and urban space zoned according to function; in short, an attempt to bring order and efficiency to cities that had grown rapidly. Although Brasília, the new, disembedded capital city of Brazil planned by Lúcio Costa and inaugurated in 1960, incorporated some of Le Corbusier's ideas, his urban plans and those of his followers were rarely implemented. Le Corbusier's legacy is more clearly to be seen in high-rise buildings of cement, glass, and steel and in the peripheral highways encircling many of Latin America's major cities.

CIVIL DISOBEDIENCE. Civil disobedience is an illegal act performed publicly in contravention of a law or laws of the government for the short-term purpose of bringing about a change in the law or laws and for the long-term purpose of improving society as a whole. It is a political act because its underlying principles are the principles of political justice that regulate the state and its institutions, and not those of private conduct. The act is called "civil" because it is courteous in the manner of its performance, not criminal in its methods or revolutionary in its effects. It presupposes the legitimacy of the state and the constitutional order, and its aim is the preservation of an improved state, not its overthrow.

Civil disobedience may be carried out by individuals or by masses of people. Its acts may be symbolic, as in the case of fasts, vigils, the burning of official documents, and so forth, or they may be substantial, as in the case of boycotts, strikes, marches, mass meetings, withdrawal of cooperation with the government and its institutions, sit-ins, occupation of public buildings, and the like.

In the late twentieth century, the idea of civil disobedience acquired a legal standing in international jurisprudence thanks

especially to the Nuremberg trials. The latter established the legal norm according to which individuals may be held responsible for not disobeying domestic laws that grossly violate fundamental human rights.

The History of the Concept

The concept of civil disobedience has evolved over a long period of time. Ideas drawn from different periods of history and from different cultures have contributed to its evolution. The idea that there is a law that transcends the laws of the state is found in Socrates (c. 470–399 B.C.E.), in some of the classical Greek tragedies, and in the Indian concept of dharma (duty). In these traditions, should the higher law and the laws of the state come into conflict, the individual had the obligation to disobey the laws of the state. In the Middle Ages, St. Thomas Aquinas (1225–1274) defended the natural-law view that unjust laws did not bind the citizen in conscience. John Locke (1632–1704) taught that the government derived its authority from the people, that one of the purposes of the government was the protection of the natural rights of the people, and that the people had the right to alter the government should it fail to discharge its fundamental duties.

Thoreau. The writer who made the theory famous, put it into practice, and gave the practice the name “civil disobedience” was Henry David Thoreau (1817–1862). His ideas on the subject are found in the celebrated lecture that he delivered in 1848 to the Concord Lyceum in Massachusetts, under the title “On the Relation of the Individual to the State.” It was first published in printed form in 1849 under a different title, “Resistance to Civil Government,” in *Aesthetic Papers*, a volume edited by Elizabeth Peabody. It first appeared under the title “Civil Disobedience” only in 1866, four years after Thoreau’s death, in a volume of his writings entitled *A Yankee in Canada with Anti-Slavery and Reform Papers*.

Two principles underlie Thoreau’s conception of civil disobedience. The first is that the authority of the government depends on the consent of the governed. The second is that justice is superior to the laws enacted by the government, and the individual has the right to judge whether a given law reflects or flouts justice. In the latter case the individual has the duty to disobey the law and accept the consequences of the disobedience nonviolently. In Thoreau’s case, he judged that the laws upholding slavery and supporting the Mexican War (1846–1848) were unjust. He chose to spend a night in jail rather than submit to the unjust laws.

Gandhi. Mahatma Gandhi (1869–1948) broadened the scope of civil disobedience and internationalized its practice. Gandhian civil disobedience originated in 1906, in South Africa, as part of his campaign for the defense of the civil rights of the disenfranchised Indian immigrants. On his return to India in 1915, he made civil disobedience the primary moral force behind his leadership of the Indian nationalist movement.

His idea of civil disobedience drew from a wide variety of intellectual sources. Plato’s *Apology of Socrates* was one of them. In 1908 he published a paraphrase of it under the title *The Story of a Soldier of Truth*. The Sermon on the Mount had a

profound influence on him, especially as interpreted by Leo Tolstoy in his *The Kingdom of God Is within You* (1893). Patanjali’s *Yogasutra* and the *Bhagavad Gita* also guided the development of his thoughts on nonviolence as it applied to civil disobedience.

When in 1906 he started the civil rights campaign in South Africa, Gandhi did not know what term to use to describe it. (He read Thoreau only in 1907). Some called the new campaign passive resistance, in comparison with the British Passive Resistance Movement against the Education Act of 1902. But he was unhappy with the comparison for two reasons. The first was that British passive resistance did not forbid violence as a means of achieving its goal; the second was that it did not require that its practitioners be free from hatred of their political opponents.

Gandhi called his practice “satyagraha,” a Gujarati word meaning “firmness in adhering to truth.” Satyagraha, free of the defects of passive resistance, introduced six elements into the theory and practice of civil disobedience:

- First, its moral basis was grounded in truth, a basis much deeper than that provided by the theory of consent. To be binding, laws had to be truthful. All untruthful laws had to be resisted, though civilly—that is, by truthful means.
- Second, civil disobedience presupposed the obligation to obey the state: only those had the right to practice civil disobedience who knew “how to offer voluntary and deliberate obedience” to the laws of the state.
- Third, commitment to nonviolence was an essential component of civil disobedience. The commitment in question could be either moral or tactical, depending on the moral aptitude of the practitioner.
- Fourth, the practice of civil disobedience required a minimum degree of moral fitness, to be acquired by the exercise of such virtues as truthfulness, nonviolence, temperance, courage, fearlessness, and freedom from greed.
- Fifth, a practitioner of civil disobedience had to accept the punishment consequent to the disobedience voluntarily, and without complaint.
- Finally, engagement in civil disobedience had to be complemented by engagement in organized social work.

For Gandhi, it was not enough to seek to improve the state; it was equally necessary to seek to improve civil society. To assist Indians to combine civil disobedience with voluntary social work, he wrote *Constructive Programme* (1941, revised in 1945). It identified the major social evils prevalent in Indian society, such as religious intolerance, caste violence, and discrimination against the untouchables, minorities, and women. The removal of these social evils by voluntary work was as important as the removal of unjust laws by civil disobedience. According to

Gandhi, “civil disobedience without the constructive program will be like a paralyzed hand attempting to lift a spoon.”

Martin Luther King Jr. The third major figure who contributed greatly to the development of the practice of civil disobedience was Martin Luther King Jr. (1929–1968). He made civil disobedience the distinguishing feature of the civil rights movement in the United States. In this he was deeply influenced by Gandhi’s methods. But he was also influenced by Christian humanism, as is evident in his “Letter from Birmingham Jail” (1963). The letter has been called the most widely read and discussed manifesto on civil disobedience since Thoreau’s essay. Addressed to his fellow African-American clergymen, it explained why immediate, direct, nonviolent action was a duty incumbent upon every American who wished to rid the nation of segregationist laws. Here King faced a dilemma. On the one hand, the law had by 1954 declared segregation to be unconstitutional, yet on the other it also tolerated segregationist practices in certain states. How then could one advocate breaking some laws while obeying others?

One could do both, he contended, because one had the right to judge each law on its own merit. And the criterion he recommended for making such judgement was drawn from Christian humanism. According to St. Augustine of Hippo (354–430), an unjust law was no law at all. And according to Aquinas, an unjust law was a human law that was not rooted in eternal and natural law. Just laws uplifted human beings, while unjust ones degraded them. The segregationist laws were unjust and dehumanizing and therefore had to be disobeyed. King contributed greatly to making civil disobedience a respected tradition of American politics. In this he marks an advance on Thoreau, who seemed to appeal, hitherto, mostly to New England intellectuals. King actualized the potential that was in Thoreau.

In the late twentieth century, civil disobedience became a tactic adopted by various protest movements worldwide. The anti-nuclear weapons movement, the green movement, and the movement against globalization have adopted it with varying degrees of enthusiasm.

Philosophic Status Today

Thoreau, Gandhi, and King were primarily practitioners rather than philosophers of civil disobedience. Even though a philosophy did underlie their practice, they themselves did not elaborate it in any systematic fashion. From the last quarter of the twentieth century onward, however, philosophers and political theorists have taken a keen interest in the philosophic aspects of civil disobedience. The most significant of these philosophers is John Rawls (1921–2002). His *Theory of Justice* (1971) integrates civil disobedience into the liberal-contractarian philosophy of justice. It grounds civil disobedience in the two principles of Rawlsian justice—namely, those of equal basic liberty of the citizens and equality of opportunity. However, a society built on these principles is not a “perfectly just society,” but only “a nearly just society.” Though it is a well-ordered society, “serious violations” of justice can and do occur in it. This imperfect character of the justice of the liberal society places the citizen in a moral quandary. There is on the one

hand the obligation to obey laws enacted under an agreed upon constitution, yet on the other there is the duty to oppose the injustices of particular laws and the right to defend the basic liberty of citizens. That is to say, the obligation to obey in a liberal society is relative, not absolute—relative to the prior right to defend one’s basic liberty and the duty to oppose injustice.

It is here that civil disobedience comes to the rescue of the embattled citizen. It permits the citizen to disobey an unjust law, but only within the bounds of fidelity to the constitutional order. In this way civil disobedience helps test the moral basis of liberal democracy. It also points to the limits of the majority principle. If the majority fails to respect the basic liberty of citizens and equality of opportunity, the grieved citizen or citizens have the right to disobey the law, irrespective of the position of the majority.

However, for Rawls, civil disobedience may not be violent in its methods; it has to be nonviolent for two reasons. First, in a liberal democratic society civil disobedience is a mode of appealing to the latent sense of fundamental justice that the majority is presumed to possess. This appeal can succeed only if the means of civil disobedience remains nonviolent. The civilly disobedient may warn and admonish, but not threaten. Second, nonviolence is a method of expressing disobedience within the limits of fidelity to the constitutional order, and of accepting voluntarily the legal consequences of disobedience. Thus, though contrary to a given law, civil disobedience is a morally correct way of maintaining the constitutional order in an admittedly imperfect society. It becomes part of free government. It gives stability to the constitutional order and helps actualize the capacity for self-correction.

Rawls’s theory has the merit of explaining why civil disobedience works only in certain societies and not in others. It works in societies whose contending members can agree on what constitutes justice. Because of this they are able to compose their differences. Civil disobedience tests the solidity of this consensus. In societies whose contending members cannot agree on what constitutes justice, there is no room for civil disobedience, but only for civil war or something close to it. Thus, Rawls’s theory can also explain why civil disobedience succeeded the way it did in unjust colonial societies such as South Africa and India. It succeeded because, paradoxically, the higher colonial administration and the civilly disobedient citizens were able to agree on the basic principles of liberal justice.

There is one major difference, however, between Rawls’s theory and that of Gandhi and King. Rawls grounds his theory in the principles of liberty and equality, without asking whether they need grounding in some other principle. Gandhi and King ground their conceptions of liberty and equality in the higher principle of the spiritual personality of human beings—atman (the spiritual self) in the case of Gandhi and the immortal soul in that of King. It is because humans have a spiritual personality that they ought to be free and equal in society. Their theory of disobedience has deeper roots than does Rawls’s. The latter operates within the limits of European Enlightenment, whereas the other two operate within a broader framework.

Disputed Questions

Although the theory of civil disobedience has achieved philosophic maturity, there are two questions that still remain unresolved. One has to do with the place of violence in civil disobedience. Theorists such as Christian Bay do not rule out the use of limited physical violence. The problem here is where to draw the line between limited physical violence and revolutionary violence. The other question has to do with the acceptance of punishment due to civil disobedience. Some, including Rawls, accept it for prudential reasons, while others such as Gandhi do so for moral reasons. Gandhi believes that the suffering of the innocent victim has a unique moral force, which civil disobedience should integrate into its moral theory.

EUROPE AND THE UNITED STATES

An ancient term of Western political and social theory, *civil society* has enjoyed enormous popularity in recent years and has outstripped its geographic origins to spread all over the world. Public leaders, newspaper writers, religious figures, social theorists, political activists, and commentators from many different perspectives now use the term on a regular basis. The term's meaning has shifted dramatically over the centuries, and different historical periods have understood it in distinct ways.

Three distinct usages can be delineated. *Civil society* first appears in classical Greek and Roman thought, which considered it to be synonymous with a politically organized commonwealth—a view that was modified by the medieval church's distaste for purely political categories and came to describe a society organized around the primacy of religion. As powerful markets and centralized states began to erode medieval institutions, a second, and characteristically modern, liberal understanding arose that conceived of civil society as the arena of economic relations and institutions. Frightened by the consequences of the French Revolution and the advent of mass political activity, a third conception developed during the middle of the nineteenth century to describe civil society as a sphere of voluntary intermediate organizations that stand between the state and the citizen. Pioneered by Alexis de Tocqueville (1805–1859), this is the way *civil society* is understood in contemporary usage. Although chronologically distinct, each of these understandings contributes important insights to political and social life and sheds light on contemporary issues of democracy and equality.

Political and Religious Commonwealths

When Cicero (106–43 B.C.E.) equated civil society with a politically constituted commonwealth, he expressed a powerful tendency to understand "civility" as the requirements of citizenship. His effort represented the most complete development of classical thinking about civil society. Plato (c. 428–348 or 347 B.C.E.) had attempted to articulate an invariant ethical center for public life, an effort that Aristotle (c. 384–322 B.C.E.) tried to correct by recognizing that people live their lives in different spheres and in multiple associations. Aristotle's respect for variation and distinction underlay a political theory that understood civil society as a moral-political association that improved the life of its citizens, but the Roman recognition of a legally protected private realm made it possible to equate civil society with republican virtues and political life. Imperial collapse led to St. Augustine of Hippo's (354–430 C.E.) devastating attack on the classical tradition's effort to organize a self-reliant public sphere, but Christian insistence that civil society could be understood only in terms of the requirements of faith and church made it difficult to organize human affairs with such depraved material as fallen man. St. Thomas Aquinas (c. 1224–1274) was more willing than Augustine to recognize that politics could sustain a measure of moral action and constitute civil society, but the corrosive effects of markets and the pressure of centralizing kings brought the first period of theorizing to a halt.

Markets, Individuals, and Interests

Niccolò Machiavelli's (1469–1527) rediscovery of classical republicanism and Thomas Hobbes's (1588–1679) insistence that only a single point of sovereign power could protect the calculating individual and his interests pointed the way toward a fully modern conception of civil society. It was not long before those interests became expressed as property, production, and acquisition. John Locke's (1632–1704) civil society was made possible by the sovereign power of states, but it was really the pursuit of private interest that made political liberty

worthwhile. Locke's clear preference for economic activity anchored many later conceptions, and Adam Smith (1723–1790) articulated the first fully bourgeois theory of civil society as a sphere of production and competition that was driven by the self-interested calculations of isolated individuals. The state played an organizing and protecting role, but Smith's conviction that economic processes could organize social life expressed liberalism's suspicion of centralized political power and its assumption that civil society is constituted by the market. Jean-Jacques Rousseau (1712–1778), Immanuel Kant (1724–1804), and Georg Wilhelm Friedrich Hegel (1770–1831) would try to infuse civil society—now equated with “civilization”—with solidarity and moral purpose, but it was plain that this tradition of thought understood civil society as a law-governed sphere where property, civil liberties, and political equality would enable self-serving individuals to make private decisions in conditions of freedom and security. If the classical view of civil society had been shaped by the ancient traditions of civil republicanism and came to an end with the fall of the Roman Empire, the second view was clearly related to the early framework of capitalism. Karl Marx's (1818–1883) desire to overcome civil society's foundation in the class relations of bourgeois society looked to a socialist state to democratize civil society itself and seemed to recapture a moment of the classical heritage. It also shed light on an important weakness in liberal theory by calling for democratic supervision of civil society's chaos and instability.

Intermediate Associations and the State

Drawing on Aristotle, Cicero, and Machiavelli for the theory of the mixed constitution, Baron de Montesquieu (1689–1755) located intermediate bodies at the heart of his aristocratic theory of civil society. His fear of royal power fed Edmund Burke's (1729–1797) defense of local privilege against the leveling and centralizing French Revolution, but it was Tocqueville's claim that voluntary activity connected individualistic, self-serving Americans to the common good that proved particularly powerful. Tocqueville's insight has fed most of the contemporary interest in civil society, in large measure because of his desire to limit the thrust of the democratic state by preserving local freedom, protecting pockets of local privilege, and nurturing traditions of self-organization. His assumption of widespread equality of condition meant that he did not have to examine how inequality and voluntary activity might reinforce one another—a matter that has become vitally important, given contemporary economic and political trends. Nevertheless, powerful American traditions of suspicion of the state and a history of local volunteerism have all but guaranteed that Tocqueville finds a ready audience in this country—particularly in politically conservative periods.

Contemporary Issues

Interest in civil society was largely confined to academic circles until the early 1980s, when dissident Polish intellectuals and journalists began talking of “the rebellion of civil society against the state.” It wasn't long before an influential body of Eastern European thought began to understand civil society as constitutional republics and intermediate associations. As Soviet-style socialism continued to be hostile to almost all

spontaneous social initiatives, it made sense that dissidents would be interested in limiting state power and would be indifferent to the market's threat to freedom and equality. But their sunny optimism would soon fade away. As the East European civic forums, underground newspapers, student leagues, “flying universities,” and other groupings began to yield to the logic of economics and the imperatives of politics, it became practically and theoretically imperative to understand how civil society can serve democracy in conditions of powerful markets and bureaucratized states. Voluntary organizations and social movements have contributed to freedom and equality in important ways, but the naive assumption that they constitute a democratic sphere of action in their own right has begun to yield to more sober questions of how local voluntary activity can serve democracy in an environment that is constituted by widening inequality and dominated by large, powerful institutions. It is important to understand how the local and the small can serve freedom and democracy with, not against, the universal and the large. Further intellectual and practical activity will be compelled to investigate how inequality and bureaucracy affect the ability to organize on the one hand, and how local activity can mitigate the effects of inequality and hold political structures to account on the other.

RESPONSES IN AFRICA AND THE MIDDLE EAST

“All vogue words tend to share a similar fate,” observes Zygmunt Bauman. “The more experiences they pretend to make apparent, the more they themselves become opaque. The more numerous are the orthodox truths they elbow out and supplant, the faster they turn into no-questions-asked canons” (p. 1). Bauman's specific subject was globalization, but he may well have been alluding to civil society. Ever since it made a blazing entry into mainstream political theory in the mid 1980s, *civil society* has had a quite remarkable career as a buzzword, both in policy and scholarly circles. Rare is that academic without a perspective on civil society. For all this analytic intensity however, civil society continues to evade the critical gaze, and seemingly definitive statements about its meaning or origin have merely given rise to even knottier dilemmas.

Ironically, history has been of little help. In most cases, historical excursion has only complicated the riddle, for civil society has not one but many genealogies. Its complex story traces back to a tangle of understandings, and scholars generally tend to privilege whatever genealogy best suits their purposes.

Apparently, many of the hurdles encountered in grappling with the idea of civil society could be scaled easily. One is the problem of definition, which, Iris Marion Young contends, has persisted simply because many scholars stubbornly hanker after a one-sentence definition. The implicit suggestion here is that deeper understanding of civil society might be gained if the inquirer were to take for granted its conceptual diversity. This may not be the vehicle that transports one to definitional nirvana, but there is at least the precognition of the inherent plurality of the subject. A second problem is the popular conflation of civil society as an idea, an ideal, and a device for the attainment of a vaguely defined “good society.” Again, as Michael Edwards suggests, the problem comes not from this trifurcation, but rather from imagining that civil society cannot be all three at the same time.

Different Understandings

This definitional problem is not new, and one way of illustrating this is to briefly explore some of the several ways in which civil society has been historically understood. We deal with a dense and richly conflicted narrative, and the distinctions made here are, of necessity, a guide. The first understanding is that of civil society as the opposite of the state of nature. In this view, civil society points to a condition of refinement, a departure from a state in which humanity was slave to its instincts and passions, to one in which it is governed by reason and rationality. This is a mere prototype of course, as many who have sadly contemplated the horrors of the past century might readily attest, but it should help in underscoring the point that most times, civil society is merely that to which groups or peoples aspire. Even more important, implicit in this definition is an undeniable gender bias, especially given that women were often described as being closer to a state of nature than men. Therefore, civil society, at least within the framework of this understanding, is profoundly patriarchal. However, scholars like Adam Seligman have provided a more historically rooted picture. For him, the state of nature could be taken as the immediate post-Enlightenment seventeenth- and eighteenth-century Europe in which there was a clear need to tame the demon of unfeeling individuation, which had been an unexpected concomitant of the new era of rapid industrialization. According to this account, the accent on rationality as opposed to feelings that was the immediate by-product of the European Enlightenment, and the emergence of the market as the arena where the new individual could realize his newly found “freedom” had to be checked by something much larger than the private individual himself, hence “civil” society; a society, in Keith Tester’s words, of “less barbarous manners.” If nothing at all, it is this “civil” or “polite” society that defines and imposes the parameters of social conduct, “reestablishing some public (and perforce communal) space to mediate what are seen as the adverse effects of the ideology of individualism” (p. 28).

A second understanding is the envisioning of civil society as connoting the possession of certain values (privacy, individual-

ism, and the market, say) that are present in and actually define the West but are, alas, in short supply or completely absent from other societies. Scholars generally trace the intellectual pedigree of this controversial formulation to Adam Ferguson (1723–1816) and Georg Wilhelm Friedrich Hegel (1770–1831), but its most forceful affirmation could be seen in the writings of Ernest Gellner. According to this view, civil society is what his “Atlantic society” has that “others” do not; “others” here signifies either other cultures or sociopolitical systems, or a combination of both. Thus, civil society becomes, “like human rights, what authoritarian regimes lack by definition. It is what the Greeks, the Enlightenment and we today have; it is what despotic governments, whether in the past or the present, the here or the elsewhere, do not have” (Goody, p. 150).

Other conceptualizations certainly exist, and admittedly, it is well nigh impossible to scour the fastnesses of the history of political thought and philosophy for every analysis of the subject of civil society. One of the more influential formulations, in reality a conceptual first, has been the Hegelian delineation of civil society as that which is separate from the state. Drawing partly on the work of the Scottish chaplain Adam Ferguson, Hegel defines civil society as “the realm of difference, intermediate between the family and the state.” His conception of civil society makes clearer sense within the ambit of his rather abstruse philosophy of history, which, mindful of the risks inherent in simplification, can be articulated thus: History is the evolution of consciousness and the modern world is the highest demonstration of that evolution. For Hegel then, civil society is “the achievement of modernity,” one *moment* (the other two being the family and the state), in which the movement of the objective spirit (*Geist*) can be analyzed (Schechter, 2000). Even though in sharp contrast to Ferguson he insisted on the ontological integrity of the state as having a “concrete existence” (Schechter, p. 38) of its own, Hegel shared Ferguson’s derision for the state-of-nature construct. His case for its rejection is based on his appreciation of historical developments, particularly in the economic sphere. While the dichotomy that the state of nature/state of civilization presumed might have possibly made some sense at a historical moment, Hegel believed that profound changes in the economic realm had made this binary otiose, or useless. The indelible consequences of this economic revolution, he thought, were to be seen in the specific transformation of what was regarded as the private sphere. More specifically, the expansion of the economy, Hegel argued, had incorporated and dominated civil society, leaving the state to emerge more clearly as a “separate political sphere.” The family, for its own part, is relegated to what is left of the by now “emaciated” public sphere.

Skeptics usually seize on this extensive mesh of meanings and nuances to assert that civil society is nothing more than a “plastic concept,” one whose shelf life will come to an abrupt halt sooner rather than later. Optimists disagree. Indeed, they argue that the hermeneutic elasticity of civil society is good both for the subject and for the various political projects in whose cause it is usually invoked. Mary Kaldor, for example, thinks that the changing meaning arises from several factors: “the changing content and coverage of the term—what it was not; the tension between normative and descriptive, idealistic

and empiricist, subjective and objective implications of the concept; and the relative emphasis on the private and the public or the individual and the social" (p. 16).

Be that as it may, policy and scholarly infatuation with civil society has shown little sign of waning. To be sure, the immediate backcloth for the contemporary revival was lent by events in former Eastern Europe, where the idea inspired dissident groups intent on rolling back the authoritarian communist state. In this specific context, civil society was the social culture, one framed by the rule of law and an institutional civility that was lacking from the social system that the dissidents sought to destabilize and disestablish. Particular inspiration for the dissidents' challenge to the state had come from the prison writings of Antonio Gramsci (1891–1937), the atypical Italian Marxist who posited, contra Karl Marx, that civil society, being the sphere of culture, ideology, and associations, is equally that of contestation. While Marx reduces civil society to the market economy, arguing that it is basically a bourgeois lie, Gramsci contends that it (that is, civil society) "offers the popular classes an opportunity to deny the ruling classes hegemony in the realm of ideas, values and culture, as a basis for the ultimate seizure of power and the transformation of capitalist property relations and the state" (quoted in Bangura, pp. 45–46). This, together with the work of Alexis de Tocqueville (1805–1859), who had speculated on the bountiful social capital accruing from Americans' "habit of association," had informed the quite successful invocation of the idea in Eastern Europe.

From Eastern Europe, the idea diffused to the rest of the world, where, fortuitously, it fed into the existing disenchantment with the welfare state across the Western world, the search for an ethical force in the wake of the perceived global slide into moral decay, the explosion in the number of NGOs (non-governmental organizations), and the anticipation of greater civility amid the rampant surge of religious and other kinds of fundamentalism. Outside the West, particularly in the developing countries, the idea of civil society emerged in the thick of the struggle for democratic liberalization and social inclusion for marginalized groups. To be sure, this idea of civil society as a useful tool in the resistance to hegemony by dispossessed groups owes much to early feminist and suffragist movements in Britain. These movements drew heavily on the postulations of John Stuart Mill (among others) regarding civil society, while at the same time seeking to make the concept more inclusive. Across Africa in the late 1980s and early 1990s, the association of civil society with democracy, or at least the possibility of its achievement, was common indeed. Many freely conflated the two, and the popular media treated them as though they were synonyms.

Alternative Genealogies

The embrace of the idea of civil society in non-Western contexts was always going to be difficult. First, there was the problem posed by the specifically Western origin of the idea, one that automatically generated the poser: Is civil society applicable or "thinkable" outside its specific Western cultural and geographic provenance, and might it be compatible with societies denounced by Gellner as "non-modular," "ritual-

pervaded," and "segmentary"? Second, if civil society actually exists outside the West, in places like Africa, Asia, and the Middle East, what might it mean, and with what unit will scholars analyze it? Contrary to general belief, these dilemmas have not been raised by scholars in the West alone. Both Africans and Africanists, like Mahmood Mamdani, Peter Ekeh, Emmanuel Gyimah-Boadi, Eboe Hutchful, Thomas Callaghy, and Stephen Orvis, have expressed deep skepticism about the usefulness of the idea of civil society ("a vague, often confusing and ever-shifting concept") in explicating non-Western or, specifically African, realities; although in the process they have generated insights that have enriched the relevant literature considerably. This has also been the case in the Middle East and Asia, where thinkers like Sudipta Kaviraj, Sunil Khilnani, Neera Chandhoke, Farhad Kazemi, and Masoud Kamali have picked up the gauntlet.

As a result, issues surrounding the so-called alien nativity of civil society have led to the emergence of a critical and fascinating oeuvre. So powerful and diverse is this emergent corpus that Jude Howell and Jenny Pearce think that it forms the core of what might well be called an "alternative genealogy" of civil society. But what are its arguments? The first is to stress the crucial fact that, its Western origins notwithstanding, civil society has over the past decade become a useful tool in the resistance to hegemony by dispossessed groups. Howell and Pearce note that if there is a common thread in the non-Western application of civil society, it is its use to legitimize citizens' right to resist the prevailing development paradigm, thus showing how truly contested the liberal meanings of the concept are. In the process, "civil society has enabled critical voices to occupy an intellectual space where an alternative set of values and propositions on how societies ought to develop and change can be put forward, challenging those that would otherwise dominate" (Howell and Pearce, p. 36).

A second argument of the emergent alternative genealogy is to say that it does not serve any purpose to lay emphasis on the rash of possible meanings of civil society outside the West, especially as even in the West itself, it is impossible to point to a single coherent narrative of civil society. This position has been seemingly corroborated by the plethora of meanings of civil society advanced by different Western scholars. Examples are the imagination of civil society as: "the natural condition of freedom" (Keane); "a condition of education, refinement and sophistication as opposed to a condition of barbarism" (Tester); a "point of refuge from the dangerous totalising systems of state and economy that threatened the life-world" (Habermas); a "metaphor for Western liberalism" (Seckinelgin), and "the anchorage of liberty" (Dahrendorf).

Afro-Arab Discourses

For obvious reasons, the debate on the possibility and meanings of civil society outside the West has elicited a more spirited discourse in Africa and the Islamic world. Gellner, we recall, had vilified Islamic societies for "exemplifying a social order which seems to lack much capacity to provide political countervailing institutions, which is atomised without much individualism, and operates effectively without pluralism"

(p. 29). The denial of civil society in Africa is inspired by a similar characterization.

In both cases, the challenge has been to postulate a theory of civil society that simultaneously recognizes the idea's Western origin and usefulness to the Afro-Arab world. This cannot be done without redefining the term, a cause that has been helped by its unique lack of a commonly agreed definition. Thus, formulating civil society as the "values of mutual support and solidarity [which] exist in the history of human sociability" (Howell and Pearce, p. 36), scholars in Africa and the Middle East argue that civil society has always existed in different forms in other societies. Not surprisingly, a wealth of literature has emerged on African and Islamic civil societies.

One outcome of these attempts, coupled with the ever-increasing policy focus on civil society is the emergence of the idea in a form that is not "civilizationally circumscribed" (Hefner, p. 221). There may be some residual skepticism about the applicability of civil society outside the West, but at least nobody seems to be saying that anymore. The global "professionalization of the third sector," to borrow the words of Michael Edwards, has led to the increased popularity of civil society, and these days the international aid industry seems to be more bothered about empowering civil society than defining it. While this ought to give cause for a pause, it seems more important to observe that in tandem with the "professionalization" of civil society, different local meanings are being created around the concept as part of an increasingly universal negotiation between citizens, states, and markets. This is the real future of the idea, and it would seem to be the next subject for scholarly research.

CLASS. The term *class* is used in a wide range of intellectual discourses, including logic, the natural sciences, and pedagogy. At its Latin origins, however, *classis* was first and foremost a social term, denoting the division of the Roman people attributed to King Servius Tullius (r. 578–534 B.C.E.). In early Rome, class connoted a distinction in rank between those who paid tribute (property tax) and those who did not, as well as the system of divisions between types of military service. In particular, *classis* often seems to have been reserved to describe citizens on the lower social and economic rungs. Only after the principate of Augustus (31 B.C.E.–14 A.D.) did *classis* come to be employed in a more general sense to mean a division of all sorts of things into groups.

Early Histories

The Latin genesis of class nomenclature does not mean that the idea behind it (in either a social or general sense) did not exist prior to the rise of the Roman Republic. Aristotle's *Organon* proposed a logical system of classification of natural and linguistic types into genus and species according to categorical criteria. For the ancient Greeks, the Few and the Many constituted a central measure of division within the social order. Both Plato and Aristotle divided social groups into functional classes whose status and power was graded according to the contributions each made to the purposes of the civil community as a whole. Plato's *Republic* famously identified within the city three parts—rulers, soldiers, and laborers—while Aristotle distinguished six socioeconomic classes—soldiers, priests, judges, farmers, artisans, and traders—of whom only the first three were deemed fully qualified to exercise the rights associated with citizenship, at least in the best political system.

Class thus has generally been associated with systems of social exclusion. Indeed, elaborate mythologies have been generated to support or justify class divisions. The tale of Noah's curse on the descendants of his son Ham, in Genesis 9:20–27, has been taken as an explanation for class inequality. Likewise,

the Koran (Sura 43:31) declares that social differentiation arises from Allah's will that the inferior should be subjected to the superior. The caste system that long governed social organization and relations in India and elsewhere in Asia purported to reflect the disparate origins of the various groups as described in the Vedas: the Brahmans from the lips of Brahma, the Kshatriya from the shoulders, the Vaisya from the thighs, and the Sudra from the feet.

During the European Middle Ages, the idea behind class distinctions was popularly captured by various forms of organic unities. Many medieval thinkers, quite possibly under the indirect influence of Plato, divided society into the three-fold functional ordering of those who fight, those who work, and those who pray. In the High Middle Ages, this was gradually replaced by the more developed organic doctrine of the body politic, the most influential exponent of which was John of Salisbury (1115 or 1120–1180). His *Policraticus* (completed 1159) contained an extensive account of how each of the organs and limbs of the human body—from the head to the toes—had a direct counterpart in society, from the king, his advisors, soldiers, and diverse magistrates all the way down to the peasants and artisans. Class divisions were natural and necessary in order to maintain justice and the common good. Essentially this view enjoyed wide currency in Europe well into early modern times.

The Renewal of Class

For the first millennium and more of European history, the term *class* was not invoked in order to describe the distinctions between and identities of social groups. Rather, *class* was invoked through what we might call “status language,” such as *gradus* in Latin, *état* in French, *Stand* in German, and “orders” or “estates” in English. At the end of the eighteenth century, however, a notable linguistic shift that renewed the nomenclature of class appeared in most major European languages. This change seems to have accompanied the transformations wrought by the industrial revolution and the rise of political economy: class conveyed an essential economic overtone that was not fully captured by the status language of earlier times. The work of authors such as Thomas Malthus (1766–1834) and David Ricardo (1772–1823) did much to disseminate class discourse, and especially phrases such as “the laboring classes” and “the working class.”

The nineteenth century was the heyday of discussions about class in this updated economic sense. Class divisions were upheld by classical political economy on the grounds that the division of labor and the competition implied therein were necessary for the efficient use of productive resources. Critics of capitalism, whether communitarians such as Claude-Henri de Rouvroy, comte de Saint-Simon (1760–1825) or utopians such as Charles Fourier (1772–1837) or anarchists such as Pierre-Joseph Proudhon (1809–1865), remained convinced that the sources of exploitation were not inherent in class divisions per se so much as in unequal distribution of property or wages or the material benefits of work. Differentiation in the contributions made by laborers thus did not excuse their subordination in economic, political, or social standing.

The Marxist Transformation

Without doubt, the most famous promulgator of the idea of class in the modern world was also its most profound critic: Karl Marx (1818–1883). Marx treated class distinction as a universal characteristic of human history from the earliest times of social organization until his own day. For Marx, classes were economic groups constituted by differential access to the means of production—that is, the technologies and natural resources necessary for human beings to reproduce their physical existence. In every social formation, there were two essential and contending classes: a working class, which used, but did not directly own or control, the means of production; and an appropriating class, which lived directly or indirectly from the labor of workers. In different economic systems, the type and nature of technology, and of the social relationships employed in organizing labor and maintaining domination over it, might vary considerably. Hence, tribal societies met the physical and extraphysical needs of their members differently than did subsequent ancient slave or feudal systems. But the fundamental clash of interests between workers and appropriators was a permanent feature of history up to the present day.

In previous social systems, Marx held, the struggle between the classes had wound up with the replacement of one exploitative mode of production (the material and social elements of the economy) with another, culminating in capitalism. On the one hand, capitalism, with its veneer of freedom and equality, produced the most intense exploitation of the worker ever achieved. Yet, on the other hand, just because the condition of the capitalist working class, termed the proletariat, was so degraded, Marx believed that it formed a “universal class,” capable of releasing and realizing all of the untapped potential of a truly liberated humanity. For this reason, Marx held that the proletariat, once it became conscious of its own circumstances and the source of its immiseration, would revolt against its capitalist oppressors and would generate a qualitatively different kind of society. The future society, which Marx called communism, would be classless, since the proletariat, as the most completely exploited class in history, would have no remaining object to exploit. Communism would see the end of human history as a dynamic series of class struggles and would instead herald a new beginning of history in which each and every individual as a full human being would have the opportunity to pursue and attain his or her freely chosen needs.

The Weberian Reply

The primary response to Marx's conception of class was proposed by the German sociological thinker Max Weber (1864–1920). Weber's main insight was to recognize the empirical faults of an exclusive emphasis on class as an economic phenomenon. Rather, Weber saw society—in particular, in the modern world—as far too complex in its stratification to fit into the straightjacket of economic determinism. It should be noted that Weber's critique was directed not just at Marx and other radical critics of capitalism, but also at the classical political economists, who shared with Marxism a stridently economic orientation.

In one sense, Weber does adopt an economic conception of *class*; it is the term he employs to designate social differentiation based on occupation and function as defined by the market. But class is simply one form of distinction. Equally important are status and power. Status denotes the factors of honor and reputation that attach to specific ways of life and are accorded deference by others. Thus, individuals of certain status (say, from a landed nobility) may enjoy greater repute than those of a given class who are wealthier but whose sources of income (say, commerce) are generally held to be debased or ignoble. Power applies to the capability of a group to impose its collective will on others, even in the face of their resistance. Weber points out how, in the modern world, those with the greatest class position or status often do not occupy the positions of administrative or bureaucratic authority. In turn, bureaucrats can and do enact policies that run contrary to the real or perceived interests of economic and reputational elites. This demonstrates that their social position depends on a source—power—that cannot be entirely assimilated to class or status.

Later social scientists have extended and enlarged the factors that influence social differentiation well beyond Weber's original triad. Such elements as kinship, occupation, race and ethnicity, and education have been added to the basic dimensions of class, status, and power. But it seems safe to say that the dominant perspective on social stratification both normatively and empirically during the last century remained Weberian in orientation.

Marxist Rejoinders

Somewhat ironically, many of the fiercest critics of the classical Marxist doctrine of class would consider themselves to fall into the Marxist camp. The failure of the proletariat to rise up against and to crush capitalism even as the conditions of its exploitation worsened led some Marxists, especially in Western Europe, to revisit Marx's conception of class struggle. The so-called Frankfurt School of Critical Social Theory renounced the crass economism of classical Marxism in favor of an analysis that emphasized the cultural sources of working-class conservatism, including the mass media, out-group scapegoating (anti-Semitism and other forms of ethnic and racial hatred), and the predominance of so-called technological rationality. Members of the Frankfurt School embraced, alternately, pessimism about the possibility of successful class struggle (as in the work of Max Horkheimer [1895–1973] and Theodor W. Adorno [1903–1969]) or optimism that other marginalized groups, such as racial minorities, students, denizens of Third World nations, women, and environmentalists, might become the bearers of the revolutionary subjectivity of Marx's proletariat (as Herbert Marcuse [1898–1979] asserted). In either instance, traditional Marxian class analysis leading to proletarian revolution was set aside as an unrealistic and unrealizable expectation.

Another school of Marxist thought, drawing upon the rigorous methodological principles of modern economics and the other social sciences, sought to wed so-called rational choice doctrines of economic behavior to a radical worldview. Authors such as Jon Elster (b. 1940) and John Roemer (b. 1938)

argue that class should be reinterpreted according to the standards of methodological individualism, so that a class is not greater than the sum of its parts, but a coordinated body of similarly positioned individual agents. Known as “rational choice” or “analytical” Marxism, this approach attempts to strip class of perceived metaphysical accretions—for example, the holism criticized by Sir Karl Popper (1902–1994)—without eliminating it as a workable foundation for a viable theory of economic exploitation.

Still other thinkers within a Marxist vein have set out to restore the “political” dimension to Marx's conception of class struggle. Historians such as Robert Brenner (b. 1943) and political theorists such as Ellen Meiksins Wood (b. 1939) stress the contingency of class relations depending on political context, and thus they foreground local juridical-coercive institutions in understanding the constitution of class identities. This perspective insists on the wholly illusory nature of the supposed separation of the economic and the political under capitalism. Political power shapes class conflict, and thus the state itself is the prime site for class struggle and opposition.

Beyond Class

An important trend in the late twentieth and early twenty-first century has been to resist both Marxian and Weberian theories of social differentiation in favor of other fundamental sources of division among human beings. Feminism provides an example of one such line of reasoning. Feminist theory claims that gender, rather than class, constitutes the defining division in human historical dynamics. Broadly stated, feminists assert that reproduction trumps production as the organizing principle around which human social institutions are fixed. Thus, it is the gender divide, emerging from the male oppression of women, that drives social processes throughout history. Patriarchalism, not classism, constitutes the major division among human beings, and the obsession with class is itself a patriarchal trick to divert attention from the fundamental struggle between the sexes.

Class-oriented conceptions of social power and dynamic have also come under attack from proponents of critical race theory. The orientation of critical race theory raises questions quite similar to those of traditional Marxism concerning the ways in which state power (in its legal-judicial and coercive applications) reinscribes and reinforces racial divides. Thus, just as gender is foregrounded in feminist analysis, so race becomes the central focus of analysis among proponents of the critical race school.

The Future of Class?

Class has become anathema in political discourse in the West. Politicians are able to silence their opponents with the mere assertion that “class war” is being invoked. Liberalism—democracy's insistence that equality constitutes the salient feature of social life—even in spite of the evident social, economic, racial, and political disparities that exist in liberal-democratic regimes—suggests that class is effectively dead as a category of social analysis and critique. Yet the discourse of class seems to reappear regularly among the intellectual categories with which

social thinkers, and social movements, narrate their self-understandings. May class yet outlive those whose interests prescribe its obsolescence?

CLASSICISM. Classicism has two dominant meanings in the West. The first concerns the Greeks of the sixth and fifth centuries B.C.E. and their influence, first on the Romans and then on Western cultures from the Renaissance on. The second meaning, evolved from the first, concerns the quality of a work—its style, its structure, and to some extent its content,

always with the quality of the Greek models in mind. The *Oxford English Dictionary* definition, “The principles of classic literature or art; adherence to . . . a classical style,” comprehends both meanings. The word *classicism* has become a common term since its first use in the nineteenth century. Classicism spread across Europe from Italy to Germany, to France, to Russia, to England, with the place and the time of its usage shading its meaning. It remains a useful term, with contextual clues indicating its intended meaning.

The intellectual and aesthetic outflow of the Greeks was prodigious and the extant aesthetic, philosophical, historical, and political writings have had a phenomenal impact on Western culture. Homer’s epics (c. 800 B.C.E.), the poetry of Sappho (seventh century B.C.E.) and Pindar (sixth century B.C.E.); the dramas of Aeschylus, Sophocles, Euripedes, and Aristophanes (fifth century B.C.E.); the sculptures of Phidias; the oratory of Pericles and the writings of Plato and Aristotle (fifth and fourth centuries B.C.E.) are but some of the most prominent Greek contributions to Western culture. In the works of these and other Greeks, future generations have found what has come to be understood as the features of classicism: beauty, balance, proportion, formal structure, intellectual vigor and depth, rational content supported by symmetrical form, often accompanied by a sense of humor and skillful satire. All of these characteristics are manifested in a humanist context. Unfortunately, much of our knowledge of this great outpouring comes to us secondhand because the originals no longer exist, although we have some fragments of the writings—a few poems of Sappho and some works of Aristotle, for example—and some remains of aesthetic works, such as the Elgin Marbles, the sculpture of Hera, friezes of the battle of the centurians, and drawings on pottery. These remains have been studied for centuries.

Much of what we know of Greek contributions comes from two sources: writings about them and copies of them. Aristotle in his *Poetics* analyzed and commented on Greek drama, vastly amplifying the evidence from the few extant dramas. Longinus illuminated the style and purpose of art. Much of what we know of Greek sculpture comes from Roman copies, and much of what we know of Greek and Roman architecture comes from Vitruvius, the Roman architect who wrote about architecture in *De re architectura* (first century C.E.), the manuscript of which was found in the fifteenth century and translated into many languages.

The Romans and Medieval Europe

The Romans, conscious of Greek art and thought, intentionally copied the Greeks. The first neoclassical age was really the Roman one between about the first century C.E. and the fifth century C.E. A good deal of what we now call classicism is a Roman continuation and expansion of Greek thought and aesthetic ideas and values. Fortunately, most of the Roman works are extant, and the writings of the poets Horace, Ovid, and Virgil, as well as the orators and prose writers including Cicero, Cato, Pliny the Elder, and Quintilian, have greatly enriched the classical tradition. Latin had a vigorous life all through the medieval period. It was the lingua franca not only

of the church but of the universities, which started in the twelfth and thirteenth centuries, as well as most serious writing.

The Renaissance

The next neoclassical period, which we call the Renaissance, exploded in Italy under the patronage of such personages as the Medicis and Pope Leo X. The Renaissance with its focus on secular life, fortified by the availability of the important literary works of the Romans and by translations of the Greeks into Latin, sometimes via Arabic, and then by the study of Greek, enabling educated people to read Greek originals, created the great flowering of classicism. Fortified by copious commentary on the ancients from such scholars as Pico della Mirandola and Ficino and stimulated by such scholars as the humanist Erasmus, educated people across Europe talked about classical language, art, architecture, and ideas. Petrarch wrote sonnets in the vernacular. Botticelli painted the beautiful *Birth of Venus*. Great works of poetry, painting, architecture, and sculpture appeared first in Italy in the mid-fourteenth century, and then surged across Europe, into France, Germany, the Netherlands, England, and elsewhere.

An excellent illustration of this sweep of classicism across Europe and into America is in architecture. Andrea Palladio (1508–1580), probably the most influential architect in Western history, rejected the medieval Gothic structures, turning instead to classical antiquity for models. He not only created beautiful classical buildings in northern Italy, but he published his ideas, complete with goals, models, dimensions, materials, and methods of construction. Designers such as the English architect Inigo Jones read Palladio’s books and went to see his buildings, then went back home to construct Palladian architecture, the most famous being the classic Queen’s House in Greenwich (1616). Its simple, clean, symmetrical elegance contrasted strongly with Tudor architecture. Over a century

later, Alexander Pope wrote a 204-line poem on English architecture ("Moral Essays: Epistle IV, Of the Use of Riches," 1734), praising the good taste of Lord Burlington, who indiscriminately applied Palladian ideas, and satirizing noblemen who built expensive mansions lacking in harmony and proportion. Palladian architecture moved across Europe, into parts of Asia, and especially to the Americas, dominating colonial architecture in the United States. Buildings across the world illustrate Palladio's influence: symmetrical structures with balanced vertical and horizontal lines, grand staircases, Greek pillars and Roman arches, porticoes and frescoes, pediments and loggias, statues in the Greek style. In each building, every part contributes to a harmonious, unified whole.

Neoclassicism

As with architecture, almost all fields were affected by classicism, especially literature. The rich collection of Greek and Roman writings, the theories of Aristotle and Longinus, and the considerable body of accumulating Italian and French literary criticism inspired many to write in imitation (mimesis) of the ancients, observing the "rules" they thought inherent in the ancient writings. The flourishing literary criticism included, for example, long discussions of the unities of time, place, and action, of decorum, and of high moral quality. France for a time became the artistic center of this new neoclassicism. Although Racine, Corneille, Molière, Boileau, and others were successful in espousing and observing the rules of classicism, an individual genius elevated their writing. The rules were followed less successfully in Joseph Addison's correct and popular, though stiff *Cato*, but Dryden and Pope in England, and Goethe and Schiller in Germany wrote many inspired classical works.

In the twenty-first century we speak of many creators prior to the early nineteenth century as being classical or neoclassical. Classicism has a recognizable core of ideas that draws creators and critics to it again and again. Behind classicism is the innate desire to make accessible the civilizing influence of great art, music, literature, and architecture. The painters Jacques-Louis David in France (1748–1825) and Joshua Reynolds in Britain (1723–1792) were influential classicists who not only painted but also put their theories into print. Even music, which has no extant models from the ancients, produced classicists: The music of Haydn, Mozart, and the early Beethoven has a strong, clear structure. Their dominant sonata form—orderly, complete, balanced—gives shape and purpose to the chaos of sound.

By the late eighteenth century the neoclassical movement began to burn itself out as artists turned elsewhere for inspiration. In a sense, classicism is an ideal not a reality, since humans almost compulsively veer into irregularities or even rebel against ideals. Classicism tried to give answers, but multitudinous questions remained. Hence countermovements arose, which critics have termed Romantic, with its concern for self-expression, and baroque, with its intentional rejection of balance and harmony. Classicism's closed form, with its completeness, balanced proportion, solid repose, and clean structure, often became a more open form, with restless parts and unstressed edges. The classical *The Ambassadors* (1533) of Hans Holbein (1497–1543), for

example, has a symmetrical structure with clear, distinct figures. In contrast, in the baroque *Christ Washing the Feet of His Disciples* (1556) of Tintoretto (Jacopo Robusti, 1518–1594), Christ at the center right of the picture is smaller than the figures on the left, and the colors and shapes blend into one another.

Though theoretically classicism aspires to produce the best art, in reality much of the best art veers from the classical or outright rebels against it. The classical critic Samuel Johnson has pointed out the many deviations from classicism of William Shakespeare's plays but still recognized their greatness. Much art has elements of classicism. Mary Cassatt's (1844–1926) many paintings, for example, have classical beauty, balance, and repose, but contiguous mothers and daughters blend. The much-admired works of Paul Klee (1879–1940) or Jackson Pollock (1912–1956) demonstrate rejection of classicism. Note the restless parts and unstressed edges of Klee's *Remembrance of a Garden* or Pollock's *Moon Woman*.

Conclusion

Still, during the many centuries of admiring and imitating the Greeks, the term *classicism* has evolved to describe an ideal, a set of aspirations that humans keep returning to. The style of classicism tends to be clear, elegant, precise, rational; the structure, to be formal, balanced, cohesive, closed; the content, to be uplifting, idealized, humanist. Classicism does not have as strong a pull as it used to, in part because it can be pushed into absolutism, and humans are increasingly seeing the world in relative terms. Classical artists from the past—Phidias, Virgil, Raphael, Michelangelo, Titian—will always be with us. But there are also modern exponents of classicism ranging from poets such as T. S. Eliot and W. H. Auden to literary critics including Irving Babbitt and Jacques Barzun, from artists such as Paul Cézanne and William Bailey to musicians like Sergey Prokofiev, Igor Stravinsky, and Béla Bartók. So ingrained is the term *classicism* that many critics use it to describe contemporary forms of art, such as jazz, or even cuisine. It implies a standard of excellence only rarely achieved. Post-modernism saw an almost total rejection of classicism in the late twentieth century, but reaction might well lead to a revival of classicism in some form or another.

CLASSIFICATION OF ARTS AND SCIENCES, EARLY MODERN. The concept of *classification* seems obvious and benign. To classify is to arrange or distribute according to a system or method, a sense of the word that has not altered since its inception in antiquity. The significance of classification lies not in what it means, but in how it is applied. How people classify—according to what principles—has evolved and altered over time as their understanding of the world has altered. How people classify also bears directly on important issues in metaphysics. Does the world come “pre-carved” into natural kinds, or is classification merely an arbitrary exercise of human volition? If natural kinds exist, then classification reveals truths about the external world. The development of ideas about classification (and the things classified) has paralleled both scientific and artistic developments in the early modern period.

Aristotelian Background

To understand the concept of classification in the early modern period, it is necessary to first understand the conceptual framework the early moderns inherited from their predecessors. The world prior to 1600 was still largely Aristotelian. Aristotle (384–322 B.C.E.) provided a classification scheme based on matching a basic kind (species) with a set of distinguishing characteristics (differentia) in order to sort things in the world. Thus a human individual is a rational animal. That is, a human is of the kind “animal” but is distinguished from all other animals by rationality. This example reveals an underlying assumption of Aristotle’s system: genuine classification provides definitions. When a thing is properly classified, it is defined. Definition, in turn, relies on the concept of essences. An essence is a property

I do not deny but nature, in the constant production of particular beings, makes them not always new and various, but very much alike and of kin one to another. But I think it nevertheless true, that the boundaries of the species whereby men sort them, are made by men; since the essences of the species, distinguished by different names, are, as has been proved, of man’s making, and seldom adequate to the internal nature of the things they are taken from. So that we may truly say, such a manner of sorting things is the workmanship of men.

SOURCE: John Locke, *An Essay concerning Human Understanding*, III.6.37, p. 462.

a thing must have to be what it is. Thus one might say that being rational is essential to being human; an individual thing is simply not a human if it lacks rationality.

In Aristotle is also found the first division between the arts and sciences. The distinction is modeled on the natural/artificial divide. *Scientia* concerns demonstrable and certain knowledge derived from nature. In nature, things develop according to natural internal principles of change (entelechies). Something is artificial if it changes because of an external source—like some clay becoming a sculpture because of a craftsman’s work. Sculptures are artificial because they do not possess internal principles of change. They are what they are because someone or something else altered them. This distinction led Aristotle to characterize science as an enterprise whose goal is to account for the internal causes or explanatory principles we find in nature. Since this goal is reached by definition (asserting the essences of things), one discovers that appropriate classification is in fact *the* scientific enterprise—the process of acquiring knowledge. (See *Posterior Analytics*, in *Complete Works*, book 2, especially 93a1–10).

Medieval Academia

Building on this Aristotelian foundation, medieval thinkers developed the core distinction between nature and artifice into an academic edifice. The sciences concerned nature. Since God is the author of nature, it follows that not only should people study nature, they also should expect to find regular order and well-defined kinds within it, as would be consonant with the perfection of the deity. Science is the practice of proper classification by definition. The arts more properly concern skills, whether mental or physical. The Latin root *artes* refers to the technical skills needed to produce something, a fact more apparent in the Greek root *techne*, as in the word “technology.” For the medieval period there is no sense of the “fine

I do not know why you and your associates always want to make virtues, truths and species depend upon our opinion as knowledge. They are present in nature, whether or not we know it or like it.

SOURCE: Gottfried Wilhelm Leibniz, *New Essays on Human Understanding*, p. 327.

arts.” All art is craft. A painter or sculptor is as much a craftsman as a carpenter or shipwright. The goal of the artist is the technical perfection of their work or trade.

Although the sciences were broadly treated and classified in the same way, some innovation occurred in the classification of the arts. In the medieval period is seen the division of the arts into those that are “liberal” (meaning that they are suitable for free citizens) and those that are “servile” (work that was typically manual and done by slaves). Hence a liberal arts curriculum is first found in the early universities. Students who completed courses of study in grammar, rhetoric, logic, arithmetic, geometry, music, and astronomy were awarded a bachelor of arts. This already implies a division in the arts, since these fields were thought to have redeeming features, whether beauty or intellectual stimulation. Interestingly, many of the fields now routinely called arts were excluded. Poetry and the visual arts, for instance, were not considered suitable subjects for inclusion. Unlike the other fields, these (and others) were not judged to be intellectual arts; competences in these areas were thought to depend on the practice of bodily skills and not on the deepening of mental skills.

Early Modern Context

In many ways the early moderns were still in the grips of the Aristotelian worldview. René Descartes (1596–1650), like the Cartesians who followed him, assumed that knowledge is a mathematical mapping of the system or structure of nature. As humanity comes to grips with the order of nature and learns to sort it into kinds, it gains knowledge about nature.

Descartes and most of the early moderns preserve the traditional distinction between the arts and the sciences. Science is acquired by the mind; art is a bodily aptitude appropriate to craftsmen. Thus Descartes notes that oratory and poetry are “gifts of the mind” and hence not properly arts at all (*Philosophical Writings*, vol. 1, p. 114). It was not until the eighteenth century that a robust separation between the fine and useful arts emerged. Parallel with this core difference between conceptions of science and art, classification within each underwent an increasingly divergent development. This development occurred although one key characteristic of early modern theory of art is that art possesses an essentially intellectual character. Perhaps in response to Cartesian and me-

dieval thinking, advocates sought to establish a place for the arts within the mental realm.

This new development generated some interesting thinking about classification. In both the arts and sciences, classification frequently depended on subject matter. Descartes did not like this method for the sciences, since it emphasized material particularity over mental universality. Thus one finds a significant point of departure for classification in the arts and sciences. Genuine knowledge comes from the application of a unified methodology. Hence Descartes argues that it is inappropriate to separate the sciences on the basis of subject matter, since quality scientists should be applying a single method of thought in all scientific matters. The arts, however, comprise separate and distinct skills. As a result, the arts should be distinguished, studied and mastered individually. Skilled craftsmen specialize; skilled intellects universalize. The arts are those intellectual enterprises that also require a practical component, but the latter should not diminish the fact of the former.

Yet as the eighteenth century unfolds there occurs a startling series of innovations in both the arts and the sciences. As the sciences mature, an understanding of what it means to classify comes into focus. The arts develop an independent character, and theories of art push thinking about the nature of classification in the arts in new directions.

Early Modern Classification in the Arts

A number of transformations in the arts took place during the early modern period. What constitutes art, how one ought to classify its various subfields, and even how one ought to judge works of art all underwent bold revisions. The nature and number of the changes is considerable, but it is worth sampling some of the more significant developments.

The concept of invention in art (in the sense of a creative process) altered in the period and would ultimately change how people think about what constitutes art. The old view (even espoused by Leon Battista Alberti, an important Italian theorist of art, as late as the fifteenth century) is that an inventive artist is one that preserves tradition, communal values, and accepted ways of thinking. By the eighteenth century, however, the artist as a solitary figure committed to breaking or superseding traditional norms and artistic methodologies was firmly entrenched. Thus a new intellectual tool developed for categorizing within art and for what counts as art. As the humanist movement took root, artists increasingly redefined their discipline and the standards of quality within their work.

How one identifies and classifies beauty also underwent substantial change as the early modern period unfolded. Prior to the eighteenth century beauty was an objective feature of things in the world. For the followers of Plato beauty was a transcendental property, a “Form” in which beautiful things participated. For others beauty was more immanent and empirical but nonetheless present *in a thing*. Thus classifying things as beautiful depended on isolating features in the objective world. In this sense, classifying objects in the world of art was similar to classifying things in the sciences. The world comes pre-jointed, and peoples’ task as aesthetes is to learn to recognize those divisions.

Beauty is no quality in things themselves: It exists merely in the mind which contemplates them; and each mind perceives a different beauty. One person may even perceive deformity, where another is sensible of beauty; and every individual ought to acquiesce in his own sentiment, without pretending to regulate those of others. To seek the real beauty, or real deformity, is as fruitless an enquiry, as to pretend to ascertain the real sweet or real bitter.

Starting with the work of Francis Hutcheson (1694–1746) in the early 1700s and best displayed in the work of David Hume (1711–1776) later in the century, theorists of art shifted the concept of beauty away from an external objective standard to an internal standard. This shift did not necessarily signal the abandonment of objectivity in beauty, but it moved the focus of attention away from the natural world to the person making aesthetic judgments. Both Hutcheson and Hume developed theories of "taste," theories of artistic sensibilities that classify on the basis of perceiving subjects and not objects.

In a similar vein, the concept of the sublime became elevated as an independent kind of experience. The sublime (roughly a lofty, elated feeling), especially in the work of Edmund Burke (1729–1797), now becomes a separate class quite distinct from beauty. Interestingly, earlier seventeenth-century discussions of the sublime apply the concept only to certain arts such as rhetoric and poetry; no mention is made of the sublime with respect to the visual arts. Jonathan Richardson (1665–1745) was one of the first to apply sublimity explicitly to the visual arts, marking yet another important step in the increasing stratification and complication of artistic categories.

In general the middle of the eighteenth century witnessed the birth of modern theory of art. In 1750 Alexander Baumgarten (1714–1762) published *Aesthetica* and established aesthetics as an independent field studying sensual cognition. Later in the same decade Denis Diderot began publishing his biennial critical reviews of the salons, effectively launching serious art criticism. With criticism comes classification, not only of quality but of many other features. It should thus be expected that during this time there would be a conceptual explosion of classification in the arts to support all of this innovation in theory of art. The expectation is not disappointed.

Perhaps the most prominent example of this classificatory explosion is seen in the work of Gérard de Lairesse (1641–1711), a Dutch painter and author who published several lengthy volumes at the inception of the eighteenth century about the vi-

sual arts. After distinguishing art (a production of the mind) from manner (a manual execution of a skill), he divides the arts into various kinds. Though divisions based on the content of what is painted had been already present for centuries, Lairesse is important because he shifted his classificatory scheme from content to modes of representation. Instead of sorting paintings and painters by their pictorial genres (landscapes, still lifes, portraits, and so forth), he advocated a system based on how the artist seeks to represent the content of the work. Kinds of brush strokes and implicit symbolizations became at least as important as the superficial object depicted. Even still lifes could have allegorical meaning, thus altering how the nature and kind of the work ought to be viewed.

Early Modern Classification in the Sciences

The core problem for the sciences regarding classification during the period concerned was how to carve the world into kinds. For instance, while natural philosophers were engaged in debates over how to classify organisms, metaphysicians asked more foundational questions, such as whether there were natural kinds. Did nature come predivided into kinds? If so, then the task of science was merely to reveal these ultimate classes. And how might this task best be done? Was it even possible to ascertain nature's "joints"? Alternatively, if nature does not come already divided, what are the implications for the sciences? Independently of whether there are natural kinds, there remains the question as to whether there is an ideal system for sorting individuals. In the history of science are found the key foundational theories for the contemporary system of scientific nomenclature being developed in this period.

The problem of natural kinds remains in the early twenty-first century. The philosopher John Locke (1632–1704), an antirealist about species (he did not believe that the world came antecedently divided into distinct species/kinds), argued that in principle one can have no access to the "real essences" of things and as a result cannot ever hope to know how reality is "really" divided. Instead, the most for which one can hope is to develop an empirical system of classification based on nominal essences—the names or appearances of things: "the sorting of things is the workmanship of the understanding" (*Essay*, p. 415). A particular lump of matter is classified as gold because it appears to have the set of properties that have been assigned to the concept of the kind gold. This view was deeply unsatisfying to many, Wilhelm Leibniz (1646–1716) in particular. Leibniz argued that nature *had* to come prepackaged into kinds and furthermore that there existed some empirical (perhaps even a priori) evidence as to what those kinds in fact are. What is important about this debate is not its resolution—philosophers continue to argue whether there is one yet—but its impact on thinking about classification generally. This debate helped to liberate scientific thinking from the Aristotelian view of classification as definition. It was no longer deemed sufficient to classify the world by simply positing one or several definitions. How the world may be classified into scientific kinds has to obey certain empirical and analytical restrictions.

Much of the work came in response to the practical issue of how best to classify in the emerging sciences. A great deal

of urgency was attached to developing coherent systems of classification, especially as human knowledge about the natural world and the variety therein continued to grow. Early modern scientific systems tended to be either artificial (classifying on the basis of convenience for identification) or natural (classifying according to natural kinds). Most of the classification systems in biology during the period were by the “habit” of the kind. So plants were categorized by whether they flower or whether they produce fruit. Animals were classified by whether they lay eggs or are nocturnal, and so on. The most important development, however, was the application of new rational systems of naming kinds. Carolus Linnaeus (1707–1778), a Swedish botanist, devised the precursor to the present system of nomenclature in the eighteenth century (although there were some, such as Jean Bauhin in the sixteenth century, who anticipated this system). His system of binomial nomenclature relied on the division between male and female as one of its fundamental kind distinctions (which is no longer used), but his basic methodology has been adopted as the standard for classification in the biological sciences.

Robert Boyle (1627–1691) is an exemplar of early modern thinkers who helped define “scientific” theories as rational and ordered methodologies. Boyle, now famous for his development of early chemical theories, argued passionately that chemical kinds had to be subject to empirical experimentation. The old chemical categories were deficient precisely because they were not subject to verifiable tests. Boyle further developed the distinction between primary and secondary qualities (though he coined the terms, the concepts can be traced back at least to Galileo), thus preparing the ground for additional scientific inquiry based on a classification of things in nature that were in principle subject to empirical testing. Thus in the debate over how to carve up nature into kinds, new meta-insights emerged that provided constraints on what sorts of classificatory schemes were acceptable. Even if one cannot know whether the particular details about the kinds one picks out in the world are accurate, there nonetheless emerges a theory of classification that indicates that how one classifies is not purely arbitrary.

It is worth noting an issue not addressed by the early moderns but that was fast approaching. All of the reasoning about classification in this period was pre-Darwinian. Phylogenetic systems of classification (those that classify according to evolutionary sequences) did not emerge until later and hence there was no pressure to suppose that there are deep connections *between* the kinds that are picked out in nature. Thus one of the constraints that would appear after the development of the theory of evolution (that species-kinds might be interrelated in definable ways) was not yet present. But one might speculate that the innovations in theory of classification in the previous century were part of what made evolutionary theory possible. That there are constraints on what could count as a good system of classification prepares one for additional deep connections in certain fields of inquiry.

Emerging into the Nineteenth Century

By the end of the eighteenth century one can detect a clear separation between theorizing about classification in the arts and

in the sciences. Thinkers preserved in the sciences the ideal of external objectivity but grappled with whether this ideal could be achieved. Most importantly, the scientific community developed theories that preserved the ideal in the face of epistemological shortcomings by positing meta-constraints on what could count as a satisfactory theory of kinds. In the arts, classification shifted away from external objectivity to more subjective and intersubjective forms of classification. This shift was facilitated by the distinction between the fine arts and useful arts and more generally by the development of new and separate theories of art. Aesthetics emerged as an independent field of inquiry with its own set of kinds and categories. The early modern period witnessed the development of separate and new ways of classifying in the arts distinct from the sciences.

By the nineteenth century the arts and the sciences were conceived of as separate disciplines with distinct classificatory systems. And as such a new question arose: How is it determined whether some activity or thing should be classified as science or as art, as scientific or as artistic? Separating art and science by how they classify does not entail that they use different conceptions of what it means more broadly to classify at all. In fact, this article has assumed the contrary. Furthermore, separating art and science does not imply that the two domains are utterly distinct. As Leo Tolstoy wrote at the close of the nineteenth century, “Science and art are as closely bound together as the lungs and the heart, so that if the one organ is vitiated the other cannot act rightly” (p. 277).

AFRICA

Conceptions and characterizations of colonialism vary considerably among scholars of Africa. Differences and debates center on four sets of interrelated issues: first, the place and importance of the colonial period in African history; second, the nature of the colonial encounter and its driving force; third, the typologies of African colonialism; and fourth, the legacies of colonialism for postcolonial Africa. These questions have been addressed from a wide variety of disciplinary and analytical traditions. In general, the historiography of colonialism in Africa has been dominated at different moments by four paradigms: the imperialist, nationalist, radical, and postcolonial.

Imperialist approaches, which prevailed in the early twentieth century, emphasized the civilizing mission and impact of colonialism. Critiques against this tradition, combined with nationalist struggles that led to decolonization, culminated in the rise of nationalist historiography, which emphasized African activities and agency. From the 1970s, influenced by a growing sense of pessimism about the developmental and democratic capacities of the postcolonial state and the rise of militant ide-

ologies and social movements, “radical” approaches emerged, centered on dependency and Marxist ideas that highlighted the economic depredations and effects of colonialism. In the 1990s, following the demise of socialist regimes and ideologies and the spread of poststructuralism and postmodernism, postcolonial perspectives were increasingly used to reinterpret the cultural and discursive dynamics and complexities of colonialism. Additional paradigms on colonialism arose, most critically those informed by feminist and environmental studies, which stress the role of gender and ecology in the construction of colonial identities, societies, and political economies.

Colonialism in African History

Imperialist and nationalist historiographies represent almost diametrically opposed views of the place and impact of colonialism in African history, with one regarding it as a decisive moment, the other, as a parenthesis. To the imperialists, colonialism in fact brought Africa into history, for in their view, Africa “proper,” to use Hegel’s moniker—from which North Africa was excised—was the land of the “Unhistorical, Undeveloped Spirit,” exhibiting “the natural man in his completely wild and untamed state” (pp. 91, 93). European colonialism, therefore, was depicted as a civilizing mission undertaken to historicize and humanize Africans.

Consequently, imperialist historians mostly discussed in positive light the policies of colonial governments and the activities of colonial auxiliaries, from European merchants to missionaries. When their narratives mentioned Africans, it was to condemn their societies and cultures or to chronicle their Westernization or modernization. Those who resisted colonial conquest or colonial rule were depicted as atavistic, while those who collaborated or accepted the colonial regime were praised for their foresight and wisdom. In fact, in-depth study of African societies was largely left to anthropology, which, with its functionalist-positivist paradigms and ethnographic present, exonerated, if not extolled, colonialism.

Nationalist historians offered an ideological and methodological revolt against imperialist historiography. Using new sources, including oral tradition, historical linguistics, and historical anthropology, together with written and archaeological sources, they chronicled the histories of African states and societies before the European colonial conquest and celebrated the growth and eventual triumph of nationalism during the colonial era. They sought to unravel painstakingly African activity, adaptations, choice, and initiative. Led by J. F. Ade Ajayi (1968) in Anglophone Africa and Cheikh Anta Diop (1974) in Francophone Africa, they emphasized continuity in Africa’s long history and reduced colonialism to a parenthesis, an episode, a digression, a footnote that had altered African cultures and societies only slightly. In this narrative, independence marked a moment of historical recovery in which the agency of the precolonial past was restored and reconnected to the postcolonial future. The linear and celebratory tales of nationalist historiography were later found wanting by numerous critics.

While both the dependency and the Marxist scholars focused on the exploitative economic structures and processes of colonialism, the former were more interested in explaining the

external forces that produced and reproduced Africa's underdevelopment; the latter preferred to concentrate on the internal dynamics. To the *dependentistas*, colonialism marked a second stage in Africa's incorporation into an unequal world capitalist system that was ushered in during the fifteenth century with the onset of the Atlantic slave trade. Marxist scholars sought to transcend the ubiquitous and homogeneous capitalism of dependency theory. Colonialism, they argued, entails the articulation of modes of production whereby precapitalist modes are articulated in their diverse relations with the capitalist mode. Hence the introduction of capitalism by colonialism does not eliminate the precapitalist modes but reshapes them; the latter are progressively subordinated to capital through a contradictory process of destruction, preservation, and transformation.

Unlike the nationalists, the imperialist, dependency, and Marxist historians share the view that the colonial period was decisive in African history. But they differ in their characterization and conceptualization of the place and impact of colonialism. Like the nationalists and unlike the imperialists, the *dependentistas* and Marxists see colonialism as an intrusive moment in the *longue durée* of African history. Insofar as dependency analyses concentrate on the external determinations of underdevelopment, they diminish African agency and echo imperialist accounts of African history, whereas the Marxist focus on internal production processes and social relations resonates with nationalist historiography.

The nationalist periodization of African history, in which the colonial moment occupies limited space, was sanctified in the Cambridge (*History of Africa*, 1977–1985) and UNESCO (*General History of Africa*, 1981–1993) histories, each in eight thick volumes, only two of which were on the colonial and postcolonial periods. Yet far more African historians currently work on the colonial period than on the precolonial period.

The Nature of the Colonial Encounter

Colonialism in Africa entailed an encounter between the continent and Europe. This encounter encompassed multiple spheres (from politics, economy, and culture to sexuality, psychology, and representations), spatial scales (from local and individual colonial territories to subregions and the continent as a whole), and social groups and inscriptions (from the colonizers and colonized to class, gender, and generation). Analyzing the nature of the colonial encounter, therefore, has proved exceedingly complex and contentious, given the range of possible analytical categories and conceptions of what indeed “Europe” and “Africa” mean. Different readings informed by disparate disciplinary or theoretical orientations emphasize the political, economic, cultural, or representational import of the colonial encounter.

Overall, some regard this encounter as essentially antagonistic while others depict it as ambivalent or even accommodative. Until recently, especially before the rise of postcolonial theory, colonialism was largely conceived in antagonistic terms as a series of encounters between the seemingly enduring and impermeable binaries of colonizer and colonized, Western and non-Western, domination and resistance, modernity and tradition, destruction and preservation, and universal and local. Post-

colonialists insist on the ambivalent nature of colonialism, its contingency and decenteredness, and the hybridities and pluralities of the identities it produced. If colonialism is primarily viewed as a political encounter among imperialist and nationalist scholars and as an economic one among the radicals, the postcolonialists emphasize its cultural and discursive dimensions.

The Bifurcated Colonial State

Studies on colonialism as politics and the politics of colonialism have tended to focus on two main issues: the nature of the colonial state and African resistance. Discussion and debate on the colonial state have centered on its specificities and construction, how to classify African colonial states and administrations, the dynamics of colonial power and civil society, and the demise or reconstitution of the colonial state into the postcolonial state. Crawford Young has argued quite forcefully that the African colonial state derives its peculiarity from the fact that it enjoyed only some of the crucial attributes of the modern state (territory, population, sovereignty, power, law, and the state as nation, an international actor, and an idea) and could not exercise some of its imperatives (hegemony, autonomy, security, legitimacy, revenue, and accumulation).

This is because the colonial state in Africa was created in the late nineteenth century, long after both the modern metropolitan state and the generic colonial state had been formed, which allowed for no experimentation. Also, as a conquest state imposed by force, its hegemony was excessively coercive, so that it enjoyed little legitimacy. Moreover, its territoriality was ambiguous, its sovereignty and institutions of rule were extrajurisdictional and resided in the imperial metropole, and its revenue base was weak. Charged with the onerous tasks of consolidating colonial rule, linking the colony to the metropole, and establishing or promoting colonial capitalism, the result was that the colonial state was both interventionist and fragile, authoritarian and weak, and exercised domination without hegemony, all of which ensured its eventual downfall.

All colonial states, irrespective of their ideologies and administrative systems, justified themselves in the names of civilization and pacification. Economic motivations of colonialism were assiduously downplayed. Moreover, all colonial powers used African intermediaries in their administrative systems because they lacked personnel and local knowledge and in order to minimize African resistance and administrative costs. They also used chartered companies in some of their colonies in the early years.

In imperialist historiography, colonial power was portrayed as unassailable because it was for Africa's good. For the opposite reason it was decried in nationalist historiography, which stressed its oppressiveness and incapacity to withstand the full might of nationalist struggle. Dependency writers tended to disregard the importance of politics because they believed that neither the colonial state nor African resistance could stop the ineluctable juggernaut of the world capitalist system, while Marxists subsumed colonial politics to either local class struggles (waged by the numerically small working classes, and only reluctantly and later were struggles by the much larger peas-

antries considered) or anti-imperialist struggles mediated by communist parties in the imperial metropolises themselves or the Soviet Union. Many of the early studies failed to examine the ways that colonial power was specifically deployed, engaged, contested, deflected, or appropriated.

It was not until Peter Ekeh published his influential essay “Colonialism and the Two Publics in Africa” that colonial civil society began to receive serious scholarly attention. He argued that colonialism created two publics that he called the primordial and civic publics, whose dialectical relationships accounted for the political problems of postcolonial Africa. The first public is associated with primordial groupings, sentiments, and activities; the second is associated with the colonial administration and is amoral, lacking the generalized moral imperatives operative in the private realm and in the primordial public. The two publics emerged because colonial ideologies of legitimation denigrated African societies and cultures and glorified European colonial rule, while African bourgeois ideologies of legitimation accepted colonial ideas and principles to justify the leadership of the elites in the fight against colonialism and the inheritance of the postcolonial state. Both ideologies envisaged and sought to separate the indigenous and colonial publics, in which different conceptions of citizenship, morality, and material expectations prevailed. Thus colonial civil society was characterized by the bifurcation of the public realm, which accounts for the centrality of ethnicity in African politics and the disjunction between the state and society that has bedeviled postcolonial Africa.

Others saw the bifurcation and ethnicization of colonial civil society differently. In his award-winning book *Citizen and Subject*, Mahmood Mamdani argued that the bifurcation of power in Africa results from the continent’s distinctive colonial experience. The configuration of colonial rule in Africa led first to the institutionalization of two systems of power under a single authority: one urban, based on civil power and rights, excluding the colonized on the basis of race, the other rural, where tradition and culture incorporated the colonized into the rule of custom. Second, colonial rule in Africa led to the privileging of state-ordained and state-enforced traditions that had least historical depth and were monarchical, authoritarian, and patriarchal, so that customary power and law became an integral part of a decentralized despotism. Finally, with custom becoming the language of force, colonial rule led to rationalizing the appropriation and management of land and the mobilization of labor under the colonial rubric.

This bifurcated state power, civil and customary, first crystallized in equatorial Africa—as “indirect rule” in British colonies and “association” in French colonies—and later spread to older colonies to the north and south, including South Africa, where apartheid represented the last attempt at reorganizing the state structure to incorporate the “native” population in a world of enforced tradition. The challenges confronting African countries in the struggles for independence and after were to democratize the state and particularly customary power, deracialize civil society, and restructure unequal external relations of dependency.

Dependent Colonial Capitalism

To many scholars, economics, not politics, is central to the colonial project. In the 1970s systematic studies began to appear on African colonial economies. Three dominant approaches emerged. The first was rooted in neoclassical economic theory and focused largely on market processes and the problems of resource allocation. Anthony Hopkins has provided the most famous neoclassical treatment of African economic history. Using vent-for-plus theory (that colonialism provided a “vent,” or an “opening”), he argues that colonialism inaugurated an “open economy” of increased market opportunities, which West Africans seized with alacrity by mobilizing previously underutilized resources. Hopkins’s economic history walked a fine line between the imperialist approaches that stressed the modernizing impact of colonialism and the nationalist emphasis on African initiatives.

The second approach was dependency, which was born out of dissatisfaction with prevailing neoclassical descriptions, analyses, and prescriptions for Third World development. Using the concepts of “incorporation,” “unequal exchange,” “development of underdevelopment,” and “center-periphery,” dependency writers emphasized external economic linkages and exchange relations, often at the expense of internal and production processes. Walter Rodney’s influential text *How Europe Underdeveloped Africa* portrayed colonialism simply as a new stage in Africa’s unrelenting slide into structural internal underdevelopment and external dependency.

Marxist scholars attacked both neoclassical and dependency writers for alleged theoretical inadequacies, empirical shortcomings, and ideological biases. They sought to employ concepts of dialectical and historical materialism—which seek to examine how specific systems originate, develop, function, and change in given historical epochs—to unravel Africa’s historical realities. For the precolonial era, it proved difficult to fit Africa into the traditional Marxian modes or to construct specific African ones. As far as the colonial economy was concerned, many Marxists found the concept of the articulation of modes of production useful and produced interesting studies on labor and workers, agriculture and peasants, and the changing structures of Africa’s incorporation into the world economy.

Despite the different emphases of the three approaches, it is possible to outline the common features shared by African colonial economies: they were all expected to provide raw materials and markets for the imperial economies and to be financially self-supporting. The colonial economy was characteristically export-oriented and monocultural and suffered from uneven productivity between sectors and outside domination in terms of markets, technology, and capital. It developed in three phases: first, the period up to World War I, when coercion—forced labor, cultivation, and taxation—predominated; second, the interwar years, characterized by regulation of the colonial economy and the disruptions of the Great Depression, which exposed its vulnerabilities and fostered new economic policies of development planning; and third, the post-World War II period, when “colonial development and welfare” policies took hold, characterized by increased state intervention and investment in “economic development.”

Typologies of Colonialism

A key challenge in analyzing African colonial economies, as with other spheres of colonialism, is their sheer diversity. The temporal division between precolonial and colonial economies and politics and their spatial development during the colonial period were manifested quite unevenly. The growth and structure of colonial economies, for example, were determined by the level of development of the precolonial economies themselves, the nature of precolonial relations with Europe, the modes of conquest and resistance, the level of development of the colonizing powers, the resource endowment of each territory, and the presence or absence of European settlers.

Several attempts have been made to construct typologies of African economies and colonialism more broadly. Three can be identified. First is the renowned tripartite division of Africa developed by Samir Amin (1972): the Africa of the labor reserves (Algeria, Kenya, and much of southern Africa), where Africans were primarily expected to provide labor for European colonial enterprises; the Africa of trade (West Africa, Uganda, Morocco, and Tunisia), where Africa produced the bulk of commodities traded by colonial companies; and the Africa of concession companies (central and equatorial Africa and the Portuguese colonies), where chartered companies enjoyed economic and administrative control over African labor and produce. Second is Thandika Mkandawire's typology distinguishing between rentier and merchant economies, in which surpluses are extracted from rents from mining and trade and taxes from agriculture, respectively. Third is the distinction often drawn between settler and peasant economies or modes of production.

The concept of peasants has a rich and controversial literature in African studies. Debate has focused on the historical origins of African peasantries, their relations with capital and the state, internal differentiations, the changing organization of peasant work—especially its complex articulations with gender and generational relations and divisions—the impact of environmental conditions and changes, the complex patterns of rural cultural construction, peasant knowledge systems, and the intricacies of peasant politics and struggles at various levels, from the household and the local community to the national and global system. In this context, not only did colonialism alter the lives of African peasantries, but the latter also profoundly shaped the terrain of colonialism in Africa.

The concept of the settler mode of production sought to capture the specificities of settler colonies. Settler colonialism was characterized by several features: the exclusion of competition (settler control of key economic resources, including land, allocation of infrastructure, banking, and marketing, at the expense of the indigenous people); the predominance of the migrant labor system (which allowed the costs of reproducing labor power to be borne in the rural reserves); generalized repression whereby direct and brutal force was used regularly; and the close intersection of race and class.

Linked to the concept of settler colonialism is the concept of internal colonialism, in which the colonizing “nation” or “race” occupies the same territory as the colonized people. This

concept found favor among some academics and liberation movements in South Africa who saw the hierarchical, exploitative, and separatist structures of segregation and apartheid as analogous to the relationship of domination and subjection between an imperialist state and its racialized colonies. Harold Wolpe attacked the concept for positing an unexplained autonomy of racial, ethnic, and cultural groups and obscuring the relationships between them, akin to the theory of plural society widely used by liberal scholars to describe South African society.

The Ambivalences of Colonial Society

The pluralist approach was widely applied by social anthropologies to explain many other African colonial societies, which were depicted as “plural societies” in which different ethnic groups and races lived in close proximity; colonial social change was attributed to “culture contact” and “acculturation.” To the pluralists, colonialism provided an arena for the acculturation of African ethnic groups to European culture and values, and so they were preoccupied with recording the patterns of what they called “detribalization” as indicated by changes in clothes, occupations, education, family forms, and leisure activities.

Marxist critics such as Bernard Magubane attacked the indices used by the pluralists and the fact that the specifics of European life and culture in Africa and their own “acculturation” or “Africanization” were ignored. Above all, in their view, the pluralists mystified the real social relations for they failed to place colonial social change in the context of colonialism as a global system of economic relations. The Marxists demonstrated that behind the processes of “acculturation” lay widespread practices of resistance. For example, the leisure activities of workers, as exhibited in work songs, often articulated African popular resistance against colonial rule. Similarly, it was demonstrated that transformations of cultural practices in the rural areas reflected peasant attempts to resist and remake the colonial situation. The Marxists maintained that religious conversions, whether to Christianity or Islam, represented not simply “acculturation” and the renunciation of the old religions but also translations of the old religions into new terms as filtered through the complex mediations of class and social consciousness.

Preoccupied as they were to show African agency, nationalist scholars were perhaps the loudest in refusing to see the processes of colonial social and cultural change simply as a product of “Westernization.” In a famous essay on the invention of tradition in colonial Africa, Terence Ranger insisted that social and cultural traditions were invented and manipulated by both Europeans and Africans to serve their own interests. Specifically, elders, men, ruling aristocracies, and indigenous people appealed to “tradition.” The elders did so in order to defend their dominance over the rural means of production against challenges from the youth; men wanted to retain control against women, who were playing an increasingly important role in the rural areas, especially in regions dominated by male migrant labor; ruling aristocracies sought to maintain or extend their control over their subjects; and in-

digenous people were anxious to ensure that migrants who settled among them did not achieve political or economic rights. This model became popular for analyzing the contexts in which various cultural and social practices in colonial Africa developed—from music and dance to law and marriage.

This constructivist approach was to be fully developed by postcolonial scholars, for whom colonialism was a regime of material and cultural relations as well as discursive and symbolic representations that affected both Africans and Europeans profoundly, although in different ways. The postcolonialists sought to dismantle the image of colonialism as a coherent and monolithic process, to transcend the dichotomy of colonizer and colonized by problematizing, differentiating, and pluralizing each group and mapping out their complex and shifting relations, and to specify the cultural configurations and discourses fashioned out of their changing identities, consciousness, interactions, and negotiations.

Postcolonialists brought into sharper focus issues previously ignored or misconstrued in structuralist and social scientific analyses of colonialism, especially those concerning sexuality, subjectivity, psychology, and language. Besides the textual notions and readings of colonial culture, analyses have increasingly come to stress the nonverbal, tactile dimensions of social practice and the corporeal regimes of bodies, clothing, and performances. Particularly influential have been Frantz Fanon's acclaimed work on the psychology of colonialism and his crucial insights that "blackness" and "whiteness" were mutually constitutive ideological constructions. Building on Fanon's insights, scholars of Africa have highlighted the construction of colonial mentalities, madness, and medicine as mechanisms for inscribing and policing racial and sexual boundaries. Kwame Appiah has shown how the ideas of race in Africa were socially constructed and how colonial and anticolonial discourses reinforced each other to fix racial essences on bodies.

The Feminist Intervention

Many of the approaches used to analyze African colonial politics, economies, societies, and cultures were often gender-blind and tended to ignore women's lives, experiences, contributions, voices, perceptions, representations, and struggles. This began to change following the rise of the feminist movement, which emerged out of both localized and transnational trajectories and intellectual and political struggles within and outside the academy. While the struggles to mainstream women and gender are far from over, African women have become increasingly more visible in histories of colonialism, which has disrupted the binaries and chronologies that tend to frame colonialism in Africa.

As the field of women's studies has expanded, African women have become more differentiated in terms of class, culture, and status, and their complex engagements, encounters, and negotiations with and contestations against the wide range of forces described as colonial are now clearer. From the large and diverse body of theoretical, methodological, and pedagogical literature that has been generated in the last three decades, vigorous debates are evident. One of the most intriguing is on the validity of the term *gender* itself, with writ-

ers such as Ifi Amadiume stressing the relative flexibility of sex/gender relations in precolonial Africa, and Oyèrónké Oyewùmí denying the existence of gender categories altogether.

In the early twenty-first century it has become well established that colonialism had a contradictory impact on different groups of women, although the dominant tendency was to undermine the position of women as a whole. Colonialism combined European and African patriarchal ideologies to create new practices, relations, and ideologies. Earlier work on colonial gender regimes focused on women in productive and commercial activities in the rural and urban areas and the acute tensions in gender relations that were created, to which the colonial state responded by tightening already restrictive customary law, leading to important changes in family structure and new forms of patriarchal power. The topic that attracted by far the most attention was that of women's resistance to colonial rule. Studies ranged from those that examined specific activists and events to general analyses of women's involvement in nationalist struggles in various countries that demonstrated conclusively women's political engagements and contributions.

More recent work has focused on issues of sexuality, constructions of gender identities, and colonial representations. According to Zine Magubane, African sexuality and its control and representations were central to ideologies of colonial domination. In colonial discourse, female bodies symbolized Africa as the conquered land, and the alleged hyperfecundity and sexual profligacy of African men and women made Africa an object of colonial desire and derision, a wild space of pornographic pleasures in need of sexual policing. Sexuality was implicated in all forms of colonial rule as an intimate encounter that could be used simultaneously to maintain and to erode racial difference and as a process essential for the reproduction of human labor power for the colonial economy, both of which demanded close surveillance and control, especially of African female sexuality.

Feminist studies on the construction of gender identities and relations have helped spawn a growing literature on the creation and transformation of colonial masculinities. Writing on Southern Africa, Robert Morrell argues that the colonial divisions of class and race produced different masculinities, some of which were dominant and hegemonic, and others, subordinate and subversive, although the latter received a patriarchal dividend over women of their class and race. These masculinities were produced and performed in different institutional contexts, each with its own gender regime and power relations, from the state, church, and school to the workplace and the home. Needless to say, masculinities changed over time and manifested themselves differently in rural and urban areas, where different gender and associational systems existed and patterns of political, social, and political change took place.

The Demise of Colonialism

Conceptions and analyses of colonialism in Africa have been affected quite considerably by how the demise of colonialism is understood. This in turn has centered on how two processes are examined—namely, decolonization, and African nationalism or

resistance—and the connections between the two. Nationalist historians contend that nationalism was primarily responsible for the dismantling of the colonial empires, while to imperialist historians decolonization was largely a product of metropolitan policy and planning. Others seek to place decolonization in the context of changes in the international relations system. Clearly, a process as complex as decolonization was a product of many factors. It involved a complex interplay of the prevailing international situation, the policies of the colonial powers, and the nature and strength of the nationalist movements, which in turn reflected internal conditions both in the metropolises and the colonies and the ideologies and visions of the postcolonial world. There were also variations in the patterns of decolonization among regions and colonies, conditioned by the way in which these factors coalesced and manifested themselves. Furthermore, decolonization was affected by the relative presence and power of European settlers and the perceived geopolitical strategic importance of each colony.

Similarly, the nature and dynamics of African nationalism were exceedingly complex. Not only were the spatial locus and social referent of the “nation” imagined by the nationalists fluid (they could be ethnic, national, regional, and continental), but multiple secular and religious visions of the postcolonial state vied for supremacy. Moreover, nationalism was articulated and fought on many fronts (political, economic, social, cultural, religious, and artistic) through different organizational forms (from political and civic organizations to cultural and religious movements) and in different terrains (rural and urban). The development and impact of nationalism also varied between different colonies even among those under the same imperial power, depending on such factors as the way the colony had been acquired and administered, the presence or absence of settlers, the traditions of resistance, and the social composition of the nationalist movement and its type of leadership.

Two key questions dominate African scholarship on decolonization and nationalism. The first is the social content and composition of anticolonial resistance. By the 1980s the old accounts of elite politics and heroic resistance had been abandoned in favor of analyses of resistance by peasants, workers, and women, and from the early 1990s more attention was paid to everyday forms of resistance by various subaltern groups, including youth. In short, the challenge was to write resistance with a small “r” rather than a capital “R” without losing, as Frederick Cooper (1994) insisted, the connections between the subaltern resistances and the larger and fluid constructs of colonialism. The second question centers on the continuities and discontinuities marked by decolonization. In the 1960s, nationalist scholars were inclined to see decolonization as ushering a radical break with colonialism. From the 1970s, the revolutionary pessimism of Fanon, who had pronounced decolonization false in his searing treatise of 1963, *The Wretched of the Earth*, gained adherents among radical scholars who stressed the structural continuities of colonialism. For their part, the postcolonialists, with their fixation on colonialism, recentered colonialism in African history.

LATIN AMERICA

Colonialism is all about the exercise of power and its consequences. Theoretically, the exercise of power entails the interaction of at least two parties negotiating (by various means or practices) their wills on one or more issues, as shown by their various actions or statements. This definition holds for interactions of both individuals and institutions. The imposition of one state's will over another is the essence of colonialism. This phenomenon can be observed in a formal sense, when, for example, a mother country dominates a colony, as Spain and Portugal controlled their kingdoms in the Americas. It can also be seen in an informal sense, when the British government pressured Argentine representatives to repay the Baring Brothers' loan in the nineteenth century.

The history of colonialism, which has been a ubiquitous part of the history of the Americas for centuries, can be divided into four parts: pre-Columbian native imperialism; early modern European colonialism; new colonialism (in the nineteenth and early twentieth centuries); and neocolonialism, which came to dominate especially after World War II. Archaeologists and historians have described two major pre-Columbian empires in this hemisphere. In the first, the Nahuatl-speaking people, who called themselves the Mexica, dominated the far-flung "Aztec" empire, which was akin to a loose confederation of city-states under one dominant power. The second great indigenous imperial regime was that of the Inca in South America. Because the Inca required all peoples newly incorporated into the empire to add the Inca Sun god to their religious hierarchy, to learn to communicate in the Quechua language, and to serve the Inca state as requested, they established an empire that was more unified and homogeneous than their counterparts in Mexico.

The age of modern colonialism began in the fifteenth century with the rise of modern nation-states and the beginning of European exploration and discovery. Both of the pre-Columbian empires of the Americas were subsequently conquered and colonized by the Spanish. Representatives of the Spanish crown quickly reorganized the indigenous population to facilitate their rule. To anchor Spaniards in place, colonial authorities—beginning with Hernando Cortez in North America and Francisco Pizarro in South America—gave to their followers grants of native peoples and the rights to their labor—called *encomiendas*. Thus imperial fiat created a new Spanish elite. The grantees or *encomenderos* ruled the native population at will until reports of misuse, exploitation, and the attendant demographic catastrophe motivated the king to establish a government to implement his law and will.

In Spain, the Council of the Indies (Consejo de Indias) was created to study and make policy for the New World, advise the king, and settle important court cases on appeal. The crown created the House of Trade (Casa de la Contratación) in Seville to regulate commerce, collect taxes, and license immigrants. In America, viceroys represented the monarch's person. Supreme courts (*real audiencias*) and treasury departments (*real haciendas*) were also established. Local representation of the king was entrusted to district governors, or *corregidores*. Each Spanish city had a town council (*cabildo*) that was entrusted with overseeing the urban population, planning and growth, sanitation, and law and order. Because the overseas state remained relatively unelaborated and weak under the Habsburgs, the Spanish king relied on the church to help rule. The church provided education to a select few; kept the baptismal, marriage, and burial records; served as a source of capital; provided the moral underpinnings of order; oversaw charity; and proved a ready channel of communication for royal mandates.

Under the Habsburg kings, the colonies provided the mother country with agricultural commodities, precious metals, and exotic products, and proved a ready and profitable market for manufactured goods, which were increasingly made elsewhere in Europe but shipped in Spanish ships in exchange for Spanish civilization and culture (language, religion, and lifeways), manufactured goods, and law and governance. Because Habsburg bureaucratic jurisdictions remained blurred and overlapping, this partnership between church and state resulted in a flexible and long-lasting system of rule that, because of the distances and difficulties in communication, gave many American districts a measure of local autonomy.

In 1700, the Bourbons inherited the Spanish kingdoms. They realized that Spain's global power had waned since the late sixteenth century and that the American kingdoms were deficient in supplying the mother country with sufficient revenues to justify their new designation as colonies. Therefore the Bourbons set about reforming the colonial structure and its personnel (1) to defend the overseas kingdoms from the encroachment of the Dutch, the French, and the British, who all wanted footholds in the Americas and access to their raw materials and markets; (2) to rationalize the administration of the New World kingdoms; and (3) to maximize the revenues flowing into the royal treasury of Spain. The Bourbons did

this in stages—working on the reforms first at home in the peninsula, then in the Caribbean, next in New Spain, and finally in Peru. Among the reforms were (1) the expulsion of the Jesuit order on charges of disloyalty and sedition (teaching new and prohibited treasonous ideas associated with Enlightenment philosophers such as Locke and Montesquieu); (2) the creation of the two new viceroyalties of New Granada (1717, 1739) and La Plata (1776) from the viceroyalty of Peru, ostensibly to bring justice closer to the settlers; (3) the replacement of the creole *corregidor* system of local administration with that of an *intendente* system of peninsular-born royal officials who enjoyed higher status and broader jurisdiction; (4) the renewal of the tax system to increase some levies (e.g., the sales tax) and create new ones (e.g., the tobacco monopoly); (5) the creation of the first true military organization (for defense); (6) the promotion of new technology (for example, pumps and the Born process to increase the productivity of the mines); and (7) the passage of legislation opening up trade.

These reforms alienated (1) the church, because of the monarch's growing anticlericalism; (2) creole families, because the Jesuits had been the favored educators of elite sons; (3) creole *corregidores*, who were replaced with peninsular-born *intendentes*; (4) people of mixed blood (i.e., the *castas*), who were particularly hard hit by increasing taxes; (5) creole militiamen, who resented the fact that the new military organization allowed persons of mixed blood to join; (6) miners, who wondered why it had taken the crown so long to send them the pump that could solve their flooding problems; (7) large wholesale merchants, who lost their monopoly on import supply; and (8) provincial towns that lost the business from overland traffic of mule teams and llama caravans in the Andes as new seaports were opened up for freer trade.

In the short run, the reforms did improve security, administrative expediency, and tax revenues. But in the long run, the imposition of the will of the mother country stifled local autonomy and was interpreted as a threat to the sociopolitical and economic interests of the creoles, causing enough resentment to heighten the desire for independence. Independence, which split the Spanish-American colonies into more than twenty separate countries in the first three decades of the nineteenth century, ended the formal unequal exchange between Spain and its American colonies.

Portuguese colonization followed the same general outlines, with some notable differences. The Portuguese overseas government in Brazil was established in the middle of the sixteenth century in part to prevent the French and other foreign interlopers from taking control of selected areas. The flight of the royal family and its court from Napoleon in 1807 and arrival in Brazil in 1808 and the presence of the royal family in the early nineteenth century resulted in a controlled independence and rule by members of the royal family, Pedro I and Pedro II, as kings of a separate Portuguese kingdom. Pedro II ruled in a relatively enlightened way, but resentment mounted nonetheless, culminating with the issuance in 1888 of the "Golden Law," freeing the slaves, that fatally undermined support for his rule and led to his exile in 1889.

Independence, which foreshadowed the age of new imperialism, however, did not bring the new republican governments total control over their own affairs. The new nations were politically independent but became subject to foreign invasions and state-to-state pressures over debts and the maintenance of law and order. Europe's industries were eager to find sources of raw materials and new markets. Investors willingly exported capital. As mentioned above, the Argentine government defaulted on its first loan, subjecting it to years of informal British diplomatic pressure for repayment. Further north, Mexico, Central America, and the Caribbean nations faced invasion to collect similar debts, as when the Spanish, French, and British governments sent troops into Mexico during the rule of the constitutionally elected presidency of Benito Juárez to collect overdue moneys.

In the twentieth century, the term "neocolonialism" referred to informal economic ties and the growing predominance of the cultures and values of the former colonial powers by which they continued to influence the cultures and outlooks of Latin-American states. Unequal terms of trade exacerbated Latin America's relations with the rest of the world as more and more products (such as bananas, coffee, sugar, and tin) were needed to buy the same or equivalent imported products. Resentment at this situation stimulated a rich intellectual life across the continent in the twentieth century; in fields as varied as economics, political philosophy, literature, and art, anti-imperialism was a hallmark of a distinctively Latin American form of modernism.

Deteriorating terms of trade and dependency on other world powers have split the populations of the various countries. The elites support the foreign loans, aid, and close trading relations because they are importers and exporters who profit from such relations or the bankers, lawyers, and politicians who negotiate the loans, write the contracts, and collect the fees for their efforts. Nationalists, in contrast, are against such dealings, arguing that their nations export low-priced products to buy relatively high-cost manufactured goods that are often inappropriate technologically to the needs of the majority of their people. These nations also pay out more in principal, interest, fees, and patent and licensing costs than they take in, thus exacerbating inequality between countries and within their own nations, perpetuating their subordinate status, inequality, and poverty.

In addition, nationalists claim that the ruling elites colonize their own compatriots, in that provincial producers sell their local products—be it oranges or potatoes—at low prices and buy high-priced manufactured goods in return. In addition, the provinces send taxes to the capital and get much less back in the form of public works and services (such as schools)—a form of internal colonialism.

Such unequal relations have left a legacy of inequality and growing suspicion of and covert and overt resistance to the rule-makers at home and abroad. Under the Habsburgs, colonial populations resisted, saying, "*obedescio pero no cumpló*" (I obey but will not comply), implying that they recognized that the king had the right to issue the law but that if he had been

better informed, he would not have done so. While they informed him of their circumstances and the reasons why the decree is not wise, it was not locally enforced. Increasingly this practice has been replaced by the attitude summarized as “*hecho la ley, hecho la trampa*” (a law passed is a law bypassed [by cheating, trickery, cleverness, or deceit]). This shows the growing cynicism and intolerance of the general population to their governments, international agencies, and unequal relations with the more developed world.

At the beginning of the twenty-first century, the picture is mixed. The fall of the Soviet Union has undermined the sense of any alternative to U.S. capitalism; at the same time, however, the disastrous economic situation that has resulted from neoliberal reforms—the latest set of policies imposed by international creditors on Latin-American nations—has fueled a new sense of resentment. At the same time, a militant desire for functioning democracy, transparency, and an end to corruption has fostered the growth of a wide variety of grassroots political movements. But for many, the only solution is to migrate, legally or illegally, north—into what a previous generation of anticolonialist Latin Americans called “the belly of the beast.”

SOUTHEAST ASIA

Studies detailing the nature of colonial policy and practice in Southeast Asia have all acknowledged its disparate nature and overwhelming range of characteristics. While many European powers shared the desire to establish colonies overseas, the manner in which this was accomplished was more random than regular. Factors contributing to this variance include differing philosophies of administrative governance, differing levels of indigenous resistance, and differing periods of influence in the region. For instance, Spanish colonial projects in Southeast Asia began in the 1560s, nearly two hundred years earlier than the efforts of the British, French, and Dutch, resulting

in a much longer and more enduring history of colonialism in the Philippines (originally a Spanish colony) than in Malaya (a British colony). The Dutch employed a more indirectly ruled system (using indigenous elites to initiate their policies) than the British, who in Burma, for example, deposed the sitting monarchy in favor of ruling more directly through an impersonal civil service administration. In French Vietnam, there was a mixture of both systems, resulting in corresponding levels of resistance in areas more intensively encroached upon by colonial authorities. In general, polities that had achieved sophisticated levels of cultural, political, and economic integration tended to resist European powers more vigorously than polities in more decentralized areas. Some polities in insular Southeast Asia, whose political relations were more tenuous because of geographical constraints, competitive economies, and personal ties, offered less sustained, organized, or intensive resistance than in the mainland kingdoms whose populations were linked by common religious, economic, and historical worldviews. Simply put, the shape of colonialism in Southeast Asia was in large part determined by the nature of precolonial regional dynamics and the ability of the local communities to interact and respond to the differing policies, attractions, and challenges of colonial governance. Yet the idea of colonialism in Southeast Asia has also been understood and considered through approaches suggested by scholars of both Southeast Asian and colonial studies. This entry, after first providing a brief historical overview of colonialism in the region, discusses the ways in which Southeast Asian studies was constructed and shaped by scholars who were writing about or reacting to colonialism, producing works that revealed the complexities of that encounter as well as the epistemological links between the two branches of study.

Historical Overview

While this article is not concerned with the history of the colonialism in Southeast Asia per se, a brief overview highlighting some of its key points is necessary. The history of Southeast Asia's encounter with Europe begins as early as the first decades of the sixteenth century, an occurrence that is indeed one of the earliest episodes in the history of colonialism as a global phenomenon. In many respects, some of the “classical” features of colonialism—such as territorial conquest; the intervention and disruption of local socioeconomic networks; and the introduction of new cultural regimes and models through various missionary and educational activity—first came into play in Southeast Asia before they appeared later elsewhere. All major colonial European powers (as well as, later, the United States and Japan) took part in the long history of colonialism in the region: In the twentieth century the Netherlands was in control of Indonesia; Portugal, of East Timor; the United States, of the Philippines (taken from Spain after 1898); France, of Vietnam, Laos, and Cambodia (so-called French Indochina); and Great Britain, of Malaya and Myanmar (Burma). The region also provides the unique example of Thailand (Siam), which was never colonized, though institutional and cultural changes were significantly connected to European diplomatic pressures along its borders. During World War II most of these territories were occupied by Japan, whose imperial designs, cultural sensibilities, and economic initiatives

disconnected Europe and America's hold on the region, which indirectly contributed to the tensions of a nationalist sentiment and Cold War competitions within the former colonies. Most of the European powers, weakened by the war, would lose their colonies after the war, though attempts were made (in varying degrees) to regain their original foothold within the region.

As the cases of the Mayla Emergency, the Indonesian Revolution, the Indochinese War, and, later, the Vietnam War show, the response to colonialism in Southeast Asia continued in the form of anticolonial resistance movements, though external observers tended to regard these wars in the context of the Cold War.

Trends in the Study of Colonialism

The story of Southeast Asia's encounter with Europe spans several centuries, leaving a long and complex record of exchange, negotiation, and domination. Colonialism in Southeast Asia might be considered one important chapter in that much larger story of global interaction. Within the region's early colonial historiography, colonialism pertained to the transformation of "traditionally" defined polities into dependent states modeled along European definitions of organization and administration. Because this approach to colonialism was significantly linked to the perspective of those who were immersed within the colonial service, it was no surprise that this understanding of colonialism was expressed through studies of administrative changes and their effects on local societies, economies, and cultures. Equally important was the overarching representation of the colonial encounter in binary terms: all that was "modern" was inherently European and became the standard to which Southeast Asian culture and history would be measured. Interestingly enough, these studies formed the foundations for the area studies disciplines, as many of the earliest doyens in the fields were from the ranks of the scholar-administrator. Early linguists, anthropologists, and historians, working within the colonial administrations, set the paradigms and agendas that later scholars would either confirm or contest, creating important but imposing discussions that would dominate the course of scholarship. Their views of the peoples and cultures they encountered set into motion a whole genealogy of scholarship that responded in various ways to their findings. For example, reports that discussed the despotic nature of Southeast Asian leadership not only reveal the way in which colonial agendas colored early documentation, they also identify why writing about "Southeast Asian kingship" was important in the first place. While these early writings relate something about Southeast Asia, they also reveal important insight into how colonialism was perceived by those working within it. Thus, the propagation of colonialism in Southeast Asia by these officials was partially responsible for the emergence of Southeast Asian studies as a field of study.

Thematically, colonialism has come to refer to a variety of processes that contributed to a fundamental change in identity, worldview, and consciousness. These institutional and cultural transformations were initiated at different levels and in varying intensities by many groups within the European com-

munity, indigenous elites, and rural populations. The complicated and complex nature of this interaction has been decoded by a variety of interpretations, affecting the many understandings and forms of colonialism. Colonial administrator-scholars referred to colonialism in terms of its policies and practices that contributed to the administrative formation of the colonies, whereas nationalist historians treated the subject as the processes of interaction, subjugation, and control that enabled the peoples and societies of Southeast Asia to come under colonial authority. Another manifestation of colonialism took its shape (although indirectly) through studies of indigenous forms of resistance and protest, whereas others explored colonialism through the multitude of indigenous social institutions it encountered and affected. More recent trends position colonialism through its relationship to the nation and the forming of national cultures; criminality, counterinsurgency, and prisons; and its forms of knowledge and various modes of representation. In addition, it has also been illustrated through technology, literature, and film. In short, the shape of colonialism has been fashioned through a variety of approaches, reflecting trends in the study of colonialism as a thematic category and through the interdisciplinary guilds within area studies.

Colonialism since 1970

Conceptions of colonialism in Southeast Asia have developed significantly since 1970, though scholarship began widening its historical gaze of the region's history and colonialism's place in it nearly a decade earlier. In response to colonial and nationalist-oriented histories of the colonial past, in which the attention was directed toward colonial administrators, policies, and interests in the region, scholars began shifting their focus, creating histories that told the same stories from internal, local, or indigenous perspectives. One of the most significant interventions was offered by John Smail, who saw a lingering problem in the historiography of modern Southeast Asian history. He concluded that both colonial and nationalist scholarship seemed to privilege the same European contexts, events, and narratives about the "colonial period" even when their political sympathies tended to diverge in analysis. In addition, the very conception of "modernity" in the region's history was automatically being associated with the trends, institutions, and ideas that emerged during the colonial period. According to Smail, modern history tended to focus on colonial narratives, concerns, and priorities that signaled a deep disjuncture with the precolonial past, whose own narratives, cultural forms, and terminology were being neglected by the grand narratives of empire, development, and modernity. In order to challenge the prevailing fixtures of colonial and nationalist historiography, Smail called for a writing and periodization of modern Southeast Asian history that applied indigenous categories of analysis, reconstituting the way in which modernity and colonialism would be defined, interpreted, and chronicled. Identifying these cultural forms that could structure the writing of an "autonomous" history of Southeast Asia during this period of intense Eurasian exchange became the overarching paradigm for scholars of the late 1960s and 1970s. This approach aimed to

address the imbalance in scholarship, which had tended strongly toward European-oriented histories (which emphasize fundamental changes in society), by favoring histories that engaged the possibility of regional cultural continuities. To Smail, colonialism would no longer mark the arrival of modernity; it would merely mark a stage within the long-term patterns and processes of the region's history.

These adjustments lifted the idea of colonialism from the confines of European studies and placed it within the framework of Southeast Asian studies, which shifted attention that previously privileged the study of history through colonial categories to studies that investigated the nature of indigenous culture during the colonial encounter. While early studies might have explored the ways in which ideas of leadership, agriculture patterns, community organization, and kinship relations were affected by colonial policies and practices, the new interest in an "autonomous" perspective urged scholars to prioritize local institutions, patterns, and terms as the main subject of inquiry, so that the study of colonialism would become integrated into the cultural history and anthropology of Southeast Asia. One example could be found in the work of Emanuel Sarkisyanz, who demonstrated through his study of Burmese Buddhism that Southeast Asians reacted and responded to colonialism through local terms and concepts inherent to their worldview. The dismantling of the monarchy, subsequent rebellions, and nationalism were all considered through the prism of Buddhism in Burma, suggesting that it was possible to view the colonial period from a more Southeast Asian perspective. At the same time, effort was directed toward the ways in which global, regional, and local forces bound and interacted with peasant societies outside state or religious institutions, shifting the terms of engagement of colonialism to everyday life and practices. Seminal works such as James C. Scott's *The Moral Economy of the Peasant* directed attention to the ways in which global market economies affected the everyday life of the peasant in Southeast Asia, fundamentally challenging local conceptions of legitimacy, economy, and authority. In addition, such approaches stretched the legacy of precolonial traditions, which were often labeled as "traditional," into an epistemological space that previously scholarship had neglected to consider. Indigenous religion, ritual, and customary laws, and other modes of the precolonial conceptual world, became categories of analysis that were now used to study the role and nature of colonialism in Southeast Asia.

Colonial Dichotomies

While the terms of the colonial encounter were being reconfigured and though scholars were seemingly decolonizing the epistemology of Southeast Asia, others began to question the direction the field had taken and the perspective in which colonialism was being discussed. Smail's "autonomous" history had fundamentally edged the scholarship toward a fresh course of research, but there were still some lingering issues that needed to be resolved. The field's leanings toward supposed indigenous categories as modes of analyses might have fallen a bit short in providing a total picture of colonialism in Southeast Asia by underestimating the impact of colonial influences on society. Scholars had merely swung the pendulum from one

end of the spectrum to the other, extending a little too much enthusiasm for the continuities and unchanging nature of Southeast Asian cultural forms.

Following the important arguments in Edward Said's *Orientalism*, scholars such as Ann Laura Stoler questioned the essential nature of these categories while at the same time challenging the "European versus Southeast Asian" perspective upon which studies of colonialism continued to rest. Although important writers such as Franz Fanon and Albert Memmi had developed their seminal arguments about those who lay between the "colonized" and "colonizer," applying these types of questions to the study of colonial society in Southeast Asia remained in its infancy. With these new callings, the study of "mixed-bloods" in Dutch Indonesia, the "métisse" in French Vietnam, "mestizos" in the Spanish Philippines, and "Eurasians" became an important challenge to the idea that colonial society and its study could be divided into simple binary categories of analysis. These studies also suggested that colonialism in Southeast Asia (and beyond) was much more complex than previously imagined, pointing to a variety of situations and scenarios in which ideas, institutions, and technology were exchanged in different and often complicated ways. Colonialism in Southeast Asia could no longer be viewed as a neat and simple process, the colonial encounter could no longer be approached through binary framings, and it became clear that the categories that had been considered intrinsically "European" or "Southeast Asian" were no longer tenable.

The realization that colonialism was a much more complicated process that occurred at different intensities, at different times, and in different places also inspired scholars to look at other domains in Southeast Asia where such mixing and blurring of ideas might occur. Many scholars had been pondering this idea for some time, outside the contours of colonial studies but within the framework of Asian nationalism. Benedict Anderson's seminal *Imagined Communities* set the agenda by demonstrating that the nation-state was articulated through cultural forms that enabled peoples to bridge the conceptual gap between kin and citizen. Many of these forms of community bonding were those introduced by colonial authorities, adopted by urban nationalists, and localized by grassroots leaders. These patterns of exchange were shown to have occurred at every level of society, and consequently colonialism's shape became influenced by the concerns and mechanics of nationalism.

Colonialism's relationship to Southeast Asian nationalism developed significantly following the important insights of Anderson. One of his students, Thongchai Winichakul, extended the connections between colonial statecraft and nationalist identity by demonstrating the influence of map-making and the creation of Thai identity in his exceptional work, *Siam Mapped*. Though his emphasis was on the notion of "Thainess" and its relationship to boundaries, Winichakul's study reinforced the idea that colonial notions of space, measurement, ethnicity, and history were being actively engaged by Southeast Asian elites—even from those who were not formally colonized. Colonial knowledge was not something that was strictly part of the European conceptual world, it was constantly being reshaped, modified, and localized to fit the needs of Southeast Asians, who in many cases

used these new ideas to emulate as well as resist European hegemony. Along the same lines, Maurizio Peleggi's *Lords of Things* demonstrates how the Thai monarchy embraced different forms of European material culture in an effort to redefine itself in the style of European monarchies, changing its public image through colonial ideas of modernization. Studies exploring the nature and origins of Southeast Asian nationalism indirectly contributed to the changing understanding of colonialism by continuing to challenge the terms and situations that characterized that encounter. Writing against the pervasive grain that had kept Southeast Asians locked in their temporal and spatial limbo, scholars began to investigate the ways in which technologies were disseminated and more often appropriated to transform the Southeast Asian conceptual world. Print culture, education, social engineering, and advancements in communication were actively being adopted to fit the needs of new and old elites alike, while at the same time these modes of colonialism were also being used to reify and remake "traditional" forms of Southeast Asian culture.

Trends in the Late 1990s and Early 2000s

Scholarship from the late 1990s and early 2000s has made provocative connections between the history of colonialism and the production of knowledge in Southeast Asia. Many of the categories and approaches used to conceptualize the region's contours—its cultures, institutions, languages, ethnicities, and histories—have been shown to be largely conceived, organized, and textualized by colonial administrator-scholars seeking to make legible the vast territories, societies, and peoples that had come under their authority. This legacy has not always been recognized, though active measures were taken by scholars in the 1960s and 1970s hoping to decolonize the epistemology of Southeast Asia by referring to categories and terms thought to be "autonomous" to the region. Although this scholarship produced the bulk of Southeast Asian knowledge, research from the late 1990s and beyond is noticing that some of these studies relied on categories and perspectives that emerged through colonial understandings of Southeast Asia. Turning to indigenous language sources or traditional perspectives was not enough—the evidence for what was considered traditional, indigenous, or autonomous was often based on the documents of officials who wrote into these sources their own agendas, concerns, and priorities.

One such example might be found in Laurie J. Sears's path-breaking study *Shadows of Empire*, which reconstructs the way in which Dutch views of traditional *wayang kulit* (shadow-puppet theater) were adopted by scholars and Javanese alike. Not only is the role of the Dutch in the "inventing" of tradition explored, but Sears also charts the way in which the meanings of these cultural symbols were contested by officials, scholars, and performers throughout history. This approach recast the way in which colonialism was being considered: Elements thought to be distinctly Southeast Asian were now being reevaluated as products of colonialism, revealing the unsettled nature of "traditional" culture and revisiting European influence on the epistemological landscape of the region.

The picture of colonialism was that its reach was far more penetrating than once held and that through the study of more benign forms of authority, the actual extent of that influence might be perceived. Leading scholars such as Vicente L. Rafael, author of *White Love and Other Events in Filipino History*, and Rudolf Mrázek, author of *Engineers of Happy Land*, have revealed how colonial photography, roads, language policy, architecture, electricity, and travel literature reflect the relationship between colonial technology, knowledge, and power. Moreover, Mrázek's work employs an important and provocative approach by suggesting that it is possible to "read" colonial society and its forms like a text. In a sense, his unique "translation" of Dutch buildings, roads, and magazines applies approaches to colonial society that are usually reserved for studying Southeast Asia's deep past. Panivong Norindr's *Phantasmatic Indochina* addresses the ways in which French colonial ideology can be gleaned from its films, exhibitions, and architecture. More importantly, the studies contained within this work address how the very idea of "Indochine" was a concept that was invented, reified, and articulated to justify political-economic policies on the one hand and how cultural forms contributed to that imagining on the other. Ironically, colonial studies has gone from one end of the spectrum to the other; while early colonial administrators tried hard to textualize the boundaries and contents of their imagined colony, scholars today are disassembling those constructs by relying on the very sources those early officials produced.

Finally, advancement in gender and identity studies has also reworked the manner in which scholars have approached the relationship between colonialism and social policies. Just as the categories of colonizer and colonized were once problematized to reveal those communities lying "in-between," approaching colonialism through gender-inspired scholars to consider how European notions of womanhood transformed sexual relations and expectations of "native" women within colonial communities. These studies have explored the role and symbol of European motherhood in the colony and the manner in which this image affected policy toward the maintenance of white communities. By doing so, they have directly confronted the image of the colony as a site for "unfettered economic and sexual opportunity" through policies that attempted to curb men from racial intermixing and "going native."

Conclusion

Scholars continue to add to this discursive body of colonial knowledge, which has only recently and sporadically been problematized. Exploring the contexts in which much of this knowledge was produced has led to new questions about what is actually known about the region and new perspectives in which the scholarly understanding of colonialism in Southeast Asia might be expanded. These sentiments suggest that colonialism and colonial society can be studied from colonialism's cultural forms—its institutions, languages, ideas, economies, and literary representations—to reveal new perspectives about the processes of change and continuity. Proponents for this anthropology of colonialism suggest that by understanding how Southeast Asia was made through "scholarship," one can

get a sense of colonialism and the effects of that encounter with the peoples and cultures of the region.

At the same time, considerable effort has been spent on delineating the actual conditions on the ground, which were much more complicated than perhaps official documents or earlier studies attempted to convey. Scholars have shifted their emphasis on rebellions as the sole sign of protest to show that resistance, subversion, and circumvention was occurring in an everyday fashion in everyday settings. Inconsistent policies toward Southeast Asians in rural and urban settings intensified incoherency, mismanagement, and competition among colonial officials while exacerbating tensions between metropole (European capitals) and colonial capitals. It is with this last trend where the idea of colonialism has taken its most current shape. Scholars within Southeast Asian studies are beginning to examine how competing interests, agendas, and concerns within colonial communities produced different boundaries in colonial society, while the contestation of categories has led to the understanding that the differences between European and Southeast Asian were created, defined, and maintained. Hybridity has not hidden the scholarly reemphasis on European colonialism within a Southeast Asian world, but if historiography repeats itself as much as history seems to, one can anticipate further studies of “Southeast Asian” hybridity in the colonial setting to emerge in the future.

COMMON SENSE. The common-sense philosophers of the Scottish school—including Thomas Reid, Dugald Stewart, James Beattie, George Campbell, and James Oswald—argued against George Berkeley and David Hume that ordinary human perception and moral judgment need not be defended against skeptical inquiry but ought to be taken as self-evident. As Campbell put it, “to maintain propositions the reverse of the primary truths of common sense, doth not imply a contradiction, it only implies insanity” (*The Philosophy of Rhetoric*, 1776). The common-sense school was criticized by Immanuel Kant for its “appeal to the opinion of the multitude” (*Prolegomena*, 1783); Joseph Priestley, for example, wrote in his “examination” of Reid, Beattie, and Oswald (1774) that common sense is for persons of “middling” capacities. Nevertheless, their ideas enjoyed immense influence, not only in Great Britain but also in Germany and elsewhere. The idea that ordinary language can express principles of common sense, emphasized in the works of the Scottish school and also present in the work of the Italian jurist Giambattista Vico, led to interest in common sense on the part of later philosophers, including Henry Sidgwick, G. E. Moore, Hans-Georg Gadamer, J. L. Austin, and Hannah Arendt.

While most members of the Scottish school are read today primarily for historical interest, the work of the Presbyterian minister and professor of moral philosophy, Thomas Reid, has undergone a revival in recent years. Reid began his career at Marischal College in Aberdeen, where he founded the Aberdeen Philosophical Society, or “Wise Club.” The group concentrated much of its energy on the work of fellow Scot David Hume. While the poet, zealous Christian, and anti-Humean polemicist, James Beattie, joined the society some nine years after its founding, most of its members were more concerned with establishing an empirical foundation for British learning than with combating potential heresy. Hume called Beattie’s *Essay on the Nature and Immutability of Truth* (1770) “a horrible large lie in octavo”; though Hume disagreed with Reid’s criticism of

his work and once suggested in a letter to a mutual friend that pastors ought to stick to “worrying” each other and leave the philosophers to their arguments, he generally treated Reid with respect.

Hume’s work was of great interest to the Aberdeen philosophers—and to members of the Scottish common-sense school in general—because it brings Cartesian skepticism to conclusions that, for them, are so contrary to ordinary human experience that they demonstrate the futility of all such philosophizing. In his *Inquiry* (1764), Reid writes that “since we cannot get rid of the vulgar notion and belief of an external world, [we ought] to reconcile our reason to it as well we can.” Half a century earlier, Anthony Ashley Cooper, third earl of Shaftesbury, had argued in a commonsensical vein that it would be easier to imagine half of mankind mad than to deny the conclusions of “natural knowledge, fundamental reason, and common sense” (“Sensus Communis,” 1710). For Shaftesbury, human beings have a natural faculty of moral sense.

One difficulty with tracing the influence of the idea of common sense is the variety of meanings attached to it even by thinkers in close geographical and historical proximity. Reid’s commonsense access to moral judgment is much more like reasoned appeal to a self-evident principle than Shaftesbury’s combination of feeling and thinking, and Francis Hutcheson’s use of the term “moral sense” implies still less reason and still more immediate sensation than Shaftesbury’s. Reid’s realism is starkly opposed to Berkeleyan idealism, yet both authors appeal directly to the authority of common sense.

These difficulties aside, however, it is possible to specify several important views that set the Scottish common-sense school apart. First, common-sense philosophy criticized both moral and epistemological skepticism from the point of view of ordinary reason. This argument sometimes took the form of ad hominem attack on Hume: “Even the author of the *Treatise of human nature*, though he saw no reason for this belief [in hardness of bodies in nature], but many against it, could hardly conquer it in his speculative and solitary moments; at other times he fairly yielded to it, and confesses that he found it necessary to do so” (Reid, *Inquiry*, 1764).

Second, philosophy takes its starting point from the self-evident principles of common sense. For Oswald, these self-evident principles included many Christian religious doctrines, and indeed a good bit of the common-sense school’s subsequent popularity lay in its claim to defend the religious views of ordinary British citizens from the perceived incursions of system-building philosophers. Reid’s position on religion and self-evidence is more complex and interesting; for example, he argues that it makes no sense to deny the validity of perception while accepting that of reason because both faculties “come out of the same shop.”

Third, not only does common sense furnish pragmatic certainty about the evidence of our senses and the existence of our selves, but it also provides natural insight into moral questions. Along with commonsense views of right and wrong comes the conviction of one’s own human agency. Reid developed this idea into what contemporary philosophers would call an in-

compatibilist defense of freedom: for Reid, free human agents begin causal chains of events independent of natural causes.

The German reception of the Scottish common-sense philosophers is frequently described by commentators as a “misreception.” Generally, while German readers were enthusiastic about the contributions of the Scots, they tended to empty the idea of “common sense” of the moral and social elements present in Reid’s and others’ work. The “popular philosophy” movement of the mid-eighteenth century in Germany shared the commonsense zeal of the Scottish school, and members of both groups criticized the absurdities of academic philosophizing. As Christian Garve put it (writing, in 1798, his observations on the most common principles of ethics), common sense is not “common because it is contemptible, but because it is, or should be, the common property of all human beings.” Unlike the popular philosophers, Kant was highly critical of the Scottish common-sense school and its reading of Hume in his *Prolegomena* (1783); however, he took the concept of common sense itself seriously in his *Critique of Judgment* (1790). There Kant distinguished between “*sensus communis*,” considered as an idea of a comparative sense, and “common human understanding,” which includes qualities exhibited by all normal human reason.

Of course Kant, unlike the Scottish school, denies that either *sensus communis* or common sense frees us from the need to justify our sensations and beliefs. However, Kant did provide some intriguing suggestions about both concepts’ functions; each, in a different way, serves to replace unavailable certainty in judgment with an approximation of collective judgment. This aspect of Kant’s treatment of common sense inspired Hannah Arendt’s interesting independent reflections on the topic, which include the suggestion that when it comes to choosing between moral approbation and disapprobation, the “criterion . . . is communicability, and the standard of deciding about it is common sense.”

TEXTUAL

Every entry in the *New Dictionary of the History of Ideas* used texts. The following is a list of entries that focused mainly on the history of a succession of texts. Each academic discipline has a succession of major authors with whom later practitioners of the discipline build upon and respond to creatively. The historian of a discipline—such as the history of political philosophy, literary history, or the history of science—considers the responses of thinkers and practitioners of a discipline to the major earlier texts in the discipline. In tracing the origin, development, and transformation of an idea, the historian of ideas considers thinkers' responses to texts from a variety of disciplines.

LIBERAL ARTS DISCIPLINES AND PROFESSIONS

This section is in accord with the university divisions of the Liberal Arts into Fine Arts, Humanities, Social Sciences, and Sciences and the graduate programs of the professions of Law, Medicine, and Engineering. The sample of Interdisciplinary Programs are listed under their most common university grouping. For example, Fine Arts includes Performance Arts; Social Sciences includes Women's Studies and Gender Studies, as well as Ethnic Studies; Sciences includes Ecology and Geology, as well as Computer Sciences; Humanities includes programs of Communication, Language, and Linguistics. Meanwhile, the growth of interdisciplinary programs reflects the increasing overlap between studies listed under the labels of Fine Arts, Humanities, Social Sciences, and Sciences. A discipline or interdisciplinary program only appears once, but an entry may appear under the several disciplines and interdisciplinary programs that influenced the scholarship of the article. Titles that appear in bold indicate entries that are especially suited as a introduction to the discipline.

Under the category Multidisciplinary Practices, there are entries on the many methods, techniques, theories, and approaches that have spread across the disciplines. The Multidisciplinary Practices help explain the contemporary trend of interdisciplinarity for which the history of ideas has long been known. At the end of this Reader's Guide is a listing of a number of entries that overlap three of the four divisions and a listing of entries that overlap all four divisions.

Especially Interdisciplinary Entries

The most interdisciplinary entries synthesized knowledge by using the methods and focusing on the topics of practitioners of several disciplines. Very few entries listed below are in only one division. Common pairs for the history of ideas are social sciences and humanities, social sciences and sciences, and humanities and sciences. In the early twenty-first century there is generally a recognition of the common overlap of the social sciences with the humanities; social scientists may take ethical and literary factors into consideration and humanists may incorporate societal contexts into their work. The presence of psychology in the sciences, as well as the quantitative nature of some social sciences work, creates an overlap of social sciences with sciences. Another interesting overlap is between humanities and sciences—topics that in antiquity were treated as philosophy or religion are now investigated by those following scientific methods.

AFRICA AND ITS INFLUENCE

The communication of ideas in and from Africa is characterized by enormous changes over time and variations among societies. Historically, as might be expected for such a large and ancient continent—the second largest in the world and the one where humanity originated—African societies have exhibited high levels of cultural diversity, uneven patterns of political and socioeconomic development, and different forms of engagement with other world regions. Africa is home to hundreds of cultural groups and languages that have influenced each other in complex ways. It has given rise to advanced societies, such as the ancient civilizations of Egypt and West Africa, which existed alongside simpler societies. Many parts of the continent in the northern and northeastern subregions, and later the western coastal regions, were integrated into extracontinental cultural and commercial traffic, while some parts in the interior were relatively isolated. It was in the zones of intensive intercultural communication that ideas from Africa were transmitted to the outside world and ideas from other regions entered Africa. Needless to say, modern African countries are at different stages of industrialization and development, and unequally integrated into the global circuits of ideas and information.

Understanding these disparities is crucial to analyzing and mapping out the changing processes and patterns in the communication of ideas in and from Africa. For one thing, it underscores the difficulty of, indeed the need to avoid, simple generalizations. The development and connections between the various modes of communication—oral, textual, visual, and performance—have manifested themselves in multiple ways across the continent at different times. Similarly diverse are the institutional forms, and their patterns of growth, through which ideas have been expressed, ranging from educational and religious institutions to civic and professional bodies and mass media outlets. As an interactive process, the communication of ideas has a spatial dynamic that entails not

only the travel of the ideas themselves from one place to another through several media, but also their transmission by human agents who move and settle in different places.

In this context, for example, the conquest of Spain by the Moors from northwestern Africa, which they ruled for nearly eight centuries, was crucial to the diffusion of ideas from Africa and other parts of the ancient world to Western Europe. So was the forced migration of enslaved Africans across the Atlantic important for the spread of countless African ideas to the Americas. Likewise, European invasions of Africa, most crucially colonization (both the ancient Roman colonization of North Africa and the nineteenth-century European colonization of the continent as a whole), played a profound role in the spread of ideas from Europe, some of which were, as is true of Christianity, ideas that previous generations of African thinkers, such as the Egyptian Gnostics and St. Augustine from the Maghreb, had contributed to their development, and that the newly converted Africans proceeded to further transform. This back-and-forth process typifies the complex flows of ideas in world history and the dangers of ethnocentric claims of exclusive cultural authorship.

Orality and Performance

Looking at the span of human history in its entirety, orality clearly antedates literacy, so deciphering the origins and development of oral and textual forms of communication in Africa, and their relationships, is not an easy task. Many Africanists used to claim that Africa, by which they often meant “sub-Saharan Africa,” was defined by oral modes of expression and communication before the intrusion of European influences from the fifteenth century and especially following colonization in the nineteenth. The contention that Africa was ontologically oral and Europe literary had both positive and negative implications. On the positive side, it led to the valorization of oral sources in reconstructions of African history and of oral narratives—what came to be known as oral literature, or orature—in African literature. On the negative side, it oversimplified both African histories and narrative traditions and reinforced the age-old analytical dichotomies in the conceptualization of African and European phenomena.

Undoubtedly, oral communication and traditions have been important modes of social dialogue and transmitting history in African societies for a long time. Oral traditions include oral narratives (epics, legends, and explanatory tales), poetry (praise poetry, chants, and songs), and epigrams (proverbs, riddles, puns, and tongue twisters). Combined, they served to link the past and the present, construct collective worldviews

and identity, educate the youth, express political views, and provide entertainment and aesthetic pleasure. The production of oral traditions often involved performance based on a participatory ethic. In many societies, there were highly trained and esteemed custodians of oral tradition. Among the Mande of West Africa, for example, they were known as *griots*, a word that acquired popularity in the United States following the 1977 airing of the acclaimed television miniseries *Roots*, based on the 1976 book in which Haley reputedly traced his African ancestry to a village in the Gambia with the help of a griot.

From Thomas Hale's fascinating history, it is clear that griots had many other functions besides being genealogists. They were historians, advisers to rulers, patrons, and other members of society, spokespersons, diplomats, mediators, interpreters and translators, musicians, composers, teachers, exhorters, warriors, witnesses, praise-singers, and ceremony participants during namings, initiations, courtship, marriages, installations, and funerals. Griots first emerged at least a thousand years ago; since then their role has changed, and so have interpretations of their history in the oral accounts themselves and in written accounts by locals and outsiders. In more recent times, the griots have taken advantage of twentieth-century technologies including radio, television, audiocassettes, and CDs to spread their knowledge to new audiences locally and globally. Also, many griot epics, such as the renowned *Epic of Sundiata*, about the legendary king of the Mali Empire, have been committed to print. While the literature has mostly discussed male griots, recent scholarship has demonstrated that there were female griots, or *griottes*, as Hale refers to them.

The case of the griots demonstrates the intricate connections between orality and performance. As a medium for the construction, dissemination, and consumption of ideas, performance in the forms of drama and music and dance were particularly important in African societies. According to Modupe Olaogun, African drama dates back to ancient times and includes pantomimes, dance-drama, mask, shadow, and court theaters, heroic recitations, praise-poetry, and market comedy by itinerant troupes, which use, in various combinations and with different degrees of sophistication, role-playing, dialogue, mime, movement, dance, song, puppetry, costume, and scenic spectacle. In the late eighteenth century, African theater entered a new era as contacts with Europe increased and European theater motifs and practices were introduced, elements of which were creatively appropriated and used to further diversify African theatrical expression. Most important was the incorporation of scripted text and reorganization of the theatrical space to separate performers and spectators. In Egypt, Ya'qub Sannu (1839–1912) founded modern Egyptian theater with distinct European influences.

Syncretized performances emerged. For example, the black township music theater of South Africa combined the indigenous dramatic modes of storytelling (the isiZulu's *ingoma* or the isiXhosa's *ntsomi*) with Western choral and vaudeville forms to create a popular theater, which from the 1930s became a powerful vehicle for antiapartheid resistance. In West Africa, where European settler influence was negligible, new theatrical practices were largely developed through educational institutions. In the 1920s, there emerged in countries such as Ghana

and Nigeria itinerant indigenous language theater. By the mid-twentieth century, European influences had waned and Africa's vibrant theater could be divided into distinct forms: literary, popular, and theater for development, each with its own styles, aesthetics, themes, messages, languages, and audiences.

Similarly, music as a mode of cultural production and communication underwent significant changes over the centuries. As with theater, different musical forms developed across the continent, depending on the performance contexts of location and audience, the nature of the performers (spontaneous groups, popular musicians, or specialized musicians), the instruments used (ranging from idiophones to membranophones including drums, aerophones, and chordophones), and their functions (whether entertainment, political, religious, and educational, work-related, or mnemonically to recall past events). According to Turino (2003), despite their obvious differences, music in African societies tended to share a participatory ethic rather than a presentational one (except for music specialists at royal courts), and music and dance were conceptualized as part of the same art form and as social processes rather than as set items or products.

Dance not only included music, but was a complex interactive affair involving movement, theater, sculpture, and religion, whose styles and organization served as social metaphors that communicated aesthetic preferences, issues of kinship, gender, status, and age. Different African societies influenced each other, and from the nineteenth century they began to feel European influences, not least missionary attacks against African dance as "lewd" or "lascivious." In the course of the twentieth century, numerous old dances were reconfigured and recontextualized and new ones emerged. In the 1950s and 1960s, formal dance companies and national dance ensembles practicing traditional dance were created in many countries. In the meantime, new dances such as highlife and rumba had emerged in Africa's rapidly expanding cities. All this demonstrates, argues Oforiwa, the continent's remarkable cultural flexibility, capability, and creativity.

Many of the new music and dance styles were adapted from the African diaspora in the Americas. Rumba, for example, was an Afro-Cuban dance genre created by slaves after emancipation in the 1880s. While African music was exported to the Americas during the era of the Atlantic slave trade, where it was further developed and transformed, as cultural contacts between Africa and the African diaspora grew from the late nineteenth-century diasporan music—from jazz, rumba, and reggae to pop music and hip hop—it was re-exported back to Africa, where it was reappropriated and converted. In the twentieth century, African music and dance became a powerful medium to express Pan-African, cosmopolitan, and nationalist consciousness, in addition to performing gender, class, and religious ideas and identities.

Written Communication

It is quite evident that African "traditional" cultures and modes of communication have demonstrated a capacity to use new communication technologies and, in the process, to transform both themselves and those technologies. This challenges many

of the simplistic generalizations and dichotomies about African cultural and intellectual history. Writing specifically about literacy and orality, Eileen Julien is critical of those who regard orality and writing as exclusive domains and successive moments in which the oral represents Africa's authentic expressive form. She argues that there is nothing intrinsically oral about Africa, that orality and writing have continually influenced each other for a long time, as Albert Gérard (1981) and Harold Scheub have shown in their exhaustive studies. This intertextuality can be seen in the works of contemporary African writers who deliberately appropriate oral forms to serve literary artistic ends.

Among the earliest African societies to develop writing as a method of recording and transmitting knowledge and information were Egypt, Nubia (whose Meroitic script [2nd century B.C.E.–5th century C.E.] has yet to be deciphered), and Ethiopia. In these early literary traditions, writing and reading were confined to a tiny religious and political elite. In Egypt, hieroglyphic writing began about 3000 B.C.E. The literature of the Old Kingdom (2650–2152 B.C.E.) was largely didactic, dominated by the “wisdom” genre. Literary genres multiplied during the Middle Kingdom (2040–1640 B.C.E.) to include more intricate literary forms such as novels, satires, and autobiographies, as well as political and social commentaries and philosophical discourses. During the New Kingdom (1539–1069 B.C.E.) a new literary genre emerged—the love poem—and writers began to abandon classical language and to write in the colloquial language of their time. Later, a new literature known as Demotic (meaning “of the people”) developed, and, after large numbers of Egyptians had converted to Christianity, a Coptic literature emerged emphasizing religious themes.

Ethiopian writing (in a language called Ge'ez) began in about 500 B.C.E. It grew when the Kingdom of Axum became Christianized (c. 400 C.E.), following the conversion of King Ezana in 330 C.E. The Bible was translated from Greek into Ge'ez and other religious translations were produced. The “golden age” of Ge'ez literature, according to Gérard (1981), was between 1270 and 1520, during which both religious and secular writing flourished. Between 1314 and 1322, the clergy, in support of a new dynasty, wrote the *Kabra Nagast* (Glory of Kings), reportedly the most venerated book in Ethiopian history. Royal chronicles, in fact, were an important genre of Ethiopian writing until the beginning of the twentieth century. In the fifteenth century, local hagiographies began to appear as nationalist homage to the holy men of the Ethiopian Church. Ge'ez writing waned from the sixteenth century, to be followed three centuries later by the development of writing in Amharic, the commonly spoken language in Ethiopia, which flowered in the twentieth century, incorporating new literary and intellectual trends.

The Arab conquest of North Africa (661–750 C.E.) ushered in a new period in African political, religious, and cultural history. It brought Islam and the Arabic language and script, which altered the modes of communication of ideas and Africa's links to the wider world. Muslim North Africa gave the continent and the world its first universities, the mosque universities of Ez-Zitouna in Tunis (founded in 732),

Quaraouiyine in Fez (founded in 859), and Al-Azhar (founded in Cairo in 969). Lulat argues that these universities influenced the development of the modern European university, which acquired five elements from the Muslims: (1) a large corpus of knowledge; (2) rationalism and the secular investigative approach of natural science; (3) division of knowledge into academic subjects; (4) the notion of the university as a community of individual scholars; and (5) the idea of the college. He concludes that “the modern university that was brought to Africa by the colonial powers is as much Western in origin as it is Islamic” (p. 16).

North African intellectuals produced a vast body of scholarship in a wide range of fields, from the natural sciences to poetry and history, and some of the world's most renowned minds including Ibn Batuta of Tangier (1304?–1377?), the traveler who visited numerous countries in Asia, Europe, and Africa and wrote extensively on his explorations, and Ibn Khaldun of Tunis (1332–1406), the historian who pioneered secular history in his monumental *Kitab-al-'Ibar* (Universal History) and three-volume *Muqaddimah* (Introduction to History).

Through trans-Saharan trade, Islam spread from North Africa to West Africa, where it began to make significant inroads in the eleventh century. Centers of Islamic learning emerged, including the mosque university of Tombouctou established in the twelfth century, where numerous works were produced, such as *Ta'rikh al-Fattash* (Chronicle of the Researcher) and *Ta'rikh al-Sudan* (History of the Sudan), written by Mahmud Ka'ti (b. 1468) and Abd al-Rahman al-Sa'di (1596–1656), respectively. In addition to writing in Arabic, West African scholars also wrote in African languages using Arabic script, writings that are called *Ajami*. Examples include the *Kano Chronicle* and the *Gonja Chronicle*, produced in modern-day Ghana in the eighteenth century. Arabic and *ajami* writing flourished in nineteenth-century Hausaland. Usman dan Fodio (1754–1817), the leader of the Islamic reform movement that created the Sokoto Caliphate, the largest state in nineteenth-century West Africa, and his brother and daughter, wrote hundreds of books and treatises on law, theology, politics, finance, history, and poetry. Senegal also produced illustrious scholars and religious leaders, among them the legendary Amadou Bamba (1850–1927), whose works remain popular to this day.

Arabic and *ajami* writing also spread to the east African coast and Madagascar. Malagasy *ajami* writing was well established by the time the first Europeans arrived in the early seventeenth century, although it did not achieve the status it did in West Africa or among the Swahili along the east African coast. *Ajami* was gradually supplanted by Roman script from the 1820s as part of the Merina kingdom's (1787–1896) ambitious modernization drive. Swahili writing, whose origins have been dated to the thirteenth century (if not earlier), produced a vigorous literature, mostly poetry and historical chronicles, such as the sixteenth-century *Kilwa Chronicle*. Classical Swahili literature entered its golden age between the mid-eighteenth and mid-nineteenth centuries, during which the work of several writers stands out: Saiyid Abdallah b. Nassar (1720–1820), Muyaka bin Haji al-Ghassaniy (1776–1840), Muhyi 'l-Din

(1789–1869), and Umar b. Amin (1798–1870), who wrote religious and epic poetry. From the second half of the nineteenth century, Swahili writing was confronted with a new challenge in the form of European imperialism.

The vast corpus of African writings in Arabic and *ajami* (much of the latter is scattered in private holdings) across the continent contains important records of African contributions to human knowledge in general and Islamic scholarship in particular. As with early and contemporary Christianity, Africans have made significant contributions to Islamic thought almost from its emergence in the Arabian peninsula in the seventh century.

The coming of Europeans in the fifteenth century, during the infamous Atlantic slave trade, crystallizing into colonization from the mid-nineteenth century, marked yet another watershed in the development of African writing and in the technologies of the communication of ideas. European Christianity was especially critical in the introduction of new cultural practices and writing to many languages that had previously had no written tradition. In Southern Africa, for example, the written literature of the Zulu and Xhosa dates to the early nineteenth century, and most of the works were initially religious in tone, including translations of the Bible and books such as *Pilgrim's Progress*. Later, a more secular and anticolonial literature emerged, especially in journals and newspapers. Dictionaries and historical works were also produced. A vibrant local language literature also developed in West Africa, especially in Ghana and Nigeria. Particularly impressive was writing in Yoruba, consisting mostly of fiction, drama, poetry, journalism, and historical works, such as Samuel Johnson's (1846–1901) landmark *History of the Yorubas* (1921).

The nineteenth century also witnessed the development of new African scripts, especially in West Africa, the most famous being the Vai script invented by Duwalu Bukele (1810–1850). Even more consequential in the long run was the development of African writing in the European languages, especially English and French, a subject that is exhaustively discussed in the edited collections by Albert Gérard (1986) and Oyekan Owomoyela (1993), among others. Initially, African writings in the European languages concentrated on autobiographies such as Olaudah Equiano's (1745–1797) *The Interesting Narrative of the Life of Olaudah Equiano, or, Gustavus Vassa, the African* (1789). In the nineteenth century, scholarly works began to be produced by such intellectuals as Edward William Blyden (1832–1912), author of tomes like *A Vindication of the African Race* (1857) and *Christianity, Islam, and the Negro Race* (1887), which had a permanent influence on African thought.

In the twentieth century, as colonialism became entrenched, European language writing and communication spread to all aspects of African cultural and social life and became a definitive part of African literature, scholarship, education, and public discourse. The use of European languages continued after independence, a period that saw an explosion in education at all levels. For example, the number of universities increased from forty-two in 1960 (many of which were in North Africa and in South Africa) to more than four hundred, enrolling about five million students, by the beginning of the new cen-

tury. Although a vast improvement compared to the colonial era, this still represented a relatively low enrollment ratio of less than 5 percent.

The mastery of the European languages by Africans can be seen in the fact that several have won the Nobel Prize for Literature and other prestigious international awards, and many African academics are among the leading figures in their respective fields. In fact, claim the authors of *Africa and the Disciplines*, “research in Africa has shaped the disciplines and thereby shaped our convictions as to what may be universally true” (Bates, Mudimbe, and O'Barr, p. xiv). Some see the European languages as a force for cultural unification, national integration, administrative efficiency, modernization, and globalization, while others contend that the dominance of these languages erodes Africa's linguistic and epistemic autonomy and its ability to define itself, pursue development, and entrench democratic rights in a situation where the languages of tuition, government, and business are not indigenous and spoken by the masses in daily life.

The Development of Modern Media

Besides educational institutions and religious institutions, the modern media have been critical channels for spreading ideas. The modern printed press dates to the turn of the nineteenth century. The first newspapers, in both African and European languages, appeared in Egypt in 1798, in South Africa in 1800, in Sierra Leone in 1801, in Ghana in 1822, in Liberia in 1826, and in Nigeria in 1859. The most important Egyptian paper in the first half of the nineteenth century was *al-Waqa'ie Al-Misriyya* (Egyptian events), founded in 1828, and from the second half of the nineteenth century until the twentieth century it was *al-Ahram* (The pyramids), founded in 1875. After the British occupation of 1882, Egyptian newspapers became vehicles of nationalist protest. Between 1900 and 1914, 250 newspapers appeared, although many did not survive. The Egyptian press entered its “golden age” after independence in 1922, and by 1937, according to Amy Ayalon, there were 250 Arabic and 65 foreign-language papers.

In West Africa, members of the Western educated elite established newspapers as vehicles to express incipient nationalism in the face of European colonial encroachment. Among the most influential papers were the *Accra Herald*, later renamed the *West Africa Herald*, established by Charles Bannerman in 1858, and the *Iwe Iborin*, founded in 1859 by African missionaries in Abeokuta, Nigeria, and written in Yoruba. During the first half of the twentieth century, when colonialism was firmly entrenched, a host of private newspapers were established by African businessmen and nationalists, from Herbert Macaulay (1864–1946), who founded the *Lagos Daily News* in 1925, to Nnandi Azikiwe (b. 1904), the first president of independent Nigeria, who founded *West African Pilot* in 1937, and whose party, the National Council of Nigeria and the Cameroons, came to control ten newspapers by the 1950s.

In the French colonies, the first African-run papers did not emerge until the 1920s, although before 1900 Senegal had three settler papers. The press expanded rapidly after World

War II: some 365 newspapers were established between 1945 and 1960, when the French colonies attained their independence. In Southern, Central, and Eastern Africa, the press was largely a European creation to serve the information, education, and entertainment needs of the European settler communities, leaving the African readership in search of alternative channels of communication. After World War II some nationalists founded their own papers—for example, *Muigwithania* (Work and play) and *Nyanza Times*, established by Jomo Kenyatta and Oginga Odinga, who later became independent Kenya's first president and vice president, respectively.

After independence the print media faced new opportunities and challenges. The growth of education and literacy levels expanded their readership base, but the emergence of authoritarian one-party states and military regimes undermined press freedom and led to the closure or imprisonment and harassment of many journalists. National news agencies were established and many of the new governments either bought existing papers or established new ones. A few governments were more concerned about the role of foreign ownership and tried to encourage local private media ownership, as was the case, for example, in Nigeria, where Moshood Abiola (1955–1998), later elected president in the annulled elections of 1992, and the Ibru Group established vast media empires. Concerns about the role of the international media—its excessive control of global news flows and misrepresentations of events in the global South—soon translated into international demands in the 1970s by African, Asian, and Latin American countries for the establishment of a New World Information Order (NWIO).

The demands for NWIO were not heeded. In any case, the prodemocracy movement that arose across Africa in the mid-1980s soon transformed Africa's media landscape. These movements were fueled by, and in turn facilitated, the rapid growth of newspapers, so that countries that had a handful of tightly controlled papers suddenly had several dozen vociferous tabloids. Another development was the creation of the Internet, which opened new possibilities for the African press to reach new audiences at home and abroad. By 2000, all African countries had access to the Internet and hundreds of African newspapers were available online.

The Internet is the latest in a long line of telecommunication technologies to be appropriated by African countries. Previously there had been the telegraph, then telephony, cinema, radio, and television, all of which, except radio, grew relatively slowly during the colonial period. The transistor radio played a major role as a vehicle of nationalist mobilization during the struggle for independence. But many countries did not have direct telephone connections with each other and it often took years to get a phone installation, a situation that persisted well after independence. Colonial Africa was generally excluded from the international agencies that regulate global telecommunications, a situation that changed as independent governments joined these organizations, such as the International Telecommunication Union and the International Telecommunications Satellite Organization, and tried to make up for lost time.

The emergence of the so-called information society and knowledge economies, fueled by the forces of global market integration and the emergence and convergence of new information technologies—what came to be known collectively as “globalization”—compelled African governments to accelerate the pace of telecommunications infrastructure development and to liberalize that sector. In pursuit of this agenda, attempts were made to forge more effective government policies, create regional telecommunication initiatives, and leapfrog old technologies by acquiring the latest technologies such as cell phones and satellites. The use of cell phones across the continent skyrocketed. In 1998, the Afristar satellite was launched, the first of its kind in the world designed to broadcast directly to consumer radio receivers.

These initiatives have borne some fruit. Numerous African institutions from governments to universities use Internet services and Africa is more connected to the rest of the world than it has ever been. Yet, many challenges remain. While the number of Internet users on the continent more than quadrupled in the 1990s, reaching 3.1 million by the beginning of 2001, this represented less than 1 percent of worldwide users, which then numbered 407.1 million. The challenge is not only to close the digital divides—within Africa and between Africa and the developed world—but also for Africa to increase its production of the technologies themselves and the content of information on the global information highway.

Thus, by the beginning of the twenty-first century, Africa's postcolonial mediascape was a dynamic and multifaceted blend of traditions, influences, and technologies. The most modern forms of communications technologies coexisted with the indigenous media, electronic outlets lived side by side with street information and rumor mills, known under various names in different regions such as *radio trottoir* in Francophone Africa, *radio boca a boca* in Lusophone (Portuguese-speaking) Africa, and *bush telegraph*, or *pavement radio*, in Anglophone Africa.

Africa and Its Influence

Through the various modes of communication identified above, ideas have been and continue to be transmitted within, from, and into Africa—ideas about religion, culture, politics, and the arts, as well as ideologies, iconographies, and images, not to mention academic theories, concepts, and methodologies. Discourses on African influences tend to be dominated by the tropes of origination, contestation, reciprocity, hybridity, and agency. *Origination* emphasizes Africa's authenticity and as the source of Western civilization associated with the work of Cheikh Anta Diop and the Afrocentricists. *Contestation* refers to Ali Mazrui's notion of counterpenetration or counterconquest, celebrating Africa's capacities to contest other civilizations at home and abroad (2002).

Reciprocity portrays Africa largely as a recipient of external influences, whether negatively, as in Walter Rodney's *How Europe Underdeveloped Africa*, or positively as in the numerous works that discuss the benefits of external interventions for Africa from colonialism and Christianity to foreign aid and globalization. *Hybridity* is inspired by postcolonial theory and, as in Kwame Anthony Appiah's *In My Father's House*, dismisses any African

essence and sees Africa as a constellation of hybrid cultures and identities. The *agency* paradigm is beloved by nationalist and radical historians who seek to show how Africans have actively fashioned their material, mental, and moral lives from the complex ebbs and flows of internal and external forces and influences.

In reality, Africa has not been constituted only from within but also from without. Indeed, it is fair to say that Africa has been constituted by the world as much as it has constituted the world in all its ramifications—historical, demographic, cultural, economic, political, and discursive.

THE AMERICAS AND THEIR INFLUENCE

The Americas were first settled from Asia by successive waves of migrants who crossed the Bering Sea from Siberia to Alaska during the last Ice Age using a land bridge, the frozen sea, and possibly open boats. Estimates as to when this began range from twenty thousand to one hundred thousand years ago. By 8000 B.C.E. settlements had reached the southern tip of South America. The new arrivals came as hunter-gatherers, but over the millennia many adopted agriculture and a few groups built civilizations comparable to what had developed earlier in ancient Mesopotamia, Egypt, and the Indus Valley.

Pre-European Communication

Anthropological research suggests a rich and historically deep tradition of oral communication among early Amerindian people in which linguistic diversity appears to have been considerable. Even within the usually accepted language groupings of North America—Eskimo-Aleut; Athabaskan, or Na-Dene; Algonquian-Wakashan; Aztec-Tanoan; Hoka-Siouan; Penutian; and Arawakan—many dialects existed, a consequence of regional diversity and the linguistic fluidity of primary oral cultures.

The communication of ideas among the first Americans, however, was not limited to spoken language. Smoke signals and the tom-toms, immortalized in Hollywood film, actually existed. The latter could transmit a variety of messages via rhythmic signatures in ways that resemble how bugle calls have been used by military groups in more recent history. The result was a form of communication over distance whereby messages could travel faster than messengers, an accomplishment often first attributed to telegraphy. Another form of long-distance communication developed by Native Americans, although they were probably not the first to come up with the idea, emerged in the nineteenth century when mirrors acquired in trade were used to flash messages across the plains. This practice inspired the United States Army to develop the heliograph, in which the signal mirrors were adapted to transmit Morse code.

One of the more remarkable achievements in communication developed by Native Americans is Plains Sign Language (PSL). It served as a lingua franca, enabling communication between tribes speaking different dialects and in some cases completely different languages. PSL is not a series of rudimentary gestures, but a full-fledged semantically open system capable of sending a virtually infinite variety of messages—it has even been used to recount episodes from the Bible. Most PSL signs are, to use the classic semiotic categories, either iconic (resembling what they represent, such as crossed fingers standing for a tepee) or indexical (where, metonymically, a part stands for the whole, as when a continuous circular motion of the index finger represents a wagon). Although the third semiotic category, the symbolic or arbitrary sign (the dominant

one for spoken language), is rare in PSL, it is not altogether absent; we find it, for example, when a part of the body such as the knee or elbow is used to represent a concept. PSL's exploration of the interface between spoken language and the nonverbal communication of gestures has prompted wide and enduring fascination—it has been studied by philosophers of language and appropriated by Boy Scouts.

New World Civilizations

It was once believed that to have civilization—a political state with a centralized government, ruling bureaucracy, complex division of labor, agricultural surplus, and monumental public works—writing had to be in use. The Americas have yielded a major exception to this rule: the empire of the Incas. Centered in Peru, this extended in a north-south direction from Ecuador to Chile, and eastward into part of the Amazon Basin. Keeping track of this enormous social experiment depended not on writing but on a communication medium capable of doing some of the same things. The Incas used the quipu, a series of woolen or cotton cords of different length, thickness, and color that could be braided and knotted in various ways. Each of these elements represented information. This enabled the quipu to be used for a variety of complex tasks, such as the recording of a census or the calculation of economic output, tribute obligations, and taxes. In conjunction with the Incan oral tradition, quipus were even used as mnemonic devices, to assist in recounting aspects of historical succession.

In contrast to the Incas, the two great Mesoamerican civilizations, the Aztecs and the Maya, developed writing. More specifically, they created a form of writing similar to, but not as elaborate as, Egyptian hieroglyphics. Numerous images and occasionally abstract signs (as opposed to the more streamlined and economical characters of an alphabet) were used to represent parts of speech rather than—as is the case with Chinese script, for example—objects and concepts. It could be argued that precursors of writing in the Americas can be found in rock art (petroglyphs) and in images (pictograms) drawn on animal skins; several buffalo hide inscriptions actually tell a story. However, the possibilities inherent in freeing writing from purely iconic representation allowed it to be used for much more elaborate forms of communication. Nowhere in the Americas has this been demonstrated more than in the case of the Maya.

Mayan history spans roughly the first millennium C.E. The Maya wrote on durable media—stone and parchment (animal skins). Although lacking metal tools, the wheel, or domestic draft animals, Mayan culture nonetheless developed ideas of considerable sophistication. Their mathematical and astronomical knowledge rivaled that of the Babylonians and surpassed that of the Egyptians. One result is a calendar of staggering complexity and accuracy. The lunar month was calculated at 29.53020 days, which compares favorably with our current reckoning of 29.53059 days. Mayans viewed world history in terms of cycles of creation and destruction. (The current cycle, or long count, places the next destruction of the world on 23 December 2012.)

For reasons that remain a source for much archaeological speculation, classic Mayan civilization collapsed dramatically

in the ninth century, whereas the fall of the Incas and Aztecs did not occur until the Spanish conquest. Although this appears to have been a case of self-destruction—an environmental degradation hypothesis has gained increasing support—the Spanish did administer a coup de grace of sorts. Under the auspices of the Catholic Church, almost all the surviving Mayan codices (parchment books) were destroyed. The few that remain, such as the famous Dresden Codex, provide a revealing, if only partial, view of Mayan thought and culture.

Colonial America

Whether the quest was for riches, as in the Spanish incursion into the New World, or for a life free from the constraints of the homeland, which motivated the settlement of most of Anglophone North America, religion played an important role. When the Spanish decided to follow plunder with colonization, taming the indigenous peoples through religious conversion became an imperative. In 1539, less than one hundred years after Gutenberg's invention of moveable-type printing, the bishop of Mexico established the first printing office in the New World. Books of religious instruction helped Franciscans and Jesuits spread Catholicism. They made religious conversions at a rate that far surpassed the later efforts of Protestants in North America, largely because of Catholicism's greater capacity to accommodate indigenous beliefs. The teaching of literacy was not a high priority in Catholic proselytizing at this time, except for those natives destined for ordination.

The seventeenth-century Puritans, in contrast, attempted to teach peoples under their purview to read various religious texts translated into the languages of the tribes in question, but the project was eventually abandoned. The Latin alphabet has only limited phonetic utility when used to transcribe non-Indo-European languages. In 1821, however, the Cherokee Sequoyia devised an indigenous writing system by modifying the Latin alphabet to represent syllables of the Cherokee language. Often referred to as an alphabet, this eighty-five-character script is, technically speaking, a syllabary. At one point it was even used for newspapers; after falling into disuse, it is now enjoying renewed interest. Other Native American groups, such as the Cree and Inuit, have also developed syllabaries.

Whether brought by Puritans, Quakers, Mennonites, or any of the other Protestant groups that settled North America, the influence of the Reformation was profound. Idolatry was rejected and vernacular literacy was encouraged so that all could have direct access to the word of God. Imported Epistles were soon supplanted by Bibles, psalm books, and catechisms minted in America after print shops were set up (1640) in Boston and Cambridge. The literacy rate in colonial New England at this time has been estimated at about 60 percent for adult males, with a figure of about half that for women. It was somewhat less in the southern colonies—50 percent for males and 25 percent for females—given the more agrarian (and, in some places, Catholic) nature of the South, where the education system tended, apart from the segment that catered to the elite, to be less well developed.

The eighteenth century saw a gradual rise in colonial literacy, along with the publication of texts besides those relating

to religion—schoolbooks, professional and technical manuals, and eventually the political tracts that would inspire the American Revolution. By 1790 American editions of English works began to appear, to be followed in several decades by a national tradition of fiction and poetry. Throughout the eighteenth century, books were relatively costly. Access to them was abetted by the establishment of subscription libraries, the prototype being the Philadelphia Library Company, established in 1731, largely through the efforts of Benjamin Franklin. Newspapers also facilitated the dissemination of ideas throughout the century, beginning in 1700 with Boston postmaster John Campbell's hand-copied news sheet, which went to print in 1704 as the *Boston News-Letter*. Within a generation a dozen such publications were available, and throughout the remainder of the century growth would be exponential.

In the decades leading up to 1776, a growing volume of printed matter urged resistance to British authority. Perhaps the most notorious document in this regard is Thomas Paine's *Common Sense*, published as the revolution began, on 9 January 1776. Although the ideals of those advocating independence included free speech and a free press, pro-British newspapers expressing Loyalist sentiments were often suppressed. By the time of the revolution there was near universal literacy in the northern colonies. Nevertheless, the importance of the oral tradition cannot be discounted. What was read was discussed and augmented by speeches in taverns, meeting halls, and other public places.

The Penny Press

In the 1830s American newspapers began their emergence as a true mass medium—one that disseminates the same information to large numbers of people. In the colonies or early republic a successful newspaper attracted only a few thousand readers at most. After the revolution, advertising helped finance newspapers, and many, if not most, had the word *Advertiser* in their title. Circulation was dependent on subscription. Early in the nineteenth century, partisan politics began to play an increasingly important role as papers aligned themselves with political parties in response to the debate between Federalists and Anti-Federalists. No matter what political constituency these journals served, the associated business interests determined their emphasis. Subscribers were generally well-off and had to sign on for a year at a cost of six cents an issue.

The arrival of the penny papers changed the industry. The idea began in New York and within a decade had spread to other metropolitan areas. Benjamin Day's *New York Sun* (1833), James Gordon Bennett's *New York Herald* (1835), and Horace Greeley's *New York Tribune* (1841) were sold on the street for a penny and reached a readership many times that of the partisan press. Many readers were immigrants, members of the traditional middle class, or from a nascent literate working class. These papers were not without political leanings, but they were not party-funded (advertising revenue helped defray costs) and were quite capable of shifting an allegiance if a candidate's platform displeased them. Local news, along with crime—the more sensational the better—human interest stories, and coverage of late-breaking events such as the war with Mexico made the penny papers immediate as well

as informative. Journalistic practice shifted from the interpretation of an event, in some cases long after the fact, to speedy, descriptive reporting. Eventually the penny papers added coverage of the arts, theater, sports, and general entertainment.

Several theories have been put forth to explain the success of the penny press. On the technological side, steam power and the rotary press facilitated mass production. The use of steam in rail and ship transportation and improved roads speeded the movement of news. By the mid-1840s that movement was no longer limited to the available means of transportation, given the advent of the electric telegraph, which prompted the formation of news agencies such as the Associated Press (1849). News was becoming a commodity—the fresher the better. Nevertheless, it must be noted that the advent of the penny press itself preceded technological influences that contributed so greatly to its success. On the human side, a literate urban population was expanding and was feeling a greater sense of empowerment through the electoral process. Being informed through regular access to news helped give direction to that empowerment.

Yellow Journalism

Penny papers dominated news reporting until the end of the nineteenth century, when they were outdone at their own game by the journalistic innovations of Joseph Pulitzer and William Randolph Hearst. Beginning in midcentury, though, there were alternative visions of what a newspaper should be. The most notable such experiment was Henry Raymond's *New York Times*, sometimes referred to as an example of the "information press." Beginning in 1851, the *Times* eschewed the base populism of the penny press and used a matter-of-fact style to report urban news, public-interest stories, and business activities. On the eve of the Civil War the *Times* became associated with the Republican Party and its antislavery position. Perhaps the paper's finest hour in its first half-century of operation occurred in the 1870s, when it helped expose the infamous New York municipal corruption ring headed by William Marcy "Boss" Tweed.

The challenge to the penny press and the information press posed by Pulitzer and Hearst gave rise to what became known as "yellow journalism." The term itself, which evokes notions of sensationalism and scandal mongering, derives from a cartoon character bent on exposing corruption, the Yellow Kid, drawn by Richard Outcault for Pulitzer's *New York World*. Pulitzer, a Hungarian immigrant, took over the paper in 1885. His numerous innovations included a populist, pro-labor and pro-union position; campaigns to expose municipal corruption and injustice; advocacy of an increased tax burden for the wealthy; investigative journalism that tackled everything from phony psychics to the dire conditions in a mental hospital; and publicity-seeking stunts to improve circulation, such as sending Nellie Bly on her legendary seventy-two-day trip around the world in 1888–1889.

Pulitzer also streamlined the prose style of his papers (he would acquire a chain of them) by avoiding colloquial and esoteric terms and shortening paragraphs and sentences. Headlines, barely discernible in the penny papers, now spanned columns. Visuals—diagrams, cartoons, along with the reproduction

of photographs using the new halftone process—earned a prominent place. This helped make Pulitzer’s papers appealing, especially to immigrants for whom English was a second language.

Hearst admired these innovations but believed they could and should be extended further. In 1895 he took over the *New York Journal* and began a battle for circulation supremacy with Pulitzer that has been described as fiercer than the Spanish-American War that both papers would cover three years later. Hearst’s moneyed background allowed him to hire away part of Pulitzer’s staff, including Outcault and his Yellow Kid.

Hearst’s journalistic exposés were not always limited to stories relating to the public interest. Sensationalism was omnipresent. Lurid scandals that we associate today with tabloid journalism sometimes made the front page, accompanied by massive, attention-getting headlines. Hearst also had a reputation for newsmaking when mere reporting would not suffice. His most famous foray in this direction occurred when he drummed up sentiment for a reluctant U.S. government to declare war on Spain. Hearst’s quip to artist Frederick Remington, who had cabled from Cuba that there was little fighting to report—“You furnish the pictures and I’ll furnish the war”—is humorously dramatized in Orson Welles’s 1941 film based on Hearst’s life, *Citizen Kane*.

Book Publishing

In addition to religious publications, a major type of book emerging from the colonial press was the almanac. Benjamin Franklin’s *Poor Richard’s Almanac* (1732), blending self-help advice with humor, became a best-seller. Book production was centered at first in Boston and Cambridge, but by the early eighteenth century Philadelphia (where Franklin was based) became a major player. Censorship limited the variety of books that could be published, and there was no enforcement of copyright. By the early nineteenth century the industry had diversified its output, and the burgeoning commercial center of the new nation, New York, had become the center of publishing as well.

In the United States, modern book publishing—featuring a diverse general list and home-grown authors—began in 1817, when James and John Harper established the firm bearing their name. They were soon followed by John Wiley, who took over his father’s fledgling business in 1826. The house scored a major coup when it signed a then-unknown James Fenimore Cooper—later referred to as “America’s Sir Walter Scott”—who went on to become the country’s first literary celebrity. In 1840 Wiley went into partnership with George Putnam, who would eventually leave to establish his own firm in 1849. In 1846 Wiley and Putnam published Herman Melville’s first novel, *Typee*, which in turn passed to Harper’s in 1849. (Melville was never a big seller during his lifetime.)

Harper’s went on to become the largest publisher in America, earning considerable sums from pirating English favorites including the Brontës, Thackeray, and Dickens. The house also produced textbooks and a magazine that bore its name, which emerged as the medium to which many people turned

for Civil War coverage, especially owing to impressive visuals (woodcut illustrations). Other well-known firms that emerged during this time include Appleton (1831), Scribner’s (1846), and D. Van Nostrand (1848). However, it was a small Boston publisher, John P. Jewett, working in the shadow of Little, Brown (1847) and Houghton (1848), who scored the century’s biggest publishing coup. After Phillips, Sampson and Company (1850) turned down the novel rights to Harriet Beecher Stowe’s serialized (in the *National Era*) story *Uncle Tom’s Cabin*, Jewett published it in 1852. The book became the biggest-selling hardcover in nineteenth-century America and had an enormous impact on the (northern) public’s attitude toward slavery and its rising antipathy toward the South.

The second half of the century saw the country secure, both in its publishing industry and in the literary ability of American authors. The old houses grew and new ones sprang up as reading tastes diversified. Harper’s even signed the once-pirated Dickens in 1867. In 1895, during a decade that saw a boom in American fiction publishing, Harper’s secured the rights to sixteen books by Mark Twain (Samuel Clemens). Twain and several other prominent writers successfully promoted their work through a series of highly entertaining public readings—performances, in the case of Twain—that recaptured, at least in spirit, the oral tradition of storytelling that had been so integral to the cultural life of both Native Americans and African-Americans.

ASIA AND ITS INFLUENCE

Asia comprises a vast amount of land divided into numerous countries, many of which have civilizations dating back thousands of years. Due to the huge scope of this topic, this entry will focus on India as an important hub for the transmission of ideas throughout Asia and how other Asian countries influenced the development of Indian civilization.

When India became independent in 1947, the new government faced the daunting task of convincing a large and highly disparate population that the various peoples of India constituted one nation. The populace was divided among a variety of religious groups, the majority of whom were Hindus (more than 80 percent). Hindus are divided into more than two thousand endogamous castes (*jati*), each of which considers itself to be different from all the others. In the early twenty-first century there are over 800 million Hindus, 81 million Muslims, 20 million Christians, 14 million Sikhs, 6 million Buddhists, 3 million Jains, and about 600,000 Zoroastrians in India. In addition, there is enormous linguistic diversity: the 1971 census (the most recent containing a survey of languages) listed thirty-three languages with more than one million speakers, and there are numerous smaller languages and dialects, many of which are mutually incomprehensible. Since independence, the government has made great strides in promoting education, but more than half of the population remains illiterate.

In this situation, oral and visual texts play a central role in communicating ideas among India’s population, which currently numbers over one billion. The ideals of nationhood and government initiatives are often disseminated orally or symbolically, and this is also true of religious ideas. Public performances of religious tales are widely popular all over India, and the annual Ramlila (“Sport of Rama”) plays generally draw huge crowds. These are based on Tulsidas’s (1543?–1623) version of the Hindu epic *Ramayana*, which tells the story of the mythical king Rama, an incarnation of the god Vishnu. When the *Ramayana* was serialized on television in the 1980s, it became a major national event, and the country came to a standstill every week when it was showing. This was followed by serialization of the *Mahabharata*, the other major religious epic of India, which was equally well received. Due to the continuing popularity of public performances and mass media presentations of religious themes, religious narratives and the ideas they convey are widely diffused in India. The spread of Internet access and growing expertise in software development in India have increased this process, at least among those who are able to use computers. It is now possible to make virtual pilgrimages to Hindu holy sites and to perform virtual *puja* (offerings and prayers) at several popular Hindu cultural Internet sites. These generally use English, the language of elite communication in India, and they appeal particularly to Indians living overseas.

Language Issues

Even after fifty years as an independent country, there is no real national language, despite government attempts to promote Hindi, which is spoken in the northern part of the country. Linguistically related to Sanskrit, Hindi is the single most spoken language in India, but even so it falls well short of a majority. In 1971 there were 153,792,062 Hindi speakers listed, but even though it is widely spoken (and linguistically related to other languages in the so-called Hindi Belt of north India), there was significant resistance to a government proposal to make it the national language.

The main opposition came from speakers of the Dravidian languages of the south and tribal groups, who felt that they would be disadvantaged if Hindi became the language of government examinations, higher education, and interstate communication. People in the north who speak either Hindi or a linguistically related language would have a significant edge, while speakers of other languages would have to become proficient in Hindi to compete. In response to these concerns, the Indian government first mandated that both English and Hindi would be national languages until 1965, after which English would be dropped, but continued pressure forced the government to retain English for an indefinite period until it could be replaced by Hindi. Many Indian nationalists deplore this situation and feel that the continued use of the language of India’s colonizers is an affront to national dignity, but the situation seems likely to continue for the foreseeable future.

A complex system of center-state communication has been devised. Most of India’s states are organized along linguistic lines, and those states in which Hindi is dominant must communicate with the central government in Hindi. Others may communicate in either Hindi or English. In India, language is closely linked to cultural identity, and there are concerted efforts in many parts of India to ensure that traditional tongues are maintained.

English and Sanskrit

The use of English as a national medium proved to be an important aspect of India’s rise to prominence in science and technology in the late twentieth century, particularly the development of computer software. Hindi and other Indian languages are poorly suited to communication of modern scientific ideas and terminology. The development of vernacular equivalents is still in its infancy, and so the widespread use of English in elite education, tertiary institutions, and the government-sponsored Indian Institutes of Technology (IITs)—which turn out the majority of Indian information technology workers—has helped India to become an international powerhouse in software technology. English also functions as a marker of elite status in India and is seen as a sign of education and upward mobility among the middle classes. Despite this, according to government estimates, only 11 percent of Indians are fluent in English, and its use is mainly confined to the educated elite.

The use of English as an elite lingua franca has parallels to the position of Sanskrit in ancient and classical India. As with Latin in medieval Europe, Sanskrit was the language of

philosophers, writers, and religious teachers, who used it to bridge the linguistic diversity of the subcontinent. The Vedas, the earliest sacred texts of Hinduism, were composed in Sanskrit, probably between 2000 and 400 B.C.E. Most of India's great classical literature, philosophy, and religious works were written in Sanskrit, and it functioned as a means for communicating ideas across the subcontinent for millennia. Despite the widespread use of writing, oral transmission has always been predominant. The main religious duty of the priestly caste of Brahmins is to memorize and transmit the Vedas to their descendants, a process that continues in the early 2000s.

The use of Sanskrit by the elite facilitated the communication of ideas within the areas that adopted it as the lingua franca. One example of its use in communication of ideas was the tradition of public philosophical debate (*vadavidya*) among rival philosophical factions. From at least the time of the Buddha (c. 563–c. 483 B.C.E.) and Mahavira (c. 599–527 B.C.E.) such debates were common. Reports of the time indicate that they were generally sponsored by rulers and often attracted large crowds. The stakes were quite high in these contests: the winners received financial rewards, government patronage, and increased status, but the losers had to publicly acknowledge their defeat and leave the area. Thus it is not surprising that underhanded techniques were commonly used to win debates, and by the first century C.E. there were several manuals outlining the rules and proper conduct for philosophical disputes. According to Akshapada, there are three types of debate: (1) honest debate (*vada*), in which both sides seek the truth and try to establish the correct view; (2) sneaky debate (*jalpa*), in which one tries to win by any means; and (3) destructive debate (*vitanda*), in which one side merely tries to demolish the opponent's position without putting forward an alternative. The most famous practitioner of the third type was the Buddhist philosopher Nagarjuna (fl. c. 150–250 C.E.). By all accounts, because the stakes were so high, the first type of debate generally was confined to members of the same philosophical school, and the primary objective in encounters with rival traditions was to defeat them and establish one's own school as dominant.

Some of the common concerns of oral philosophical debates were: What is the meaning or purpose of life? Should one pursue sensual pleasures, or does asceticism lead to better results? Is the world eternal? Is there an individual soul, and if so, is it eternal? In ancient India there was an enormous diversity of philosophical schools, and one of the key focal points of debate concerned what should function as valid means of knowledge (*pramana*). There were a number of commonly accepted *pramanas*, such as direct perception (*pratyaksa*), inference (*anumana*), verbal testimony (or scripture, *abda*), and analogy (*upamana*). Some of the most vigorous intersectorian debates centered on issues of validity; some schools accepted all of the *pramanas*, some orthodox Brahmanical schools relied ultimately on scriptural testimony, and the Buddhists only accepted direct perception and inference. These philosophical debates were waged for millennia between rival philosophical factions, and the interchange of ideas they fostered led to significant developments within all major philosophical traditions.

Trade and the Exchange of Ideas

Because India was a major cultural and commercial center, it had widespread influence in the region. Sanskrit was not only the language of ruling elites in India but also extended into neighboring countries. Sanskrit was adopted as the language of statecraft and a symbol of royal legitimacy in Angkor (whose name derives from the Sanskrit word *nagara*, city), and was used by ruling elites ranging from Prambanam in central Java to Annam (modern-day Vietnam) to Peshawar in Gandhara (modern-day Pakistan). The languages of neighboring countries such as Ceylon (Sri Lanka), Thailand, Indonesia, and Malaysia are strongly influenced by Sanskrit and contain many cognate words. Versions of the *Ramayana* and *Mahabharata* are found all over South and Southeast Asia and continue to be widely performed, and Indian thought, myth, and cultural themes pervade the region.

In addition to being a hub of ideas and technology, India was the nexus of trade in the region. Early records indicate that guilds run by Brahmins dominated regional commerce and document commercial interactions with Thailand, Alexandria, Lebanon, Burma, island and mainland Southeast Asia, China, Vietnam, and the Philippines. India's major international trade routes began at Patna in the north and went on to Taxila, through the Hindu Kush mountains to Bactria and Seleucia, and west toward Damascus and the seaports of Ionia. Trade with China is documented as early as the first century C.E., when embassies were sent between the two countries, and a major expansion of trade took place during the Tang dynasty (618–907). The most important avenues of trade were the silk routes, which brought goods and technology by sea and overland through Central Asia. The overland trade routes from northern India went to the north and south of the Tarim Basin and met at the Chinese frontier at the Jade Gate near the oasis city of Dunhuang. The famous caves of Dunhuang were constructed between the fifth and eighth centuries and were used to store texts and images. Dunhuang became a major center of interchange between Indian and Chinese culture, and during the period that it was annexed by the expanding Tibetan empire (ninth century) it also served as a conduit for Buddhist learning and literature from Tibet, Central Asia, and China.

Beginning in the second century C.E., Buddhist missionaries began to follow the trade routes through Central Asia and made their way into China. In 142 a group of monks led by An Shigao established a translation bureau in Loyang to render Sanskrit Buddhist texts into Chinese. For several centuries interest in Buddhism was largely confined to émigrés from Central Asia, but in the fourth century significant numbers of Chinese began to convert. This led to increased importation of texts and ideas from India as well as increased pilgrimage by Chinese Buddhists to India. Among the most famous of these intrepid travelers was Faxian, who traveled overland to India in 399, and Xuanzang, who journeyed overland through Central Asia to India. Xuanzang spent a total of sixteen years there (629–645) and traveled all over the subcontinent, chronicling Buddhist institutions and schools. He brought back numerous texts and spent most of the rest of his life translating and interpreting them.

During the Tang dynasty there were reportedly thousands of Indians in China's major cities. Some were traders and others were Buddhist missionaries. Some, such as Bodhiruchi (fl. 508–537), brought more than just Buddhist learning: Bodhiruchi was born into a Brahman family and was learned in Samkhya philosophy, astrology, mathematics, medicine, and grammar. He translated fifty-three volumes of the Buddhist canon under the patronage of the emperor and was also influential in introducing the court to other aspects of Indian learning and technology. Pilgrims and traders who returned to India brought peaches, pears, vermilion, and Chinese silk with them, and many also studied Chinese medicine, astrology, and mathematics during their stay.

Conquest, Invasion, and Emigration

In addition to these generally amicable trade relations, conquest and invasion played major roles in the transmission of ideas into India. India is geologically separated from the rest of Asia; the Himalayas—the world's highest mountains—constitute its northern border, but their passes have been crossed by innumerable invaders, migrants, and travelers. One important early group of migrants was the Aryans, who probably originated in Europe and arrived in India in the second millennium B.C.E. They spoke a proto-Sanskrit language and brought their sacred texts, the Vedas. Over the course of centuries they became predominant in northern India, but their culture probably absorbed elements from India's indigenous inhabitants.

Alexander the Great crossed the Indus River in 326 B.C.E. and easily conquered the divided kingdoms of northern India, but his troops revolted at the Beas River and refused to advance, so his expansion into the subcontinent was halted. In the political vacuum left by Alexander's withdrawal, an Indian dynasty, the Mauryas (321–185 B.C.E.), conquered the Gangetic plain and the Indus River valley, but the dynasty fell apart several decades after the death of the great emperor Ashoka (r. 269–232 B.C.E.). After this there were some small dynasties, such as the Shungas and Kanvas, but none were able to match the Mauryas' power. In the following centuries there were invasions by several groups of foreigners, including Bactrian military commanders of Alexander's frontier provinces. They were followed by Persians, Scythians, and Central Asian barbarian tribes.

The Bactrians carved out small kingdoms in the northern parts of the subcontinent, and their rule was a time of cultural exchange between the Greek cultural world and India. There is evidence of transmission of technology and literature as well as medical and astrological knowledge. The works of Plato were brought to India, and the *Mahabharata* was read by some Greeks. In one famous example of intercultural exchange, the Bactrian king Menander (fl. 160–135 B.C.E.) reportedly had a series of philosophical dialogues with the Buddhist sage Nagasena, which are preserved in the *Questions of King Milinda* (*Milindapanho*). This became one of the classics of Buddhist philosophy and was translated into Chinese as early as the fourth century C.E. In this text, Menander poses questions from the perspective of classical Greek philosophy, and Nagasena answers from a Buddhist perspective. Menander is presented as

an admirer of the Buddha and his doctrine, and he seems to be familiar with Buddhist philosophy.

Buddhist thought and culture were also spread into Southeast Asia beginning in the third century B.C.E. The first successful Buddhist mission was reportedly sponsored by Ashoka, who sent his son Mahinda, a Theravada Buddhist monk, to Ceylon. After becoming established there, Theravada spread to other areas of Southeast Asia and became the dominant religion in Thailand, Burma, Cambodia, and Laos. Beginning in the seventh century, Mahayana Buddhism was adopted by the kings of Tibet, who began a process of importation of Indian Buddhist culture and learning. They sponsored Tibetan scholars to study in the great monastic universities of north India, and Indian scholars were brought to Tibet to spread their religion and to translate the Buddhist canon into Tibetan.

Beginning in the eighth century, a series of Islamic invaders penetrated into India from the north. One of these, Mahmud of Ghazni (971–1030), conquered large areas of northern India and also engaged in widespread destruction and looting of religious sites. As a result of the depredations of his armies and later Muslim invaders, the Buddhist monastic universities were destroyed, and by the thirteenth century Buddhism had largely disappeared in India. In the thirteenth century, the Ghurids from Central Asia established the Delhi sultanate, which ruled much of northern India until 1526. They in turn were defeated by the armies of Babur (1483–1530), a descendant of Genghis Khan and Timur, who established the Mughal dynasty, which ruled most of India until 1856. The Delhi Sultanate and the Mughal Empire established a prolific trade in both ideas and commerce between India and the Islamic world. Persian was the language of the Mughal court, which patronized the arts and philosophy. The height of the Mughal dynasty was a period of cultural flourishing in India, and ideas, literature, and technology circulated among India, Persia, and the Middle East as well as the rest of Asia.

In 1656 the Mughal emperor Dara Shukoh had sections of the Upanishads translated into Persian, believing that they were secret scriptures referred to in the Koran. Sufi writings and teachers also exercised significant influence in India, and this continues in the early twenty-first century. The great emperor Akbar (r. 1556–1605) was highly influential in the interchange of ideas in India and is reported to have held philosophical and religious discussions with representatives of a range of religions and traditions. Following an expansion of the empire under Aurangzeb (r. 1658–1707), internal pressures weakened it, and local hegemonies began to carve out small states.

European traders began to arrive in the sixteenth century. The first were the Portuguese, who established Goa as their trading base in 1510. In 1608 the British East India Company founded its first trade headquarters in Surat, followed by Madras in 1641 and Calcutta in 1691. During the next century, the East India Company gradually extended its control and by the eighteenth century had overcome most of its rivals. Following General Robert Clive's defeat of French forces at Plassey in Bengal 1757, Britain became the dominant power in the subcontinent and began to create rail and communications networks. In the early 1850s the East India Company

spent £110,250 on telegraph lines linking the presidencies of India (the areas under direct British rule), which along with the railways and a postal service created by the British allowed for transport of goods and ideas all over the subcontinent. In 1865 a cable link was established between Britain and India.

Indians at first perceived the British as low-caste invaders, but gradually elites began to recognize the benefits of British education and started sending their children to study abroad. At the same time, the British established English-medium schools in India for their children and those of Indian elites. As British scholars began to explore India, interest in its classical literature increased dramatically. Chairs for the study of Sanskrit and Indian culture were established at leading British universities, and religious, philosophical, and literary classics were translated into European languages. Initially the main emphasis was on classical studies, and German scholars were at the forefront of this movement. The pioneering Indologist Max Müller published the first printed versions of the Vedas in Oxford between 1849 and 1873. A French translation of the Upanishads (from the Persian translation sponsored by Dara Shukhoh) was published in 1801–1802.

At the same time, European humanism and political philosophy were widely disseminated among British-educated Indians. The most influential leader of India's independence movement, Mohandas K. (Mahatma) Gandhi (1869–1948), first read the *Bhagavad Gita* in Sir Edwin Arnold's English translation after joining the London Vegetarian Society while studying law in London. His writings indicate that in addition to the *Gita*, he was profoundly influenced by Leo Tolstoy, the Sermon on the Mount, and Henry David Thoreau. As with many other Indians educated in British schools, his thought was a mixture of traditional Hinduism and Western thought.

During their study in British schools, India's independence leaders learned about Western notions of democracy and used these against their colonizers. In addition, the British-built railroads enabled activists to travel all over the subcontinent and to speak with like-minded people in distant areas. This, along with the availability of instant communications via telegraph and, later, telephone and wireless, facilitated the process of learning to imagine themselves as constituting one people belonging to a unified nation.

Because of India's diversity, the process of nation-building and the task of fostering nationalist consciousness among its various religious, linguistic, racial, and tribal groups continues in the early twenty-first century. The growing penetration of telephone service, television, radio, and other forms of mass communication is part of this process. Probably the most pervasive and influential medium for the dissemination of ideas is "Bollywood" films, which are produced en masse and are widely popular not only in India but also Nepal, Tibet, and Southeast Asia. Most of these use a simplified version of Hindi (often referred to as Hindustani), and they function as cultural markers that contain lessons about morality, behavioral norms, courtship and marriage, political issues, and religious themes. The plots are generally thin, characters tend to be stereotypical, and the acting is mediocre at best, but they are enormously

popular and are important texts for both Indians and outsiders in regard to popular attitudes and current ideas. They also have helped to spread oral comprehension of Hindi throughout the subcontinent and even beyond, which may in time aid the government's goal of making it the national language. As it continues to define itself in the aftermath of its colonial period, India is once again emerging as a major center for the development and dissemination of ideas in Asia, and Indian thought and technology have become part of the global inheritance of humanity.

EUROPE AND ITS INFLUENCE

By the first millennium B.C.E., major world civilizations were flourishing in Mesopotamia, Egypt, the Indus Valley, and China. Each had developed a distinct form of writing, along with urban centers for administration and record keeping. In contrast, Europe was largely a series of diverse nonliterate village farming communities steeped in the conventions of primary oral communication. The eventual emergence of a literate tradition in Europe took place in Greece—at its cusp,

one of the most celebrated works in the history of Western civilization.

Orality and Literacy in Greece

Homer's *Iliad* and *Odyssey* occupy an important early niche in the history of European literature. It has been argued, however, that the Homeric epics, strictly speaking, are not even literature. In *An Essay of the Original Genius and Writings of Homer* (1775), the English diplomat and archaeologist Robert Wood initiated a continuing debate by arguing that Homer could not read or write and that the poetic character of the epics facilitated memorization and therefore oral transmission. More recent research has shown that these narratives share important characteristics with the oral histories of nonliterate societies around the world. Their aural resonance results from the use of devices such as hyperbolic turns of phrase, metrically patterned formulae, and extensive clichés.

Sometime between 700 and 550 B.C.E., the Homeric epics were committed to writing, using an alphabet the Greeks had recently adapted from the twenty-two-character Phoenician consonantal alphabet, which some scholars insist should be called rather a syllabary or consonantal syllabary. The Greek variant modified the original characters and added several new ones in order to represent a series of independent vowel sounds. This made writing easier to learn, a more complete approximation of speech, and a medium capable of transcribing different dialects and even other languages—such as Coptic, an Egyptian language recorded using modified Greek characters. Within a hundred years the convention of writing left to right displaced the right-to-left Phoenician (and Semitic) tradition. Before this conversion the Greeks briefly experimented with boustrophedon, the seemingly logical but ultimately impractical style of alternating the direction of the script in each line.

The literacy revolution in Greece had significant cultural consequences, but it must be remembered that at first what was transcribed reflected the extant oral tradition, as in the poetics of Homer. Over the next several centuries, writing would gradually take a less flowery and more prosaic turn. This evolution, in which the content of a new medium is at first that of the previous mode of communication, is a central tenet in the communication theory of Marshall McLuhan. It recurs throughout the cultural history of Europe. In the fifteenth century, for example, the incunabula, or first wave of printed books, replicated not only the content but the calligraphic style of the earlier manuscripts—the Gutenberg Bible was even printed on parchment, the preferred medium for manuscripts—and before the rise of newspapers in the seventeenth century, during the period when reports of major news events were printed in pamphlets and broadsides, they were often written in verse. Eventually, more efficacious ways of using a new medium change the forms of discourse conveyed by that medium, and so it was with alphabetic literacy in Greece.

Until the fifth century B.C.E., a teacher in Greece taught from transcribed texts that were steeped in the conventions of the spoken word. Students were expected to commit the information conveyed to memory (similarly, in the Middle Ages, a scribe might read a manuscript passage aloud in order to

ensconce it in auditory memory). By the end of the fifth century, in the period coinciding with Plato's early education, what had been recited was now read by students schooled in the new mode of communication. How widespread literacy was at this time—it was limited in theory to free male citizens—is still subject to debate. Nevertheless, its influence on institutions, such as the law, as well as on philosophy and knowledge in general, was profound. Learning the new alphabetic script was facilitated through the use of several easily accessible media—sand, slate, and waxed tablets. More permanent texts were inscribed on papyrus (imported from Egypt) and parchment (obtained from the skins of domestic animals).

Plato's Critique

Standing on the cusp of this information revolution, Plato saw benefits and liabilities in the transformation. In the utopian vision of his *Republic*, he has harsh words for both the oral tradition of Homeric verse and the later legacy of dramatists such as Aeschylus, whose writings have poetic overtones. Their emotionality, heavy reliance on sensory experience in describing the world (a signature trait of primary oral languages), imprecise use of language, and ambivalent portraits of the world and the gods Plato saw as exerting a corrupting influence on youth. On the other hand, he did not hold the new literate education, capable of circumventing these conceits, to be without its own limitations. In his *Phaedrus*, Plato uses a dialogue with Socrates—not a recorded conversation but literary prose imitating speech—to lament the attenuation of memory that is a consequence of literacy. He argues that dependency on an external source, such as writing, will diminish the internal resources of thought and memory and thereby weaken the mind. Also, since the written text is passive, a dialogic give-and-take is not possible. Yet despite these reservations it was writing—phonetic literacy, to be precise—that would facilitate the type of abstractions underlying Plato's philosophy and much of subsequent Western thought.

Alphabetic literacy fostered the gathering of a wide variety of data that would be difficult to retain using the relevance structure of primary oral communication. That this data could be analyzed and preserved for posterity is attested to by numerous texts that have come to us from ancient Greece, among them the geography of Anaximander (610–547 B.C.E.), characterized by a visionary cartographic impulse; the histories of Herodotus (c. 484–c. 420 B.C.E.); Hippocrates' (fl. c. 600 B.C.E.) treatises on medicine; the philosophy of Aristotle (384–322 B.C.E.); and the geometry of Euclid (fl. c. 300 B.C.E.), with its verbal arguments as well as figures. To this list must be added the imperial legacy of Alexander the Great (ruled 336–323 B.C.E.), abetted as it was by literate administrators.

Rome

The legacy of Hellenic culture would eventually and selectively pass to Rome. It was preceded by the art of writing itself. The Roman alphabet, nearly identical to the one we employ but limited at the time to block capitals, resulted from the modification of a Greek variant sometimes known as the Euboean or Western Greek alphabet. This diffused into the Italian peninsula under the auspices of the Etruscans, who eventually

ceded it to Rome, where it was modified into the alphabet used in most of western Europe, sub-Saharan Africa, Australasia, and the Americas. The contrasting Ionian or Eastern Greek alphabet became the standard for written communication in the fifth-century B.C.E. Athens and the model for the modern Greek alphabet; it also provided inspiration for the later Cyrillic alphabet, used to write Russian and several other Slavic languages.

Many historians contend that the intellectual and artistic achievements of Rome failed to surpass the legacy of Hellenic civilization. However, it appears that in both the Roman Republic (fifth to first centuries B.C.E.) and Roman Empire (first century B.C.E. to fifth century C.E.) the literacy rate was higher—yet oratorical eloquence was just as prized and cultivated as it had been in Greece. Earlier views suggesting that mass literacy might have existed in Rome have been tempered by recent estimates restricting it to anywhere from 5 to 20 percent of the population. Nevertheless, writing, in the form of signage and inscriptions on altars and monuments, was widespread. The ruins of Pompeii even reveal electoral posters, along with graffiti drawing on the poetry of Ovid and Propertius, which suggests that even some members of the underclass must have been able to read and write. In wealthier homes slaves were sometimes taught to be household scribes. Literacy was also not unknown among the gladiators.

The book trade, in the form of papyrus scrolls, flourished under the empire. Teams of scribes were able to produce hundreds of copies and occasionally revised “editions” of a given work—a feat usually linked with the printing revolution. Bookstores were established, and even advertised. Papyrus was, however, expensive (ordinary correspondence usually employed wax tablets) and many private libraries accumulated written materials more for status—conspicuous consumption, to use Thorstein Veblen’s term—than for the sake of having a repository of knowledge.

More so than in Greece, the communication of ideas in Rome emphasized practical arts such as the building of roads, aqueducts, bridges, and mills. Literacy also served administration and law, especially in rationalizing the transition from republic to empire. The growing body of law regarding contract and property rights and other legal obligations further inflated a growing bureaucracy. Communication over distance was accomplished through an efficient imperial postal system and an early forerunner of the newspaper, the *acta*—a sheet of relevant news that would be distributed, copied, redistributed, and when necessary, read aloud to those who were not literate. Coordinating events in time was expedited through the calendrical reforms overseen by Julius Caesar (100–44 B.C.E.), which laid the foundations of the calendar we use today. The variable (against the solar year) 12-month lunar calendar, in which the year starts in March, was displaced by a 365.2-day, (366 every fourth year), 12-month year starting in January, with the number of days in each month adjusted accordingly.

The Middle Ages

The usually accepted date for the fall of the Roman Empire and dawn of the Middle Ages is 476 C.E., when the Teutonic

prince Odoacer deposed the youthful figurehead Romulus Augustulus, thus ending the imperial succession. However, as the historian Henri-Jean Martin insists, the death throes of classical culture had begun before and continued for several centuries after that date. Earlier barbarian invasions, crippling taxes, corrupt administration, and, most likely, food shortages and epidemics all contributed to the collapse of Rome. In the fourth century, in the face of growing instability, the emperor Constantine had adopted Christianity, and Rome had eventually followed suit. Constantine had also established Constantinople as the capital of the Eastern (Byzantine) Empire, which would outlast the Western Empire by almost a thousand years.

The Middle Ages saw a more limited and ecclesiastical form of written communication than was the case in classical antiquity. The parchment codex, or *pergamenum*, displaced the papyrus scroll. Its form resembles that of the modern book, with facing pages written on both sides. The codex manuscript began appearing in the first century C.E., became common in the third and fourth centuries, and then established itself as the dominant medium for written knowledge until the advent of the printed book in the fifteenth century. The codex could compress more information into a smaller space than the scroll. Parchment is also far more durable than papyrus and has the advantage of reusability when washed, resulting in a palimpsest that often reveals traces of the original text; and although costly, it could be produced locally at a time when trade with Egypt was being curtailed.

The Roman Catholic Church assumed administrative leadership in postimperial Rome, with popes replacing emperors. Europe became a decentralized, largely nonliterate patchwork of feudal estates based on rural agriculture. The centuries that followed are usually seen as a period of cultural decline, often referred to as the Dark Ages—a term now dismissed, however, by many historians; Lynn White, for example, has argued that while classical learning may have been eclipsed, significant developments were occurring in agricultural practice (the plow and crop rotation), the mechanical arts (accurate clocks), and technology (multipurpose water-powered mills).

Monastic Expansion

By the end of the sixth century, under the auspices of Pope Gregory the Great (reigned 590–604), another invasion of Europe from Rome began. The monastic tradition, founded by St. Benedict (c. 480–547) and originally dedicated to prayer and asceticism, now formed itself into a proselytizing militia. When the churchmen moved north they were met with accommodation more than resistance as local rulers availed themselves of the literacy-based administrative skills the monks could provide. None were more appreciative or proactive in accepting what the newcomers brought than the Frankish king Charlemagne (742–814). Although his capacity to read and write is debated by historians—apparently he sought to acquire the skill as an adult—he promoted the cause assiduously, overseeing the creation of written legal charters and of schools for the teaching and standardizing of Latin, which had become plagued with inconsistent usage. This Carolingian Renaissance, as it is called, although short-lived (his empire fragmented in

the ninth century), left a profound imprint on subsequent European communication. It also yielded a new script, Carolingian miniscule, using lower-case characters with clean lines and improved punctuation.

Written knowledge became ensconced in monastic libraries that might contain several hundred to a thousand manuscripts. In contrast, however, libraries in Damascus, Cairo, and Córdoba, when Spain came under Moorish occupation in the tenth century, had upward of one hundred thousand volumes. These collections, fully employing the new medium of paper, evidenced far greater intellectual diversity than was permitted in Christendom, where the Catholic Church aggressively censored what was copied and knowledge was steeped in theological assumptions. When the church did allow secular classics from antiquity to become available, they were subject to revisionist interpretation—thus, for example, Plato was appreciated for the otherworldliness of his philosophy and his disavowal of sensory experience. Medieval texts were usually read aloud; although silent reading would begin to appear in the later Middle Ages and became the norm after printing, for most of the era it was the exception. In his *Confessions* (c. 400), St. Augustine of Hippo expresses both bewilderment and admiration when he observes St. Ambrose reading silently.

Sacred vs. Secular

The worldview of the churchmen, sometimes referred to as a cosmography, regarded nature as a book to be interpreted, not a domain amenable to empirical discovery or rational analysis. However, with new ideas entering Europe from the Crusades and through the Islamic presence in Spain, as well as from the newly emergent church-founded universities, some accommodation became necessary. In response, Thomas Aquinas (1225–1274) argued for a partial application of rational methods to an understanding of the world, provided scriptural revelation remained the final arbiter. The Franciscan Roger Bacon (1214–1294) abused this license with a series of experiments, most notably in optics, that resulted in his imprisonment. The fate of others who transgressed Catholic ideology is chronicled in the history of the Inquisition.

In communicating its teachings to the mostly nonliterate masses, the church employed a rich iconography. Cathedrals were texts to be read; each image told a story. By the thirteenth century, clerics, drafting voluminous contracts, charters, and wills, began to increasingly serve the needs of both secular rulers and a merchant class that had been growing since the emergence of towns two centuries earlier. Still, in this mostly oral world, the language of everyday life remained poetic. Rhymes were used to remember everything from agricultural practice to accountancy, and newsworthy events were conveyed in song by traveling troubadours. The period also saw the beginnings of writing in local languages, or vernaculars, facilitated through the spread of paper, which had initially entered Europe via trade and by the fourteenth century was increasingly being manufactured there. Vernacular literatures emerged, as evidenced in the writings of Dante (1265–1321), Petrarch (1304–1374), and Chaucer (c. 1342–1400).

The Print Revolution

Although few scholars would argue that any single technology merits the label “historical prime mover,” moveable-type printing is certainly one of the few likely candidates. It gave new impetus to the Renaissance already underway, opened the door to modernity, and offered a technique for mass production that would proliferate during the industrial revolution. Johannes Gutenberg, a goldsmith from Mainz whose forty-two-line Bible was printed in 1455, is usually deemed the creator of the new medium. It must be remembered, however, that printing from wooden blocks had begun seven hundred years earlier in China, and that by the eleventh century the Chinese were experimenting with moveable type using baked clay characters. Since Chinese print shops required thousands of such characters, given China’s nonalphabetic script, and since the results were less aesthetically appealing than block books, the experiment had not endured. By the late fourteenth century Korea had developed both an alphabetic script and moveable-type printing using bronze characters. This remained a temporary development. It was the European variant of the technology that would eventually sweep the world.

By 1501, European printers had turned out twenty-seven thousand known publications totaling over ten million copies. Further growth would be exponential. Early print runs produced from two hundred to a thousand copies of a book at a cost far below that of scribal labor, not to mention the greater affordability of paper versus parchment. Although literacy rates rose steadily, nothing approaching mass literacy would emerge until the nineteenth century. Churchmen and scholars were the first to avail themselves of the new printed texts, with Bibles, prayer books, and the Latin and Greek classics having priority. By the sixteenth and seventeenth centuries, however, dictionaries and treatises on philosophy, science, and medicine, often with woodcut illustrations, became widespread. Practical manuals in the technological arts also proliferated, diminishing a dependency on face-to-face apprenticeship in a number of fields.

The printed book assumed a look that was clearly different from that of the medieval manuscript. Printers such as the Venetian Aldus Manutius (Aldo Mannucci; 1449–1515) reduced its size (his Aldine editions prefigure the contemporary pocket book), streamlined the font, and made many Greco-Roman classics available in translation at a relatively low cost to the Renaissance consumer. Other features that we often take for granted began to appear: a regularized title page indicating the date and place of publication, improved punctuation, and layouts that made silent reading the norm. The index, once an oddity in manuscript culture, was now often used to make reference works easier to use.

The spread of knowledge brought about through printing increasingly drove a wedge between the world of the theologians and the views of both secular scholars and an emerging bourgeoisie with vested commercial interests. Print also abetted a schism within the church itself, when religious leaders saw it as a way of expediting the reproduction and sale of papal indulgences. This, along other church “indulgences,” led a German theologian, Martin Luther, to nail to a Wittenberg

church door ninety-five theses (1517) advocating reform. His grievances were soon printed and the church responded in kind, resulting in a full-scale war of words and, ultimately, the Protestant Reformation.

Philosophy and Literature

Although Luther oversaw the first vernacular edition of the Bible, in German—only to be perturbed by how some in his flock interpreted various passages—the first two centuries of the print revolution saw Latin still used for most scholarly publications. But it was a language on the wane, as was the influence of theology on both natural science and the newly emerging human sciences. Nicolaus Copernicus (1473–1543) and Galileo Galilei (1564–1642), the former somewhat reluctantly (he was averse to seeing his work in print) and the latter stridently, challenged theological orthodoxy in scientific matters. By the eighteenth century in France, the Enlightenment philosophes demanded the removal of theological explanations from the realm of history. They also sought a science of man based on the models and methods of the natural sciences. Many were inspired by and participated in one of the great book publishing ventures in history, the French *Encyclopédie*, edited (1751–1772) by Denis Diderot and Jean d’Alembert. The seventeen volumes (eleven volumes of plates) identified its contributors, defied government and church attempts at censorship, and symbolized the age more than any other writing project.

Print also brought into wider circulation the vernacular literatures of Europe. At first this did not require widespread literacy, as broadsheet ballads and chapbooks could be read aloud to the nonliterate. Authors were usually funded by a patron. The eighteenth century also saw an increase in the literacy rate, though, with writers now becoming dependent on the whims of the marketplace. Book purchase was often beyond the means of an expanding audience of readers; rental from a growing number of circulating libraries, however, became a viable option.

The nineteenth century, sometimes referred to as “the age of the novel,” saw a series of changes that made books less costly and would by its end usher in nearly universal literacy. The making of linen rag paper moved into the world of industrial mass production as waterpower replaced manpower, and was in turn replaced by steam. Early beneficiaries included Walter Scott, whose *Waverley* (1814) became a best-seller, as did Charles Dickens’s *Pickwick Papers* (1836). The last quarter of the century witnessed a further drop in the cost of books resulting from the process of manufacturing paper from wood pulp rather than rag. This served to make not only novels but also works dealing with travel, adventure, and popular science affordable. Small personal libraries, once the preserve of the aristocracy, gentry, and later the bourgeoisie, now became an aspect of many working-class homes.

News

Orators in antiquity, the Roman *acta*, medieval troubadours, and handwritten and early printed broadsides were some of the ways through which news had circulated in premodern Europe. The first true newspapers, defined by a regular publication schedule, were weeklies that began in Germany in the

first decade of the seventeenth century. Other countries quickly embraced the idea. Written in the vernacular, these publications were in part a response to the rise of nation-states and their growing economic interdependence. Freedom of the press was virtually nonexistent. In most countries a government license was required to publish newspapers as well as books, which meant submitting to censorship and high taxes. Circulation was limited to a few thousand readers at best. Domestic news was minimal and any critique of the government could lead to a charge of treasonous libel, for which several printer/publishers were executed. “Safe” domestic stories included the occasional and usually sensationalized account of a gruesome murder—an intriguing link with contemporary tabloids.

Beginning in London in the first decade of the eighteenth century, the daily newspaper became a fact of life in many large European cities. Greater public access to information, coupled with the ideals of the Enlightenment, especially free speech, led to laws guaranteeing freedom of the press. The first of these was passed in Sweden in 1766, and by the end of the next century most European countries had followed suit. During this period newspapers became a true mass medium. Contributing factors included the rotary steam-driven press, which reduced production time; the viability of engraved illustrations, a feature popularized by the *Illustrated London News* when it began in 1842; and the spectacular increase in the speed of information movement the electric telegraph brought to news gathering—demonstrated dramatically in coverage of the Crimean War (1853–1856). By the turn of the century, wood-pulp paper, the linotype machine (invented in the United States), the half-tone process for reproducing photographs, and increased advertising allowed newspapers to expand their size and scope without a substantial increase in price. These changes also helped give them a look that would endure well into the twentieth century.

MIDDLE EAST AND ABROAD

The great continental Eurasian landmass, with its vast steppes stretching east to west in a more or less uniform climatic belt, has been a useful path for the transit of ideas and techniques throughout history, with what is now the Arab world as the fulcrum of the exchange between China and Europe. Over roughly the first thirteen or fourteen centuries of the Common Era, there was a slow, steady diffusion of ideas and, particularly, technology from East to West.

The Ancient Near East

The administration of large political entities, whether kingdoms or empires, required skills in writing and numeracy for administrative purposes, so that the ruler's writ could be understood by his officials and communicated throughout the land. In ancient empires there was a priestly monopoly on secular, as well as esoteric, knowledge. In societies whose cultural "memory" was limited by their inability to store large quantities of data in archives, the centralization of all knowledge was no doubt functional. Monopoly of knowledge was based on stone (later papyrus) and pictographs in Egypt, clay tablets and cuneiform in Mesopotamia. Difficult scripts were ultimately a constraint on both governance and trade, so expanding empires required conventionalization of the written language.

Conquest, in turn, involved the mixing of languages and writing systems. The Sumerians had a word-value writing system, while that of the Akkadians was based on syllable values. Simplification of writing was paired with the adoption of the sexagesimal counting system in the centralized bureaucracy established by Hammurabi (1792–1750 B.C.E.; Old Assyrian Empire, 1800–1375 B.C.E.). The sexagesimal system had been passed on after 2000 B.C.E. from the Sumerians to the Babylonians and Assyrians, "together with their cuneiform script, which they adapted to their Semitic languages" (van der Waerden, p. 667).

The alphabet was invented by Semitic peoples, possibly in Palestine, on the fringes of the Babylonian and Egyptian

empires before 1500 B.C.E., and perfected along the Phoenician coast. The alphabet formed part of an integrated writing system that came to include papyrus and the reed pen. Two families of script emerged: one Phoenician (reflecting demands of maritime trade and an alphabet that could be used with papyrus), the other Aramaic (responding to demands of land-based trade and, possibly, the use of parchment). The alphabet was flexible, and it favored the growth of trade and the rise of cities. Extensive oral traditions of the ancient Jews and Egyptians now could be written down. The written letter replaced the graven image. The ban on graven images in Judaism (and, later, in Islam) may well reflect ancient rivalries with peoples whose writing systems were based on pictographs.

The centralization of power (Assyrians, then Persians) involved problems of communication and transportation, both of which were reflected in administrative capacity (the ability to move documents over space) and continuity (the ability to store documents over time). Laws and edicts had to be delivered to provincial governors and also stored over time in a central archive to promote continuity and stability, both in administration and in law.

Conquest has always been a powerful means of cultural diffusion. When the Persians conquered Egypt in 525 B.C.E., they set off a century of intense cultural exchange. Babylonian astrology may have first reached Egypt then (Parker, p. 723). Conquest also had systemic effects on language use. The Roman conquest (and doubtless that of the Arabs later on) had the effect of destroying oral cultures and replacing them by a more standardized written one. This has been a constant of Middle Eastern history.

Ease of communication meant that there were continuous or intermittent cultural exchanges over long periods of time between the same places, in both directions. Thus, Indian mathematical astronomy received a constant infusion of new ideas from the West: in the fifth century B.C.E. from Mesopotamia via Persia; in the second and third century C.E. from Mesopotamia via Greece; in the fourth century C.E. directly from Greece; in the tenth through the eighteenth centuries from Persia; in the nineteenth century from England. In the first three transmissions, the Indians got theory that was either out-of-date in its country of origin or else was deviant, so there was virtually no reflection of Ptolemaic astronomy in India until the seventeenth century (Pingree, p. 533). At the same time that elements of Greek astronomy reached India, the Arabs introduced Indian astronomical tables in the Middle East and adopted their format.

Medieval Communication and Transportation

The East-to-West process of diffusion picked up pace subsequent to the Islamic conquests, when the Islamic world acquired (in the words of Joseph Needham) "a focal character in the process of diffusion." The innovations diffused included a package of Indian crops and the irrigation technologies needed to grow them in arid or semiarid environments that the Arabs recognized as comprising a distinctively Indian style of agriculture, which they called *filaha hindiyya* (Indian agriculture). The package included the *noria* (an animal-powered

water-lifting wheel), and a whole roster of crops including sugar cane, rice, citrus trees, and the watermelon. From Persia came the *qanat* or filtration gallery (a way of tapping water for irrigation that became attached to the Indian package), perhaps the windmill, the artichoke, and the eggplant. China was the most fecund source of technological innovation (paper, block printing with a press, the compass, gunpowder, to name only the most salient). The agents of diffusion were varied, mostly merchants and soldiers fulfilling their characteristic historical role as bearers of new ideas, but agricultural innovations were typically borne by folk migrations of tribal segments or clans, such as those who left Arabia in the seventh century and whose children and grandchildren settled in Islamic Spain, where they introduced Indian-style agriculture.

The Silk Road was an overland caravan system (with a number of auxiliary sea routes via India) that brought silk from China to Mesopotamia or the Roman frontier around the first century C.E., and to Baghdad after the Arab conquests. Not much merchandise besides silk was carried because there was little demand in China for Western products, with some exceptions such as Roman glassware. However, once established, the route became a conduit for the spread of ideas and techniques. Medieval Arab and European travelers (for example, ibn Battuta [1304–1365] and Marco Polo [1254–1324]) used it, as did merchants, and some specific Chinese techniques, such as textile machinery, are known to have reached Europe via the Silk Road. Chess is thought to have been a diversion perfected by Muslim Silk Road merchants. Persian merchants bore ideas to and from China to Persia from the fifth through the tenth centuries.

Richard Bulliet describes a reciprocal relationship between the decline of Roman roads and the introduction of the camel. Camels do not need paved roads. The Muslim conquest represented, in its early centuries, the dominance of nomads over settled areas, made possible by the adoption of the North Arabian camel saddle. Once the dominance was established, a decisive cost factor (20 percent) over shipping by wagon quickly led to the disappearance of wheeled vehicles in most areas of the Islamic world. Roman roads were already in decline and the caravan routes that replaced them were shortened long-distance overland trade routes because wheeled vehicles required fairly gentle gradients (following the crest lines of ridges rather than heading straight across valleys). With respect to trade, caravan routes were linked to overseas trading networks, forming a great web for the transportation of goods that knit together the “world economy” of the Islamic Empire. Trade over long distances led to the invention in the Islamic world of methods of business organization and credit that later were adopted, first in Italian commercial ventures, then those of other European countries: the partnership among merchants, called *commenda* in medieval Europe, was known in the Arab world of Muhammad (Arabic, *shirka*, “partnership”) and the European bill of exchange was modeled on the Arabic *sufiyya*, the check on Arabic *sakk* (both conceptually and etymologically). The Muslim world economy functioned as a kind of free-trade zone (propitious as well for the transfer of ideas and techniques), powered by the gold *dinar* and the silver *dirham*.

Medieval Translation Movements

The great translation movement that began in ninth-century Baghdad displays an overall pattern quite similar to that of the westward movement of technology from China, India, and Persia. The movement began through an internal mechanism: the Sassanid kings of Persia (224–651 C.E.), whose mantle of authority and legitimation the Arab Abbasid caliphs (750–1256 C.E.) sought, had maintained a palace library and manuscript copying office whose task was to carry out an ideological precept of the Sassanid state, which was that Persian and other ancient lore should be preserved in a central place. One of Persian kingship’s claims to legitimation was that it was the guardian of knowledge. Under Arab rule, this palace library, with the same task, was known as the Dar al-Hikma (House of Wisdom). The Abbasids clothed this preexisting rationale with a geopolitical cloak: its message to both the Persian elites to the East of Baghdad and the Greek-speaking masses to the West was that the caliphate was the only legitimate heir to their respective cultural traditions. Thus did the entire extant corpus of Greek wisdom come to be translated into Arabic; to it were added, in particular, Persian and Indian components. Among the latter was a family of celestial charts that, when coupled with Ptolemy’s theoretical astronomy, laid the basis for medieval Arab, and later Latin, astronomy, which, along with Indian numerals (including the zero) and the place-value system, formed the core of the medieval scientific achievement.

This scientific movement, based at first on translation and the retrieval of ancient lore, was an epiphenomenon of the ease of communication within the Eurasian landmass, facilitated by the political unity provided by the Islamic empire of the early Middle Ages. Travel for the sake of knowledge (Arabic, *al-rihla fi-talab al-ilm*) was characteristic of both Muslim and Jewish scholars, who traveled from one end of the Islamic world to the other in order to study the religious and secular sciences with famous teachers.

The assimilation of knowledge originating in cultures different from that of the core society always involves not only a range of linguistic problems associated with translation but also culturally rooted conceptual problems. Among all the peoples involved in medieval “translation movements” (Greek and Persian into Arabic, Arabic into Latin, Hebrew, Chinese, and European vernacular languages), there was a fairly standard debate about the relative merits of literal versus free translation (Latin, *ad verbum* and *ad sensum*, respectively). In some cases, defective texts bearing alien conceptions were passed along in the most literal fashion possible in order to preserve what sense there was. Such was the case of Aristotle’s *Posterior Analytics* (350 B.C.E.), which survived in the form of student notes and which, having passed through an Arabic translation, became one of the keystones of scientific method in both medieval Islam and Europe. The Arabs also had conceptual difficulties with Aristotle’s *Poetics* (350 B.C.E.), much of which presumes familiarity with drama, because there was no such literary tradition in their culture. In the case of alchemy, a series of translation errors that confused the color gold with the metal, dating to classical antiquity, led to an increasingly esoteric body of knowledge that, at each successive step, compounded the error.

Once a core of science existed in Arabic, it was then diffused again in both directions from Islamic civilization through the Eurasian plain, eastward to China and westward, through Sicily and Spain, to Latin Europe. Arab astronomy (and its practical side, astrology) reached Latin Europe in the early twelfth century, several decades after the Christian conquest of Toledo (1085), and reached China about a century later. The Chinese founded observatories and staffed them with Muslim personnel. Interest in both East and West was pre-eminently practical: astronomical calculation of calendars and the practice of “political astrology,” the assessment of favorable times for military, political, and economic activities.

When one considers the relative importance of oral versus written culture in the communication of knowledge, perhaps one can profitably begin with the case of mathematics (which has the advantage of reducing ideological issues to a minimum). Even after the reception of Indian calculation (*hisab al-hind*) in the Arabic-speaking world, calculation (among merchants, for example) continued to utilize hand signals. If the intermediate steps were written, a dust board (the original sense of *abacus*) was used, then erased, and the results were often written down in alphanumeric form. So in mathematics and commerce there was always a range of media available and, in practice, they were mixed according to various utilitarian principles. Similar mixes of oral and written culture were probably equally useful in other areas of human experience.

The game of chess originated in India, and was then cultivated in Persia, the immediate sources of the Arabic game *al-Shatranj*. It followed the same path of diffusion westward as did Indian astronomy and mathematics and had the same audience, namely educated people attracted to mathematics and logic. The first technical treatises on chess in Arabic appeared in the ninth century. There was also a popular variant of the game that was astronomical in nature, played on a round board divided into the twelve houses of the zodiac. Part of the reason that chess was popular among Muslims and Jews is that gambling was forbidden by both religions, an example of a cultural stimulus to the adoption of an innovation.

Paper and Literacy

The culturewide significance of media of communication can be appreciated from the example of paper. Paper reached the Arabs in 751 C.E. when they conquered Turkistan and found Chinese papermakers there: “It is stated that craftsmen from China made [paper] in Khurasan like the form of Chinese paper” (Ibn al-Nadim, I, 39–40). The technique reached Iraq in the precise moment that the Abbasids were consolidating power, with administrative as well as cultural consequences. The caliph Harun al-Rashid (r. 786–809 C.E.) instituted the first of several bureaucratic reforms based on the use of paper. The chemistry associated with the fabrication and use of paper and inks reflects a characteristic mix of Indian, Persian, Greek, and Babylonian elements that appears in the movement of translation, especially early Arab alchemy. With an administrative reform of the early tenth century, all Abbasid edicts had to be copied on paper for provincial governors and for preservation in registers. Thus, paper was crucial to administrative expansion and bureaucratic consolidation, giving the

Abbasids an augmented capacity for governing far-flung provinces effectively.

Paper was associated with a vertical mill, whereby a water wheel turns a horizontal axis fitted with hammers. Paper was one element in a unified set of Chinese technologies that diffused simultaneously westward along with the mill type: preparation of different kinds of oil, paper, sugar, indigo, lacquer, and tea—all of which require pounding or maceration (Daniels, pp. 30–39)—bringing the paper and sugar industries to the Middle East simultaneously. The names *al-Warraq* (papermaker) and *al-Sukkari* (sugar maker) appear in ninth-century Iraq.

It is thought that, because of the democratizing effect of paper, literacy was more widespread in the Islamic world than in medieval Europe, where both writing (on parchment) and reading were the province of a small, mainly clerical elite. But the definition of literacy has recently broadened somewhat: a person may well have a piece of paper (a deed, a horoscope, a prescription) that cannot be completely read, but the contents are generally understood. There was a great deal of what might be called partial literacy, and many people who could read (at whatever level) could not write. The two skills were not as tightly linked as they have been in recent centuries. Among Muslims and Jews, reading in particular and, to a lesser degree, writing, were skills that were required for an ordinary religious life, dependent on mastery of scriptural and other religious texts (hadith, Talmud). The Cairo *Geniza* (a repository of tenth-century documents written in Hebrew and Judeo-Arabic) shows a certain democratization of ideas: almanacs, amulets, horoscopes, prescriptions, and other such quasi-scientific paraphernalia were widely circulated.

Sacred objects were visualized in different ways. Judaism and Islam were iconoclastic, the Persians less so, thus human figures adorn their manuscripts. But the Muslims liked other kinds of representations such as huge, ornately lettered Korans.

The Ottomans and Early Modernization

There was an eastward reflux of technological diffusion when Jews and Muslims were expelled from Spain, the Jews in 1492 and the Moriscos, in a steady flow of emigrants from 1492 through the definitive expulsion of 1610. The Moriscos took back to North Africa a version of Indian agriculture (Arabic, *filaha hindiyya*) updated especially with New World crops (maize, tomatoes, American beans, chili pepper, *opuntia* [cactus], and tobacco). The Ottomans (and the Mamlukes before them) received firearms from different sources, but the Moriscos diffused the Spanish approach to artillery. Ibrahim ibn Ahmad ibn Ghanim, a Morisco who had been an artilleryman in Spain, arrived in Tunis in 1609–1610 and wrote an influential artillery manual in Arabic, in great part paraphrased or translated from Luis Collado’s *Plática manual de artillería*.

Spanish Jews introduced a new, modern textile industry, that of broadcloth, into the Ottoman Empire, the new cloth being the result of the introduction, from Spain, of a fulling mill that made for a stronger, cheaper brand of textile. A French traveler in Istanbul in the mid-sixteenth century remarked that the Marranos “were the men who have taught the

Turks how to trade and to deal with those things that we use mechanically.” In Cristóbal de Villalón’s pseudonymous sixteenth-century *Viaje de Turquía*, the author explains that the Turkish artillery corps

had no masters to teach them (particularly how to mount pieces on carriages) until the Jews were thrown out of Spain. They showed them how, as well as how to fire muskets, to make forts and trenches, and whatever devices and strategies there are in war, because before they [the Turks] were no better than animals.

The report is exaggerated, but all the crafts of the Renaissance military engineer are represented. Giovanni Soranzo (doge of Venice, r. 1312–28) is said to have prevented the expulsion of the Jews from Venice in 1571 on the grounds that Jewish refugees from Spain had taught the Turks how to make cannons, cannonballs, and other armaments. That Jews had modernized medicine in the Ottoman Empire had become a cliché in European commentary by the eighteenth century. Villalón, referring to Jewish physicians in the Ottoman court, says they practiced there “almost by inheritance.” Those physicians diffused a kind of compendium of late medieval European medicine.

The traditional culture of the Middle East also offered ample resistance to innovations: some opposed the telegraph because they supposed that spirits inhabited the wires. Jews or Christians generally established the first printing presses in the Ottoman Empire or Islamic world because Muslims had long opposed printing on religious grounds. The first government gazette in the Ottoman Empire appeared in Turkish and Arabic in 1867, the first newspaper, the following year (the first newspaper did not appear in Persia until 1935).

Modernization

The predominant pattern of innovation in the nineteenth century was that the Ottomans filtered the European model of modernization and diffused specific techniques to selected sites in their empire. Centralization was the dominant political ideal associated with modernization. In terms of Arab society, this translated into bringing tribes under central control, which, in turn, involved a stepped-up military capacity and favored spatially unifying technologies such as the telegraph and the railroad. Bedouins realistically viewed the telegraph as an unwelcome government intrusion. The first Ottoman telegraph lines were built in 1855. Beirut was linked to Damascus in 1861 and to Istanbul two years later. Then Iraq was linked by telegraph to Istanbul, but also to India, a move that was thought to enhance the economic stability of the country (England pushed for this to enhance its control over India after the Mutiny of 1857–1859). Istanbul was linked to Arabia in 1901, complementing the Hijaz railroad, which linked Syria to Arabia. The telegraph and railroads were a unifying force economically (because they increased the volume of commerce in the towns and districts along their routes and in their termini) and politically. Because the Hijaz railroad carried pilgrims, it became a visible, material symbol of Pan-Islamism.

The telegraph and railroad were designed to reduce the time and distance factors across the great Eurasian landmass.

Ottoman imperial administration differed in places that had the telegraph, where communication was instantaneous, and those that didn’t, where it took days for dispatches to arrive, with palpable results in law enforcement, tax collection, price and wage regulation, and so forth. The telegraph was also a spur to democratization, as citizens used telegrams to petition the central government directly. As a result, the pace of innovation may have quickened, at least in cities, and selected rural economies certainly benefited. However, the deeper cultural manifestations of such technologies have yet to be explored.

Darwinian evolution illustrates how acceptance or resistance to modern scientific ideas was channeled along religious lines. The Syrian Protestant College in Beirut (later American University of Beirut) was famously a node of diffusion of Darwinism. The chief backer of Darwin there, Edwin Lewis, was fired for his efforts, but not before having passed the idea to students, mostly secular writers of Christian origin who continued their advocacy of Darwin in Lebanon and Egypt. Among Muslims, interestingly, Shiite theologians tended to have a more moderate view of evolution than did their Sunni counterparts. Religious opposition was uniformly based on scriptural authority, although moderate (generally Shiite) commentators stressed that there was no specific Koranic warrant to oppose the theory.

What explains the receptivity to innovation in the early Islamic world and the rejection of innovation in the modern Islamic world? Under what circumstances did Islam itself become a barrier to the diffusion of ideas and techniques? In the broadest possible terms, so long as a minority of Muslims ruled a majority of non-Muslims (a garrison state model), it was to the advantage of the rulers to be open to whatever innovations might increase their power and augment their prestige. Once Muslims were in a majority, a kind of cultural self-sufficiency set in, which turned the interests of the elite inward, toward refining the Islamic system, which was (in theory, at least) a kind of theocracy in which no distinction was made between religious and civil (legal) spheres and in which religious law regulated all aspects of daily life. Innovation was viewed as arbitrary, having no basis in recognized tenets of Islam. The traditional education system, mosque-based schools (*madrasas*), never evolved into a system that could encompass exogenous elements. In such a cultural system, innovation is irrelevant. *Bid’a* (Arabic, “innovation”) was held to be both good and bad, betraying ambivalence (at the least) toward innovation, and was invoked selectively against, for example, tobacco, coffee, and various aspects of modern science.

ORALITY AND THE ADVENT OF WRITING

The communication of ideas is not basically different from any other type of human communication. It is founded on the unique human skill of speech, a highly developed and formalized system of audio communication, which links with animal sounds and other forms of the communicative act but is infinitely more sophisticated. The jury is still out on the question of the genetic component in spoken language, but that need not affect this analysis of its consequences.

Communication of Ideas in Oral Cultures

The development of human society over the long term is affected by the speed and accuracy with which ideas are transferred from one individual or group to another. In the Old Stone Age, or Paleolithic period, such a process was slow since

communication in the sense of physical movement was slow. And with oral communication, virtually all transfer had to be face-to-face, a matter of constant conversations over time. Nevertheless, ideas were exchanged and human life slowly changed, for example, from using one type of stone tool to another in parallel ways throughout the world. Of course, one reason for this commonality could be the intrinsic logic of development, in which intergenerational communication would also be important, but the intergroup transfer of ideas has been of overwhelming significance in much of human history.

How is it that nonutilitarian ideas, for example, even about witchcraft and sorcery, about mystical aggression, are so similar in preindustrial societies in many parts of the world? The standard answer would be phrased by reference to some version of the idea of "primitive mentality," that these ideas were appropriate to "primitive societies." At a very general level, such a contention may be valid but circular. It follows a line of thinking that sees similar environmental conditions (for example, in hunting and gathering economies) as producing similar sets of ideas. That is a tenable position. But the degree of similarity is the crucial issue. These ideas of witchcraft, like the idea of the alphabet, seem very close to one another in contexts where the possibility of alternative conceptions seems to be wide open. So there is not simply the question of the general appropriateness of ideas to a particular set of socioeconomic circumstances but of the communication of more specific notions over time, possibly in this case internally from a common source.

A clearer case is that of the folktale. The collections of Stith Thompson trace distinct thematic similarities over many parts of the world, some of which, like the Cinderella stories, show considerable resemblances over wide areas. It is highly unlikely that such tales have emerged independently, given the common features, nor yet that their distribution reflects some early wanderings of peoples. Rather it is surmised that they represent the transmission of particular stories from one community to another by travelers or by itinerant storytellers, who provide a precise mechanism for their circulation. Naturally such stories have to be "acceptable" to the recipients, but acceptability does not mean that they have to reflect in any precise way the sociocultural conditions of those who listen and adapt the stories. In northern Ghana, folktales incorporated the notion of chiefship (*nalo*) even among chiefless groups who had never had, or had rejected, the institution but who knew that it existed in neighboring states. One aspect of the folktale was therefore "imaginary" in some communities, embodying ideas of authority that they did not accept as part of their own way of life. So such tales were unlikely to have arisen independently but rather by some process of intergroup communication since their thematic content was not functionally or structurally integrated with the cultures themselves. In this case intercultural communication occurred in oral cultures by means of a specific mechanism, the traveler or the wandering "teller of tales."

That process continues to be of great significance in the spread of ideas and information even in written cultures, where wandering scholars, past and present, are important elements

in the process of communication. Physical movement is still of great significance in the early twenty-first century. Despite electronic means of communication that supplement and could perhaps eliminate them, conferences proliferate, not simply as an excuse for academic tourism; in certain fields at least they are seen as ways of gaining access to the latest ideas, or perhaps to the creators of those ideas. In other words they are seen as contributing to the exchange of knowledge. Above all they serve to set up personalized networks that have the function of leading to collaboration between individuals and groups working on similar topics, contacts that serve to facilitate the flow of ideas by establishing informal (oral) communication to supplement the more formal and more widespread type made possible by the use of the written word.

Such international conferences, involving an increased tempo and range of contact, depend upon the development of new modes of transport, especially relatively cheap air travel that is changing ways of life in other less formal ways. Whatever doubts may be expressed about travel broadening the mind, it has certainly led to some shifts in terms of everyday behavior, such as food and drink. Even if mass tourism has not led to any very evident changes of a more conceptual kind, it seems likely that the opportunities for the youth of Europe to travel to India or Nepal has resulted in an increased interest in the religions of those areas, and hence in Buddhist, Islamic, or Hindu philosophical notions. Vegetarianism and a different attitude toward the slaughter of animals, and to the nature of the boundary between “us” and “them,” becomes an important part of the belief systems of the Western world that had hitherto been largely characterized by its addiction to the eating of meat. For such persons the notion of animal rights includes their right to stay alive.

Written Communication of Ideas

The communication of ideas took on somewhat greater possibilities when humankind moved into the graphic age in the Upper Paleolithic, with the elaboration of cave art and the use of signs, such as the palms of hands and what have been called “traces” by Jacques Derrida, though under this rubric he includes not only graphic marks but also the memory traces of speech. However, these were not “writing” in the full sense since they did not systematically represent the spoken word externally, but they did mean that visual signs with restricted meanings, as in the North American wampum belts, could be communicated to others at a distant destination. Obviously there had to be some community of understanding, for example, that an arrow meant danger, but a full linguistic code came only with the invention of writing in the Fertile Crescent of the Near East around 3000 B.C.E. Then a whole sentence or conversation could be transferred over space and over time with greater speed and accuracy given that it was preserved in a relatively permanent form, on tablets or on papyrus, as “visible language.” As a result, ideas could be transmitted from the past, from earlier civilizations (in the strict sense of that word) without any human intermediaries. The works of Aristotle might be forgotten, lost for a while, by Europeans and then brought back into circulation by way of Arabic translations some thousand years later. So his ideas never disappeared in the way they

did in oral cultures of which the Senegalese author Amadou Hampaté Bâ wrote that “when an old man dies, a whole library is burnt.” With writing, the previous generation is no longer the only or main source of cultural ideas. They can now be bypassed by reference to books that form a quite independent source of knowledge. One is no longer limited to folk wisdom, to the sayings of the elders; one can refer to the works of Plato, of Moses ben Maimon (Maimonides), of Mencius, or of Indian philosophers, which one’s teacher, either in the family or outside, may have never read or possibly even heard of. Intellectually and in other ways, the relationship with one’s family is dramatically changed. The death of an old man is of less account since his ideas are already recorded or irrelevant. The educational process takes on a totally different character.

Turning speech into a visual, material object also makes possible the communication of ideas and information at a distance. An individual can send a message far away without being involved face-to-face. That has had disadvantages as well as advantages. The former mean that verbal messages became divorced from the wider context of speech, so that one misses the accompanying gestures and tonality and moves to a great decontextualization of language and a certain depersonalization of the process of communication. But the great advantage lay not only in giving linguistic communication a permanent frame but at the same time in making it more “abstract.” It did not, of course, introduce abstraction but it did increase the resort to more abstract notions; nouns were often preferred to verbs; what had been implicit speech became more explicit in the written register. The latter, being visible, enabled a more detailed examination of linguistic expressions by the eye, which could range back and forth over the page, reappraising and reviewing the ideas that had been formulated there. Once again such a considered approach to what was being said was not impossible in oral intercourse, but it was not easy and inevitable as it became with the written word, which then saw the virtual birth of activities that were later to be named “philosophy” or “theology.” Both the “sophia” and the “logos” were stimulated by the use of writing, subsequently giving birth to a whole range of topics that had remained only implicit in purely oral cultures. It is true that then one can speak of ethnoscience such as ethnogeography or ethnobotany. All societies have concepts of space and time, and all resort to some classification of the animals and plants that surround them. But those fields of enquiry are significantly advanced by the use of written lists that impose a beginning and an end on particular sequences and hence give rise to explicit questions of inclusion and exclusion that probe the nature of categories.

In some written languages, the category is even shown in the way a word is constructed. In Mesopotamian cuneiform, for example, a certain suffix may indicate whether one is referring to a god or a town to which the god is attached. That is one of the advantages of nonphonetic scripts; they can point to the range of phenomena or ideas in which one can search whereas phonetic scripts such as alphabets are necessarily limited to the information contained in the oral forms.

This attempt to classify ideas and information was promoted by the development of schools, which were necessary to teach

the techniques of reading and writing, so that the system could be passed down from one generation to the next. Unlike other innovations, that transfer could not be achieved within the family. It was now useful for pupils to be segregated from the family and to have lists of plants and animals as exercises, a process that led to the consolidation of lists in encyclopedias, such as the *Onomastica* of Egypt, as well as to the emergence of distinct fields of enquiry, such as zoology, and to the development of more integrated, more precise, more “scientific” sets of ideas, which became more readily communicated to those who had studied a particular field than to the public in general. As such sets of ideas developed, they were more readily communicated to a specialist audience, except in a watered-down, “popular” form. Since some ideas became more difficult to communicate unless to an “educated” audience, the relative unity of knowledge in oral cultures with memory storage became shattered into particular spheres with writing.

Literate and Illiterate Communication

The greatest division of this kind was between those who could read and those who could not, a division that applied not only to cultures, literate and nonliterate, but to individuals within societies, literate and illiterate. For the first five thousand years of the history of writing until the end of the nineteenth century, writing was (with a few, marginal exceptions) acquired only by a minority of the population. In many ways, the literate minority made most of the running intellectually. They were responsible for the written religion, for the schools, the administration, the written works of literature, drama, music, and poetry, producing and communicating many of the dominant ideas. The rest of the population were, of course, affected by these developments, for example, by way of the “Bible of the Poor,” through images; their intellectual apparatus was also influenced by techniques such as “oral arithmetic,” which it took writing to invent. And they had their own, often vigorous, “popular” culture that was in turn affected by the narratives produced by the literates and in turn impinged upon the latter’s achievements. But as far as most literate activities were concerned, they played very much a subordinate role. Only with the gradual extension of education, based on learning to read and write, was this situation largely changed.

It has been claimed by some recent writers, unwilling to accept the absence of writing in, for example, Africa, that any visual signs, even memory traces, represent writing. Such a position is held by certain well-meaning persons who wish to play down intellectual differences of the kind that are embodied in Levy-Bruhl’s notion of a “primitive mentality” that failed to perceive contradiction, were prelogical, and resorted to mystical participation. Such notions need to be set aside, as was done by the anthropologist Evans-Pritchard in the work on Azande witchcraft where he tried to demonstrate that their ideas about witchcraft were in fact “logical.” One specific case he took was the Azande explanation for why a man was killed by a brick falling off a wall as he passed underneath; the Azande would not accept the notion of an accident, insisting that some person or force had mystically caused the brick to drop at that particular time.

Certainly his position could not be considered “prelogical” in Levy-Bruhl’s terms. On the other hand, that logic had in turn to be differentiated from the “logic” of Greek philosophers and others, which depended critically on developments in the written sphere, in the formality that characterizes the treatment and composition of written statements such as the syllogism. While embryonic forms may exist in oral discourse, the syllogism itself, *a* is to *b* and so on, must be considered as a product of writing that in this way extends and elaborates the range of “technologies of the intellect” available to humans. Equally one can posit that many notions of mathematics, anything except simple multiplication and division, are, unlike addition and subtraction, dependent upon the written mode. So the advent of writing does not simply allow the communication of ideas but strongly influences the nature of the ideas to be communicated.

Paper and Communication

Not only the advent of writing but the use of cheaper and more flexible writing materials helped the communication of ideas and the democratization of knowledge through the spread of education. An important stage was reached with the use of paper. Previously the media for visible language consisted of clay tablets (as in Mesopotamia), of other solid materials, of wax tablets, of papyrus, and in the West of parchment (of skins). Papyrus gave Egypt a considerable advantage for the sending of messages and recording of information, but in the West that material had to be imported at considerable expense and the local use of parchment meant that a manuscript of 150 pages required the skins of a dozen sheep, only possible in a “carnivorous society” (Braudel, p. 497). Paper was cheap and could be manufactured out of local vegetable or waste material. But it was a long time coming to the West and when it did so, like writing and later printing, represented “the conquest of the East.” Invented in China at the beginning of the common era, it was adopted throughout the Islamic world from Central Asia, to Baghdad around 1000 C.E., to Spain where paper mills were turning in the twelfth century. In Christian Europe, paper was first manufactured in Italy two hundred years later. The enormous advantage this gave to Islamic cultures in the communication of ideas is illustrated by the fact that the library of the caliph of Cordoba in the twelfth century consisted of 400,000 volumes, while the number in the monastery of St. Gall in Switzerland, one of the largest in the north, was six hundred. The discrepancy was enormous and represented the great lag in Western knowledge systems before the Renaissance and the advent of the printing press, also probably from China, at the end of the fifteenth century.

In Asia, the expense of communication was in copying (and creation) rather than materials; the use of paper enabled ideas and information to be communicated rapidly from East to West. The notion of zero and Arabic numerals that made such a difference to mathematical calculation were just part of a transfer that paved the way for the Renaissance and the “scientific revolution,” including the revival of interest in the classical civilizations. Hence the rush of Western scholars to Palermo (such as Adelard of Bath) or to Toledo (the mathematician Gerbert of Aurillac) in search of what the Islamic world had to offer.

Printing

The balance of intellectual power partly shifted to Europe with the advent of printing following Gutenberg. Its success was partly due to the great advantage of the alphabet, which enabled movable type to be used with a minimum number of units, unlike the more complex logographic scripts of the Far East. Paper was essential in this shift since it provided a flexible, smooth, and inexpensive surface for the press; it was then that the milling of paper really took off in the West. In the Islamic world, which had diffused the production of paper from China to Europe, the acceptance of printing was very different; scriptures sacred to Muslims had at first to be written, not printed. In contrast to earlier times, with the mechanization of writing, the circulation of ideas and information became much less costly and more rapid in Europe than elsewhere. The value of rapid exchange of ideas at a distance can be seen in the correspondence of members of the Royal Society in Britain, where the impetus of the scientific revolution was certainly supported by such communication between scholars in various fields and countries, in the same

way, but much faster than had earlier happened in the vast Islamic world as a result of the use of paper as a writing material. Now it was possible to send printed versions of scientific papers to a wide range of people known to be interested in the same topic.

Mass Media

The speed and openness of the communication of ideas and information generally is increased even more by the appearance of the mass media, including electronic ones. In a sense mass media began in the early days of printing with broadsheets and newsletters. Indeed printing itself eventually enabled the large-scale production of almanacs as well as of textbooks for schools, as the price decreased. That process developed yet further with the coming of the roller press in the nineteenth century, which ensured the wider distribution of newspapers and magazines whose contents ranged from the sports and leisure activities to more serious ideas of a popular kind; but academic discussion, too, increasingly took place in journals that were taken by the growing number of libraries,

established earlier in monasteries, and later in universities, colleges, schools, and eventually in towns and even villages.

Electronic media further speeded up the process of transmissions, through the telephone from the 1880s for brief individual messages, to more substantial broadcasts through the radio, the cinema, and television. But for scholarly purposes the great breakthrough came with the development of communication by means of interconnected computers that enable immediate access to huge stores of information throughout the world. Those living in remote areas, away from libraries, can download material from the latest journals worldwide and keep up with the most recent developments in their topic. Indeed in some scientific fields, research workers are expected to post their findings without waiting for formal publication. The rapidity of the access to and the flow of scientific ideas promotes their application and hence the “innovativeness” of human society. The problem then becomes one of finding a way around this mass of information, for which purpose a number of “search engines” have appeared to assist with enquiries.

SOUTHEAST ASIA AND ITS INFLUENCE

Trade has always accompanied the spread of knowledge throughout Southeast Asia. From ancient times, exchange networks linked the mainland's coast with the Red, Mekong, and Chao Phraya Rivers, while by the second half of the first millennium B.C.E. Indian traders had arrived with goods and religiously based concepts of government.

Precolonial Southeast Asia

The Lao-Thai culture area, encompassing modern Thailand, Laos, Cambodia, and Burma (present-day Myanmar), has a common history of Hinduized states and Theravada Buddhism. Pali (the language of early Buddhist texts) and Sanskrit (the language of early Hinduism) are also Indian in origin. Vietnam, while sharing aspects of mainland Southeast Asian culture and society, represents the cultural influence of Han Chinese and Confucianism overlying indigenous traditions.

The major language groups of Southeast Asia include Austronesian (Cham on the mainland and many languages throughout the islands of contemporary Malaysia and Indonesia), Mon-Khmer, Burman, Tai (Thai/Lao), and Vietnamese. Of these, Mon-Khmer, Burman, Thai, and Lao have Indian-derived writing systems. In the case of societies influenced by Hindu and Buddhist cultures, the primary purpose of text was to convey religious knowledge. However, the role of written text and its use in everyday life varied significantly among Southeast Asian societies, as discussed below. The Hindu-Buddhist states possessed rich oral traditions, passed down through dramatic performances and shadow-puppet plays featuring the *Ramayana* and other Indian epics, with the *Ramayana* in particular presenting models not only of the ideal ruler but of ideal male and female roles in society. Buddhism is an important religious tradition throughout much of Southeast Asia in the early twenty-first century.

The Age of Commerce

With the advent of Muslim traders in the thirteenth century and Europeans in the sixteenth, Southeast Asia encountered a new set of cultures and languages as Islam and Christianity exerted their influence. Europeans came seeking Asia's fabled wealth, particularly spices essential for preserving meat, but later trade gave way to conquest and settlement. By 1900 Europeans had divided the region among themselves, introducing a new set of languages: Spanish in the Philippines, French in Indochina (present-day Laos, Cambodia, and Vietnam), English in Burma, and Dutch in the Dutch East Indies. Spanish control of the Philippines effectively ended the eastward spread of Muslim influence. Many English loanwords from Southeast Asian languages (e.g., godown, gong) date from this period.

Anthony Reid suggests that despite ideas of male superiority entrenched among courts and urban elites due to the male-dominated written traditions of Hinduism, Buddhism, Confucianism, and Islam, women played a surprisingly influential role in society during the period of early European exploration. Because they were heavily involved in trade, including long-distance and wholesale marketing, women often knew multiple languages. European visitors left numerous accounts of female merchants who translated for them and acted as diplomats and negotiators for indigenous governments.

European traders also reported a high level of literacy among women as well as men in several locations. Reid suggests that literacy in Southeast Asia may actually have declined between the sixteenth century and the early twentieth century as Islamic and Christian education systems displaced a different, older

Hindu temple of Angkor Wat, erected in the twelfth century in Cambodia. Much of the communication in Hindu and Buddhist cultures involved the sharing of religious or historical knowledge. type of literacy. In the Lampung districts of southern Sumatra, the Philippines, southern Sulawesi, and the island of Sumbawa, the old Indonesian *ka-ga-nga* alphabet was written on bamboo or palm leaf, and women actively perpetuated the writing tradition by teaching it to household members. Literacy in these areas apparently existed for the sole purpose of courtship, that is, the composition of love poetry. Visitors also noted high literacy in Java and Bali. When Muslims began to dominate a region, the traditions were quickly stamped out, and women's literacy was discouraged. In contrast to these early reports, recent accounts of Southeast Asian Buddhist societies describe a disadvantaged position for women with regard to literacy. Because Buddhist texts were written in the Pali language and only males became monks and received their education in temples, women's education during the last century lagged behind that of men. In Laos, for example, which received little in the way of development resources from its French occupiers, few women became literate in Lao until the late-twentieth-century generation.

Colonial Society

By the late nineteenth century and early twentieth century, colonial rulers in Malaya, Burma, Indochina, and the Dutch East Indies were introducing formal Western education. Colonial governments established schools, teacher-training institutions, medical colleges, and universities. Where colonizers wanted to develop a class of indigenous civil servants, instruction was given in European languages. In the Dutch East Indies, for example, Malay and Dutch were both taught in Roman characters, and in Vietnam instruction was in French. In Laos, however, which had already been staffed with French-speaking Vietnamese ad-

ministrators, the colonial government of 1941 to 1945 actively encouraged Lao language standardization and the creation of a distinct Lao identity to enlist local support for French rule.

Daniel Marr notes that "among all the countries of Southeast Asia, Vietnam probably enjoyed the most favorable conditions for meaningful intellectual activity" (pp. 32–33). For one thing, 85 percent of Vietnamese spoke the same language. Literacy, however, was a major issue. At the beginning of the twentieth century, four different writing systems were available: (1) Chinese characters; (2) nom (demotic characters); (3) French; and (4) *quoc-ngu* (romanized script developed by seventeenth-century French missionaries). Chinese knowledge had been important for civil exams in the nineteenth century but declined in the twentieth. Although only about 5 percent of the Vietnamese population could read by the mid-1920s, school enrollment increased, and people learned *quoc-ngu* informally after that. The French established the University of Indochina (now the University of Hanoi) and upgraded it in the 1930s because too many Vietnamese were going to France and learning anticolonial ideas. Both government and private Vietnamese schools expanded in the 1930s, while French works were translated into *quoc-ngu*.

The French conquerors brought the first modern printing press to Vietnam, and French-language bulletins were published in Saigon as early as 1861; the first Vietnamese (French-language) newspaper went to press in 1917. By the 1930s, however, both Vietnamese nationalism and *quoc-ngu* were developing together. Intellectuals sought to use the script as a vehicle to modernize Vietnamese culture, while revolutionaries, particularly after the founding of the Democratic Republic of Vietnam in 1945, made the elimination of illiteracy a top priority. Vietnamese publication was remarkably prolific, unparalleled by any other Southeast Asian country: roughly fifteen million bound publications were produced in the two decades before the August 1945 revolution (about eight or nine books or pamphlets per literate individual).

The most important European concepts to influence Southeast Asia were probably nationalism and the idea of the nation-state, made possible by growing literacy in indigenous languages and the development of the local press. Prenationalist movements grew not only because of direct experience with colonial injustice but also as the result of influences from abroad, including the Meiji Revolution in Japan and the 1911 Chinese Revolution of Sun Yat-sen. The 1917 Russian Revolution led to the establishment of Communist Parties in Southeast Asia. Young men (including the Vietnamese leader Ho Chi Minh) were attracted to the Communist Party abroad because of its anticolonialism. Marxist ideas, such as nationalization and state-controlled economies, kept their popularity in several Southeast Asian countries after independence.

Postcolonial Society

The introduction of secular education and a Western curriculum in the twentieth century had profound effects on Southeast Asian language and culture. Necessary skills for preserving and transcribing old texts have been lost, while Western cultural traits have become a source of status. After publishing houses were es-

TIMELINE—SOUTHEAST ASIA

Mainland Southeast Asia consists of the present-day states of Myanmar (Burma), Thailand, Cambodia, Laos, and Vietnam. Maritime or island Southeast Asia includes the Malay part of the peninsula and a large archipelago divided between Indonesia and the Philippines.

PRECOLONIAL ERA

- c. 500 B.C.E. Indian trade with mainland Southeast Asia begins, leading to the spread of Hindu-Buddhist ideology and the influence of Sanskrit and Pali on local languages.
- c. 1 C.E. With the spread of trade into the islands, west and central maritime Southeast Asia comes under the influence of Hindu and Buddhist traditions.
- 1st millennium C.E. Mon-Khmer people settle Irawaddy Valley, Bangkok Plain, and Mekong Delta; Khmer site of Angkor Wat (ninth century) typifies court of Hinduized Southeast Asian state. Red River Valley (southernmost extent of Chinese Empire) occupied by Vietnamese. Chams (Malayo-Polynesian language group) inhabit coast from the Red River Valley to the Mekong Delta.
- Early 2nd millennium C.E. Burmans move into the Shan Hills from the eastern Himalayas; conquer Mon-dominated Irawaddy River Valley. Thai and related Lao move into what is now Laos and Thailand from Southeast China.
- 1300 C.E. Islam expands into island Southeast Asia from the Indian Ocean, following trade routes; Muslims introduce Arabic as they convert local populations.
- 14th–18th centuries. Vietnamese push south, dominating Chams and taking the Mekong Delta from the Khmers.
- 16th century. Spain annexes the Philippines, bringing Christianity and Spanish and blocking the eastward spread of Muslim conversions. Portuguese and then the Dutch occupy the Spice Islands.
- 18th century. Four ethnic groups dominate mainland Southeast Asia by this time: Burmans (Irawaddy River Valley), Thais (Bangkok Plain), Lao (northern and central Mekong Valley), and Vietnamese (eastern lowlands). The contemporary states of Myanmar

(Burma), Thailand, Laos, and Vietnam take their names from these ethnic groups.

COLONIAL ERA

- 1824–1885. British acquire Burma, which becomes an Indian province in 1885.
- 1858–1885. French take over the Nguyen dynasty of Vietnam; French becomes the language of administration in French Indochina (present-day Vietnam, Laos, and Cambodia). French introduce the printing press to Vietnam; the first French-language bulletins appear in 1861. Malay (later the Indonesian national language) develops a popular literature, spreading ideas of modernization and nationalism from the late nineteenth century on.
- 1885–1945. Western schools rapidly expand by the early twentieth century. First Vietnamese (French-language) newspaper is printed in 1917. First Thai publishing houses are established in the 1930s. In Vietnam a remarkable expansion of literacy in *quoc-ngu*, romanized Vietnamese script, takes place between the 1920s and 1940s. Early nationalist movements develop throughout Southeast Asia in response to colonialism and the introduction of Western thought.
- 1945–1954. Most of Southeast Asia is decolonized in the aftermath of World War II.

POSTCOLONIAL ERA

- 1954–1975. The expansion of radio in the 1960s and 1970s creates a community of listeners in Southeast Asian countries for the first time. The Vietnam War, ending in 1975 with the fall of Saigon, results in massive devastation, population loss, and displacement within mainland Southeast Asia as well as an unprecedented international refugee flow.
- Mid-1980s. Television is introduced to Laos and Bali. The refugee diaspora stimulates use of new media, such as video. Literary analysis and the first women scholars emerge in Laos during the late twentieth century.
- 1990s. Television viewing greatly expands with the advent of satellite television.
- 2000. Cell phones, fax machines, computers, and cybercafes permeate city life. The Thai language, in both spoken and written forms, increasingly dominates neighboring Laos.

tablished in Laos and Northeast Thailand in the 1930s, writing on palm leaves became obsolete. In the late twentieth century a new field of Lao literary analysis emerged in which female as well as male Lao scholars participate.

The last two decades of the twentieth century brought modern mass media within reach of most Southeast Asians, though access varies. Television first appeared in Thailand during the 1950s but was not available outside the capital until rural electrification took place in the late 1970s. During the 1980s color television sets and then videocassette recorders became common, and by the next decade television viewing had greatly increased. In Bali (Indonesia), famous for its popular theater, the effect of television on live theater was so great that eight out of ten theater troupes vanished during the 1980s. Siam's (present-day Thailand) confrontation with Western colonialism in the nineteenth century led to a concern with boundaries and remodeling of the Siamese administration system after the model of Dutch and British colonial practice. One of the first Asian countries to use new media to further national development, Thailand has promoted an "official" national cultural identity for at least ninety years through its public education system and mass literacy in Central Thai. By the late 1980s television programming was used to introduce new, nonindigenous patterns of consumption, such as the presentation of Christmas gifts. Due to Thai control of modern mass media, the Thai language in both spoken and written forms increasingly dominates neighboring Laos. Whereas Thai and Lao are closely related, the Thai language modernized more rapidly; Lao scholars are still debating the standardization of its writing system.

Communication of ideas on the popular level in mainland Southeast Asia in the early twenty-first century is largely within an Asian sphere of influence; for example, Thai boxing and beauty contests, Hong Kong dramas dubbed into Vietnamese or Thai. Foreign ideas and the English language have begun to enter Thailand to some extent as a result of the increase in tourism after 1987. The influence of Southeast Asian refugees on both their host countries and countries of origin should not be ignored, particularly now that former refugees can visit or even return permanently to Southeast Asia; new ideas include more rights for women, increased individualism, and democracy. The political legacy of the Vietnam War remains a part of global, particularly U.S., consciousness.

COMMUNISM.

EUROPE

"A spectre is haunting Europe—the spectre of Communism." The famous opening line to *The Communist Manifesto* evokes the expectations and fears that have been associated with European communism. Published in 1848 amid a tumultuous period of political unrest across the continent, this polemical pamphlet was an idealistic call to arms directed at an emerging male working class ("the proletariat") that was identified with the growth of industrial capitalism. The authors, Karl Marx and Friedrich Engels, predicted that this new class would become the agent of a revolutionary transformation of the existing social order and that they would in turn create a new form of society in their own image: communism. This they foresaw would be an egalitarian proletarian civilization that abolished divisions based upon private property and the market and in which oppressive states would disappear to be replaced by "an association, in which the free development of each is the condition for the free development of all." All other social groups would disappear, in particular the industrial middle class ("the bourgeoisie"), which they identified as the dominant force in the modern world. The struggle to create this new form of equal society, as close to perfect freedom as possible, would be one of the most titanic and final in human history.

Karl Marx and the Origins of Modern Communism

In articulating this powerful vision of a future society, the authors of the *Manifesto* appropriated the concept of communism to themselves—so much so that communism and Marxism have often been taken as inseparable, if not synonymous, establishing a line of political thinkers and activists from Marx onward who contributed to the development of both. This link was strengthened further after the Bolshevik revolution of 1917 and the establishment of the Soviet regime (U.S.S.R.) in Russia, which claimed to be creating an authentic communist society in direct connection with Marx's ideas, and by political movements that sought to spread that revolution worldwide. Communism seemed to become an established feature of European political culture and conflict. Its significant impact on European societies was deepened yet further by the spread of Soviet-style regimes to most of Eastern Europe after 1945, which suggested that the most significant political choice of modern times was between accepting and rejecting communism. However, the reality of life under these dictatorships was increasingly at odds with the ideals that they supposedly stood for. Any sense of permanence was then shattered in the period from 1989 to 1991 by the complete collapse of these states and of most of the communist movements elsewhere in Europe. From the perspective of the early twenty-first century the whole conception of Marxist communism in its European context appears redundant as a form of political theory and practice.

The above description serves as a useful starting point, reflecting an image of communism that has dominated current understanding of it. But not all communists have been Marxists, and not all Marxists have been communists. In reality communism has been a more complex and contested doctrine, as was evident even when *The Communist Manifesto* was written.

In fact, hardly any single element of the *Manifesto's* conceptualization of communism was truly novel—including the use of the term itself. It was already used by a variety of minority groups across Europe, religious as well as political, to indicate an egalitarian, communally organized society. Marx and Engels took it from socialism, which developed from Enlightenment thinking as a rejection of liberalism and in reaction to the failure of the French Revolution of 1789 to produce a more complete social transformation. From Gracchus Babeuf's ill-fated *Conspiracy of the Equals* in 1796 and his attempt to produce a "commune," *communism* became a term indicating the most extreme end of the spectrum of French socialist thought. It indicated those groups most committed to the complete rejection of existing society and a belief that violent means were needed to achieve this goal. As such Marx and Engels's use of *communist* derived from their attempt to identify their own particular brand of thinking within the socialist market. More particularly, the *Manifesto* was published as the badge of a tiny organization they had founded, the German Communist League. At the same time, other groups, such as that of Louis-Auguste Blanqui, also described themselves as communist.

Other ideas in the *Manifesto* also predated Marx and Engels in socialist thinking: that industrialization was transforming human relations; the identification of the working

class as agents of change; the idea of a class struggle and that a "dictatorship of the proletariat" would be required before communism could be achieved. Nor was their very brief and generalized description of the nature of a future communist society particularly novel. They also included a series of immediate demands made by the league, including universal male suffrage, that were even less unusual. As it turned out, Marx and Engels had misread the immediate prospects for revolutions of the type they predicted. The year 1848 did not mark the start of the final crisis of capitalism as they conceived of it; in fact capitalism was only just developing, and that crisis was to be endlessly postponed.

What made Marx's version of communism distinctive was his bold claim that it embraced a "scientific" worldview and the fact that he placed his analysis of communism in a much broader context. The latter reflected his major preoccupation in life, which was the analysis of contemporary society and of trends in its development. He engaged with the most significant intellectual movements of his age. In addition to French socialism, he brought German philosophy, British political economy, and above all the new methods and language of the natural sciences into a brilliant synthesis. Marx described the result as "scientific socialism," which he distinguished from the "utopianism" of his many forebears and rivals. His aim was to unify theory and practice, to marry the analysis of society to political action. This was what made Marx and Engels's analysis of the coming communist society so powerful: their brand of socialism would succeed not because of mere striving and wishful thinking but because it was based in scientific study and represented the culmination of an inevitable trend in the modern world. Accordingly the *Manifesto* contained little discussion of political organization or revolutionary activity. Instead it presented communism as the direct product of a process of historical change involving a class struggle that was rooted in the effects of industrialization. The working class was destined to become a majority in society, and it would be bound, in the face of obvious economic oppression, to demand change, which could only be achieved by seizing economic and political power. In this view societies passed through great epochs: as feudalism had given way to capitalism, so capitalism would give way to communism. It was this faith in the inevitability of communism, as predicted by scientific socialism, that was Marx's great contribution. From it the possibility of communism as a political ideology in its own right and as a secular religion could be fashioned, but this did not happen immediately.

Non-Marxist Communism

Ironically, after the collapse of the German Communist League in 1850 *The Communist Manifesto* remained largely unread until rediscovered later as a prophetic work. No new political creed and form of political organization followed its publication, nor did Marx or Engels wish to separate themselves from other revolutionary currents. In fact, no other movements describing themselves as "communist" appeared again for seventy years. Nevertheless, the use of the term *communism* did resurface, but it was largely used by individuals and movements that were

unconnected with Marx's ideas. The Russian anarchist thinker Mikhail Bakunin had used the term as part of his early political lexicon. Again he used *communism* rather loosely to indicate a future form of egalitarian society; decentralized and communally organized, it would be free from domination by the propertied classes and above all from a dictatorial state. Bakunin argued that the peasantry, and not just the working class, could be revolutionary agents and that communism could be based on peasant institutions. However, by the time the International Working Men's Association (IWMA, 1864–1876) was formed, Bakunin had changed his views. The First International, as it became known, was an attempt to create cooperation between all the European political groups that claimed to speak on behalf of the working class, but within a few years the organization foundered in a welter of internal disputes.

By the 1880s, however, a fully fledged version of anarchist or "libertarian" communism had appeared that was most closely associated with another Russian revolutionary, Peter Kropotkin. As well as expanding the theoretical basis of anarchist thinking, Kropotkin also provided a critique of the state-centered approach of socialist communism to revolution. He argued that the state must be destroyed for a communist society to exist, as the state in any form was always an oppressive force. In contrast, Marx and Engels, and their later followers, asserted that the state needed to be captured and used by the workers in the "dictatorship of the proletariat" of the revolution. It would then "wither away" as the emergence of communism made it either completely or partly redundant. Other non-Marxist socialist movements also espoused forms of communism, most notably the Socialist Revolutionaries (SRs), who appeared in Russia in 1902. Following in the footsteps of the Russian Populists of the 1860s and 1870s and writers such as Alexander Herzen, who had again argued that the peasantry could be the basis of a revolutionary society, the SRs proposed an agrarian form of socialism that would be based upon village communes. Once again, a perfect society was the aim, though the nature of that society and the means to achieve it were quite distinct from Marxist communism.

Marxism and European Socialism

If not all communists were Marxists by the 1880s, more strangely, hardly any Marxists actually called themselves communists at this time. Most mainstream socialists began to describe themselves as Marxists, but hardly any labeled themselves as "communists." From 1850 until his death in 1883, Marx himself never again felt the need to distinguish his notion of socialism as communist. This reflected the passing of a particular moment in the late 1840s but also the way in which socialism was developing. Though falsely welcomed, by Marx as well as many others, as the first genuinely "proletarian revolution," the horrific aftermath of the Paris Commune of 1871 largely dealt a death blow to the idea of "spontaneous" insurrection as a path to socialism. There was also the realization that the vaguely defined working class would not automatically opt for socialism and that organization was required to win over workers to a cause previously espoused by small groups of intellectuals. Accordingly European socialists created permanent political bodies that could attract mass support and cam-

aign for change. By the late 1880s the most influential model was provided by the German Social Democratic Party (SPD), first formed in 1875. And by the 1890s social democrat movements had appeared in every major European country. Although formed on national lines—reflecting the consolidation of nation-states and of national economies in Europe—they also joined together in the Second International. This was formed in 1889, during a conference to celebrate and examine the achievements of the French Revolution of 1789, as a confederation of socialist parties. Every party was officially committed to a revolutionary Marxist analysis and theoretically to the notion that socialism would lead to a society without classes, private property, and the oppressive state. Whatever appearances might suggest, however, this did not represent the triumph of a communist version of socialism.

Marxist orthodoxy in the International was adapted for everyday purposes by a series of interpreters and popularizers, the most prominent of whom were Engels (until his death in 1895), August Bebel, G. V. Plekhanov, and Karl Kautsky. Indeed Kautsky's *The Class Struggle* was the bible for social democrat activity, though it is doubtful to what degree the rank and file of these movements was really aware of the nuances of even this version of Marxism. The analysis of capitalist society, the revolutionary mission of the proletariat, the role of class struggle in causing change, and the inevitable triumph of socialism were all there, as was the language of science in which the whole was couched. Also present was the "stages" view of historical and economic development, but here Marx's essentially economic analysis was qualified by a more practical political approach. The leading spokesmen of the Second International believed that not just a capitalist society but a liberal democratic ("bourgeois democratic") political system was required before real socialism could be achieved. Within such a system the workers' movement could develop and gain influence and eventually power. The state could be conquered by essentially peaceful means, using the growing numerical superiority of the working class, and the socialist stage could then be attempted. This downplayed the need for a seizure of power by force and reformulated the notion of a dictatorship of the proletariat. The aim was still a socialist revolution and eventually a communist society, but these were now longer-term aims that awaited a crisis of capitalism. The immediate priority was to organize politically and economically, to campaign for liberal democratic reforms, and to obtain immediate improvements in the lives of workers. The centrality of class struggle was further qualified by other issues. European imperialism and the threat of war became major preoccupations. In fact, the desire to prevent war through working-class solidarity across national boundaries became the major preoccupation of the Second International. And for the first time, equality between the sexes also became a significant issue for mainstream Marxists. Both August Bebel and Engels wrote tracts on the "woman question," and an increasing number of socialist-feminist women followed suit. In 1907 Clara Zetkin, the leading socialist-feminist of the SPD, organized the Socialist Women's International to campaign for working women's rights and female suffrage. However, insistence on the primacy of class over gender also divided social democrats. Some parties, led by the Austrians, rejected separate organizations for women and resisted the call for women to receive the vote. Many female activists,

such as Rosa Luxemburg, also argued that revolution would automatically bring gender equality and that campaigns on women's issues were simply a diversion.

Small groups of dissenters within social democracy took different elements of Kautsky's ideas and pursued them to different conclusions. Revisionists within the SPD, particularly Eduard Bernstein, questioned the very possibility of revolution, let alone its inevitability in modern industrial capitalism, proposing as a consequence that socialists should abandon the rhetoric of a revolutionary transformation, accept the permanence of capitalism, seek legality, and participate in existing institutions with the aim of securing democracy and improvements for workers. Socialism would come through the success of capitalism, as a means to redistribute its products more fairly, rather than through its collapse. These were still radical aims for the time, and the growth of social democrat representation in western European countries with parliamentary institutions and a working-class franchise lent plausibility to this strategy. Even so, revisionism was rejected by the mainstream as a heresy and even more vigorously by other factions that took seriously the revolutionary rhetoric of social democracy. For them, socialists should make revolution a reality by taking more active immediate steps to take power and overturn capitalist society. What they really rejected was the deterministic idea that revolution would come about through a process of inevitable historical change; instead it had to be made by revolutionary activists. A variety of factions and leaders became associated with this more forceful approach, the best known being the German Spartacists led by Rosa Luxemburg and Karl Liebknecht and the Russian Bolsheviks headed by Vladimir Ilich Lenin. But none designated themselves as "Communists" or sought separation from social democracy. Even in Russia, where the social democrats divided into two separate Bolshevik and Menshevik factions in 1903, both groups maintained their adherence to the International, and the ideological differences between them were far less than they were later to be presented. What was distinctive was the Bolsheviks' approach to organization and revolutionary activity. Lenin believed that conventional parties, particularly in the conditions of the tsarist autocracy, were futile and that workers had to be led by a "revolutionary vanguard" of tightly organized revolutionary professionals—the conspiratorial and military overtones were striking and prophetic.

In 1902 Lenin published *What Is To Be Done*, in which he laid out his ideas relating to the role of the party and party organization in the revolutionary movement. Little read at the time, it was to become a founding work of Leninism, the most significant ideological expression of twentieth-century communism. But while social democracy remained united, it served to constrain these more radical and revolutionary voices on the fringe of European socialism.

Splits in the European Social Democratic Movement

World War I and its aftermath shattered the delicate unity of the International. With the outbreak of war the overwhelming majority of socialists abandoned their pacifist and antinationalist stance. With the exception of the Serbian and both

Russian movements, all the parties pledged themselves to their respective war efforts and in many cases joined governments of national unity. They gained respectability, a new status, and shared responsibility for government actions. But as the war progressed and antiwar sentiment grew, they also faced growing dissent from within their own ranks. War deprivation, inflation, labor disputes, and growing social and political unrest in many European states divided socialists. In Germany an antiwar group broke away from the SPD to form the Independent Social Democratic Party (USPD, 1916). As the war dragged on to its close in late 1918, uncoordinated social and political unrest broke out in much of Europe, starting in Russia in February 1917 when the tsar abdicated and was replaced by a weak liberal government supported by the Mensheviks. Governments also collapsed in much of central and eastern Europe and were weakened elsewhere, including in states such as Spain that had been neutral in the war, creating power vacuums that were often filled by a plethora of ad hoc committees. Many of those involved in this so-called council communism in countries such as Austria, Germany, Hungary, and Italy were dissident socialists, but militants from other political movements, radicalized soldiers, and the previously uncommitted also participated. Women were also prominent in many of the activities of these committees, which challenged state authority and became a chief feature of the revolutionary unrest that gripped parts of Europe until 1921. They were heterogeneous in both their participants and in their political outlook, taking different forms in different places and at different times. In Austria, Germany, and Hungary during 1919 to 1921 workers and soldiers' councils became the basis for revolutionary insurrections that were suppressed by counter-revolutionary force. Elsewhere protest was essentially syndicalist in nature, with workplace committees formed as part of economic activities. These were significant in Britain, France, and Belgium and most widespread in northern Italy, where a wave of factory occupations spread across northern cities in late 1920. Revolutionary activists were galvanized by these events, even where they fell far short of an outright seizure of power. Once again the long-awaited crisis of capitalism seemed at hand. It was out of this chaotic situation that self-proclaimed communist movements and ideas appeared once more.

Bolshevism and the Emergence of the Communist International

It was Bolshevism that self-consciously promoted itself as a model for a new kind of revolutionary Marxist party and ideology. After February 1917 and considerable discussion within the movement, the Bolsheviks declared their opposition to the liberal government. While the Mensheviks concentrated on the liberal-democratic phase of revolution, Lenin declared that this could be skipped and that a "workers and peasants state" could be established. In an agrarian country, the Bolsheviks substituted the revolutionary party for the working class as the agent of revolutionary change. Never a mass movement, the Bolsheviks gathered support among soldiers and civilians disillusioned with the war and, crucially, in the committees (soviets) that sprang up in the major cities. Converts to the Bolshevik cause included the

Menshevik leader Leon Trotsky. With less success they also tried to extend their influence into those parts of the countryside where peasants had seized control of the land and their localities. By October 1917, with the government discredited by its own failures to end the war and carry out social reforms, the Bolsheviks were able to seize control in the main cities by force.

This was really only the beginning of the Bolsheviks' struggle to secure power, let alone to fulfilling their declared aim of creating a communist society and a world revolution. This process was accompanied by the creation of a mythology that legitimized the violent revolutionary methods of the Bolsheviks as the only path to communism. Lenin's main theoretical contribution was laid out in two works, *The April Theses* and *The State and Revolution*, both published in 1917. Once again theory and practice were unified. Bolshevik leaders, particularly Lenin, were lauded as the only true revolutionaries and interpreters of Marxist thought, farsighted and infallible in their judgments. In that sense successful revolution represented the triumph of the will of these leaders, and an authentic socialist revolution leading to communism could be carried out only by Bolsheviks. Similarly the party they led was the only representative of the interests of the working class. Indeed the party was needed to make up for the deficiencies of workers, who, left to their own devices, would not develop a "revolutionary consciousness." The path to true communism was through true bolshevism, and all other claims to revolutionary status were therefore fraudulent. Bolshevism's minority status and tenuous links to mainstream Marxism and socialism were glossed over, as was the fact that other groups within Russia—as elsewhere—also claimed revolutionary status as "communists": particularly the Socialist Revolutionaries and anarchist communists who rejected a centralized state and were supported by sections of the peasantry. By March 1918 the Bolsheviks began to describe themselves as the Communist Party.

In fact, the real route to power came through pragmatic compromises and a bloody civil war that lasted until 1921 in which the real instrument that established Bolshevik rule was not the party but the Red Army. The result was that opponents of all political persuasions, from the ultraleft to the tsarist right, were either crushed or marginalized. The main claim to the primacy of what after Lenin's death in 1924 became called the Marxist-Leninist approach to revolutionary communism came from the success of the Bolsheviks in seizing power in Russia and retaining it. Not surprisingly, all interpretations of communism had to contend with Lenin's ideas and the Soviet regime. However, there was no unquestioning acceptance of Bolshevik ideology and practice; far from it. From the start, questions abounded as to whether Leninism was Marxism or even socialism, and whether the Soviet Union was evolving as a communist society. For a majority of European Marxists, who continued to call themselves socialists, and for many who called themselves communists, the answers to these questions were negative. Kautsky, for example, was quick to condemn both Leninism and the Soviet Union as perversions of Marxism and socialism. Likewise, as a witness to the destruction of Russian anarchist communism at the hands of the Bolsheviks, Kropotkin wrote to Lenin denouncing the regime as a betrayal of communist ideas of free-

dom and humanity. Lenin's response to these critics, at home and abroad, was to denounce them as utopians in "*Left-Wing Communism: An Infantile Disorder*," published in 1920.

Paradoxically, the international attractions of Leninism as a universal ideology were increased by the fact that the Bolshevik revolution proved to be an exception. Short-lived Soviet governments were proclaimed in Munich and Hungary, but Bolshevik-style revolution was defeated everywhere outside Russia. Mainstream social democrats often played a pivotal role in this process, eschewing violence and opting instead to secure liberal-democratic regimes in power. The result was a deep and enduring division between the majority of social democrats and the dissenters. It was institutionalized in 1919 by the formation of a new Communist International (Comintern) based in Moscow. Its creation was based on the notion that Bolshevik-style revolution had failed not because developments in Russia were a peculiar case but because other countries lacked a proper Bolshevik party. Therefore the Comintern was to be a world Communist Party organized on Bolshevik lines, with different sections in each country, which aimed to spread Bolshevism beyond the borders of Soviet Russia. Adherents in each country were required to agree to a twenty-one-point charter based on Leninist principles of organization and activity. Between 1919 and 1921 Communist Parties of this "new type" were created in most European countries, drawing in mostly dissident socialists but also others who saw Bolshevism as the path to revolution.

Leninism offered a path to power, but what to do with it was a more difficult matter. The formulations of Lenin and other leading Bolsheviks such as Leon Trotsky on how communism was to be created or what it would look like in practice had been as vague as those of all the preceding generations of Marxists who assumed that it would emerge out of an advanced industrial society rather than a rural one. In reality, they had no blueprint. The regime that emerged in Russia called itself a Soviet democracy with a constitutional apparatus. Significantly, neither the U.S.S.R. nor later Communist states actually claimed to be communist societies. Their governments argued that they were living through a socialist stage, "the dictatorship of the proletariat" again, and were in the process of building communism. In practice this meant the permanent dictatorship of the party and the creation of a party-bureaucratic state that, in theory if not in practice, subsumed all aspects of society to it. Nor could any rivals—not just political but also religious—be tolerated. Throughout all the considerable changes, conflicts, and real debates about policy that took place in Soviet society and government, this was to be the constant reality that inhibited pluralism and independence, even during the genuinely radical early phase of Bolshevism, with its cultural and social experimentation. Symptomatic of the trend that set in was the case of Alexandra Kollontai, a strong advocate of the equality that the Soviet regime promised to women. Though initially prominent in the party and government, she and her writings were gradually marginalized, as was the question of real equality.

After Lenin's death in 1924 the question of how to create a communist society in a country that lacked an industrial working class was at the heart of the struggle for the party

leadership. Although a political and personality dispute as well, the three main contenders—Nikolai Bukharin, Leon Trotsky, and Joseph Stalin—all shared this basic goal but differed over how it was to be achieved. Bukharin favored a gradualist approach, while Trotsky argued that a “permanent revolution” was required—a swift transformation and a determined effort to secure the spread of the revolution worldwide. Rather than contributing wholly new ideas to these disputes, Stalin maneuvered between them and emerged triumphant. His approach was domestic and sought to create a specifically Russian version of communism, “socialism in one country.” However, the second revolution that he announced in 1928 borrowed heavily from Trotsky’s ideas in terms of the elimination of the peasantry through the collectivization of agriculture and rapid industrialization. The application of state power to centralize economic and social control that followed could only be achieved through considerable force and at the cost of millions of lives and was accompanied by a Stalinist terror that eliminated political enemies both real and imagined. Ideological conformity to Marxism-Leninism, as now defined by Stalin, became a prerequisite for survival. Nonconformist communists were accordingly particular targets, usually labeled as “Trotskyists” whether they were followers of Trotsky or not. This created a permanent division among Marxist communists, all of whom saw themselves as the heirs of Lenin and Bolshevism, between those who accepted the Soviet Union as it developed under Stalin and those who did not.

These disputes and developments in the Soviet Union inevitably impacted on the wider international communist movement. Stalin was mostly contemptuous of the Comintern, seeing foreign communists as inadequate and other communist parties as failures and sources of dissent. And in terms of recreating Bolshevik success this was a correct assessment, as no other successful revolution occurred in Europe despite some serious efforts in the early 1920s. The International went through various strategic twists and turns until it was finally dissolved in 1943, all of which proved futile and, for Stalin, simply proved his point. Individual parties did often play a prominent political role, particularly in liberal-democratic conditions. But for the most part international communism provided a threat and a justification for the authoritarian and Fascist movements that rose in Europe in the 1920s and 1930s—a threat that was without any real substance. After 1928, developments in the Soviet Union increasingly divided communists. On the one hand, many were appalled at the excesses of Stalinism and either became dissenters or abandoned communism completely. But on the other hand, the apparent achievements of collectivization and industrialization could also be a matter of pride and an example that communism offered a real alternative to the unemployment and economic depression that gripped Europe after 1929. As a result, and encouraged by the Comintern, Communist Parties turned in on themselves in pursuit of dissidents—many of whom were expelled as Trotskyists. Some formed small rival Communist groups, and Trotsky himself, in exile until his murder by Soviet agents in 1940, attempted to form a rival International.

For non-Russian communists questions about why the Bolshevik revolution could not be repeated and of the direction

taken by Soviet communism became central preoccupations. Most of the discourse of the orthodox Communist Parties simply aped that of the Soviet government and the International. In particular, the idea that the Bolshevik path was simply unrepeatable in the conditions in the more economically and socially advanced societies in the rest of Europe was officially unacceptable. Even so, some creative intellectuals, often called the Western Marxists, did flourish. Chief among them were Antonio Gramsci, Karl Korsch, György Lukács, and some members of the so-called Frankfurt School (particularly Herbert Marcuse). They were active in the first flood of revolutionary enthusiasm for the Soviet experiment, when there was more space for creative thinking within communist movements. Questions about the significance of culture and aesthetics in Marxist analysis concerned them as much as, if not more than, economics and politics. They were aware that cultural and social circumstances often conditioned political possibilities. Often implicitly, rather than explicitly, they offered a critique of Leninism in all its variations (including Trotsky’s). Gramsci in particular, without ever rejecting the Soviet model, suggested a path to revolution that contained the same sense of human agency as Lenin’s views but rejected its insurrectionary and conspiratorial strategy as well as the primacy placed on the material conditions necessary for revolutionary change. In complex Western societies, Gramsci argued, revolution was intimately bound up with a competition or struggle for cultural dominance (*egemonia*). In order for socialism to be established it had to be as consensual as possible—more akin to the triumph of the Italian Renaissance. Such thinking remained a minority concern and was decisively marginalized after 1928 in the drive to impose Stalinist orthodoxy on all communists. Either purged from their parties, recanting their views, exiled or imprisoned by their governments, they were silenced and their writings ignored by contemporaries.

In many respects, the fund of genuinely new ideas about communism, in Europe at least, began to dry up by the 1940s. The consolidation of Soviet rule under Stalin and the failure of communism outside of Russia contributed to that feeling. But once again a world war transformed the fortunes of communism in Europe. The war effort allowed Stalin to combine Soviet rule and Russian nationalism—a potent combination that was also to be successful outside of Europe after 1945. The isolation of the Soviet Union was also ended between 1945 and 1949, when Soviet rule spread to Eastern Europe under military occupation by the Red Army, and Yugoslavia was liberated by Communist partisans under Marshall Tito. In Western Europe as well, Communists also gained greater respectability and popularity as a result of the prominent role they played in the civilian resistance movements in parts of occupied Europe. Powerful and popular parties developed in France, Greece, and Italy. After 1945 Communists even participated in governments, though they were ejected by 1947 as the Cold War developed and political divisions hardened. Increasingly, political choices were dominated by attitudes toward communism, both domestically and internationally. This was, in fact, to mark the highpoint of communist success and, though not clearly perceivable at the time, the trend was from then on to be decline. Both within the Soviet-style regime and

within the Western Communist Parties, as well as in the wider world of communist thinking, communism ossified. And the search for renewal, and the recycling of old ideas, began to dominate.

Without World War II it is extremely unlikely that Soviet-style regimes would ever have emerged in this region. Even so, communism was not established overnight. By 1949, however, Communist Party rule prevailed throughout Eastern and Central Europe. At first many elements of Stalinist policies were imposed on the newly formed regimes: collectivization of agriculture, state economic control, the suppression of religion and class differences. But by the time of Stalin's death in 1953 it had become apparent that, due to the distinctive social, economic, and cultural conditions that existed in each of these countries, attempts to create systems in the likeness of the Soviet Union could never be completely successful. Yugoslavia was the one country in the communized part of Europe that completely escaped Soviet domination. Thanks in large measure to the partisan leader, Josip Broz, or Tito, from 1948 on Yugoslavia followed an independent course of Communist development. However, this extension of Communist rule also marked the beginnings of decline and the eventual destruction of communism as a state ideology in Europe. Following Stalin's death the problems of cultural, economic, and social stagnation steadily mounted. Opposition to Communist dictatorship also grew, including from intellectuals within party ranks who used the tools of official Marxism to dissect the failings of their own societies. The growth of dissent and the rejection of the regimes by many of their own supporters were to be key features of decline.

The central, unsolvable problem for all the Communist states became how to liberalize and renew themselves without rejecting party rule. The first serious attempt to do so came in the Soviet Union during the mid-1950s when a new premier, Nikita Khrushchev, surprised the world by denouncing the crimes of Stalinism and promising a renewal of communist ideals. The slogan "communism within a generation" was accompanied by attempts at economic reform and political liberalization. However, a conservative backlash unseated Khrushchev and destroyed the drive for reform. Similar experiments under Imre Nagy in Hungary in late 1956 and in Czechoslovakia under Alexander Dubcek in the spring of 1968 resulted in military intervention by the Soviet Union and Warsaw Pact countries. By the 1980s all the Communist states suffered from "stagnation" (*zastoy*), the term used by Russians to describe conditions under the leadership of Leonid Brezhnev. Any serious belief that communism could renew itself as a state ideology had finally passed. In Poland a powerful independent trade union organization, Solidarity, emerged in the early 1980s and soon posed a serious challenge to the regime. It contained a coalition of ideas ranging from Catholicism to dissident Marxism. Only direct military rule was able temporarily to contain it.

The End of Communism

What would turn out to be a significant shift in Soviet leadership occurred in 1985, when the reform-minded and relatively youthful Mikhail Gorbachev became head of state. His plans for more open debate (*glasnost*) about new ideas and policies

were accompanied by an attempt at restructuring (*perestroika*) the Soviet economic system. Gorbachev also made waves on the foreign policy front. Early in his administration he made it clear that the Soviet Union was no longer going to impose its policies over Communist regimes in Eastern and Central Europe, which set in motion the dissolution of the political, economic, and military ties that had formerly bound these countries to the Soviet Union. By 1989 nearly all the Communist regimes had imploded, and the fall of the Berlin Wall reunited Germany, effectively ending the Cold War. The Soviet Union was, once again, isolated as the only Communist state. However, in 1991 a failed military coup by conservative hard-liners, dismayed at Gorbachev's reforms and the loss of the Eastern European regimes, precipitated a final crisis. Gorbachev was sidelined, and more radical groups within the Soviet Communist Party, led by Boris Yeltsin, announced the dissolution of the regime.

Developments in Western communism took a parallel but distinctive course. After 1949 the hopes of spreading revolution to the West became ever more remote, confirmed by the defeat of the Greek Communists in the civil war of 1944–1949. Though still linked to the Soviet Union, the trend in Western parties was for increasing independence and a search for a more distinctively "Western" approach to communism. During the 1940s and 1950s, the atmosphere of the Cold War and the political restrictions it brought about inhibited free discussion of Marxist ideas in Europe—ironically paralleling the situation in the Soviet bloc. But by the late 1950s and 1960s, when de-Stalinization in the Soviet Union eased the Cold War, many Western parties adopted a policy of National Communism in an attempt to adapt themselves to specific conditions in different countries. This was due to a number of reasons, including rejection of many of the tenets of Leninism as unsuitable, and a reaction to many of the aspects of Soviet rule and to the failure of liberalization. Western parties also faced competition from dissenting communist movements—Trotskyites and also new models derived from the Third World (Maoism, Castroism). Communists also found themselves radically out of step with the long economic boom that transformed Western European capitalism from the early 1960s onwards. Many orthodox Communists embraced Eurocommunism, which broke entirely with the Soviets and was particularly influential in Italy and Spain. This involved the frantic rediscovery of many of the Western Marxists of the 1920s, particularly Antonio Gramsci, who was particularly promoted by the leader of the Italian Communist Party, Palmiro Togliatti, in a search for distinctive ideas. However, these developments came too late and only tended to divide Western Communists. By the 1980s the trend in all parties was toward decline and, in many cases, eventual disappearance.

Beyond some very basic ideas, there has never been a consensus about communism, nor a fixed body of doctrine that has underpinned it. Historically it has been a concept in a constant state of redefinition, used and interpreted in a diversity of ways. Even the appropriation of the term by Soviet-style regimes was but one definition of what communism could mean. It would now seem to have exhausted the possibilities for further renewal. The remaining standard-bearers for communism in Europe re-

flect this eclectic heritage. So-called unreconstructed Stalinists remain as a dying breed. Where communist parties remain they have tended to downplay their Marxist-Leninist credentials and have embraced the broader agendas of the feminist, ecological, and antiglobalization movements. It has been their erstwhile opponents on the dissident Far Left, anarchist communists, and “Trotskyites” who have retained their revolutionary purity on their own terms. All these are vestiges of the past. Whether a new form of thought that calls itself “communist” can ever emerge in Europe remains an unknown.

LATIN AMERICA

Latin America in the 1890s was a society primed for the dissemination of socialist ideologies. It was ruled by autocrats and oligarchs who were exploiting an increasingly discontented peasant populace and perpetuating a sharply divided two-class social structure. During this time, increased productivity and foreign investment ushered in the earlier stages of exploitative capitalism as well as a wave of European immigrants advocating the Marxist philosophies upon which socialist and communist movements were being built in Europe. The spread of this ideology was acutely evidenced by its recurrent presence in Latin American literature and art, most notably in the Mexican mural movement in the 1920s and 1930s. Led by famous artists such as Diego Rivera (1886–1957), José Clemente Orozco (1883–1949), and David Alfaro Siqueiros (1896–1974), the mural movement initiated decades of controversial

ANTICOMMUNISM IN LATIN AMERICA

A period of increased productivity and foreign investment in Latin America during the latter part of the nineteenth century attracted a wave of Italian, German, and Spanish immigrants who spread Marxist ideas throughout Latin America. This feudal, medieval, Catholic, and patrimonial region translated these ideas into a movement against its hierarchical two-class agrarian-based system. Following the Great Depression of the 1930s, leftist political parties emerged that promoted a strong role for the state in directing change, a leftist ideology, and anti-American nationalism. The next two decades were marked by instability and conflict as authoritarian, democratic, and communist groups vied for power.

In 1954 the United States intervened in Guatemala to overthrow a leftist regime that the United States said was communist. Four years later Fidel Castro led the successful Cuban Revolution. Cuba became the first openly socialist country in Latin America, the first to ally itself with the Soviet Union, and the first to openly turn its back on the United States. As a result, anticommunism in the region gained powerful U.S. military, political, and covert backing. Cuba added a new Marxist-Leninist “model” for Latin America and consequently made the prevention of “another Cuba” the central focus of United States policy. The United States chose time and again to support anticommunist military regimes over unstable democracies that believed in freedom for leftists. As workers, peasants, and guerrillas mobilized throughout the region, the traditional elite power-holders turned to their armies for support and received the backing of the United States, thereby ushering in twenty years of conflict and military–authoritarian rule.

The most famous U.S. anticommunist engagements in Latin America included the 1961 Bay of

Pigs fiasco, in which the CIA trained and financed 1,400 Cuban exiles who were supposed to incite a popular revolt against Castro, but were instead arrested upon arrival. In 1962, the Cuban Missile Crisis brought the world to the brink of nuclear war, when the United States discovered that the Soviet Union was attempting to assemble nuclear missiles in Cuba. In 1965, the United States intervened in the Dominican Republic to prevent what it thought was a communist uprising.

Internal anticommunist movements also emerged throughout the region. One notable example of this was in Chile. In 1973 General Augusto Pinochet, head of the Chilean army, overthrew democratically elected, but Marxist, Salvador Allende in an attempt to save the country from communism. Leftist parties were banned and their supporters exiled, tortured, or killed. Pinochet subsequently shut down the old political system and established a personalist dictatorship that maintained power through violent repression for more than a decade.

In Nicaragua, a Marxist guerrilla movement known as the Sandinista Liberation Front gained much domestic and international support by the late 1970s. It forced the powerful Somoza family from power and established the second openly socialist regime in Latin America. The *contras* emerged as an armed anti-Sandinista resistance movement and were strongly supported by the United States. The *contras*’ resistance, combined with a U.S. boycott that devastated the economy, undermined Sandinista control. Internationally supervised elections were held in 1991. As in the majority of Latin American states that had democratized since the 1970s, the Marxists did not win a majority of the vote in Nicaragua but continued to participate as a significant player in the democratic political process.

socialist and revolutionary expressions in art and culture throughout the continent.

Revolutionary socialism seemed to “fit” Latin America’s two-class society, but it was strongly opposed by the Roman Catholic Church, the armed forces, and the oligarchy.

Meanwhile, the Great Depression ushered in a series of revolutions that placed power in the hands of the middle class, began an era of organized labor’s political influence, and fostered the emergence of Marxist-socialist political movements and parties. The twenty years that followed were plagued with

instability as communist, authoritarian, and democratic groups vied for power.

The Cuban Model

In 1959 the Cuban Revolution, led by Fidel Castro, established the first Marxist-Leninist regime in Latin America and set an example for like-minded movements throughout the region. Cuba became an active participant in regional politics and engaged in extensive revolutionary activism abroad. Its alliance with the Soviet Union led to the Cuban Missile Crisis of 1962, with the American discovery of Soviet nuclear missiles being assembled in Cuba leading to the brink of nuclear war.

Like other Latin strongman leaders (caudillos) of his generation, Castro, a socialist caudillo, claimed to personify his country, led through repression, and had no tolerance for political dissidence. He ushered in attractive changes in health, education, and social mobilization, but his administrative mistakes, combined with the fall of communism abroad and a continued American boycott, have left Cuba's increasingly declining economy with little prospects for recovery. What began as a popular revolution deteriorated into the last communist dictatorship in the region, one mired in poverty and oppression.

Guerrilla Insurgents

However, in the 1960s, at the height of its regional influence and revolutionary appeal, Cuba joined with the Soviet Union in funding and training Marxist guerrilla groups throughout Latin America. Following Cuba's lead, these movements chose armed conflict over electoral competition as a means to their deliverance from exploitation. What followed in many countries were two decades of civil wars and military-authoritarian rule as powerful elites turned to their armies, as well as to the anticommunist strategies of the United States, to repress the guerrilla insurgents. The most successful guerrilla insurrection was the Sandinista Liberation Front in Nicaragua, which eventually established the second officially socialist regime in Latin America. Although this regime was ousted through elections in 1991 with the help of an economic boycott and support of anticommunist Contra forces by the United States, Marxists remained a powerful force in the newly democratic system. As a wave of democracy began to overtake the continent by the late 1970s, many communist and guerrilla movements transitioned into political parties and contested for power through the democratic process.

Diverse forms of Marxism and communism developed in other countries, reflecting their diverse histories, sociologies, and levels of development. Indeed that was a major problem for Marxist movements, how to adapt a quite rigid ideological formula to different nations and circumstances. In Peru the socialist Aprista movement and the more rigid communist groups were bitter enemies for decades. Nicaragua had Christian socialists as well as independent Marxists and Leninists. Colombia has four different Marxist and guerrilla movements. Throughout the continent, rivalries between socialists and communists, and various types of each, have been intense.

Democratic Transition

As the twentieth century came to a close, a phenomenal shift occurred in Latin America from authoritarian and—in the case of Nicaragua but not yet Cuba—communist regimes to incomplete democracies. With the fall of the Soviet Union and the poor economic and social conditions of the four remaining communist states in the world (China, North Korea, Vietnam, and Cuba), the Marxist-Leninist model was less appealing than ever. The nineteen Latin American democratic states, with Cuba remaining the only nondemocratic one, each had a unique experience with a liberal transition, but the region as a whole changed from a rural peasant-agricultural society to a modern, urban, industrial, and diversified one. While it experienced improved economic conditions, better human rights records, and political liberalization after its transition from authoritarianism, Latin America was still far from stable in the early 2000s.

The gap between rich and poor was the largest in the world and still widening. Economic development was continuing at a slow pace, with major collapses in several states. Political participation and civic engagement were not entirely free; patrimonialism, cronyism, and corruption continued, with most governments closely monitoring and regulating political parties and associational life. In the view of most Latin Americans, democracy had yet to deliver on its promises, and polls indicated declining support for it. This disillusionment, exacerbated by the continued two-class system and the dire straits of the poverty-stricken masses, made a return to authoritarianism increasingly appealing to many Latin Americans and led to a revival of Marxist language, but a resurgence of communism or communist parties is highly unlikely. With globalization, new openings in free trade, and numerous successful models of liberal economic and political systems worldwide, it is unlikely that Marxism-Leninism will be revived or that even the Cuban regime will remain communist for long after the eventual passing of the resilient Fidel Castro.

Conclusion

While the turn of the nineteenth century ushered in a wave of socialist ideology that gained much momentum in the art, culture, and politics of Latin America, with the new millennium came a waning tide for socialist ideals and movements. The twentieth century witnessed varieties of communist movements in Latin America, including international Marxists, Fidelistas, guerrilla insurgents, and communist parties participating in the political process. Although democracy seems to have outlasted the alternatives, the book is not closed on the future of the partially consolidated and still transitioning democratic regimes of the region. With continued economic and political instability and an exceptionally large income gap, Latin America might be ripe for renewed Marxist appeals, as it was in the late nineteenth century. Although guerrilla insurgents and socialist parties remain and leftist coalitions may be securing power in states such as El Salvador, the future may likely see a rise in new forms of statism and authoritarianism, but a return to the failed model of Marxist-Leninism or even a resurgence of strong Marxist movements is unlikely.

COMMUNITARIANISM IN AFRICAN THOUGHT.

This essay explores representative Africanist thought on personhood and community, highlighting especially the debate between Ifeanyi Menkiti and Kwame Gyekye on communitarianism, defined generally as relating to social organization in small, cooperative, partially collectivist communities. The general debate on these issues in Africa can be traced to important studies of personhood and psychology in African life and thought championed by French ethnologists and British and American social anthropologists as well as African scholars in different fields. The groundbreaking work, *La notion de personne en Afrique noire*, edited by Germaine Dieterlen (1973), which grew out of the French ethnological tradition, inaugurated a vigorous debate on personhood that has bearing on questions of individualism and communitarianism. In his insightful 1986 essay, “The Person and the Life Cycle in African Social Life and Thought,” Paul Riesman explored Africanist literature relevant to personhood, individuality, and community. Riesman argued that the Marcel Griaule school developed interest in personhood and community and that scholars such as Griaule and Dieterlen underscored concepts of individuality and community. In British social anthropology, Meyer Fortes grounded his studies of personhood in customs, behavior, and personality. Other scholars focused on the powers of a person’s obligations and social roles as well as on conflicts, legal systems, and individual responsibility.

The 1987 Uppsala symposium “African Folk Models and Their Application” also addressed personhood and personal experiences. Introducing the book published after this conference, Ivan Karp argued: “Quite simply, persons sometimes experience themselves in a human way, sometimes in a Lockean way, and sometimes, as in the case of positivist social scientists, as Kantian transcendentalists. However, these modalities of experience should not be reified and then debated as competing epistemologies. Rather they should be seen as descriptive of the varying ways human beings experience the world according to widely varying needs and interests” (Jackson and Karp, p. 17). Victor Turner’s studies also called attention to individuality. Jean Comaroff argued that there was widespread

conception of an “essence” of the person, whose soul was not a privatized interiority but a being-in-the-world. Ellen Corin argued that societies do not always overshadow individuals because certain modalities allowed an individual to particularize to defend himself or herself from “‘collectivizing’ pressure of the clanic image” (p. 146). Michael Jackson also highlighted individuality in the phenomenological approaches, and V. Y. Mudimbe approached the subject from the viewpoint of inequality of power.

Since 1950 the Africanists Elinore Bowen, Mary Smith, Sarah LeVine, and Marjorie Shostak have articulated personhood, individuality, self-consciousness, and self-identity in community. Philosophers Ifeanyi Menkiti of Nigeria and Kwame Gyekye of Ghana have brought the debate into sharp relief by articulating positions on individualism and communitarianism. Menkiti has articulated a communitarian ethos, while Gyekye has defended a balanced perspective, which he calls moderate communitarianism. Gyekye has pointed out that the debate on individualism and the community in Africa affects the way people think of philosophical and moral issues. Philosophically, the debate probes whether an individual stands on his or her own and does not depend on the community or the individual is naturally embedded in social relations and a community. The moral concerns explore whether individual rights are primary and cannot be violated for any reason or people should instead pursue the common good.

Menkiti on Communitarianism

In “Person and Community in African Traditional Thought” (1984), Menkiti argued that, in Africa, the community had priority over the individual. He distinguished between Western views, which generally hold that a person is a lone individual, and African views, in which a person is defined “by reference to the enviroing community,” quoting John Mbiti’s statement, “I am because we are, and since we are, therefore I am,” to support his thesis (p. 171). According to Menkiti, “as far as Africans are concerned, the reality of the communal world takes precedence over the reality of individual life histories” (p. 171). Thus the communal ethos has ontological and epistemological precedence. Menkiti also defended the communitarian view on biological and social grounds because the individual comes from a common gene pool and belongs to a linguistic community: “Just as the navel points men to umbilical linkage with generations preceding them, so also does language and its associated social rules point them to a mental commonwealth with others whose life histories encompass the past, present, and future” (p. 172). Menkiti stated emphatically that personhood is defined by community and not by qualities such as rationality, will, or memory.

Menkiti underscored his views of personhood by affirming a *processual*, or procedural, mode of being in African thought in which an individual becomes a person through social and ritual incorporation. Menkiti conflates the facticity of personhood with quality. He does this by distinguishing between *muntu mutupu* (a man of middling importance) and *muntu mukulumpe* (a powerful man, a man with a great deal of force). It is not clear why both persons cannot hold the status of “person,” even though one is “middling” and the other is already great. Menkiti

rejects the Western minimalist definition of a person, “whoever has a soul, or rationality, or will, or memory; the African view is ‘maximal.’” Menkiti uses the word *maximal* to indicate that the African view of personhood includes other criteria and is not limited to soul, rationality, or will. Since personhood is achieved, not endowed, in Africa, one could fail at achieving it. There are rules governing social rituals of incorporation that are designed to help the individual attain selfhood. The older an individual becomes, the more of a person that individual becomes. Menkiti quoted an Igbo proverb, “What an old man sees sitting down, a young man cannot see standing up,” to support his claim that personhood is a quality acquired as one gets older. While this proverb hints at differences of perspective between older and younger individuals, it is not implicit that personhood is an acquired quality. Opponents might agree with Menkiti that a youth has a different point of view from that of an older individual but might also affirm, in contrast with Menkiti’s views, that both are persons.

Menkiti defended the communitarian ethos by arguing that people use the neuter pronoun *it* to refer to a child rather than the personal pronouns *him* or *her* because the child has not yet attained personhood. He also stated that when a child dies, the funeral ceremonies are brief. However, when an older person dies, elaborate funeral celebrations take place because the older individual has achieved personhood and has now become an ancestor who lives among the people. In general, when one dies, he or she ceases to be a person. At the beginning of life, an individual who has no name will work toward personhood, and at the end of life, that individual loses personhood because he or she has departed for the next world. The departed ones may be referred to with the neuter pronoun *it* because their contact with the human community has been severed.

Thus it is clear that people at both ends of life are not persons because the young have yet to attain personhood while the dead have completed their development. “It is the carrying out . . . [of] obligations that transforms one from the “it”-status of early childhood, marked by an absence of moral function, into the person-status of later years, marked by a widened maturity of ethical sense—an ethical maturity without which personhood is conceived as eluding one” (Menkiti, p. 176). Meyer Fortes also argued that, among the Tallensi, “No one can be certainly known to have been a full human person until he is shown, at the time of his death, to have been slain by his ancestors and therefore to deserve a proper funeral” (1987, p. 257).

But Menkiti’s view that brief mourning periods indicate the degree of personhood of the deceased is contested. Elias Bongmba has argued that funeral rites of children among the Wimbun are brief and sad for reasons that do not reflect a child’s status as a person but because the Wimbun people mourn the fact that the young person has not lived life fully. They take personhood for granted but consider the death of a young person *rkwi bipsi shu*, meaning “death that has spoiled the mouth.” This means that the death of a young person shocks and numbs the appetite for food or drink, which people consume when an elderly person dies (Bongmba).

Menkiti cited John Rawls, who argued that justice is owed a moral personality, “a potentiality that is ordinarily realized in due course,” to support his claims that individuals acquire personhood as they carry out their obligations (Rawls, pp. 505–506). However, one could argue that Rawls emphasized moral potential and not personality. Whereas for Menkiti personhood is acquired when one develops and carries out moral acts, Rawls’s position is that an individual who is already a person has the potential of becoming a moral person. Menkiti rejected Jean-Paul Sartre’s definition of individualism because it stipulated unconditioned freedom and choice, which Sartre assumed was available to all. The African view is that such an idea of freedom is wrong because it ignores the community, which plays an important role in the life of the individual. According to the Africanist view, Sartre was wrong to place children and adults on the same level of choice. Finally, Menkiti rejected Western views that the community is a collectivity of self-interested individuals. This makes the community an aggregation of separate individuals. In Mbiti’s phrase “I am because we are,” the “we” is not additive “but a thoroughly fused collective we” (Menkiti, p. 179). African societies thus emphasize duty, while Western societies emphasize rights.

Gyekye on Moderate Communitarianism

Gyekye has argued that Menkiti overstated claims and that his views are misleading. Other factors, such as rationality, virtue, evaluation of moral judgments, and choice are important in determining personhood in Africa. People are born into community and have an orientation toward others. The Akan proverb, “A person is not a palm tree to survive alone,” summarizes human interdependence. Individual capacities, talents, dispositions, goals, and needs are met in interaction with others in society. Gyekye has also argued that it is a mistake to conclude that there are no individual dimensions to personhood in Africa. He cites another Akan proverb in which the view that individuals exist prior to community is implicit: “One tree does not make a forest.” “Community existentially derives from the individual and the relationships that would exist between them” (Gyekye, p. 38). Thus the reality of the community is derivative, not primary, and individuals choose whether they want to belong to a community or not. The community allows an individual to actualize his or her potential and develop personality in the social world without destroying his or her own will.

Gyekye quoted another Akan proverb to support his views of individuality. “A clan is like a cluster of trees which, when seen from afar, appear huddled together, but which would seem to stand individually when closely approached.” Two other Akan proverbs underscore individuality: “One does not fan [the hot food] that another may eat,” and “The lizard does not eat pepper for the frog to sweat.” Individuals have particular attributes, which they often exercise in contrast to the community. In opposition to Menkiti’s position that one earns personhood, Gyekye has argued that the term *person* is ambiguous. For example, what is implied in the expression *onye onipa*—“He is not a person”—is that the person does not display the norms of human behavior such as kindness, generosity, compassion, benevolence, and respect for other people. The Akan also say of someone, “He is a person,” meaning the

person fulfills his or her obligations. Personhood also involves responsible action that leads to success.

Exercising one's potential cannot be seen as the process of becoming a person in the sense in which Menkiti describes it. Individuals have a rational, moral sense and a capacity for virtue and judgment that the community nurtures. Individuals can also question what they do not agree with. Individuals are self-directing and self-determining and for that reason possess autonomy. Individual autonomy should not be equated with morality; instead, a moral agent must have the capacity to distinguish between good and evil. Although there is no conceptual link between autonomy and morality, there is a link between autonomy and freedom. Actions that result from a person's vision (visionary acts) concretize individuality because visionaries are always ahead of the public. Individuals who have visions can come up with innovative things to do even though such innovation might draw from the past history and narrative of the community.

Gyekye also has advocated moderate communitarianism because communities are more than associations of individuals; communities share values and obligations, and members of the community often express a desire to promote communal interests. Thus members of the community often invest intellectual, ideological, and emotional attachment to the community and engage in reciprocal social relations within the family, clan, village, ethnic group, neighborhood, city, and nation. Community, in this sense, refers to a cultural community, one that shares values and practices, not simply to a language group. The idea of community implies a common good, which is not merely the combination of individual interests but shared values, working together to meet the necessities of life and a common humanity, and not merely a surrogate of total individual goods. Thus "the common good" refers to all the values a community shares: peace, freedom, respect, dignity, security, and satisfaction.

Gyekye has argued that Western communitarians like Alasdair MacIntyre and Michael Sandel, who argue that individuals are only part of a community because they inherit their narratives from the community in which they are embedded, have overstated their case. One may indeed start from a certain narrative, but the fact that one can also reject sections of the narrative or practice one finds immoral is an indication that an individual person is not entirely constituted by the social. Radical communitarians thus exaggerate the impact of history and communal structures on individual autonomy. Furthermore, communitarians have rejected the construction of political thought solely from a foundation of individual rights. According to MacIntyre, "the truth is plain: there are no such rights, and belief in them is one with the belief in witches and in unicorns" (1984, p. 69). Communitarians would want to replace the politics of right with the idea of common good. By contrast, Gyekye has argued that rights are indispensable to self-assertion and the evaluative process. The idea of rights strengthens human dignity. Advocates of rights anchor their beliefs in the theistic perspective that human beings have intrinsic value because God created them.

Finally, rights can also be derived from nature because an individual has a rational faculty that allows him or her to strive

to be the best he or she can be. Therefore a community cannot disregard individual rights. Moderate communitarianism, however, is not obsessed with rights alone but also emphasizes, according to Gyekye, social values such as peace, harmony, stability, solidarity, mutuality, and reciprocity. Individual rights should be matched with responsibility. A sense of responsibility implies that supererogation is not necessary to morality, but that morality should be open, with no limits placed on individual self-sacrifice.

This view of personhood allows for consideration of, among other things, human rights in the African context. Postcolonial leaders stressed communitarian views, assuming that this kind of communal spirit would easily translate into the more complex needs of a nation-state. Politicians were eager to champion socialism and communal essentialism, and their preference for a communitarian ethos has compromised the debate on human rights in Africa. The human rights question suggests and implies that individuals have certain rights and should therefore possess self-determination. Strengthening individuality cannot be seen then as a concession to Western values because the Western tradition also supports communitarian perspectives. Moderate communitarianism is appealing because a radical communal thesis paints only a partial portrait of the dialectic between individualism and communitarianism.

COMPOSITION, MUSICAL. The term *composition* (from the Latin *com*, together, and *ponere*, to put) is commonly applied in Western music to a notated work, and

in non-Western systems to a consistently united progression or organization of sounds. Although Western music compositions have been defined by their narrative structure (i.e., progression toward a climax, etc.) a more accurate definition, encompassing modern Western experimental music and much non-Western music, is that of music composition as an alteration of a listener's "normal" acoustic environment through the creation of an artificially created acoustic environment by the joint activities of a composer and performer—movement through time rather than specifically narrative. In the field of music perception, composition is described scientifically, as a combination of linguistic elements (grammar, syntax, communication), the brain's bias toward finding pattern and regularity, and psychoacoustic factors (the physical limitations of the human senses). The details of this article on music composition will largely focus on Western classical music, but as necessary with such a wide-ranging term, other countries and styles are included in a limited form as well.

Cultural Roles

Music compositions are not constructed in a vacuum, but fill a cultural role in society. Composers provide music for many activities, including entertainment, social ritual, religious enlightenment, educational study, accompaniment to drama, and healing, both emotional and physical. These artificial social divisions are of course not inflexible, as music written for entertainment can be used in a learning environment and religious music has entered the concert hall. Entertainment music includes the immense diversity of Western art music composed for the concert performance, from Gustav Mahler's (1860–1911) *Symphony of a Thousand* to John Cage's short silent work *4'33"*, and also incorporates the many uses of background music. Music compositions used for religious purposes are diverse, including chant from all religions (most without attribution), hymns, spirituals (also without attribution), complex polyphony for Christian services, both Catholic and Protestant, and the mbira compositions improvised upon by Shona performers to aid in spirit possession ceremonies, or *bira*. Educational music is seldom attributed to specific composers, despite its universal nature and scope—from nursery chants and simple teaching songs to the extensive historical sagas found in eastern Europe consisting of thousands of stanzas. Music for drama is subsidiary to text and plot, and includes incidental music for plays, Broadway show tunes, opera, and Japanese Noh theater. Composition is often altered through improvisation during performances of folk music, jazz, many types of non-Western music, and Western art music of the Baroque and Classical periods.

Composers have a societal function as well. In many eras and cultures, composers have a well-defined job—providing music to those who can pay within the limitations set by the occasion. The importance of a composer's work, however, is directly dependent on the distinction between composer and performer, so in cultures that focus on improvisation, composers have little to no place. For example, in religious chant and much folk music, composers are unspecified and therefore receive no recognition. In the twenty-first century, however, composers have a clear and important place in Western

society—Beethoven’s name makes the comic pages in *Peanuts*, and Mozart is the subject of the award-winning movie and musical *Amadeus*.

Despite the common perception that musical skill or talent is the major factor in their success, composers have attained high positions as artists because of social factors such as rank, race, political connections, heredity, and gender. Until the twentieth century, for example, women were not accepted as major composers of Western art music. In south India, the Brahman caste is traditionally associated with music. Composers’ financial status in the West is determined by payments from performers and organizations for new works, sales of music of existing works and fees from concert performances, and royalties from recordings and broadcasts on radio. Composers also teach and perform music—passing on the ability to compose and perform their works to the next generation.

Changing Definitions

The transformation of the definition of composition can be seen through a study of changes in music over time. Although musical composition was obviously a part of earlier Greek, Egyptian, and Roman society, based on evidence from the visual arts and literature, the lack of musical notation makes it impossible to reconstruct the works, as only texts survive to earlier compositions. The earliest pitch notation in Western compositions is found in the eighth century, in notation for Gregorian chant. Gregorian chant, however, did not have composer attribution; Pope Gregory I (r. 590–604) received it from heaven, according to legend. As the medieval period drew to a close, composer’s names became attached to works and compositions became more elaborate, incorporating greater rhythmic complexity (syncopation, hocket, meter changes) and harmonic subtlety (use of modes, polyphony, use of *cantus firmus*, greater use of triads, thirds, and dissonance).

In late-medieval and Renaissance music (1500–1650) compositional rules and techniques became codified. The enormous outpouring of musical composition based on these rules included lively dance works, simple songs, and complex vocal works organized by strict pitch rules (counterpoint). Renaissance composers such as Josquin des Prez (c. 1440–1521) and Giovanni da Palestrina (c. 1525–1594) were respected members of the art world of the Renaissance just as their counterparts Shakespeare, Rembrandt, and Leonardo da Vinci were. As a reaction to the complexity of music from the high Renaissance, works in the Baroque period (1600–1750), such as Claudio Monteverdi’s (1567–1643) *Orfeo* (1607), focused on the relative simplicity of solo lines accompanied by clearly stated harmonic progressions. These harmonies were delineated by realizations of a “figured bass” by two instruments, one low melodic instrument (cello, trombone, bassoon) playing the bass line, and the other chordal instrument (harpsichord, guitar, lute, harp, organ) presenting harmonic realizations. This method of composition—open for improvisation in the harmony part and closely linked to the emotions of a specific text—was so controversial it became known as the “second practice.” Balancing the freedom and textual expression of the early Baroque with tightly structured counterpoint was an achievement of late Baroque (1700–1750) composers such as

Johann Sebastian Bach (1685–1750) and George Frideric Handel (1685–1759).

In the Classical period (1750–1820), Wolfgang Amadeus Mozart (1756–1791) and Franz Joseph Haydn (1732–1809) explored abstraction and the expression of Enlightenment ideals in music through a combination of carefully balanced structures with graceful expression. Ludwig van Beethoven’s (1770–1827) early works are in the simpler, balanced style of the Classical period, but the power, intensity, emotionalism, and unconstrained attitude toward Classical-era forms place much of his work closer to the Romantic style. Extramusical inspirations from such sources as patriotic fervor, literature, and the visual arts became tools for Romantic period (1820–1900) composers to use in mining emotional depths. They sought extremes in emotions expressed through extended dissonances, and unique structures such as the tone poem.

Tonality was still used in a large part of music in the Modern epoch; as the basis of pop, rock, film, and jazz music as well as many works of Western art music by composers such as Aaron Copland (1900–1990), Leonard Bernstein (1918–1990), Dmitry Shostakovich (1906–1975), Sergey Prokofiev (1891–1953), and Igor Stravinsky (1882–1971). Those composers using tonality in the twentieth century, however, did so with a strong awareness of historical precedent. In the late Romantic–early Modern environment, tonality had become so extended as to seem, to Arnold Schoenberg (1874–1951) and his students Alban Berg (1885–1935) and Anton Webern (1883–1945), irrelevant as an organizational system, especially in the explorations of atonality. In Schoenberg’s alternative to tonality, serialism, each piece begins with a series—a group of equally important tones. This system, dependent on mathematics and democracy instead of tonality’s traditions and hierarchy, was a complete break with part pitch organization and musical traditions. Serialism became one of the predominant compositional forces of the twentieth century, expanded after World War II to include the organization of rhythms, dynamics, and note length as well and as reviled by audiences as it was embraced in academic environments. The twentieth century also fostered a strong community of compositional rebels, including Charles Ives (1874–1954) and John Cage (1912–1992), as composers experimented with unusual combinations of sounds, extended silences, and chance procedures as compositional tools.

Throughout the twentieth century and continuing in the twenty-first century, the music world has splintered into factions with contradictory compositional outlooks. Although Western music focuses largely on pitch distinctions, as seen above, distinguishing features of compositions can vary. In other cultures, folk, pop, and jazz, text changes, phrase alterations, or changes in usage also can be seen as defining features for distinguishing individual compositions.

Conclusion

Musical compositions all have a common foundation—the acoustic and physiological realities of the human body. Composers combine these physical realities with an awareness of the sociocultural context and the emotional and aesthetic

ramifications of patterns, acoustics, and language. The inability of defining such a complex process, a delicate balancing act between the physical, emotional, spiritual, and intellectual is at the heart of Frederic Rzewski's description of composition as seen by a composer: "Composition is a constant search for reproducible patterns in the sound-universe and for rational symbols to describe them. It is a mystery how deep unconscious processes can somehow be expressed in a symbolic form, which makes them comprehensible to other minds" (Lecture at the Hochschule der Künste Berlin, 21 June 1994).

COMPUTER SCIENCE. Computer science is often defined as "the systematic study of algorithmic processes, their theory, design, analysis, implementation and application." An algorithm is a precise method usable by a computer for the solution of a problem. The term *algorithm* comes from the last name of a Persian author, Abu Ja'far Mohammed ibn Musa al Khwarizmi (c. 825 C.E.), who wrote an early textbook on mathematics. Some computer scientists study broad classes of algorithms, while others study algorithms for a specific task. Algorithms must be written down in some notation. Often the notation used is a programming language, as algorithms written in a programming language can be transformed and executed on a digital computer. Such algorithms are called computer software. Computer science is also concerned with large software systems, collections of thousands of algorithms, whose combination produces a significantly complex application. For these systems new issues become prominent: reliability, security, dependability, scalability, and modifiability of both the computer software and hardware. Another aspect of computer science is the impact it has had on other disciplines. Computer science "thinking," namely the modeling of processes by algorithms, has had a major impact on researchers in other fields.

Early History

The field called computer science was born in the 1940s, though its roots extend back to the nineteenth century and even earlier. One of the early founders of the field was Alan

Turing (1912–1954), a citizen of Great Britain, who in 1937 published his famous paper entitled "On Computable Numbers with an Application to the Entscheidungsproblem." In this paper he introduced the concept of an abstract computing device, later dubbed a Turing machine. It was precisely the simplicity of his model that permitted scientists to ask, and answer, fundamental questions about the nature of computation. Any computer can be simulated by a Turing machine, and the converse is also true. Moreover, the complexity of Turing machine computations yields insights into the efficiency of computations on real computers. Two other famous mathematical logicians who made early contributions to computer science were Alonzo Church (1903–1995) and Kurt Gödel (1906–1978). Church developed a system called the lambda calculus, which makes possible logically precise expressions of mathematical propositions. The lambda calculus proved to be a model for functional programming, and the popular LISP programming language used the lambda calculus as its theoretical base. Of equal import was the so-called Church thesis, which states that every effectively calculable number-theoretic function is lambda-definable. The importance of this result is that it ties numerical computation to string manipulation, an initially surprising result. Kurt Gödel is best known for his proof of "Gödel's Incompleteness Theorems." As early as 1931 he proved fundamental results about axiomatic systems, showing that in any axiomatic mathematical system there are propositions that cannot be proved or disproved within the axioms of the system. In particular the consistency of the axioms cannot be proved.

Computer science was not founded solely by mathematicians. An equally important group was electrical engineers, who focused on actually building a computing machine. World War II identified and spurred a need for computing devices, machines that could help carry on the mechanics of war. Enlisted into this cause were some of the greatest scientists of the day. One of these was Howard Aiken (1900–1973), who in 1944 built the Automatic Sequence Control Calculator (Mark I) at Harvard University. Another groundbreaking effort was the development of the ENIAC computer by John Mauchly and John Presper Eckert at the Moore School of Electrical Engineering of the University of Pennsylvania. Mauchly and Eckert were in turn influenced by John Vincent Atanasoff (1903–1995), who is now widely recognized as the inventor of the world's first electronic computer, the so-called Atanasoff-Berry computer (ABC machine). The ABC machine employed all of the basic units of a modern digital computer, including binary arithmetic, a separate arithmetic unit, and vacuum tubes for emulating logical switching circuits such as adders. The mathematician-turned-computer-scientist John von Neumann (1903–1957) worked closely with Mauchly and Eckert, and among many results he is usually credited with the idea of the stored program computer, the idea that a computer would contain within it both a program for processing the data as well as the data itself.

Computer Science Chronology

During the early period (1950s–1960s), a great deal of computer science work focused on understanding and refining

essential elements of a computer system. Operating-systems software was developed to facilitate the control of the functional units of a computer: the processor and the input and output devices. Programming languages were devised so programmers could more easily express the computations they wished to accomplish. FORTRAN (Formula Translation), developed by John Backus and a team at IBM around 1954, was the first popular, high-level programming language. Its focus was on efficient numerical calculation. LISP (LISt Processor), developed by John McCarthy at MIT around 1956, focused on symbolic programming. Both languages had major impacts and, though less popular, were still in use in the early twenty-first century.

The study of algorithms. As the definition of computer science is the systematic study of algorithms, it is not surprising that the decade of the 1970s was a period when the study of algorithms was dominant. One aspect of this research was the development of a theory of algorithms. Building on the theories of Church and Turing, computer scientists asked questions such as “Is there an algorithm for any Turing machine such that it decides whether or not the machine eventually stops if it is started in some initial state?” This is termed the Halting Problem. The Halting Problem has been shown to be unsolvable. Another aspect of the theory of algorithms has to do with problem reducibility. For example, it has been shown that if an algorithm did exist for the Halting Problem, then it would be possible to solve Hilbert’s “tenth problem”—namely, given a Diophantine equation, determine a procedure that decides in a finite number of steps if the equation has an integer solution. Computer scientists have shown that Hilbert’s problem is reducible to the Halting Problem and is therefore unsolvable.

A second aspect of algorithm studies concerns the development of new algorithmic solutions for specific problems. Topics such as sorting, searching, and graph theory were closely studied from an algorithmic point of view. Many new and efficient algorithms for these topics have been produced—for example, Hoare’s Quicksort algorithm for sorting, hashing as a technique for searching, and Tarjan’s algorithm for determining graph planarity, to name just a few. As the search for new algorithms proceeded, new techniques for analyzing the performance of these algorithms were developed. Methodologically, worst-case, best-case, and average-case analysis have become standard questions to address when presenting an algorithm. There are standard mathematical notations for presenting these results. Algorithm design techniques were identified, for example, divide-and-conquer, depth-first search, greedy method, and dynamic programming.

No discussion of computer science would be complete without a discussion of its most famous problem, “Does $P = NP$?” P is the set of problems that can be solved in deterministic polynomial time. That means that for a problem with inputs of size N , there must be some way to solve the problem in $F(N)$ steps for some polynomial F . F can be any polynomial, even N to a very high power. For example, sorting a set of N numbers can be done in polynomial time. This problem is in the set P . NP is the set of problems one can solve in

Difference Engine No. 1, a differential calculating machine invented by Charles Babbage (1792–1871). In the early nineteenth century, British mathematician Babbage constructed machines to perform basic numerical computations. True computer science, however, did not exist until the mid-twentieth century. © BETTMANN/CORBIS

nondeterministic polynomial time. That means for a problem with inputs of size N , there must be some way to solve the problem in $F(N)$ steps for some polynomial F just as before. In NP , however, the program is allowed to make lucky guesses, though it must prove the solution is correct. Many problems are in NP —for example, the traveling salesman, finding a Hamiltonian cycle, satisfiability of propositional expressions, finding a maximum clique, integer knapsack problem, and the optimal scheduling problem.

All problems in P are also in NP . You do not need to use nondeterministic guesses in an NP program if you do not want to. But does $P = NP$? This problem was first posed by Steven Cook (1971). No one has ever proven that they are equal and no one has ever proven they are not. But despite this failure, the “ $P = NP$?” problem has contributed a great deal to our understanding of algorithms. This has come about because computer scientists have been able to identify a large class of problems, all of which are reducible to each other, that is, solving one of these problems will immediately lead to a solution for the others. This class is called the NP -complete problems. The fact that NP -complete problems are (intuitively) the most difficult in NP follows from the fact that we may prove P equals NP if and only if some NP -complete problem has a polynomial-time algorithm. In his original formulation of the “ $P = NP$?”

Mark I computer, built in 1944 by Howard Aiken (1900–1973). Aiken's calculator replaced mechanical components with electromagnetic ones and responded to instructions it was fed from punched cards. Aiken later introduced a computer science program to Harvard University, the first of its kind. THE LIBRARY OF CONGRESS

problem, Cook showed that the satisfiability problem (find an assignment of values to Boolean variables in a logical statement to make it true) was a member of the NP-complete problems (this is called Cook's Theorem). However, despite many efforts, no one has ever shown that an NP-complete problem is also in P. Because no one has found such an example, many researchers believe that P is not equal to NP. And yet computer science is relatively new, and lots of other difficult problems have remained unsolved for centuries before someone came up with a solution, so perhaps this one just needs more time.

Artificial intelligence. The 1980s saw a great deal of work in the field of artificial intelligence (AI). AI is the subfield of computer science that is concerned with the computational understanding of intelligent behavior and with the creation of systems that produce such behaviors. One approach has been to develop computer programs that mimic the way humans behave. A second approach is to produce a computational model of some intelligent behavior, regardless of whether the model imitates human processes or not. One of the earliest examples of the latter approach was James Slagle's SAINT program for performing symbolic integration at the level of a college freshman. AI researchers early on emphasized heuristics as a problem-solving approach. Heuristics differ from algorithms in that they may not converge (or produce) the correct or exact answer, but experience shows that they often produce acceptable answers. For example, computers that play chess must evaluate the worth of their position at every step. Since it is computationally infeasible to work out the worth of all of the possible moves, researchers have developed heuristics that return a numerical assessment of the worth of a future move.

Returning to Alan Turing, in an article he published in 1950 he described a game in which a human interrogator

attempts to determine, solely on the basis of a written interrogation, whether the identity of the "person" answering his questions is in fact a person or a computer. This has come to be known as the Turing test. This challenge inspired a great deal of AI research. Of special mention is the ELIZA program developed by Joseph Weizenbaum, which appears to emulate a nondirective therapist. If the person being interrogated says "I am very happy," ELIZA might respond with "Why are you very happy?" and so it goes. Other researchers attempted to develop computer programs that would exhibit behaviors that were believed to be signs of human intelligence. Playing chess or proving mathematical theorems were two such areas of intense study. There are many subareas of artificial intelligence, including natural language understanding, general problem solving, knowledge representation and reasoning, learning, machine vision, robotics, and autonomous agents.

Personal computers and the Internet. An important phenomenon of the 1980s was the success of industry in producing a low-cost, miniaturized computer processor. This brought about the personal computer. Initially these machines might include 640,000 bytes of memory, no disk (only a floppy drive), and a processor whose speed might be 1 KHz (kilohertz) or less. The cost of such a machine was approximately \$5,000. As technology improved, prices steadily dropped while capabilities were enhanced, and computers moved from the exclusive domain of the government and large corporations into the home and small business arena. A personal computer in 2004 might have 1 billion bytes of memory, a disk with a capacity of 100 gigabytes, and a processor whose speed is 10 MHz (megahertz) and might cost less than \$2,000. Word processing and accounting (spreadsheets) became dominant applications. But this had little effect on computer science per se.

SOME EXAMPLES OF COMPUTER SCIENCE MERGING WITH OTHER FIELDS

Library science, which is concerned with the archiving of texts into digital libraries so the information can be efficiently and accurately retrieved. With the advent of the Internet, digital libraries are causing major changes to the traditional bricks-and-mortar library.

Management science, which is concerned with the development of computer models to help businesses perform their planning and forecasting functions. It also uses computer databases to store business transactions and to mine those transactions to better understand the critical elements of the company.

Economics, which uses computer models to forecast economic conditions and to evaluate the effects of varying strategies.

Medicine and biology, which use computer models to diagnose and treat disease. Modern imaging methods such as magnetic resonance imaging (MRI) critically rely on computers, graphics algorithms, and software.

Psychology and cognitive science, which are concerned with understanding human thought and emotion. Computer models are used to gain insight into the operation of the human mind and nervous system.

Linguistics, which is concerned with the use of computers for speech recognition and synthesis and for machine translation between languages.

In the 1990s research that had started back in 1969 with the U.S. Department of Defense, and that led to the digital network of computers called the ARPAnet, became accessible to everyone as the Internet. Research on packet switching and network protocols led to the development of TCP/IP (transmission control protocol/Internet protocol), the standard that now enables any pair of connected computers to communicate. As the number of Internet users grew, computer scientists began to study how best to exchange information between them. This culminated in the development of the World Wide Web by Tim Berners-Lee (c. 1990).

In the early twenty-first century new issues challenged computer researchers. People studied how digital sensors by the thousands can be coordinated to do things like predict the weather. Others developed methods for connecting thousands of idle personal computers together to work on a single problem (GRID computing). And simulations of physical processes down to the atomic level could be achieved, as digital computer speeds reached Teraflop level (a thousand billion instructions per second).

Basic Methodologies of the Field

The digital computer is the center of computer science. Abstract models are developed in the hope of capturing essential elements, but the models need sufficient accuracy so conclusions reflect what will actually occur on a real digital computer. Algorithmic thinking requires one to express solutions to problems as a sequence of steps, each one sufficiently precise

that it could be translated into the elemental steps of a digital computer, and then to analyze the efficiency of these steps.

Another fundamental mode of thinking for a computer scientist is representation—namely, the way in which data is stored so that algorithms making use of the data will compute efficiently. For example, a phone book is organized alphabetically so we can easily locate a person's phone number if we know his or her name. On the other hand, if we know a phone number and want to know the name of the person who has that number, the phone book is useless. Organizing the data so questions can be answered efficiently is the end goal of data representation. Representation does not only refer to ways to organize data but also ways to encode data. For example, how does one represent a mathematical expression that needs to be differentiated or integrated, or how should one encode speech, sound, or a movie so that it is compact yet is able to be faithfully rendered? Compression algorithms have succeeded in reducing the size of popular songs to approximately 3 megabytes (3 million characters), but a full-length feature movie, using the best encoding scheme of the day, requires approximately 1,000 megabytes. The former can be transferred across the Internet in a matter of minutes, while the latter requires several hours or more. Computer scientists are researching both sides of the problem, studying how to increase the bandwidth of the network while also improving the degree to which compression algorithms work.

Computer scientists have differing approaches to problems. Theoreticians aim to bring order to rapidly emerging subfields.

They attempt to develop models or analytic methods to help understand what is going on. In some computer science areas formal models exist, such as automata theory, switching theory, graph theory, and formal languages. However, for some fields, such as operating systems, programming languages, and compilers, theory has had a limited impact. Experimenters build systems and then use them to test out a variety of questions. Performance analysis and comparisons of different architectures are often the results of such experimentation.

Relationships to Other Disciplines

Computer science originated within mathematics, mainly through mathematical logic, and through electrical engineering with the use of Boolean algebra and switching theory to describe electronic circuitry. Conversely, computer science has strongly influenced mathematics. In some cases computers have been used to help prove theorems. One example is the question of whether four colors are sufficient for coloring any planar map, called the Four Color problem. This problem remained unsolved for more than one hundred years until the Four Color Theorem was proven by Kenneth Appel and Wolfgang Haken in 1976. As part of the Appel-Haken proof that four colors are sufficient, they use a computer to investigate a large but finite number of potential counterexamples.

Computer science has an equally strong connection with engineering, and in many ways the connection is much stronger than with mathematics. Computers are now indispensable when it comes to designing and building any complex structure, from a skyscraper or submarine to a computer. CAD/CAM systems (computer-aided design/computer-aided manufacturing) rely on a combination of computer graphics, specialized algorithms, and a complex of supporting software to provide the engineer with a set of tools by which one can master the complexity involved.

In the late 1990s and early 2000s a new bond grew between the physical sciences and computer science. The fields of physics, chemistry, biology, geology, and astronomy posed grand challenge experiments, problems that require massive high-speed computations. Human-genome sequencing is one such problem. Biologists view DNA as an encoding of information needed to generate a unique organism. The international effort to sequence the 3 billion DNA letters in the human genome, accomplished on 14 April 2003, was considered by many to be one of the most ambitious scientific undertakings of all time. Computer science played a pivotal role. All of the sequence data generated by the Human Genome Project has been deposited into public databases and made freely available to scientists around the world. Assembling and interpreting this data has required new levels of coordination and collaboration of computer scientists and biologists to formulate the necessary computing algorithms, data-management approaches, and visualization systems. In short, high-performance computing has fundamentally changed the way biologists do science; parallel computing systems have enabled high-throughput genome analysis; and modern search engines are allowing access to unprecedented amounts of biological data.

Another grand challenge is the Human Brain Project. This is a broad-based effort involving neuroscientists and information

scientists (computer scientists, engineers, physicists, and mathematicians). The goal is to produce new digital capabilities providing a World Wide Web (WWW)-based information management system in the form of interoperable databases and associated data management tools. Tools include graphical interfaces, information retrieval and data analysis, visualization and manipulation, and biological modeling and simulation. It is expected that the neuroscience databases will be interoperable with other databases, such as genomic and protein databases. From these two examples and many more one sees that researchers from many fields are now regarding computation as a third paradigm of scientific investigation, alongside theory and experimentation.

CONFUCIANISM. The word *Confucianism* implies the existence of a philosophy, a religion, or a worldview that goes by the name. "Confucian" ideas or attributes are assumed to have roots in ancient China, to be part of the common heritage of people of Chinese ancestry in other parts of the world, and to be shared by the peoples of Korea, Japan, and Vietnam, who have been heavily influenced by Chinese culture. *Confucianism* has been used to identify an ideology of benevolent kingship used by empires to legitimize themselves in various parts of eastern Asia. It is often applied to the practice of ancestor worship or simple respect for family elders. Yet, although there was an ancient Chinese word for "scholar" (*ru*), referring to those who studied ancient texts, the term *Confucianism* has no precise equivalent in Chinese. In order to understand why so many different phenomena have gotten lumped together in this fashion, we had better start with Confucius, or "the master," whose name was Kong (551–479 B.C.E.).

Confucius

The master speaks to us in the *Lunyu* (Analects), which contains brief, disconnected sayings attributed to him, conversations he had with disciples, and additional sayings or comments by some of those disciples. The text portrays Confucius as mentor and patron to a group of younger men who

sought to serve in the government of a small state called Lu between 510 and 479 B.C.E. It is from their questions and answers that the notion of Confucian “learning” derives. Confucius describes himself simply as one who loves to learn and as a transmitter of wisdom from the ancient past. That he also learns from his students demonstrates that learning, knowing, and holding to the truth were considered parts of a continuous process, which was at once intellectual, practical, and spiritual. Learning was essential to knowing, knowing was essential to doing, doing was essential to spiritual fulfillment, and spiritual fulfillment was essential to learning. This process was held up as a standard against which the corrupting influences of wealth and power could be measured. After his death, it was the learning of Confucius that his disciples sought to emulate, and the standards he set were what students in later times struggled to achieve.

The concepts the learners used were appropriated from the pre-Confucian discourse of a broad class of warriors across the North China Plain. In this discourse power and virtue ideally were one (*de*). The worlds of men and of spirits (*gui* or *shen*) were separate but communication between the two was possible, and so was mutual intervention. Shamans and oracles were the agents of communication, while the warriors’ sacrificial rites (*li*) were intended to mollify the spirits and to prevent their capricious intervention in the affairs of men. Five hundred years before the time of Confucius, astrologers in the service of a particular coalition of warrior clans called Zhou had interpreted the movements of stars and planets as signs of the movement of spiritual forces in an ordered cosmos. From this they had extrapolated the overarching idea of a Mandate of Heaven (*Tian Ming*), which legitimated the Zhou claim to order the world under heaven (*tianxia*) with a clarification of the ritual duties of all the warrior clans, in accordance with their rank. At the apex of this ritual hierarchy was the head of the house of Zhou, who alone among men bore the title of king (*wang*), but who by the time of Confucius no longer had any real political power.

The wisdom that Confucius sought to transmit was expressed in the language of Zhou texts and embodied in the performance of the rites as codified by the original Zhou patriarchs. But in the absence of Zhou power, the wisdom of the ancients with respect to bringing peace and order to the world could only be validated by the conscience, or benevolence (*ren*), of especially virtuous “gentlemen” (*junzi*) who rejoiced in the prospect of placing duty, or righteousness (*yi*), above personal gain. Resisting the temptation to validate the Mandate of Heaven by appealing to revealed truth, the early Confucians held that human virtue, without reference to spiritual intervention, was both necessary and sufficient for bringing order to a world fraught with conflicts over wealth and power.

Warring States Confucianism

Until the time of Mencius (Mengzi; c. 371–c. 289 B.C.E.) the principal proponents of Confucian learning resided in Lu, where they studied and taught the ancient texts and proper performance of the rites. The text that bears the name Mencius confirms historians’ judgments that this era, the height of

the Warring States period, witnessed a rapid change in the ethos of the ruling class. The rulers of the larger states all appropriated the title of king for themselves. They accelerated the development of institutions of direct taxation and conscription within their borders and belligerently applied new technologies in their efforts to expand beyond these borders. They actively sought advice on how to develop, defend, and expand their states, inviting scholars from throughout the known world to participate. Two opposing tendencies appear to have defined a new discourse involving a “Hundred Schools of Thought.” On the one side were ideas that reflected and further encouraged the standardization of institutions and laws, the simplification and clarification of administrative methods, and the realistic pursuit of political goals. On the other side were ideas that reflected and further encouraged belief in divine retribution, spiritual intervention, and the Mandate of Heaven. Mencius revived the early Confucians’ concepts of conscience, duty, ritual performance, and wisdom within this discourse.

The Confucius of the *Analects* answered a question about the meaning of wisdom by advising the questioner to “revere the spirits but keep them at a distance.” He had very little to say about heaven. The Warring States discourse defines the domain of man as the space between heaven and earth. In this domain there is a Way (*dao*)—a set of principles and/or activities—that parallels, follows, approximates, resonates with, or reflects the “Way of Heaven and Earth.” In Mencius the “Way of Man” is moral and the “gentleman” is its agent. The Warring States discourse also anticipates a reappearance of the spiritual forces that were manifest in the Zhou Mandate of Heaven. In Mencius the Mandate of Heaven appears at two levels. At one level Mencius advises kings and lesser rulers as to how they must act if they expect to receive the mandate and become a “true” king. At another level the text defines the “gentleman” as one who is able to grasp and hold onto the original moral “mind,” or “heart” (*xin*), which was heaven’s mandate to each individual human, and thereby to “transform the environment through which he passes and invest with spirituality (*shen*) the place in which he resides.” At both levels, the idea of the Mandate of Heaven is inseparable from the idea that in the mind of every person originally there are the seeds both of benevolence and of the duty to spread it in the domain of humanity.

In political thinking the idea of a world ordered by ritual was being displaced by the idea of a world ordered by law, or rewards and punishments. Yet proper performance of the rites remained important to the ruling elite, who still sought to legitimize their status by showing respect for their dead parents and ancestors as well as reverence for the gods of local communities over which they ruled. Mencius included the rites among the four virtues that were seeded by heaven in the human mind, but the Legalists—those who would reform the world by enforcing new laws—dismissed them as artifacts of a world that was no more, while the Daoists, for whom the Way was not moral but natural, regarded them as the last means of moral suasion before a ruler resorted to force. In the middle of the next century, as the powerful state of Qin mounted its conquest of the world, Xunzi (c. 298–c. 230 B.C.E.)—the last of the great Warring States scholars to ap-

ply the early Confucians' concepts—revived the concept of ritual with a stunning attack on the Legalists, the Daoists, and Mencius alike.

Xunzi argued that in the absence of benevolent rulers, it was the principles inherent in the performance of the rites that preserved the wisdom of the ancients and provided the means by which the “gentleman” could transform the world. The Daoists were right about heaven; it was neither moral nor responsive to human pleas for help. But, in addition, it was the origin of all life, and it provided man with a mind capable of learning by observing nature and by moderating the natural drive toward self-gratification. Human nature could not be distinguished from animal nature by its goodness, as Mencius had argued. Humans could understand the meaning of the word “good” because humans had invented it to contrast with the natural urge to gratify their desires. This natural urge was enhanced by emotions that, if allowed to prevail, led to ever increasing conflict and ultimate self-destruction. Social order, in short, was invented by the sages, and the rites were their means of channeling the emotions between the extremes that would destroy that order. For Xunzi, ordinary men find benevolence unattractive because they are naturally inclined to pursue pleasure and profit, leaving benevolence to the sages, but everyone benefits from a social order that keeps our angry and acquisitive urges at bay.

Xunzi replaces the moral mind of Mencius with a mind that is “empty, unified, and still.” Like the Daoists, Xunzi argues that reasoning—moving the mind, filling it with things, and analyzing them—forces us to make distinctions that lead us away from first principles and into petty disputes. Because the “gentleman” understands the principles behind the rites, an understanding that guides him to the middle ground between keeping to form and releasing the feelings, he finds comfort in carrying them out. Officials only maintain them, while ordinary people perform them because they are customary and believe they have something to do with spirits. As for laws and regulations, or rewards and punishments, these are necessary but not sufficient tools for governing. “Although there can be disorder where the laws are good, I have never heard of a case of disorder where the ruler was a ‘gentleman.’”

Han Confucianism

With the successful completion of the Qin conquest (221 B.C.E.) and gradual development of imperial rule under the Han by the time of the emperor Wudi (141–86 B.C.E.) came another shift in political and cosmological discourse within the ruling class. The unique title of the emperor (august lord; *huangdi*) placed him above the warriors, scholars, magistrates, and economic managers who ran the state, and also above the complex array of magicians, shamans, and religious cults that made up the spiritual landscape. The ruler now occupied the position of cosmic pivot. The cosmos was explained as constantly changing, its primordial energy, or the psychophysical stuff of which all things are made (*qi*), being differentiated by the complementary interaction of bipolar valences (yin and yang). Every part of the cosmos resonated with the changes occurring in the others. Small changes in climate, ecology, production, and administrative policy were related to a larger process that moved in grand cycles through five phases. Scholars gathered at the imperial academy

and many lesser academies across the realm to improve their understanding of heaven, earth, and human sciences based on this cosmology. Dong Zhongshu (c. 179–c. 104) is credited with the revival of early Confucian textual studies and the Mencian idea of “moral mind” within this context.

What modern scholars have called “Han Confucianism” comprised a broad spectrum of beliefs, social practices, and textual scholarship. The Five Classics on which imperial academy scholars based their interpretations were the *Changes*, *Documents*, *Odes*, and *Rites*—all purported to be Zhou classics—and *Spring and Autumn Annals of Lu*, an extremely spare text attributed to Confucius. Dong Zhongshu used the *Spring and Autumn Annals* as a prophetic text, giving it more power in imperial academic discussions. One commentary on this text, the *Gongyang zhuan*, imagined in it cryptic references to a past and future age of “great peace,” which readily fit into the discussions of continuous cycles of change and cosmic resonance. Dong advocated studying the past to prepare for the future. He interpreted specific natural disasters that damaged symbolic imperial structures as warnings to the emperor that corruption and dishonesty at court were moving the human world away from the “great peace” and toward cosmic disorder. Although contemporary scholars increasingly conclude that this version of “Han Confucianism” never subsumed the larger cosmology of which these moral arguments were a part, the image of Confucius as a sage continued and the idea of a Confucian vision of a utopian future reappeared in the nineteenth century. The radical reformer Kang Youwei (1858–1927) applied it to the modern world.

As the male educated elite of the Later Han period (25–220 C.E.) found themselves dependent more on large landed estates, inherited titles, and marriage ties than on official positions with the Han state, they found other uses for the texts. The families of the titled elite used the *Rites* as their guide to social relations. Confucius had become something like a patron saint of scholars (*ru*), and education in the classics had become a necessary part of elite status. An early Han text called *Filial Piety* preached devotion to parents and ancestors. If education for men had carried with it the obligation to serve both one's parents and the public good, education for women entailed the obligation to serve both the family of one's birth and the family of one's marriage in their roles as daughters, wives, and mothers. The rituals of ancestor worship distinguished elite male lines of descent, while the rituals of marriage and childbirth defined the passage of women from one line to another. Ban Zhao (c. 48–c. 119), an educated woman of the highest status during this period, has been celebrated for her literary talents and exemplary role in further propagating these family values in her essays *Admonitions to Women*. With this text also begins a discussion of gender using Confucian concepts, as the author reminds her male readers that if a “gentleman” owes his status not to conditions of birth but to “Confucian” learning, then the same must be true of the exemplary woman.

Neo-Confucianism

For nearly a thousand years after the disintegration of the Han empire, the maintenance of elite family rituals and repeated invocation of filial duty were the only distinctively “Confucian”

markers of the political elite in China. The classics, now labeled “New Texts,” were replaced by more recently discovered “Old Texts,” which joined Buddhist scriptures and imperial institutions as the eclectic markers of civilization. This was the civilization that spread to the Korean Peninsula and the Yamato Plain of Japan. The great Tang state of the seventh century left the elite families and their self-defined hierarchy in place. The Tang model resonated with the interests of great families in Korea and Japan. But not until the eleventh century, in an East Asian world that was divided among shifting imperial states but increasingly integrated by an expanding commercial economy, did another new ethos invite the recasting of early Confucian ideas.

The recasting, which has led Western scholars to coin the term “Neo-Confucianism” in an effort to define it, developed at the intersection of three social-intellectual trends. First, in the great Song empire of the eleventh century an emergent scholar-official elite, in their discussions of statecraft, tended to support their arguments on all sides with appeals to “native” precedents and values, in contrast to “imported” religious values and the imputed values of a rising commercial class. This nativist trend produced “moral learning” (*daoxue*), which centered on early Confucian ideas of the Way and self-cultivation. Second, with the development of woodblock printing, the growth of unprecedentedly large commercial urban centers, and the appearance of private academies, there emerged a new metaphysical discussion that subsumed Buddhist and Daoist philosophy. This metaphysical trend was labeled “principle learning” (*lixue*). Third, as an increasing number of scholar-official families relocated in rural areas in central, eastern, and southern China where they could invest in land and form strategic alliances with other locally prominent families, they began to appropriate the genealogical rules, forms of record keeping, contracts for incorporating property, and family rituals of the old hereditary elite as part of their localist social strategies. This localist trend led to the reinvention of the rites to suit their needs, while raising new problems for those scholar-officials who were engaged in “moral learning.”

Zhu Xi (1130–1200), the great master of Song “principle learning,” brought these three trends together in his copious writings on learning, statecraft, family rituals, cosmology, and the sciences. Philosophers of the previous century, especially Cheng Yi (1033–1107), had challenged the Buddhist view that prior to something (i.e., prior to the mind’s effort to distinguish one thing from another) there is nothing (*wu*). They turned to the cosmology of the *Changes*, according to which all things come into being with the movement of the complementary valences of yin and yang. Their movement is limited only by the finite amount of *qi* in the cosmos, and this limit (*ji*) is called the “great ultimate” (*taiji*). In other words, they argued, prior to something there is a principle (*li*), which is best understood as both the ultimate limit and that which has no limit (*wuji*). The mind’s awareness of principles in things is not, as the Buddhists argued, something that it invents and confuses with reality but, rather, the completion of the process by which something simultaneously comes to exist and becomes knowable as principle. In the words of Zhu Xi, the “investigation of things,” which, according to one ancient

text, the *Great Learning*, was the first step in the process of learning that led to self-cultivation and world peace, meant the “exhaustive comprehension of principle.” Drawing on this and another ancient text called the *Doctrine of the Mean*, he also argued that the unity of principle and mind was a manifestation of the Mandate of Heaven, which could only be understood as good, thereby merging the moralist with the metaphysical trend. He wrote commentaries on these two texts along with the *Analects* and *Mencius*, supplementing the commentaries by Cheng Yi, and advocated their study as a unit called the Four Books.

The moralist trend intersected the localist trend as the rites of upwardly mobile families began to change and the value of women in marriage arrangements began to rise. In the commercial world, especially in the households of urban and geographically mobile small traders and shopkeepers, a woman’s value could easily depend more on the talents and abilities she brought to the trade than on her conformity to Ban Zhao’s model. For a landowning scholar-official family, on the other hand, a woman’s value was determined primarily by the family’s rank, wealth, and local status. As daughters tended to marry upward on the social scale, dowries rose to a level that moralists regarded as grotesque. Concurrently, scholar-official families began to perform ceremonies at gravesites and to include in their ancestral rites greater generational depth. To further enhance their pedigrees, they began compiling genealogical records, which then became the currency of social relations locally, regionally, and empire-wide as time went on. When appeals to moral principles proved insufficient to counter these trends, scholars adapted the ancient texts and traditions to the setting of official standards for the new practices. Zhu Xi himself wrote copiously on issues of the family rituals that were the tools, or the cultural capital, of this class. Marriages, deaths, burials, ancestral rites, genealogical record keeping, and patterns of descent group formation were all contributing to a new discussion, the vocabulary of which derived from ancient ritual texts and concurrent discussions of learning and morality among the scholar-official elite.

After the Mongol expansion and domination of Asia, the texts and commentaries of Song “Neo-Confucianism” emerged as the orthodoxy on which success in the examination system of the Ming and Qing imperial civil service depended. A broadening stratum of educated elites in rural and urban communities throughout China drew on this tradition of learning to construct the nexus of power between the imperial state and local society. At the same time, the tradition’s dual focus on self-cultivation and public duty defined a new debate on the role of individuals quite apart from the state. By the mid-sixteenth century a newly vibrant urban culture, based in part on global trade and silver flows, challenged the scholar-officials’ nexus of power. An alternative reading of the ancient texts proposed by Wang Yangming (1472–1529) produced an array of new traditions that differed from the Song moralist trend. Wang argued that the “exhaustive comprehension of principle” could not occur in the first stage of learning because knowledge of principles was inseparable from the act of knowing. Learning entailed the “unity of knowledge and action,” so that only when the mind actively applied itself to something could the principle be

According to Confucius, the point of “learning” was to attain confidence in one’s own understanding of the Way, which also entailed the duty to restore virtue to power through benevolence and the use of ritual. One who understood this was called a “gentleman,” to be distinguished from a “petty man,” who did not. The core of this teaching can be found in a few pithy quotations from book 4 of the *Analects*:

The benevolent man is attracted to benevolence because he feels at home in it; the wise man is attracted to benevolence because he finds it to his advantage (4:2).

There is no point in seeking the counsel of an officer who sets his mind on the Way, if he is ashamed of poor food and poor clothes (4:9).

The gentleman cherishes virtue in power; the petty man cherishes his native land. The gentleman cherishes justice; the petty man cherishes mercy (4:11).

The gentleman understands what is right; the petty man understands what is profitable (4:16).

When you meet someone better than yourself, turn your thoughts to becoming his equal. When you meet someone not as good as you are, look within and examine your own self (4:17).

If one is able to run the state with rites and deference, then what is the difficulty? If one is unable to run the state with rites and deference, then what good are the rites? (4:13).

Mencius believed that humans were inclined to goodness by nature and that this original goodness could be found by looking into one’s heart (or mind), which heaven had made sensitive to the suffering of others: “Suppose one were, all of a sudden, to see a young child on the verge of falling into a well. One would certainly be moved to compassion. . . . The heart of compassion is the germ of benevolence; the heart of shame is the germ of duty; the heart of deference is the germ of the rites; the heart of right and wrong is the germ of wisdom. Having these four germs is like having four limbs. To say that one cannot use them is to cripple oneself; to say that one’s ruler cannot use them is to cripple one’s ruler.”

Mencius also counseled rulers of states on how to recover and apply the compassion that was in their hearts. The key was to “take this very heart here and apply it to what is over there. . . . Why is it that your bounty is sufficient to reach animals yet the benefits of your government fail to reach the people? . . . The people will not have constant hearts if they are without constant means. Lacking constant hearts, they will go astray and fall into excesses, stopping at nothing. To punish them after they have fallen foul of the law is to set a trap for the people. How can a benevolent man in authority allow himself to set a trap for the people?”

Xunzi believed that humans were inclined to selfishness and that goodness was the result of the conscious activity of the mind (or heart). Neither “goodness” nor the rites were mandated by heaven; both were created by men who understood that ritual and deference were necessary for social order and the collective good. “The former kings looked up and took their model from Heaven, looked down and took their model from the earth, looked about and took their rules from mankind. Such rules represent the ultimate principle of community harmony and unity. . . . Hence the sacrificial rites originate in the emotions of remembrance and longing, express the highest degree of loyalty, love, and reverence, and embody what is finest in ritual conduct and formal bearing.” Man shares energy, life, and intelligence with the animals; why is man superior? “Because he is able to organize himself in society and they are not. Why is he able to organize himself in society? Because he sets up hierarchical divisions. And how is he able to set up hierarchical divisions? Because he has a sense of duty.”

Zhu Xi believed that one could be said to have learned something only when the principle in a text had revealed to one the principle that was buried in one’s mind: “When one’s original mind has been submerged for a long time, and the moral principle in it hasn’t been fully penetrated, it’s best to read books and probe principle without any interruption; then the mind of human desire will naturally be incapable of winning out, and the moral

principle in the original mind will naturally become safe and secure. . . . In reading, we cannot seek moral principle solely from the text. We must turn the process around and look for it in ourselves. . . . We have yet to discover for ourselves what the sages previously explained in their texts—only through their words will we find it in ourselves.”

Wang Yangming believed that “learning” required both knowing and acting, and it was not

necessarily aided by reading books. “In all the world, nothing can be considered learning that does not involve action. Thus the very beginning of learning is already action. To be earnest in practice means to be genuine and sincere. This is already action.” “In the basic structure of mind there is neither good nor evil; when the mind moves purposively, then there is good and evil; knowing good and evil is what is meant by ‘moral knowledge’; doing good and destroying evil is what is meant by ‘the investigation of things.’”

known. By the same token, insofar as the substance of mind was empty and still, it was neither good nor evil, but a clarified mind in action “naturally” or “intuitively” conformed to what was “good.” This, he argued, is what Mencius had meant by “moral knowledge” (*liang zhi*). Some of the new traditions developed closer affinities with Buddhist and Daoist enlightenment. Some gave a much higher priority to individual enlightenment than to educational status. Some made it a duty to convert wealth into charity or to spread the enlightenment attained through self-cultivation to women and to social classes that were outside the nexus of power. Some even pointed out the ways in which the structures of family, lineage, and state impeded the learning process for men and women alike.

Ming challenges to Song Neo-Confucian orthodoxy continued to influence the personal moral choices of educated Chinese during the Ming decline and Qing conquest in the seventeenth century, but they did not displace that orthodoxy in the examination system. Nor did they prevent the Qing from using Confucian state ideology, demanding loyalty and compliance with prescribed norms in regular readings of the emperor’s “Sacred Edict,” or providing official support for patriarchal lineage institutions throughout the empire. On the other hand, a new trend of “evidential scholarship” (*kaozheng*) emerged to challenge the antiquity of the pre-Han texts on which the orthodox commentaries depended. By the mid-eighteenth century, philological studies of ancient texts had developed into a science known as “Han learning” that complemented the learning imported by Jesuits into the Qing court’s bureau of astronomy, weakening the cosmological underpinnings of the imperial state without challenging its political dominance. As Han learning gradually eroded the validity of the “Old Texts” of the Confucian tradition, new champions of the early Han “New Texts” also appeared. When alternative cosmologies and political philosophies arrived along with British gunboats and opium in the early nineteenth century, Chinese scholars and reformers responded not simply by reinforcing imperial Confucian ideology, but by drawing on current evidential scholarship and renewed debates over ethics that were strikingly relevant to the modern age.

In Korea the Chosŏn dynasty officially implemented Confucian rituals for local control using texts propagated by Zhu Xi, whose commentaries also remained orthodoxy in imperial examinations. By the eighteenth century Chosŏn state power had declined but a thoroughly ensconced local elite maintained a strict social hierarchy using Confucian family and community rituals, prescribed by law. In Tokugawa Japan, on the other hand, Confucian scholars found it difficult to reconcile Neo-Confucian ideas with *bakufu* military governance, as distinct from imperial authority, and the strict social distinction between a *samurai* class and common folks. Ogyū Sorai (1666–1728) and his successors in “Ancient studies” (*kogaku*) challenged the Neo-Confucian worldview with observations akin to Xunzi’s about the need to implement rites that are appropriate in time and place. A school of “National learning” (*koku-gaku*) arose and went even further, blaming Chinese learning in general for corrupting the native traditions of Shinto and the idea of imperial power. In response, Japanese “Han learning” promoted the study of the literary products of Chinese civilization as a valuable tradition in its own right. In the nineteenth century the Mito school devised a new formula, according to which the Chinese sages, as understood by the Duke of Zhou and Confucius, had formulated for China a philosophy whose principles were intrinsic in the Japanese imperial cult and original Shinto practice. Holding to the idea that Chinese civilization reflected universally true ideas, they concluded that the Way of the sages and the Way of the gods (Shinto) were actually one.

Modern Confucianism

After 1868 the Meiji leaders of Japan reinvented Shinto as a state religion in the effort to create a Japanese nation that could compete in a world dominated by modern imperialist powers. In its new imperial discourse it would also claim righteousness and demand loyalty of Korean and Chinese subjects in Confucian terms. In China, moderate reformers tried to combine Confucian traditions of education, political unity, and social order with modern technology and institutional reforms to enable the Qing empire to compete as well. With its capture of Taiwan in 1895 the Japanese empire emerged as both the greatest threat to China and the most obvious model for inventing

a Chinese nation. Kang Youwei, a visionary who captured the imagination of a younger generation of reformers, drew on the “New Text” tradition to reinvent the image of Confucius himself as a radical reformer who envisioned an egalitarian world without political or cultural borders. The eras of “great peace” and, eventually, “great unity” would be China’s contribution to a world that would eventually emerge from this era of imperialist expansion. At the same time, Kang and the other radical reformers hoped to place the young Guangxu emperor in a position analogous to that of the Meiji emperor in Japan, as the symbolic head of an empire strong enough to resist demotion at the hands of foreign powers.

In the revolutionary tide that engulfed China over the century after the failure of the Qing reforms, Kang’s vision was dismissed as an artifact of a world swept away by modern change. But the very way in which it was dismissed demonstrates the role Confucianism has played in revolutionary discourse. The reformers’ adaptation of ideals of self-cultivation, family loyalty, and Confucian education to a modern national identity galvanized support for the effort to save China among overseas Chinese in Southeast Asia and elsewhere, contributing to a culturally specific style of engaging the modern world that is still thriving. As educated Japanese increasingly distanced themselves from the “backward” cultures of East Asia, blaming the failures of Neo-Confucian idealism in large part, educated Chinese increasingly identified themselves with humanistic Confucian traditions to combat the rampant “superstition” of popular religious culture and the “backwardness” of the imperial state. Liang Qichao (1873–1929), who was the most influential of Kang Youwei’s followers, forced into exile in 1898 after the failed reform effort, tried to meld Xunzi’s realistic concepts of a social order based on group obligations with German authoritarian notions of law in order to overcome both the impractical idealism of the Song tradition and the disintegrative effects that a more liberal political philosophy would likely have had on China. By the 1920s he was urging politically dispossessed students to learn from Wang Yangming’s philosophy of *liang zhi* and the unity of knowledge and action. The Communist revolutionary leader Liu Shaoqi, on the other hand, urged the educated cadre to apply the unflagging selflessness of Confucian learning to the socialist cause. To combat Communism, the Nationalist regime appropriated the image of Confucius as authoritative teacher, lover of tradition, and counselor of respect for parents, elders, and rulers—the very opposite of the radical, visionary Confucius imagined by Kang Youwei.

More recently Confucian cultural norms have been credited for the Asian “economic miracle,” the political stability and unprecedented economic development of China since the fall of the Soviet Union, and the educational success of East Asians in general. The same norms have been shamelessly invoked by dictators and blamed for the relative weakness of opposition politics, cronyism, and persistent gender inequality. Samuel Huntington has claimed that “Confucian civilization” provides a set of norms and symbols that opponents of the progressive ideas and institutions of “Western civilization” can use to maintain power in their own countries. Such a view represents a powerful position on the geopolitical struggles of the post–Cold War world, but it does not re-

flect the complex history or diversity of the ideas and practices associated with the Confucian tradition.

Other scholars have tried to understand the ways in which new traditions of Confucian learning appeared over time as economic and social conditions changed. Much postwar Japanese scholarship on Confucianism has focused on the libertarian and communitarian tendencies in China and Japan since the time of Wang Yangming. The same tendencies have led others to focus on tensions related to social mobility, increasing literacy, and shifting gender roles. Tu Wei-ming has argued that Chinese on the intellectual and geographic periphery have been the most creative in adapting Confucian learning to modern change. He believes that others will benefit from the lessons learned by those on the periphery and continue to develop new modern identities while renewing their Confucian roots. Chinese scholars of Confucianism in Hong Kong, Singapore, and more recently Taiwan and China have turned their focus to arguments about the balance between human rights and political authority, pressing politicians and entrepreneurs to attend to grievances, provide for education and welfare, value the law, and share the wealth. In a postcolonial, postrevolutionary world, the future of Confucian learning can hardly be predicted, but it seems unlikely that it will cease.

OVERVIEW

Consciousness has three distinct meanings in the modern world. First it refers to immediate subjective experience. Second, it is the source of immediate and certain knowledge of mental states. For example, if I am in pain, I am conscious of pain and certain of this knowledge of my mental state. Third, it is

self-consciousness, a concept of the self that answers the question “Who am I”?

From the seventeenth to the later part of the nineteenth century, the first two meanings of *consciousness* were indistinguishable and often joined by the third meaning: The presence of immediate private experience was assumed, and infallible truths about states of mind and personal or collective identities were derived from it. Since the later nineteenth century, these three ideas of consciousness have been distinguished from each other and subjected separately to criticisms and doubts.

The etymology of *consciousness* is derived from the Latin *con* (with, together) and *scire* (to know). When Romans shared particular knowledge, they had con-sciousness. Sharing knowledge with oneself is the etymological source of *conscience*. In medieval Latin, for example in the works of St. Thomas Aquinas (c. 1224–1274), *consciousness* came to mean a knowing subject, as distinct from an unconscious person or a plant. However, the first two modern senses of *consciousness* were introduced largely by René Descartes (1596–1650).

Consciousness in Modern Philosophy

Since its inception in the seventeenth century, the history of the modern idea of consciousness is intertwined with the history of the idea of science and the scientific worldview. Consciousness has been on the rims of the scientific worldview, at once a challenge to the applicability of the scientific method for understanding consciousness, and an alternative possible source of knowledge, more certain than scientific empirical knowledge that must rely on the senses.

The Cartesian revolution. When Descartes initiated the discussion of consciousness in Europe, it was against the backdrop of the scientific revolution of the seventeenth century. Science presented then a materialist and mechanistic worldview. Pre-Newtonian science considered the universe to be composed of material particles that generate motion and change by direct physical interaction and transmission of force, much like clockwork or a billiard game. Descartes proposed to distinguish humans from artificial or organic machines (brutes) by the presence of mind, language, reason, and consciousness. Descartes believed that consciousness provides an intimate and certain source of knowledge, superior to empirical knowledge that is founded on the fallible and often misleading evidence of the senses. What we take as our sensory input may be a dream; we may be “brains in a vat,” as later epistemologists put it. But conscious introspection can provide sure knowledge about ourselves that is independent of the senses. For example, Descartes’s famous saying, *cogito ergo sum*, “I think, therefore I am,” suggests that any act of thinking implies the presence of a thinker, a person, and therefore self-knowledge of personal existence is certain. Descartes then divided the universe into material things, *res extensa*, that exist in space, and *res cogitas*, consciousness, a mind that thinks but has no material extension. The resulting duality of mind and body came to be known as dualism. Dualists must explain how mind and body interact in the person despite their qualitative differences, and respond to attempts to reunify mind and body in monistic philosophic systems that consider everything

to be either ideal, part of immaterial consciousness, or material, so that consciousness is part of the material world that science describes—brain states, for example.

The phenomenological tradition. Immanuel Kant (1724–1804) revolutionized philosophy by distinguishing the introspective study of the structure of pure consciousness as the subject matter of philosophy, distinct from the study of nature, the subject matter of science. Kant studied how any sensory input must appear in consciousness, in what he called the categories such as time, space, and causal order. However, Kant also concluded that while philosophical introspection may offer an infallible knowledge of the structure of consciousness, there could never be knowledge of the world as it is independent of consciousness.

Georg Wilhelm Friedrich Hegel (1770–1831) attempted to reunify consciousness with the world in an idealist monistic scheme according to which the world is a spirit, and our consciousness is that part of the world that can achieve self-consciousness. Consciousness, then, is what determines being, what happens to exist materially at any moment.

In his 1874 *Psychology from an Empirical Standpoint*, Franz Brentano (1838–1917) introduced the thesis that all conscious states are intentional. We experience the world against the background of our intentions, manifested in a sense of meaningfulness or meaninglessness. For example, my current conscious state includes my thoughts about this entry, vision of a computer screen, the sounds of a Mahler symphony in the background, and so forth. All these experiences are imbued with meaning against my intentions, to write a comprehensive and informative entry, to enjoy listening to my favorite composer, and so on. Had my intentions been different, say to earn a lot of money and to become better acquainted with contemporary rap, my state of consciousness, though including the same sights and sounds, would have been different and the experience much less meaningful.

Brentano taught at the University of Vienna. Among his most remarkable students were both Edmund Husserl (1859–1938) and Sigmund Freud (1856–1939). The first founded the philosophical school of phenomenology, the culmination of the tradition that considered consciousness to be the subject matter of philosophy and direct introspection the sure method. The second extended intentionality to unconscious states, but also shifted the focus of intellectual discourse from consciousness to the unconscious.

Husserl's phenomenology is the last great school of philosophy to attempt to found certain knowledge on introspection of our consciousness. Husserl thought that with the scientific revolution, people lost awareness of pristine and immediate consciousness, which has been emptied of meaning because they objectify, abstract, and conceptualize. Husserl sought to recapture and philosophically analyze this immediate consciousness. Husserl called his method *epoché*, the suspension of belief in the distinction between subjective and objective phenomena that allows immediate consciousness to "appear." Within *epoché*, consciousness appears full of meaning, prior to conceptualization, and so the philosopher who

follows Husserl's method will be able to analyze the universal aspects of consciousness. Husserl called what should appear to anybody who goes through *epoché* the "life-world." Husserl's description of the life-world he discovered may be interpreted as a reaction against increasing modernity, urbanization, and loss of traditions and security in Europe in the early twentieth century; against the loss of a pristine bucolic world of farmers rooted in their land; and against the growing gap between the scientific worldview of matter and energy, galaxies and atoms, and the human perspective on the world of earth and sky, flowers and friends. Husserl's method of *epoché* proved susceptible to personal biases and so generated accounts as different from each other as those of Martin Heidegger and Emmanuel Levinas (1906–1995). Husserl was also criticized for not considering possible differences between human consciousness in different historical eras or cultures, though such philosophical anthropology has never been his purpose.

The gap between the modern scientific worldview and human point of view also spurred the explorations of the French philosopher Henri-Louis Bergson (1859–1941). Bergson was particularly interested in our consciousness of time. Physics (except for Newton's law of entropy, which stipulates increasing disorder in the universe in the direction of time) is indifferent to the direction of time from past to future. Einsteinian relativity considers time as a dimension that can be stretched or compressed in relation to gravity and velocity. Our conscious experience of time is quite different. Bergson attempted to distinguish our conscious experience of time as a continuous duration from its scientific divisibility into moments.

At the same time, "stream of consciousness" novelists such as Henry James, Arthur Schnitzler, Virginia Woolf, and especially James Joyce in *Ulysses* explored consciousness and time through a narrative method that attempted to record everything that goes through their protagonist's minds.

The Unconscious

Freud broke with the philosophic tradition that had identified the mental, the mind, with consciousness and consequently considered the introspective study of consciousness as the source of certain knowledge. Freud divided our mental lives into the conscious and the unconscious. Freud's unconscious is composed of desires that are suppressed, expelled from the conscious self because they are unacceptable or too painful especially in connection with suppressed memories of traumas suffered especially during early childhood. Still, though unconscious, these motives and memories express themselves in dreams, neurotic obsessive symptoms, phobias, slips, jokes, sublimated art, and under hypnosis. It is impossible to learn of the content of the unconscious by direct introspection, but indirectly, through free association and the symbolic interpretation of dreams.

Freudian psychoanalysis offered to cure neurotics through recollection of the suppressed memories of the events that caused the suppression of desires. This "catharsis" should increase consciousness at the expense of the unconscious. Since the suppressed memories are painful, people devise a variety of defense mechanisms to avoid confronting them consciously.

Consequently, the Cartesian tradition of gaining certain knowledge through introspection collapsed: introspection is useless for gaining access to the unconscious, indeed it may be misleading because of defense mechanisms. The correspondence between one's thought and thoughts about thoughts (self-consciousness) has come under even greater criticism since Freud. For example, Gilbert Ryle in his *Concept of Mind* (1949) argued that introspection, inward perception of mental entities, is fallible and incomplete.

In a larger historical context, Freud responded to the rise of irrational political forces in Europe that appealed to unconscious, uncontrolled, and ultimately destructive mental forces that eventually dominated the middle of the twentieth century in Europe. Freud wished to devise a method that would bring the unconscious under the control of the rational conscious. Other trends within depth psychology, art, and politics sought quite on the contrary to release the unconscious powers, dreams, and nightmares and allow them to dominate the conscious. Younger psychoanalysts like Carl Jung (1875–1961) and Jacques Lacan (1901–1981) offered alternative characterizations of the conscious and the unconscious.

Contemporary Philosophy of Mind

The middle of the twentieth century witnessed a decline in discussion of consciousness. The research programs associated with the chief intellectual trends of the time had no fruitful implications for our understanding of consciousness: Martin Heidegger (1889–1976) directed phenomenology toward ontology and hermeneutics; structuralism and poststructuralism studied texts and languages; Marxism considered subjective consciousness to be derived from the more basic and objective material relations of production; in psychology, behaviorism ignored consciousness, while in philosophy logical positivism ignored in principle what cannot have immediate operational, empirical, effects. Behaviorism and positivism, the dominant schools respectively in academic psychology and philosophy until the sixties, ignored the study of consciousness because it could not be reduced to observable behavior or empirically verified. Since the study of private consciousness was beyond the methods associated with the research programs of either school, it was left to literature and mysticism.

In the last few decades of the twentieth century several intellectual developments led to refocusing of philosophy, especially in English-speaking countries, on the problem of consciousness. The failure of philosophical positivism to explain actual scientific theories that contain nonobservable concepts such as *energy*, and the uselessness of behaviorism for the solution of many problems in psychology in comparison with alternative research programs, spurred an academic search for more fruitful research programs and a return to the problem of consciousness.

Advances in neurology; the physical study of the brain, using brain scanning, rare cases of localized brain damage, and so forth; the discovery of genetic causes for a variety of mental illnesses; and research into the effects of drugs on the brain allowed scientists for the first time to offer physiological, ma-

terial explanations to a variety of states of consciousness. At the same time, advances in computer technology generated advanced forms of artificial intelligence. For the first time, humans created artifacts that appeared more intelligent than themselves. This led to a reexamination of popular conceptions of the distinctive essence of humanity. If not intelligence, perhaps consciousness could distinguish us from our machines?

Philosophers, scientists, and writers wondered about the prospects for conscious artificial intelligence, and hence about the meaning of consciousness. The knowledge acquired about complex information processing through the analysis of systems, such as those of artificial intelligence, prepared expectations for attempting to understand the mind as a complex information-processing system, and consciousness in those terms. These developments have led to the founding of the new, yet controversial, “cognitive science”—“cognitive science” for its detractors.

The discussion of consciousness in recent philosophy of mind may be traced to Thomas Nagel's (1974) groundbreaking reformulation of the mind-body problem, the relation between the physical and the mental. Nagel asked whether the physical-material external description of brain states could ever explain the mental internal experience of consciousness. Nagel argued that there is and always will be an “explanatory gap” between our consciousnesses and what a science of the mind may explain, however sophisticated it becomes. It will never be able to explain “what it is like” to have specific points of view, for example, what it is like to be a bat, hang upside down from the ceiling, and sense radar rays.

Much of the subsequent debate centered on reasons for affirming or denying the existence of the explanatory gap. Dualists like Nagel and John Searle suggested that though consciousness is a natural phenomenon, we lack the concepts and theories to close the explanatory gap. Eliminativism claims that there is no explanatory gap because consciousness does not exist; it “eliminates” the explanatory gap by eliminating consciousness. Daniel C. Dennett (1991), following Julian Jaynes (1976), claimed that consciousness is a cultural construct that emerged in ancient Greece.

Functionalists such as Australian philosopher D. M. Armstrong and Hilary Putnam proposed to characterize states of consciousness by their causes and effects, rather than by their internal properties. Physicalists claim that ultimate reality is material and described by physics. Both consider the explanatory gap as a problem of reduction of the mental to the physical. They recognize that there is at present an explanatory gap, but they believe that it may be possible to close it through a successful scientific reduction of the mental to physical theories. Some advocated that such a reduction will prove that a type of conscious state such as being in love or seeing red will be reduced to a physical or chemical description of a brain state. Others, such as Patricia and Paul Churchland, envisioned the reduction of what they call “folk psychology” to an advanced neuroscience along the lines of the reduction by chemical theories of ordinary descriptions of chemical interactions to a small number of types of basic elements and the laws that govern their interactions. Such a reduction may demonstrate correspondence between several types of physical interac-

tion and the same conscious state, as the same tune may be played by a variety of different orchestral arrangements.

Frank Jackson (1982) and David Chalmers (1996) argued that scientific material external explanations cannot explain consciousness, since it is possible to conceive of a universe where the descriptions of material states of affairs that explain consciousness are true, but people do not develop consciousness, a world of zombies that act in response to stimuli without being conscious. For example, people may react to hunger by eating and to danger by defending themselves without being conscious of dining or fighting. Such a problem does not exist when scientists reduce water to two atoms of hydrogen and one atom of oxygen. Colin McGinn (1991) went further by suggesting that human beings are forever blocked from knowing the link between physical brain states and consciousness because introspective consciousness provides no immediate knowledge of brains, while neuroscientific knowledge of brains provides no access to consciousness.

Frank Jackson (1982) further attacked physicalism by demonstrating that some qualia, the subjective qualities of conscious experience, cannot be reduced to physical facts. Jackson introduced the following thought experiment: Suppose that a scientist named Mary was locked all her life in a room where everything was in black and white but had access to the world outside through black and white books and television. Mary could learn everything that science can teach us about colors, optics, and wavelengths, how they interact with the eye and transmitted to the brain, and so forth. Still, though Mary would be familiar with the physicalist-scientific explanation of color, it would not prepare her for anything like the actual experience of red, because it is irreducible to scientific physical descriptions.

Physicalist responses to Jackson's thought experiment claimed that Mary's new experience of red would not add to the number of facts she knows, rather it would represent knowledge of old facts in a new way, or a broadening of Mary's imagination. The description and explanation of mental causation of physical effects is a major problem for dualists like Jackson. Eliminativists do not think there is consciousness, only perceptions of it, no qualia, properties of experience, but perceptions of qualia "as if" there were mental objects. So, mental causation of physical events is not a problem for them because they deny the mental. Jackson advocated epiphenomenalism; he considers consciousness to be a side effect of physical processes that connects physical causes with effects. Consciousness is irrelevant for the generation of physical events. Consciousness emerges then from physical interactions, has properties that are irreducible to those of a physical lower level, and so is more than the sum of its parts. A related question is whether the emergence of consciousness may be explained by Darwinian evolution as conveying some sort of adaptationist advantage.

Historical Self-Consciousness

Self-conscious introspection was presented as a source for certain knowledge of history as well as the person. Philosophies of history presented themselves as that part of the historical process

that is conscious of itself. As Nathan Rotenstreich has suggested, Giambattista Vico (1668–1744), Hegel, Marx, Benedetto Croce (1866–1952), and Robin George Collingwood (1889–1943) tried to base the very possibility of historical knowledge on the identity of subject and object. They constructed metaphysical entities like "ideal eternal history," "the spirit," "organic civilizations," "clashing civilizations," and so forth, to designate what they took to be the essence of history. If a philosophy of history is the self-consciousness of history, not just a consciousness of history, how history appeared to people who lived at a place and time, philosophers of history must occupy a privileged position within the historical process, at its end, the end of history. From the temporal vantage point of the end of a process, whether it is linear or cyclical, it is possible to discern its direction and meaning. Therefore philosophies of history from Vico to Francis Fukuyama, through Hegel, Marx, and Arnold Joseph Toynbee, have had to include apocalyptic themes in their philosophy to justify their claim to be conscious of the whole historical process. Still, mutually inconsistent philosophies of history seem to have been reflecting the consciousnesses of their particular eras rather than of the whole of history.

Self-Consciousness and Identity

Consciousness may refer to self-identity. As Locke put it in his *Essay Concerning Human Understanding*, "as far as . . . consciousness can be extended backwards to any past action or thought, so far reaches the identity of that person."

Hegel, Marx, György Lukács, Heidegger, and Jean-Paul Sartre (1905–1980) elaborated on the extent to which one's self-consciousness may not depend on introspection, but on how others conceive of oneself. Hegel introduced the master-slave dialectics, where the master's consciousness depends on the slave, since without the recognition of the slave, the master is not a master. Marx interpreted ideology as false consciousness, self-identity that does not conform to objective class interests, derived of relations to the means of production as owners or laborers. The Hungarian György Lukács (1885–1971) combined Hegel's phenomenology with Marx's materialism to present a theory of class-consciousness that became influential among European Marxists and emphasized reification and alienation. Heidegger analyzed alienation in modern mass societies where self-consciousness is imposed from without by the mass media and mass society, molding all people to become identical and anonymous. Sartre criticized the reduction of persons to roles, the promotion of essence above existence.

Under these influences, especially through the writings of Michel Foucault (1926–1984), historians have been tracing the history of such constructed and imposed self-consciousnesses, of sexual identities, madness, deviance and crime, ethnic and national identities, and so forth. These contributions to the history of consciousness have an emancipatory as well as a scholarly purpose, they intend to discover the history of self-consciousness as well as liberate groups from identities that were imposed on them from without to control and dominate.

Another debate within the writing of history and social sciences is about the primacy of consciousness and human intel-

lect over being, material conditions and especially economic structures, in history. Materialists attempt to explain historical changes in consciousness including scientific theories and new religions and artistic styles, as resulting from economic changes, whereas idealists attempt to show the opposite. As the new president of free Czechoslovakia and a former political prisoner, playwright Václav Havel put it in his speech to the joint houses of Congress in February 1990: "The experience [of totalitarianism] has given me one great certainty: Consciousness precedes Being!"

CHINESE THOUGHT

Human consciousness in Chinese thought may be seen in three layers, each of which requires the other two for both development and understanding. While these three layers of consciousness are constructed for analytical purposes, in reality they are interconnected. Psychologically, they represent different frames of reference, but they are also different dimensions of the same individual and/or collective human consciousness. The first layer, cosmological consciousness, defines the objective world of being and becoming for the human person. The second layer, consciousness of the human self, provides a world of human distinction based on the self-reflection of the human mind and heart in which a human self can be uniquely identified in the life-world of humanity. The third layer, po-

litical consciousness, is where the human self projects or reconstructs an ideal political and practical world of reality in which the human self could realize its desires for power, creativity, and freedom of action. Hence we may regard the three layers as forming an integral part of each other so that any human action and human language could impart and receive meaning relative to these three layers.

Cosmological Consciousness

Chinese cosmological consciousness was first described in the texts of *Zhouyi* (also called *Yijing*). The symbolic realism of the *Zhouyi* presents a world of changes that are embodied in symbolic forms of what may be called an onto-cosmological consciousness. Later, in the sixth to fifth century B.C.E., the Daoist text *Dao de jing* presented the development of a cosmogony from the reality as void.

The Chinese metaphysical tradition is distinguished from the Western tradition by a dialectical understanding of reality as a dynamic presentation of events and things in a context of universal and profound interconnectedness. The central idea is creative change (*yi, shengsheng*), which manifests itself in the generation of life, in the transformation of states of being, and in the two modes of becoming referred to as yin and yang, the invisible and the visible, the formless and the formed, the soft and the firm, the creative and the receptive. Transformation (*hua*) of things in these two modes of becoming is the subtle creative movement of reality in growth and decline, in an interchange of vital forces (*qi*), which also embodies relevant forms and principles (*li*). Hence any event-thing in reality is both concrete and principled, both phenomenal and noumenal. The phenomenal and the noumenal cannot be separated and their unity is realized in a cosmological process that is also ontologically understood. There is no way to speak of the ontological except by referring to it as the ultimate creative source and origin of the cosmological, the *taiji*. Based on this understanding, we may observe several features of this onto-cosmological consciousness.

Onto-cosmological reality as a process. Onto-cosmological reality is a process that has a primordial origin and source of abundant creativity because all the ten thousand things are generated from it by way of yin-yang interaction. This reality is exhibited in the phenomenon of heaven and earth and forms a space-time in which all things take place in the contexts or in the form of a situation: all situations are portents of future development and embody a history. The development of situations follows an implicit ordering of yin-yang interaction, difference, conflict, balance, and harmony.

In this process of onto-cosmology, the human person is conceived to be generated as arising from the best spirits of heaven and earth and thus embodies a nature of goodness of cosmic creativity, which matches heaven and earth by development of culture and morality. The thesis of unity of heaven and man (*tianren heyi*) is given an actual meaning and an ideal meaning: a human being is endowed with a nature and a function from heaven and earth in his birth and thus is capable of producing and creating like heaven and earth on the higher level of mind and intelligence. The ultimate goal of human life is to strive for

self-realization in moral cultural creativity derived from the onto-cosmological creativity of heaven and earth.

Indeterminate and boundless creativity. It should be noted that the onto-cosmology of *yi* (change) is not theological. Unlike the Greeks, who sought a creative force and a motivating value ending in a transcendent deity or power, the Chinese view of reality is creation from an internal creative source called the *taiji* or the Dao, not an external God. It is also unlike the Hebrew religion, which conceived God as personal and spiritual and absolutely transcendent over and above the human person, in that the ultimate reality is conceived as a spontaneous process called the Dao, and its creative indeterminateness is not confined to any personal qualities.

Perhaps it is because of the early presence of this notion of the indeterminate and boundless creativity that no personalistic religion ever came to predominate. The Chinese believer may take any and all religions as compatible and contributing to a whole of human goodness. It is also due to the early presence of this onto-cosmology that there is a lack of mythology in the early history of Chinese consciousness. This is indeed noteworthy, because almost all main cultural traditions in the world have a rich repertoire of mythological figures.

Although the Chinese onto-cosmological consciousness is not about a god, it can be described as a divine consciousness in so far as the divine (*shen*) suggests creativity from what is given to what is not given and from what is not to what is. It is in this sense that the Chinese notion of heaven and the *taiji* could also be said to be transcendent, either continuously or noncontinuously. Continuous transcendence is creativity based on what is given to produce what is not given, without excluding what is given in the new states of being. As it always links the created to the source of the creative, it is both internal and inclusive. Noncontinuous transcendence is external and exclusive in the sense that it creates things from a prior unrelated source and supervises what is created without being an integral part of it.

This may lead to the question of creation from the non-being and void, which is explicitly developed in the Daoist texts. It must be pointed out that the development of the Daoist cosmo-ontology in the *Dao de jing* is not separable from the *Yijing* onto-cosmology. In so far as the *Yijing* stresses the movement from the internal ontology of creativity to a dynamic and harmonious cosmology of universe, the Daoist sees the process of creative change as a comprehensive way of balancing all things and forces and as a process of return to the origin. This process and totality is called the Way (the Dao). The first Daoists were motivated by a desire to seek peace and tranquility of mind and spirit in the human person after witnessing the corruption of human cultures and morality and the destructiveness of wars. They wished to go back to a starting point where desires and greed in the human person had not yet been provoked and where people could appreciate the value in taking no action. For them, natural and spontaneous action embodied a morality, which is creative and harmonious for human life. It is in this light that they came to see the importance of understanding the void (*wu*). The void is without determinateness of being and is yet full of creativity of being.

It is also the formless source from which all things will return. With this notion of the void, we can see how the void gives rise to being by nonaction or spontaneous action (*ziran*) in so far as being can be seen to arise out of spontaneity.

We must of course distinguish this view of nonbeing giving rise to being from the argument *creatio ex nihilo* in Christian theology on one hand and from the argument of dependent co-origination (*yuangqi*) from emptiness (*sunyata*) in Buddhist philosophy. The *nihilo* is absolute nothingness, and God simply creates everything from this absolute nothingness by his powerful act of creation. The *sunyata* is not absolute nothingness but a state of nonclinging and no-desires in the human mind. The formation of mind is from delusion of mind, so that all things we come to know come from a co-origination, which needs to be dissolved in *sunyata*.

Natural realism. Compared with these two forms of creation, we must recognize in the *Yijing* and in Daoism a sense of natural realism that stresses different aspects of the creativity of a natural reality. The Chinese concept of consciousness is radically different from the Western scientific materialism, which reduces mind to matter, and from the Western transcendent dualism, which bifurcates the human from the divine and which separates the bodily from the spiritual. In the Chinese onto-cosmology there is no reduction but holistic correlation, no dualism but comprehensive organicism. The cosmic consciousness is not separable from the human consciousness but exists as a part of it. There is a sense of the origin and a sense of the way of development and return. There is also a sense of a potentiality for creative development from internal creativity that is both transcending and inclusive, both transforming and harmonizing. This natural realism is to be experienced as a result of comprehensive experience based on both observation and reflection. This experience is also practical and pragmatic, as what one has experienced could be applied for furthering one's life and enhancing one's pragmatic and moral actions.

Consciousness of Human Self

The development of morality in Confucianism and Mohism heightened the development of human consciousness of humanity as both individual and community. We can explain this first in terms of the formation of the *li* (ritual) as an institution that links the human individual development to the development of a society or community and to the state.

Li serves to maintain a social order founded on family relations. It is therefore a particularistic and concrete practice of relating people so that the society not only becomes ordered but also becomes affectively consolidated. In a deeper sense *li* is the sentiment showing practical care for concrete people in particular contexts and thus becomes a matter of *ren* (benevolence, humanity, human-heartedness, human goodness). But when *li* becomes merely a form without the concern or the feeling, it loses its meaning. This is the background against which the Confucian *Analects* and *Records of Li* (*Liji*) called for the reform of *li* and an awakening to *ren*.

Ren is the deep feeling of a person beyond desires, a feeling of the unity of humanity, and a consciousness of an underlying

bond among human persons that would lead to the love, care, and regard of one for the other. This deep feeling of unity is experienced as inherent in human existence. Confucius (551–479 B.C.E.) believed that the practice of *li* based on the feeling of *ren* would render *li* a meaningful and living force that would both regulate oneself inside and harmonize human relationships outside. On this basis, the world would be ordered, and the well-being of people would be secured.

Confucius thus suggests that *li* can be restored and instituted as part of social and community life. With *ren*, old forms could be modified and new forms of conduct could be adjusted and made to fit particular relationships and situations. The individuating principle of *yi* (righteousness/rightness) enables us to see how differences in situations and relationships exhibit a need for relating, which is only fulfilled by the formation of the concrete rules of *li*.

Hence, Confucius proposed three sets of virtuous relationships: the relationship between *ren* and *yi* is one of generalization and particularization; the relationship between *ren* practice and *li* is one of a general content and general form; the relationship between *li* and *yi* is one of concrete form and particular content. These three relationships represent a challenge to the old order of morality that depended exclusively on the particular forms of *li*. The principles of these relationships also form an endowment for the human mind to define its own forms of understanding and conduct. The power of seeing right and acting right is wisdom (*zhi*), which is native but which needs to be refined by practice and experience. Having attained *zhi*, a person will not be perplexed, just as having attained *ren*, a person will not have anxiety. Confucius also speaks of moral courage (*yong*) as absence of fear. When one acts right with genuine heart for *ren*, there is natural absence of fear, and there is moral courage.

Ethics and morality. Confucius takes *ren* as the basis of both ethics and morality. If *ethics* means norms governing human relationships, it is clearly founded on *ren* in consideration of human relationships. It is *ren* embodied in *yi* (righteousness) and *li* (propriety) as guided by *zhi* (wisdom). There is a dimension of *ren* that reveals the deep bond of universal humanity with heaven conceived as the ultimate metaphysical source of humanity. Confucius says the ultimate truth, or Dao, may be found in light of the experience of this ultimate source.

This deepened and heightened sense of *ren* as a vertical and uplifting force contrasts with the horizontal and expanding sense of *ren*, which includes a family, a clan, a community, and a whole world of people. We can see *ren* in either sense as a form of transcendence, a transcendence of inclusion and absorption as earlier described. In the ideal state the vertical uplifting sense of *ren* may even include the horizontal and expanding sense of *ren* (while the latter may not include the former). It is in this ideal state that we can see how the moral consciousness in Confucianism comes to a full realization of the humanity in a person.

Mencius and Zhongyong, Daxue and Xunxi. Confucianism developed in two distinct ways: Mencius (Mengzi;

c. 371–c. 289 B.C.E.) and Zhongyong emphatically expounded the upward-transcending aspect of *ren* (or *ren* in a vertical uplifting sense), while Daxue and Xunxi (c. 298–c. 230) expounded the across-transcending aspect of the Confucian *ren* (or *ren* in a horizontal expanding sense).

The uplifting sense of *ren* leads Mencius to explicitly define the essence of a human being as a moral being, with four root feelings of morality: sympathetic care, self-restraint, reverence, and distinction between the right and wrong. Zhongyong explicitly recognizes human nature as derived from heaven or from the mandate of heaven (*tianming*) and hence capable of participating in the creative and ceaseless creation and preservation of being. Zhongyong further identifies the uplifting sense of *ren* as a sense of reality by holding that if one is sincere (in the sense of having full reflection of oneself without self-deception and without withholding oneself to the openness to reality) one's mind will become illuminated.

Unlike Zhongyong, who relates the self to ultimate reality, Daxue confronts the self with the extended world of things, so that the self has to have an experiential understanding of the real world before one can relate to things and then relate to other people. Whereas the bright virtue (*mingde*) of Daxue focuses on one's ability to love and renovate people with one's self-cultivation and the cultivation of moral relations, the *daqingming* (great purity and clarity) of Xunzi focuses on renovating people with institutional design for education and governmental organization. In other words, Xunzi's approach to renovation of the people is political and economical rather than merely moral and moralistic.

It is obvious that classical Confucianism developed a system of morality that integrates humanities, education, and even religion. It is a unique system based not on a single idea of value, but on a unity of principles and ideas of *ren* and *li*. This system is truly both knowledge and value. It includes both the theoretical and the practical. As this system is continuous and coterminous with the onto-cosmology described in the first section, it can be regarded as a human development of the onto-cosmology, which leads to the unity of the heaven and the human (*tianren heyi*) through a unified process of self-reflection, self-cultivation, and self-practice (*zhixing heyi*).

Philosophical Daoism and Mohism. Two alternative systems exhibit equivalent consciousness of totality and human action. Both are critical of the Confucian system: the Daoist system rejects the practice of *li* and together the invention and development of culture and knowledge. The Mohist philosophy sought to redefine *yi* in order to achieve a standard of social justice.

Two great classical Daoists who respectively represent the initiation and development of the school of philosophical Daoism were Laozi and Zhuangzi. Laozi presents the Dao as a source of being from which things rise and to which they would return. He urges a simple style of living that is consistent with the primordial dao. His vision of reality is in fact a partial adaptation from the *Yijing's* onto-cosmology with an emphasis on the principle of receptivity and passivity as the ground and as reason for the natural creation of the world. Hence he

sees human culture as a blocking of the Dao. But for Zhuangzi (c. 369–c. 286 B.C.E.), the emphasis is not on a variant of onto-cosmology, but on how one may practice the nonseparation between oneself and the Dao where the Dao is to be embodied in all things in the world, large or small. The whole world of being is to be understood by an open and creative mind, which would link the out-world of nature to the inner world of human spirit.

The Mohist philosophy as represented by Mozi (468?–376 B.C.E.) criticizes Confucianism for its excessive engagement with *li* and thus for lacking a sense of universality and a sense of productivity. In the spirit of *li*, the Confucians practice *ren* as self-control and graded love, which Mozi sees as leading to a society of hierarchy of difference and circles of dissension. Further, Mozi sees Confucianism as dividing social classes into the ruled and the ruling, which lack a common base for solidarity. He sees the continuous wars of his time as an inevitable result of an inequitable society that lacks a sense of social justice. What then is social justice? According to Mozi, social justice must be founded on one identical standard. He uses the same word, *yi*, that Confucius used, but he intends a meaning that is objective. To establish this identity and objectivity of *yi*, Mozi appeals to the will of the heaven (*tianzhi*), with which everyone should comply. But his doctrine of identity compliance (*shangtong*) is also hierarchical, as he assumes a hierarchy of ranks that enforce the compliance. This would amount to enforcing the ideology of those upper-class leaders in the name of the *tianzhi* and this no doubt assumes or leads to a political dictatorship or totalitarianism that Mozi would build on the foundation of selection/election of the talented who are devoted to the government and consequent meritocracy.

Mozi diagnoses the cause of continuous wars as the lack of love among people. In order to reach peace among warring states, he advocates the doctrine of universal love (*jian-ai*). Love is universal (*jian*) if it can be shared on an equal basis. Thus one should love other people's family as one loves one's own family. The point is that we should not love our own family to the exclusion of other families in consideration of benefits to be shared. (But later Mencius misinterprets this as meaning treating another's father as one's own father and thus denies the unique status of one's own father). The doctrine of universal love if universally practiced would eliminate wars because it allows each group of people or state to care for its own land and property without trying to ravage lands of other states and other groups of people. There is also the more desirable consequence of this doctrine: namely the mutual benefit of states and peoples. This leads to the ultimate ideal of Mozi: every person, every people, and every state would live on an equitable basis, and a society of human life would flourish just as a society of natural life flourishes under the compassionate will of heaven.

This social idealism of Mozi is criticized for its unrealistic and utopian projections. But a more serious difficulty is the contradiction between his prescription for social justice on the basis of identity compliance and his argument for equitable love of mutual benefit. The problem results from his lack of consideration of the feelings and moral freedom of the individual,

which the Confucians make great efforts to evince as the natural basis of society and government.

Political Consciousness

Since the Daoist and the Mohist philosophies did not become the guiding principles for the development of political governance in Chinese history after the Warring States period (475–221 B.C.E.), one may ask why Confucianism became the dominating and received political ideology in the early Han period, and hence the mainstream moral and political axiology in post-Qin Chinese history. In order to answer this question, we have to understand how Legalism (*fajia*) and legalist politics failed during the Qin period, which preceded the Han. *Legalism* refers to a trend of thought focused on administrative power and punitive laws and regulations that culminated in Han Fei Zi (c. 280–233 B.C.E.). In this system the notion of law (*fa*) as a tool of punishment is too narrow a representation of the actual use of law, which was generally to the exclusion and at the expense of social morality. Legalism was based on an understanding and manipulation of human desire for reward and fear of punishment, with total disregard for human needs for freedom and trust. Because of this narrow instrumentation of the law, Legalism is identified with strict authoritarianism, which is couched in laws and regulations set by the ruler's own desire for power and wealth. Its failure to address equally fundamental and important needs in human nature doomed the Qin power to a short span despite its great work in unifying China. It also laid the foundation for a need and desire to return to Confucianism as a tradition of human nature in the trust of moral virtues.

Return to Confucianism. The return to Confucianism and especially to the political consciousness of Confucianism in the early Han period thus is not surprising, especially as there were no better alternatives as far as political governance is concerned. Confucianism more than any system presented an axiology of well-related and integrated values that were rooted in history and that could be defined or redefined as norms of a political ideology to be used to regulate the behavior of the people. Dong Zhongshu (179–104 B.C.E.) developed the Confucian justification and promotion of political ideology for political rule. Dong speaks of the harmonization and preservation of humanity and community as the primary concern of a ruler, who should extend his *ren* from the moral to the political domain. Thus Dong transforms the values of five virtuous relationships into three basic norms of organization and leadership: the people obey the ruler, the son obeys the father, and the wife obeys the husband.

This set of norms, based on Confucian virtues and a vision of a grand unity and harmony among different groups of people, worked in Chinese society for the next 2,000 years but collapsed confronting the demands for openness, equality, and individual freedom in the beginning of the twentieth century. Yet, the rejection of the three norms did not lead to the rejection of the five virtuous relationships among people. Instead there arose the opportunity to examine the political significance of the primordial Confucian proposition on the unity of inner sageliness (*neisheng*) and outer kingliness (*waiwang*) as a core of political consciousness in Confucianism and hence as the everlasting feature in Chinese philosophy.

Righteousness and the ability to rule. To rule or to govern (*zhi*) is to have power to cause others to follow or obey an order. To be aware of and practice *ren* is the first and foremost requirement for a self-cultivating person to be able to rule or to govern. A good ruler must know both what the people want and what is really good for them, and he must be worthy of their trust. The second requirement is that a ruler be led by *zhi* (wisdom) to make enlightened decisions and policies and avoid mistakes of ignorance and short-sightedness. A man of *ren* of course further requires ritual (*li*) to make his action sustainable, but this must be made on the basis of the presence of *ren*. To have *ren* and to conduct oneself right in terms of wisdom and the moral form of appropriateness, one can be said to set a good example for people to follow and emulate so that people can be satisfied with their leaders.

Rectification of names. Another essential requirement of successful governance is the Confucian doctrine of rectification of names. In the *Zilu* chapter of the *Analects* Confucius says:

If names are not rectified, then language will not be smooth, if language is not smooth, things will not be done. If things are not done, then rituals and music will not flourish. If rituals and music will not flourish, then punishments will not meet their target. If punishments will not meet their targets, then people do not know what to do.

Thus, names and language reflect reality but they also determine what reality is, particularly with regard to social and political matters. One may interpret this observation of Confucius as requiring a system of correct names and language that would order social and political relationships as the basis for political administration.

Once basic moral and social relationships among people are set in order, a political order should ensue. In order to reach such a state, the ruler has to set things right beginning with himself as a moral example. This does not preclude the institution of laws of punishment to ensure the moral order. However, the Confucian vision is that once basic order is established, then political order will be easily implemented without necessarily appealing to laws of punishment.

This point needs to be made clear: Confucius is not opposed to laws for any state. Rather, he holds that we should aim at going above the requirement of law and reach for the Dao. The political consciousness of a moral ruler is to hold oneself to the standard of the Dao so that one would not deviate from the Dao. Of course, one could still find that what one does with the intention to do good may still be wrongdoing. Rather than an intentional wrong, that would be a factual mistake, which one must conscientiously be willing to correct.

Compatibility with democracy. It has often been asked whether Confucianism is compatible with the modern Western concept of democracy, or rule by the people. The answer can be ambiguous depending on what is perceived as the goal of political rule. If the goal is social and moral order, in so far

as modern democracy will lead to such a desirable state of society, democracy is compatible with the Confucian moral patriarchy. On the other hand, if democracy is geared toward achievement of basic freedom of the people to decide how to rule themselves, then the moral patriarchy of Confucian political consciousness is indeed a problem. The basic assumption of Confucianism is often that people are incapable of making such decisions and therefore require a wise and benevolent leader to take care of them and to put their lives in order. Hence the ruler is given the whole and sole responsibility to take care of the people for the benefit of the people. On the other hand, it is believed that people can tell a good ruler from a bad ruler and that people could complain about their rule and even rise up to remove a ruler, as Mencius makes clear.

This implies that the people can also rise to choose a new ruler. The morally superior person (*junzi*) can be said to be a potential candidate for becoming a ruler. It may be argued that if he continues to develop himself in moral superiority by acquiring all the moral powers of relating to all people, he could be elected to the position of ruler. Since Confucius urges and educates all people to be morally superior persons, it logically follows that everyone can become a candidate for political rulership and could be considered engaged in a competition for successful development of oneself as a moral person in order to be eventually selected or elected to be the ruler. We must note that for the implicit mandate of the people to develop into the democratic consciousness of a modern nation-state, the major step of entrusting people to make a popular election must be made.

We may also note that the Confucian idea of the moral cultivation of a *junzi* suggests the presence of a potential democracy, because the *junzi* must win the people's trust as a good ruler. The moral requirement for political rectitude suggests that a rational understanding is needed to transform the implicit moral democracy into an explicit political practice. This transformation would represent a new development of the moral-political philosophy of Confucianism. This would amount to a revolution in the Confucian political consciousness by way of a deep rational reflection.

Two further observations of the Confucian political consciousness can be made. First, in comparison with the Greek city-state, where people were more actively concerned with the political affairs of the community, the Chinese society was primarily based on agriculture, and the people, having little time for self-governance, relied on their leaders to impose order. Once China became industrialized and people became better educated, the demand for democratic government was greater, and democracy will eventually prevail. Historically, China as a political entity has been involved in a process of consolidation of political power and integration of large groups of people for purposes of defense, so that the demand for democracy did not even arise. There is also a lack of rational reflection and understanding on the process of succession of political power to the extent that the inevitability of dynastic cycling by way of intrigue or force has become a historically conditioned belief among the large mass of people.

Second, when Confucius wrote his historical *Annals of Lu* (*Lu Chunjiu*) in which he praises moral and condemns immoral actions of dukes and ministers, he established a tradition of moral critique of political figures in light of their individual actions instead of their institutional practice. This suggests that the political consciousness of Confucianism subjected a rational consideration of institutions to a moral consideration of personal action. But we do, however, see in Confucius a critical awareness of a need for adaptiveness of a ritual system and hence a critical awareness of the question of appropriateness and timeliness of a given ritual system or institution in the governance and personal action of a ruler.

Conclusion

We have dealt with the mainstream schools of Chinese philosophy in the classical period and their contributions to human consciousness in a threefold structure. In the development of these schools a fundamental consciousness of reality emerges as the leading force of influence, namely the consciousness of the ultimate reality that is the incessant source and foundation for the building of a system of morality and a system of politics in later times. But this consciousness of the ultimate that is rooted in a human person can also be described as an original consciousness of reality as a body of truths or a system of truths (*benti*) as experienced by self-conscious individuals. This idea of *benti* has its own inner logic of development as described on the three levels of human consciousness in Chinese philosophy. In later history we see projects of realizing emptiness and achieving enlightenment in Chinese Buddhism. We also witness efforts to incorporate Buddhist insight into a Confucian framework as well as efforts to integrate various strains of thought in new syntheses and formulations of the world and the self. These efforts have continued into the twenty-first century while facing a still larger challenge: the integration of the Chinese and the Western.

INDIAN THOUGHT

There is enormous diversity among the various traditions of classical Indian philosophy concerning the nature of

consciousness and the place of humanity in the cosmos, but there are a number of presuppositions that are shared by many of India's great thinkers. Most classical Indian philosophical schools agree, for example, that living beings are reborn over and over again in a beginningless cycle (*samsara*) and that one's present situation is determined by past actions (*karma*). The final goal of most of these systems is also the same: liberation (*moksa*) from the cycle of birth, death, and rebirth.

Brahmanical Systems

In the Brahmanical systems, karmic actions are closely related to one's social duty (*dharma*), which is determined by the endogamous group (*varna*) into which one is born. Morality is not individual, but collective, and in making decisions one is not expected to decide for oneself what is and is not moral; rather, one determines what people of one's type ought to do in particular situations, and one group's morality might differ significantly from another's. For example, while killing is characterized as immoral for most groups, it is the duty of a member of the warrior caste (*ksatriya*) to slay enemies in a just war. The tension between the demands of *dharma* and the dictates of conventional morality is highlighted in the *Song of God* (*Bhagavad Gita*) in which the warrior Arjuna balks at the idea that in an imminent battle he will be required to kill relatives and teachers—people with whom he has intimate karmic obligations—and he decides to escape his *dharma* by becoming a world renouncer (*sannyasin*). The god Krishna informs him that this is not a viable option and that it would lead to ridicule from his fellow *ksatriyas* in this life and negative karmic consequences in future lives.

Atman. The *Bhagavad Gita* upholds a notion that is found in most Brahmanical systems: that every being has a permanent, unchanging essence or soul (*atman*) that transmigrates from life to life, appropriating bodies and life situations that are directly concordant with past karma. According to the *Upanishads*, however, the *atman* is not directly affected by the vicissitudes of one's rebirths; although in some texts it is described as being pure consciousness, it is not directly aware of, or affected by, change. It moves from body to body, but the individual is normally unaware of it. All beings have an intellect (*buddhi*), which when trained leads one toward direct understanding of the *atman*, but actual perception of it is the result of yogic training, in which one learns to control the senses and look within, differentiating the apparently real phenomena of perception and the truly real *atman*.

The search for the *atman* figures prominently in several *Upanishads*. In the *Katha Upanishad*, for example, a Brahman boy named Naciketas asks Yama, the lord of death, to reveal the truth of what becomes of the individual after the body dies. Yama first tests him to see if he is psychologically ready to learn the truth and, after Naciketas rejects offers of riches and fame as merely transitory, Yama decides that he has no interest in the material world and tells him of the eternal, unchanging *atman*. At the culmination of his speech, Yama pronounces the famous "great statement" (*mahavakya*), "You are that" (*tat tvam asi*), indicating that the individual *atman* is the same as the ultimate reality, referred to as *Brahman*. Brahman is described in the *Upanishads* as pure being (*sat*); it never

changes, and it is the sole reality. All the phenomena of existence are merely projections of Brahman, and when a sage learns to perceive reality as it is, everything other than Brahman is revealed as illusion.

According to the *Katha Upanishad*, the sufferings of ordinary beings are due to their lack of control over their senses (*indriya*). Yama states that the intellect is like the reins of a chariot, which the charioteer uses to control his horses. The horses are compared to the senses. Without the restraint of a firm charioteer, the horses will run rampant, just as unrestrained senses pursue fleeting sense objects. A skilled charioteer gains control over his horses in the same way that a yogi restrains his senses through meditation. The chariot is compared to the body, which is motivated to pursue attractive things by unrestrained senses but attains a state of peace through meditative practice. The atman is like a passenger who travels along with the chariot, but exercises no control over it. Liberation is attained by those who directly perceive the atman. When one recognizes that individual existence is merely illusion, all sense of separateness from Brahman is transcended, and the individual atman is merged with it, like a wave that is absorbed into the ocean.

The world of appearances. In the Non-dualist (*Advaita*) Vedanta system of Shankara (c. 8th century C.E.), the world of appearances is said to be merely the sport of Brahman (*brahmalila*). Brahman projects the illusion of ordinary reality for its own enjoyment, but ultimately none of it is real. On the conventional level, phenomena operate according to laws, and so conventionally Shankara accepts the validity of direct perception (*pratyakṣa*). From the ultimate perspective the multiplicity of appearance is false, however, and so in seeking the truth one should learn to overlook the evidence of one's senses and initially rely on the Vedic scriptures (of which the Upanishads are a part), which reveal the way things really are. Scriptural statements are later confirmed by introspective meditation.

Arguments regarding valid means of knowledge (*pramana*) figure prominently in intersectarian disputes among Indian philosophers. Most schools of classical Indian philosophy accept the primacy of direct perception, as well as inference (*anumāna*) based on sense experience. For Shankara, however, the evidence of the senses is false, and so ultimately only scriptural testimony (*śabda*) is valid. The scriptures themselves require no validation, because they “are like the sun which reveals itself while revealing colors.” The Vedas are part of the very fabric of reality and are eternally true. They have no author (*apauruṣeya*) and are directly perceived by “seers” (*ṛṣi*), who reveal them, but do not alter their content.

The Nyaya school—which like Vedanta is regarded as one of the six “orthodox” (*astika*) traditions of Brahmanical philosophy—takes issue with several of these ideas. According to Nyaya, it is ridiculous to claim that the Vedic texts have no author; instead, the Naiyayikas hold that they are composed by God, who is omniscient. God's position as the being who knows all things serves to validate the truth of Vedic statements. In addition, God is also the author of the medical texts of the *ayurveda*, and the fact of their effectiveness serves as an analogical proof that Vedic statements that cannot be verified

by ordinary humans are also true. They are further corroborated by the testimony of trustworthy persons (*apta*), and so ordinary humans can accept them with confidence.

Like the Advaita Vedantins, the Naiyayikas assert the existence of an eternal atman, which is the locus of each individual's karma, but unlike Shankara, they claim that the atman is able to acquire knowledge, feeling, and volition. It is not the sort of spiritual entity postulated by Advaita Vedanta, and each atman has its own mind (*manas*), which is connected with it until it reaches liberation. At that point, the atman becomes completely liberated from everything, including mind. The path to liberation for Nyaya begins with reasoning, which brings correct knowledge.

In common with other Indian classical philosophical systems, the Nyaya asserts that living beings are caught up in transmigration as a result of ignorance (*avidya*), which manifests in the form of mistaken ideas. Correct reasoning, guided by scripture, is an essential prerequisite for liberation. It eliminates wrong ideas and reveals the truth of things, and thus serves to overcome ignorance. One does not engage in argument for its own sake; correct reasoning leads to certainty, and is in accord with Vedic statements. On this basis, one can engage in introspective meditation, by means of which one is able to directly validate the truth of scripture. Liberation in this system is not conceived of as bliss, as in some other Indian traditions, but rather as absence of pain. Bliss requires its opposite, but in the liberated state one transcends all qualities and dichotomies. In liberation the atman is separated from the physical body—and all other physicality—and attains a state of absolute neutrality.

Buddhist Systems

The Buddhists, while accepting the notions of *karma*, *samsara*, and *mokṣa* (or *nirvana* in common Buddhist parlance), reject many of the core assumptions of the Naiyayikas, as well as important doctrines of the Upanishads and Advaita Vedanta. One of the cornerstones of Indian Buddhist schools is the doctrine of “no-self” (*anatman*), which rejects the Brahmanical belief in a permanent, unchanging soul. The Buddhists rely mainly on the *pramanas* of direct perception and inference, and reject the atman as a conceptual construct that is unfindable either by the senses or by reasoning. The Buddha pointed out that the central reality of all existence is change. All phenomena come into being as a result of causes and conditions, they change in every moment, and eventually they pass away. If there were some disembodied, unchanging entity, it would have no relation to any individual, and because it lies beyond the world of the senses it could never be perceived.

Epistemological tradition. The “Epistemological” (*Pramana*) tradition, whose most influential exponent was Dharmakīrti (c. 530–600), further contends that an unchanging entity would have no causal efficacy, and so it would be entirely unrelated to the world. Dharmakīrti's approach is pragmatic and empirical: he asserts that there is no point in discussing things that can never be verified by sense experience and that have no impact on the physical world. In his

pragmatist system, all statements and cognitions are subject to falsifiability: a statement is true only as long as subsequent perceptions and analysis do not show it to be false. In addition, Dharmakirti believes that there is no point in discussing merely theoretical topics (such as the atman) and that an essential test of validity is the possibility of effective activity (*artha-kriya*). Practical application is one of the conditions of valid knowledge. In his system, statements become true through a process of verification: they must be able to withstand subsequent analysis and be corroborated by relevant perceptions. Those that meet this test may be accepted as true, while others (even statements contained in Buddhist scriptures) should be rejected.

In his major work, the *Commentary on [Dignaga's] Compendium of Valid Cognition (Pramana-varttika)*, Dharmakirti only accepts the *pramanas* of direct perception and inference, and rejects others that are accepted by the Naiyayikas, such as comparison (*upamana*) and scriptural testimony. The former is unreliable because it is not based on direct experience, and the latter only convinces those who already accept the cited scriptures as normative. Dharmakirti asserts that any truth claim must be verifiable by analytical reasoning and direct perception. Direct perception is defined as being "free from conceptuality and incontrovertible." In his system, only the first moment of perception counts as direct perception, and subsequent moments are overlaid with conceptuality. They are not produced by cognition of a directly perceived sign, but instead are merely based on the initial perception and interpreted by the mind.

The epistemological tradition also claims that the nonexistence of the atman can be confirmed by developing a special cognitive capacity called "yogic direct perception" (*yogi-pratyaksa*), which allows meditators to directly perceive truths that are hidden from ordinary beings. In most Indian philosophical traditions, there is a close link between meditative practice and philosophy, and the training regimens of the various schools begin with study of doctrine, which is reinforced by yoga. The paths of Indian philosophical/religious traditions are intended to ensure that meditators directly perceive the tenets of the system in which they are training, and philosophy is often a reflexive exercise that uses reasoning to argue for the insights gained in meditation. Doctrine is derived from practice, and those whose experiences differ from the tradition's doctrines are either brought into line or expelled (and sometimes they become founders of new schools).

Transmigration and liberation. In rejecting the atman, the Buddhists were widely seen as being vulnerable on the question of what transmigrates from life to life. The Buddha is said to have taught that the belief in a permanent self is shared by all ordinary people, but despite its universality it is a false concept, and one that leads to grasping after material things and mistaken notions about reality. Those who seek liberation must overcome the innate belief in a self, and this requires meditative training. In searching for the atman through introspective meditation, Buddhists find that there is no enduring essence (either atman or Brahman), and that instead individuals are composites of five "aggregates" (*skandha*): form,

feelings, discriminations, consciousness, and compositional factors. The first refers to physical form, and the second comprises one's emotional responses to phenomena. These are discriminated into positive, negative, and neutral, and this process leads to desire for certain phenomena and aversion toward others. The aggregate of consciousness encompasses one's mental events and includes phenomena that are generally regarded as part of the unconscious in Western psychology. Compositional factors are other elements that are part of the innate sense of self, and mainly consist of karmic factors.

According to most Buddhist schools, consciousness is the aggregate that transmigrates from life to life. It is commonly described as being of the nature of "clear light" (*prabhasvara*), and all defilements are said to be adventitious (*agantuka*). One's volitional actions produce karmas, which move consciousness in certain directions and determine the nature of one's rebirth, but consciousness, unlike the atman, changes in every moment and is directly affected by the vicissitudes of one's life. Meditative training aims to remove mental defilements like anger, desire, and obscuration, while simultaneously cultivating good qualities like patience, morality, and wisdom.

In classical Indian philosophy, Buddhism was one of the main "heterodox" (*nastika*) systems. The Buddhists rejected the authoritative Vedas and claimed that their own scriptures contained correct doctrines and the only truly effective path to liberation. They asserted that the core existential problem is suffering (*dukkha*) and that it is caused by ignorance. Because beings misunderstand the true nature of reality, they make choices that lead to suffering and result in continuing transmigration. Since the problem is a cognitive one, the solution is also cognitive: liberation requires that one overcome mistaken ideas and acquire correct understanding. One of the most basic misconceptions, according to the Buddhists, is the notion of the atman. They assert that anyone who clings to a permanent self or to an ultimate reality (whether conceived as God or Brahman) will inevitably continue to transmigrate from life to life, and they hold that only those who free themselves from such false notions are able to attain liberation.

For all of the traditions discussed in this essay, the central concern of philosophy should be liberation. Indian philosophical texts commonly state in their introductions that the purpose of composition is to aid others in the pursuit of *moksa*, which indicates that philosophy is not viewed as an exercise in discussing semantic problems, but ideally should be a matter of profound concern for anyone seeking to comprehend reality as it is and thus attain the ultimate goal.

CONSERVATISM. *Conservatism* lends itself to misunderstanding because its political designation is easily confused with popular usage. To be conservative in the sense of preferring the familiar to the unfamiliar is a common form of behavior. Since this attitude toward life is universal, it issues from no necessary political commitment. For any person, even the most bohemian, not to develop a settled habit or a lingering attachment would be almost inconceivable. However, it is possible to conceive of persons having such habits and attachments and yet being radical in his or her politics. That would have been true, for instance, of Adolf Hitler. Equally, to be conservative in the sense of wishing to maintain a position of authority, privilege, reverence, or wealth is another universally recognizable form of behavior that issues from no necessary political commitment. It would be exceptional for someone who has achieved or inherited such powerful status not to want to secure it. This would have been true, for instance, of Joseph Stalin. Both of these popular meanings of conservatism—as shorthand for individual or social characteristics—are inadequate to understanding conservatism in politics. Both of them are primordial in their instincts, general in their applications, and empty of content.

Conservatism in politics, on the other hand, is a relatively recent historical phenomenon, particular in its significance, and as a consequence has a distinctive, if differentiated, character. Conservatism is best understood as a set of propositions about the activity of governing, defined against those radical ideologies with roots in eighteenth-century speculation, like liberalism and socialism, that were to have such a profound effect on world history in the course of the nineteenth and twentieth centuries. It is opposed to grand schemes for the political emancipation or salvation of humankind to which such radical speculation can lead. Conservatism advocates limited ambitions in politics, argues that the aspiration of government should be modest, and emphasizes the value of continuity in the state. Conservatives believe that government can be authoritative only when it is limited, modest, and continuous. If it were possible to identify a distinctive desire uniting all forms of conservatism, it would be the desire to be left alone to enjoy the benefits of a well-ordered society. As the nineteenth-century British prime minister Lord Salisbury (Robert Arthur Talbot Gascoyne-Cecil) once put it, conservatism is like a

policeman: if there were no (radical) criminals to protect against, there would be no need for it. However, conservatives will not be left alone.

Origins of Conservatism: Britain, France, and Germany

Restricting the scope of politics in this manner has made conservatism appear at odds with the promise of modernity. Certainly, any political project to remove evil from the world is for the religious conservative an act of impiety, just as any project to perfect humankind is for the secular conservative an act of dangerous folly. The difficulty remains that these fundamental criticisms of modern hubris are easily dismissed as nostalgic, self-interested, and most damning of all, irrationally prejudiced. If conservative irrationalism can be ascribed to any particular failing, it is thought to be the presumption of resisting historical progress. In this view, conservatism and modernization are antithetical, since to be modern is to assume history to be linear and its meaning to be emancipation from ignorant custom. That is an audacious concept of politics that understands traditional restraints to be obstacles to manifest destiny.

Conventional historical wisdom has been that the event that transformed these terms of political argument was the French Revolution. That convention is a sound one. The main currents of European intellectual life were drawn into the revolution, and out of it emerged the modern narrative of progress versus reaction, improvement versus obstruction, and reason versus tradition that was to shape political reflection in the course of the following two centuries. This has been an influential narrative and a persuasive one. In its light, conservatism at best serves as a prudential brake on the wheels of change, at worst as an insufferable denial of human development. In neither case is it thought to involve anything of substantial value or intellectual significance. Nevertheless, the temptation to interpret conservatism as "antimodern" should be resisted, for to be conservative does not entail a passive acceptance of the status quo. Rather it involves a critical encounter with what exists. *Conservatism* was itself a nineteenth-century neologism for a modern, novel, self-conscious disposition in politics and as such is a contemporary of *socialism*, *liberalism*, and *nationalism*. Its meaning has been given by modern experience and its content by the recurring expression of certain principles in the work of thinkers alarmed into reflection by revolutionary activity. Conservatism, in other words, has a history, not a nature, and that is an insight owed to the Irish "philosopher in action," Edmund Burke (1729–1797).

Britain. If Burke is taken to be paradigmatic of conservative thought, it is by attribution rather than by design. Burke drew on a large repertoire of ideas, such as the social-contract tradition of Thomas Hobbes (1588–1679) and John Locke (1632–1704) and the skeptical conventionalism of David Hume (1711–1776), and marshaled them like a great melodist to challenge the abstract "speculatism" of the French revolutionaries. Writing from within a culture of constitutional monarchy that had only recently and precariously secured its legitimacy (albeit with the loss of the American colonies), Burke's intent in *Reflections on the Revolution in France* (1790) is to warn against

the implications of revolutionary principles, which he thinks are as subversive of good government as they are of bad. If society is indeed a social contract, it is a contract “between those who are living, those who are dead, and those who are to be born,” and in that formulation Burke tries to make safe two of the potentially radical loose ends bequeathed by Locke. Political society, Burke argues, is not dissolvable according to demands made by the present generation, and the “tacit” consent of contemporaries is assumed because of their inherited obligations and future responsibilities. Burke does refer these obligations and responsibilities to laws of nature, but he is aware that nature can be a false friend. It is those very “natural” rights, so beloved by revolutionaries in France, that he dismisses as being incompatible with the “real” rights of political society. For Burke, to “follow nature” is not a radical invitation to rebel against society but an injunction to accept one’s “second nature” as a dutiful member of a historically achieved political order. Since history is a record of experience and since all practical knowledge is a product of experience, history supplies a sufficient guide to political activity. From that empiricist rather than natural-law premise, Burke proposes that prudence, circumstance, utility, convenience, and respect for order provide the proper conditions for liberty, while abstract theorizing delivers the condition of “rational despotism.”

For some, this committed Burke (and conservatism) to an “organic” theory of society. That is an understandable interpretation, but a degree of caution is required because the argument is more subtle and the content less mysterious than the expression “organic” sometimes implies. Burke’s notion of the constitution assumes an arrangement in which order and liberty presuppose one another. It assumes that the individual is part of and has meaning within a social order of classes or estates and that the state is an authoritative expression of that social order. The “little platoons” of immediate identity are functional to stability because their education in local and social affection forms the basis of patriotism. On the one hand, the state cannot be absolute, for its existence depends on the life of its parts and it has a duty to secure them. On the other hand, reasons of state cannot be reduced alone to the protection of the rights of individuals. If revolutionary theorizing would dissolve these historical associations into dust and make social relationships as evanescent as the “flies of summer,” Burke’s model was not an alternative blueprint. Unlike the revolutionary’s vision of France as “nothing but *carte blanche*, upon which he may scribble anything he pleases,” Burke is defending what he takes to be the actual life of the British state, monarchical, aristocratic, and constitutional.

The paradigmatic conservatism of Burke’s thought lies in its evocation of sympathy for what is enduring in a political association. While revolutionary politics proclaim a profound incompatibility between the values of the people and the principles of traditional structures of government, Burke proclaims a deep congruence. Tradition, which is shorthand for a politics of congruence, emerges from his work as an important value in conservative politics. Conservatism puts the idea of tradition to work in defense of the political order. It seeks to encourage people to accept the world around them, for it just

happens to be the world in which we do live and it is one that sets limits to political change. In the British case, the ability of the political order to secure its authority through prolonged periods of economic and social change appeared to confirm Burke’s maxim that a state without the means of reform is without the means of its own conservation. It also appeared to confirm his assumption that the advancement of civilization owes more to the advantages of stability than it does to the pursuit of abstract rights. In the conduct of reform, continuity is secured because improvements are never wholly new and what is retained is never wholly obsolete. Of course, the reconciled condition that conservatism proposes is reconciliation within the ideology itself and not necessarily reconciliation in experience. It is possible to conceive of reality as being seriously at odds with the ideology.

France. This was the case for conservatives in France, where, unlike the happy condition of Britain, the experience and effect of revolution had disconnected the state from what they believed to be the true spirit of society. This compelled thinking through with passionate intensity questions of order and legitimacy, and it fostered a politics that made fundamental distinctions between what is true and what exists. In this case what mattered was the fractured rather than the coherent relationship between political structures and spiritual truth. The legitimacy of those who had usurped power in the name of reason could never be secure against the consecrated authority they had displaced. The task of conservative political argument was to recall people to their true allegiance by clarifying the principles that had been forsaken.

For Joseph-Marie de Maistre (1753–1821), the French Revolution represents divine retribution for the sins of the godless Enlightenment and the “century of blasphemy” that had preceded it. One consequence of that blasphemy is the rationalist misconception involved in the creation of a written constitution. The true constitution is not to be found in the fine words of such a document but in the public spirit that should animate it. For de Maistre, “what is written is nothing.” The constitution is divine in origin, and only when one acts in harmony with God can his or her actions be creative. Once separated from the Creator, people’s actions are rendered negative and destructive. The rule of number, implied by popular sovereignty, has nothing to do with the rule of justice and would ultimately prove to be self-destructive. This is what the course of revolutionary history reveals to conservatives—a succession of failed constitutions of increasing perniciousness and impiety. That disastrous history is as much the fault of the internal corruption of the ancien régime as of the arguments of the philosophes. Ironically then, the revolution will serve as a necessary purgative and will lead to the inevitable, because divinely ordained, restoration of monarchy, religion, and nation. That dissociation between the social and the political as well as the theocratic justification for the restoration of the ancien régime is also found in the work of Louis de Bonald (1754–1840). Monarchy and church, throne and altar, will together bring back into harmony the body and spirit of the nation that the French political revolution had willfully divided. It will, moreover, defeat secular nationalism and replace it with ultramontane Catholicism.

Like Burke, de Maistre and de Bonald associated the terror and the chaos in France with the new, rapacious, self-seeking, revolutionary elite, and they formulated a sociology as well as a pathology of revolution to account for it. They recall to attention the monstrosity of humankind when liberals may prefer to flatter humanity, and they remind one that original sin may be a better guide to modern history than natural goodness. Nevertheless, there are a number of problems with their denunciation of revolutionary presumption. Like radicalism, their thought conveys a profound alienation between what is and what ought to be and, like radicalism, presents itself as a science of politics with a blueprint of restoration as grandiose as the Declaration of the Rights of Man and Citizen. Moreover, de Maistre's celebrated recommendation that if "you wish to *conserve* all, *consecrate* all" is a proposition that transforms the sacred into human artifice, as impious to the true faith as the revolutionary consecration of the cult of the Supreme Being. The intelligent reflection necessary to make the case for conserving all tends to corrode the myths upon which traditions depend and collapses conservatism into very unconservative reaction.

Germany. If conservatism in Britain defended the congruence and conservatism in France demanded the restoration of harmony between the social and political orders, then conservatism in nineteenth-century Germany aspired to bring together an idea of the social and an idea of the political. Here revolutionary France in all its horrible fascination was instructive, demonstrating not only the radical dangers of popular sovereignty but also the military effectiveness of national unity. A romantic evocation of the cultural and racial characteristics of the *Volk* existed alongside a statist philosophy of *realpolitik*. Both were to contribute to an aggressive nationalism favored by those who thought German culture threatened by alien influences and by those who thought its state insufficiently powerful. If these tendencies are present in some measure in all conservative politics, they were to take a radical and racist turn in twentieth-century German history when combined in the detraditionalized, de-Christianized, alienated, genocidal (and so unconservative) shape of National Socialism.

A very different sort of reconciliation is provided by Georg Wilhelm Friedrich Hegel (1770–1831), whose philosophy courageously addresses the central problem of modernity—the idea of progress—that conservative thought either chose to veil (like Burke) or to deny (like de Maistre). The conservative suspicion of progress is that it denies the present in pursuit of the future. A restless and limitless ambition for change, based on an abstract model of human experience, makes modernity into a political *project* to be implemented rather than a *process* (for good and ill) to be understood. The French Revolution was such a political project, and Hegel attempts to map the lineage and the lineaments of the modern state in order to contain the destructive potential of the ideal of emancipation (that Hegelianism was not the *project* of modernity, the fulfillment of which demanded a new science of revolution, was well understood by that most insightful student, Karl Marx). On the conviction that the rational is actual and the actual is rational, Hegel argues in *The Philosophy of Right* (1821), the "plain man like the philosopher takes his stand." The task of the philosopher is to reveal

the rationality of the common-sense intuition of the plain person. Hegel does not approve an institution on the basis of Burkean prescription—that its survival alone is sufficient justification of its rationality—but on the basis of its conformity with the rational self-understanding of the age. Such rationalism and historicism sit uneasily with conservative traditionalism, which often despises the self-understanding of the age and believes that the best reason for a practice is that no reason need be given. Despite his philosophical ambivalence, Hegel's appeal to the conservative is twofold. His reflections satisfy the need to feel that the enjoyment of present liberties is meaningful and should not be sacrificed to some abstract "ought to be." They also satisfy that deep desire to arrest the disturbing uncertainties of modern life within stable political institutions. Ironically, it has been these emotional satisfactions rather than his rational metaphysical system that constitute Hegel's enduring attraction to conservative thinkers.

The Challenge of the Modern

If there has been a specter haunting conservatism in modern times, it is the specter of "mass society." The fear of mass society is a product of two related possibilities. The first is the disintegration of traditional allegiances in the name of liberation and personal freedom. Since conservatives hold that such allegiances are the condition of identity, the consequence would be the loss of individuality. Liberalism, ironically, promotes the death of liberty. The second fear concerns the manipulation of that disintegration by ideologies that promise material satisfaction in return for absolute political power. Having destroyed individuality, mass society would demand abasement before the secular image of its collective power, the state. Socialism, ironically, promotes the death of the social.

In the nineteenth century and for much of the twentieth century, conservatism defended property, religion, and family as bulwarks against the feared drift to "mass" society in which the decencies of civilized life would be subverted by popular barbarism. This disposition helps to capture what is distinctive about the conservative idea of the nation, the one form of popular politics to which it not only adapted but which it also helped to define. For conservatives, the nation is understood as a political community united in acceptance of the legitimacy of traditional political arrangements. The "people" is not some abstract category but the historic nation in its regional and social variety, with its traditional beliefs, particular affections, and long-standing prejudices. To be conservative is another way of professing one's sympathy for the "real" character of the nation, and like de Maistre, conservatives would agree that they have met the French, English, Germans, or Americans but have yet to meet "Humanity."

In rejecting the universal claims of radical politics, conservatism has been compelled to identify exactly what it is that makes the nation distinctive. What differentiates conservatism from right-wing ideologies is the nature of that distinctiveness. In right-wing thought the idea of the nation serves to mobilize the people in order to assert its distinctive purity, honor, and greatness. In conservative thought, the idea of the nation serves to foster piety toward its distinctive social and political

institutions. This differentiation has nothing to do with the intensity of national feeling. It has to do with the source of national feeling. Right-wing thought locates it in the will of the people. Conservatism locates it in the inherited practices of a way of life and has been concerned to limit the popular will in the name of tradition and order. In Europe between the two world wars, conservatism was outflanked by radical right-wing movements because an appeal to tradition and order appeared irrelevant in conditions of economic collapse and social disintegration. The sense of political decadence made an ideology of popular salvation, like fascism, a powerful alternative to traditional conservative patriotism. Britain was the exception, and the experience of British conservatism was thought to illustrate the distinction between the politics of the moderate right and the politics of the extreme right.

While the drama of modern European history has been taken to be exemplary of this difference, an American illustration is more appropriate. Harvey C. Mansfield Jr. considered that the great achievement of American politics has been the replacement of the idea of the sovereign people with the idea of the constitutional people. "The warmth of their republican genius must somehow be cooled; the confidence in their own sovereignty, which is responsible for the factiousness of democratic majorities, must be restrained" (Mansfield, p. 57). The practice of constitutional politics educates democracy in the responsibilities of government, in particular the need to limit power in order to enjoy life, liberty, and happiness. All elements of government "are derived *from* the people but none of them *is* the people," and populism, with its tendency to deny limit and constitutional constraint, is just as subversive of good government as any other species of radicalism (Mansfield, p. 55). This does not imply that there are no elements of populism in conservatism or that conservative politics has not appealed to its prejudices against innovation. However, conservatism's suspicion of political enthusiasm of all kinds makes it uncomfortable with the fickleness as well as the hubris of popular opinion, especially when it proclaims itself to be "the moral majority."

Resisting democracy, defending tradition. Of course, resisting the claims of democracy in the name of limited constitutional politics can be interpreted as an offense to modern sensibility, and defending tradition in a world of rapid change can be seen as either irrelevant or willfully ignorant. Conservatism always faces an enormous challenge in making these ideas persuasive in a world of programmatic politics. It appears insufficiently purposeful to those who are seeking a political faith and insufficiently principled to those who are seeking an alternative to radicalism. To such critics, conservatism is always right, but its inability to be proactive also means that it is always wrong. For example, Friedrich Hayek (1899–1992) thought conservatism incapable of offering "an alternative to the direction in which we are moving" because it does not and cannot indicate another direction (p. 398). Since Hayek famously believed that the socialistic path along which society was moving was the road to serfdom, then clearly conservatism, for all its useful maxims, would not do. This attitude helps to distinguish conservatism from that other species of recent politics, the New Right.

What Hayek assumes is the modernist belief in history-as-project, and this makes politics into an engagement between

projects, either a capitalist one or a socialist one. That modernist assumption, at the heart of New Right dogmatics about liberty and choice, finds systematic expression in neoconservatism. Indeed, some of the leading neoconservatives, like Irving Kristol, have radical political backgrounds. Their contribution in the last half of the twentieth century was to provide a systematic critique of "big government" and its policy failures and to show that the market was not only compatible with moral values but also more efficient in the delivery of social goods. Neoconservative arguments helped transform the political climate in the 1970s and 1980s and contributed to the intellectual defeat of socialism. However, there does exist a tension in neoconservatism between market fundamentalism and conservative skepticism. As Michael Oakeshott (1901–1990) once argued, a plan like Hayek's to end all planning is still a species of rationalism and one with which conservatives can only feel uncomfortable. It abstracts the market from the institutional and cultural traditions necessary for its flourishing, and for the skeptic, conservatism does not have a project to realize. That is its strength and not its weakness, for it properly designates the restricted competence in human affairs of such projects like market liberalization. If conservatism has an attitude toward capitalism, it is the endeavor to sustain those conditions that favor the political economy of freedom, a very different notion from the minimal state.

Postmodernism, human rights, and multiculturalism.

If in the early twenty-first century revolutionary ideologies like communism no longer threaten, arguments in favor of egalitarianism and the aggrandizing state have taken a new shape. As a result, conservatism has been obliged to engage with new discourses, such as postmodernism, human rights, and multiculturalism. In 1959 Hannah Arendt (1906–1975) wrote that distinction and difference had become private matters of the individual and that simple insight, with its contradictory effects, continues to have profound implications for conservatism. Traditionally, of course, conservatism held distinction and difference not to be private matters at all but to be ones of public significance. According to Robert Nisbet, this is the key to understanding the conservative sociological imagination, where such differences, articulated in social institutions like Burke's "little platoons," mediate the relationship between the state and the individual.

The trend toward privatization has disordered that notion in two ways. First, the contemporary state has come either to absorb many of the functions of these institutions, like the educational responsibilities of churches, or to incorporate them into centrally determined policy networks. Second, it has become attractive for the individual to retire into a private world and to cede public duties to the care of professionals. The consequence of both aspects is an expansion of state influence that many conservatives do believe is inimical to individual freedom and social autonomy. For the conservative, the old radical dynamic that required a straightforward faith in state-fostered egalitarianism to be achieved through the redistribution of wealth between social classes has been replaced by a politics of inclusion that requires a rather contradictory faith not only in cultural "difference" but also in the redistribution of "worth" between social groups. The dynamic in this case is toward

the removal of all obstacles in the way of social inclusion, and the motor is a refurbished language of abstract rights.

This new politics is understood to be yet another strategy to achieve the utopian objective of radical democracy, and conservatives believe that the only way it can be realized is by calling on the state to implement an ever-expanding body of entitlements. The influential neoconservative critique of modern liberalism has its roots here, and the concern is that the emphasis on rights will weaken the informal bonds of society and permit the state to become dangerously intrusive in the lives of citizens, destroying the distinction between public and private. Diversity is officially “celebrated,” but what is fostered is a culture suspicious of independent thought or behavior or “political incorrectness.” This is reminiscent of what George Santayana (1863–1952) once called “vacant liberty.” Santayana’s problem with the prescriptions of liberalism is its high-minded egalitarianism of respect, which he believes to be at odds with the very pluralism it seeks to promote. For Santayana, unlimited toleration would achieve the “euthanasia of differences,” and as a consequence everybody “would be free to be what he liked, and no one would care to be anything but what pleased everybody” (p. 449). This anticipates a common, two-pronged, conservative criticism of contemporary liberalism. First, liberalism defends difference only in theory but cannot really come to terms with it in practice when it discovers that goodwill alone is not enough. Second, it is actually intolerant of dissent from political correctness and seeks to impose a modern version of “rational despotism.” Two strands of conservatism, the civil and the cultural, can be identified in response to contemporary political trends.

Conservatism: Civil and Cultural

Civil conservatism draws on a recognizable tradition of limited politics. On the one hand, it proposes that government should not plan the lives of citizens or be an instrument of their collective enlightenment but should uphold a framework of law. On the other hand, it argues that the rights of civil society should not be translated into claims on public expenditure but should be valued as the condition of self-reliance and creativity. Limited but authoritative government remains the proper complement to a society of “difference.”

This understanding owes much to the work of Oakeshott, who in turn owes much to Hobbes. Indeed, Oakeshott’s celebrated essay “On Being Conservative” draws its inspiration from a distinctive reading of Hobbes’s *Leviathan*. Commentators seduced by his poetic description of conservatism as a preference for “the tried to the untried, fact to mystery, the actual to the possible, the limited to the unbounded, the near to the distant, the sufficient to the superabundant, the convenient to the perfect, present laughter to utopian bliss” (Oakeshott, 1991, p. 408) sometimes fail to note that Oakeshott believes this disposition to be inappropriate “in respect of human conduct in general” (p. 415). However, conservatism does remain appropriate in respect of government, all the more so indeed in a modern society that puts so much store by its individualism.

Governing, for Oakeshott, “is recognized as a specific and limited activity; not the management of an enterprise, but the

rule of those engaged in a great diversity of self-chosen enterprises” (1991, p. 429). The philosophic basis of this view of government is explored in *On Human Conduct* (1975). This text has provided fruitful reflection for a diverse range of thinkers seeking a method to secure political legitimacy in contemporary multicultural societies and who identify a common threat to civility in utopian liberalism. Noël O’Sullivan, for example, has attempted to develop a vision of “formal politics” where the bond of association “is neither an agreed end, nor personal approval of the ruler and his actions, but acknowledgement of the procedural considerations which confer authority” (pp. 204–205). He argues that formal politics does not mean a commitment to liberalism but rather a rejection of the sort of “programmatically politics” with which modern liberal politics has become associated. The problem with the formal politics favored by civil conservatives is that it may be (ironically) too abstract and too detached from public sentiment to engage the loyalty of citizens. Certainly, it appears very distant from that sympathy for a traditional way of life normally associated with conservative politics.

Cultural conservatism, by contrast, assumes that a sense of unity rather than diversity is the foundation of political legitimacy. As Roger Scruton argues, the civil vision discounts “prejudices,” and for Scruton (as for Burke), prejudices are those prepolitical affections, such as a sense of national belonging, upon which a stable political order depends. As he succinctly expresses it, “Unity is, in the normal instance, social rather than political, and ought also to be national” (1990, p. 54). This sets out a clear skeptical agenda for conservatism on issues—such as immigration, feminism, multiculturalism, and human rights—that are thought to present challenges to the substance of national identity. This cultural conservative agenda can be distinguished from that of the extreme right because of its respect for the conventions of established institutions. The great difficulty with it is that the social unity it assumes is a contentious one and, far from being self-evident, presents an easy target for those who would dismiss conservatism as nostalgic and elegiac. Contemporary conservatism, then, remains an ambiguous identity, a hybrid of civil and cultural elements.

Conclusion

In a century of ideological extremism like the twentieth century, conservatism often appeared something of an affectation and marginal to the march of history in which the advancing forces of modernization were thought certain to rout the retreating forces of conservatism. Insofar as many people have lost faith in the “grand narratives” of the nineteenth and twentieth centuries, like Marxism and other emancipatory ideals, then the conservative disposition may no longer appear so reactionary. Since conservatism never subscribed to the grosser forms of the modernist faith, contemporary skepticism comes as no surprise to it. However, as befits a philosophy of modesty and imperfection, conservatism cannot assume a final victory.

CONSILIENCE. "Consilience of inductions" is a phrase that was invented by the nineteenth-century English historian and philosopher of science William Whewell (1794–1866; pronounced "Hule"), and introduced in his *Philosophy of the Inductive Sciences* (1840). Whewell was trying to capture the notion of what Isaac Newton (1642–1727) had labeled a "true cause," or *vera causa*, the kind of cause that supposedly lies at the center of the very best kinds of scientific theories. Whewell's friend, the astronomer and philosopher John F. W. Herschel (1792–1871), had argued (in an empiricist fashion) that a true cause is something that we ourselves experience

directly or analogically. We know for instance that a force is pulling the moon toward the earth, because we have had direct experience of the tug of a string as we are whirling around with a stone tied to its end.

Whewell, to the contrary, in a rationalist fashion, wanted to characterize a true cause as something that is not necessarily experienced at all, but that is adequate to explain the empirical facts as we know them. He argued therefore that such a cause must be at the center of a scientific explanation, explaining all of the disparate facts and in turn being explained by them. If such a cause can predict and explain new and excitingly unexpected facts, then so much the better. Such a fan-like construction, with the cause at the apex, Whewell labeled a consilience of inductions. He argued also that such a situation is as simple as it is possible for a theory to be, and hence a true cause is also marked by the fact that it is the most economical of explanatory forces, with many parts being reduced to one fundamental mechanism.

For Whewell and Herschel, the paradigmatic example of a true cause was Newtonian mechanics, which used the one force—gravitational attraction—to explain not just the heavenly motions of the planets but also the earth-bound motions of such things as cannonballs. Johannes Kepler's (1571–1630) laws of celestial motion and Galileo Galilei's (1564–1642) laws of terrestrial motion were brought beneath one force. But Whewell and Herschel themselves were arguing over the science of their day, most particularly the nature and causes of light. The beginning of the nineteenth century was the time when the wave theory of Christiaan Huygens (1629–1695) was conquering the particle theory of Isaac Newton. The problem is that no one sees waves. Herschel argued that we have experienced analogous phenomena to light waves, for instance the waves of water in a pond. Hence it is reasonable to suppose that light waves produce such things as interference patterns. Whewell replied that there is no need of analogies—it is enough that the wave theory explains many phenomena that are impossible to explain with the particle theory. The patterns produced by something such as Thomas Young's (1773–1829) double-slit experiment are themselves enough to confirm that light travels in waves and not in particles.

Also dividing Whewell and Herschel was the true nature of geology, with Whewell arguing that it is permissible—even obligatory—to invoke unseen upheavals (catastrophes), and with Herschel agreeing with the uniformitarian geologist Charles Lyell (1797–1875) that unlimited time is enough to produce all changes, given the kinds of causes (rain, sleet, earthquakes, and so forth) that we see around us today. A young scientist who took deep note of Whewell's arguments was Charles Darwin (1809–1882), who, realizing that no one can ever see evolution actually occurring, consciously modeled his *Origin of Species* (1859) on Whewell's thinking. Having introduced his mechanism of natural selection, Darwin then spent the rest of the work showing how selection explains so many different areas—instinct, biogeography, paleontology, embryology, morphology, classification, and more—and how these areas in turn confirm natural selection as a true cause. When challenged, Darwin always referred to this strategy, even though, somewhat

paradoxically, Whewell himself never became an evolutionist and supposedly would not allow the book on the shelves of the Cambridge college of which he was principal.

Consilience in Modern Science

The consilience of inductions figures high in modern science. Its broad explanatory power was the main reason that so many geologists were so quickly converted to the theory of plate tectonics. Supposing that the continents move explains so much—the shape of the continents, the position of earthquakes and volcanoes, the trenches in the middle of oceans, the magnetic lines, and much more. In recent years the idea has been extended into philosophy and to thinking about science and knowledge generally. The Harvard student of the ants and of social behavior (sociobiology), Edward O. Wilson, argues that all of human knowledge is heading toward a consilience—a consilience where evolution will be the all-powerful joining and explaining idea. We have a kind of gene-culture coevolution, where culture tries to impose its ways and norms on human behavior and thought, but where the genes always constrain the flights of fancy and make sure that human nature never strays too far from the basic biological.

Wilson argues that morality for instance cannot exist as a disembodied ethereal enterprise, but must be rooted firmly in our evolutionary background—morality exists because and only because it was and is of use to us as creatures struggling to survive and reproduce. Those humans who worked together did better than those who did not. Likewise, religion serves to bind humans together in well-functioning units. It has no correspondence to reality but serves as an adaptation toward the greater success of *Homo sapiens*. Wilson argues that we must strive to achieve ever-greater consiliences between disparate parts of human knowledge until all is bound together in one big super-picture. Only then will we humans recognize the extent to which we are part of this big picture—a picture that includes all of natural diversity. Only then will we humans be truly motivated to the preservation of the living world around us, something from which we emerged and something without which we can never hope to survive. Consilience has therefore moved from the epistemological norm of William Whewell to the moral imperative of Edward O. Wilson.

CONSTITUTIONALISM. Constitutionalism is commonplace in modern political discourse in the West and beyond, yet it remains an elusive concept. Some have considered it impossible (and unnecessary) to give a definition of it.

Nonetheless, one can discern several common features of the concept: the rule of law, not of men; limitations of political authority; the protection of civic rights and liberties; and rule based on the free consent of the ruled. Placing limitations on the exercise of political power is central to the notion of constitutionalism, and measures for that end include admonition to the deviant ruler; the assertion of the people's right to resist, punish, or depose a tyrant; the division of sovereignty via federalism; and the separation of powers, or other checks and balances.

Paradoxical as it may seem, the presence of a constitution is not necessarily a manifestation of constitutionalism. A constitutionalistic constitution forms a political entity, establishes its fundamental structure, and determines the limits within which power can be exercised politically. But some constitutions in the modern world, like those of the former Soviet Union and the People's Republic of China, do not limit the exercise of political power. A constitution of this sort is designed to constitute and empower the state, but not to control it.

Ancient Conceptions

The idea of controlling political power goes back to ancient Athens, where all state officials were accountable to the citizens who sat on the jury court. This jury-court system is the hallmark of the Athenian constitutionalism based on popular participation, yet it was never conceptualized by the leading Greek philosophers, including Plato (c. 428–348 or 347 B.C.E.) and Aristotle (384–322 B.C.E.). For Plato, democracy—rule by the ignorant masses—was fundamentally flawed. His vision of the ideal state, therefore, allows no space for an assembly or a court: a countervail to the contemporary practice of Athenian politics. Aristotle's tripartite conception of the just political structure—monarchy, aristocracy, and *politeia*—resulted in the idea of the mixed constitution combining the virtues of three. This idea, ill defined by Aristotle, was often confused with the idea of the ideal constitution. The political practice of Republican Rome was described and celebrated by Cicero (106–43 B.C.E.) as the “mixed constitution,” which was, however, a pure aristocracy according to his own description. The nature of Republican Rome's political institutions remains elusive: in contrast with Cicero, Polybius (c. 200–c. 118 B.C.E.) depicted them as part of a constitutionalist system, with the popular assembly controlling legislation and the election of magistrates.

Medieval Conceptions

The medieval model of constitutionalism is often associated with Magna Carta (1215); in it, the constitutionalistic idea that personal liberties should be protected from the authority of the prince by established legal procedures was already present. But the medieval contributions to constitutional theory may be found in the sphere of ecclesiology under the label of conciliarism. Conciliarism was the idea that the pope was not an absolute ruler but a constitutional monarch whose authority was ministerial and delegated to him for the common good of the church. The ultimate authority in the church, then, resides in the whole body of the believers or their representatives—namely, the general council. According to twelfth-century canonists, who

grappled with the questions surrounding the possible abuse of power by the pope, the pope was an intrinsic part of a general council and the authority of the pope with a general council was greater than without: an argument parallel to the secular idea of the supremacy of the king-in-parliament. The divine nature of papal authority did not necessarily result in theocratic absolutism because of the idea that the power of jurisdiction came from God through the people; the power of the papal office originates from God, but the choice of a person who assumes the office depends on the consent of human cooperation.

The exaltation of papal sovereignty in thirteenth-century mendicant ecclesiology was countered by secular masters' "episcopal" view: Christ conferred supreme authority not to Peter and his successors alone but equally to the twelve apostles and their successors; thereby ecclesiastical sovereignty was divided. All these elements of thought constituted conciliarism in the later Middle Ages, represented by such thinkers as Pierre d'Ailly (1350–1420) and Jean de Gerson (Jean Charlier; 1363–1429). The historian J. N. Figgis describes early modern constitutionalism as "the last effort of medieval constitutionalism," but the extent to which medieval constitutional thought influenced its modern counterpart remains debatable.

Early Modern Conceptions

Widespread administrative abuses and ecclesiastical corruption in late-sixteenth-century France generated a number of polemical pamphlets, which asserted the rights of the people to depose a tyrant. Huguenot political writers including François Hotman (1524–1590; *Francogallia*), Théodore de Bèze, (Theodorus Beza; 1519–1605; *The Rights of Magistrates*), and Duplessis-Mornay (Philippe de Mornay, Seigneur du Plessis-Marly; 1549–1623; *Vindiciae contra tyrannos*; A defense of liberty against tyrants) made important contributions to early modern constitutionalism by defining the right to resist and depose a tyrannical monarch as the ultimate guarantee of a set of particular controls on political authority. Their works rejected resistance by private individuals but asserted the right of resistance by constituted public power, especially of the Estates and lesser magistrates. Huguenot political thinkers upheld the doctrine of the division of sovereignty between the monarch, representative institutions, and lesser magistrates, whilst their contemporary Jean Bodin (1530–1596), a powerful proponent of the indivisibility of sovereignty, saw anarchy as the alternative to monarchy (just as Thomas Hobbes would do in the following century). Jean Bodin's theory of sovereignty circulated widely in seventeenth-century England, and served to bolster the idea of unlimited monarchical sovereignty manifested by James I (ruled 1603–1625) and Charles I (ruled 1625–1649). Sir Robert Filmer (c. 1588–1653) and Thomas Hobbes (1588–1679) conceptualized the doctrine of monarchical authority. But political authority in England had already been pluralistic, and this reality was crystallized in Sir Edward Coke's (1552–1634) idea that the English judiciary was independent from the crown as well as from Parliament. A more direct reaction to the Bodinian doctrine came from Johannes Althusius (Joachim Althaus; 1557–1638), who attributed indivisible sovereignty, unlike Bodin, to the people as a collective entity.

The people as individuals are under the ruler, and yet the people as a collectivity is superior to the ruler. Althusius's novelty lies in his vision of federalism: he conceived a political community as a hierarchy of corporations, and took care to specify the way in which smaller communities are associated together in larger political entities, which resulted in a system of checks and balances.

Perhaps one of the most important sources for the authors of the American constitution was the epoch-making *L'esprit des lois* (1748; *The spirit of the laws*) written by Charles-Louis de Secondat, baron de Montesquieu (1689–1755). This eminent lawyer was deeply inspired by the English system of government that, in his view, had effectively secured what he called "political liberty." Montesquieu observed that the highest expression of political liberty was to be found in England. English constitutional practice had protected each citizen from each other, from foreign enemies of the state, and from the state itself. The key to this success, according to Montesquieu, was the functional separation of powers: legislative, executive, and judicial. The institutional separation of powers secured effective control of the coercive authority of the state: a significant departure from the "mixed constitution" model.

The late eighteenth century was the age of constitutions; the first modern written constitution was enacted in the United States of America (1787), followed by the French Declaration of the Rights of Man and the Citizen (1789). *The Federalist*, eighty-five papers written by Alexander Hamilton (1755–1804), James Madison (1751–1836), and John Jay (1745–1829), vindicated the theoretical foundations of the U.S. Constitution that underlined the limits on federal power by means of federalism, separation of powers, and the effective independence of political institutions. These institutional constraints were designed to augment the citizen's exercise of civic virtues to prevent monarchical despotism and to maintain liberty.

What constituted an important intellectual backdrop was republican constitutional ideas. Republicanism, upheld by influential figures such as Montesquieu, Jean-Jacques Rousseau (1712–1778), and Immanuel Kant (1724–1804), distinguished the people as a legislator (constituent power) from the people as a legislative power (constituted power) and envisioned the "good order" of society—that is, the fundamental principles of the working of a political society, or the means by which good laws and good rulers should be made. On the other hand, the U.S. Constitution was initially criticized for the omission of a specific statement concerning basic citizen rights. This was later drawn up as the Bill of Rights, now considered an integral part of the constitution.

Modern Conceptions

The U.S. Constitution generated reaction from British constitutionalists, and at the heart of the debate was the idea of sovereignty. Walter Bagehot (1826–1877), the author of *The English Constitution*, criticized the ambiguity of the locus of sovereignty in it, whereas Albert Venn Dicey (1826–1877) thought highly of the federal system of government that divided legislative powers between national and state authorities. The nightmare of totalitarianism in the first half of the

twentieth century, on the other hand, demanded the vindication of constitutionalism, which was quintessentially crystallized in Charles H. McIlwain's *Constitutionalism, Ancient and Modern*.

In the early twenty-first century, issues over constitutionalism became ever more complex. Constitutionalism did not grow out of democratic thought, yet most contemporary states with a constitution are constitutional democracies. This demands that the relationship between constitutionalism and democracy be defined more precisely. The reconciliation between liberal right-based constitutionalism and republican democratic constitutionalism has also been sought. Furthermore, there exists a plurality of constitutions. The British model, for example, manifests parliamentary sovereignty, whereas the American model locates sovereignty in the people. The wide reception of constitutionalism beyond the West has created new varieties of constitutionalism (transformative constitutionalism). The emerging European Union after World War II, followed by the post-1989 developments in Eastern Europe in particular, has brought the debate over constitutionalism to an entirely new phase: constitutionalism beyond the framework of the nation state, and even the possibility of global constitutionalism.

Islamic Conceptions

The idea of limited government was not unknown in early Islamic political thought; the Muslim ruler was more limited than Christian princes in the sense that he had no power to legislate. The Holy Law (*shari'a*) however, was not effective in limiting political power due to the dearth of institutional machinery that imposed the limitations.

In Persia (Iran) in the 1850s, the government reformed the legal system to limit the power of the *'ulama* (scholar-teachers), and introduced the Western notion of constitutionalism. The promoters of constitutionalism, such as Malkom Khan (1833–1908) and Mirza Yusef Khan Mostashar od-Dowle (d. 1895), endeavored to demonstrate that the new idea was anchored in Islamic law and tradition. Mirza Yusef Khan's treatise, *Yek Kalameh* (n.d.; One word), contrasted Western prosperity with Persian stagnation and saw the solution of this problem in *yek kalameh*, a political structure based on law. He highlighted the virtues of the French constitution and demonstrated its compatibility with Islamic ideas. Such endeavors contributed to incorporating the Shiite religious group successfully into the constitutionalist movement, thereby paving the way to the Constitutional Revolution (1905–1911). Similarly, the young Ottomans, including Namik Kemal (1840–1888), who admired the constitution of the French Third Republic, reinterpreted passages in the Koran as arguments for constitutional democracy. Khayr al-Din al-Tunisi (1822/23–1890), who dreamed of the independence of the Islamic world community, was, like the Ottoman and Persian reformers, receptive to the Western constitutional idea that personal liberty and justice should be achieved by the rule of law. But his constitutionalism also echoed the Islamic intellectual tradition, especially the political ideas of Ibn Khaldūn (1332–1406).

Chinese Conception

The term that signifies “constitutional law” is of ancient origin in the Chinese language, and yet it denoted none of the

Western ideas associated with modern Western constitutionalism. For the Chinese, constitutionalism was a Western import, dating back to the early nineteenth century. But the idea was not seriously assimilated until Japan established the first constitutional law in East Asia in 1889.

K'ang Yu-wei (1858–1927) was the leader of the Hundred Days of Reform, the movement for constitutional reform. He embraced the evolutionist view that constitutional change from monarchy to democracy was a historical necessity. His 1898 reform program, which included the creation of a parliament and the adoption of a constitution, was welcomed by the Emperor Kuang-hsü, (ruled 1875–1908), but its translation into practice was aborted by the coup d'état under the initiative of the Empress Dowager Tz'u-hsi (1835–1908).

Japan's victory in the war against the Russian Empire in 1905 demonstrated, in the eyes of the Chinese constitutional reformists, the victory of constitutionalism; this gave added momentum to the reception of the idea in China. The Ch'ing government drew up an “Outline of Constitution” modeled on the Japanese constitution, which never took effect, however, due to the 1911 revolution led by Sun Yat-sen (1866–1925) and the downfall of the Ch'ing dynasty. The Republic of China, established in 1912, promulgated a Provisional Constitution, the first modern constitution, modeled on the U.S. Constitution. Sun Yat-sen's *Sanminzhuyi* (1924; The three principles of the people)—the Principle of Nationalism, the Principle of Democracy, and the Principle of People's Livelihood—was inspired by Abraham Lincoln's (1809–1865) Gettysburg Address (1863), and his guiding principle of constitution-making known as the separation of five powers—the powers of administration, legislation, judiciary, examination, and impeachment, the last two being uniquely Chinese—was built upon Montesquieu's notion of the separation of powers.

Japanese Conceptions

The Japanese reception of Western constitutionalism, following the collapse of the Tokugawa Shogunal regime (1603–1867), was motivated by the diplomatic and military needs of national independence. The strengthening of the military needed to be augmented by “the concord of the People's mind (*jinwa* or *jinmin kyōwa*),” which could be achieved through the introduction of Western constitutional government. One of the pressing tasks in domestic politics was to settle the conflict between powers by entrusting supreme authority to parliament. Hence, in his *Tonarigusa* (1861; Grass next door), the first treatise on constitutionalism in Japan, Katō Hiroyuki (1836–1916) proclaimed the establishment of parliamentary politics. The perception of a constitution as the symbol of a modern Western-style state was widely shared by the political leaders of the new Meiji government, which led to the speedy creation of the Meiji Constitution, the first constitutional law in East Asia. Yet, the adoption of a “Westernized” constitution, officially an imperial gift to the Japanese subjects, was not accompanied by wide acceptance of the idea of controlling the power of the state. The prevalent Confucian language that equated the private with the evil and the public (namely, the state, not the civil society) with justice undercut the constitutional idea of the protection of individual liberties.

After Japan's defeat in World War II, constitutionalism, which had experienced a serious setback during the war, was rehabilitated under the new Constitution of Japan. This Constitution, however, was created not by popular demand, but by the initiative of the occupation authority. Ever since, Article 9, which proscribes the use of military means in diplomatic conflict, has been the focal point of post-war constitutional debate.

CONSUMERISM. Consumerism, the central economic and social policy of contemporary capitalism, is a doctrine of growing the economy through constantly increasing the consumption of commodities and services. The term *consumerism* is also used to describe movements to protect the rights and interests of consumers.

Consumerism and Mass Production

While the consumption of commodities has always been an aspect of human society, consumerism was not possible until after the first and second industrial revolutions (1760–1840 and late nineteenth and early twentieth centuries, respectively). The industrial revolutions, led by Great Britain and the United States, gradually caused the replacement of the artisan system, in which goods were produced locally by skilled workers on a

small scale. Technological innovations, like the spinning jenny (1764), allowed fewer and less-skilled workers the ability to produce more goods, while the creation of national transportation networks, such as railroads, allowed for their wide dissemination. The factory system, in which labor was organized by specific tasks, rose into prominence, leading to the growth of cities, rising immigration, and the depletion of natural resources.

As the labor process was divided into separate tasks, laborers became estranged from the products of their labor, destroying the pride in craftsmanship they had experienced in the artisan system. Karl Marx (1818–1883), political economist and theorist of capitalism, described this disconnection as "alienation." Alienation allowed commodities to be seen not as the products of labor, which was hidden from consumers, but as fetishes, things imbued with an almost animate power in the world. A commodity's usefulness, or, in Marx's terms, use-value, became increasingly subordinated to its exchange value, or its social worth (generally its price or monetary value). As commodities lost any connection with objective value, they became fetishized. Advertising has aided and exploited commodity fetishism by suggesting that commodities have magical properties—that is, that buying a product will increase the consumer's social status or attractiveness. As the commodity has become the central aspect of social life, areas that were once outside of the economic sphere, such as the family or religion, are recreated as commodities for sale in the market.

While the industrial revolutions allowed for mass production, it was not until Henry Ford (1863–1947) introduced his assembly-line system for automobile production that goods could be produced in huge quantities cheaply enough to be widely accessible. Using Frederick Taylor's scientific-management principles, Ford assigned workers small, repetitive tasks that by 1913 allowed a car to be produced every ninety-three minutes. While the nature of this work was potentially unfulfilling for workers, Ford paid them well—his legendary five-dollar-per-day minimum wage—as a means of ensuring that he would have a mass of people able to afford the Ford Model T. The success of Ford's venture so changed the American economy and capitalism in general that the Italian Marxist Antonio Gramsci (1891–1937) coined the term *Fordism* to describe it. Fordism is defined by an economy dominated by centralized mass production, state welfare, unionized workers, and consumption of standardized commodities, of which the Model T is the ideal example. This car was designed to appeal to all consumers regardless of class, race, gender, and so on. Under Fordism, yearly or seasonal product changes are minimal or nonexistent.

While advertising had existed previously—from town criers to handbills—advertising as a rationalized, scientific profession began only in the 1850s. In the mid-nineteenth century a variety of products, such as patent medicines, had come to be widely consumed in the national marketplace. Advertising became important as a means of creating desire for new, standardized products and especially of proving to consumers that these products were superior to homemade or local ones. In their search for status as professionals and experts, advertisers

sought to distance their practice from the carnivalesque methods of peddlers, snake-oil salesmen, and other hucksters by relying on factual information soberly offered. Yet the carnival tradition never entirely disappeared, and even in this era, pictorial advertisements using magical and sensual imagery continued to appear in mass periodicals, though they were managed by the new national advertising agencies and therefore became increasingly standardized.

By the 1880s and 1890s the modern advertising system was in place. Instead of simply serving as middlemen between businesses and media outlets, advertisers sold their services as designers of campaigns, promoters of products, and experts on the media. Branding, in which products came to be known by a specific brand name, became increasingly important in differentiating essentially similar products from each other in the market. As these brand-name products were distributed across formerly insurmountable barriers of geography by steamships and trains, people in diverse regions could consume the same products, inculcating a sense of nationalism. In this way, the

Fordist era promoted a nation founded on the “democracy of goods” in which everyone used the same consumer products, collapsing consumerism with national identity. Yet this “imagined community” was highly stratified by race, gender, ethnicity, and class. While the Fordist era of mass production shifted the United States, as well as other nations, from a country of artisan production, regional cultures, and individualized commodities to one of national brands, this nationalism came at the expense of many members of the nation itself, particularly people of color, the working class, and women. Blacks, for example, were portrayed in advertisements of this era almost exclusively as happy servants or as icons of slavery, such as Aunt Jemima and Uncle Ben. Working-class people were also rarely seen in advertisements, which presented a relentlessly middle- or upper-class world.

Consumerism and Post-Fordism

The term *post-Fordist* has been used to describe the shift from an economy based on mass production and mass consumption

SOAP

Soap was first sold under a brand name in Great Britain in 1884, placing it indelibly within the history of British imperialism and Victorian notions of gender and race. Soap advertisements portrayed soap as a fetish, imbued with the power to cleanse and bring civilization. As Reverend Henry Ward Beecher (1813–1887) argued in an 1885 testimonial for Pears soap, “If Cleanliness is next to Godliness, then surely SOAP is a means of GRACE.” Soap advertisements consistently used magical imagery to hide the intense labor performed by working-class maids employed in middle-class homes. Middle-class women were never shown as laborers, creating a gendered ideology where middle-class women were “angels of the household” whose major role was that of consumer.

Soap advertisements also offered a racial ideology, described as “commodity racism” by Anne McClintock. A Pears soap advertisement of 1899 argued that “The first step toward lightening THE WHITE MAN’S BURDEN is through teaching the virtues of cleanliness. PEARS’ SOAP is a potent fact in brightening the dark corners of the earth as civilization advances.” The scientific racism that posited evolutionary notions of biology and history came to be projected onto commodities, which would do the work of empire. Soap became the symbolic carrier of whiteness, imperialism, and Victorian gender roles.

of identical goods to one distinguished by “flexible specialization.” Production is specialized through the use of technology. The post-Fordist labor force is multiskilled and global, which has eroded the class consciousness of Fordist labor movements. Importantly, consumption has become specialized as well. No longer is there one product designed for the mass of consumers. Instead, products are target marketed to particular niches, using demographics, psychographics, and other marketing techniques. At this point, style becomes the major method of differentiating products. Advertisers encourage consumer desire to become more volatile and individualized. Products are not marketed by extolling their utilitarian value but by proving to the consumer how he or she can use them to display a particular identity to the world. The development of a post-Fordist economy is difficult to pinpoint, though scholars suggest that the 1970s in the industrial West was a turning point. Even within one economy, such as the United States, the development of post-Fordism did not occur unilaterally through all industries. While current Western economies can be described as post-Fordist, Third World economies are not necessarily so, though First World post-Fordism relies on the exploitation of labor, resources, and markets within the Third World.

Scholars agree, however, that one of the most significant aspects of the post-Fordist economy is the reliance on market segmentation as opposed to mass consumption. Market segmentation emphasizes particular aspects of a product or creates a particular product to appeal to specific market segments, which are differentiated by income, gender, race, ethnicity, age, geography, and so on. This marketing para-

digm developed out of the baby boom of the post-World War II era and the social and identity movements of the 1960s that became the predominant paradigm by the 1970s and 1980s.

The social and identity movements of the 1960s suggested that people understood their identities as differentiated by a number of characteristics. In response, advertisers and marketers explored the potential for “breaking up America” and the world into an ever-increasing number of segments of people who had “lifestyles” that were defined by the particular commodities they consumed. The development of cable television is an ideal example. Beginning in the late 1970s, cable networks were designed to appeal to particular types of viewers, whether women (Lifetime), African-Americans (Black Entertainment Television [BET]), and youth (Music Television [MTV]), through the content of their programs as well as the flow of shows and commercials. As important as “signaling” or attracting the desired type of viewers, however, was ensuring that unwanted types of viewers were not watching.

Race and ethnicity are becoming increasingly critical market segments. In 1994, according to *Brandweek*, at least half of all Fortune 500 companies were using ethnic or racial marketing techniques. Latinos, for example, are one of the fastest-growing ethnic minorities in the United States, and corporations are searching for ways to appeal to this segment, which is divided into a variety of subsegments (Mexican-American, Puerto Rican-American, Cuban-American).

PSYCHOGRAPHICS

Psychographics is a method of market segmentation based on personality, lifestyle, and geodemographics. These techniques promise to offer marketers the ability to define their target buyers by their beliefs, values, and self-perception. This allows for micromarketing, or marketing tailored to the level of very small segments, such as neighborhoods. For example, a department store that serves a neighborhood of young unmarried people may not carry children's products, while the same department store in a different but nearby neighborhood, with a different geodemographic profile, might do so. Psychographics also allows marketers to appeal to consumers based on their perceived self-perceptions. Does this consumer generally make decisions based on status? Beliefs? The online service "You Are Where You Live" offered by the marketing analysis company Claritas in the early 2000s is an example of the use of psychographics and geodemographics.

An important corollary of these developments is that as style becomes central in product differentiation, it is necessary for styles to change rapidly. What has been described as the essentially postmodern practice of pastiche is an outgrowth of these marketing and economic changes, in which capital recycles old styles in a desperate attempt to create products that seem "new and improved." As the commodity becomes even more divorced from use- or exchange-value, it becomes a sign, able to be given a variety of possible and mutable meanings depending on the particular market segment. Price fluctuates not according to actual production costs but according to how much a particular consumer will pay. Cultural intermediaries, or those members of the professional-managerial class that work in cultural industries such as advertising or public relations, serve as cultural guides for the middle class, helping these consumers navigate the array of potential commodities available for consumption and offering their lifestyles as models of how to live successfully in this new world of constant consumption.

The Politics of Consumerism

As consumerism has become the fundamental doctrine of contemporary capitalism, individuals have been encouraged to consider themselves primarily as *consumers* rather than as citizens, workers, or members of religious denominations. While in many ways this ideological shift has been spurred by capital as a means of ensuring a continual increase in consumer spending as a means of growing the economy, numerous individuals and organizations have used this consumer identity as a way to encourage government control over business and to protest social, racial, political, and economic injustice. For example, during the Great Depression of the 1930s women's organizations such as the General Federation of Women's Clubs and the League of Women Shoppers led consumer protests for food legislation and against rising meat prices. Dr. Kathryn McHale, the general director of the American Association of University Women, summarized the consumer

movement's philosophy in 1935 when she said "there is no interest which is more fundamental than that of consumers. All residents of our nation are consumers in large or limited way. No matter what our other interests, we have in common one function—that of consumption" (Cohen, p. 34).

Even the civil rights movement of the 1950s and 1960s utilized consumer identity to justify its claim for equal rights. The first and most-remembered protests were the Montgomery bus boycott, when African Americans refused to consume public transportation as a protest against their inferior treatment in the transit system, and the lunch-counter sit-ins, when protesters refused to move from whites-only dining areas. These tactics showed the government and the American public the correlation between citizenship and the right to consume—in the consumerist world of post-World War II America, being banned from consumption demonstrated second-class status.

While consumer movements have been successful to a degree in protecting certain rights, they can be faulted for accepting the overwhelming ideology of consumerism and, more widely, capitalism. Instead, other individuals and organizations have sought to protest the ideology of consumerism through a variety of methods and means. While consumerism relies on the creation of desire, anticonsumerist movements focus on "need." Religious sects such as the Amish and the Shakers adapted the Christian idea of voluntary poverty, for example, to create a more godly existence based on need, while the counterculture of the 1960s used voluntary poverty to justify its renunciation of material goods and capitalism. However, even voluntary poverty or its secular corollary, "voluntary simplicity," created by Duane Elgin in the 1980s, have been adapted by the mass media and business. In the 1970s the Stanford Research Institute, a nonprofit corporation that offers corporate clients advice on emerging trends, estimated that almost 75 million Americans had "simple" sympathies that business should utilize (Kleiner, 1996). Still, many people advocate voluntary simplicity as necessary to limit the negative environmental

impact of a consumer-driven economy, which produces huge amounts of waste and uses resources at an ever-quickening pace.

Another central critique of consumerism is related to globalization. Multinational corporations are cited for destroying local and indigenous resources and cultures in order to make way for their products. The term *McDonaldization* has been coined to describe the phenomenon of local cultures being stamped out by multinational corporations spreading a homogenous Western (usually American) culture. However, scholars dispute the effects of McDonaldization. While many see local cultures being destroyed by the forces of globalizing popular culture, others assert that local cultures incorporate and adapt these forces, creating a syncretized culture. Still, either side must acknowledge the uneven power relationships that exist between a cultural behemoth like the United States and Third World markets.

CONTEXT. Like "text," the word "context" is a metaphor derived from the Latin *texere*, "to weave." In the fourth century C.E. the Latin noun *contextio* described the text surrounding a given passage. In the Middle Ages, *contextio* came to mean "literary composition," but an interest in what we call "context," especially in biblical exegesis, was expressed through the term *circumstantiae*. In the ninth century, Sedulius Scotus enunciated the rule of "seven circumstances"—person, fact, cause, time, place, mode, and topic.

Texts in Context

It was in the sixteenth and seventeenth centuries, especially in Italian, French, English, and German, that the term "context" (*contesto*, *contexture*, *Kontext*) began to be used with frequency. From the sentences before and after the passage to be interpreted, "context" came to refer to the coherence of a text, the relation of the parts and the whole. The term was also extended to include the intention (*scopus*) of the writer.

"Circumstances" remained a key term. Jurists discussed circumstantial evidence. Moralists studied "cases of conscience," the ethical equivalent of case law. Interpretations of the Bible invoked the need to take circumstances into consideration. The sixteenth-century Florentine historian Francesco Guicciardini offers an example of contextual thinking in early modern style. Guicciardini's *Considerations* on the *Discourses* of his friend Niccolò Machiavelli criticized the generalizations because they were "advanced too absolutely" (*posto troppo assolutamente*), since human affairs "differ according to the times and the other events" (*si varia secondo la condizione de' tempi ed altre occorrenzie*).

The thrust of the movements we call the "scientific revolution" and the "Enlightenment" was anticontextual in the sense that participants were concerned with formulating generalizations that would be valid whatever the circumstances. By the late eighteenth century, however, these "enlightened" attitudes were coming to be viewed as part of an intellectual old regime against which a more "historicist" generation revolted around the year 1800, stressing differences between individuals and cultures at the expense of general laws.

The Rise of Cultural Context

This "Counter-Enlightenment" was associated with a further expansion in the meaning of the term "context," increasingly concerned not only with local circumstances but also with the "historical context" of an entire culture, society, or age. A famous example is Madame de Staël's essay *De la littérature considérée dans ses rapports avec les institutions sociales* (1800; The influence of literature upon society). Within the German tradition of hermeneutics, the classical scholar Friedrich Ast distinguished in 1808 between the literal or grammatical level of interpretation, the historical level (concerned with meaning), and the cultural level, concerned with grasping the "spirit" (*Geist*) of antiquity or other periods.

Karl Marx was a contextualist in another sense, concerned to locate consciousness and its expressions within "life," especially social life. Marxists and non-Marxists alike were increasingly concerned with *Zusammenhang*, the connection between the parts and the whole.

Material context was also taken more seriously in the early nineteenth century than before. In archaeology, the increasing concern with stratigraphy in the early nineteenth century implied a concern with context or location. Antoine Quatremère de Quincy denounced the looting of Italian works of art by Napoleon, Lord Elgin, and others on the grounds that this uprooting or *déplacement* deprived the objects of their cultural value. Later in the century, the German anthropologist Franz Boas caused a sensation in museum circles by arguing that artifacts should be arranged by “culture area” rather than evolutionary sequence because an object could not be understood “outside of its surroundings.”

The Discovery of Situation

In a number of disciplines in the 1920s and 1930s, especially sociology, psychology, history, and anthropology, the term “situation” came to play a central role. Karl Mannheim, for instance, one of the pioneers of the sociology of knowledge, treated ideas as socially situated (literally “tied to the situation,” *Situationsgebunden*). At much the same time the sociologist William I. Thomas was stressing the importance of what he called “the definition of the situation” for social action. In psychology, Lev Vygotsky and Aleksandr Luria argued that the mentality of illiterates was characterized by “concrete or situational thinking.”

In the case of history, we might contrast the French with the British approach. Marc Bloch’s famous study *Les rois thaumaturges* (1924) attempted to make the belief in the supernatural power of the royal touch intelligible by presenting it as part of a system of “collective representations,” while R. G. Collingwood and Herbert Butterfield concerned themselves with contexts and situations at the individual level. For Butterfield, the historian’s task was to place an individual action “in its historical context.” For his part, Collingwood declared that “every event . . . is a conscious reaction to a situation, not the effect of a cause.”

Anthropology is sometimes perceived as the contextual discipline par excellence. More exactly, it became this kind of discipline in the 1920s, thanks to Bronislaw Malinowski. Meaning, he argued, is dependent on the “context of situation.” In a famous example he referred to a stick that might be used for digging, punting, walking, or fighting. “In each of these specific uses,” he claimed, “the stick is embedded in a different cultural context.” Malinowski’s ideas about context were taken further by his pupil Edward Evans-Pritchard, in a study of witchcraft, oracles, and magic among the Azande in which the author argued that “an individual in one situation will employ a notion he excludes in a different situation.”

The Contextual Turn

In the last generation we have seen what might be called a “contextual turn,” on the analogy of so many other turns in intellectual history. One sign of change is the increasing use of terms such as “contextualism,” “contextualization,” and “de-contextualization.” In the case of theology, the “contextual reinterpretation” of religion has been under discussion. In ethics, a movement known as “situationism” has effectively revived casuistry under another name. In philosophy, John Austin’s analysis

of the “occasion” and “context” of utterances remains influential. In educational sociology and psychology, the work of Basil Bernstein and Jerome Bruner on “context-dependent” and “context-independent” learning illustrates the trend.

In literary criticism the idea of placing a poem “in context,” or even “in total context,” was defended by the Cambridge critic F. W. Bateson and denounced by F. R. Leavis, who argued that “social context” meant merely “one’s personal living.”

In the 1950s and 1960s, sociolinguists such as Dell Hymes and William Labov noted that the same people speak differently according to the context or situation. Even in the case of the law, concerned with general rules, the rise of “context sensitivity” has been noted. In sociology, Anthony Giddens described “locale” as essential to what he calls the “contextuality” of social interaction, while feminists such as Donna Haraway revived and revised Mannheim’s concept of “situated knowledge.”

A concern with situation and performance has become increasingly visible in recent decades in musicology and art history. Thus the phrase “performative context” has come into use to refer to the adaptation of music to suit a certain place, occasion, and audience. In art history, where an artist’s style was once taken to be an expression of his or her personality, it is now interpreted as a kind of performance. A movement for a “contextual archaeology” has made its appearance.

In intellectual history the concern with context is even more explicit, above all at Cambridge University. In the 1950s, Peter Laslett argued the case for placing Locke’s *Second Treatise of Government* in a “revised historical context.” In his *Barbarism and Religion* (1999) J. G. A. Pocock, a student of Butterfield’s, set out “to effect a series of contextualizations” of Edward Gibbon’s *Decline and Fall of the Roman Empire* (1776–1788). Quentin Skinner’s work relies still more on the idea of context, whether linguistic, intellectual, or political. In the philosophy and history of science, the foundation of the journal *Science in Context*, in 1987, offers another example of context-consciousness, at once an attempt to emulate the historians of political thought and a response to a continuing debate over the status of scientific knowledge, universal or local.

CONTINENTAL PHILOSOPHY. The term *continental philosophy* was coined by English-speaking analytic philosophers in Great Britain and the United States shortly after World War II. Since then, the term has been used primarily by English-speaking philosophers but not by western European philosophers, who see no need to call themselves "continental."

The differences between analytic and continental philosophy are rooted in eighteenth-century European Enlightenment. Generally speaking, analytic philosophers tended to view the Enlightenment positively, while continental philosophers viewed it critically. Taking different stances toward the German philosopher Immanuel Kant (1724–1804), analytic philosophers focused primarily on Kant's epistemological work, *Critique of Pure Reason*, while continental philosophers stressed Kant's ethical and aesthetic works, the *Critique of Practical Reason* and the *Critique of Judgment*. The final divide between analytic and continental philosophy occurred in their respective stances toward post-Kantian German idealism and Romanticism, especially toward the dialectical system of the "Absolute Spirit" posited by Georg Wilhelm Friedrich Hegel (1770–1831). Deeply influenced by Hegel and by the critique of religion devised by Hegel's former student Ludwig Feuerbach (1804–1872), Karl Marx (1818–1883) and Friedrich Engels (1820–1895) transformed Hegel's dialectical idealism into dialectical and historical materialism. In keeping with this post-Kantian philosophy, contemporary continental philosophers are concerned primarily with man's history and culture and with religious, moral, and social issues.

Wittgenstein and Analytic Philosophy

In order to understand continental philosophy, one has to refer indirectly to analytic philosophy, which originated in Germany and Austria through the work of Gottlob Frege (1848–1925) and the Austrian-born British philosopher Ludwig Wittgenstein (1889–1951), its most famous representative. Analytic philosophy was preceded by the logical positivism of the "Vienna Circle" of the 1930s and drew its name from its logical "analysis" of language. Analytic philosophy soon became the mainstream philosophical movement in the English-speaking world, especially after the publication of Wittgenstein's *Tractatus logico-philosophicus* in 1921. With great originality, the later Wittgenstein overshadowed almost all of analytic philosophy with his posthumous book *Philosophische Untersuchungen* (1953; *Philosophical Investigations*), which brought

about a new "linguistic turn," wherein language came to be understood in terms of cultural diversity, or "language games," including ordinary, religious, moral, and aesthetic language. In his later years Wittgenstein criticized his own *Tractatus* and its one-sided, representational "picture theory" of language. The later Wittgenstein reinterpreted language as embedded in the action-oriented, social context of historical "forms of life." In addition, Wittgenstein was deeply concerned with the foundations of religious faith, the nature of religious language, fideism, and ethical and aesthetic issues, which brought him closer to the European, "continental" philosophy of Kant, Arthur Schopenhauer (1788–1860), and even Martin Heidegger (1889–1976).

Wittgenstein opened the way to encounters with continental philosophy. In spite of ongoing differences in subjects and methods, in the late twentieth and early twenty-first centuries continental and analytic philosophers have opened promising new dialogues as exemplified by Richard Rorty, Herbert Dreyfus, Charles Taylor, John McDowell, Hilary Putnam, Stanley Cavell, Alistair McIntyre, Hans-Georg Gadamer, and Jean-François Lyotard, among others. Contemporary philosophy of science, with its historical and sociological sensibility, has also been influenced by continental philosophy as exemplified by Thomas Kuhn, Gaston Bachelard, Jürgen Habermas, Karl-Otto Appel, Ernst Tugendhat, Ian Hacking, Paul Feyerabend, Patrick Heelan, Joseph J. Kockelmans, Ted Kiesel, and Thomas M. Seebohm. Continental philosophy has especially impacted Heidegger-influenced existential psychoanalysis as exemplified by the work of Jean Piaget, Ludwig Binswanger, Medard Boss, Erich Fromm, William J. Richardson, and Jacques Lacan.

With its roots in the Enlightenment, the analytic tradition, for the most part, stresses clarity and precision in thought and language, an ahistorical view of truth, reason, and human nature. It tends to critique traditional religion, morality, and metaphysics. With the exception of the more conservative Wittgenstein, analytic philosophers, for the most part, adhere to a progressive, liberal, and democratic worldview. In contrast, heavily influenced by Hegel's ideas about the intrinsic historicity of human thought and action, continental tradition, for the most part, is concerned with the historical, cultural, and social conditions of human life and tends to be focused on issues of liberation and "emancipation" from individual and social injustice. Some continental philosophers are critical of modernism and liberal democracy, especially Heidegger and some postmodernists. There are many exceptions, including the liberal Western Marxists György Lukács (1885–1971), Ernst Bloch (1885–1977), and Antonio Gramsci (1891–1937), as well as the Frankfurt School. In the twenty-first century, continental philosophy is strongly represented by French philosophers.

Because of the great impact of nineteenth-century German idealism and European Romanticism on continental philosophy, some continental philosophers, in the footsteps of Schopenhauer, Max Weber (1864–1920), Max Scheler (1874–1928), and Oswald Spengler (1880–1936), have been critical of modern, urbanized, and industrialized society. Haunted by

the loss of a mostly idealized ancient, medieval world of agricultural and hierarchical life forms, they have sought to recover a holistic view of human life as adumbrated in the “philosophies of life” of Friedrich Nietzsche (1844–1900), Wilhelm Dilthey (1833–1911), and Henri-Louis Bergson (1859–1941). Some continental philosophers, especially feminist philosophers, have emphasized the dimensions of the aesthetic life, the emotional, imaginative, creative, and “unconscious” aspects of human existence.

Freud and the Unconscious

The pioneering work of Sigmund Freud (1856–1939) on the unconscious had a deep influence on modern literature, literary criticism, and on continental philosophy. When continental philosophy rediscovered the unconscious, it inspired a deeper appreciation of the human body and of human sexuality and also supported the rejection of the dualism of René Descartes (1596–1650). Concerned with issues presented by Freud’s work, French philosophers such as Jean-Paul Sartre (1905–1980), Simone de Beauvoir (1908–1986), Maurice Merleau-Ponty, Jean Baudrillard, Michel Foucault, Jacques Lacan, and the feminist philosophers Luce Irigaray (b. 1930), Julia Kristeva (b. 1941), Sarah Kofman (1934–1994), Michele Le Doeuff (b. 1948) and Helene Cixous (b. 1937) are now at the forefront of the crossroads between philosophy, linguistic theory, Marxism, psychoanalysis, and literature. For example, Irigaray writes: “Sexual difference is one of the major philosophical issues, if not the issue, of our age” (*Ethique de la différence sexuelle*, 1984; *An Ethics of Sexual Difference*, p. 19).

Phenomenology of Consciousness

In eighteenth-century Germany, Johann Heinrich Lambert (1728–1777), Kant, and Hegel, who wrote *Die Phänomenologie des Geistes* (1807; *Phenomenology of Spirit*), used the term *phenomenology* in different contexts. Edmund Husserl (1859–1938), the founder of contemporary phenomenology, used the term as a pre-suppositionless description of human consciousness in constituting meaning. From his teacher Franz Brentano (1838–1917), Husserl adopted the theory of “intentionality,” the notion that every mental act is directed toward something. According to Husserl, phenomenology describes the essential contents (*noema*) of our intentional acts (*noesis*), not objects in the world. The content of consciousness is neutral as to its reality or nonreality.

In his famous *Logische Untersuchungen* (1900–1901; *Logical Investigations*), Husserl sought to go “back to the things themselves” (*Zu den Sachen selbst*) as they appeared to pure consciousness in perceptual and “categorical intuition.” Husserl maintained that “being” is given to “categorical intuition” like any other ideal essence. Heidegger critiqued Husserl, maintaining that being is not an “object” of intuition but is understood from the pretheoretical context of man’s concrete, factual life. Heidegger transformed Husserl’s phenomenology of consciousness into a hermeneutical and existential phenomenology of “being.”

Husserl’s first work, *Philosophie der Arithmetik* (1891; *Philosophy of Arithmetic*), was written in terms of “psychologism,”

according to which “logical meaning” could be reduced to “psychological acts.” When Frege criticized “psychologism,” Husserl discarded it and developed a new method, which attempted to gain access to the data of “pure” consciousness by taking a step back (“reduction”) from the “natural attitude” of common sense and the sciences. In his new method, Husserl described two different “reductions”: (1) *phenomenological reduction*, or *epoché* (suspension), which “brackets” the ordinary, natural world, that is, the “existence” of things, and (2) *eidetic reduction*, which describes the *eidos*, the “essence” of noematic content. Husserl called the intentional activity of consciousness “object-constituting subjectivity” by which all meanings are “constituted,” that is, disclosed and made manifest. Although Husserl remained within the Cartesian tradition of subject-object dualism, he consigned this dualism to the noetic-noematic structure of the intentional act. Thus, he undermined the modern “epistemological” problem of an isolated subject and an “external world.”

In his early work *Ideen zu einer reinen phänomenologie* (1913; *Ideas: General Introduction to Pure Phenomenology*), Husserl and his students held a “realist” position, focusing on the contents of consciousness, whereas the later Husserl changed to a more “idealist” position, which he called “transcendental,” that is, that the world is always “for” a mind. According to Husserl, transcendental consciousness “bestows” meaning upon everything, including its own functioning. In some respects, the later Husserl paralleled Heidegger by turning his phenomenological investigations to questions of “temporality,” that is, the temporal flow of transcendental consciousness, and to “intersubjectivity” or social existence. In his later years, Husserl also focused on a “genetic” phenomenology in which the original “genesis” of intentional acts and objects is something passive for consciousness (“passive synthesis”), prior to any voluntary activity of transcendental consciousness. Husserl also became interested in the historical character of science and in the problem of the constitution of the “life-world” (*Lebenswelt*) upon which science is based. Ironically, the later Husserl believed that phenomenology could even constitute the “essence” of the life-world.

Merleau-Ponty was one of the most famous French phenomenologists. Influenced by Husserl and Heidegger, opposed to Cartesian subject-object dualism, he developed an “ontology of the flesh,” which centered on the primacy of perceptual experience and the role of the lived and living body as the primary access to a spatio-temporal world (*Phénoménologie de la perception* (1945; *Phenomenology of Perception*). One’s perceptions, which are always connected with the flesh of the living body, are historically situated interpretations of the world. Perceptions cannot be reduced to pure “source-data” of intentional consciousness.

Heidegger and the Phenomenology of Being

Heidegger studied Scholastic philosophy and theology at the University of Freiburg, where he became acquainted with Husserl’s new phenomenological movement. In 1927 he published his most famous work, *Sein und Zeit* (*Being and Time*). In 1933 he served briefly as the rector of the University of Freiburg but was stripped of his professorship in 1945 because

of his personal involvement with the national socialist movement and his membership in the Nazi Party. After the war, his stubborn silence about Nazi atrocities and the Holocaust cast a dark shadow over his otherwise brilliant career. He died in 1976, and in accordance with his wishes, he had a Catholic funeral.

In his student days, when he read Brentano's *On the Manifold Meaning of Being since Aristotle* (1862), Heidegger became absorbed with the question of time as experienced by human beings and with the question of the meaning of being (*Seinsfrage*); that is, what it means "to be." He gradually came to the conclusion that all Western philosophy, beginning with Plato's theory of suprasensible Forms, had conceived *being* and *time* as opposites, mutually exclusive of each other. Even Aristotle had interpreted time as constant "presence" and as a "now," without reference to being and past and future horizons. Western metaphysics had described God too as eternal "Now" (*Nunc stans*), beyond all time. Heidegger called attention to this "onto-theological" character of metaphysics and maintained that the actual, unitary relationship between being and time in human existence had been "forgotten" in lieu of dualisms such as time and eternity.

In addition to Heidegger's existential interpretation of such terms as *techné*, *phronesis*, and *sophia* in Aristotle's *Ethics*, his studies of time in early Christianity, Augustin, Luther, and Kierkegaard had a great influence on *Being and Time*. In turn, Heidegger had a deep impact on contemporary Protestant and Catholic theology.

Reevaluating the relationship between being and time, Heidegger argued that human existence must be understood from three dimensions of "ec-static" (i.e., existential) time: past, present, and future in their intimate, ontological interdependence. He used the German word *Dasein* to describe the human being with his/her implicit understanding of being. The "Da" or "there" of *Dasein* expresses that the human being is not a thing-like "substance" (Aristotle) or an enclosed "subject" (Descartes). Rather, the human being is an open realm, a "clearing" (*Lichtung*) as in a forest, wherein the understanding of being, of other human beings and things, and of man's own self takes place simultaneously. *Dasein* is always already a "being-with-others" in a shared, communal way of life. For Heidegger, *Dasein* is ontologically gender neutral. Because of its temporal character, *Dasein* is not a static entity but a "potentiality-for-being" (*Seinkönnen*), a temporal movement of possible ways of being, which the individual chooses or lets others choose for him. *Dasein* is always a projecting of oneself into the future toward death, its "authentic" acceptance or its "inauthentic" denial.

Another related term for *Dasein* is *existence*, from the Latin *ec-sistere*, meaning "standing out" into the openness of being. Existence applies only to human beings and is characterized by "mineness," which can be "authentic" or "inauthentic." Still another relational word for *Dasein* is "*being-in-the-world*," which negates the subject-object dualism of Descartes and Husserl, and articulates *Dasein's* holistic and practical involvement with, and comportment toward, the world. *Dasein* is not disclosed to us through "categories" of things, but rather

through its prescientific characteristics, which Heidegger called "existentials" such as *disposition* (*Befindlichkeit*), existential *understanding* (*Verstehen*), and *speech* (*Rede*).

According to Heidegger, in *Identität und Differenz* (1957; *Identity and Difference*), Western metaphysics erred in its inadequate understanding of time as pure "presence" for a subject. Furthermore, Western metaphysics forgot the primordial "ontological difference" between "being" and "beings" in favor of only "ontical differences" between beings such as God, world, and humanity. Heidegger maintained that metaphysics had to be "deconstructed" in order to positively unearth and retrieve its forgotten, primordial experience of being as the "unthought" in Western metaphysics. In Derrida's "deconstruction" of texts, which was originally influenced by Heidegger, the term took on a more critical, "disruptive" interpretation of literary texts. Heidegger "deconstructed" Western metaphysics by reinterpreting the texts of numerous Western thinkers from the sixth-century-B.C.E. Greek philosopher Parmenides to Nietzsche.

In his analysis of "being-in-the-world," Heidegger also distinguished between things "ready-to-hand" (*Zuhanden*)—objects of practical concern with a historical and/or social context—and things "present-at-hand" (*Vorhanden*)—things abstracted from their context and made objects of our theoretical, scientific knowledge. Heidegger demonstrated that Western philosophy overlooked the original human context of "ready-to-hand" things in favor of "present-at-hand" things, "objects" in abstract space and time, as exemplified by theoretical, scientific reasoning. In this "metaphysics of presence," being itself was described as a property or essence, constantly present in things as a "substance."

One can only enumerate a few other "existentials" in *Being and Time*, such as the anonymous "they" (*das Man*); temporality in which "care," with its threefold structure of projection, thrownness, and fallenness is rooted; existential "guilt" and "conscience"; anxiety (*Angst*); "death" as the ultimate disclosure of "my" finitude and mortality, the impossibility of all my possibilities. A central place in *Being and Time* and other writings is devoted to the distinction between "logical truth" and "ontological truth" as standing in the light of being. According to Heidegger, the Greeks already implicitly distinguished ontological truth as "unconcealment" (*aletheia*) emerging from the background of a deeper "concealment" (*lethe*) prior to any logical, propositional truth.

Heidegger's later philosophy, after his so-called turn (*die Kehre*), was first expressed in the *Brief über den Humanismus* (1947; *Letter on Humanism*), according to which Western "humanism," with its one-sided emphasis on "subject" and "reason," is, nevertheless, rooted in the prior but forgotten relationship of *Dasein* to being. As opposed to traditional "calculative" thinking, as critiqued in *Beiträge zur Philosophie 1936–1938* (1989; *Contributions to Philosophy*), Heidegger's later, "meditative" thinking concerned itself with many new themes, such as art, language, science, and technology. In a highly speculative apocalyptic manner, the later Heidegger considered the present technological stage of the history of being as the abandonment of humankind by being itself. Yet,

Heidegger's later thinking, which he understood as a "thank-ing" response to the call of being, is focused on an "other beginning" for humankind. Humans must "listen" and respond in a new meditative-poetic thinking, which might lead to a transformed way of life after the ages of metaphysics, a "letting-be" (*Gelassenheit*) of beings, a term taken from Johannes Eckehart (c. 1260–?1327) and German, medieval, mystical tradition. In a few German poets (Hölderlin, Trakl, George) Heidegger saw the hidden prophets of the future "destining" (sending) of being itself to humans.

In his growing skepticism even about the use of the word "being," Heidegger looked for new words that would mark the postmetaphysical era. He chose the term "disclosive appropriating Event" (*Ereignis*, from *ereignen*, "appropriate," and *er-augen*, "to see and disclose"), a pure subjectless happening, from which the "fourfold" regions of the world, in their interplay between heaven, earth, mortals, and the divinities, emerge into the nearness of humanity. Heidegger's other attempts to say the "unsayable" in expressing the mystery of being (which is not in human control) include the phrases: "dif-ference" (*Unterschied*) of the simultaneous withholding and unfolding of being in beings; and the "fissure" (*Zerklueftung*) of being itself. Finally, he talked about the singular "Event" that gives and approximates being (*es gibt Sein*) and time by a simultaneous self-withdrawal and "expropriation" (*Enteignung*).

Existentialism

Existentialism, as originally presented by Sartre, de Beauvoir, and Albert Camus (1913–1960), emphasized the importance of individual existence, choice, and personal responsibility. It was opposed to impersonal systems of thought and to modern mass society. Partially rooted in the Judeo-Christian tradition of faith, existentialism has also been influenced by Søren Kierkegaard (1813–1855), Fyodor Dostoyevsky (1821–1881), Nietzsche, and by Husserl and Heidegger. Kierkegaard's ethical-religious works impacted many twentieth-century religious existentialists such as Martin Buber, Paul Tillich, Karl Barth, Gabriel-Honoré Marcel, and Emmanuel Lévinas, while Nietzsche's supposed nihilism and atheism ("God is dead") deeply influenced Karl Theodor Jaspers, Heidegger, Sartre, Foucault, Jacques Derrida, Gilles Deleuze, and Luce Irigaray.

Sartre was a philosopher, playwright, social critic, and political activist who became famous with his work *L'existentialisme est un humanisme* (1946; *Existentialism Is a Humanism*) and his phrase "Existence is prior to essence." In the late 1950s, he supplemented this individualistic, existential humanism with social and critical Marxism as expressed in his book *Critique de la raison dialectique* (1976, 1985; *Critique of Dialectical Reason*). In his early work *L'être et le néant* (1943; *Being and Nothingness*), influenced by Husserl and Heidegger, Sartre described the tension between human consciousness ("being-for-itself," *pour soi*), which is "not a thing" but an activity, and the brute existence of things ("being-in-itself," *en soi*). According to Sartre, man has absolute freedom, even in the most constrained situations as exemplified by Sartre's own experiences in the French resistance movement and his imprisonment in Germany. For Sartre, the self is always an embodied, situated self. Sartre also talked about "bad faith," which he

defined as "inauthentic" flight from the anguished burden of choice and responsibility.

Sartre's lifelong companion Simone de Beauvoir, who had a great influence upon Sartre, especially upon his later socially oriented work, wrote the famous early feminist work *The Second Sex* (1949), which described the historical and existential situation of women. According to de Beauvoir, women continue to be defined within a masculine worldview, which assumes an "eternal feminine," an unchanging biological destiny, and a feminine "essence." Men assume that women are "the other," a designation limiting women's freedom and autonomy. De Beauvoir insisted that femaleness is a social construct: "One is not born but rather becomes a woman." De Beauvoir proposed the way for the first philosophical discussion of "sexual difference" within the context of the structures of powers, and forces of desire in later feminist writers.

Camus, like Sartre, de Beauvoir, and Merleau-Ponty, one of the famous representatives of the post-war existentialist movement in France, is known for his notion of the "absurd" as expressed in his poetic writings such as *The Plague* (1947). According to Camus, the absurdity of existence provokes the question of the meaning of life and the act of suicide as "the only truly serious philosophical problem" (*Le mythe de Sisyphe*, 1942; *The Myth of Sisyphus*, p. 1). The human being must engage in an ongoing "revolt" against absurdity: "I rebel—therefore we exist" (*L'homme révolté*, 1951; *The Rebel*, p. 22).

Jaspers (1883–1969), similar to the early Heidegger, saw the historically situated freedom of the individual within certain "boundary situations" such as guilt, suffering, anxiety, and death. Existence can only be realized in communication. He considered existences a gift of Being, which he called Transcendence, God, or the "Encompassing."

Hannah Arendt (1906–1975), who had studied under Husserl, Heidegger, and Jaspers, emigrated to the United States and became a renowned political philosopher despite her sometimes controversial involvement with the Jewish cause. In her works on totalitarianism, anti-Semitism, and imperialism she took a stance against National Socialism and Heidegger's involvement with it, and against Marxism. She favored political freedom, constitutional democracy, and pluralism in her adopted country, the United States. In addition to Claude Lefort, Cornelius Castoriadis (b. 1932), and Habermas, Arendt is the best known political philosopher in the continental tradition.

Hermeneutics

Hans-Georg Gadamer (1900–2002), Heidegger's student, who taught at many German and American universities after World War II, is the father of contemporary ontological hermeneutics. His great work, *Wahrheit und Methode* (1960; *Truth and Method*), points to the problem underlying all modern philosophy (epistemology) from Descartes to Husserl, namely, the relationship between the original "truth" of human understanding within the "life world" and historical "traditions" on the one hand, and the "methods" of the sciences on the other. Inspired by Heidegger and influenced by Hegel

and German Romanticism, Gadamer transformed the method of hermeneutical understanding (*Verstehen*) in the human sciences, history, law, arts, and theology into a “universal” ontological hermeneutics. He went beyond the work of Friedrich Schleiermacher (1768–1834) and Dilthey, who had introduced the “hermeneutical circle” as the relationship of the parts to the whole, and the “implicit” to the “explicit,” out of the correspondence of the knower to the known in any interpretation. Gadamer rejected natural sciences’ explanations (*Eklären*) as the *only* way of understanding reality.

Gadamer maintained that as the art of interpretation, hermeneutics is based upon the human, linguistically constituted “life world,” the living conversation and dialogue between people that is the horizon of all human experience and knowledge. Hermeneutics aims at mutual understanding between an historically situated “author” of a text and an historically situated “reader” or interpreter. Gadamer called the hermeneutical encounter between an author and a reader the “fusion of horizons.” As such, in historical events, literature, or works of art, hermeneutics is always the relationship between two horizons of understanding and interpretation within a tradition, and it has the prospective goal of “consensus.”

Criticizing Enlightenment for its ahistorical perspectives and denying that the methods of the natural sciences are the only means to “objective knowledge,” Gadamer emphasized the deeper truth in historical understanding, which passes from generation to generation through written texts, which are—contrary to Derrida’s primacy of “writing”—always rooted in the living language. As texts are interpreted and reinterpreted throughout history, they produce a “history of effect” (*Wirkungsgeschichte*), which shape and influence our present and future understanding of reality. Since there are hidden presuppositions and cultural “prejudices” in each interpretation, Gadamer sees that hermeneutics does not focus on the isolated “true meaning” of a text or on the author’s intention. Rather, universal Hermeneutics focuses on the different suppositions and presuppositions of all interpretations in both the human and natural sciences. After the failed attempt for a fruitful encounter between Gadamer’s “phalological” hermeneutic and Derrida’s “Deconstruction” in the 1980s, which both originated in Heidegger’s work, hermeneutics and Deconstruction remain two as yet unreconciled paradigms in contemporary philosophy. The third paradigm is Habermas’s “critique of ideology,” which rejects Gadamer’s positive evaluation of tradition, consensus, authority, and “prejudice,” as the continual “distortion of communication” by masked social and political interest. Thus, the special, yet unacknowledged interest of modern bourgeois, capitalist society disrupts and disguises understanding and communication in a worldwide global consumer society.

Paul Ricoeur (b. 1913), the proponent of a phenomenological hermeneutics, is focused on narrative, symbol, metaphor, dreams, and ideologies as the means by which our experience of the world is interpreted. Opposed to postmodernism’s abolition of the “subject,” he elaborates a notion of “subject” stripped of modern subjectivism. In contrast to Gadamer, Ricoeur does not concede a dualism between “truth”

(philosophy) and “method” (science) but bridges them by his interest in the methodological “validation” of interpretation by the methods of the human sciences. He calls the critical point of hermeneutics “the hermeneutics of suspicion” as it reveals the hidden, ideological meaning of texts, events, and social practice. For Ricoeur, the great “masters of suspicion” are Marx, Nietzsche, and Freud.

Postmodernism

Modernism is characterized by Enlightenment values; that is, trust in the autonomous human “subject,” scientific reason, and universal principles of law, morality, politics, and economics. In different ways, postmodern philosophers oppose the main ideas of the Enlightenment. Instead, they focus on a “decentered” subject, human knowledge as conditioned by history, and the mistrust of the “grand narratives” of modernity (Kant, Hegel, Marx). The French philosopher and novelist Georges Bataille (1897–1962) initiated the poststructuralist notion regarding the death of the “subject” in order to overcome its isolation in experiences of “excess” (laughter, tears, eroticism, death, sacrifice, and poetry). Similar to Nietzsche’s “perspectivism,” postmodernism critiques “objective” truth and favors a theory of multiple “interpretations” of texts. Postmodernism was preceded by poststructuralism in literature, the humanities, social sciences, and even architecture in the 1960s and 1970s. Poststructuralism partially opposed the linguistic structuralism of Ferdinand de Saussure (1857–1913). Similar to much of the analytical philosophy, Husserl, and also Derrida, Saussure saw language as a self-contained system of signs rather than as an ongoing, historical process of conversation and dialogue in the Socrates sense. In contrast to “subjective” existentialism, structuralism focused on super-individual structures such as language, kinship, and ritual in order to understand human existence. Saussure influenced the anthropological structuralism of Claude Lévi-Strauss (b. 1908), the Marxist structuralism of Louis Althusser (1918–1990), the social critique of Foucault, the political and cultural critique of Roland Barthes (1915–1980), and the psychoanalytic structuralism of Lacan. Rejecting the scientific pretensions of structuralism, poststructuralism questioned the “objectivity” of knowledge and truth, of the “subject” as a unified self, the oppressive nature of modern institutions, authority, and power. Postmodernism was marked by the abandonment of dogmatic Marxism by French intellectuals, especially after the student-worker revolution of 1968, its critique of Western imperialism, racism, and antifeminism.

Lyotard (1924–1998), through his book *La condition post-moderne* (1979; *The Postmodern Condition*), represents the postmodern movement and its great influence on the literary, political, and cultural milieu beyond professional philosophy. Lyotard pointed out the demise of grand, foundational, totalizing “metanarratives”; that is, grand theories or systems of thought such as liberalism and Marxism, which are being replaced by local narrative or smaller stories of everyday life, which are expressed in limited but pluralistic “language games” (Wittgenstein). Lyotard uses the term “differend” (*differend*) for the incommensurability or heterogeneity of these different language games, literary genres, and idioms, which can never

be reduced to logical or ontological “sameness,” not even to a political “consensus” in the sense of Gadamer, Habermas, or Rorty. For Lyotard, the knowledge of irreducible differends, that is, disputes and dissensions in politics, is the most important form of resistance to capitalism and its uniformity and injustice. In *Heidegger et “les juifs”* (1988; *Heidegger and “the Jews”*), Lyotard criticized Heidegger’s silence on the Shoah (Holocaust). He pointed out the philosopher’s duty to stand for the “marginalized” and “the Forgotten.”

The Algerian-born French philosopher Jacques Derrida (b. 1930) has had almost as much impact on French continental philosophy as Foucault, but he is hardly criticized by analytic philosophers such as John Learle. Like Heidegger, Derrida attacks the traditional Western “metaphysics of presence” and its reduction of “being” to “substance” (entity). Like Wittgenstein, Derrida asserts that logical meaning is always embedded in the historical, social, and cultural matrix of language. He accuses Western metaphysical tradition of “logocentrism” and “phonocentrism,” which favor the immediacy of the “meaning” of the spoken word rather than writing, which is characterized by distance, repeatability, and uncertainty of meaning. According to Derrida, logocentrism utilizes oversimplified, “binary opposites” such as reason-emotion, soul-body, male-female, and so on, which presuppose an unquestioned hierarchy of subordination in classical, philosophical texts and in political discourse.

Derrida’s method of “deconstructing” the logocentrism demonstrates that a particular text usually does not have just one clear meaning, understood as what the author intended to convey. Rather, it may have alternative meanings (“alterity”), which do not fit into traditional notions of “binary opposites.” The “double meaning” of texts reveals hidden ambiguities and “indeterminacies” of meaning underlying the text. In principle, it is impossible to show what a text “really means.” In Derrida’s writings, an important neologism is the term *différance*, which is a pun on a French verb meaning both “difference” of meaning and endless “deferral” of a fixed and privileged meaning. Meaning is only possible within a context and within a system where words have a “trace” of other, related words, just as speaking has a “trace” of writing.

Gilles Deleuze (1925–1995) and the psychotherapist Felix Guattari (1930–1992) also opposed the metaphysics of presence (“identity”), the representation of an “object” by a “subject.” They favored a metaphysics of difference. In their controversial *L’anti-Oedipe* (1972; *Anti-Oedipus*), they synthesized their neo-Marxist rejection of capitalism with their rejection of Freudian psychoanalysis, which they criticized as a bourgeois repression of instinctual life (“desire”) in the name of the bourgeois family (Oedipus complex). Although human nature is controlled socially, it is rooted in the chaotic presence of desire as expressed in its extreme form in schizophrenia. Deleuze also published works on theater, painting, and cinema.

Jean Baudrillard (b. 1929), whose analysis of contemporary culture was influenced by Marx, by structuralism, and by the communications theorist Marshall McLuhan’s analysis of electronic media, reversed the Marxian distinction between epiphenomenal “superstructure” (culture, the “symbolic”) and

fundamental “infrastructure” (economy, material production). He pointed out that the “symbolic” is primary for the contemporary media and consumer society, in which the boundary between image and truth, as well as between the virtual and the real, has been transformed into a new symbolic “hyper-reality” in the age of electronic media.

In the tradition of Hegel, Marx, and especially Nietzsche, Michel Foucault (1926–1984) focused on the structures used to create meaning and order in human knowledge and experience. In his early studies in the “archaeology of knowledge,” Foucault showed how our present thoughts and social-institutional practices, especially in psychology, psychiatry, and medicine, are the historically contingent outcomes of past, anonymous “epistemes” (paradigms and frameworks of discourse), which can be changed and replaced by new forms of “epistemes.” On the “threshold of modernity” at the end of the eighteenth century, the modern episteme brought about the emergence of the modern “subject” and the corresponding “human sciences,” which prescribed how the individual (psychology) and society (the state) should act. Foucault attacked modern, universalizing mega-narratives of history as well as the notion of a pre-given “human nature.” He saw the self (that is, the “subject”) as always historically conditioned within particular situations and contexts. Foucault’s antihumanist and anti-Enlightenment critique of the modern notion of “reason” is based upon very detailed historical studies, for instance, his investigations of “mental illness” and “madness” in the age of Enlightenment (*Histoire de la folie à l’âge classique: folie et déraison*, 1961; *Madness and Civilization: A History of Insanity in the Age of Reason*).

In his other works, Foucault discussed the theoretical, “discursive” practices within the larger context of “nondiscursive” practices as manifestations of social control and “power.” According to Foucault, these “disciplinary power” systems and their power techniques (as exemplified by Jeremy Bentham’s prison “panopticon”) have paralleled the development of the human sciences, which have defined what is “natural” or “deviant,” especially in sexual behavior. As the human sciences developed, the modern “subject” was defined both as a “self-responsible subject” and as an “object,” controllable by disciplinary power. These definitions first appeared in modern psychology and medicine and were then applied in education, hospitals, asylums, factories, and military barracks. Like Nietzsche, Foucault called this later work a “genealogy,” which explained the origin of the modern individual as a “subject” within institutional systems of nondiscursive power relations.

In his last work about sexuality, Foucault further developed his analysis of the subject in terms of “practices of the self.” He was especially concerned with historical, aesthetic, and repressive practices regarding sexuality. According to Foucault, sexuality is not a category of an unchanging human nature, but is historically conditioned by social “power” practices.

Foucault summarized his work by maintaining that in spite of our involvement in power relations, we are free to struggle against and to resist systems of power by relating to ourselves in new alternative, creative ways, beyond society’s system of order and discipline.

Lévinas and the “Other”

Emmanuel Lévinas (1906–1995), the Lithuanian-born, French-Jewish philosopher, introduced France to the work of Husserl and Heidegger, whom he later opposed. He was imprisoned in a German labor camp between 1940–44 and later became a professor at the Sorbonne. Like Buber, Marcel, Simone Weil (1909–1943), and Jaspers, he is usually classified as a philosopher of religion. Lévinas was deeply influenced by Franz Rosenzweig (1886–1929), the German-Jewish philosopher, and his book *The Star of Redemption*, which critiqued Hegel’s philosophical totalitarianism in favor of a metaphysics of creation.

In his masterwork *Totalité et Infini* (1961; *Totality and Infinity*), Lévinas accused Western philosophy, from Parmenides to Husserl and Heidegger, of having reduced the “Other” (that is, the other person), to an “object” of consciousness and/or to a neutral, existential relationship. From the vantage point of his Jewish background, he asserted that the ontology of the “same,” of being, and of identity leads to the idolatry of power and domination, as for example in Hegel’s master-slave dialectic and in Heidegger’s “fateful destiny of being.” The “face” of the other, its absolute “alterity,” cannot be objectified or totally comprehended. The “other” includes the victims of the Holocaust, vulnerable and defenseless, claiming: “Thou shalt not kill!” The face of the “other” reveals the priority of ethics over ontology. The infinity of the “other,” which defies any objectification, leads to God, to the “Other” beyond the human “other.” Human beings do not encounter God through “proofs” for God’s existence but rather through their relationship to the human “other,” who is a “trace of God.”

Habermas and the Frankfurt School

Retrieving some of Marx’s early humanistic writings, the original Frankfurt School of the 1920s and 1930s applied critical neo-Marxism to the analysis of the eventual transformation of modern society. The Frankfurt School was also known for its critical neo-Hegelianism, which resembled the phenomenological existentialism of certain neo-Marxist Italian philosophers such as Enzo Paci, the Polish neo-Marxists Adam Schaff and Leszlek Kolakowski, and the Yugoslavian existential-phenomenological Marxists associated with the journal *Praxis*. Max Horkheimer (1895–1973), Theodor Adorno (1903–1969), Walter Benjamin (1892–1940), Erich Fromm (1900–1980), and Herbert Marcuse (1898–1979) expressed the Frankfurt School’s critical theory in various ways. Their theory was based on a synthesis between critical theory and social “practice” according to Marx’s famous statement that appears as the eleventh of his “Theses on Feuerbach”: “Philosophers have always interpreted the world, the point is to change it.”

In contrast to orthodox Soviet Marxism and to the literary critic Fredric Jameson’s economic interpretation of “late capitalism” and postmodernism, the Frankfurt School increasingly emphasized the importance of the society’s “superstructure,” including culture and ideology rather than its material “infrastructure.” Furthermore, the Frankfurt School combined Marxist theory with Freudian psychoanalysis as important for the emancipation from social domination and from the repression of the individual mind.

Some members of the Frankfurt School, especially Horkheimer and Adorno in their collaborative work *Dialektik der Aufklärung* (1947; *Dialectic of Enlightenment*), stressed the importance of the arts, fantasy, and imagination because of their potential to subvert and emancipate society from its dependence on the one-sided, instrumental rationality of the Enlightenment and on modern science and technology. Yet, because of the failure of Soviet Marxism and the integration of its nonrevolutionary working class into the capitalist system after World War II, some members of the Frankfurt School lost confidence in a future Marxist revolution. Their initial revolutionary fervor gave way to political and cultural pessimism.

Jürgen Habermas (b. 1929), the German philosopher and social theorist, developed a new version of “critical theory” and a partially optimistic view of modernity as an “unfinished project of Enlightenment.” Opposed to dogmatic Marxism, to positivist, empirical sociology, to uncritical elements in Gadamer’s “universal hermeneutics,” and to anti-Enlightenment postmodernism, Habermas attempted to harmonize the best of Kant, Hegel, Marx, and Wittgenstein with the scientific, explanatory systems of modern social science. In his early work *Erkenntnis und Interesse* (1968; *Knowledge and Human Interests*), he argued against the prevailing positivism of the social sciences, distinguishing three basic, human, cognitive interests: (1) *technical*; that is, control of nature; (2) *practical*; that is, communication with the goal of an “ideal speech situation”; and (3) *emancipatory*; that is, the removal of limits to freedom and causes of alienation, oppression, and suffering, with the goal of building an open, liberal-democratic society.

In his book *Theorie des Kommunikativen Handelns* (1981; *The Theory of Communicative Action*), Habermas developed a “critical theory of modernity,” which was founded on the difference between “instrumental” and “communicative” rationality. Habermas also critiqued modern society’s systems of rationalization, which increasingly “colonize” and destroy the “life world.” Habermas’s later “discourse ethics,” which provided the linguistic background for communicative action, elaborated an intersubjective ethics of practical reason. This ethics too was directed against the modern, one-sided philosophy of the “subject.”

Feminist Philosophy

Feminist philosophy examines gender issues and male-oriented “ideological” solutions in Western philosophy and science, while feminist epistemology, which is centered primarily in the analytic tradition, focuses on illegitimate authority and power relationships inherent in modern concepts of the knowing, scientific “subject.” In general, feminist philosophers discuss human knowledge, truth, and objectivity in the broader context of gender, class, age, and race, while feminist moral philosophers demonstrate the importance of feminine “caring” in contrast to masculine “justice.” Addressing the work of Wittgenstein and Heidegger, feminist philosophers emphasize the contextual, historical, and social aspects of language, while simultaneously critiquing male/female dichotomies, hierarchies, and “power-structures” in traditional “masculine” philosophy and science, which are assumed to be “universal” and “objective.”

In her book *The Man of Reason* (1984), Genevieve Lloyd demonstrated that a metaphysical dualism of masculine “reason” and feminine “sense perception” and “emotion” dominates Western philosophy. According to Lloyd, the misogynistic notions of Schopenhauer and of Nietzsche are extreme forms of this antifeminist bias, which has permeated cultural, political, and economic development in the West.

In the late twentieth and early twenty-first centuries, French and North American feminist philosophers have questioned traditional, masculine interpretations of gender issues. Michèle Le Doeuff (b. 1948) has even discussed the inherent tension between being a woman and being a philosopher in the West. The American philosophers Judith Butler, Jean Grimshaw, Sandra Harding, Nancy Hartsock, Helen Longino, Seyla Benhabib, and Susan Bordo have made significant contributions to feminist philosophy, while the French philosophers Luce Irigaray and Julia Kristeva have become the most notable in the field.

Luce Irigaray (b. 1932) critiqued “masculine”-oriented Freudian and Lacanian psychoanalysis and was subsequently expelled from the Paris Psychoanalytic Association and from the University of Paris, after which she became a private psychoanalyst and writer. Best known for “deconstructing” the work of Plato, Kant, Hegel, and Freud, Irigaray demonstrates woman’s unique sexual differences; that is, her body and desire (*jouissance*), which contradict masculine-oriented theories of “identity” and “sameness.” Women, who have been defined traditionally in terms of “lack,” “absence,” and “default,” have been allowed to gain “identity” only by “mimicking” male language and male behavior. Going beyond social “gender roles” in the liberal, feminist fight of legal “equality” with men, Irigaray insisted on the unique “sexual difference” of women, their unique rights, and on the regaining of their own “subjectivity.” She often uses Sophocles’s *Antigone* and Hegel’s interpretation of the play as the example of the masculine bias in Western civilization where Antigone loses her life against the command of king Creon.

The Bulgarian-born French feminist philosopher Julia Kristeva (b. 1941) showed an early interest in the problems of psychoanalysis and linguistics. Influenced by the Russian literary theorist Mikhail Bakhtin (1895–1975) and by Dostoyevsky, Kristeva distinguishes between “semiotic” language (as expressed in the unconscious maternal world of “drives,” music, and poetry) and “symbolic” language (the logical world of the “father”). She maintains that “semiotic” language often “erupts” into “symbolic” language and subverts both male and female sexual identity. In contrast to Irigaray, who looks for a specific “female voice,” Kristeva questions the very concept of identity, male or female. For Kristeva, the oppression of women is only a portion of contemporary society’s more universal social, political, and economic oppression of “marginalized groups.” Contrary to Freud and Lacan, Kristeva not only emphasizes the *social* role of the mother in the development of the human subject but also the important role of the child. Yet both are rooted in the mother’s contact with the child prior to the “law of the father.”

CORRUPTION. Consider the first sentence of Jean-Jacques Rousseau's (1712–1778) *Discours sur les arts et sciences* (Discourse on the arts and sciences, 1750): “Has the restoration of the sciences and arts contributed to the purification of mores, or their corruption?” Corruption denotes deterioration, a qualitative decline from an original (absolutely or relatively) natural or pristine state; related terms include decay, deterioration, disintegration, corrosion, and degeneration. Corruption is sometimes used in a related (but distinct) sense, to denote a state of affairs—a “state of corruption”—often in contrast to one characterized by virtue. In either form (verb or noun) corruption is an intensely historical term, describing either a process of qualitative spoliation or the end result thereof.

The discourse of corruption and virtue offers critics and philosophers a powerful rhetorical tool with which to indict societies’ perceived shortcomings vis-à-vis some past standard. When placed into narrative form, corruption accounts generally contain four elements: (1) a description of the symptoms of corruption (social, moral, political); (2) identification of an agent of corruption; (3) a timeline by which critics identify the agent’s appearance and trace its corrupting influence; and (4) a call to action to turn back corruption and restore lost virtues.

In the history of ideas and historiography, the discourse of corruption has often, though not exclusively, been associated with the tradition of civic republicanism. More recently, a significant body of research has brought the tools of social science to bear on the identification and measurement of corruption in the political sphere, and offered general theories about conditions under which corruption is fostered or retarded. This entry will point out, in an admittedly abbreviated manner, some of the main lines of research and refer the reader to key texts in the literature on corruption.

Corruption, Civic Republicanism, and Republican Historiography

Perhaps the most rhetorically powerful and historically influential language of corruption appears in the tradition of civic republicanism associated with Italian Renaissance humanists like Niccolò Machiavelli (1469–1527), Francesco Guicciardini (1483–1540), and Leonardo Bruni (c.1370–1444), which emphasizes the civic and social nature of the human good. Drawing on such classical sources as Aristotle (384–322 B.C.E.) and Cicero (106–43 B.C.E.), republicans see the realization of civic virtue as requiring the active involvement of relatively equal citizens in making decisions about their common life. Thus, anything that distracts citizens from the common good—internal factions, luxury, security, foreign influences, great disparities of wealth (even, for some thinkers, Christianity itself)—can be seen as an agent of corruption. Conversely, anything that fosters or rewards citizens’ mutual self-regard and

keeps their efforts focused on the good of all promotes civic virtue and helps stave off corruption. Drawing on both classical and Renaissance ideas, Rousseau advances the single most important modern theory of republican virtue.

Republican concerns about virtue and corruption are not limited to Europe: the tradition has also fundamentally affected the historiography of the American experience. Alongside the American obsession with Lockean individualism, a republican school emphasized the Founders’ concern for civic virtue in the citizenry. Connecting Italian humanism and the American founding was the contribution of J. G. A. Pocock’s monumental *The Machiavellian Moment: Florentine Political Thought and the Atlantic Republican Tradition* (1975). For Pocock, a discernible discourse about corruption, virtue, and the very nature of the political task ran from Renaissance Italy through England’s civil wars and across the Atlantic, where it facilitated the development of the American character and the split with England. The ideal of the active citizen, of republican politics as the effort to preserve civic virtue and keep corruption at bay, has exerted a strong pull on the political imagination down to our own time.

Political Corruption

Political scientists have developed sophisticated analyses for the study of political corruption. No single definition of political corruption can avoid controversy since, barring consensus on the proper nature and extent of legitimate politics, we necessarily lack agreement on how to define corrupted politics. Nonetheless, as one would expect, researchers emphasize political, institutional, or bureaucratic locations of corruption; the misuse of public power; or “behavior which deviates from the formal duties of a public role because of private-regarding . . . pecuniary or status gains; or violates rules against the exercise of certain types of private-regarding influence” (Nye, p. 419).

Political corruption presents itself in a host of settings. Susan Rose-Ackerman considers the legislative and bureaucratic arenas, and presents political corruption as an economic, cultural, and political phenomenon with important implications for democratic societies. More broadly, scholars have attempted to analyze political corruption in a variety of global contexts (Heidenheimer, 1970; Heywood, 1997). Nor has this research necessarily involved a turning-away from historical concerns with equality and participation: Patrick Dobel offers a general theory of corruption that draws on classical authors yet speaks to contemporary political life, suggesting practical steps toward staving off corruption in modern states.

Other Contexts

Countless reform movements within the world’s major religions have framed their critiques by denouncing the corruption of pure or pristine doctrines. Indeed, on one view, Buddhism itself grew out of a deep dissatisfaction with the corruption and increasingly complex nature of Hinduism, not entirely unlike the early Protestants who attacked the corruption of the Roman Catholic Church and called for a return to simpler ancient doctrines. Often these critiques point to the effects of wealth and luxury on the purity of religious doctrines

and practices, and moral standards more generally: echoing civic republican themes, the fourteenth-century Islamic scholar Ibn Khaldun bluntly asserted that “luxury corrupts morals” (pp. 131–132).

The biblical account of the Fall is perhaps the paradigmatic corruption metanarrative, with its account of a lost, originally virtuous, condition and the ongoing struggle for redemption. But other religious traditions draw on the images of corruption as well: according to the Buddhist *Milindapañha* “[t]he virtuous and well-conducted man . . . is like a medicine in destroying the poison of human corruption; is like a healing herb in quieting the disease of human corruption; is like water in removing the dirt and defilement of human corruption” (ch. 5, sec. 98). The virtue here described is, of course, not social republican virtue, but rather a specifically religious understanding of what is required to stave off the corruption that can grow from within.

Finally, we should note the classical tradition that utilizes the terms “generation and corruption” in reference to the body and things subject to growth and decay in the physical realm. Plato (c. 428–348 or 347 B.C.E.) describes philosophers as those who love eternal verities “not varying from generation and corruption,” and regards gymnastic, given its emphasis on the body, as “having to do with generation and corruption” (*Republic* 485b, 521e). Indeed, Aristotle (384–322 B.C.E.) announces in

the first sentence of his *On Generation and Corruption*, that his task is “to study coming-to-be and passing-away.” Later, Augustine (354–430) brought a Christian view of the immortal soul to this classical understanding, describing the “soul pressed down by the corruptible body, and weighed down by earthly thoughts, many and various” (*De Trinitate*, 8.2).

Conclusion

How might we explain the widespread appeal of discourses on corruption? The truth likely remains somewhere deep within the individual and collective dynamics by which people attempt to come to grips with change in their lives, and to construct a meaningful narrative connection between past, present, and future. The power of corruption rhetoric seems to lie in its recognition of the inherent fragility of all human endeavor—indeed, of human bodies. Talking in terms of corruption, for civic republicans, often makes sense of a host of social changes by placing them into a coherent, purposive, and meaningful frame of reference, highlighting past glories, and spurring audiences on to greater things in the future. Corruption accounts, like all political speech, are inherently partial and moralistic, but they are also extremely effective in pointing to the price paid for progress, be it technological, political, or economic. When Adam Smith (1723–1790) boasted, in his *Inquiry into the Nature and Causes of the Wealth of Nations* (1776) that the poorest English laborer lives in material comfort undreamed of by an African king, Rousseau was there to ask about the price paid for this economic “progress,” using the language of corruption to frame and reinforce his critique.

But is corruption, however variously defined, always to be lamented? A few scholars have ventured the hypothesis that corruption is necessary, though indeed not sufficient, for such tasks as the smooth operation of an economy. Business practices routinely denounced as “corrupt” may serve a variety of extremely important social and economic functions. Such a view, overtly or not, hearkens back to Bernard Mandeville’s (1670–1733) famous dictum that private vices yield public benefits.

CORRUPTION IN DEVELOPED AND DEVELOPING COUNTRIES.

While corruption, in one form or another, has perverted virtually all human societies throughout history, it has not had uniform impact on any one of them. Scholars who study corruption in an effort to find ways to minimize it have had to deal with the fact that it is difficult to define and measure, making empirical testing very difficult.

Defining Corruption

Modern social science defines corruption in terms of three basic models: First, corruption is related to the performance of the duties of a public office. According to J. S. Nye, corruption is

[b]ehavior which deviates from the normal duties of a public role because of private-regarding (family, close private clique), pecuniary or status gains; or violates rules against the exercise of certain types of private-regarding influence. This includes such behavior as bribery (use of reward to pervert the judgment of a person in a position of trust); nepotism (bestowal of patronage by reason of ascriptive relationship rather than merit); and misappropriation (illegal appropriation of public resources for private regarding uses). (p. 419)

Second, corruption is related to the concept of exchange derived from the theory of the market. Jacob Van Klaveren argues that the bureaucrat views his public office as an enterprise from which to extract extra-legal income. As a consequence, the civil servant's compensation package "does not depend on an ethical evaluation of his usefulness for the common good but precisely upon the market situation and his talents for finding the point of maximal gain on the public's demand curve" (p. 26). In an economy pervaded by high levels of government regulations, civil servants may devote most of their time and effort to assisting entrepreneurs in evading state laws and statutes. In exchange the civil servants are paid extra-legal income (Mbaku, 1992).

Finally, the definition of corruption is couched in terms of the public interest, as argued by Carl Friedrich:

[t]he pattern of corruption may therefore be said to exist whenever a power holder who is charged with doing certain things, that is a responsible functionary or office holder, is by monetary or other rewards, such as the expectation of a job in the future, induced to take actions which favor whoever provides the reward and thereby damage the group or organization to which the functionary belongs, more specifically the government. (p. 15)

Friedrich argues further that the opportunistic activities of corrupt bureaucrats can severely damage the public interest and should be considered important variables in the study and evaluation of corruption.

Public choice theory and corruption. Economists, dissatisfied with these explanations for corruption, have turned to public choice theory, which sees corruption as post-constitutional opportunism designed to generate benefits for individuals or groups at the expense of the rest of society. According to public choice theory, the scope and extent of corruption in a country is determined by that country's institutional arrangements and not necessarily by the character of its civil servants and politicians. Once the constitution has been designed and adopted and a government established, there is an incentive for individuals and groups to subvert the rules in an effort to generate benefits for themselves. Rules subversion, if successful, can allow individuals to secure benefits above and beyond what would have accrued to them otherwise. This kind of behavior can occur in both democratic and nondemocratic societies.

Bureaucrats, whose job it is to design and execute public policies, may attempt to use the process to maximize their private objectives at the expense of serving the general public efficiently and equitably. The desire by civil servants to maximize their private objectives and the effort by organized interest groups to subvert the rules and to extract benefits for themselves create opportunities for corruption. For example, an entrepreneur who wants to secure a lucrative import or production permit may bribe a clerk at the ministry of trade in order to (1) secure the permit and (2) make sure that the bureau protects his new monopoly position by not issuing additional permits to entrepreneurs from the area in which he operates. In exchange for providing the entrepreneur with opportunities to earn supranormal profits, the civil servants at the ministry of trade "earn" extra-legal income, and the importer who receives the permit earns an above normal rate of return on investment, but society loses.

Government regulatory activities usually impose significant transaction costs on enterprise owners and severely affect the profitability of their operations. To minimize these regulation-induced costs, some entrepreneurs may seek help from the civil service, whose job it is to enforce the laws. Usually, the business owner pays a bribe to the government regulator in order to receive preferential treatment and minimize the burden of the regulations on his or her operations. Public choice theorists argue that bureaucratic corruption is directly related to the scope and extent of government intervention in private exchange (i.e., in markets). Effective control of corruption, then, must be based on a modification of existing rules in order to change incentive structures and constrain the ability of the state to intervene in private exchange and create artificial scarcities.

The International Dimension of Corruption

Since the end of the Cold War, policymakers in many countries have recognized the global nature of corruption and are now making efforts to coordinate their control and cleanup

efforts. Thus, instead of viewing corruption as a domestic problem caused primarily by the interaction of the bureaucracy with the private sector, many lawmakers, especially those in the developing and transition economies, are now acknowledging the contributions of transnational corporations to the problem.

Many governmental and nongovernmental organizations—including the United Nations (UN), the Organization of American States (OAS), the International Chamber of Commerce, Transparency International (TI), the World Economic Forum (WEF), World Bank, Interpol, and the Organization for Economic Cooperation and Development (OECD)—have developed an interest in dealing with corruption.

Several reasons have been advanced to explain the sudden interest by these organizations. Changes in international political relations during the period from 1989 to 1991 significantly reduced people's tolerance for incompetence, malfeasance, and venality in the public sector. As part of the movement toward improved governance, citizens of many countries demanded the elimination of corrupt practices. Thus, since the late 1980s, the balance of power in many countries has been shifting in favor of more open, transparent, and participatory governance structures.

Scholars have identified three changes that have contributed to the globalization of corruption. First, greater levels of economic integration have increased chances that corruption in one region of the world will have an impact on economic and political activities in other parts of the world. For example, when the corrupt activities of the Bank of Credit and Commerce International (BCCI) forced it into insolvency in 1991, many economies around the world were affected. In fact, several countries in Africa suffered significant financial losses from the BCCI collapse.

Second, developments in communication technology have revolutionized the international financial system and enhanced the ability of traders to engage in corruption. The emergence of electronic networks for the transfer of funds has made it quite difficult for countries to deal effectively with corruption. Many anticorruption organizations have argued that the ease with which funds can be transferred to Europe or the Caribbean from different parts of the world implies that corrupt civil servants can effectively hide their extra-legal income from the public, making it virtually impossible for such funds to be recovered in the event of conviction. Fortunately, policing agencies, especially in the West, continue to innovate and come up with technology that can effectively monitor traffic in these electronic networks. Such technology could prove very helpful in the fight against global corruption.

Third, since the end of the Cold War there has been a significant increase in the number of cooperative alliances between economic units, within countries and across borders. Continued globalization exacerbates the problem of corruption; however, it also offers opportunities for its control.

Pervasive corruption is a major threat to the maintenance of a free, multilateral trading system. In order for a global competitive economy to function properly and efficiently, participants

must play by the rules. Opportunism (e.g., corruption) by some market participants can derail the international trading system since it (i.e., corruption) invariably creates an unlevel playing field. For example, corporations or countries that do not tolerate corruption will be placed at a competitive disadvantage. Those countries that encourage their companies to engage in corruption abroad and offer favorable tax treatment for bribes paid to foreign public officials place these firms at a competitive advantage over those from countries in which corruption (including paying bribes to foreign public officials) has been criminalized. In fact, many American firms, which are prohibited by U.S. law from offering bribes to foreign officials, have complained bitterly of the disadvantage that they suffer since, until recently, many of their European counterparts were allowed and often encouraged by favorable tax treatment by their national governments to engage in corrupt practices abroad.

Many policymakers around the world, especially in the developed countries, have come to realize that the long-run social, economic, human, and political costs of global corruption are enormous and that it poses a threat to the rule of law. It can also cause citizens to lose confidence in their leaders and distort market incentives and negatively affect the flow of investment and, hence, wealth creation. Perhaps more important is the fact that corruption can prevent the poor from gaining access to welfare-enhancing and even life-saving public goods and services.

Controlling Corruption

Four strategies have been employed in the past by successive governments to deal with corruption, usually with varying degrees of success. These are societal, legal, market, and political strategies.

In the societal strategy, each society defines a common standard of morality, which can then be employed to determine if a given behavior qualifies as corrupt. Civil society is encouraged to remain vigilant and watch out for individuals who engage in corruption and report them to the police. The government and civil society organizations are expected to educate the general public about corruption and its negative effects on economic growth and development. Through such an educational program, citizens can significantly improve their ability to determine if behavior is corrupt and report perpetrators to the relevant authorities for further action. The private press plays an important role in this approach to corruption cleanup—it investigates and exposes corruption, paving the way for the police to gather the evidence needed for effective prosecution by the judiciary.

In the legal approach, the judiciary, the police, and the mass media are expected to lead the fight against corruption. First, national laws define the responsibilities of civil servants and properly constrain them in the performance of their duties. Second, the law defines corruption and corrupt behavior. Third, citizens are encouraged to be vigilant and report any suspected corrupt activities to the police. Fourth, the police are expected to thoroughly investigate such activities, gather the necessary information, and present the latter to the judiciary. Fifth, the judiciary then prosecutes the accused and imposes

the appropriate punishment if found guilty. Special commissions of inquiry or special prosecutors can be constituted and used by the government to investigate incidents that point to large-scale corruption and public malfeasance. Commissions of inquiry are especially important in cases where high-ranking officials have been implicated in corruption.

Police and judiciary officers can only perform their functions properly and efficiently if they are not corrupt—that is, they are effectively constrained by the law. If, on the other hand, these institutions are pervaded by corruption, it would be prudent to first engage in reforms to improve their efficiency before engaging them in the fight against corruption.

In many developing countries, low salaries for public servants have been given as a reason why some of these workers may engage in corruption. As part of the effort to minimize corruption in the civil service, it has been suggested that pay scales in the public sector be made competitive with those in the private sector. One must note, however, that higher pay in the public sector may simply force opportunistic civil servants to demand higher bribes to compensate for the probability of losing what is now a relatively more important and lucrative position. It has also been suggested that any civil-service reforms be supplemented with counteracting agencies such as an independent judiciary or some kind of independent review board, an ombudsman, or other investigative body. One must consider the fact that such bodies can become politicized (as evidence from many developed and developing countries shows) and used by incumbent ruling coalitions to punish the opposition and continue to monopolize political spaces.

The market approach to corruption cleanup is based on the belief that there exists a discernible relationship between market structure and corruption. Government regulation of private exchange creates opportunities for regulators to extort bribes from enterprise owners. The remedy that scholars have usually recommended is decreased government regulation and more reliance on markets for the allocation of resources. Such an approach has at least two problems. First, it is based on the manipulation of outcomes within an existing or given incentive structure (i.e., existing institutional arrangements). Second, the problem here is not with the market but with the incentive structures that traders are facing. Rules define the incentive structure faced by participants in markets and, hence, determine the behavior of these traders and market outcomes. If the government's regulatory activities are reduced and resource allocation made more dependent on the market, there is not likely to be much of a change in outcomes if the incentive structure has not been altered. The most effective way to minimize opportunistic behaviors, including corruption, is to reform or modify existing rules and, by implication, change the incentives faced by traders. Changing or modifying the rules does not imply deregulation, but reconstitution and reconstruction of the state through democratic constitution-making to provide transparent, participatory, and accountable governance and economic structures.

The political strategy emphasizes decentralization of power and argues that the concentration of power in the center

enhances the ability of the ruling coalition to engage in corrupt activities. The recommendation is that the public sector be made more transparent. For example, the public budget process should be made more open and participatory and the outcome (i.e., the budget) should be published and made available to the mass media and any other interested individuals and groups. Unfortunately, such reforms can easily be reversed (and power reconcentrated in the center) by subsequent governments in response to lobbying from interest groups.

Traditional approaches to corruption control depend on the effectiveness and professionalism of the country's counteracting institutions (e.g., the police, judiciary, and the mass media). It is assumed that institutions such as the police and judiciary are well constrained by the law and that they are free of corruption. First, a significantly large number of countries around the world do not have fully functioning private media that are free to investigate and expose corruption without fear of censure by the incumbent government.

Second, the judiciary systems of many countries are not independent of the executive branch of government. Instead, the country's chief executive controls the judiciary and retains the power to appoint and dismiss judiciary officers.

Third, many public institutions, especially in the developing countries, are pervaded by high levels of corruption. Hence, a corruption cleanup program developed and implemented by any of these institutions is not likely to be successful. An effective anticorruption program, then, must begin with the selection of appropriate new rules that (1) constrain the exercise of government agency and (2) provide the necessary foundation for the design and adoption of new and more effective counteracting agencies (e.g., an independent judiciary, a well-constrained police force, a professional and neutral military, an independent central bank, a free press, etc.).

Public Choice Theory and Corruption Control

Corruption is a "rules-related" problem. Rules determine the incentives faced by participants in markets. Unless the analyst understands the laws and institutions of the economy being examined, any attempt to study corruption and other forms of opportunism will not yield policy-relevant results.

In a 1985 study, Brennan and Buchanan argue that rules (1) determine the nature of the interaction between individuals within society; (2) provide the means for the peaceful resolution of conflict; (3) provide information to market participants, enhancing the ability of each individual to anticipate the behavior of others; and (4) constrain the behavior of individuals, as well as that of collectivities within the society. To deal effectively with corruption, for example, it is necessary that the police, who investigate and collect evidence to be used in the prosecution of those accused of corruption, be adequately constrained by the law. Since the rules determine the incentive structures faced by market participants, any effort to deal with corruption and other forms of opportunism (e.g., rent seeking) must begin with a negotiated modification of existing rules so that the economy can be provided with a new set of rules that effectively constrains state custodians and makes it quite difficult for them to behave opportunistically.

Rules can be implicit (e.g., tribal custom and tradition) or explicit (e.g., a written constitution). After a country has developed and adopted a constitution, corruption can be seen as post-constitutional opportunism—that is, behavior on the part of individuals or groups designed to generate extra-legal income for themselves, usually through the subversion of rules. One can see corruption then as part of the larger problem of constitutional maintenance or how to enforce compliance to the rules. Here, opportunism is defined as behaviors designed to improve the welfare of an individual or group at the expense of other citizens and includes such behaviors as shirking, corruption, adverse selection, moral hazard, and free riding.

The key to producing a sustainable and effective anticorruption campaign is a thorough and complete examination of the country's existing rules and by implication, its market incentives. This approach to corruption control has many benefits. First, institutional reform, especially if undertaken democratically, can produce rules that (1) reflect the values of the relevant stakeholder groups and hence are most likely to be considered legitimate tools for the regulation of sociopolitical interaction, improving the chance that people would respect and obey them; and (2) effectively constrain the state and make it quite difficult for civil servants and politicians to extort bribes from the private sector.

Second, institutional reform can be used to entrench economic freedom and improve entrepreneurship and wealth creation. Finally, institutional reform can provide each economy with more viable and effective structures for the management of ethnic diversity, resulting in a reduction in communal violence. A more peaceful society should significantly improve the environment for investment and wealth creation.

Hindu cosmologies are among the oldest surviving cosmologies in the world, dating back as far as the Vedic writings of the second millennium B.C.E. The oldest sections of the Vedas are the Samhitas (hymns), which express a relatively simple cosmology consisting of either two (earth and sky, representing male and female, respectively) or—more commonly—three parts (earth, atmosphere, and sky or heaven). There seems to be some indication of an underworld, although this is located sometimes in one of the aforementioned parts of the cosmos and at other times simply "beyond" them. Moreover, in these early Vedic works it is unclear if the gods created the cosmos (and if so, which ones) or if they were created within the cosmos. For example, in one famous account *purusha* (the "cosmic man") is sacrificed by the gods and his body divided to form the various aspects of the cosmos and the caste distinctions of Vedic society (*Rig Veda*, book 10, hymn 90). Yet in another prominent cosmogony, the author marvels at how nothing—neither being nor non-being, nor even the gods themselves—existed before the creation of the cosmos, and questions how anyone could know from whence the cosmos arose (*Rig Veda*, book 10, hymn 129). One of the significant contributions to Hindu cosmology in the Vedic hymns, however, is the notion of *rita* (roughly, "cosmic order"). Although it is not the focus of any particular hymn, the concept surfaces explicitly and implicitly in a number of Vedic hymns, and indicates an eternal law, moral standard, and underlying truth that applies to the cosmos generally and to human society in particular. In the hymns, however—and, for the most part, in the subsequent *Brahmanas* and *Aranyakas*—*rita* only suggested a ritual connection of sacrifices, devotion, and observance of a basic caste system with aiding the gods in maintaining cosmic order.

The Upanishads, the concluding sections of the Vedas written in the first millennium B.C.E., provide a more systematic and philosophically sophisticated cosmology. Most significant was the emphasis on the concept of *Brahman* (the ultimate as found in the cosmos as a whole), and its association with *Atman* (the ultimate as discovered through introspection). This shifted the entire focus of the cosmology—indicative of a larger shift in Hindu thought—from maintaining cosmic order (*rita*) to the achievement of liberation (*moksha*) from the cycle of reincarnation through identification with the Ultimate (*Brahman*). Maintaining cosmic order remains important, although it is understood in the Upanishads primarily in terms of *dharma*, which refers not only to the descriptive and normative dimensions of the cosmic order itself (as did *rita*) but also to that order as it applies to the individual's lot in life. Consistent with the identification of *Brahman* with *Atman*, achieving *moksha* is in large part a matter of understanding and observing the *dharma* of the cosmos as it applies to oneself. Although the Upanishads mark an important shift in Hindu cosmology, this shift was developed—like much of the Upanishads—on the basis of the Vedic hymns. For example, where the hymns distinguished two or three parts to the cosmos, the Upanishads distinguish seven, including a number of higher parts that correspond with achieving *moksha*. Perhaps the best example of this, however, is in the Upanishadic development of the “cosmic egg” cosmology first introduced in the *Brahmana* section of the Vedas: when split in two, the egg—which, significantly, is associated with *Brahman*—formed the earth and sky from its shells, and the mountains, streams, and the like from its insides (*Chandogya Upanishad* III.xix; see also *Shatapatha Brahmana* XI, 1, 6).

While the Upanishads mark the end of the Vedas, the cosmologies introduced there continue to be developed in the subsequent texts (for example, the *Manava Dharmashastra* or *Manusmriti* [Laws of Manu], the *Vishnu Purana*, and sections of the *Mahabharata*). While these texts differ somewhat in content, they mutually inform what has come to be the prevailing cosmology in the Hindu tradition. This cosmology draws on the Vedic account of the “egg of *Brahman*” (*Brahmanda*), although it develops the account with much greater elaboration. The world created from that egg—which, again, is identified with *Brahman*—is centered on a mythical Mount Meru, an inverted mountain that not only stands at the center of the world of the living, but also links it to numerous levels of heaven above and still more numerous hells below. The cosmography of the world includes highly figurative descriptions of geometrically oriented mountain ranges separating different lands, concentric seas of unusual liquids (for example, wine or molasses), and series of ring-shaped islands.

Accompanying this cosmography is an equally detailed account of cosmic time, according to which the world (that is, the world of living beings, as opposed to the cosmos as a whole) passes through four ages (*yuga*): the first is a golden age, and each age degrades further until the world is destroyed after the first. These four *yuga*, however, constitute but one day of Brahma, and—following a night of Brahma, which is a sustained period of cosmic rest—the world is created anew and runs through the four ages once again. This process is often

interpreted with respect to the actions of the gods Brahma (the creator, not to be confused with the impersonal *Brahman*), Vishnu (the preserver), and Shiva (the destroyer), which are seen to be three aspects of the world's continual regeneration and renewal. These accounts of time proceed to distinguish periods of time ranging from mere fractions of a second to the span of Brahma's life (numbering in the billions of years).

What is most notable about the development of Hindu cosmology is the extent to which it develops in concert with its social structures. In early Vedic literature, these structures (such as the caste system) are present, but only in their basic contours, just as is the case with Hindu cosmologies. By the time of the Upanishads, however, they have evidently taken on considerably more sophistication—again, as have the cosmologies. Finally, in the post-Vedic literature, caste distinctions and social obligation have been laid out in considerable detail, mirroring the exacting scholasticism present in the accompanying cosmologies. While the precise relation between cosmologies and social structures is a matter of ongoing debate, the development of Hindu cosmologies provides strong evidence that there is at least an important link between the two.

Buddhist Cosmologies

Buddhists are both interested and uninterested in cosmology. They are uninterested, first, because all of the distinctions that are typically taken to characterize the cosmos are seen as expressions of utmost ignorance with respect to the true nature of things. For Buddhists, there are no stable, unchanging things; rather, all things are in perpetual flux, and it is only through one's ignorance and desire that one takes them to be substantive and distinct. As this account of their lack of interest in cosmology should indicate, however, Buddhists are also very interested in cosmology, because it is not only the problem but also the solution that is cosmological. Not only can a cosmology constructed through “skillful means” (*upaya*) illumine the way to overcome ignorance, but overcoming this ignorance is itself adjusting one's understanding of the cosmos.

Thus, Buddhist cosmologies can be, but need not necessarily be, read as objective accounts of the nature of the cosmos; rather, the ultimate aim of these cosmologies is always on the achievement of enlightenment (*nirvana*), and they must be understood as means to that end. For example, in the *Vissuddhimagga* (*Path of Purification*), Buddhaghosha (fifth century C.E.) describes the “world” not in detailed spatial and temporal terms but in terms of possible destinations for rebirth: gods, humans, ghosts, and animals, and hell (strangely, the last is a spatial reference, but primarily indicates a realm for tortured souls). Likewise, in the *Abhidharmakosha*, Vasubandhu (fifth century C.E.) locates a cosmology much like Buddhaghosha's within but one of three spheres (*dhatu*): the sphere of desire (*kamadhatu*); beyond this is a sphere of pure form (*rupadhatu*), and finally a sphere of no-form (*arupadhatu*). Despite their differences, these two prominent early cosmologies serve as a roadmap for the path to enlightenment, complex enough to exemplify the key points of Buddhist doctrine, yet simple enough to serve as an accessible means for traveling along that path.

Buddhist cosmology becomes inordinately more complicated, however, with proliferation of worlds and Buddha-realms. The concept of multiple worlds is already evident in Theravada literature, where one Buddha oversees many worlds at one time; however, this concept becomes much more prominent in Mahayana texts, where most of these worlds are associated with particular Buddha-realms (*buddhakshetra*). Each *buddhakshetra* is overseen by its own fully enlightened Buddha, and is seen as pure, impure, or mixed, depending on the degree of desire and ignorance manifested there. Our own world, Saha, is the *buddhakshetra* of Shakyamuni (the historical Buddha), and is seen alternately as impure or mixed. Significantly, this association of worlds with different Buddhas is what gave rise to Pure Land Buddhism in the Chinese and Japanese contexts: the so-called “Pure Land,” Sukhavati, is a pure world overseen by the Buddha Amitayus/Amitabha (Infinite Life/Infinite Light), and all people who are born into this realm—something attained by faith rather than merit—are sure to achieve enlightenment in one lifetime.

It should be noted that, while Buddhist cosmologies are generally intended to embody the Buddhist path to enlightenment, this does not mean that they do not also draw on the cosmologies of other religious traditions—although this is always done with some modification. For example, Buddhist cosmography, like other Indian cosmographies, is traditionally centered on Mt. Meru, although the cosmography is given a distinctively Buddhist slant by placing the entire world of the living under the dominion of *Mara* (death). Likewise, the Buddhist notion of cosmic time borrows from the Hindu account of four *yugas* after which the world is destroyed and formed again; yet this account is again given a Buddhist slant by ridding the process of any creative deities and ensuring that the unenlightened souls are preserved during these recurrent destructions. This process of borrowing and adapting would continue as Buddhism spread into China, Tibet, Korea, and Japan; what would remain constant, however, is the ultimate aim of Buddhist cosmology: namely, enabling those still suffering in ignorance to ultimately achieve nirvana.

Chinese Cosmologies

Chinese cosmologies are, like Indian and Buddhist ones, manifold in their diversity. Some of the oldest originated from the Shang dynasty (c. 1554–1045/1040 B.C.E.), and appear initially to account for the general characteristics of the observed world. For example, the cosmos is often understood as consisting of a dome-shaped heaven (represented as a circle) and a square earth; China, the “Middle Kingdom,” is situated at its center, with the surrounding world represented as kingdoms situated at each of the four cardinal points and mountains at each of the corners. Allan notes that this cosmology not only resembles a turtle (as many have observed), but more importantly that it resembles the plastron (breastplate) of a turtle; this association is significant because it points to the mythic overlay that accompanied these cosmologies: the plastron was among the most prominent mediums for divination in early Chinese rituals. In this basic cosmology, two of the most prominent features of Chinese cosmologies are already starting to develop: first, the duality between heaven and earth

anticipates the later and broader duality between *yin* and *yang*; second, there is an assumed correlation between the cosmos in its entirety and the cosmos as found in any one of its parts (such as the turtle plastron). Yet Shang cosmologies remained for the most part very basic, overseen by the supreme Lord, Shang Di, and controlled by various spiritual beings.

The Zhou dynasty (roughly 1100–250 B.C.E.) inaugurated a move from tribal society to feudal society, and the cosmologies of this period reflect that change. For example, the king takes on the title of “Son of heaven,” thus situating himself cosmologically as that which links heaven and earth. This move simultaneously afforded him cosmic legitimacy, while also constraining him with the responsibility of ensuring that the order of earth appropriately modeled the order of heaven. This latter responsibility was termed the “Mandate of Heaven,” and was taken to be a universal moral law that rulers could either observe (and continue to rule) or neglect (and lose their right to rule). Both duality and correlative thinking remained evident in Zhou cosmology, although the anthropomorphic spiritual powers of the Shang were replaced by moral principle in the Zhou in a way that both validated and restrained rulers even at the highest level, as seen in the *Shijing* (*Classic of Odes*) and the *Shujing* (*Classic of Documents*).

The cosmography of the Zhou also developed that of the Shang in much greater detail. Whereas the Shang understood earth to be square in a broad sense, the Zhou came to see space generally in terms of square units. In order to provide a more detailed description of the earth, squares were divided into nine smaller squares, each of which could be further divided to the desired level of detail; typically, this took the form of a 3 by 3 grid, but there are other variants. The result of such division was that most of Chinese cosmography was understood in terms of nines: nine domains in the Zhou empire, nine branches of the Yellow River, and so on. The most famous example of this division is the well-field system of taxation, whereby eight farmers would each farm one of the peripheral plots on a 3 by 3 grid, with the center square tended by all eight and its yield being given as a tax payment to the government. It is remarkable that even the division of land and labor was taken to be best ordered as a microcosm of the larger cosmic landscape.

What is perhaps most important about Zhou cosmologies, however, is that they set the terms for all subsequent Chinese cosmology. The most prominent features are fourfold: the duality between *yin* and *yang*, the five agents (water, fire, earth, wood, and metal), and the sixty-four hexagrams. First, the duality between *yin* and *yang* is taken to be characteristic of the cosmos as a whole, embodied in the dualities between dark and light, weak and strong, cold and hot, female and male (respectively); the profound message of this duality, however, is that these apparent opposites are actually fundamentally related, balancing, propagating, and flowing out of one another, for example, the *Daodejing* (*Classic of the Way and Virtue*) and the *Yijing* (*Classic of Change*). The theory of the five agents, in turn, represents the perpetual transformation of things as a characteristic and entirely natural feature of the cosmos; Zhou cosmologists correlated these with virtues, feelings, and arrangements of time, and used them to explain changes in

The earliest written accounts of Japanese cosmology are found in the *Kojiki* (“Records of Ancient Matters,” 712 C.E.) and the *Nihongi* (“Chronicles of Japan,” 720 C.E.). These texts originate in a time in Japanese history when Buddhism was already a significant influence, and thus serve not only as mythico-historical accounts of the origins and history of the Japanese people but also as the founding documents for the Shinto religion (which had hitherto been transmitted in spoken word and ritual practice). The presence of external influences is already apparent in these documents: the *Nihongi*, for instance, compares the initial state of the cosmos to an egg that, as heavy and light parts separate, form the heavens and the earth (as seen in many other Asian cosmogonies). The most significant influences, however, appear to stem from Chinese thought: most notably, *Yin* and *Yang*, presented in the *Nihongi* as the complementary forces underlying the cosmos, arguably stand as Japanese representations of *yin* and *yang*.

Despite their apparent external influences, Japanese sources also reveal their distinctiveness, as found most clearly in the epic of Izanagi and Izanami as found in *Kojiki*. Izanagi (“male-who-invites”) and Izanami (“female-who-invites”) represent the last generation of a series of spontaneously generated primordial gods, who develop out of one another in increasing complexity and differentiation. Izanagi and Izanami descend from High Heaven (*Takamahara*) to the unformed world to create the islands of Japan. These islands, as well as a host of smaller gods (*kami*), are brought about primarily as products of the sexual union of Izanagi and Izanami. Ultimately, however, Izanami dies while giving birth to the god of fire—she is scorched to death,

producing even more gods in the process—and descends to the land of the dead (*Yomi-no-kuni*). In his rage Izanagi destroys the god of fire for his matricide, and in his grief he enters into the land of the dead to recover his wife. However, when he finds her and sees her decaying corpse, Izanami becomes enraged and pursues him with a host of demons. When he reaches the path between the land of the living and the land of the dead, Izanagi seals the path with a large stone. Following rituals of purification and grief (through which still more gods were created), Izanagi ascends to High Heaven, leaving the land of the living to the gods he has created. These gods continue to propagate and differentiate, eventually giving birth to the Imperial Family, the Japanese people, and the rest of the creatures and features of Japan.

This basic creation myth establishes the basic tripartite cosmology of the Shinto religion, consisting of High Heaven, the world of the living, and the world of the dead. It is also used to account for a wide variety of features of the cosmos, from such mundane features as the prevalence of fire (attributed to the pulverization of the god of fire for his matricide) to the victory of life over death (as embodied by the victory of Izanagi over Izanami at the path to the land of the dead). Although Japanese cosmology would become increasingly influenced by more pan-Asian religious and philosophical traditions—most notably, Buddhism—the Shinto cosmogony and cosmology laid out in the *Kojiki* and the *Nihongi* continue to influence popular belief in Japan. Indeed, insofar as these accounts serve to express the mythical origins of the Japanese people, they have become all the more influential as the Japanese have sought to develop and emphasize their own distinctive national identity.

everything from seasons to dynasties (for example, the *Shujing*, the *Xunzi*, the *Lüshi chungiu* [*Springs and Autumns of Mr. Lü*]). Finally, the sixty-four hexagrams consist of sets of six lines that are each either broken (associated with *yin*) or unbroken (associated with *yang*); whereas earlier Chinese tradition had used these for the purposes of divination, Zhou cosmologists began to attribute cosmological significance to them by associating them with all of the possible types of change within the cosmos.

Whether explained with respect to *yin* and *yang*, the five agents, or the sixty-four hexagrams (texts often drew on all three), Chinese cosmologies ultimately grounded these differentiations in a common source. This is identified in a number of different ways, but most commonly as the Supreme Ultimate (*taiji*, which generates *yin* and *yang*), or the Dao itself (which is prior even to the *taiji*). The primary point of Chinese cosmology is that, while the cosmos embodies a wide

variety of oppositions, changes, and transformations, these are ultimately the natural expressions of an underlying cosmic balance and harmony. While subsequent Chinese would alter the precise nature of the grounding and differentiation of the cosmos, both the terms laid out in the Zhou and its emphasis on cosmic balance and harmony would remain landmarks of Chinese cosmology.

If the Zhou introduced the main tenets of Chinese cosmology, it was the Han (202 B.C.E.–220 C.E.) who brought these tenets together and systematized them. For example, it was during the Han that the great commentaries on the *Yijing* and the *Chunqiu* (*Spring and Autumn Annals*) were written. Characteristic of this systematization is the heightened role of correlative thinking, which takes on a detailed, precise, and often even numerical character. Perhaps the most prominent example of Han cosmology is that of Dong Zhongshu (c. 195–c. 105 B.C.E.), as found in his *Chunqiu fanlu* (*Luxuriant Gems of the Spring and Autumn Annals*). Whereas the *Yijing* had related all things on a general level, Dong related them in exact detail: every thing or event can be seen as the direct result of other things and events, resulting in a highly complicated but also highly ordered cosmos. More importantly, this order of the cosmos as a whole is replicated at every level of existence, such that the human body, social relations, and imperial governance are all seen to be perfect microcosms of the larger cosmos. Dong's interest in the *Chunqiu fanlu* thus arises from his desire to use past records of interaction to aid present decisions in better modeling the balance and harmony of the cosmos.

Yet for all of their systematization and rigor, Han cosmologies proved too rigid for subsequent dynasties. Scientific advances compromised the perfect order asserted by Han cosmologists, persistent political upheavals rendered many of their political associations irrelevant, and the introduction of Buddhism into China shifted philosophical interest away from cosmology and toward metaphysics. In the Song dynasty (960–1279 C.E.), which witnessed a revival of interest in classical Chinese sources amid the rise of Neo-Confucianism, many of the terms and concepts informing Chinese cosmology were revived—for example, Zhou Dunyi's *Taijitu shuo* (*Explanation of the Diagram of the Supreme Ultimate*) and Shao Yong's *Huangji jingshi shu* (*Book of the Supreme Ultimate Ordering the World*). In both the Song and the Ming (1368–1644 C.E.) dynasties, these concepts were often reworked with remarkable ingenuity—the most prominent example of this is Zhu Xi's (1130–1200 C.E.) reinterpretation of the cosmos in terms of *li* (principle) and *qi* (material form)—although it must be noted that Neo-Confucian interest, following the lead of Neo-Daoism and Buddhism, was decidedly more metaphysical than cosmological. Ultimately, not even this resurgence of interest succeeded in stemming the tide of increasing cosmological skepticism in Chinese thought.

In the Qing dynasty (1644–1912), this skepticism reached its height. Seventeenth-century China experienced a marked increase of interest and renaissance in mathematics, astronomy, and geography, due in part to the introduction of Western science by means of the Jesuits. However, these new studies ran counter to the Chinese traditions of numerology, correlation

of the orders of heaven and earth, and geometric cosmogony, thus calling these traditions into serious question. Such critique was far from unprecedented (for example, Wang Chong [c. 27–c. 100 C.E.], Ouyang Xiu [1007–1072 C.E.]), but it is only in the late Ming and Qing dynasties that scientific development had enough momentum to seriously call into question such long-standing Chinese traditions (for example, Gu Yanwu [1613–1682 C.E.], Wang Fuzhi [1619–1692 C.E.]). According to John Henderson, this shift was so significant as to inaugurate something of an “anti-cosmology”—a cosmology that, in contrast to the traditional Chinese approach via correlative thinking about an ordered cosmos, took irregularity and nonuniformity to be defining characteristics of the cosmos (for example, Wang Tingxiang [1474–1544 C.E.]). Henderson goes on to argue that it was ultimately this distrust of correlative thinking in cosmology that led to a similar distrust of scientific models in China, thus effectively cutting it off from the broader scientific revolution and global cosmological conversation.

COSMOLOGY AND ASTRONOMY

Early cosmologies, or worldviews, envisioned a universe subject to the whims of gods and were anthropocentric: focused on the role and fate of human beings. As such, cosmology and religion were often intertwined.

Babylonian Cosmology

Elimination of everything other than empirical observation and mathematical computation from Babylonian astronomical texts of the Seleucid period has been hailed by some as the first appearance of modern science and cosmology. Ancient Babylonians studied how the celestial motions went, but not why. Nor did they seek causes for physical phenomena or develop comprehensive theories about the universe. Consequently, some scholars dismiss Babylonian cosmology and astronomy as merely a set of mechanical procedures with no more theoretical content than recipes in a cookbook. They look instead to the Greeks for the birth of modern science.

Greek Cosmology

For two millennia, the Aristotelian physical cosmology of rotating spheres carrying the sun, moon, planets, and stars around the central earth permeated Western thought. The natural place for earthy material was at the center of the universe, and earthy material tended to move to its natural place. Planetary spheres rotated because that was their natural motion. Aristotle's teleological explanations, with the world fulfilling a purpose formed by a superhuman mind, would not necessarily be incompatible with Christian philosophy, which also envisioned the world as inherently meaningful and purposive. Concurrent with Aristotle's physical cosmology was Plato's geometrical cosmology, in which astronomers strove "to save

the appearances": to explain apparently irregular planetary motions with combinations of circular motions at constant speeds.

In the context of modern science, saving the appearances with uniform circular motions is an arbitrary and absurd task. The task was, however, widely accepted and pursued for around two thousand years, from the Greeks in the fourth century B.C.E. through Copernicus and the European Renaissance in the sixteenth and seventeenth centuries C.E. The historical importance of a cosmology is not necessarily negated by its absurdity, especially when that label is applied in hindsight by different people in a different age with different standards and values.

Saving the appearances is plausible in the context of Plato's philosophy, which in turn can be understood as his reaction to the moral and political chaos of his age, which left him highly dissatisfied with the physical world. His concept of an ideal reality is simply illustrated. A circle drawn on paper is an imperfect representation in the visible world of experience of a perfect circle, which exists only in the world of thought. In his *Republic*, Plato wrote that the sky was part of the visible world, and the true revolutions of the planets, sun, and moon were to be discerned by reason and thought, not by sight.

Interregnum

Greek geometrical cosmology was systematized and advanced, with rigorous geometrical demonstrations and proofs, by Claudius Ptolemy (second century C.E.). He did for astronomy what Euclid had done for geometry and earned a reputation as the greatest astronomer of the ancient world. Indeed, his *Almagest*, of about 140 C.E., was so comprehensive that its predecessors ceased to be copied and failed to survive.

The match between Ptolemy's reported observations and his theory is too good to be true, and the *Almagest* has been called the greatest fraud in the history of science. It is not a modern scientific research paper, however, but a textbook, and it is in this context that Ptolemy should be judged. He made many observations; errors largely canceled each other out; and he thus obtained an accurate planetary theory. Next he would have selected a few observations in best agreement with the theory to illustrate it, and even fabricated examples to neaten up his pedagogy. The Greek astronomical tradition was far more concerned with general geometrical procedures than with specific numerical results.

Islamic scientists rescued the Aristotelian and Platonic cosmologies when Western civilization crumbled; they transmitted Greek learning back to the West when learning revived there. Initially, Aristotelian cosmology, including the eternity of the world and denial that God could make other worlds, seemingly contradicted dogmas of the Christian faith, and in the thirteenth century the bishop of Paris condemned hundreds of Aristotelian propositions. The condemnations helped free cosmology from Aristotelian dogma and also led to the nominalist, instrumentalist, or positivist thesis. Cosmology was understood as a working hypothesis, the truth of which could not be insisted upon because God could have made the world in a different manner but with the same observational

consequences. Imaginative and ingenious discussions, including possible rotation of the earth, subsequently flourished.

Hypothetical cosmologies, however, are not the stuff of revolution. Confidence that the essential structure and operation of the cosmos is knowable would be essential to the achievements of Nicolaus Copernicus (1473–1543), Galileo Galilei (known as Galileo; 1564–1642), Johannes Kepler (1571–1630), and Isaac Newton (1642–1727).

The Copernican Revolution

Ptolemy's planetary theory matched observations, but in Copernicus's opinion, it violated the standard of uniform circular motion. Also, Ptolemy's scheme did not automatically produce phenomena that followed naturally in Copernicus's heliocentric model. An unauthorized foreword to Copernicus's 1543 *De revolutionibus orbium coelestium* presented the heliocentric theory as a convenient mathematical fiction. Copernicus, however, believed that he was describing the real world.

Revolutions in science, as in politics, often exceed the limited changes envisioned by their creators. The sphere carrying the stars was now obsolete, and soon human imagination distributed the stars throughout an infinite space. Furthermore, the earth was no longer unique. Galileo's telescopic observations emphasized that the moon was uneven and rough, like the earth. Also, Jupiter had four satellites similar to the earth's satellite.

Logical consequences of the Copernican system, Galileo's telescopic discoveries, and the principle of plenitude, which interpreted any unrealized potential in nature as a restriction of the Creator's power, all encouraged belief in a plurality of worlds. Also, political and societal critics used the moon as a literary convention, its inhabitants' arrangements being either a model of perfection or a mirror of the earth's vices. Faith in an anthropocentric universe lay shattered, leaving people's relationship with God uncertain. John Donne's 1611 poem *An Anatomy of the World*, its line the "new Philosophy calls all in doubt," and later "all Relation: / Prince, Subject, Father Son, are things forgot," refers to Christian morality as much as to the relative positions of the sun and earth.

The Newtonian Revolution

Tycho Brahe's (1546–1601) observations of comets coursing through the solar system shattered the Aristotelian crystalline spheres, and his observation of a nova, a star flaring up in brightness, pierced Aristotelian belief in an unchangeable heaven. Belief in uniform circular motion died next when Kepler used Brahe's observations to show that planets travel around the sun in elliptical orbits. A new explanation of how the planets retrace the same paths forever around the sun became a central problem of cosmology. Newton showed mathematically how a force of attraction or gravitation toward the sun continually draws planets away from straight-line motion and holds them in Kepler's elliptical orbits.

The Newtonian example of general laws in natural philosophy excited searches for general laws in other realms, including economics. In this branch of philosophy, Adam Smith

(1723–1790) played Newton's role. Also inspired by Newton's achievement, Voltaire (1694–1778) and Montesquieu (1689–1755) searched for natural laws of politics. The French Revolution owed much to Newton.

Newton was convinced that his discoveries demonstrated God's wonders. Yet the revolution in thought following from his new cosmology, particularly the concept of a mechanical, clocklike universe, threatened the historic link between cosmology and religion in Western thought. Writers of the Romantic period sought to breathe divine life back into an overly mechanized and increasingly godless universe. Under the sway of the French Enlightenment's atheistic approach to nature, however, Pierre-Simon Laplace (1749–1827) happily replaced the hypothesis of God's rule with a purely physical theory. According to legend, when Napoléon Bonaparte (1769–1821) asked Laplace whether he had left any place for the Creator, Laplace replied that he had no need of such a hypothesis.

The Newtonian solar system provided Immanuel Kant (1724–1804) a model for the larger stellar system. The same cause that gave the planets their centrifugal force, keeping them in orbits around the sun, could also have given the stars the power of revolving. And whatever made all the planets orbit in roughly the same plane could have done the same to the stars. Nebulous-appearing objects in the heavens became, in Kant's mind, island universes, like colossal solar systems. Late in the eighteenth century, William Herschel's (1738–1822) large telescopes expanded the heavens from a starry sphere to a three-dimensional firmament. He observed that most stars seemed to lie between two parallel planes. This stratum, seen from earth, is the Milky Way.

Twentieth-Century Cosmology

At the beginning of the twentieth century, it was generally thought that the Earth's galaxy was some ten thousand light-years across and that the solar system was near the center of the galaxy. This vision of the universe was soon replaced with a revolutionary new conception. Harlow Shapley at the Mount Wilson Observatory showed that the galaxy is hundreds of thousands of light-years in diameter and the solar system is far from its center. The significance of humans and their particular planet had dwindled still further. Shapley noted a historical progression from belief in a small universe with humankind at its center to a larger universe with the earth farther from the center. The geometry had been transformed from geocentric to heliocentric to acentric. The psychological change was no less, Shapley insisted, from homocentric to acentric. Furthermore, the galaxy containing the Earth is but one of many "island universes," as Edwin Hubble soon proved. Next Hubble found that the universe is expanding. Georges Lemaître, a Belgian priest and astrophysicist, explained the expansion of the universe from an initial "cosmic egg." Einstein confirmed that Lemaître's theoretical investigations fit well into the general theory of relativity.

Advances in nuclear physics fed speculations about an expanding universe resulting from thermonuclear reactions in an early, hot, dense phase. Fred Hoyle at mid-century derisively

called it the “big bang,” and the term stuck. Hoyle championed instead steady-state creation, in which the universe expands but does not change in density because new matter continuously appears. Pope Pius XII announced in 1951 that big-bang cosmology affirmed the notion of a transcendental creator and was in harmony with Christian dogma. Steady-state theory, denying any beginning or end to time, was associated with atheism, though Hoyle associated it with personal freedom and anticommunism. The debate was resolved observationally with detection of a faint cosmic background radiation, a remnant of the big bang.

In 1979 an American particle physicist, Alan Guth, proposed that important cosmological features can be explained as natural and inevitable consequences of new theories of particle physics. Guth’s theory of inflation states that in the first minuscule fraction of a second of the universe’s evolution, a huge inflation occurred. After that, the inflationary universe theory merges with the standard big-bang theory.

COSMOPOLITANISM. Cosmopolitanism refers to both a lifestyle incorporating aspects from all or many parts of the world and an ideology based upon the premise that every human shares, or should share, equal status as a “citizen of the world.” The two are not exclusive of one another, but it is certainly possible to encounter either the ideal or the lifestyle without the presence of the other. Though similar to the concept of multiculturalism, cosmopolitanism should be distinguished from this term. Whereas cosmopolitanism entails the “recognition, acceptance, and eager exploration of diversity,” multiculturalism includes more concern for boundary maintenance than for empathetic border crossings (Hollinger, p. 84).

The Ideal of Cosmopolitanism

The word *cosmopolitan* can be traced to the Greek Cynic philosophers Antisthenes (c. 445–365 B.C.E.) and his student Diogenes of Sinope (d. c. 320 B.C.E.). In the fourth century B.C.E., Diogenes likely responded to inquiry about his citizenship by boldly asserting, “I am a citizen of the world.” His statement, though often used as a humanistic slogan, expressed a rather negative notion. Since he was not a citizen of any particular locale, he was not obligated to serve his particular city-state. He offered his allegiance to no single government. The Stoic philosopher Zeno of Citium (c. 335–c. 263 B.C.E.) articulated a similar sentiment, but with more constructive implications. He imagined citizenship as a series of concentric circles. The self inhabited the innermost ring of this inclusive model, followed by family, city, region, and so on. Thus Zeno understood the individual as a part of all other affiliations.

Early Christianity also offered a unique notion of cosmopolitanism: The disciple obtained a new, spiritual citizenship that transcended the bonds of local government and regional identity through following the teachings of Jesus. St. Paul (c. 66) expressed this in an open letter to devotees in Colossi, proposing that “there is no distinction between Greek and Jew, circumcised and uncircumcised, barbarian, Scythian, slave or free” (Col. 3:11). This deconstruction of status and ethnicity represented a significant development in the cosmopolitanism as a concept, even if the established Christian church has often been a source of division.

Several humanist intellectuals advocated a cosmopolitan ideology during the Enlightenment of the seventeenth and eighteenth centuries. The philosophes imagined themselves as inhabitants in a republic of letters that transcended mere national boundaries. Believing in the preeminence of reason and scientific discovery, these men forged bonds of intellectual discourse throughout the North Atlantic. The ideas of the German philosopher Immanuel Kant (1724–1804) were especially influential through the beginning of the twenty-first century.

His writing advocated perpetual peace between nation-states during a time when nations were still being defined.

Contemporary scholars have implemented the cosmopolitanism of nineteenth- and early-twentieth-century Indians alongside that of Kant. Swami Vivekananda (1863–1902) united the teachings of the Indian religious leader Sri Ramakrishna (1836–1886) with claims of scientific validity to increase awareness of the physical and spiritual practice of yoga. His contemporary, the poet Rabindranath Tagore (1861–1941), an undoubted anticolonial himself, chided the political and religious leader Mohandas Gandhi (1869–1948) for his penchant toward national self-reliance. Instead, Tagore pleaded for a transnational interdependency. The work of these men still exercises influence upon spiritual and political cosmopolitanism.

In each of these contexts, the ideal of cosmopolitanism sought to eclipse local or regional loyalties with the belief that humans share a bond free from provincial affiliations. Whether predicated on mysticism or reason, cosmopolitanism as an ideal locates the individual within a world community. However, those espousing the ideal have not always turned this admirable belief into a reality. Religious exclusion and ethnic nationalism have continued to flourish despite these recurrent appearances of a cosmopolitan ideal. However, this is not to say that cosmopolitanism has not been practiced in various times and locales.

The Practice of Cosmopolitanism

As a lifestyle, cosmopolitanism embraces, participates in, and combines the customs of several different cultures. The cosmopolitan is not tethered by local or national habits and prejudices. Rather, he or she welcomes encounters with those from different regions and aspires to fluidly navigate from one cultural context to another.

Cosmopolitanism has been achieved in disparate historical and geographical settings. The Ottoman Empire of the fifteenth and sixteenth centuries encouraged the mingling of Northern African, Iberian, and Middle Eastern peoples. In the medieval period, Islamic scholars incorporated the works of ancient Greeks into their learning. Cities such as Istanbul became centers of trade and cosmopolitanism, even housing Freemasonry lodges in the nineteenth century.

At times, people may adapt a cosmopolitan way of life out of necessity as opposed to ideological conviction. Daniel M. Swetschinski's study of Portuguese Jews in the Netherlands of the seventeenth century recounts an historical setting in which members of a displaced ethnic group incorporated the customs of others. These "reluctant cosmopolitans," as Swetschinski calls them, became part of the flourishing Danish mercantilism. Landing in ports all throughout the Atlantic and Mediterranean, they interacted with multiple cultures while maintaining a Jewish identity.

Certain social groups are almost always associated with cosmopolitanism. Intellectuals, diplomats, creative artists, the wealthy, and merchants each to a certain extent maintain a lifestyle that might be described as cosmopolitan. Certainly since the time of the Enlightenment, academia has extended beyond

local influence. Intellectual communities, in both the humanities and the sciences, collaborate and compete along disciplinary lines rather than national borders. Diplomats, by the very nature of their profession, must be charming in midst of profound cultural difference. Adaptability to unique settings and a thorough understanding of distinct worldviews qualify political emissaries. Visual, literary, and performing artists, as well as their patrons, have long displayed a fascination with exotic subjects and media. International movements within the arts often indicate the merging of traditionally distinct ideas and people-groups. Historically, though, one need not display any of the aforementioned skills to live a cosmopolitan life. A person might become a world citizen by possessing the means to travel extensively. By journeying to distant climes, speaking foreign languages, and acquiring and displaying exotic goods, the wealthy could be included among the ranks of other cosmopolitans.

However, perhaps more than any other social group, merchants have both exemplified cosmopolitan lifestyles and prompted others to do the same. With the emergence of global capitalism, traders and business people are regularly in contact with multiple cultures and ethnic groups. Transnational enterprise demands its participants be capable of interacting with diverse populations. Moreover, through the commodification of goods produced in foreign lands, merchants encourage consumers to desire nonindigenous wares.

Opposition to Cosmopolitanism

Cosmopolitanism, as both an ideal and a lifestyle, has often been critiqued. Given those who have historically been considered cosmopolitans, it is not surprising that skeptics label it elitist. Cosmopolitanism most often required either remarkable talent or extraordinary financial means, and sometimes both. The vast majority of people simply did not have the option to participate in such a life.

Nationalists and some ethnic leaders have also attacked the concept. Because cosmopolitans lack the "roots" of others, these critics believe they cannot be loyal to the political process of a given geographic region. Ethnic essentialists are similar in that they disdain cosmopolitanism because it involves the internalization of others' cultural beliefs and practices. To the essentialist, people simply are not able to fit into any ethnic group other than their own.

Ironically, global capitalism coupled with national and religious extremism has created a nonelite group of cosmopolitans. Immigrants and refugees now bring a heterogeneous picture of humanity from their respective homelands. Moreover, relatively affordable travel and dazzlingly diverse urban landscapes bring the exotic within reach of many. In the technologically saturated, polyethnic world of the twenty-first century, the ideal and the practice of cosmopolitanism seem much more similar than they have in the past.

CREATIONISM. Creationism in a general sense refers to the theory that God made the world on his own, by miraculous means, out of nothing. In a more specific sense, the one encountered in America today, creationism is the theory that the Bible, particularly the early chapters of Genesis, is a literally true guide to the history of the universe and to the history of life, including us humans, down here on earth. This encompasses a number of beliefs: a short time since the beginning of everything (“Young Earth Creationists” think that Archbishop Ussher’s sixteenth-century calculation of about 6,000 years is a good estimate); six days of creation (there is debate on the meaning of “day” in this context, with some insisting on a literal twenty-four hours, and others more flexible); miraculous creation of all life including *Homo sapiens* (with scope for debate about whether Adam and Eve came together or if Eve came afterward to keep Adam company); a worldwide flood some time after the initial creation, through which only a limited number of humans and animals survived; and other events such as the Tower of Babel and the turning of Lot’s wife into a pillar of salt. Creationists have variously been known as fundamentalists or biblical literalists, and sometimes (especially when they are pushing the scientific grounds for their beliefs) as scientific creationists. Today’s creationists are often marked by enthusiasm for so-called intelligent design.

History of Creationism

Creationists present themselves as the true bearers and present-day representatives of authentic traditional Christianity, but historically speaking this is simply not true. The Bible has a major place in the life of any Christian, but it is not the case that the Bible taken literally has always had a major place in the lives or theology of Christians. Tradition, the teachings and authority of the Church, has always had main status for Catholics, and natural religion—approaching God through reason and argument—has long had an honored place for both Catholics and Protestants. Catholics, especially dating back to Saint Augustine (354–430), and even to earlier thinkers like Origen (c. 185–254), have always recognized that at times the Bible needs to be taken metaphorically or allegorically. Augustine was

particularly sensitive to this need, because for many years as a young man he was a Manichean and hence denied the authenticity and relevance of the Old Testament for salvation. When he became a Christian he knew full well the problems of Genesis and hence was eager to help his fellow believers avoid the traps of literalism.

It was not until the Protestant Reformation that the Bible started to take on its unique central position, as the great Reformers—especially Martin Luther (1483–1546) and John Calvin (1509–1564)—stressed the need to go by Scripture alone and not by the traditions of the Catholic Church. But even they were doubtful about totally literalistic readings. For Luther, justification by faith was the keystone of his theology, and yet the Epistle of Saint James seems to put greater stress on the need for good works. He referred to it as “right strawy stuff.” Calvin likewise spoke of the need for God to accommodate his writings to the untutored public—especially the ancient Jews—and hence of the dangers of taking the Bible too literally in an uncritical sense. The radical branch of the Reformation under Huldrych Zwingli (1484–1531) always put primacy on God’s speaking directly to us through the heart, and to this day one finds modern-day representatives like the Quakers uncomfortable with too biblically centered an approach to religion.

Eighteenth- and nineteenth-century revivals. It was really not until the revivals of the eighteenth and early nineteenth century in Britain and America—revivals that led to such sects as the Methodists—that a more full-blooded literalism became a major part of the religious scene. Then, the emphasis was on Christ’s dying on the cross for our sins (the Atonement), the priesthood of all believers, and the primacy of the Bible as a guide to the converted heart, although even then there were many opposed, often quite violently. To take but one example, the most significant movement within the Church of England (Anglicanism; Episcopalianism in America) was the High Church movement known as Tractarianism, the Oxford movement of the 1830s, led most significantly by the future Catholic cardinal, John Henry Newman (1801–1890). No one was more vitriolic and sarcastic on the subject of biblical literalism than was Newman. In one of his major writings, Tract 85, he ridiculed those who would use the Bible as a guide to science or religion, and, with the vigor of a hardened humanist, he pointed out inconsistencies in the sacred book.

In America particularly, however, literalism did take hold, and especially after the Civil War (1861–1865), it took root in the evangelical sects—especially Baptists—of the South. It became part of the defining culture of the South, having as much a role in opposing ideas and influences of the North as anything rooted in deeply considered theology. This was the time of Charles Darwin (1809–1882), whose great work, *On the Origin of Species* (1859), provoked much theological opposition. But for the great Christian opponents—Samuel Wilberforce (1805–1873), bishop of Oxford in England, and Charles Hodge (1797–1878), principal of Princeton Theological Seminary in America—simple biblical literalism was far from the front of the objections. They were certainly keen on

what became pretty standard arguments against evolution in general and Darwinism in particular. Gaps in the fossil record played a major role, as did the origin of life and the nonexistence of the direct observation of natural selection changing species. But crude reference to the Bible had no place in their scheme of things. Six thousand years of earth history was as far from the thinking of Wilberforce and Hodge as it was from that of Darwin. Problems of natural theology were far more pressing, as were topics that only tangentially have their basis in Genesis, such as the existence of immortal souls.

Early twentieth century. Creationism became more than just a local phenomenon in the early part of the twentieth century, thanks to a number of factors. First, there were the first systematic attempts to work out a position that would take account of modern science as well as a literal reading of Genesis. Particularly important in this respect were the Seventh Day Adventists, especially the Canadian-born George McCready Price (1870–1963), who had theological reasons for preferring literalism, not the least being the belief that the Seventh Day—the day of rest—is literally twenty-four hours in length. (Also important for the Adventists and for other dispensationalists—that is, people who think that Armageddon is on its way—is the balancing and complementary early phenomenon of a worldwide flood.) Second, there was the realized energy of evangelicals as they succeeded in their attempts to prohibit liquor in the United States. Flushed from one victory, they looked for other fields to conquer. Third, there was the spread of public education, which exposed more children to evolutionary ideas, provoking a creationist reaction. Fourth, there were new evangelical currents afloat, especially the *Fundamentals*, tracts that gave the literalist movement its name. And fifth, there was the identification of evolution—Darwinism particularly—with the militaristic aspects of Social Darwinism, especially the Social Darwinism supposedly embraced by the Germans in World War I.

The “Scopes Monkey Trial.” This battle between evolutionists and “fundamentalists” came to a head in 1925 in Dayton, Tennessee, when a young schoolteacher, John Thomas Scopes (1900–1970), was prosecuted for teaching evolution in class, in defiance of a state law prohibiting such teaching. There was more at stake than just the facts, evolution versus the Bible. Local businesspeople welcomed the opportunity of a high-profile court case to put their community on the map and to reap financial rewards. The American Civil Liberties Union (ACLU), backing the defense, was eager for such a case to bolster its standing with America’s liberals and to highlight its existence (it was founded in 1920). Indeed, the ACLU actively sought out someone who would be willing to stand trial. Prosecuted by the three-time presidential candidate William Jennings Bryan (1860–1925) and defended by the noted agnostic lawyer Clarence Darrow (1857–1938), the “Scopes Monkey Trial” caught the attention of the world, especially thanks to the inflammatory reporting of the *Baltimore Sun* journalist H. L. Mencken (1880–1956). Matters descended to the farcical when, denied the opportunity to introduce his own science witnesses, Darrow put on the stand the prosecutor Bryan. In the end, Scopes was found guilty and fined \$100, although this was overturned on a technicality on

appeal. Despite never again being enforced, the Tennessee law remained on the books for another forty years.

Toward the Present

After the *Scopes* trial, the creationism movement declined quite dramatically and quickly. This was not due to Americans losing interest in the science-religion relationship, for now was the time of the foundation of such organizations as the American Scientific Affiliation, which tried seriously to seek a meeting ground between science and various forms of evangelical Christianity. But as is shown well by the trials of this particular organization—forever torn by the quarrels over geology and evolution—full-blooded Creationism no longer captured universal support among biblical Christians. Yet Creationism had its lasting effects, in that textbook manufacturers increasingly took evolution—Darwinism especially—out of their books, so that schoolchildren got less and less exposure to the ideas anyway. Whatever battles the evolutionists may have thought they had won in the court of popular opinion, in the trenches of the classroom they were losing the war badly.

Things started to move again in the late 1950s. A major factor was that, in the years since the *Scopes* trial, evolutionary thinking had not stood still. Indeed, the three decades from 1930 to 1960 were times of great ferment and development, for Mendelian genetics (and after this, molecular genetics) had reached such a point that it could be synthesized with Darwinian selection to make a fully integrated evolutionary theory, known variously as “neo-Darwinism” or the “synthetic theory of evolution.” Naturally enough, evolutionists were excited and vocal about their advances, and particularly contemptuous of all who did not follow them down to the last detail. At celebrations in 1959 in Chicago to celebrate the hundredth anniversary of the publication of *On the Origin of Species*, fundamentalist objectors to the new paradigm were objects of particular scorn. This set a general background of unease and determination by biblical literalists, adding to a causal mix that had already started to ferment a year or two earlier when a more specific yeast had been added. It was then that, thanks to Sputnik, the Russians so effectively demonstrated their superiority in rocketry (with its implications for the arms race of the cold war), and America realized how ineffective was the scientific training of its young. In response, the country poured money into the production of new science texts. In this way, with class adoption, the federal government could have a strong impact and yet get around the problem that education tends to be under the tight control of individual states. The new biology texts gave full scope to evolution—to Darwinism—and with this the creationism controversy again flared up.

Fortunately for the literalist, help was at hand. A biblical scholar, John C. Whitcomb Jr., and a hydraulic engineer, Henry M. Morris, together wrote what was to be the new Bible of the movement, *Genesis Flood: The Biblical Record and its Scientific Implications* (1961). Following in the tradition of earlier writers, especially those from Seventh Day Adventism, they argued that every bit of the biblical story of creation given in the early chapters of Genesis is supported fully by the best of modern science. Six days of twenty-four hours, organisms

arriving miraculously, humans last, and sometime thereafter a massive worldwide flood that wiped most organisms off the face of the earth—or rather, dumped their carcasses in the mud as the waters receded. At the same time, Whitcomb and Morris argued that the case for evolution fails dismally. The gaps in the fossil record show that there can have been no evolution; the nature of natural selection is such that it allows no genuine check and even if it did, it could not account for the complexity of life; the measures of earth time are dicey; and much, much more.

Genesis Flood enjoyed massive popularity among the faithful, and led to a thriving creation science movement, where Morris particularly and his coworkers and believers—notably Duane T. Gish, author of *Evolution: The Fossils Say No!*—pushed the literalist line. Particularly effective was their challenging of evolutionists to debate, where they would employ every rhetorical trick in the book, reducing the scientists to fury and impotence with their bold statements about the supposed nature of the universe. By the end of the 1970s, creationists were passing around draft bills, intended for state legislatures, that would allow—instruct on—the teaching of creationism in state-supported public schools. In the biology classes of such schools, that is. By this time it was realized that, thanks to Supreme Court rulings on the First Amendment to the Constitution (which prohibits the establishment of state religion), it was not possible to exclude the teaching of evolution from such schools. The trick was to get creationism—something that *prima facie* rides straight through the separation of church and state—into such schools. The idea of creation science is to do this—although the science parallels Genesis, as a matter of scientific fact, it stands alone as good science. Hence, these draft bills proposed what was called “balanced treatment.” If one was to teach the “evolution model,” then one had also to teach the “creation science model.” Sauce for the evolutionist goose is also sauce for the creationist gander. In 1981, these drafts found a taker in Arkansas, where such a bill was passed and signed into law—as it happens, by a legislature and governor that thought little of what they were doing until the consequences were drawn to their attention.

At once the American Civil Liberties Union sprang into action, bringing suit on grounds of the law’s unconstitutionality. The judge agreed, ruling firmly that creation science is not science, it is religion, and as such has no place in public classrooms. And that was an end to matters, reinforced by a similar decision (that did not go to trial but that was appealed all the way up to the Supreme Court) in Louisiana.

Phillip Johnson and Naturalism

Nevertheless, by the beginning of the 1990s, creationism had again reared its head. The spark was an antievolutionary tract, *Darwin on Trial* (1991), by a Berkeley law professor, Phillip Johnson. Although smoother in presentation, the work covered familiar ground: gaps in the record, the complexity of DNA, the origin of life, the randomness of mutation. The main difference in Johnson’s strategy was to turn the debate in the direction of philosophy. He argued that the creation-evolution debate was not just one of science versus religion or

good science versus bad science, but rather of conflicting philosophical positions—with the implication that one philosophy is much like another, or rather with the implication that one person’s philosophy is another person’s poison and that it is all a matter of personal opinion. Thus, if it is all a matter of philosophy, there is nothing in the U.S. Constitution that bars the teaching of creationism in schools.

Crucial to Johnson’s position are a number of fine distinctions. He distinguishes between what he calls “methodological naturalism” and “metaphysical naturalism,” and contrasts them with what he calls “Christian theism” or “theistic realism.” A methodological naturalist is one who assumes there is no god when he or she does science. All must be explained through unbroken law. A metaphysical naturalist is one who believes that there is no god. He or she is directly opposed to any kind of theist, who starts with the assumption that there is a god who was and is active in the creation. According to Johnson, although you might think that you can be a methodological naturalist, something which he links with evolutionism, without necessarily being a metaphysical naturalist, in real life the former always slides into the latter. Hence, the evolutionist is the methodological naturalist, is the metaphysical naturalist, is the opponent of the theistic naturalist, which for Johnson is the equivalent of denying God’s existence—that is, denying theistic realism. So ultimately, it is all less a matter of science and more a matter of attitude and philosophy. Evolution and creationism are different world pictures, and it is conceptually, socially, pedagogically, and with good luck in the future, legally wrong to treat them differently. More than this, Johnson’s argument suggests that creationism (a.k.a. theistic realism) is the only genuine form of Christianity.

Irreducible Complexity

One oft-made criticism of Johnson was that he was too negative. It was obvious that he was against evolution, but he left unsaid whether he was a young-earth creationist like Whitcomb and Morris or whether he believed in something more moderate, perhaps an old earth and some kind of guided, law-bound creation. Later in the decade, with Johnson’s encouragement, a number of younger thinkers produced an alternative to Darwinian evolution. This they called “intelligent design theory.” There are two parts to this approach, beginning with the empirical. Lehigh University biochemist Michael Behe identifies something that he calls “irreducible complexity.” This is “a single system composed of several well-matched, interacting parts that contribute to the basic function, wherein the removal of any one of the parts causes the system to effectively cease functioning.” Behe points out that there is no way that something like this could be produced by a slow, gradual evolutionary process, for all of the parts need to be in place in order to get any functioning.

But are there such systems in nature? Behe argues that there are, and he instances the micro-world of the cell and of mechanisms (or “mechanisms”) found at that level. Take bacteria, which use a flagellum, driven by a kind of rotary motor, to move around. Every part is incredibly complex, as are the various parts combined. The external filament of the flagellum (called a “flagellin”), for instance, is a single protein that makes

a kind of paddle surface contacting the liquid during swimming. Near the surface of the cell, just as necessary is a thickening agent, so that the filament can be connected to the rotor drive. This requires a connector, known as a “hook protein.” There is no motor in the filament, so that has to be somewhere else. “Experiments have demonstrated that it is located at the base of the flagellum, where electron microscopy shows several ring structures occur” (p. 70). All are much too complex to have come into being in a gradual fashion. Only a one-step process will do, and this one-step process must involve some sort of designing cause. Behe is careful not to identify this designer with the Christian God, but the implication is that it is a force from without the normal course of nature. Darwinism is ruled out and we must look for another explanation. There is only one possible answer. Irreducible complexity spells design.

The Explanatory Filter

Backing the empirical argument are the conceptual arguments of the philosopher-mathematician William Dembski, who introduced the notion of an “explanatory filter.” We have a particular phenomenon. The question is, what caused it? Is it something that might not have happened, given the laws of nature? Is it contingent? Or was it necessitated? The moon goes endlessly round the earth. We know that it does this because of Newton’s laws. End of discussion. No design here. However, now we have some rather strange new phenomenon, the causal origin of which is a puzzle. Suppose we have a mutation, where although we can quantify over large numbers we cannot predict at an individual level. There is no immediate subsumption beneath law, and therefore there is no reason to think that at this level it was necessary. Let us say, as supposedly happened in the extended royal family of Europe, there was a mutation to a gene responsible for hemophilia. Is it complex? Obviously not, for it leads to breakdown rather than otherwise. Hence it is appropriate to talk now of chance. There is no design. The hemophilia mutation was just an accident.

Suppose now that we do have complexity. A rather intricate mineral pattern in the rocks might qualify here. Suppose we have veins of precious metals set in other materials, the whole being intricate and varied—certainly not a pattern you could simply deduce from the laws of physics or chemistry or geology or whatever. Nor would one think of it as being a breakdown mess, as one might a malmutation. Is this now design? Almost certainly not, for there is no way that one might prespecify such a pattern. It is all a bit ad hoc, and not something that comes across as the result of conscious intention. And then finally there are phenomena that are complex and specified. One presumes that the microscopical biological apparatuses and processes discussed by Behe would qualify here. They are contingent, for they are irreducibly complex. They are design-like for they do what is needed for the organism in which they are to be found. That is to say they are of prespecified form. And so, having survived the explanatory filter, they are properly considered the product of real design.

Although his arguments are philosophical, Dembski and his supporters see his work as supportive of the empirical case made by Behe. Most particularly, it speaks to an obvious

theological problem that is raised by irreducible complexity. If indeed such a phenomenon exists and if one has to suppose a designer to explain its origins, then presumably this designer was also involved in the production of the reducibly simple. And this being so, why did he do such a bad job? We have some mutations, like sickle-cell anemia, that have horrendous physical effects causing massive pain, and yet are triggered by the smallest of changes at the molecular level. Surely the designer could have prevented these? Not so, according to Dembski. Malmutations are just chance, and hence no one’s fault, especially not that of the designer. Hence he gets credit for the good and is saved from blame for the bad.

Conclusion

Not surprisingly, many Christians (both Protestant and Catholic) as well as scientists object strongly both to traditional creationism and to the more recent intelligent design theory. Both Christians and scientists deny vehemently that being a methodological naturalist at once tips you into being a metaphysical naturalist. In addition, Christians assert, as they always have, that creationism in any form is a distortion of real traditional Christianity. There is absolutely no warrant for literalistic readings of Genesis, whether or not they are dressed up as science. In like fashion, scientists object that traditional creationism (the kind to be found in *Genesis Flood*) is simply wrong in every respect, and that intelligent design is little better. It simply is not true to say that there are examples of irreducible complexity that could never be explained through evolution. Even if all the parts are now necessary for proper functioning, it may well have been the case that the parts were assembled in ways that allowed for incomplete (or completely different) functioning before they reached their present interconnected forms.

Yet, whether or not creationism is good or bad religion, and whether or not creationism is good or bad science, it would be foolish to deny its ongoing appeal. In the early twenty-first century, opinion polls regularly found that 50 percent of Americans supported some form of creationism, and most of the others thought that blind law could never, unaided, have led to the production of the higher animals, especially humans. It would therefore be unwise to pretend that creationism is about to go away or will never raise its political head. It still has the potential to force us back to the 1920s and to attempt to legislate the contents of the science curricula of publicly funded schools.

CREATIVITY IN THE ARTS AND SCIENCES. Because creativity is a complex concept, it has multiple definitions. Of the various conceptions, however, three are currently most common. These are the product, person, and process definitions. According to the first, creativity is manifested in an identifiable outcome, such as a poem, painting, invention, or discovery. Moreover, this product must fulfill two essential conditions. First, it must be original or novel, at least with respect to an individual's discipline or culture. Simply repeating what has already been done does not count as bona fide creativity. Second, the product must be useful in some manner. For instance, a scientific discovery will have to satisfy certain theoretical or experimental standards, whereas an artistic creation will have to meet specific aesthetic criteria. This second condition is required to separate creative products from original but psychotic hallucinations and delusions.

The remaining two definitions are closely related to the product definition but shift perspective on the phenomenon. According to the person definition, creativity is whatever attributes individuals must possess to conceive creative products. These attributes may include both cognitive traits, such as intelligence, and personality traits, such as motivation. For the

process definition, in contrast, creativity is the process or set of processes by which a person conceives creative products. This definition obliges the investigator to focus on various problem-solving operations, such as insight, intuition, incubation, and even trial and error.

The choice of definition clearly determines how a researcher or scholar studies creativity. Where some assess the attributes of creative products, others examine the characteristics of creative persons, and still others scrutinize the features of the creative process. Nevertheless, despite the diversity of analytical perspectives, it is assumed that all three approaches are looking at the same underlying phenomenon.

Creativity can be manifested in a great variety of situations, from the play activities of young children to industrial research and development teams. However, discussion here will be confined to creativity in the arts and sciences. The discussion begins with historical conceptions of creativity and ends with an overview of contemporary research on the phenomenon.

Historical Conceptions

As a concept, creativity is most strongly associated with European civilization. This is not because other civilizations have not displayed creativity. On the contrary, there is no doubt that other world civilizations—such as the Chinese, Indian, and Islamic—have produced creative geniuses of the highest order. The difference stems largely from how creativity is conceived in various cultures. The basis for the difference is to be found in the very definition of the phenomenon. Although an idea is not creative unless it is both original and useful, the exact proportions of originality and usefulness are not fixed.

At the same time, world civilizations vary greatly in the relative importance they place on individualism versus collectivism. Therefore, more individualistic cultures assign more weight to originality because that feature provides a means to demonstrate personal uniqueness. In contrast, more collectivist cultures tend to stress usefulness. To be “useful” in that case means that an original idea must be compatible with societal values and cultural traditions. If not, then those ideas cannot work insofar as they would prove divisive rather than consensual.

This cultural contrast can be illustrated by looking at philosophical creativity. On the originality-individualistic side is René Descartes (1596–1650), who launches his inquiry by doubting everything he has ever learned and experienced, eventually arriving at a highly egocentric, even autistic first principle—I think, therefore I am (*cogito, ergo sum*)—on which he could base his entire philosophy. On the usefulness-collectivist side is Shankara (c. 700–c. 750), the Indian thinker who communicated his highly influential Vedanta philosophy by writing commentaries on the principal Upanishads and other ancient scriptures. Although great philosophers in other intellectual traditions frequently use the same *modus operandi*, this tactic is extremely rare in European civilization. Even in the Middle Ages, when Greco-Roman individualism had to yield some ground to the more collectivist values of Christianity, intellectual innovations were seldom embedded in commentaries on traditional texts. For example, Thomas Aquinas's (1225–1274)

Sixteenth-century painting by Qiu Ying depicting Li Bo receiving visitors. Although the concept of genius being linked to madness or unconventional behavior was more prevalent in European societies, one exception was the Chinese poet Li Bo, a reputed drunkard and carefree wanderer. THE ART ARCHIVE / PRIVATE COLLECTION PARIS / DAGLI ORTI

Summa Theologica (1266–1273) synthesized classical philosophy and Christian theology not through commentaries on Aristotle and Augustine but rather by means of a stand-alone treatise. Admittedly, like all generalizations about whole civilizations, many exceptions exist. For instance, the place of poetic creativity in China is not unlike that in Europe.

In any case, although historical conceptions of creativity are quite diverse, three views have been especially prominent: divinity, madness, and craft.

Divinity. In antiquity, creativity was a divine attribute, a capacity narrated in the creation myths that are almost universal in human cultures. Examples include the Creator of the Judeo-Christian-Islamic tradition, Odin of Norse mythology, Ormazd of Zoroastrianism, and Brahma of the Hindu trinity. Even when creativity was attributed to individual human beings, the ultimate source often remained spiritual. This connection is illustrated in the ancient Greek belief in the Muses. According to the myth, Zeus, the reigning god in the pan-

theon, fathered nine daughters with Mnemosyne, the goddess of memory. Each of these nine daughters presided over a different domain of human creativity. In particular, these muses were responsible for epic poetry, lyric poetry, sacred poetry and hymns, tragedy, comedy, music, dance, astronomy, and history. Each muse was thought to provide a guiding spirit or source of inspiration for the mortal creator. This usage underlies several common expressions, such as to say that one has lost one's muse when one has run out of creative ideas. Given this view, human creativity remained subordinate to divine creativity.

The religious or spiritual roots of creativity are also evident in the concept of genius, an idea that would later become intimately identified with creativity. According to Roman mythology, each individual was born with a guardian spirit who watched out for the person's distinctive fate and individuality. With time, the term was taken to indicate the person's special talents or aptitudes. Although in the beginning everybody could be said to "have a genius," at least in the sense of pos-

CORE CONTROVERSIES CONCERNING CREATIVITY

Despite the abundance of scientific research on the subject of creativity, several central issues continue to escape successful resolution. Of these, the following three are probably most critical:

1. **Nature versus Nurture**—Is creative genius born or made? Or, to phrase the question in less dichotomous terms, what are the relative contributions of genetic endowment and environmental influences, such as family background, education, and training? One special manifestation of this question regards how gender, race, and ethnicity determine individual creativity.
2. **Madness versus Mental Health**—How much truth is there to the traditional concept of the “mad genius”? Although both psychiatrists and psychologists continue to find provocative connections between creativity and psychopathology, it is also clear that the two phenomena are far from equivalent. Furthermore, humanistic psychologists argue

that creativity can actually be considered a sign of supreme mental health.

3. **Individual versus Society**—To what extent is creativity embodied in the individual and to what extent is creativity a representation of larger sociocultural phenomena? This is often expressed as the debate between genius and zeitgeist theories of creativity. Because psychologists, psychoanalysts, and psychiatrists favor the individual as the unit of analysis, they tend to support some form of the genius theory. In contrast, anthropologists, sociologists, and Marxist philosophers, who prefer cultures and societies as analytical units, are more prone to advocate some version of the zeitgeist theory.

Probably any resolution will be inclusive rather than exclusive. That is, creativity will eventually emerge as a function of nature and nurture, madness and mental health, the individual and society.

sessing a unique potential, the term eventually began to be confined to those whose gifts set them well apart from the average, such as the creative genius. Outstanding creativity then became the gift of the gods or spirits, not a human act. Even during the Italian Renaissance rudiments of this ascription persisted. For instance, when Giorgio Vasari (1511–1574) wrote his biography of the “divine Michelangelo,” he explicitly asserted that “the great Ruler of Heaven” sent the artist to earth to serve as an exemplar of artistic genius.

Madness. As European civilization became increasingly secularized, especially after the Enlightenment, creativity’s spiritual connotations gave way to more naturalistic conceptions. One prominent viewpoint was that creativity, and especially creative genius, was closely linked to madness. This linkage became especially popular during Europe’s Romantic period, attaining a peak in the first half of the nineteenth century. It was also during this period that creative genius began to become associated with alcoholism, drug addiction, and other pathological conditions. In the Preface to “Kubla Khan,” for example, Samuel Taylor Coleridge (1772–1834) claimed to have conceived this poetic masterpiece in an opium stupor.

Eventually the mad-genius conception of creativity received scientific endorsement from psychologists, psychiatrists, and psychoanalysts. For instance, Cesare Lombroso (1836–1909) attributed exceptional creativity to a genetically based “degenerative psychosis.” The only conspicuous disagreements concerned

the specific nature of the mental disorder. Unlike Lombroso, Sigmund Freud (1856–1939) saw creativity as a variety of neurotic behavior, whereas William James (1842–1910) viewed creativity as a form of “borderline” personality. Related to this issue was a debate about the extent to which creative genius bears any relation to criminality. Some psychiatrists argued that genius, madness, and criminality were all consequences of the same underlying genetic disorder.

The mad-genius view of creativity is less common in non-European civilizations, but it still appears. An example is the Chinese poet Li Bo (701–762). Popularly known as a “banished Immortal,” he was notorious for his undisciplined wanderings and incessant drunkenness. Legend even had him drowning after trying to capture the reflection of the moon while spending an evening intoxicated in a boat.

Craft. In most cultures and civilizations throughout the world, creativity was often inseparable from craft traditions. Rather than artists, there were artisans. The knowledge and skills necessary to make culturally valued objects were passed down from generation to generation through parent-child or master-apprentice relationships. Even in European civilization, the linkage between creativity and crafts persisted in many domains for many centuries. It is telling that not all forms of creativity in ancient Greece had their muses. Evidently, creativity in certain areas required no divine intervention but merely the acquisition of the necessary expertise. Even much later, painters, sculptors, and architects

would hold the status of artisans rather than artists. This position held for painters until the time of Giotto (1276–1337). And musical creativity in Europe did not completely emancipate itself from the craft image until the time of Ludwig van Beethoven (1770–1827).

Although creativity came to be separated from craft, many still considered the phenomenon as the outcome of the acquisition of some special expertise. Creativity remained a skill that anyone could acquire if they first mastered the requisite knowledge and skills. The painter Joshua Reynolds (1723–1792) expressed this view in his *Discourses on Art*, which were based on his lectures at the Royal Academy of Art. Unsympathetic to notions that artistic creativity required any special talent or genius, he argued that creativity in the arts demanded only that the student be willing to study and practice. Those who have done so sufficiently, according to Reynolds, would be indistinguishable from the so-called natural genius.

Conceptions of scientific creativity included a variation on this position. Science was defined by a special method—the logic of inference or investigation—by which scientists arrive at their discoveries and inventions. This position was first explicitly stated in Francis Bacon’s (1561–1626) *Novum Organum*, which presented his inductive method. A little later Descartes advocated his own method based on deductive reasoning. Eventually, creativity in science became the chief concern of a whole new discipline, the philosophy of science. Notwithstanding the disparate opinions of various philosophers of science, most agreed that scientific creativity consisted of a well-defined method. Like any craft, this method, once mastered, enabled the individual to become a creative scientist. Indeed, some thinkers, such as José Ortega y Gasset (1883–1955), insisted that scientific creativity required no outstanding abilities.

Contemporary Research

In the early part of the twentieth century, distinguished researchers from many different disciplines investigated artistic and scientific creativity. For example, the topic attracted the attention of the anthropologist Alfred Kroeber and the sociologist Pitirim A. Sorokin. However, as the century progressed, the research was increasingly confined to just three fields: psychiatry, psychoanalysis, and psychology. The psychiatrists were primarily interested in the association between creativity and psychopathology, whereas the psychoanalysts were mostly dedicated to psychobiographical studies of eminent creators. Only the psychologists approached the phenomenon from a tremendous diversity of theoretical and methodological perspectives. Perhaps as a result of this breadth, by the end of the twentieth century psychologists came to dominate the study of creativity. Notwithstanding the diversity of approaches, the bulk of the psychological research falls into the following four categories:

1. Cognitive psychology—Cognitive psychologists are interested in the mental processes involved in the creative process. For instance, Howard Gruber has studied Charles Darwin’s notebooks to detect the cognitive processes that he used in arriving at the theory of evolution, and Kevin Dunbar has studied the mental operations in sci-

entific laboratories by analyzing recordings of research meetings. Using more experimental techniques, Albert Rothenberg has examined special forms of thinking in artistic creativity, while Tom Ward and his colleagues have studied the cognitive processes involved in invention.

2. Differential psychology—Psychologists from this subdiscipline seek to identify how people vary on various intellectual and personality traits. For example, Robert J. Sternberg has examined the impact of cognitive styles and John Baer has investigated the role of divergent thinking. Gregory Feist has synthesized the accumulated research to indicate how scientific and artistic creators differ on a large number of personality traits.
3. Developmental psychology—Developmental psychologists are interested in two major phases of creative development. The first phase concerns the acquisition of creative potential. Examples include Mark Runco’s work on the growth of creativity in children and Mihaly Csikszentmihályi’s studies of talent development in teenagers and young adults. The second phase concerns the manifestation of that creative potential in adulthood. An instance is Ravenna Helson’s longitudinal investigation designed to determine why some talented women succeed in realizing their potential and others do not.
4. Social psychology—Social psychologists are dedicated to understanding how creativity is influenced by social context, including interpersonal relationships, group dynamics, and sociocultural systems. For example, Teresa Amabile has studied how certain social expectations can either enhance or inhibit creativity, while Paul Paulus has investigated group problem-solving behaviors (“group-think”). At a more aggregate level of analysis, Colin Martindale has examined the impact of aesthetic traditions on artistic creativity and Dean Keith Simonton has scrutinized ways in which the social, political, and cultural environment shapes creativity in both the arts and sciences.

Even though more researchers than ever before are studying creativity, inquiries still have a long way to go before the phenomenon is completely understood. In particular, some core controversies have yet to be resolved. The field is also in dire need of a theoretical system that will successfully integrate the diverse empirical findings. Although several explanatory accounts have been proposed—including computational, economic, and Darwinian models—no theory has earned sufficient assent to dominate the field.

CREOLIZATION, CARIBBEAN. The concept of creolization lies at the very center of discussions of transculturalism, transnationalism, multiculturalism, diversity, and hybridization. This essay begins by examining the term's roots in the ethnic and cultural complexities of the Caribbean experience. It then goes on to look at the transformation of this experience into a theoretical framework for pluralism that consciously sought to avoid the binary pitfalls of its antecedents. It concludes with a brief look at the work of several key authors and surveys recent critiques of the Caribbean creolization movement.

Despite its currency in literary, cultural, and critical circles, the term *creolization* cannot be fully understood without taking into account its historical background and geographical context. In these terms, creolization must be seen not simply as a synonym for hybridity but as a phenomenon that is indispensable to understanding the New World experience. Although the history of the term dates back several decades earlier, its critical status in the early 2000s is largely the result of a number of publications emanating from the French Caribbean in the 1980s.

Caribbean Context

The origins of creolization for the Caribbean region arguably lie in the contested and interrelated processes of colonization, slavery, and migration that both brought the New World into being and gave it impetus and direction. Once the indigenous New World populations were decimated, the growth and development of plantation economies that arose in the

Caribbean in the seventeenth century produced pathbreaking patterns of economic and cultural exchange between Europe, the New World of the Americas—including Central America, the Guianas, Mexico, and Brazil—and the African continent. Catalyzed by the slave trade, which forcibly removed untold numbers of peoples of diverse racial, cultural, and geographical origin from their African homelands and transplanted them onto vast island plantations, these already variegated groups subsequently came into contact with other transplanted peoples from Europe, South Asia, China, and the Middle East. As a result, the Caribbean region quickly became a key nodal point in what would become the creolization of these composite populations.

It was the product of these intersecting influences—the inauguration of a creole society in the Caribbean Sea—that became the subject of the text *Eloge de la créolité/In Praise of Creoleness* (1989). Written by Raphaël Confiant and Patrick Chamoiseau, two Martinican novelists, in conjunction with Jean Bernabé, a Guadeloupean linguist, this manifesto can be seen in one sense as an attempt to come to terms with the paradox of French overseas departmentalization. The fact of these former colonies' incorporation into the French nation in 1946, and the conferral of French citizenship on their citizens, had done nothing to negate the ongoing material differences in history, geography, culture, and ethnicity that continued to separate these territories from the metropole, creating a double trajectory that made their citizens feel both French and West Indian. The “double consciousness” imposed by the duality of their legal and cultural status encouraged these thinkers to come to terms with the dilemma of belonging posed by departmentalization. Their solution was to seek out the origins of this pluralism, and to celebrate it.

Importantly, however, they were certainly not the first to do so. Some twenty years earlier, the Barbadian historian and poet Edward Brathwaite sought to establish patterns of creole interaction as a sort of sociological foundation for Caribbean societies. In his *The Development of Creole Society in Jamaica, 1770–1820* (1971), Brathwaite proposed that the principles of cultural distinction and unitary origin through which societies were typically analyzed and categorized be abandoned in the Caribbean case, recognizing instead the intrinsic ethnic and cultural pluralism of the islands. The cultural intersection, ethnic admixture, and linguistic cross-fertilization that lay at the core of the Caribbean experience would be made to contest the historical discontinuity and geographical and political fragmentation through which the region traditionally had been framed.

From Experience to Theory

On the surface, creolization would appear to be of a piece with *criollo* and *mestizaje* in Spanish, and with *métissage* in French. However, although each of these categories responds to the implicit pluralisms of the colonial encounter, each also reflects specific differences within the colonial experience that are not easily rendered in general terms. What the authors of the *Eloge* sought to convey above all was the abandonment of negative binaries in favor of the creative openness that lies behind any conception of the creole. “Neither Europeans, nor Africans,

PATRICK CHAMOISEAU

Patrick Chamoiseau was born in 1953 in Fort-de-France, Martinique. The son of working-class parents, Chamoiseau studied sociology and law in Paris before moving back to Martinique, where he became a social worker. His third novel, *Texaco*, won France's top literary award, the Prix Goncourt, in 1992, making him world-famous. The novel was eventually translated into more than twenty languages. Chamoiseau continues to live in Martinique, where he writes novels as well as short stories, screenplays, autobiography, childhood memoirs, and texts for pictorial histories.

Despite the publication of other novels such as *Solibo le magnifique* and *Biblique des derniers gestes*, *Texaco* remains by far Chamoiseau's best-known work. The novel traces 150 years of postemancipation Martinican history through the eyes and voice of Marie-Sophie Laborieux, the aging daughter of a freed slave. It is Laborieux's encounter with an urban planner, and her attempt to convince him to abandon his plan to raze, in the name of progress, the shantytown of the title that provides the framework for this episodic story of struggle and resistance. This structure, and its trademark of creole existing alongside and transforming the French language, allows the key nuances of ethnic and cultural exchange and linguistic wordplay to assume pride of place in a portrait of Martinique's creolized society.

nor Asians, we proclaim ourselves Creoles" (Bernabé et al., p. 75). Indeed, their aim more specifically was to develop modalities for creative expression in the arts that would reflect and embody the multiplicity and complexity of the creole mosaic. "Our history is a braid of histories . . . We are at once Europe, Africa, and enriched by Asian contributions, we are also Levantine, Indians, as well as pre-Columbian Americans in some respects. Creoleness is 'the world diffracted but recomposed' . . . a Totality" (p. 88; emphasis original).

Thus the creole language serves as a fundamental metaphor for the key goals and tenets of French Caribbean creolization. As Chamoiseau and Confiant point out in their critical work *Lettres créoles*, this language was the product of the experience of colonization and slavery. Born and nurtured on the plantation, it was brought into being both by the interaction of slaves deliberately separated by ethnic group to forestall the possibility of communication that might lead to resistance and revolt, through the influence of Maroons (runaway slaves) and by the interaction of these groups with the colonial culture. The creole language thus symbolizes cultural continuity, resistance to oppression, and the richness of ethnic admixture; as such, it serves to valorize the region's oral tradition even as it reinforces the qualities of pluralism and transformation that sum up the heterogeneity of the French Caribbean experience in particular.

Antecedents

The arc of this experience explicitly acknowledges the antecedent influence of two other key Martinican writers and thinkers, Aimé

Césaire and Edouard Glissant, and the literary movements with which their names are respectively linked: negritude and *antillanité*, or Caribbeaness. The *créolistes*, as the authors of the *Eloge* are called, address the importance of negritude to their thought formation: "To a totally racist world . . . Aimé Césaire restored mother Africa . . . Césaire's Negritude gave Creole society its African dimension" (Bernabé et al., p. 79). Indeed, they make specific reference to the irreplaceable role played here by Césaire himself. "It was Césaire's Negritude that opened to us the path for the actuality of . . . Caribbeaness . . . We are forever Césaire's sons" (p. 80).

At the same time, however, it must be recognized that the *créolistes* simultaneously acknowledge the limitations of the African model of cultural origin for the complex realities of the Caribbean basin. The basic paradox intrinsic to such an approach lay in the fact that adopting the negritude paradigm would simply amount to exchanging one unitary model of culture for another. Neither the European nor the African paradigm could contain the myriad ethnic influences and creative cultural exchange that had given rise to the Caribbean. To adequately account for the region's plural character, another model was necessary. For this, they would turn to the work of Edouard Glissant.

An accomplished novelist and poet as well as an important cultural theorist, Edouard Glissant had produced more than half a dozen creative works by the time he published his groundbreaking *Caribbean Discourse* in 1981. In this work, he

EDOUARD GLISSANT

Edouard Glissant was born in 1928 in the commune of Sainte-Marie in Martinique. A poet, novelist, dramatist, and essayist, Glissant studied philosophy at the Sorbonne and ethnology at the Musée de l'homme. In the 1950s he co-founded the *Front Antillo-Guyanais pour l'indépendance*, and went on to found the Institut martiniquais d'études in 1970. In 1982, he went to work as editor of the UNESCO *Courier*, was named Distinguished University Professor at Louisiana State University in 1988, and left there for a position at the City University of New York's Graduate Center in the mid-1990s. He began publishing in the mid-1950s, and his novels, plays, essays, and volumes of poetry have won many outstanding prizes. Perhaps the premier contemporary French West Indian cultural theorist, his influential concepts of *antillanité* (Caribbeanness) and *poétique de la relation* (cross-cultural poetics) promulgated in *Le Discours antillais* (Caribbean Discourse) seek to creatively anchor the Caribbean experience of fragmentation and disjuncture in a framework that gives voice to its central tenets of diversity and hybridity. The interpenetration of languages and cultures that lies at the core of this process of creolization posits contact and chaos, cultural relativity, and exchange and transformation as key tools in a polyvalent system of thought that redefines traditional notions of identity.

also sought to take his vision of Caribbean reality beyond the epistemological boundaries of negritude. Realizing that a response that simply negated the tenets of a colonial discourse did nothing to expunge its essential properties, Glissant sought to specify the terms and conditions of a creole culture that would be inclusive of the wider English, Spanish, and Dutch Caribbean as well as the French overseas departments of Guadeloupe and Martinique, one that would give rein to the region's constant creative flux and its insistent patterns of transformation and exchange. The core of this Caribbean vision, the one on which the *créolistes* would draw, he termed *antillanité*, or Caribbeanness.

Glissant locates the key axes of this concept between uprooting and transformation. Within these patterns of intersection and exchange, he demarcates the terms of Caribbean survival. "I feel that what makes this difference between a people that survives elsewhere . . . and a population that is transformed elsewhere *into another people* . . . and that thus enters the constantly shifting and variable process of creolization . . . is that the latter has not . . . collectively continued the methods of existence and survival, both material and spiritual, which it practiced before being uprooted" (Glissant, p. 15; emphasis original). This generative framework stresses principles of mixture and combination rather than confrontation and rupture; the infinite openness and fluidity of its practice expresses the diversity of the Caribbean collective identity in a way that allowed the architects of *créolité* scope to articulate structurally similar concerns. The productive multiplicity of the Caribbean, one that draws on its peoples and cultures to

continually transform and reinvent themselves, is thus a core principle of both *antillanité* and *créolité*.

Critiques

While the Caribbean focus of these twin discourses was seen as a much-needed corrective to metropolitan visions of the Caribbean as a region mired in fragmentation and loss, an alternative view took a much more critical line, accusing the *créolistes* of having appropriated the issue of creolization and of imbuing it with restrictive, essentialist characteristics that valorized exclusivity over process. From this viewpoint, despite the specific historic context and catalyst of migration, colonialism, slavery, and indentured labor, the concept of creolization was applicable to many cultures and civilizations beyond the Caribbean basin.

By contrast, the creolization of Glissant's *antillanité* sought to subvert universalist notions of pure and impure, positing the world as subject to ceaseless cultural transformation, a joining of braiding and becoming: "Creolization as an idea is not primarily the glorification of the composite nature of a people: indeed, no people has been spared the crosscultural process. . . . To assert peoples are creolized, that creolization has value, is to deconstruct in this way the category of 'creolized' that is considered as halfway between two 'pure' extremes" (Glissant, p. 140).

In their turn, Bernabé, Chamoiseau, and Confiant managed to expand and buttress their own positions in a key interview published some years after their manifesto. Here, they stress the

pluralities of creoleness: “our position is that there are several *créolités*” (Taylor, p. 142); valorize the role of pluralism: “*créolité* is all about understanding mosaic, multiple identities” (p. 153); and suggest that creolization is a process that encompasses more than a simple synthesis, more than *métissage*: “There’s *métissage* in creolization, but creolization is chaos—shock, mixture, combination, alchemy” (p. 136). In these terms, creolization establishes its specific difference from hybridity, reflecting its beginnings in colonialism and slavery as well as the ceaseless redefinition and rebirth that are its primary constituent elements.

CRISIS. The term *crisis* comes from the Greek noun *kri-sis* (choice, decision, judgment), deriving from the Greek verb *krinein* (to decide). The word makes an ancient debut in Greek historical writing via the legal, medical, and rhetorical terminology as the turning point in a decision, illness, or argument.

Its definitive reappearance with reference to historical events, periods, or processes dates from the late eighteenth century, its classic formulation from the second half of the nineteenth century, and its proliferation as a catchall term for a crucial or decisive stage or state of affairs from the last half of the twentieth century. The history of the notion of crisis veers between failed attempts at precise definition and its inflation and devaluation as a tool of analysis.

Focus and flexibility inhere in the concept of crisis and account for much of its appeal. Crises, to be regarded as such, must occur in the course of specific events, but they can be characterized in organic, mechanistic, or revolutionary terms as critical episodes in a life cycle, indices of structural dysfunction, or corollaries of revolution. In the ideological reckoning with the great upheavals of modern history since the revolutions of the late eighteenth century, historical crises have often been cast as liberating by the Left and as proof of human fallibility by the Right. The language of crisis can be charged with drama, plotted as narrative, objectified as analysis, and pinned to empirical data.

Modern Concepts of Crisis

Karl Marx and Jacob Burckhardt brought out alternative emphases in their benchmark reflections on crisis. Marx (*Das Kapital*) developed a theory of economic crisis centered on the economics of overproduction, specifically on the chronic disequilibrium between production and consumption under capitalism; each crisis, he believed, would be more severe than the last until a “general crisis” occurred wherein the working class would rise against their exploiters. Burckhardt took politics and culture as a starting point for his pronouncements on crisis in one of his lectures on world history, first delivered in the 1860s. Historical crises typically begin with a “negative, accusing aspect,” then peak in utopian visions before giving way to reactions and restorations; the permanent results are “astonishingly meagre in comparison with the great efforts and passions which rise to the surface during the crisis.” The typology, based on the French Revolution and the European revolutions of 1848, is clear enough, but it dissolves in a rush of historical examples underwritten by the patrician conservative’s anxieties over modernization and not a little *Schadenfreude* in praise of crisis (Burckhardt, pp. 289–290).

More specialized—if less demanding—usage was widespread by the later nineteenth century and is still current, for example in political or diplomatic crisis, financial or commercial crisis, or *crise de conscience*. However, until as late as 1960, the fields of economics and economic history produced the only relatively systematic theories of crisis. Marx’s views were developed, debated, and projected back in time for a crisis of European feudalism variously dated between the fourteenth and the seventeenth centuries. Non-Marxist versions concentrated on cyclical fluctuations in price data or on the “checks” of famine, disease, and war to surplus population in Malthusian demographic cycles of preindustrial society. The thesis of a general crisis of the seventeenth century (as the transition from feudalism to capitalism) was advanced in 1954 by the British Marxist historian Eric Hobsbawm (Aston, pp. 5–58) and became a debating point in a long-running controversy

over the timing and extra-economic dimensions of what was alleged to be the formative crisis of the modern world.

By the 1960s, crisis had become a broad and expanding catchword—an alternative to the more potent idea of revolution—for practically any challenge-and-response situation or scenario. The tumultuous events of midcentury, from World War II, the collapse of colonial empires, and the Cold War to the traumas of the 1960s, were cast as symptomatic of the crisis not only of Western civilization but of established orders everywhere.

Field-specific crisis literature depended on the discourse or discipline but shared a preoccupation with breakdown or breakthrough in an established system of behavior or belief. A neoorthodox Protestant theology of crisis, a psychology of identity crisis following Erik Erikson (1902–1994), and an epistemology of crisis in “paradigm shifts” during scientific revolutions as analyzed by Thomas Kuhn (1922–1996), had their own extensive literatures. The crises of the Italian Renaissance, the Protestant Reformation, and the seventeenth-century English aristocracy were major topics for historians of early modern Europe, and a U.S. textbook series on major crises in history, including the crisis of August 1914 and the Great Depression of 1929, appeared in 1962. The Cuban missile crisis of that year became the exemplary real-world case of international diplomatic crisis at a time when crisis management, based on game theory, had become a political science specialty recognized by U.S. government research contracts.

Contemporary Definition and Usage

Two comprehensive entries on crisis in the *International Encyclopedia of the Social Sciences* (1968) and the first *Dictionary of the History of Ideas* (1968) cited, respectively, “unrestricted usage” and continuing “uncertainty.” Any number of studies had accumulated on crises of moments, decades, even eras; on political, social, economic, mental, and moral crises; on minor, major, and mid-level crises. The most exacting definitions were abstract and redundant, as in the decision-planners’ twelve “generic dimensions” of crisis (*International Encyclopedia of the Social Sciences*, v. 2, s.v. “crisis”). While suggestive connections were being made across fields, they came at the expense of clarity and coherence and sometimes recycled arguments that had already been discounted by experts in their own disciplines. Both articles placed hope in more precise future work.

In fact, the widespread interest in and development of crisis studies had already peaked by the early 1970s. Toward the end of the twentieth century, the language of crisis was worn out by overuse even as it was being eclipsed by the triumphalism of post-Cold War ideologies that prophesied, however credulously, the end of history and the containment of the upheavals and confrontations that had fueled it. The big crisis debates among historians mostly receded before the emphasis on long-term structural trends, the dismantling of so-called grand narratives, the deconstruction of the rhetoric of history, and the unfazed appreciation that conflict and confrontation were not the exception but the rule in history. The most concerted theoretical attention to crisis came from political scientists who continued to model schematic strategies for “crisis management,” especially in international affairs.

They salvaged analytical precision only by abstract model building and academic distinctions such as a sequence of phases of international crises from onset and escalation to de-escalation and impact.

The most conspicuous use of crisis terminology in the early twenty-first century is activist and political. Social movements, nongovernmental organizations, and government institutions, including the United Nations, have appropriated the term on occasion as a watchword to promote intervention in “crises” of genocide, women’s rights, HIV-AIDS, environmental degradation, or economic globalization. A “crisis of liberal values” has become a target of both radical supporters of multi-cultural politics and self-styled traditionalists who feel called upon to defend their ideals of family, patriotism, and religion. These developments, together with the leveling effects of everyday usage, have furthered the depletion of the term as an all-purpose slogan or a banal cliché.

CRITICAL RACE THEORY. One of a family of related progressive movements in the law—others include critical legal studies, Latino critical legal studies (“Lat/Crit”), and feminist legal theory—critical race theory sprang up in the late

1970s in response to a widespread perception that the powerful civil rights coalition of the 1960s and early 1970s had stalled. Conservative administrations and an American public that seemed increasingly weary of hearing about race required new strategies and theories to deal with subtle, institutional, or color-blind forms of racism and a judiciary that no longer seemed eager to champion civil rights.

Derrick Bell, an African-American professor of law at Harvard Law School (later at New York University) and Alan Freeman, a white scholar teaching at SUNY-Buffalo Law School, laid the foundations of the movement that came to be called critical race theory and that would go on to transform our understanding of the relationship among race, racism, and official power. For his part, Bell contributed groundbreaking analyses of conflict of interest in civil rights litigation and of the role of white elite self-interest in explaining the twists and turns of blacks' racial fortunes. In an impressive article in *Yale Law Journal*, Bell pointed out that lawyers for elite civil rights organizations like the NAACP (National Association for the Advancement of Colored People), where he himself worked before entering law teaching, often were eager to pursue one agenda—law reform and innovation—while the client community wanted something else—say, better schools. The NAACP Legal Defense Fund, for example, relentlessly and courageously pursued school desegregation, while black parents often wanted something different—better funding for black schools.

If the first essay produced consternation and soul-searching among his colleagues in the civil rights movement, a second piece, on the role of interest convergence in determining the course of racial reform and retrenchment, raised eyebrows even higher. In “*Brown v. Board of Education* and the Interest Convergence Dilemma,” Bell posited that the breathtaking advances of the early civil rights years came about not so much because of moral breakthroughs by the American public or liberal judges. Rather, they were needed in order to burnish America's tarnished image in the eyes of the rest of the world and also to avert the possibility of racial unrest at home. At the time, the United States had just concluded a world war of mammoth proportions and was in the early stages of a Cold War against the forces of godless, soulless communism. In this campaign for the loyalties of the uncommitted Third World (much of which was black, brown, or Asian), it ill served this nation for the world to see front page stories and photographs of lynchings, the Emmett Till murder, and southern sheriffs turning vicious police dogs loose on peaceful civil rights leaders such as Martin Luther King Jr.

At the same time, wartime service in the U.S. military had exposed black and brown servicemen and -women to environments comparatively free of racism, in which diligent service brought rewards, promotions, and even battlefield commissions. These black and brown soldiers, having fought and exposed their lives in defense of American democracy and freedom, were unlikely to return to the former regime of menial jobs and servile relations with white society. Unrest loomed.

This convergence of black and white self-interest—rather than altruism or advancing morality—brought about *Brown v.*

Board of Education (1954), the 1964 Civil Rights Act, and other reforms of that era. And when black advances no longer served the interests of elite whites, they were quietly withdrawn or limited by narrow judicial interpretation, administrative foot-dragging, or delay. Although his skeptical hypothesis was met at first with cries of outrage, Bell subsequently applied his interest-convergence hypothesis to explain the full sweep of black civil rights history, showing how the material interests of elite whites explain practically every major advance or retreat. And Mary Dudziak, a white professor teaching at the University of Southern California Law Center, verified Bell's hypothesis by examining a host of documents, memos, and archival material related to *Brown v. Board of Education*.

Around the same time Bell was writing, Alan Freeman was carrying out an extraordinary reinterpretation of the role of the U.S. Supreme Court in guiding the course of civil rights progress. Freeman showed how our usual interpretation of the role of the liberal Warren court was both right and wrong. The Court did indeed champion civil rights causes. But in doing so, it also served as a powerful legitimating tool by confining change to manageable dimensions and denying relief for any but the most clear-cut violation.

An Organization Forms

Others (including Richard Delgado, one of the authors of this essay) soon joined Bell and Freeman, and in the summer of 1989 about thirty law scholars of color from around the United States met at a convent outside Madison, Wisconsin, to forge a new movement in the law. Settling on a name (critical race theory) and a general program, the group resolved to coordinate their scholarship and hold future meetings aimed at developing a new, radical approach to race, racism, and American law. Since then, the group has held a series of public conferences and periodic smaller workshops aimed at the development of particular themes. The group's scholarship grew rapidly to include a few dozen books and hundreds of law-review articles and essays. Many law schools around the country include critical race theorists among their ranks; perhaps two-thirds of all law schools offer one or more courses on it or a related subject.

The movement's ideas also spread to other fields. Educators use its approaches and theories to help understand hierarchy in schools, tracking, school discipline, and battles over the Western canon. Political scientists are intrigued by its studies of the role of courts in law reform; sociologists, by its analyses of racial power and authority; American Studies scholars and rhetoricians, by its use of storytelling, counterstorytelling, and revisionist history. What are some of the movement's dominant ideas? Critical race theory is a very loose collection of scholars, not all of whom would agree on this or any other platform or set of defining tenets. But most “race-crits” would acknowledge some of the following as the movement's defining themes:

Interest convergence and material determinism. Just as the movement began with Derrick Bell's impressive analysis of the role of white institutional self-interest and its relation to racial reform, critical race theorists have continued to explore

this dimension of American society. Scholars such as Lani Guinier examine how voting behavior and laws affect the quality of the representation that the minority community receives in national and state legislatures. Guinier and others study the idea of merit, standardized testing, and occupational qualifications in order to see how seemingly neutral measuring instruments and criteria incorporate bias. Writers such as Spencer Overton examine the role of property, wealth, and ownership in inhibiting black advances. A host of scholars examines affirmative action and job-hiring patterns in higher education.

Racism as ordinary and normal. Most Americans believe that their society is fair and just, and the legal system frames antidiscrimination law and doctrine with this presupposition in mind. Most critical race theorists believe the opposite is true, however; racism for them is ordinary, normal, and deeply embedded in everyday life and institutions. From songs, rhymes, and nursery stories such as Snow White, to movie roles and stereotypes, job and school criteria, and old-boy informal networks, favoritism for white, European ways exerts a subtle, ever-present force. If racism and race-themed ideas and preferences are everywhere, this makes them invisible and difficult to confront. They seem ordinary and natural; the person seeking to challenge them strikes others as impossible, nitpicky, or lacking in a sense of proportion. Litigants suing for discrimination confront the same obstacle. Unless what the defendant did was outrageous, intentional, and outside the pale, courts are unlikely to award relief.

Critique of color blindness. Currently, one of society's—and the legal system's—dominant approaches to race is color blindness. This perspective insists that race does not matter. The law should not take account of race either for the purpose of helping or handicapping any group. By the same token, advocates of color blindness assert that in ordinary life one should behave the same way—simply refusing to take note of the race of people with whom one comes into contact.

Some critical race theorists have mounted a powerful and sustained attack on the idea of color blindness, pointing out, for example, that to disregard another person's race, one first has to notice it, and that many color-blind institutions—such as an alumni preference at private colleges—strengthen white privilege and disadvantage blacks and other minorities.

The social construction of race. Most race-crits hold that race is not real and objective but that ideas of race nevertheless exert great social power. Supported by scientific findings that individuals of different races share a huge majority of their genes (perhaps as much as 99.9 percent) and the scientific community's agreement that the few genes that do account for minor differences such as hair texture and skin color cannot possibly influence distinctively human traits such as intelligence, personality, or propensity for moral or immoral behavior, critical race theorists examine how we nevertheless come to believe in the reality of race. If race is a social construction—something we choose to believe in the face of scientific evidence to the contrary—what are the mechanisms of that social construction and what keeps them in place? Social

constructionists examine how scripts, narratives, stories, and habits enable society to continue to believe that something important distinguishes blacks and whites, for example, and hold to those beliefs even in the face of evidence that people everywhere are pretty much alike (some good, some bad). They also examine the role of law in maintaining racial lines and classifications through such measures as immigration categories, rules forbidding intermarriage, and state statutes defining blackness, such as the “one-drop rule,” according to which any individual with a detectable trace of black blood is black.

Differential racialization. A recently developed theme within critical race theory discourse is differential racialization. This theory holds that the various racial groups in the United States—blacks, Latinos, Asian-Americans, and Native Americans, for example—have been racialized in different ways in response to different needs of the majority group. Moreover, the laws and legal structures society devises for each group—such as English-only laws for Latinos, alien land laws for Asians, and Jim Crow laws for blacks—operate differently in the case of the various groups. The groups feature different histories and struggles. They had to contend with different sets of discriminatory laws and practices. With Indians, for example, society wanted their land; with blacks, labor; with Latinos, first land, then labor; and so on. Social stereotypes of the various groups changed accordingly over time to facilitate society's obtaining what it wanted from the group in question. For example, during slavery, when southern whites had matters well in hand, the dominant narratives, songs, and stories about blacks were reassuring: Blacks were happy with their lives and pleased to serve whites. Later, when blacks received their freedom and were perceived as a threat, social images of them changed. Writers, cartoonists, and filmmakers depicted blacks as frightening, larger-than-life figures with (in the case of men, at least) designs on white women. These figures, of course, justified cruel repression. They would not have served well during the slave period because they would have suggested that blacks were unhappy with their lot.

The black/white binary of race. Related to the above is the notion that American concepts—and laws—related to race incorporate a black/white binary paradigm, in which two, and only two, races define the study, and system, of race. Those two races are, of course, the white and the black. Other groups, such as Latinos, Asian-Americans, Indians, and Filipinos enter into the equation only insofar as their treatment and experiences can be analogized to those of African-Americans. Sometimes the analogy holds. If antidiscrimination law would afford redress for an African-American worker whose supervisor calls him a “lazy n——” and assigns him to the least desirable tasks, it would also provide relief for an Asian worker called a “damn chink” and sent off to do unpleasant work.

But suppose the basis for discrimination is that a Latino or Asian worker speaks with an accent, or because the employer fears, wrongly, that such a worker may be an undocumented alien. Neither accent nor national-origin discrimination affects most blacks; therefore, remedial law coined with them in mind may afford no redress for these other kinds of discrimination. By the same token, Asians may be discriminated against

because of a radically different set of stereotypes—the superachiever or humorless drone who steals jobs from more well-balanced American workers, while Latinos may suffer because of the opposite stereotype—the happy-go-lucky lover of song, dance, and women. Again, none of these stereotypes affects blacks generally, with the result that courts and other decision makers are apt to be unschooled in the need to be on guard against them.

Intersectionality and antiessentialism. A further critical theme that, like differential racialization and the black/white binary, has to do with categories and power is intersectionality and antiessentialism. Opposite sides of the same coin, these two themes draw attention to the evils of overgeneralization. Both have to do with identity. Intersectionality names a phenomenon in which individuals are often found to exhibit identities that are complex. A Latino may also be black, or gay. An African-American may be female and a single parent. An Asian-American may have a parent who is Filipino or a grandparent who is Latino, and so on.

Complex identities may turn out to have legal consequences. For example, imagine an African-American woman worker who suffers discrimination on the job site because of her black womanhood. Her supervisor may dislike black women, believing them lazy or haughty. The supervisor may harbor no such dislike for black men or white women, and may treat them fairly. His discrimination runs only to black women.

Suppose that our hypothetical worker sues for workplace discrimination. How would she frame her case? She could invoke one existing body of case and statutory law that redresses discrimination on the grounds of sex. She is, after all, a woman, and her boss does discriminate against her because she is a woman—a black woman. Alternatively, she could file suit on the grounds of racial discrimination. Her supervisor treats her badly, in part, because she is an African-American. Regardless of the avenue she chooses, however, her suit will confront serious obstacles. Her boss can maintain, truthfully, that he does not discriminate against all women. In particular, he treats white women well, promoting them when they deserve it and otherwise treating them fairly.

He can also prove that he does not discriminate against African-Americans across the board. In particular, he likes black men and treats them well at work. The black woman's claim, then, could fail because her discrimination is intersectional—aimed at her because of her status as a black woman, someone with an intersectional identity. All individuals with complex identities run the risk that a system of power and authority that hinges on prefabricated categories, none of which perfectly fit the individual's situation, fails to do them justice.

Antiessentialism points to the mirror image problem. An organization, such as a woman's group, whose dominant membership is, let us say, white, may give short shrift to the needs and priorities of nonwhite members because it thinks in terms of an "essential" woman, who is, of course, white. The organization then devises strategies to advance the objectives of this member, whose aims and needs are considered to be representative of the group. The needs of nonstandard members—say,

white lesbians, or black single mothers—are deemed of secondary importance. The group will deal with them as soon as the needs of women, as women, are dealt with. And this paradigmatic woman is apt to turn out to be white and middle class.

Legal storytelling and narrative analysis. Out of the concern that conventional legal discourse—and perhaps discourse of any kind—will fail to do justice to the needs, experiences, and histories of minorities, critical race theorists have been experimenting with new modes of presenting their ideas. These new vehicles include legal storytelling and narrative analysis. Legal storytelling received a large boost when Derrick Bell, at the height of his career, received a prestigious invitation to write the foreword to *Harvard Law Review's* 1985 Supreme Court issue, devoted to the analysis of recent opinions. Disdaining the usual heavily footnoted, ponderous prose in which most of the forewords are written, Bell instead published a series of conversations—"The Civil Rights Chronicles"—with an imaginary superheroine lawyer named Geneva Crenshaw. His alter ego is young and brash; his own voice is tempered and moderate. The two discuss the current racial scene and developments in the law. Bell tries to defend the system and its steady, incremental progress. Geneva destroys every illusion with devastating wit and analysis.

Others followed Bell's lead, using fable, myth, and close observation to unmask items of the liberal faith, such as that blacks are making constant progress, color blindness is capable of redressing most racial ills, and most social institutions are prepared to grant minorities full access so long as they meet the institution's standards. Storytelling aims at increasing empathy and allowing the reader a glimpse into what life is like for the author of color. Counterstorytelling aims to debunk the many myths and generalizations that white people believe and that enable them to be comfortable in a system in which they enjoy a disproportionate share of the benefits and privileges. Both types of writing aim at a broad, multiracial audience. Storytellers such as Patricia Williams, Robert Williams, and Richard Delgado have won wide audiences and national acclaim for their work.

Attorneys and legal scholars have also applied the lessons of legal storytelling and narrative analysis to judicial proceedings and the dynamics of the courtroom. A trial is, in some respects, a battle of narratives. And the relationship between an attorney and a client may be seen as an effort to impose a narrative, or understanding, on their mutual journey. Writers such as Lucie White and Anthony Alfieri show how attention to the narrative side of lawyering allows lawyers to understand their function and provide a better brand of justice.

Hate speech. Along with the above-mentioned emphasis on language, discourse, and narrative comes a focus on an especially problematic form of expression—hate speech. Some of the earliest critical race theory work, which continues today, examines the law's treatment of racial epithets, slurs, and name-calling. Speech is a highly protected value in our legal system, yet vicious put-downs based on a person's unchangeable characteristics endanger another set of values, including health, psychological well-being, and equality. Critical theorists such

as Mari Matsuda, Charles Lawrence, and Richard Delgado analyze this conflict between free expression and equal dignity in an effort to provide greater protection for the latter value. Some have participated in the drafting of campus hate-speech codes aimed at assuring an atmosphere conducive to equal participation. They also address issues such as the Confederate flag, teams that sport demeaning Indian logos, and public monuments that memorialize slavery and a segregated past.

Spin-Off Movements

Critical race theory has spawned a number of successor movements that, while continuing to maintain relations with the original movement, pursue courses and directions of their own. Concerned about an unduly Afrocentric emphasis in critical race theory and inattention to groups falling outside the black/white binary of race, Latino scholars in the mid-1990s began caucusing separately during critical race theory meetings, then broke off to form their own multiracial organization, the conference on Latino/Critical studies. The group focuses on a number of issues—such as immigration law and policy, language and accent discrimination, and discrimination based on conquest or territorial status—to which the parent organization gives short shrift.

In similar fashion, a national organization of radical Asian-American scholars meets separately to develop a body of knowledge related specifically to the needs and problems of that population, including many of the above-named issues and, in addition, such issues as Orientalism and the notion of Asians as a model minority. For their part, gay and lesbians of color have been developing a sophisticated set of ideas and a body of scholarship devoted to sexual minorities. Critical race feminism examines issues pertaining to women within the various communities of color, including sweatshop labor, sexual abuse in minority communities, and global human rights, including resistance to genital mutilation and other practices directed against women.

A final spin-off movement is critical white studies, in which scholars apply the techniques and approaches of critical race theory—including social constructionism, historical revisionism, and close attention to myth and narrative—to whites. Scholars such as Ian Haney-López examine Supreme Court cases dealing with the legal definition of whiteness and the requirement—which endured until recently—that an applicant seeking to naturalize (acquire American citizenship) establish that he or she is white. Others examine the abovementioned “one-drop” rule and laws governing interracial marriage and adoption in an effort to learn how white preference figures in. Still others examine seemingly race-neutral laws, such as the income tax code, in search for provisions that favor whites and tacitly enact a system of white privilege, while a final group examines white-collar crime and leniency afforded sympathetic white defendants who have erred over ones who are less sympathetic, nonwhite, but who committed the same offense.

Criticism

As the reader might imagine, audacious movements championing sweeping insights into American society and employ-

ing nontraditional forms of scholarship have come in for their share of criticism. At first, criticism was relatively muted. Book reviewers and tenure committees welcomed the new scholarship and gave it a warm reception. However, critics have taken the movement to task for making undocumented assertions and substituting personal experience and anecdote for provable fact. Other critics have focused on the movement’s critique of merit and other Eurocentric mainstays. With merit, for example, Daniel Farber and Suzanna Sherry ask, what will replace it as a basis for distributing jobs, places in a law school class, and other scarce social goods? And, what are we to make of the current distribution of wealth and influence? If it was improperly gained, as the critics suggest, through a series of rigged competitions, what of minority groups such as Asians and Jews who have done well under the current regime? Perhaps the critique of merit is implicitly anti-Semitic.

Critics from the left level a different type of criticism. Interest convergence, a Supreme Court that subtly discourages racial reform even in the act of advancing it, and other bleak scenarios are too depressing to serve as rallying cries for liberal reformers. Moreover, they are poor tools for students and young attorneys, who require more action-oriented, inspiring fare. Derrick Bell and his colleagues reply that happy myths about progress and faith in the law that, in the end, turn out to be untrue discourage the activist even more and lead to disillusion and dropout. The solution for the reformer is to learn to derive meaning from the act of struggle itself—whether or not it brings immediate victory.

Other mainstream critics take the movement to task for departing from a conception of law as a system of exact, predictable, formal rules and teaching, instead, that it is full of indeterminacy and veiled, clashing interests. Some of these critics charge that critical race theory’s focus on narrative and subjectivity, instead of objectivity and uniform rules, is dangerous. Jeffrey Rosen, legal affairs editor for the *New Republic*, for example, rebuked several critical race authors for providing the basis for the O. J. Simpson acquittal. When Simpson’s lawyer, Johnny Cochrane, successfully appealed to the jury to imagine a different story from the one the state prosecutor advanced—a story in which the Simpson prosecution was infected at every stage with racial prejudice—Cochrane was simply using applied critical race theory. This strategy—“playing the race card,” in Rosen’s view—amounted to a dangerous departure from what should have been the main objective of a trial: finding the truth.

Methodology

As the above description suggests, critical race theorists address a broad span of issues having to do with race, and from a variety of perspectives. Most pay close attention to context and historical situation, valuing the individual over the universal in social and legal analysis. They also credit multiplicity, for example of narratives and identities, over broad generalization. They emphasize how legal rules and regimes look from the perspective of the disempowered and outsider groups—in Matsuda’s memorable phrase, “looking to the bottom.” And a significant faction places primary importance on material factors—labor demand, immigration needs, conquest,

DERRICK BELL

Raised in Pittsburgh, Pennsylvania, the son of working-class parents, Derrick Bell graduated from Duquesne University and the University of Pittsburgh law school, where he was the first African-American to gain membership to its prestigious law review. After graduating from law school, he worked for a number of law reform agencies, including the NAACP, then entered teaching at Harvard Law School in 1969, the first of his race to teach in a tenure-track capacity there. At the end of 1980, he left Harvard to assume the position of dean at University of Oregon Law School, the first black to lead a major, white-dominated law school in the United States. After leaving Oregon in protest over the faculty's refusal to hire a well-qualified Asian-American female professor, he returned to Harvard Law School, where he mentored students and young scholars across the country, helped found the critical race theory movement, and constantly pressed for liberalization of racial policies at his school. His persistent, heroic, sometimes quixotic struggles are recounted in two books and countless newspaper stories. An inspiration to two generations of lawyers and scholars, Bell taught as a permanent visiting professor at New York University law school in the early 2000s.

RELATED LEGAL MOVEMENTS

One of a group of progressive movements in the law, critical race theory bears close relations with a forerunner movement—critical legal studies—that flourished in the 1960s and 1970s and was still alive in the early 2000s. Building on the insights of the early-twentieth-century legal realists, critical legal studies scholars attacked the ideas of legal determinacy—that every legal problem has exactly one correct solution—and autonomy, the notion that law exists in a realm by itself. Instead, the critical legal studies scholars urged, law bears a close relation to economics, politics, social science, and even art and aesthetics. Critical race theorists build on all these ideas, as well as on the Continental school of philosophy from which many critical legal studies scholars draw inspiration.

Critical race theory also builds on some of the key ideas of radical feminism, including hierarchy, patriarchy, and the notion that everyday terms, categories, and roles advance implicit agendas and encode power relations in a way that benefits those in charge. The movement also learned from revisionist historians, such as Charles Beard and Patricia Limerick, who examined history from hitherto unexplored perspectives, such as those of women, workers, and members of outsider groups. Finally, critical race theory scholars such as Derrick Bell and Richard Delgado draw from neo-Marxist theory in exploring how race relations in the United States reflect economic struggles, shifting labor needs, and the clash of interest groups.

international tensions—in understanding the ebb and flow of U.S. racial politics. Critical of both liberal incrementalism and conservative color-blind philosophies, critical race theorists carve out new ground that places central importance on power, economics, narrative, and social construction in coming to grips with America's social problems.

The next wave of critical race theorists will likely consider the relationship between race and class, the role of minorities in a two-party political system, and the implications of globalization for domestic minorities. The United States' population of color is rapidly growing and was expected to exceed 50 percent sometime in the mid-twenty-first century. Latinos

were expected to surpass blacks as the nation's largest group of color. The implications for race relations and civil rights of all these developments are sure to be on critical race theory's agenda well into the future.

The movement is sure to remain controversial—but, of course, many social movements were in their early years. Yet in some respects, it has become the new orthodoxy. Some judges now apply its insights in understanding the racial dynamics of particular cases. Mainstream presses publish its authors; undergraduates study its teachings on hate speech, narrative, and race coding. Two critical race theorists were nominated for high positions within the Clinton administration, but proved too controversial to be confirmed. As the United States struggles to come to terms with a multiracial world and a domestic population that is increasingly black, brown, and Asian, the insights of these progressive, divergent thinkers are apt to become more and more relevant.

CRITICAL THEORY. In the humanities, the term *critical theory* has had many meanings in different historical contexts. From the end of World War II through the 1960s, the term signified the use of critical and theoretical approaches within major disciplines of the humanities such as art history, literary studies, and more broadly, cultural studies. From the 1970s, the term entered into the rapidly evolving area of film and media studies. Critical theory took on at the same time a more specialized sense describing the work of the Frankfurt School that itself spread steadily through many disciplines of the humanities and social sciences in the English-speaking world from the 1970s on.

While critical theories were entering the humanities throughout the world, a proliferation of new theoretical

approaches from France, often associated with structuralism and then poststructuralism and postmodern theory, generated new discourses that were also assimilated to the cover concept of critical theory. Moreover, different groups such as women, gays and lesbians, and people of color also developed specific critical theories within a wide range of disciplines from the 1970s into the early twenty-first century. The situation was further complicated when many of the theoretical discourses (such as deconstruction) were associated with philosophy, which in turn gave rise in the humanities to a tendency to speak of Theory with a capital *T* when describing the proliferation of critical theories and methods and to privilege them as a necessary instrument of criticism.

To sort out this complex trajectory, it is useful to first broadly sketch the role of critical theory in the various fields of the humanities, then present the Frankfurt School version of critical theory, and finally engage the mutations of critical theory from the theory proliferation of the 1960s and 1970s, the rise of the “posts,” the interconnection of critical theory with groups associated with new social movements, its connection with philosophy, and the emergence of Theory as a privileged discourse. While this narrative is partly historical, it is mainly analytical, for in the contemporary context, different people use the term *critical theory* in diverse and contested ways following the various models and stages of the discourse. Thus there is not one single or dominant understanding of critical theory in the university of the early twenty-first century.

Critical Theory in the Disciplines

As Jürgen Habermas has documented, during the Enlightenment of the eighteenth century various modes of political, literary, and cultural criticism emerged from the salons, public houses, and other sites of the bourgeois public sphere, leading to the production of journals and books that discussed the latest cultural fashions and political trends. Major eighteenth- and nineteenth-century writers such as Jonathan Swift, Alexander Pope, Charles-Pierre Baudelaire, and Edgar Allan Poe practiced forms of criticism, as did nineteenth-century novelists such as Jane Austen, Charlotte Brontë, Charles Dickens, and George Eliot.

Critical discourse in a broad range of cultural criticism developed from philosophical and critical responses to genres of art and evaluative responses to specific art works. From Aristotle’s *Poetics* through Matthew Arnold and F. R. Leavis in the literary arts, critical aesthetic theories attempted to define the key features of genres and to distinguish what constituted artistic excellence and experience.

Critical approaches in literature, art, music, dance, and the arts began emerging as a specific discipline in the nineteenth century throughout the Western world. In the first decades of the twentieth century, critics such as György Lukács, Ernst Bloch, and Walter Benjamin began applying Marxist theory to a broad range of the arts. Freudians such as Ernest Jones began using psychoanalytic theory to study culture, while Herbert Read deployed Jungian theory. By the 1950s, a variety of schools of critical theory started using major theoretical discourses of the period to discuss, analyze, interpret, and critique

the arts. There was a reaction against this theory turn, however, both from those who wanted a more scientific approach to the aesthetic work, such as I. A. Richards, and from those who wanted a more empathetic immersion in cultural artifacts, such as some members of North American New Criticism, who advocated close readings of literary texts without what they saw as the blinders of theory.

Some critical theories and methods such as Marxism, feminism, psychoanalysis, and semiotics were taken up in the 1960s in the new disciplines of film and media theory, which also developed their own autonomous discourses and methods. Critical approaches to mass communication and culture, however, were first developed by the Frankfurt School, which generated its own concept of critical theory.

The Frankfurt School and Critical Theory

“Critical theory” stood as a code for the quasi-Marxist theory of society developed by a group of interdisciplinary social theorists collectively known as the Frankfurt School. The term *Frankfurt School* refers to the work of members of the Institut für Sozialforschung (Institute for Social Research) that was established in Frankfurt, Germany, in 1923 as the first Marxist-oriented research center affiliated with a major German university. Max Horkheimer became director of the institute in 1930, gathering around himself many talented theorists, including Erich Fromm, Franz Neumann, Herbert Marcuse, and Theodor W. Adorno. Under Horkheimer, the institute sought to develop an interdisciplinary social theory that could serve as an instrument of social transformation. The work of this era was a synthesis of philosophy and social theory, combining sociology, psychology, cultural studies, and political economy, among other disciplines.

In a series of studies carried out in the 1930s, the Institute for Social Research developed theories of monopoly capitalism, the new industrial state, the role of technology and giant corporations in monopoly capitalism, the key roles of mass culture and communication in reproducing contemporary societies, and the decline of democracy and of the individual. Critical theory drew alike on Hegelian dialectics, Marxian theory, Friedrich Nietzsche, Sigmund Freud, Max Weber, and other trends of contemporary thought. It articulated theories that were to occupy the center of social theory for the next several decades. Rarely, if ever, has such a talented group of interdisciplinary intellectuals come together under the auspices of one institute. They managed to keep alive radical social theory during a difficult historical era and provided aspects of a neo-Marxian theory of the changed social reality and new historical situation in the transition from competitive capitalism to monopoly capitalism.

During World War II, the institute split up because of pressures from the war. Leo Lowenthal, Marcuse, Neumann, and others worked for the U.S. government as their contribution to the fight against fascism. Adorno and Horkheimer, meanwhile, moved to California, where they worked on their collective book, *Dialectic of Enlightenment*, which discussed how reason and enlightenment in the contemporary era turned into their opposites, transforming what promised to be instruments

of truth and liberation into tools of domination. In their scenario, science and technology had created horrific tools of destruction and death, culture was commodified into products of a mass-produced culture industry, and democracy terminated into fascism, in which masses chose despotic and demagogic rulers. Moreover, in their extremely pessimistic vision, individuals were oppressing their own bodies and renouncing their own desires as they assimilated and created their own repressive beliefs and allowed themselves to be instruments of labor and war.

After World War II, Adorno, Horkheimer, and Friedrich Pollock returned to Frankfurt to reestablish the institute in Germany, while Lowenthal, Marcuse, and others remained in the United States. In Germany, Adorno, Horkheimer, and their associates published a series of books and became a dominant intellectual current. At this time, the term *Frankfurt School* became widespread as a characterization of this group's version of interdisciplinary social research and of the particular critical theory developed by them. They engaged in frequent methodological and substantive debates with other social theories, most notably "the positivism dispute" in which they criticized more empirical and quantitative approaches to theory and defended their own more speculative and critical brand of theory.

The Frankfurt School eventually became best known for their critical theories of "the totally administered society," or "one-dimensional society," which analyzed the increasing power of capitalism over all aspects of social life and the development of new forms of social control. During the 1950s, however, there were divergences between the work of the reestablished institute and the developing theories of Fromm, Lowenthal, Marcuse, and others who did not return to Germany, which were often at odds with both the current and earlier work of Adorno and Horkheimer. Thus it is misleading to consider the work of various critical theorists during the postwar period as members of a monolithic Frankfurt School. Whereas there was both a shared sense of purpose and collective work on interdisciplinary critical theory from 1930 to the early 1940s, thereafter critical theorists frequently diverged, and during the 1950s and 1960s *Frankfurt School* as a term can really be applied only to the work of the institute in Germany under Horkheimer and Adorno.

From Structuralism to Poststructuralism and Beyond

The development of structuralism and poststructuralism in France in the 1950s and 1960s and rapid global transmission of books and ideas contributed to the development of an interdisciplinary mode of theory that became prevalent in the humanities. Structuralism is often associated with the French anthropologist Claude Lévi-Strauss, whose studies of myth, culture, and language discerned a binary structure in myth, for example, between nature and culture or the raw and the cooked. For Lévi-Strauss, culture was articulated into systems that could be described with the precision and force of a science.

Structuralism spread through the human sciences in the 1960s and 1970s, moving from Lévi-Strauss's anthropology

and study of myth, to structuralist theories of language (often combined with semiotics), to structuralist Marxism that produced structuralist accounts of the capitalist economy (Louis Althusser) and state (Nicos Poulantzas).

The human sciences were conceptualized by structuralists as self-contained systems with their own grammar, rules, and structuring binary oppositions. Texts were seen as structured networks of signs determined not by what they referred to so much as through their differential relation to other signs. Structuralist critical theory thus focused on detecting the system of binary oppositions through which textual systems were structured, and it delineated oppositions between synchronic and diachronic arrangements, or *langue/parole*, with the former referring to the synchronic social system of language and the latter referring to specific speech at a particular time.

Whereas structuralism had ambitions of attaining the status of a super science, which could arbitrate among competing truth claims and provide a foundational discipline, poststructuralism challenged any single discipline's claim to primary status and promoted more interdisciplinary modes of theory. Poststructuralism turned to history, politics, and an active and creative human subject, away from the more ahistorical, scientific, and objectivist modes of thought in structuralism.

The poststructuralist moment was a particularly fertile one as important theorists such as Roland Barthes, Jean-François Lyotard, and Michel Foucault wrote new poststructuralist works and younger theorists such as Jacques Derrida, Jean Baudrillard, Paul Virilio, and others entered into productive periods. The poststructuralist turn was evident in the famous 1966 conference on "Critical Languages and the Sciences of Man" at Johns Hopkins University, which featured an important intervention by Derrida, "Structure, Sign, and Play in the Discourse of the Human Sciences." Rejecting structuralist theories of language, Derrida stressed the instability and excess of meaning in language, as well as the ways in which heterogeneity and difference were generated. Derrida also questioned the binary opposition between nature and culture upon which Lévi-Strauss had erected his system, thus undermining a certain glorification of the human sciences in the humanities and opening the discipline for a greater appreciation of philosophy, literature, and less-scientific modes of discourse.

Derrida became one of the most prolific writers of his generation and generated great interest in philosophy throughout the humanities, but he also crossed boundaries between disciplines and contributed to both a proliferation of critical theories and more interdisciplinary humanities. Derrida's deconstruction took apart philosophical and closed scientific systems, showing that their foundational beliefs affirmed one side or another of the binary oppositions, for example, nature, with Jean-Jacques Rousseau; or culture, with cultural anthropologists who described the constructed nature of society and culture (a theme that would move into poststructuralism and many of the humanities).

Poststructuralism stressed the openness and heterogeneity of the text, how it is embedded in history and desire, its political and ideological dimensions, and its excess of meaning.

This led critical theory to more multilevel interpretive methods and more radical political readings and critiques. Foucault described how texts and discourses are embedded in power; Edward W. Said articulated the “Orientalism” of Western-centric ideology and the construction of non-Western cultures in both colonial and postcolonial discourses; and feminists described how patriarchy and the concepts of totalitarianism and subordination are inscribed in texts.

Following the poststructuralist moment of the late 1960s and 1970s, there was a proliferation of new theoretical moments of critical theory that connected with new social movements, producing a proliferation of “posts” and theory wars from the 1970s into the early twenty-first century. Baudrillard, a French theorist, took up poststructuralism and deconstruction in idiosyncratic ways. His early work analyzed the “system of objects” and “political economy of the sign” in the media and consumer society, showing how the system of commodities and consumer values were organized in a hierarchal system. Yet by the mid-1970s, Baudrillard entered a deconstructive and poststructuralist phase, taking apart in sequence the claims of Marxism and political economy, Freud and psychoanalysis, Foucault, and other forms of theory. For Baudrillard, the consumer and media society was generating novel forms of sign and signification, technology, and cultural spaces, which produced a break with modernity itself. While modern societies, he argued, were organized around production and political economy, postmodern societies were organized around technology and generated new forms of culture, experience, and subjectivities.

In *Le différend*, Lyotard valorized those voices that had been suppressed or muted in social and academic spheres. He advocated “the end of grand narratives” in the humanities and politics, and the production of small, “minor narratives” and microanalysis. This theme was also taken up by Gilles Deleuze and Félix Guattari who proliferated a dazzling range of critical theories to engage salient cultural, social, economic, and political phenomena of the day.

French poststructuralist critical theory is extremely hard to categorize as it combines social theory, cultural and political commentary, philosophy, literary stylistics, and many social and human sciences in its work, crossing boundaries between academic disciplines and fields. This interdisciplinary focus links French critical theory to Frankfurt School critical theory and to certain types of feminism and other cultural theories that practice “border crossing” (that is, they cross the borders between disciplines and the traditional division of topics and academic labor).

The proliferation of theories also produced a tendency to use the term *Theory* (with a capital *T*) to describe the wealth of conflicting critical theories. In this sense, Theory replaces philosophy as the most abstract and general mode of theoretical discourse. Theory has emerged as an autonomous enterprise in many academic disciplines, giving rise to a tendency to do work in Theory, which engages various critical theories, problems, and concepts, or explores the nature and function of theory itself in the academic disciplines.

Critical theory turned to a “politics of representation” during the 1960s and 1970s. This enterprise involved analysis of the ways in which images, discourses, and narratives of a wide range of cultural forms—from philosophy and the sciences to the advertising and entertainment of the media culture—were embedded in texts and reproduced social domination and subordination. British cultural studies, for instance, showed how problematic representations of gender, race, class, sexuality, and other identity markers were found throughout cultural forms. Cultural studies developed different critical theories and methods to analyze the production of texts, their multiple meanings, and their complex uses and effects.

Critical theories were also developed within feminism, critical race theory, gay and lesbian theory, and other groupings associated with new political movements, making critical theory part of political struggle inside and outside the university. Feminists, for instance, demonstrated how gender bias infected disciplines from philosophy to literary study and was embedded in texts ranging from the classics of the canon to the mundane artifacts of popular culture. In similar ways, critical race theorists demonstrated how racist images and discourses permeated cultural artifacts, while gay and lesbian theorists demonstrated how their sexual orientation was negatively represented and marginalized.

These critical theories also stressed giving voice to groups and individuals marginalized in the dominant forms of Western and then global culture. Critical theory began going global in the post-1960s disseminations of critical discourses. Postcolonial theory in various parts of the world developed particular critical theories as a response to colonial oppression and to the hopes of national liberation. Frantz Fanon in Algeria, Wole Soyinka in Nigeria, Gabriel García Márquez in Latin America, Arundhati Roy in India, and others all gave voice to specific experiences and articulated critical theories that expanded the global and multicultural reach of critical theory.

The past decades have thus witnessed a proliferation of critical theory to the extent that the very concept is a contested area. In the early twenty-first century, conflicting models of critical theory are used by different individuals and groups in various fields of inquiry in different parts of the world. There is also a tendency to combine critical theories in one’s work, following a recommendation by Foucault in the 1970s that many have taken up. Others who took up the anti-theory discourse of Richard Rorty and various critics of Theory have called for rigorous empirical and contextual engagement with topics and subject matter. *Critical theory* is thus a multidimensional term that continues to take on differing connotations and uses and is embedded in many different disciplines and debates.

CULTURAL CAPITAL. The concept of cultural capital originated in the work of Pierre Bourdieu (1979, pp. 10, 12), who defined it as high cultural knowledge that ultimately redounds to the owner's financial and social advantage. An example would be knowing how to "dress for success." This cultural knowledge can pay off. Although they naturally seek competent personnel, employers also prefer executives who dress, talk, and comport themselves in accordance with their elite status. As a result, a job-seeker's sartorial knowledge commands a salary beyond what his or her productivity alone would have commanded. In effect, the well-dressed candidate gets a salary bonus. Most people do not know how to dress for success, do not even know the importance of doing so, and do not, in fact, do so. For this reason, the acquisition of high cultural knowledge and style, including stylish dress, table manners, golf, knowledge of wine, the right neighborhood, and arty chit-chat, represents a capital resource of the owner, vested in the owner, but it is not human capital. Usually human capital and cultural capital go together because people who have one usually have the other as well, but the two capitals are in principle distinct. Anyone may have human capital without cultural capital, or cultural capital without human

capital. In principle, adults might acquire cultural capital by hiring a tutor (Eliza Doolittle benefited from one in *My Fair Lady*). However, cultural capital is prohibitively inconvenient and expensive to acquire that way. In reality, people normally acquire cultural capital informally when they grow to maturity in advantaged socioeconomic households.

Forms of Capital

Capital: A store of value that facilitates action.

Financial capital: Money available for investment.

Physical capital: Real estate, equipment, and infrastructure of production.

Human capital: Education or training that increases productivity on the job.

Cultural capital: High cultural knowledge convertible into social and economic advantage.

Social capital: Relationships of trust embedded in social networks.

Examples of Cultural Capital

Bourdieu defines cultural capital narrowly as fluency in a society's elite culture. Fluency in low- or middle-status culture does not represent cultural capital because these cultural fluencies do not transmute into elite status; they transmute into middle or low status. Bourdieu was interested in how elites reproduced themselves from one generation to the next. High-status culture emphasizes classical art, music, dance, and literature, but it also includes furniture, architecture, cuisine, vacation resorts, and clothing. Knowledge of these arts represents capital because and to the extent that this knowledge can be turned to the owner's financial and social advantage at multiple points in the owner's life span. For example, when Josephine Smith wears the right suit, handbag, and shoes to a job interview on Wall Street, she makes a favorable impression and lands the job. Josephine's mother and peers taught her how to dress, a culturally monitored skill that paid off when Josephine landed a lucrative job. When Josephine subsequently marries a millionaire and obtains a share of his fortune, her cultural capital has produced additional financial capital.

Upper-class people acquire cultural capital in the family and in formal schooling. When the school curriculum reinforces the home curriculum, as it routinely does for children of the affluent, students obtain additional access to their own culture in school. Conversely, when the school curriculum contradicts or subverts the home culture, as it does for poor, immigrant, or ethnic minority children, students have to master a foreign culture at school while mastering their own at home. Even if they accomplish this difficult task, poor, immigrant, and minority children still do not learn everything they need to know in order to access the upper class later in life. Schools do not teach all the cultural knowledge needed for that access. For example, they do not teach dress, table manners, and demeanor. The parallel curriculum of the up-

per-status home teaches children much class-linked knowledge that schools ignore. Since poor or minority children cannot acquire many forms of class-linked cultural knowledge at school or at home, this cultural knowledge is virtually impossible for them to acquire at all.

The parallel curriculum gives children of the affluent a superior endowment in cultural capital. However acquired, at home or in school or both, cultural capital is converted to social and economic advantage in several ways of which the principal is prestige diplomas. Although formal education culminates in diplomas, degrees, and certificates, cultural capital is quite different from human capital, which also emerges from formal education. The difference between human capital and cultural capital resides in how the capital benefits its owner. Human capital increases its owner's productivity, a competence employers reward with high wages. In contrast, cultural capital conveys social recognition and acceptability on the strength of which people get desirable jobs, marriages, and business contacts. Therefore, the same diploma has value as human capital and as cultural capital; and the difference depends on whether we emphasize the real vocational competencies that diploma represents or the prestige recognition it commands. When a person's education has bestowed both enhanced productivity and prestige recognition, that person has two forms of capital (human and cultural), both of which transmute into money and social networks.

Occupational Culture and Competence

Although Bourdieu analyzed the high culture of the bourgeoisie, calling this cultural capital, he neglected the occupational culture of the bourgeoisie. This disjuncture led George Farkas to complain that cultural capital ignored competence. Sociologists understand culture as a tool kit, not a veneer. Crafted for a special purpose, Bourdieu's narrow concept of cultural capital stresses aesthetic judgment as if entrepreneurs and chief executive officers (CEOs) had only to attend art openings and poetry readings. In actuality, entrepreneurs and CEOs discharge real responsibility, which requires real vocational competence. Granted, some well-connected people obtain lucrative jobs on snob appeal alone, but an economy cannot run on snob appeal. What Brigitte Berger has called "the culture of entrepreneurship" is an occupational culture, not an aesthetic culture. The occupational culture of the business class is the skills, knowledge, attitudes and values needed to run a market economy. Like its aesthetic culture, the occupational culture of the business class is transmitted from one generation to the next at home as well as in schools. Bourgeois occupational culture means cultural traits (values, skills, attitudes, knowledge) characteristic of business owners and executives around the world. A business class equips its youth with class-appropriate cultural capital, both aesthetic and vocational.

Immigrant Experience

Oddly, immigration studies have provided a favorable context for the application of cultural capital theory as well as for its criticism and improvement. This advantage arises from often-remarked disparities in socioeconomic mobility of immigrant groups. Some groups move up the social ladder more quickly

than others (consider Jews, Koreans, and Cubans). Often this disparity arises because immigrants bring quite different financial resources with them. Some are wealthy on arrival, others impoverished. These cases are easy to explain. The most perplexing cases have been those in which equally impoverished immigrant groups obtain unequal socioeconomic results after one or two generations. Such cases compel attention to intergroup disparities in cultural capital. For instance, in 1900, Jewish, Polish, and Italian immigrants arrived in the United States. All were equally and wretchedly poor, but two decades later, the Jews were well ahead of the others in business ownership. Similarly, in the 1920s, southern-born black Americans and Caribbean-born black immigrants arrived in New York City. Both groups were impoverished, but the Caribbean blacks soon owned more businesses than did the American-born blacks. Again, in the 1960s, Cubans and Haitians arrived in Miami as impoverished immigrants, but a generation later, Cubans had built a flourishing and lucrative enclave economy whereas Haitians still worked in the informal sector.

In all these cases, socioeconomically mobile immigrant groups had more access than less mobile counterparts to vocationally relevant cultural capital. In two cases, this capital belonged to ethnic rather than class cultures, but it served nonetheless as a functional equivalent to the vocational culture of the business class. Among the Jews and the Caribbean blacks, entrepreneurship had been honed and built into the ethnic culture by centuries of harsh necessity. Although poor on arrival, they knew how to run businesses. Expropriated by the communists, Cuban business owners left their money and property in their island homeland, but they took with them their cultural capital. Thanks to this cultural knowledge, they recouped their money and property within two generations through entrepreneurship. Knowing how to run a business is an obvious advantage for socioeconomic mobility. Cultural capital's vocational component conveys exactly this know-how. Like the aesthetic knowledge that Bourdieu emphasized, this vocational capital is transmitted intergenerationally in households. Normally, we do not expect poor people to understand entrepreneurship, but infrequently they do, and, when they do, they obtain socioeconomic advantages from the knowledge.

CULTURAL HISTORY. As a discipline, cultural history is a bit over two centuries old, but it has an extensive prehistory going back to Renaissance scholarship, especially in areas of the history of literature and the history of philosophy. In the Renaissance, *cultus* or *cultura* was commonly associated with the cultivation of literature, philosophy, eloquence, law, arts, and sciences, whose fruits were the human virtues necessary for civil society. In the seventeenth century the form "culture" (*cultura*) was employed by Francis Bacon, Thomas Hobbes, Samuel Pufendorf, Gottfried Wilhelm von Leibniz, Johannes F. Buddeus, Christian Thomasius, and others, who spoke of the cultivation of the soul, mind, intellect, or reason (*cultura animi, mentis, intellectus, rationis*); and Leibniz, for one, rendered it into the vernacular as "Cultur," or "Kultur."

The terminology was shifted from an individual to a social level as a way of indicating levels of civilization and judging "which peoples may be judged to be barbaric and which cultivated," in the words of Pufendorf in 1663. "True culture" (*vera cultura*), according to Buddeus, was an indication of morality, sociability, and emergence from an animal state; and the first question centered on the "origin of human culture and civility" and their emergence from a "primeval condition." In 1774 Jean-Bernard Mérian wrote of primitive savages as "a people of hunters, navigators, without culture, without laws, without arts." Thus "culture," together with its companion, "barbarism," represents the judgments passed by Europeans on their own and other societies, past and present.

"Cultural history" (*Kulturgeschichte*) arose as a term and a concept in the later eighteenth century, as "culture" replaced earlier equivalents, including "spirit" (*mens, esprit, Geist*, etc.), which was extended from individual psychology to collective

mentality (e.g., *Volksgeist* or *Zeitgeist*), and literature, referring to all the written remains of human cultural achievement. The "history of the human spirit" (*historia intellectus humani; histoire de l'esprit humain; Geschichte des menschlichen Geistes*) was a phrase often used by eighteenth-century historians of particular disciplines. "Literary history" (*historia literaria*), was a major genre, treating (as the seventeenth-century polyhistor Gerhard Joannes Vossius wrote) "the lives and writings of learned men and the invention and progress of the arts." As Nicholas Wickenden has put it, "What Vossius called 'literary history' was really what would now be called cultural history."

Culture and Language

In 1781, the year when Immanuel Kant's *Critique of Pure Reason* marked a revolution in philosophy, Johann Adelung, in his *Versuch einer Geschichte der Cultur des menschlichen Geschlechts*, identified "the first beginnings of culture" with the origins of language, adding that thereafter, through the development of agriculture and private property, "language follows culture," and furthermore, "Since the language of every nation has the closest relationship with its culture, its history can never be understood without continual reference to the conditions and progress of culture." For Adelung "culture is the transition from a more instinctive and animal-like condition to the more complex relations of social life" so that "When culture ceases, so does true history." Deliberately or not, Adelung set a terminological and conceptual fashion that has figured prominently in modern historiography and the human sciences for two centuries.

The best-known convert to the new terminology was Johann Gottfried von Herder, whose *Another Philosophy of History* (1784) told the story of the development of the "human spirit" from its appearance in the state of nature to the emergence of the *Volksgeist*; but a decade later, in his *Ideas for the Philosophy of History of Mankind*, he referred to the process or "chain of culture" in the sense of the cultivation of intellectual and linguistic attributes. To Kant's "critique of pure reason" he opposed a "metacritique," arguing that the object of criticism must be not pure but human reason, not transcendent and ahistorical spirit but concrete, temporal manifestations, beginning with language, without which "reason" could not express itself. For Herder, cultural history aspired not only to criticize but even to replace philosophy as the foundational discipline of human understanding. And other scholars followed Herder in associating cultural history with critical philosophy, including Christoph Meiners, Karl Franz von Irwing, K. H. L. Pöhlitz, Dietrich Hermann Hegewisch, and Johann Gottfried Eichhorn.

"Cultural history" had an extraordinary *fortuna* in the generations after Adelung and Herder. The quantity of published works was striking, and their topics were global and local, ancient and modern, general and special (including cultural histories of literature, medicine, commerce, etc.), and they were often designed for a general rather than merely a learned readership. The heyday of cultural history in this tradition was reached in the Victorian period with the voluminous publications of Wilhelm Wachsmuth, Gustav Klemm, Georg Friedrich Kolb, Gustav Freitag, Wilhelm Riehl, Friedrich

Anton Heller von Hellwald, Otto Henne am Rhyn, Karl Grün, J. J. Honegger, and Julius Lippert. Klemm, who was the founder of an extraordinary ethnographic museum in Dresden, an early model for the Smithsonian Institution, asked such questions as “What were the oldest tools of the human race? and How did early man eat, drink, shelter and cloth himself?” His *Allgemeine Cultur–Geschichte der Menschheit* (1843), while paying homage to the old Herderian tradition, presented its subject from an entirely “new standpoint,” according to which human thought and action were seen not primarily in a Biblical framework but in a prehistorical, evolutionary continuum that denied supernatural privilege to humanity and emphasized what, long before Fernand Braudel, was called “material culture” (*materielle Kultur*).

Material and Spiritual Culture

In the nineteenth century as today, the most important interdisciplinary connection of cultural history was the new field of anthropology. In the famous formula of Edward Tylor, father of modern anthropology, in his *Primitive Culture* (1881): “Culture or Civilization taken in its wide ethnographic sense is that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society.” Tylor referred in particular to Klemm’s conception of “Culture–History,” which he preferred to the more conventional terminology of “civilization.” And the influence was mutual, reflecting back on German scholarship: “What is Culture?” asked the cultural historian J. J. Honegger in 1882 and, by way of answer, gave a paraphrase of the very definition given by Tylor in 1865.

Victorian scholars were poised, or torn, between two conceptions of culture. One was the material culture rooted in primitive life and the other the spiritual culture reflected in such human creations as art, literature, philosophy, and religion. “Culture and anarchy” was the famous formula of Matthew Arnold, who sought, in an idealized and progressivist culture, “the study of perfection” and perhaps “a great help out of our present difficulties.” Opposed to the focus of scholars such as Klemm were the cultivated students of spiritual culture (*geistige Kultur*), of whom Jacob Burckhardt was the most notable representative. While the first took the low road, the latter took the high road to the study of culture, although Burckhardt did not ignore popular culture, as shown by in the pages of his *Civilization of the Renaissance in Italy* (*Kulturgeschichte* was his term) devoted to costume, etiquette, domestic life, festivals, and other topics rediscovered recently by the “new cultural history.” Like Klemm, Burckhardt was a collector, drawn especially to art and literature, and he defined culture “as the sum total of those mental developments which take place spontaneously and lay no claim to universal of compulsive authority.” Suspicious of modern power politics, he was also critical of the material progress of his age, which he regarded as a principal threat to his cultivated world. “We may all perish,” he wrote, “but at least I want to discover the interest for which I am to perish, namely, the culture of old Europe” (*Letters*, p. 197).

By the end of the century, cultural history had achieved high public visibility and a significant academic base, with a

large bibliography, several journals, and historiography of its own; and it became a subject of contention among historians. The battle of methods (*Methodenstreit*) began in 1888 when Dietrich Schäfer gave a lecture denouncing the trivialities of cultural history and reasserting the primacy of politics. This manifesto was answered the next year by Eberhard Gothein, who defended cultural history against the charges of materialism and urged the value of other cultural forms—religion, art, law, and economics—in the effort to understand historical change. This was the view also taken by Karl Lamprecht, who for a generation occupied the storm center of the historical *Methodenstreit* heralded by this exchange and who became the leading figure in the theory and practice of cultural history before World War I.

In 1886 Lamprecht turned to his lifework, *Deutsche Geschichte*, which was a survey of the whole cultural history of Germany; he established at the University of Leipzig a “historical seminar” and then a more ambitious Institute for Cultural and Universal History. In his late years Lamprecht’s public life was torn by controversy about the status, role, and value of cultural history in scholarship and teaching. Lamprecht’s “new history,” as it was pejoratively called, was based on advances in linguistics, archeology, art history, economics, and especially recent psychology (i.e., *Völkerpsychologie*, social psychology). Although few of his professional colleagues, aside from students, accepted his eccentric and aggressively argued views, and he died in some disrepute, the popularity of his work testified to the appeal of his arguments.

Lamprecht’s “new history” had counterparts elsewhere in the West, especially France and the United States, which also emphasized the central role of culture. Henri Berr was already working out the agenda expressed in his concept of “synthetic history,” which underlay the efforts of his younger colleagues leading to the formation of the *Annales* school of history. It was in the wake of such discussions that James Harvey Robinson of Columbia University, in 1912, proclaimed his own version of the “new history,” which was likewise opposed to conventional political history. These views were echoed by other scholars, including Johann Huizinga, who delivered his manifesto on “the task of cultural history” in 1926. After World War I a kind of cultural history was continued in Germany in a debased form in the racist *Volksgeschichte*, which reinforced the ideology and imperialist policies of the Third Reich.

In the French and Anglophone world the semantic rival of “culture” was “civilization” (replacing “civility”), which was also a neologism of the eighteenth century, associated with Voltaire and what Carl Becker called the “new history” of the Enlightenment and which was also contrasted with “barbarism” and intended to designate the highest stage of human development. The classic history of the rise of “civilization” in the West was that of François Guizot, for whom “civilization is a fact like any other,” and indeed “the fact par excellence,” which in his famous lectures, given before the Revolution of 1830 drew him into politics, he traced from classical antiquity down to the French monarchy, which was the highest expression of this fact. Guizot set the line of argument for several

generations of cultural history in France. In England Henry Thomas Buckle's *History of Civilization in England* was hardly less influential, although its doctrinaire scientism and materialism eventually rendered it unfashionable and indeed obsolete.

Twentieth-Century Developments

The writing of cultural history expanded further in the twentieth century as textbooks and popular works presented the results of generations of research and interpretation. Notable examples were the one hundred volumes of Henri Berr's series *Evolution of Humanity* (begun in 1920); Egon Friedell's *A Cultural History of the Modern Age* (1931), which, dedicated to Bernard Shaw and glorying in its journalistic style, carried the story from the Renaissance to psychoanalysis and the "collapse of reality"; Preserved Smith's *History of Modern Culture* (1934), which, in the spirit of Robinson's new history, surveyed early modern sciences, humanities, social control, and "spirit of the times"; and *European Civilization: Its Origin and Development*, edited by Edward Eyre (7 vols., 1934–1939), which included also global frontiers beyond the West. In such works the whole world, private and public, real and imagined, natural and social, becomes a field of anthropological inquiry, interpretation, and speculation.

From the beginning the defining feature of cultural history, shared with anthropology, has been an inclination to holism—the effort to grasp "the history of everything," in Berr's famous phrase, or as Harry Elmer Barnes wrote of the new history, "the recording of everything which has happened in the past"—but of course "in the light of twentieth-century knowledge and methods." Yet cultural history was turned to analysis as well as synthesis, and so in 1940 in the United States, for example, there appeared a volume, *The Cultural Approach to History* ("edited for the American Historical Association"), which explored a wide range of techniques of cultural analysis, means of analyzing social groups, nationality, institutions, and ideas as sources of cultural history.

In this generation little has changed save the rhetorical claims in the "new cultural history," so-called since the publication of the volume by the same name by Lynn Hunt in 1989, supplemented also by the "new historicism," which has made its own contributions to cultural history, and by the study of mentalities and cultural practices carried on from the *Annales* school by Roger Chartier. In general, recent cultural history has come to embrace a wide and miscellaneous range of topics, such as crime, madness, childhood, old age, gesture, humor, smells, space, and other items (appearing on the world wide web) from addiction to unbelief. In terms of theory this self-proclaimed "new cultural history" has arisen out of the wreckage of scientific and Marxist history, which sought the concealed mechanisms of social change beneath the surface of collective behavior. This is true in the sense not only that many new cultural historians such as Natalie Davis and Lynn Hunt have emerged from the materialist assumptions of socioeconomic historical practice and/or Marxist theory, but also that cultural history has always contained a powerful critique of such methods.

In general, cultural history rejects economic and political reductionism, gives up the noble dream of objectivity, recognizes the role of imagination in historical reconstruction, and, no longer aspiring to rigorous explanation, turns instead to what has been called "interpretive social science." As represented by Clifford Geertz and Charles Taylor, interpretive social science places understanding (*Verstehen*) above explanation and so hermeneutics above causal analysis as the principal access to a knowledge of the human condition, past and present. Explanation requires some sort of reduction of experience, or evidence, to crucial factors at the expense of excluding other experience, or evidence, which not only lends color or, as Geertz says, thickness to description but also qualifies simplistic and naturalistic notions of causation.

The new cultural history may entail a sort of relativism distasteful to historians of the older schools, but the positive aspect is a more critical awareness of the meaning of the historian's craft. Not only the objects of history but the works of historians are themselves subject to the conditions of their cultural environment, and so (in contemporary parlance) "culturally constructed." Yet the premise of the new cultural history that, as Hunt writes, "the representations of the social world themselves are the constituents of social reality," is an insight not unfamiliar to earlier cultural historians; for as Huizinga reminded us, "The historical discipline is a cultural process." And like culture it is still changing and renewing itself, though not always with much appreciation for its own history.

CULTURAL REVIVALS. The term *cultural revival* refers to the formation of group identity around a common culture, where a claim is forwarded that the aspects of culture with which the group identifies have been recovered after losses due to colonization, forced or voluntary relocation, oppression, or modernization. Cultural revival is predominantly associated with minority populations and frequently underwrites demands for rights, restitutions, and political or legal recognition as an ethnic group. Much scholarship on the subject has taken examples of cultural revival at face value, undertaking to document the strategies such groups employ and analyze the cultural practices and materials they recover. Work by historians, anthropologists, and sociologists in the 1980s and 1990s, however, theorized the phenomenon as a hallmark of social formations under capitalist modernity.

According to these scholars, cultural revival is a tactic pursued—consciously or unconsciously—by minority communities to consolidate political identity and gain recognition through an appeal to foundationalist cultural logic—that is, the belief that “authentic” traditions are unchanging and ancient, unique to and defining of a given community, and properly transmitted only to members of that group through heredity and ancestry.

Critical Approaches

Scholarship on cultural revivals has been shaped by theoretical developments in three major areas: ethnicity, nationalism, and modernity. Since the work in the 1960s of Nathan Glazer and Daniel Patrick Moynihan, theories of ethnicity have regarded ethnic groups as “interest groups”: ethnic identity is

proposed, maintained, or solidified when political or economic gains accrue to the group through doing so, rather than because primordial ties, distinctive customs, and cultural heritage cannot be relinquished. While early scholars were interested in the persistence of ethnic identification among migrants in an assimilationist United States, subsequent Marxist anthropologists have focused on cultural revivals and ethnic nationalisms. They link them to competition between subnational communities over access to material resources and suggest that the uneven nature of capitalist expansion creates spaces in which marginalized groups bid for access to the benefits of development with culture operating as their symbolic legitimation and means of solidifying group loyalty.

Moving beyond this “instrumentalist” position, but also remaining skeptical of the “primordialist” claims of revivalists themselves, the insights of historians of nationalism have shed light on the crucial role of cultural practices, understandings, and performances in the formation and functioning of cultural revivals, and the affective experience of those involved in them. Like cultural revival, cultural nationalism is predicated on a supposed shared language, tradition, and culture, and an appeal to foundational history, which, no matter how artificially constructed (through the suppression of minority dialects, for example), is experienced as profoundly real and binding. The work of Benedict Anderson illuminated the cultural means through which the abstraction of nation produced for its members a sense of deep loyalty and belonging—an “imagined community”—otherwise absent in a secular, atomized, competitive, and individualist modernity. An influential collection by Eric Hobsbawm and Terence Ranger similarly troubles the primordialist claims of cultural revivalism while pointing to its cultural and historical significance and the power of its appeal. The essayists in *The Invention of Tradition* argued that significant bodies of what we regard as “tradition” are, in fact, of comparatively modern origin, “responses to novel situations which take the form of reference to old situations, or which establish their own past by quasi-obligatory repetition” (p. 2). The editors proposed that the rapid changes and violent discontinuities of modernity (including the dislocations of diaspora, colonization, and forcible “modernization” that frequently occasion later attempts at cultural revival) called for the formalizations of tradition that “established and symbolized social cohesion or the membership of groups, real or artificial communities” through ritual performance (p. 9).

Postmodernist interpretations of cultural revival are premised on the axiom that “culture” is a text, which, like all texts, is an assemblage of signifiers from the sign systems of cultural discourse at large. While specific signifiers become attached to specific groups by social convention (a doughnut is associated with the United States, the attribution of heightened aesthetic sensibility attaches to the French), these relations are essentially arbitrary (doughnuts, for example, originated in Germany, and heightened aesthetic sensibility is a rhetorical proposition rather than an empirical claim). Arguments that specific signifiers authentically, naturally, or historically belong to a given group—the central claim of cultural revival—operate as “truth claims,” attempts to secure and authorize a particular version of reality against possible competing versions. The irony of this

analysis for cultural revivalists is that the cultural elements reclaimed by reviving groups can, more frequently than not, be proved to be integral aspects of the sign system of the dominant culture against which the revivalists stake their claim. The idea that an indigenous people lives in harmony with nature, for example, is a recurrent theme of cultural revivals and can be argued to have much more to do with postindustrial Western romantic structures of belief than with the historical lifeways of specific indigenous populations. (See Hanson for a concise, and later controversial, application of postmodernist analysis to Maori cultural revival). Theorists such as Dean MacCannell have gone further in suggesting that contemporary cultural revivals are not only semiotic constructions (like other cultural and ethnic identities), but that they are a uniquely postmodern phenomenon that he calls “reconstructed ethnicity,” in which authenticity itself has taken on a commodity value. This fetishization of authenticity, he argues, stunts cultural agency and evacuates the particularity of local cultural expression, as groups come to project and identify with a generalized and interchangeable image of “traditional” values.

While some thinkers in the postmodernist or poststructuralist camp believe the essentialist logic of cultural revivalism—the idea that members of the group are distinguished by their unique possession of an inherent, authentic, and unchanging essence expressed through culture—to be an inherently unsound basis for a resistant politics, and devote their critical energies to discrediting such claims, others (among them, Gayatri Spivak) understand it to be a strategic necessity that can authorize beleaguered minorities (with “scrupulously conscientious” aims) to speak as political subjects within a dominant system.

Fourth World Revivals

Perhaps the most dramatic and effective cultural revivals have been those of “Fourth World” populations, defined as indigenous peoples who hold the status of political and/or numerical minorities within the nation-states that encompass their ancestral territories. These groups include North American Indians, New Zealand Maori, Australian Aboriginal, Norwegian Sami, and many others. In these contexts, cultural revival appears as a logical response to histories of state-supported genocide, assimilation, and the disruption or prohibition of cultural practices. Where such state strategies attempted, usually deliberately, to erode ethnic allegiances that opposed state hegemony, cultural revival seeks to reconstruct these communities and networks as the first step in resistance to domination. It thus indirectly addresses the conditions of socioeconomic deprivation, prejudice, and lack of opportunity that have for these groups been the corollaries of colonization, by validating cultural identities devalued by dominant or colonial culture, and providing the basis for collective pride, unity, and action. The long-term sustainability of such initiatives, however, is frequently determined by existing institutional and governance structures, both within and outside the community in question.

An example of a successful Fourth World cultural revival is the case of New Zealand Maori. After the devastating losses of a century and a half of colonization, cultural assimilation, and urbanization, a “Maori renaissance,” beginning in the

1970s, was centered around the fight for rights to land illegally taken during colonization and was inspired by independence movements in still-colonized territories and civil rights struggles in the United States. Early goals of this revival were the promotion of Maori language learning (spoken by less than one percentage point of the population in the 1970s) and the rehabilitation of knowledge of *Maoritanga* (Maori culture, custom, and identity), particularly among the youth of the community. In both of these matters, the Maori revival has been extremely effective, fostering Maori language use throughout the population and training a whole generation of Maori political leaders whose primary commitments are to their ethnic community and who understand themselves as acting in consonance with Maori priorities and customary protocol. Aided by the resilience and strength of tribal networks that survived the ravages of colonization, the united front presented by early protests forced a reconsideration of land-rights policy by the state, and subsequent restitution processes have led to the recognition of Maori cultural considerations as an integral element in national governance. While claims to authenticity were strategically important in legitimating the revival during its early stages, primordial arguments have given way with the securing of state recognition to a broad understanding that Maori culture is a living, inventive, and syncretic set of practices that provides a flexible basis for collective identity and action in changing conditions.

In contrast to these Fourth World examples, the rhetoric of cultural revival is rarely observed in postcolonial states where previously colonized ethnic groups have gained the power of self-governance, giving further credence to the theory that cultural revival is a tactic pursued predominantly by the politically marginal. In postcolonial states, culture-based claims are more likely to be suppressed in favor of the liberal individualist humanism that legitimates Western-style government, or alternatively, to be branded as divisive and backward.

Ethnic Nationalisms and Race-centered Solidarities

Similar processes of politically motivated cultural revival can be seen at work even in cases where cultural continuity has been violently severed, and collective heritage has been erased by historical traumas such as occupation or slavery. An example of this kind of revival is the race-based solidarity forged by black nationalists in the United States. Recognizing the failure of strategies of racial accommodation and integration in the face of continued structural oppression, black nationalism offered not only a framework for analysis—the black nation was colonized by white America—but a strategy for resistance: collective, anticolonial struggle. Advocates such as Harold Cruse argued in the language of cultural nationalism, claiming that championing an autonomous cultural heritage would not only create unity in a vastly diverse population, but it would also foreground and counter the colonial exploitation and derogation of black culture by whites within the United States, with all its destructive psychological effects, and suggest radical alternatives to liberal accommodationism of civil rights. Movements such as the Harlem Renaissance, Negritude, and pan-Africanism were cultural revivals in that they recognized, celebrated, and discovered cultural continuities

with a shared African heritage, fostered invented traditions (such as Kwanzaa), and authorized their ideological claims through reference to this resurgent culture.

Theoretical Trajectories and Contemporary Contexts

While it may seem at first glance that cultural revivals work to undermine the political hegemony of the nation-state, and oppose themselves to dominant cultural and economic interests, these relationships are complex and frequently ambivalent. A new generation of research on cultural revivals parses their role in the sociopolitical formations, economies, and belief systems of nations.

Antimodernism, revival, and the tourism and heritage industry. Scholars have noted the constitutive place that appeals to lost heritage have in the rhetoric of modernity. If to be “modern” is to be severed from one’s ethnic past and the holistic sense of community it represents, critiques of industrial modernity tend to be expressed through the idealization of heritage and the cultural integrity of “primitives” or “exotics.” This yearning for a lost wholeness and authenticity results in support for salvage and preservation efforts that in turn present the “lost” or “recovered” cultural materials for the consumption of the dominant, modern culture, frequently as tourist or heritage attractions. The ironic structure of belief underpinning this process has been called “imperialist nostalgia”—where imperialist or capitalist expansion causes the ongoing damage and erasure of traditional lifeways, and is “nostalgically” lamented by its agents even as they continue to perpetuate it, or “ethnological antimodernism,” expressing one’s commitment to the superiority and normativity of modernity through a romantic, consumerist overvaluation of “premodern” peoples and their cultures.

In material practice, this can lead to an uncomfortable symbiosis as the group in the process of cultural revival becomes a symbolic resource and economic asset for the very state that is responsible for their oppression as an ethnic minority. The power to articulate cultural identity, meanwhile, remains clearly in the hands of the state, the market, or the dominant ethnic interest: cultural identities are validated insofar as they conform to hegemonic agendas, and particular forms of cultural expression (a ritual, distinctive costume, or festival, for example) are selected for preservation and display while others are neglected or actively repressed. At best, cultural revival under these conditions can offer some minimal form of recognition, representation, or leverage that can be capitalized on by a minority group.

Theorists such as Barbara Kirshenblatt-Gimblett have elaborated these observations, suggesting that the action of naming and presenting a set of cultural practices as heritage constitutes in itself an ironic form of cultural revival. The culture that becomes “heritage” is both given a second life (endowed with cultural and economic value by its prospective consumers) and declared dead in the same gesture, as it enters the domain of cultures deemed to belong to “history.” An instance of this is the preservation of closed Welsh coalmines by local governments with the aim of reconstituting them as tourist attractions that feature the lifeways and work of the

colliers of a past age. This development strategy obviously has mixed implications for those for whom this way of life is a living concern and whose political energies are devoted to encouraging reinvestment in coal production by the British government.

Liberal multiculturalism. Some scholars have examined the paradoxical codependence of cultural revivals and the states against which they articulate themselves through the lens of political discourse and juridical practice. Anthropologists such as Elizabeth Povinelli, drawing on work in radical political theory, have noted that liberal multiculturalism demands the demonstration of cultural difference to validate its prevailing ethic as a “rational, non-violent form of association based on competing knowledges and moral values” (p. 6). Yet the national recognition of difference is always conditional, disqualifying differences that prevailing morality finds repugnant, however irrationally, or that are incompatible with Western constructions of “tradition” (preferring, for example, continuity over revival, spiritual over economic or material orientation). This logic is particularly conspicuous in cases where revival is accompanied by legal procedures for restitution. As in the Aboriginal land hearings that Povinelli discusses, court proceedings function as public revival rituals, occasions for the collective demonstration of national repentance and the celebration of majority tolerance, which center paradoxically around the state’s legislation of what constitutes “traditional custom,” and its demand that aboriginals not only identify with but perform this version of culture as a prerequisite of their recognition as political subjects.

Globalization and revival. The phenomenon of cultural revival is entering a new phase with the changes in social and political formation that accompany globalization, giving rise to cultural revivals that operate above the level of the nation-state, linking members of an ethnic group residing in geographically distant locations, and appealing for recognition not just to national governments but to transnational publics. Scholars of contemporary cultural revival are beginning to focus on the new strategies and discourses that emerge as revivals are shaped by their challenge to transnational rather than national relations of ethnicity and race, and operate predominantly through the dissemination of images and discourse in communications media, rather than through the immediacy of cultural performance and territorial sentiment. What new forms of affinity and belonging do global revivals draw on? What new ideas about culture do they produce, and which old ones do they perpetuate? These may well be the questions asked of cultural revival in the future.

CULTURAL STUDIES. Cultural studies is one of the more controversial intellectual formations of the 1990s and the first decade of the third millennium. It has experienced a period of rapid growth in the academy, appearing at many universities in a variety of forms and locations (although rarely as degree-granting departments). At the same time, it has been broadly attacked both from inside the university and outside academia.

Definitions

There are at least five distinct uses of cultural studies, making it difficult to know exactly what people are attacking or defending. It has been used to describe, alone or in various combinations:

1. Any progressive cultural criticism and theory (replacing "critical theory," which served as the umbrella term of the 1980s);
2. The study of popular culture, especially in conjunction with the political problematic of identity and difference;
3. So-called "postmodern" theories that advocate a cultural or discursive constructionism (and, thus, supposedly embrace relativism);
4. Research on the politics of textuality applied broadly to include social life, especially based in poststructuralist theories of ideology, discourse, and subjectivity;
5. A particular intellectual formation that is directly or indirectly linked to the project of British cultural studies, as embodied in the work of Ray-

mond Williams, Stuart Hall, and the Centre for Contemporary Cultural Studies (CCCS).

This entry discusses only the last of these referents even though it is especially difficult to define this intellectual formation. Even the simple claim of British origin is, in the end, probably unacceptable. Still, it provides a reasonable starting point for this discussion. The English origins of cultural studies can be linked to at least four elements of the post–World War II context. First, one of the major issues organizing political debate was framed as the challenge of Americanization, which was perceived in largely cultural terms, both in the growing presence of U.S. popular culture and in the apparent disappearance of many aspects of traditional, working-class culture.

Second, the New Left emerged as a small but influential discussion group, and included many immigrants from the "colonies." It was sympathetic to (but not aligned with) the growing Campaign for Nuclear Disarmament. The New Left had a specific and ambivalent relation to Marxism, engaging Marxist theory and politics even as it criticized it for its failure (and inability?) to account for and respond to the challenges posed by the importance of ideology, colonialism and imperialism, race, and the failures of existing socialism. This work was enabled by the translation and publication of the early writings of Marx and a wide range of European Marxist thinkers.

Third, the British university system was, to put it mildly, elitist and classist, in terms of its student population and in its isolation, aestheticization, and limitation of culture to the field of the arts. Many of the influential early figures in cultural studies were working-class or immigrant students attending university on scholarship, who were driven to look for other accounts of culture that both expanded its referent and took it more seriously.

Finally, many of these figures were deeply influenced by their experience as teachers in various institutions of adult education outside the university. If nothing else, this experience played a role in convincing them, first, of the importance of culture (and intellectual work on culture) to both political struggle and people's everyday lives, and second, of the fact that the important questions do not usually respect the disciplinary boundaries of academic competence and expertise.

Culture and Context

In this context, a number of writers—especially Raymond Williams and Richard Hoggart—began to explore the political and theoretical significance of the concept of culture in relationship to the broader contexts of social life. Trained as literary critics, they argued that cultural texts provided insights into social reality unavailable through the traditional social sciences and enabled one to understand what it felt like to be alive at a particular time and place—to grasp what Williams called "the structure of feeling." They sought to describe culture's concrete effects on people's lives. Hoggart's *The Uses of Literacy* (1957), for example, entered into the debate over Americanization, using close textual analyses to ask whether the new forms of popular culture were unsettling the established relations between working-class cultural practices and

the patterns of everyday life of the working classes. Williams—in *Culture and Society* (1958) and *The Long Revolution* (1965), and in other works throughout his career—sought the theoretical and methodological tools that would allow for description of the concrete relations among cultural practices, social relations, and organizations of power.

In 1964 Richard Hoggart set up the CCCS to continue these efforts when he was hired as professor of English literature at the University of Birmingham. This was done with the permission of both his department and the university, but with only their minimal support. He funded the Centre himself from monies he received for testifying in defense of D. H. Lawrence at an obscenity trial, and he hired Stuart Hall, who had already published *The Popular Arts* (1964) with Paddy Whannel. Hall became director in 1969 when Hoggart left to become assistant director of UNESCO. When Hall took a position as professor of sociology at the Open University in 1980, he was replaced by Richard Johnson. In the following years, the Centre was transformed and combined in a number of administrative incarnations until 2002, when the University of Birmingham dismantled the Department of Sociology and Cultural Studies.

The Centre undertook, both individually and collectively, a wide range of sometimes evolving and sometimes discontinuous researches, both theoretical and empirical, into culture and society, and was characterized internally by a wide range of positions and practices. Externally, it came to represent a more limited body of work as it engaged over the years in a number of highly visible public debates with other groups interested in the politics of culture. The Centre is most widely known for having offered a number of models of cultural studies from the mid-1970s to the mid-1980s, including models of: ideological analysis; studies of working-class cultures and subcultures, and of media audiences (all of which, taken together, constituted a particular understanding of culture as a site of resistance); feminist cultural research; hegemonic struggles in state politics; and the place of race in social and cultural processes. The Centre was primarily associated, quite commonly, with the work of the Italian Marxist Antonio Gramsci.

The work of the Centre was not known widely outside of England, and only marginally known in the United States—primarily in departments of education and communication—until the mid-1980s. In the summer of 1983, a series of events organized around the theme “Marxism and the Interpretation of Culture” at the University of Illinois brought Hall and other key figures from the Centre to the United States. In the mid-1980s, the *Australian Journal of Cultural Studies* was founded, and when it followed its editor John Fiske (a student of Raymond Williams who had emigrated to Australia) to the United States, it became the first international journal explicitly devoted to the field.

In 1992 the University of Illinois hosted a second major conference, “Cultural Studies Now and in the Future.” During and after this conference, the validity of assuming British cultural studies to be the origin of cultural studies on a larger scale was increasingly challenged. It became clear that the

British tradition was less an origin than a term around which a set of similar projects from all over the world could gather and work. People from Latin America, Asia and the Pacific Rim, Europe, and Africa offered their own indigenous traditions of cultural studies, many of which had developed without any knowledge of the British work, and often had no agreed-upon common label. During the 1990s cultural studies became visible—as something both claimed and contested—in many of the major disciplines of the humanities and social sciences (especially literary studies and anthropology) in the United States and in other parts of the world. In 2002 the first international Association for Cultural Studies was launched.

The founding insight of the British tradition was that what had been traditionally approached as an external relationship between two objects of study—the relation of culture and society—was somehow inscribed in the very complexity of culture itself: culture as a set of privileged activities (inevitably raising questions of value); culture as the uniquely human, mediating activities of symbolic life (for example, textuality, sense-making, signification, and representation); and culture as a whole way of life (linking culture to the totality of social life, including conduct, relations, and institutions). Cultural studies is about the relationship of anthropological, hermeneutic, and aesthetic discourses and practices of culture. It treats culture, then, as more than either a text or a commodity. It looks at culture as the site of the production of (and struggle over) power.

Formations of Cultural Studies

Cultural studies is concerned with describing (and intervening in) the ways cultural forms and practices are produced within, inserted into, and operate in and affect the everyday life of human beings and social formations, so as to reproduce, struggle against, and perhaps transform the existing structures of power. That is, if people make history—but within conditions not of their own devising—cultural studies explores the ways this process is enacted with and through cultural practices, and studies the place of such practices within specific historical formations. Cultural studies explores the historical possibilities of transforming people’s lives by trying to understand the relationships of power within which individual realities are constructed. That is, it seeks to understand not only the organizations of power but also the possibilities of survival, struggle, resistance, and change. It takes contestation for granted, not as a reality in every instance, but as an assumption necessary for the existence of critical work, political opposition, and even historical change. Cultural studies is not simply about texts or ideologies, but about the relationships that are historically forged among cultural practices and the contexts in which they operate.

Any further attempt to define cultural studies poses rather unique problems. It cannot be equated with any particular political agenda or with any particular theoretical position. Thus, on the one hand, while British cultural studies is often thought to have investigated class politics, it includes many examples of both feminist cultural studies and cultural studies invested in the politics of race, ethnicity, or post-coloniality. Unlike post-1960s academic formations associated with a particular political agenda (and a pre-constituted

constituency outside the academy), cultural studies has no such guaranteed agenda or constituency. On the other hand, cultural studies is not a school of thought that can be linked irrevocably with a particular theory. Again, the British school is assumed to be grounded in Marxism (and especially in the work of Gramsci), but this is only because the diversity of that tradition has been reduced to a single, small set of representatives and examples. In fact, in England as well as elsewhere, cultural studies has drawn upon, and embodied, an enormously wide range of theoretical positions, from humanism to poststructuralism, from Marx to Foucault, from pragmatism to psychoanalysis.

Raymond Williams's distinction between the common project of cultural studies, and its many different formations, recognizes that practicing cultural studies involves redefining it in response to its changing context (its geographical, historical, political and institutional conditions).

The Project of Cultural Studies

The most basic—and most radical—assumption of cultural studies is that the basic unit of investigation is always relationships, and that anything can only truly be understood relationally; thus, studying culture means studying the relationships between configurations of cultural texts and practices on the one hand, and everything that is not in the first instance cultural—including economics, social relations and differences, national issues, social institutions, and so forth—on the other. It involves mapping connections, to see how those connections are being made and where they can be remade. As a result, cultural studies always involves the study of contexts—sets of relations located and circumscribed in time and space, and defined by questions. And cultural studies is always interdisciplinary because understanding culture requires looking at culture's relationship to everything that is not culture.

Moreover, cultural studies is committed to a radical contextualism; it is a rigorous attempt to contextualize intellectual (and political) work. This contextualism shapes the project of cultural studies profoundly, and involves a commitment to complexity, contingency, and constructionism.

Contexts are not random and chaotic collections of bits and pieces on which people attempt to impose order or meaning; they are already ordered or configured when the scholar embraces them in their complexity rather than reducing them to a simplicity defined ahead of time by a theoretical or political agenda. Cultural studies refuses to reduce the complex to the simple, the specific to the exemplary, and the singular to the typical. It refuses to see this complexity as an inconvenience to be acknowledged only after the analysis. It employs a conjunctive logic—where one thing is true, another may also be true—and thereby refuses the illusion of a total, all-encompassing answer. It avoids confusing projects with accomplishments (as if intentions guaranteed effects); and it refuses to put off until later the resistances, the interruptions, and the fractures and contradictions of the context.

Cultural studies believes in contingency; it denies that the shape and structure of any context is inevitable. But cultural

studies does not simply reject essentialism, for anti-essentialism is, in its own way, another version of a logic of necessity: in this case, the necessity that there are never any real relations. Cultural studies is committed to what we might call an anti-anti-essentialism, to the view that there are relationships in history and reality, but they are not necessary. They did not have to be that way, but given that they are that way, they have real effects. Above all, there are no guarantees in history (or in reality) that things will form in some particular way, or work out in some particular way. Reality and history are, so to speak, up for grabs, never guaranteed. Cultural studies operates in the space between, on the one hand, absolute containment, closure, complete and final understanding, total domination, and, on the other hand, absolute freedom and possibility, and openness.

Finally, cultural studies assumes that relationships are produced or constructed, and not simply always the result of chance. The relations that make up a context are real through the various activities of different agents and agencies, including (but not limited to) people and institutions. Insofar as we are talking about the human world—and even when we are describing the physical world, we are within the human world as well—cultural practices and forms matter because they constitute a key dimension of the ongoing transformation or construction of reality. However, the effects of cultural practices are always limited by the existence of a material or nondiscursive reality. Cultural studies, then, does not make everything into culture, nor does it deny the existence of material reality. It does not assume that culture, by itself, constructs reality. To say that culture is constitutive—that it produces the world, along with other kinds of practices—does not mean that real material practices are not being enacted, or that real material conditions do not both enable and constrain the ways in which reality functions and can be interpreted. Cultural studies is, in the first instance, concerned with cultural practices. To put it simply, the culture we live in, the cultural practices we use, and the cultural forms we place upon and insert into reality, have consequences for the way reality is organized and lived.

The commitment to a radical contextualism affects every dimension of cultural studies, including its theory and politics, its questions and answers, and its analytic vocabulary—which includes concepts of culture (text, technology, media), power, and social identity (race, gender, sex, class, ethnicity, and generation). Cultural studies derives its questions, not from a theoretical tradition or a disciplinary paradigm but from a recognition that the context is always already structured, not only by relations of force and power, but also by voices of political anger, despair, and hope. Cultural studies attempts to engage the existing articulations of hope and disappointment in everyday life and to bring the messy and painful reality of power—as it operates both outside and inside the academy—into the practice of scholarship.

Cultural Studies, Theory, and Power

While cultural studies is committed to the absolute necessity of theoretical work, it sees theory as a resource to be used to respond strategically to a particular project, to specific ques-

tions and specific contexts. The measure of a theory's truth is its ability to enable a better understanding of a particular context and to open up new—or at least imagined—possibilities for changing that context. In this sense, cultural studies desecralizes theory in order to take it up as a contingent strategic resource. Thus, cultural studies cannot be identified with any single theoretical paradigm or tradition; it continues to wrestle with various modern and postmodern philosophies, including Marxism, phenomenology, hermeneutics, pragmatism, poststructuralism, and postmodernism.

Cultural studies does not begin with a general theory of culture but rather views cultural practices as the intersection of many possible effects. It does not start by defining culture or its effects, or by assembling, in advance, a set of relevant dimensions within which to describe particular practices. Instead, cultural practices are places where different things can and do happen. Nor can one assume, in advance, how to describe the relation of specific cultural formations to particular organizations of power. Consequently, the common assumption that cultural studies is, necessarily, a theory of ideology and representation, or of identity and subjectivity, or of the circulation of communication (production-text-consumption), or of hegemony, is mistaken. Cultural studies often addresses such issues, but that is the result of analytic work on the context rather than an assumption that overwhelms the context.

Like a number of other often overlapping bodies of intellectual and academic work that have emerged since World War II (feminism, critical race theory, postcolonial theory, and queer theory, among others), cultural studies is politically driven; it is committed to understanding power—or more accurately, the relationships of culture, power, and context—and to producing knowledge that might help people understand what is going on in the world (or in particular contexts) and the possibilities that exist for changing it.

The project of cultural studies, then, is a way of politicizing theory and theorizing politics. Cultural studies is always interested in how power infiltrates, contaminates, limits, and empowers the possibilities that people possess to live their lives in dignified and secure ways. For if one wants to change the relations of power—if one wants to move people, even a little bit—one must begin from where people are, from where and how they actually live their lives. Cultural studies attempts to strategically deploy theory (and empirical research) to gain the knowledge necessary to redescribe the context in ways that will enable the articulation of new or better political strategies. Cultural studies also approaches power and politics as complex, contingent, and contextual phenomena and refuses to reduce power to a single dimension or axis, or to assume in advance what the relevant sites, goals, and forms of power and struggle might be. Consequently, it advocates a flexible, somewhat pragmatic or strategic, and often modest approach to political programs and possibilities.

Two of the most important political assumptions of cultural studies are also among its most controversial. Cultural studies refuses to assume that people are dupes, constantly manipulated by the producers of culture and ignorant of their

own subordination. On the other hand, it does not assume that people are always in control, always resisting, or operating with an informed understanding of the context. That does not mean that cultural studies doesn't recognize that people are often duped by contemporary culture, that they are lied to, and that at times—and for a variety of reasons—either don't know it or refuse to admit it. But it does mean that cultural studies is opposed to the vanguardism of so much of contemporary political and intellectual discourse.

Cultural studies is committed to contestation, sometimes as a fact of reality, but always as a possibility that must be sought out. Contestation can also serve as a description of cultural studies' own strategic practice, which sees the world as a field of struggle and a balance of forces. Intellectual work is required to understand the balance and find ways of challenging and changing it. Of course, cultural studies recognizes that the relations among survival, change, struggle, resistance, and opposition are not predictable in advance, and that there are many forms and sites that each can take and has taken; these range from everyday life and social relations to economic and political institutions. Cultural studies, then, is an effort to produce knowledge about the context that will help to strengthen, existing struggles and constituencies, helping to relocate and redirect them, or to organize new struggles and constituencies. It seeks knowledge that will make the contingency of the present visible and open up possibilities that will help to make the world a better, more humane, place.

While it attempts to put knowledge in the service of politics, cultural studies also attempts to make politics listen to the authority of knowledge. It believes that its political commitment (and its desire for intervention) demands that it maintain a justifiable claim to authority in the face of the threat of a relativism often linked to contextualist and constructivist projects. Cultural studies, like many of its political allies in the academy, rejects foundationalism. It does believe that knowledge is dependent on its context, and hence, that all knowledge is limited and partial. There is no knowledge that is not always marked by the possibilities and the limits of the position and perspective from which it is constructed and offered.

Yet cultural studies also rejects relativism, for like foundationalism, relativism assumes that knowledge and culture exist on a different plane from the context they purport to represent. But if the knower is a constituent part of the very context he or she is trying to know, the description plays an active part in the construction of the very context it describes. The question of better or worse knowledge is, then, no longer a matter of comparing two things (the description and the reality) as if there were some place outside the reality that we could stand in order to compare them. The question is rather a matter of the possible effects of the knowledge on the context—what possibilities for change does it enable? The better the knowledge, the more (new) possibilities it will offer for transforming the present. That is what cultural studies means when it talks about knowledge without truth, and about useful knowledge. Cultural studies does demand a kind of self-reflection on its own limitations, but this is not, as in some

other projects, a requirement that one define one's identity as if it were determining, but rather that one offer a rigorous analysis of institutional conditions and a reflection of one's own contextual existence.

The question of what cultural studies will (or should) look like is only answerable within the particular context that calls cultural studies into existence. Cultural studies is not alone in privileging the questions of power or in its commitment to relationality and constructionism; it is not alone in its embrace of contingency and contextuality or in recognizing the importance of culture. But the practice that is defined by the intersection of all these commitments—*that* is the project of cultural studies. Cultural studies is an intellectually grounded practice for intervening into the “becoming” of contexts and power. It attempts, temporarily and locally, to place theory in-between in order to enable people to act more strategically in ways that may change their context for the better.

Diversity in Cultural Studies

The diversity of cultural studies is as important as its unity; yet there is no obvious single best way to organize or describe that diversity. One could display the range of objects and discourses that cultural studies has explored—including art, popular culture, media culture, news, political discourses, economics, development practices, everyday practices, organizations, cultural institutions, and subcultures. One could display the different theoretical paradigms (including pragmatism, phenomenology, poststructuralism, Marxism, and so forth) or theoretical influences (Harold Innis, Michel de Certeau, Gramsci, and Michel Foucault, among others). One could display the different political agendas—feminist, Marxist, anti-racist, anti-homophobic, anti-postcolonial, anti-ageist—or the more positive political agendas of socialism, radical democracy, and global justice, that have driven the work. One could consider the different ways the major concepts of culture, power, articulation, and context have been used. One could describe the implications of disciplinary diversity—literary studies, anthropology, sociology, communication, history, education, and geography, among others—and methodological diversity—forms of textual analysis, ethnography, interviewing, archival research, statistical analysis, and so forth. Finally, one could speculate about the significance of geographical diversity, which has become increasingly visible and important. A more useful way might be to describe some exemplary instances of cultural studies.

A first model, found in the work of Raymond Williams, reads texts as ideologies in context. That is, it uses texts to try to locate and define the common structure (e.g., homology, structure of feeling) that unites the disparate elements of social formation into a unified social totality. But this common structure of unity is available only by thinking of ideology contextually—that is, by looking at the relations among texts, and between texts and other discursive and nondiscursive practices.

A second model, found in the work of communication scholar James Carey, looks at particular cultural practices as

rituals that reenact the unity—shared meanings, structures, and identities—of a community.

A third model locates cultural texts and practices within a dialectic of domination and resistance and was closely associated with the CCCS in the 1970s, especially in the early work of David Morley, Dick Hebdige, and Angela McRobbie. The politics of culture are determined by the relations among a number of relatively autonomous moments—primarily of production and consumption—but later work added distribution, exchange, and regulation. It provided an alternative model of media communication (encoding-decoding) with an emphasis on the audience as an active interpreter of messages and of subcultures in which subcultural styles were seen to be expressions of, and symbolic responses to, lived contradictions—defined by class and generation—of the social experiences of the members of the subculture.

A fourth model explores cultural and social identities as complex sets of relations. It involves the production of differences (or structures of otherness such as race and gender) within a population, the effort to naturalize such identities as biological, the distribution of people into those categories, and the assignment of particular meanings to each identity. These differences provide the basis, along with the inequalities of power and resources, that are defined within a particular society. But they are not natural, inevitable, or fixed; instead, identities are the site of constant work and struggle over the practices by which people come to be represented and to represent themselves. This work studies the dialectical production of identity and difference, often in a kind of Hegelian dialectic of recognition. This is a logic in which the formation (identity) of one term (the self) can only be constructed through, or on top of, the assimilation and exclusion of the other. There are various tropes for this process circulating throughout the cultural studies literature (and beyond), including difference, border-crossing, hybridity, third space, and most recently, diaspora (although the last often attempts to escape the Hegelian negativity of difference). Obviously, such work in cultural studies overlaps here with many other bodies of related work, but its influence—through the work of people like Stuart Hall, Paul Gilroy, Angela McRobbie, Gayatri Spivak, and Judith Butler—has been profound.

A fifth model is concerned with the relationship between culture and the state. Influenced in part by Gramsci, such work was best illustrated by the important work of Stuart Hall and John Clarke on hegemony as an alternative to notions of civil politics as ideological consensus. Hegemony, as a struggle for the gain and consolidation of state power, involves the attempt by a particular coalition of social factions to win popular consent to its leadership. Hegemony is not a battle to the death between two camps, but a constant attempt to negotiate with various factions to put together temporary agreements for the leadership of the ruling bloc at different sites. It therefore works on (and through) the popular languages and logics of the society, and reconfigures the national common sense in order to reconstitute “a balance in the field of forces.”

A sixth model of “governmentality” emphasizes the variety of ways in which culture is used by state and other institutions to produce particular kinds of subjects and to regulate their conduct. This work focuses on the material effects of bureaucratic cultural apparatuses; it looks at how institutional discourses produce a particular structure of the subject itself as an historical effect of power. For example, Tony Bennett looks at cultural institutions such as museums in terms of the way they discipline people, organizing their behavior and teaching them, as it were, to behave properly in public as citizens. Similarly, Bennett has also argued that the pedagogy of cultural criticism functioned to render students always inadequate and incomplete, not only in terms of the classroom but as human beings in need of constant self-improvement. In his view, it is only the teacher who can recognize the politically problematic claims of any text, while the students are always guaranteed to fail. Another example involves the work of Nikolas Rose and his colleagues, who attempt to analyze the contemporary forms of neoliberal state power by looking at the micropractices of institutions and everyday life.

Finally, the seventh model looks at culture as formations or organizations of both cultural and noncultural practices, often related to, or even identified with, particular institutions. Such cultural apparatuses function in complicated ways to produce and organize social reality itself. That is to say, they are “technologies of power” that are connected on the one hand to the lived realities of everyday life (itself understood to be an organization of power) and, on the other hand to the larger structures of political and economic power. Cultural or discursive practices are integral pieces of the institutional formations of power that organize the very lived reality and structures of power in space and time. Examples of such work can be seen in the anthropological critiques of development offered by Akhil Gupta and Arturo Escobar, and in Meaghan Morris’s studies of the place of history as a cultural formation in Australian social life.

CYCLES. The idea that history is composed of cycles is ancient. Many peoples (including the Egyptians, Chinese, Babylonians, Hindus, Maya, and Greeks) observed recurrences in astronomical phenomena. These early observations were often related to calendar systems and were the foundation for later written schemes of cosmic and historical cycles in various parts of the world.

The Ancient World

One of the oldest written systems of historical cycles originated in India among the Hindus. Hindu cosmology operates within vast cycles of time, or world ages: the universe exists for the life span of the creator god Brahma (quadrillions of solar years), disappears at his death, and is reborn when a new Brahma arises. A brahmic day and night (*kalpa*) consists of one thousand *maha yugas* (great ages). A *maha yuga* is comprised of four cyclic *yugas* (ages) of 4,000, 3,000, 2,000, and 1,000 divine years (one divine year being nearly 130,000 solar years) with intervals of latency between the ages. The advancement through the *yugas* is characterized by spiritual and moral decline. The present time is considered a dark age and falls near the beginning of the fourth *yuga*, which began at Krishna’s death in 3002 B.C.E.

Greek philosophers postulated the existence of cosmic cycles. Some of them (such as Empedocles, c. 495–c. 435 B.C.E.) proposed that the events within a given cosmic cycle were iden-

tical (or very similar) to the events in earlier cycles. The Stoics held a clear conception of historical cycles. Largely based on the physics of the pre-Socratic philosopher Heraclitus (c. 535–475 B.C.E.), the Stoics theorized that the sun would periodically heat the world and cause a great conflagration (*ekpyrosis*). Unlike Heraclitus, the Stoics identified this purgative fire with God, who would subsequently recreate the world from the condensation of the elements (air, water, earth, and fire). The process of creation and destruction would then begin again.

Plato (427?–347 B.C.E.) understood cosmic and human history to be cyclical. He included statements about the cyclic nature of the world and accounts of natural disasters from which human civilization had reemerged in his *Statesman*, *Timaeus*, *Critias*, and *Laws*. Aristotle (384–322 B.C.E.) also presented history as cyclical. He mentioned the possibility of periodic cataclysms in the *Politics* and the *Meteorologica*. He stated in the *Politics* and *De caelo* (On the Heavens) that human knowledge had repeatedly been lost and rediscovered. In addition, Aristotle advanced the notion of the degeneration of governmental forms. He proposed that governments devolve in a specific order: monarchies fall into oligarchies, followed by tyrannies, and then democracies. This idea was adopted and further developed by the Greek historian Polybius (c. 203–c. 120 B.C.E.). In the *History*, he postulated a theory of constitutional cycles (*anacyclosis*). According to Polybius, six forms of government devolve in succession: monarchical governments, tyrannies, aristocracies, oligarchies, democracies, and finally rule by the mob. The cycle would then repeat.

The Early Modern Period

Polybius's ideas were revived in the Renaissance and especially influenced Niccolò Machiavelli (1469–1527), who argued for the superiority of mixed governments in his *Discourses* (1512–1517). However, notions of cyclical history were evident before the revival of Polybius. For example, a system of cyclic historical development is apparent in the *Chronicle of Florence* by Giovanni Villani (c. 1275–1348). A later example is Giorgio Vasari's (1511–1574) theory of cycles in the history of art in his *Lives of the Artists* (1550 and 1568). Vasari viewed the history of art as a long series of advances and declines. However, he believed that art had reached a peak of perfection in his own age in the works of Michelangelo; having been perfected, art could not rise further but would either be maintained or decline.

In the eighteenth century, Giambattista Vico (1668–1744) divided history into three ages in his *New Science* (1725): the age of gods, the age of heroes, and the age of humans. He saw history as the occurrence (*corsi*) and recurrence (*ricorsi*) of these ages. According to Vico, every nation follows a similar pattern of development. During the first age, nations invoke imagination in order to comprehend the world as the creation of the gods. The age of gods then gives way to the second age, wherein humans use imagination to establish moral values and institutions following heroic models. The age of heroes declines into the third age, a time when social order is created through reason. Vico's vision of history was the infinite repetition of these three ages.

The Twentieth Century

In the twentieth century, Oswald Spengler (1880–1936) and Arnold Toynbee (1889–1975) presented important theories of historical cycles. In *The Decline of the West* (1918–1922), Spengler proposed that individual societies have a life cycle similar to living organisms: they experience periods of growth, maturity, and decline. According to him, these cycles repeat themselves as new societies develop. Toynbee was influenced by his reading of Spengler's work. In *A Study of History* (1934–1961), he argued that civilizations emerge when faced with physical or social challenges. He believed that the history of a civilization was largely the record of its response to a unique challenge. On a larger scale, he saw that history moved through periods governed by universal states followed by shorter periods of religious rule. In Toynbee's view, societies decline when they fail to surmount a challenge and thereafter lose social cohesiveness. However, he acknowledged the possibility that a civilization could repeatedly meet its challenges.

Another prominent twentieth-century historian who proposed a theory of historical cycles was Fernand Braudel (1902–1985). Associated with the Annales school of historians, Braudel developed a system that encompassed short-term (individual), medium-term (social), and long-term (geographical) time periods. While acknowledging the significance of short-term events, he emphasized their integration with larger historical cycles. He incorporated an interdisciplinary approach that examined the complex interactions between history, economics, geography, politics, and culture. His major works include *The Mediterranean and the Mediterranean World in the Age of Philip II* (1949) and *Civilization and Capitalism: 15th–18th Century* (1967–1979).

CYNICISM. The word *cynic* generally conveys negative ideas in modern languages. It describes someone who is unduly critical and suspicious, apathetic about certain issues and rebellious in response to others, selfish, and indifferent toward

traditions and accepted beliefs, and unconcerned with the public welfare. The cynic is often viewed as a person who has severed all ties with his social context. To be cynical in the midst of political issues and events is equivalent to being aloof from such things—the cynic does not participate because he has lost his faith in others.

Cynicism, however, has an ancient meaning, the roots of which are traceable to the classical Greeks, specifically to Socrates and his associates in the late fifth century B.C.E. A review of the history of Cynicism reveals that its meaning is significantly different from what modern cynicism has come to mean, and it is not unreasonable to agree with what Bertrand Russell said—namely, that modern cynics have hardly anything in common with the classical Cynics. As a result of a curious perversion of language, the meaning of modern cynicism appears to have been transformed into the opposite of what it once meant, despite undeniable external similarities between the old and the new cynics.

The word *cynic* is etymologically related to the Greek word *kynikos*, which literally means “like a dog.” When Aristotle, for instance, refers to Diogenes of Sinope (d. c. 320 B.C.E.), he calls him “the Dog” because that is how Diogenes was known. Likewise, when Lucian speaks of the crowds of Cynics found in every Roman town in the second century C.E., he calls them “the Army of the Dog.” The association between the Cynics and dogs seems to have originated not among the Cynics themselves, but among outsiders who discerned in them behavioral traits reminiscent of dog behavior. Beginning with Diogenes, however, the Cynics accepted the uncomplimentary appellation with enthusiasm and were happy to call themselves “the dog philosophers.”

The question as to who the first dog philosopher was has been often raised. Some argue that it was Antisthenes (c. 445–365 B.C.E.), an associate of Socrates, and others opt for Diogenes, a disciple of Antisthenes, and see Diogenes as the “founder” of Cynicism. It must be borne in mind, however, that Cynicism was not a school of philosophy comparable to Plato’s Academy or Zeno’s Stoa. Accordingly, it had neither a founder nor an identifiable place of origin nor a set of principles or beliefs. For this reason, the classical Cynics constitute an assortment of different types of individuals (men and women) who exhibited diverse styles of life and held a variety of beliefs. What allows us to distinguish them from other philosophers is a certain attitude toward their cultural and political world, as well as a distinctive way of expressing their rejection of that world.

The history of Cynicism begins in the early fourth century B.C.E. and ends in the fifth century C.E. We can define Cynicism as a practical philosophy that exhibits a permeating and inflexible commitment to saying no to the values, norms, beliefs, practices, traditions, and all other forms of living which, in the light of what the Cynics called clarity of mind, appear to be senseless or misguided. The Cynics persisted in the conviction that most people live as if immersed in a cloud of smoke (*typhos*) that prevents them from seeing clearly and does not allow them to use that which distinguishes humans

from animals—namely, the capacity to reason. In abandoning this capacity, people forsake their true nature. Diogenes often said that the human world is an enormous madhouse in which every sort of madness is found everywhere: cruelty, greed, deception, mendacity, brutality, uncontrolled hedonism, and the rest of the all-too-common diseases that afflict humanity and have become endemic in the form of things such as religion, patriotism, tradition, and other manifestations of irrationality. It was against such a condition that the Cynics declared war.

Cynicism can be understood, accordingly, as a philosophy of revolt. Although certain principles can be identified in it, the scarcity of primary sources makes this task difficult. Cynic writings are mostly nonexistent, and we suspect that even if they were available they would not be helpful because the Cynics expressed their convictions not so much through writings, but through actions and speech. It is, for example, difficult to understand precisely the sense in which the Cynics understood the concept of reason except by literally looking at what they did. A good idea of Cynicism can be gathered by reviewing the countless anecdotes found in secondary Greek, Latin, and Arabic sources, in which we encounter the Cynics in action and in many of which there is probably some element of historical truth. From such sources we can compile a list of Cynic virtues—that is, modes of behavior through which the Cynics sought to combat the world: they opposed avarice and greed with poverty, servility and submissiveness with independence and self-sufficiency, patriotism and factionalism with cosmopolitanism, addiction to pleasure with abstinence and asceticism, deceptiveness and fraud with truth-telling, social distinctions and prejudices with egalitarianism, faith in religion and superstition with skepticism and agnosticism, chatter and gossip with silence, prudishness with impudence, and irrationalism and brutality with an undeviating attachment to reason.

Although Cynicism eventually came to an end, it is undeniable that its influence has persisted until our time. After all, the Cynics exemplified a human tendency found among a small number of people of every culture and time to stand in opposition to what is unnatural and irrational. Stoicism, for instance, owed its inception and development to the ideas of the Cynics. Indeed, as long as the world remains the madhouse recognized by Diogenes, there are bound to be cynics—both in the modern sense of this word and in its ancient sense. In the former, cynicism takes the form of rebelliousness born out of selfishness and irrationality, and in the latter, it assumes a stance of defiance rooted in a desire to return humanity to its true nature, which entails a return to reason.

DADA. Presided over by the poet and essayist Tristan Tzara (1896–1963), who served as its principal spokesman, dada was the first truly international avant-garde movement. Although the term *dada* was invented in Zurich, the movement's origins were by no means limited to Switzerland. The dada spirit existed previously in several other countries, where it expressed itself in outrageous avant-garde activity. Dada's chief concern was the achievement of total liberty: social, moral, and intellectual. Its members questioned, through their art, poetry, and performance, the basic postulates of rationalism and humanism as few had done before.

The period 1912–1914 witnessed the emergence of two of the movement's influential figures in Paris: Francis Picabia (1879–1953) and Marcel Duchamp (1887–1968). After World War I erupted, the two men moved to New York, where they proved to be important catalysts. The first dada journal had already appeared in print a few months earlier. Entitled *291*, it was edited by a group centered around Alfred Stieglitz (1864–1946) and his review *Camera Work*. Another contingent met at Walter Conrad Arensberg's apartment at 33 West 67th Street. The two groups welcomed the French artists, who were soon joined by friends and family, and emulated their latest experiments.

Emerging independently in 1916, the Zurich dadaists published an eclectic journal entitled *Cabaret Voltaire*. Named after the artistic cabaret founded by Hugo Ball, which was notorious for its outrageous productions, the journal was replaced by *Dada* in 1917. Ball himself was soon eclipsed by the flamboyant Tzara, who became the movement's chief theorist and publicist. Consisting of Romanian expatriates and former German Expressionists, the Zurich group included several accomplished poets and artists but specialized in theatrical performances. A third dada faction was situated in Barcelona during the war. Revolving about the Dalmau Gallery, it included several French expatriates in addition to Catalan artists and writers such as Joan Miró and Josep Maria Junoy. The Barcelona movement gained momentum in 1917 with the arrival of Francis Picabia, who founded the iconoclastic journal *391*.

After the War

Following the end of World War I, the dada movement underwent a significant transformation. While the original three groups continued to exist, the balance of power shifted from countries situated at the war's edge to Germany and France. Beginning in 1919, the German branch was composed of three separate factions. Dominated by Richard Huelsenbeck and

Marcel Duchamp (1887–1968). The French-born Duchamp moved to the United States in the early twentieth century and helped introduce the concept of dada to his new country. Duchamp dabbled in many different art forms, among them sculpture, painting, and even short film. © CORBIS-BETTMANN

Raoul Hausmann, Berlin dada was preoccupied with a series of political issues. In addition to satirizing politics in their art, its members sought to create a new social order. Centered around Jean Arp (also known as Hans Arp) and Max Ernst on the one hand and Kurt Schwitters on the other, Cologne dada and Hanover dada were more concerned with aesthetic issues. Despite the three groups' relatively brief lives, they were a potent force for social and artistic change. In Paris, the dada movement coalesced around four future surrealists: André Breton, Louis Aragon, Paul Eluard, and Philippe Soupault. Other participants included Francis Picabia, Marcel Duchamp, and Tristan Tzara, who arrived in 1920. In spite of dada's impressive vitality, the international movement ceased to exist a few years later. Some members, such as Picabia and Schwitters, continued to incarnate the dada spirit in their work, but most became surrealists or developed new interests.

motto Tzara's declaration "Thought is made in your mouth," they strove to liberate language in particular.

Like their artist colleagues, the dada poets wished to stimulate thought and to achieve new states of consciousness by exploring their medium. While the dadaists valued scandal above all else, they also prized spontaneity. Both tenets derived from the fanatical devotion to freedom that characterized the dada adventure. Just as the dadaists were interested in the activity of the mind, so their preoccupation with spontaneity and the gratuitous reflected their fascination with prelogical experience and thought. In attempting to grasp our being in its primitive coherence (or incoherence), they strove to discover absolute psychological reality. In particular, the dadaists believed that the playful dimension of art offered a path to liberation. Although their poetry was necessarily verbal, it communicated on a primal level by means of images, emotions, and rhythms. Combining discursive and nondiscursive strategies, the dadaists discovered that words could be used to convey information situated outside the linguistic arena.

Critical Reevaluation

At first glance, many dada works seem impervious to critical analysis. For one thing, they contain an irrational streak that was intensified by the war and by the accompanying decay of social values. For another, their aesthetic strategies exploit the calculated misuse of convention. Employing the techniques of subversion, distortion, and disruption, dada compositions are fervently antilogical. Rejecting bourgeois values in life and in art, the dadaists considered logic to be a correlative of traditional authority. Like the latter, it was reviled for confining and debasing mankind. Because the dadaists deliberately cultivated scandalous behavior, their readers and viewers tended to react to them with hostility. Like the hapless members of the audience, contemporary critics assumed that the dada movement was a hoax. Dada was a purely destructive phenomenon, they declared, whose sole virtue was to have prepared the way for surrealism.

By contrast, the 1960s witnessed an enthusiastic neo-dadaist revival that permeated art, literature, music, and the theater. Inspired by the *Cabaret Voltaire* and similar ventures, performance artists invented a new postmodern genre: the happening. The latest in a long series of dada derivatives, including the Theater of the Absurd and abstract expressionism, the neo-dada movement shows no signs of abating. While current audiences have grown used to pop, op, and kinetic art, they continue to be scandalized by sound poets like Henri Chopin, visual poets like Fabio Doctorovich, junkyard sculptors like Robert Rauschenberg, aleatory composers like John Cage, and experimental choreographers like Alwin Nikolais. With the rediscovery of dada in a sympathetic light, the movement's positive aspects have become more apparent. The end of the twentieth century and the beginning of the twenty-first have witnessed a steadily increasing interest in dada and a series of benchmark studies by scholars such as Mary Ann Caws, J. H. Matthews, Michel Sanouillet, and Henri Béhar. Although the movement is as resistant to logical analysis as ever, it has acquired a certain respectability that threatens, ironically, to undermine its basic premises.

Despite its geographical distribution and diversity, the dada movement was amazingly cohesive. Although there was no central committee to regulate what transpired, there was widespread agreement about dada's methods and goals. Interestingly, André Breton's efforts to organize such a committee in 1922 spelled the death of Paris dada. Paradoxically, as Tristan Tzara explained to the Spanish critic Guillermo de Torre, dada's surprising unity stemmed from its lack of direction. Despite the absence of rules and regulations, the dadaists were united in their opposition to any form of authority. Dada was not an artistic credo, in any case, but a common set of values. Its adherents shared an adventurous lifestyle and a rebellious *joie de vivre*.

Reconstructing Reality

Outraged at the carnage of World War I, which they attributed to the stupidity of bourgeois politicians, the dadaists strove to wipe the slate clean so that they could begin all over. Reducing aesthetic expression to its fundamental elements—sound and typography in poetry; sound, gesture, and action in theater; color and line in art—they experimented with new, uncorrupted genres. Besides reconstructing reality to more accurately reflect modern experience, they adopted an anti-art stance that revolutionized artistic expression. Adopting as their

DANCE. Dance is broadly conceived as physical movement organized into patterns in time and space. Writings on dance grounded in the European intellectual tradition have tended to distinguish dance from other systems of organized movement (such as sport, military drills, synchronized labor, festival processions, and sometimes ritual) by identifying a dimension of conscious craft or artistry. The discipline of anthropology has shown that this distinction is not universal by investigating how organized human movement functions in different cultures, as well as how it relates to music, theater, pantomime, storytelling, and other kinds of performative behavior.

Dance in Intellectual Traditions

The idea of dance varies within intellectual traditions. Two ancient treatises serve as examples. Where ideas are treated as a function of language, and knowledge is derived from analysis of phenomena, the body is often written out of epistemological projects. Aristotle's *Poetics* (fourth century B.C.E.), for example, analyzes the plot structure, poetry, and ethical issues presented by fifth-century Athenian tragedies. The *Poetics* mentions only briefly the physical movement of the tragic chorus as a contributor to the effect (emotional or intellectual) of a theatrical experience or as a component in knowledge. In contrast, where cognitive processes, observation, and abstract thinking include bodily experience, physical movement is thought to generate and represent abstract concepts. The body and corporeal experience have a more prominent place in the formation of ideas. The Indian treatise *Natyasastra* (c. second century B.C.E. to second century C.E.), describes in meticulous detail how correct performance of hand gestures, eye movements, posture, steps, coordination with music, and posture will affect an audience's comprehension of the narrative and its meaning.

The *Poetics* and *Natyasastra* both assume dance to be inseparable from the performance of music, theater, poetry, and dress (including masks and makeup). Both treatises also assume that performance takes place in a ritual context, where form and content are already dictated by established conventions.

Even so, the relationship between movement, emotion, and cognition is conceptualized differently in each treatise, which suggests the need for continued attention to the intellectual formulations that define the interpretation of human movement.

Until relatively recently, dance has been on the margins of the modern Western intellectual tradition. Dance appears as an object of study in two particular domains of modern Western thought: aesthetic criticism and anthropology. Aesthetic criticism, emerging in eighteenth-century dictionary projects and then taking root in nineteenth-century philosophy parallel with the development of the romantic ballet, considers dance to be an artistic practice. As performance, dance is distinguished from folk, social, or ceremonial dancing (though it may represent them) and requires formal training. The idea of dance as a formalized performance tradition is usually associated with industrial economies, urban societies, and a culture's economically secure or educated classes. Appreciation of technical mastery and performance conventions is considered evidence of cultural sophistication or artistic sensibility; meaning is communicated primarily in the visual realm of symbolic representation, mimesis, and technique. Dance criticism is an intellectual project involving analysis of choreography, performers' skill, aesthetic conventions, historical developments in dance styles, innovations in genre, and the success of performances.

Aesthetic Criticism and Analysis of Culture

In dance practice, at the beginning of the twentieth century Sergey Diaghilev's (1872–1929) experimental productions with the Ballets Russes famously challenged the aesthetic sensibilities of classical ballet by introducing parallel feet, ambiguous story lines, a lowered center of gravity, and representation of "primitive" cultures. The creation of new forms of art dance, such as expressionistic modern dance in Europe after World War I and Butoh in Japan after World War II, deliberately defied ballet's conventions of beauty but stayed within the domain of artistic performance. Aesthetic criticism accounted for and dealt with the creation of new dance genres. The purpose of aesthetic criticism remains a greater understanding of established and new dance styles, choreography (recorded in notation systems such as Labanotation), individual performances, and criteria on which stage performances can be evaluated.

The emergence of anthropology as a scientific discipline in the mid-nineteenth century, parallel with aesthetic criticism's elevation of dance as an art form and tensions in experimentation with the form, expanded a Western idea of dance to non-Western cultures and societies, often treating dance practices as folk traditions. Franz Boas (1858–1942), A. R. Radcliffe-Brown (1881–1955), and E. E. Evans-Pritchard (1902–1973) included social dancing, ceremonies, and rituals in their field studies. Curt Sachs's *World History of the Dance* (English translation, 1937) offered an evolutionary and universalizing theory of world dance forms and was followed by Franziska Boas's collection, *The Function of Dance in Human Society* (1944). Though guided by the scientific commitment to objectivity and evaluation of empirical data, early anthropological studies interpreted dances from non-Western cultures as less aesthetically developed than those on the European stages and presented the

dance traditions of North Africa, the Middle East, India, Asia, and the Americas as more primitive forms of dance. The images provided by early anthropologists were reproduced as artifacts of exotic cultures in World's Fair exhibits and romanticized in exoticized, popular stage performances such as those of Ruth St. Denis (1879–1968) and Ted Shawn (1891–1972).

Since the 1960s and 1970s, this early anthropological work on dance has been significantly revised. The idea of dance, expanded to the broader notion of movement practices, allows for greater attention to the categories that define movement systems within individual cultures, nations, or societies, as well as for comparative studies. For anthropology and its related disciplines (folklore, ethnomusicology, ethnology, and ethnography), aspects of culture are revealed in dance practices. These disciplines also look at dancing itself as a culturally constructed activity that offers information about human behavior and, by extension, culture. These interrelated disciplines, along with methods drawn from sociology, kinesthetics, and linguistics, operate with a heightened sensitivity to the imposition of Western values and desires on non-Western, indigenous, or nonindustrial cultures.

Awareness of Western ethnocentric tendencies in dance research generated different categories of analysis and new questions. Researchers began to work toward a deeper understanding of the language, customs, social structures, and modes of thinking governing localized “dance events” before attempting to interpret them. Adrienne L. Kaeppler's work on Tongan dance in the late 1970s did much to advance the study of structured human movement in a specific cultural context. In the late 1980s Paul Stoller advocated the importance of a sensual dimension in ethnographic work. Major contributors to the assessment and development of anthropological approaches to human movement in the 1960s, 1970s, 1980s, and into the 1990s include Gertrude Prokosch Kurath, Anya Peterson Royce, Helen Thomas, and Judith Lynne Hanna.

The treatment of dance as a social practice and a form of expressive culture goes beyond descriptions of local customs, ceremonies, and movement idioms. Through proscribed methods of observation, data collection, documentation, interviewing, participant observation, and interpretation of data, these methods analyze how human movement relates to culture. Many studies analyze the function and meanings of dances or dancing in situated contexts. Others track changes in the performance and interpretation of dance styles such as the tango, rumba, samba, flamenco, and hula as they are transmitted across cultures, including in the inquiry of the mechanisms of transmission. Still other studies are concerned with visual and kinesthetic communication, or how dance communicates as a kind of language. Behaviors surrounding a dance performance, such as audience participation and dancers' preparation, may be as important as the performance itself. Religious beliefs, political restrictions, integration of dance with other performance forms, and vocabularies used by practitioners to describe movement are all significant to interpreting data gathered in fieldwork.

Theory and Praxis

In the 1990s and into the twenty-first century, the critical concerns of feminism, postmodernism, poststructuralism, new historiography, cultural studies, semiotics, race and ethnic studies, and queer theory have brought to light a wide range of issues that remain crucial in studies of dance and human movement systems, namely, how dance constructs or challenges gender and sexuality, how dance practices negotiate power relations, the effects of colonialism and cultural imperialism on dance practices, exoticization of cultural “others,” institutionalization of dance practices, how dance is used to demonstrate cultural or ethnic difference, cultural ownership and authenticity of dance idioms, dance as a display of national identity, dance in marketing and tourism, the effects of stylistic hybridity on individual or group identities, performers' agency, multiple meanings in complex symbol systems, how dance practices link to social class, dance as a means of building ideological consensus, and dance as a medium of resistance and social change.

The work of scholars such as Jane Cowan, Cynthia J. Novack, Ann Daly, Sally Ann Ness, Jane C. Desmond, and Susan Leigh Foster has opened interdisciplinary territory in the effort to address these and other issues in the study of human movement in culture and as a means of cultural production. Their theoretical work has broken down the notion that Western art forms are a model of aesthetic progress. Studies of female dancers in Egypt and Morocco in the 1990s, for example, have used methods from sociology to examine performance in social conditions that define both dance and dancer. More recent attention to these concerns through ethnographic methods has shown how social control was exercised in the costuming, movements, songs, and visual spectacle in women's dances at rallies for political candidates in Malawi.

Methods of inquiry rooted in anthropology take aesthetic conventions as culturally determined rather than as marks of progress or as by-products of modernity. Aesthetics can thus serve as an entry point, whether the project is to understand culture through human movement, or human movement through culture. Applying anthropological methods to the aesthetics of classical ballet reveals, for example, that control of the body and individuality against uniformity are Western values. Cross-cultural comparisons of ballet's reception as scandalous in non-Western cultures, in contrast, show how ballet performs a desire to expose and transcend the body in contrast to local movement practices that value a body's individuality and are grounded in everyday activities. Joann Kealiinohomoku's (1983) work on ballet as ethnic dance has been followed by studies of ballet's adaptation in non-Western cultures and of how ballet choreography structures desire in its narratives.

Information made available through anthropological approaches has also led to popular appropriations of local dance forms within new cultural or social contexts. National dance troupes, such as Ballet Folklórico de México, present indigenous social dances as commercial art with aesthetic aims, often with an educational mission. Ceremonial, ritual, and

communal dances may be taken out of context, adapted for the stage, and performed as a recuperation or preservation of “traditional” cultures. Scholars have interrogated the affected aesthetics, claims to national identity, and cross-cultural misinterpretations at work in such performances. While dance forms identified with specific cultures are staged for international audiences, the same dance forms might be reinterpreted and invested with new meaning within the home culture. Kathak and Bharata Natyam as popular dance practices in India, for example, have been analyzed as resistance to the colonial legacy and as recuperation of the precolonial past. Such analyses show how adaptations of traditional dances within a culture can be used to define national, cultural, or class identity.

Reciprocity between theory and practice is evident in other areas as well. By the mid-twentieth century, ethnic fusion forms such as Afro-Cuban-jazz combined Western dance styles with those of other cultures, sometimes raising issues of cultural authenticity and appropriation. Dance forms identified with ethnicity within a dominant culture, for example African-American dance, have been analyzed as distinct and unique and, conversely, as in the process of adapting or challenging movement idioms from the dominant culture. Contemporary Western “belly dance” has been shown to remain deeply bound to nineteenth-century European Orientalist fantasies.

Dance as Experience

Though their methods, goals, and objects of inquiry differ, both aesthetic criticism and anthropology deal at some level with the fundamental question: What is being communicated, to whom, and how? This disciplinary imperative takes the human body as an agent of communication in an interpretive community or as an embodied subject acted upon by social forces. The psychological experience of dancing is generally irrelevant to aesthetic criticism’s analysis of dance as a visible medium and tangential to research grounded in kinesthetics or linguistics (though audience response can be analyzed). Beyond Romanticism and notions of the sublime in art in the Western philosophical tradition, phenomenology has offered the most appropriate frame for the ephemeral qualities of human movement, as Maxine Sheets-Johnstone demonstrated in 1966. First-person descriptions of movement as a conduit for spiritual or metaphysical experience are, however, not easily adapted to Western modes of thinking and analysis, even in studies of mainstream liturgical dance.

Paranormal experiences, dissociational states, expressions of deep inner feelings, mystical experiences, and intense emotion generated by participating in a dance are usually associated with non-Western, nonindustrial, or indigenous cultures. Movement practices that produce such experiences are identified by terms such as shamanic dancing, trance dancing, exorcism, healing dance, voodoo, spirit possession, and ritual dance. In the Western stage dance tradition, such states may be represented in artistic performance, as with the expressionist choreography of Mary Wigman (1886–1973). Numerous dance forms in Western popular culture, for example Gabrielle Roth’s “Ecstatic Dance,” the appropriation of African dances as “healing dance,” and so-called “spiritual belly dance” do

emphasize altered states of consciousness and/or physical healing. Such practices—especially those that identify with practices of nonindustrial or non-Western cultures in their costuming, symbols, stories, and idioms—offer rich sources for cultural analyses. Though some work has been done to integrate experiences of altered states of consciousness into scholarly discourse, this area requires attention.

As suggested by the example of how the ancient Greek *Poetics* and Sanskrit *Natyasastra* frame dance, understandings of human movement are not uniform across cultures. In the early twenty-first century, collaboration among researchers from different intellectual traditions reveals differences in research methods, modes of interpretation, analytical vocabularies, descriptive categories, and goals in dance research. International conferences such as the Congress on Research in Dance (CORD) and the World Dance Association (WDA) insure that ongoing research will reflect a diversity of intellectual as well as movement systems.

DAOISM. Defining the features of Daoism (or Taoism) as one of the predominant trends in the history of Chinese thought involves accounting for its religious traits. As often happens outside the Western hemisphere—Buddhism may be the best-known example, but the same is true of Islam—the boundary between thought and religion in China is tenuous, unstable, and sometimes simply impossible to identify. Daoism, Buddhism, Confucianism, and other legacies have defined themselves as “teachings” (*jiao*) or “lineages” (*jia*, a word that primarily means “house” or “family”). The terms for “philosophy” and “religion” (*zhexue* and *zongjiao*) have become part of the standard Chinese vocabulary through late-nineteenth- and early-twentieth-century translations of Western books.

In the most general way, Daoism may be defined as a traditional form of thought and religion, based on some central notions, cults, and practices but never subject to systematization as a whole, and syncretic but at the same time self-contained—in the sense that it integrates many elements from other traditions, but frequently emphasizes its distinction from them. These basic features underlie different formulations of doctrinal notions and a large variety of practices, ranging from self-cultivation to communal rituals.

Daoism and Chinese Thought and Religion

Historically, the Daoist tradition has consisted of several schools, or rather lineages, usually based on one or more primary texts and associated with one or more divine or semi-divine beings. As a whole, these lineages and corpora have represented the higher but “unofficial” form of native religion in China. This definition points to the complexity of questions that surround the status of Daoism and its relation to Chinese religion; it is also relevant to its relation to Chinese thought, for the status of Daoism as a religion was often defined with reference to ideas and notions formulated in its early doctrinal texts.

In relation to the different forms of common religion in China, the stated purpose of Daoism is “transforming” (*hua*) people, in the sense of educating them to venerate pure deities that impersonate the Dao, instead of joining other cults—those defined as “vulgar” (*su*) or “illicit” (*yin*), which often included sacrifice and involved the assistance of spirit-mediums. The continuous incorporation of new deities and ritual forms, resulting from the interaction of Daoism with local communities and cults, upgraded these deities by admitting them into the “correct” (*zheng*) hierarchy of gods and of amending them by integrating them into the proper way of communicating with the divine world. As has often been noted, the spirit-medium, and not the Confucian officer or the Buddhist monk, was the first competitor of the Daoist priest within local communities.

The relation between Daoism and Buddhism has been fertile, with reciprocal borrowings of doctrinal formulations, theological elements, technical terminology, and forms of practice. Even though Buddhist polemical authors have often accused Daoists of appropriating Buddhist notions and topoi and even of plagiarizing their scriptures, these disputes have usually occurred in the surroundings of the imperial court. In that milieu, providing evidence of doctrinal preeminence in order to obtain official patronage was more important than highlighting any shared ground. Daoism provided Chinese Buddhism with some of that ground in the early stages of its development and, in turn, drew from it in later times. For the average faithful, anyway, subtle doctrinal distinctions surely were not the main concern, and Daoist or Buddhist deities could equally be addressed as suitable and practicable.

Daoism’s relation to Confucianism—the dominating influence behind the system of social norms, upheld by the central government, maintained by the local officers, supported by the literati, and transmitted through education—has been complex. Classical Confucianism focuses on the social aspects of human life. Daoism is by no means uninterested in these issues, but its views are based on different doctrinal grounds. Despite this, and with exceptions with respect to Neo-Confucianism, the contrast between Daoism and Confucianism has not primarily involved their philosophical views (the respective claims in this respect were known and quietly acknowledged by both), but their religious aspects. As Anna Seidel has noted (1997, pp. 39–41), although Daoism is the higher form of Chinese native religion, it has always occupied a position subordinate to the imperial—that is, official—cults. For the Confucian officers, the Daoist priests represented spiritual powers over which they had no control. Replacing the state ceremonies to Heaven and Earth, or to paragons of Confucian virtue, with rituals performed by Daoist priests and addressed to the divine personifications of the Dao, would be equivalent to granting Daoism an official role in the administration of the empire. For this reason, the Confucian officer and literatus did not hesitate to acknowledge Daoism only in its philosophical, mystical, or literary aspects, and even to regard it as equal to common religion.

The Roots of Daoism

The main early Daoist text is the *Daode jing* (Scripture of the way and its virtue), a short work consisting of aphorisms attributed to Laozi (the Old Master, or Old Child). Although some scholars have suggested that other sources might be slightly earlier, virtually all movements and lineages within Daoism consider this as the founding scripture of the entire tradition, even though they may venerate their own texts and their own founders. Another early work, the *Zhuangzi* (Book of Master Zhuang), has provided Daoism with doctrines, notions, and technical vocabulary throughout its history.

The present general consensus among scholars is that the *Daode jing* was not written by a single author, and that Laozi is the appellation of the symbolic Daoist sage whose doctrines are reflected there. The text appears to have existed in a form close to the present one between 350 and 300 B.C.E., but many of its statements likely derive from oral traditions whose dates are

impossible to determine. The *Zhuangzi*, which is deemed to be one of the masterpieces of Chinese literature, is different from the *Daode jing* from the point of view of its formal features and consists mainly of stories, anecdotes, and reflections. Zhuangzi himself probably authored the seven so-called Inner Chapters in the late fourth century B.C.E., with the other portions dating from one or two centuries later. Despite differences in emphasis, the two texts present the same view of the Dao and its relation to the world, outlined below on the basis of the *Daode jing* (references in parentheses are to the number of sections in this text).

The Dao. The word *dao* has two main meanings, “way” and “method.” These two meanings refer, respectively, to the way in which something is or the way it functions, and to the way of doing something (including the extended meaning of “practice” in a religious sense). The early Daoist texts are the first ones to use this word to mean the Absolute (Robinet, p. 26). For the *Daode jing*, the Dao has no name and is beyond any description or definition; the word *dao* itself is used only because one “is forced” to refer to it (25). The Dao is unknowable, has no form, and therefore does not undergo change (41), is “constant” (1), and is “invisible, inaudible, and imperceptible” (14). The two principles of Non-being (*wu*) and Being (*you*) are contained within it. Yet the Dao, in spite of its being “indistinct and vague” (*huanghu*), contains an “essence” (*jing*) that is the seed of the world of multiplicity (21). Under this second aspect—which can be distinguished from the previous one only within the domain of relativity—the Dao is the “origin” of the world and its “mother” (1).

The faculty that the Dao has to give life to the particular objects is its *de*, or “virtue,” and is described as “a mystery within a mystery” (1). The *Daode jing* outlines this process, which happens spontaneously and has no cause or purpose, in a famous statement: “The Dao generates the One, the One generates the Two, the Two generate the Three, the Three generate the ten thousand things” (42). According to this formulation, which like all similar outlines found in Daoist texts is meaningful only from a relative point of view, the Dao first generates the One (*yi*), the principle of the unity of existence in which the individual entities defined by forms and names are included, but have not yet emerged. The One differentiates itself into the two polar and complementary principles, Yin and Yang. The Three is the product of the joining of Yin and Yang; it represents the One reestablished at the level of each individual entity. The “ten thousand things” (*wanwu*) are the sum of entities generated by the joining of Yin and Yang. The sentence of the *Daode jing* quoted above therefore formulates both a metaphysics, by arranging the single items in a hierarchical sequence designed to show their ultimate origin in the Dao, and a cosmogony, which does not take place once and for all *in illo tempore* but is continuously reiterated within each of the cosmic cycles that the Dao brings into existence.

Both the Dao and the manifested world model themselves on *ziran* (25), a term that literally means “to be so of its own.” In reference to the Dao, the principle of *ziran* means that the Dao only regulates itself upon itself; in reference to the world generated by the Dao, *ziran* means that there is no ultimate reason for things being as they are: the Dao generates the “ten

thousand things,” but while for the relative the Absolute is its “mother,” for the Absolute the relative does not even exist. Aside from generating the world, therefore, the Dao does nothing else: it does not act in it, it is not affected by the transformation, decay, and disappearance of the forms it generates, and it neither rejoices in nor is hurt by what is, in a relative sense, good or bad.

The saintly person. Just as the Dao does nothing, so is “non-doing” or “non-action” (*wuwei*) the way to attain to it. Non-action is the practice of *ziran* in the human world: one fully responds to circumstances and events, doing no more and no less than what is required, without taking the initiative unless there is an immediate need to do so, and without being moved by personal desire, interest, or advantage (3, 19, 34, 37, 57). In particular, there is no need of striving to perform what is “good,” and even less so of attempting to impose it on others, for “when everyone knows the good as good, evil is already there” (2).

The person who has “returned to the Dao” (28, 40, 52) is called in the *Daode jing* the *shengren*, a term that in a Daoist context may be translated as “saint” to distinguish him from the Confucian “sage.” As the highest realized human being who has achieved liberation in life, the Daoist saint has transcended the limitations of individuality and form; he continues to remain in the world of multiplicity until he has completely fulfilled his function in it, but from an absolute point of view, which is the one in which he constantly dwells, his self-identity is already null, for he is identified with absolute principle. Death for him, therefore, is not even a change of state, for he has attained the state in which no change can occur. In the human world, he “practices the teaching without words” and “makes it possible for the ten thousand things to function, but does not start them” (2). He does not take an active leading role in society but benefits his fellow human beings by his mere presence. This is so even when the saint is the ruler, a figure to whom the *Daode jing* devotes much attention. In that position, the saint governs according to the principle of non-action, and that is how he ensures the well-being of his country and his subjects. In the ideal description given by the *Daode jing*, no one even needs to know who the ruler is. “Therefore the saint in his government empties their heart [i.e., their mind], fills their belly, weakens their will, and strengthens their bones. He always wants people to be without knowledge and without desires.” He does so because “not exalting the worthy prevents people from competing, not valuing goods hard to obtain prevents people from becoming thieves, and not seeing desirable things prevents the people’s heart from becoming confused” (3).

Revelations and Textual Corpora

To a significant extent, the history of Daoism may be seen as a continuous restatement of the principles enunciated in the early founding texts. To an equally significant extent, its development has been marked by the adaptation to varying historical circumstances, the response to the needs and demands of different social groups, and the incorporation of notions, beliefs, cults, and practices derived from other trends of thought and religion. These multiple factors gave rise to the

idea, apparently unknown to the early Daoist thinkers, that the Dao may appear under the guise of gods or other divine beings, and may through them take an active role in the world, in particular by granting revelations to some adepts.

The first Daoist revelation. The process that led, in the second half of the second century C.E., to the formation of the first major Daoist religious movement can only be understood in the light of the politico-religious ideals of ancient China, synthesized in the notion of Great Peace (*taiping*) and shared by different traditions including Confucianism. At the center of that process was the deification of Laozi, now represented not only as the sage who expounds the metaphysical doctrines of the *Daode jing*, but also as a messiah who embodies the Dao and reappears at different times either as a sage counselor of political rulers, or as the inspirer of religious leaders (Seidel, 1969). Scholars have pointed out the association among the spread of beliefs concerning Lord Lao (Laojun, i.e., Laozi in his divine aspect), the cults offered to him outside and even within the imperial court in the second century, and the political decline of the Han dynasty (202 B.C.E.–220 C.E.). Based on the notion that the emperor symbolized and guaranteed the balance between Heaven and Earth, the weakening of political power at the end of the Han, and the concurrent natural disasters and social unrest were deemed to reflect a rupture between the supernatural and the human world. Hence the millenarian beliefs and the messianic wait for a Savior—a new incarnation of Lord Lao who would restore Great Peace and confer the Celestial Mandate (*tianming*) to a new ruler.

In one of his transformations, Lord Lao appeared (in 142 C.E., according to the traditional date) to a healer, Zhang Daoling, in the southwestern region of Sichuan. Lord Lao established a covenant (*meng*) with Zhang Daoling, revealing to him the teaching of Orthodox Unity (*zhengyi*) and bestowing upon him the title of Celestial Master (*tianshi*). This revelation, which has been dubbed “the New Testament of the Dao” to distinguish it from the teaching of the *Daode jing*, is at the origin of the Way of the Celestial Masters (*Tianshi dao*), a priestly lineage that continues to exist in the present day (the current Celestial Master resides in Taiwan). The early Celestial Masters established a theocratically based enclave in Sichuan that maintained its political semi-independence for several decades, until the end of the Han period. Its purpose was not to terminate and replace the imperial power; rather, the intent of Zhang Daoling and his successors was to realize the kingdom of the Great Peace on earth until a new sovereign would receive the mandate to rule from Heaven.

The administrative structure of the early Way of the Celestial Masters was based on that of the Han empire; both in turn reproduced on earth the bureaucratic ordering of Heaven. Since that time, Daoist texts have often represented Heaven as an administration divided into ministries and offices, with a hierarchical classification of primary deities (often called “emperor,” *di*) and a host of ancillary gods. The same bureaucratic features are displayed in Daoist ritual, which is based in part on the forms established by the early Way of the Celestial Masters: requests of audiences in the courtly halls of celestial palaces,

arrangement of the deities on seats arrayed according to their rank, and written petitions delivered to the gods.

The Three Caverns. The diaspora of the Celestial Masters’ communities after the end of the Han resulted in the expansion of the new religion to other parts of China. Its spread in Jiangnan, the region south of the lower Yangzi River, was one of the prerequisites for the formation of two other major corpora of Daoist doctrines, texts, and practices in the second half of the fourth century. The representatives of the religious legacies of Jiangnan responded to the newly imported cults by reformulating and codifying some aspects of their own traditions in ways that admitted elements of the practices of the Celestial Masters, but were mainly based on the local traditions, which included meditation, alchemy, self-cultivation practices, and various methods for communicating with the gods and expelling demons. The first corpus, known as Shangqing (Highest Clarity), derived from revelations that occurred from 364 to 370 C.E. and was centered on meditation practices; the second, known as Lingbao (Numinous Treasure), derived from revelations that occurred between circa 395 and 405 C.E. and was based on communal ritual. These two codifications clearly define, for the first time, the two main poles of the Daoist religious experience, namely inner, individual practices on the one hand, and collective practices for the community of the faithful on the other.

The relations among these traditions were formally codified in the early fifth century in the system of the Three Caverns (*sandong*). Its main purpose was to hierarchically arrange the different legacies of Jiangnan, assigning the higher rank to Shangqing, the intermediate one to Lingbao, and the lower one to other earlier and contemporary traditions. Around 500 C.E., the corpora associated with the *Daode jing*, the *Taiping jing* (Scripture of Great Peace), alchemy, and the Way of the Celestial Masters were assigned to the so-called Four Supplements (*sifujin*). The Three Caverns also provided the formal schema for other important aspects of Daoist doctrine and practice, including the ordination stages of the Daoist priest (*daoshi*) and the arrangement of scriptural and other writings in the collections of Daoist texts (*Daozang*) that began to take shape from the early fifth century.

This model continued to perform this function even after the contours of Daoist religion were reshaped by various new revelations and codifications during the Song period (960–1279) and later, and by the creation in the early thirteenth century of Quanzhen (Complete Reality, or Complete Perfection), a monastic order that is, along with the Way of the Celestial Masters, the main branch of present-day Daoism.

Cosmos and Gods

The cosmos generated by the Dao and the heavens inhabited by deities that personify the Dao are intermediaries between the Absolute and the human world. These two domains overlap to a significant extent, for certain deities and certain features of the cosmos correspond to each other. Both of them play an essential role in the various ways that Daoism provides for “returning to the Dao” (*fandao*), which are addressed either to the single individual or to the community as a whole.

Correlative cosmology. The features and workings of the cosmic domain are explicated in Daoism largely by means of the language and images of the standard Chinese cosmological system. This system, often referred to as “correlative cosmology” by scholars, is based on several patterns of emblems (*xiang*) such as Yin and Yang, the five agents (*wuxing*), and the eight trigrams and sixty-four hexagrams of the *Book of Changes* (*Yijing*). These emblems function as categories to which the single entities or phenomena can be assigned. The five agents, for instance, emblemize the modes or states in which the one Original Pneuma (*yuanyi*) appears in the cosmos, represented by Wood, Fire, Soil, Metal, and Water. Directions of space, segments of time cycles, numbers, colors, planets, viscera of the human body, musical notes, and so forth can be assigned to one of these emblematic categories in order to define not only the relations that occur among the elements of a series, but also those that occur among the different domains. Wood, for instance, is associated with the east, spring, the numbers 3 and 8, the color green (or blue), Jupiter, the liver, and the note *jiao*. The purpose of correlative cosmology, therefore, is not so much to explain what causes an entity to exist or a phenomenon to occur as it is to define its relation to other entities and phenomena. An important corollary to this view is that an event or action happening or performed in one domain may affect the corresponding components in another domain according to the principle of “stimulus and response” (*ganying*), by which things of the same “category” (*lei*) influence each other.

Correlative cosmology, which took shape as a comprehensive system between the third and the second centuries B.C.E., is not tied to any specific intellectual or religious legacy and is the result of an effort to create a comprehensive analytic and synthetic system with contributions both by thinkers and by specialists of various traditional sciences, including diviners, astronomers, and physicians. Daoism is one of several traditions that have drawn upon correlative cosmology to formulate its views and to frame its techniques or practices. In Daoism, correlative cosmology serves not only to explicate the functioning of the cosmos, but also to illustrate the notion that single entities and phenomena ultimately originate from the Dao and that the different forms in the world of multiplicity are governed by the One, the principle of the unity of the cosmos. At the same time, the emblems of correlative cosmology serve to regulate the process of “returning to the Dao” through the support of a microcosmic framework—the ritual area, the alchemical laboratory, or the human being itself. The ritual area, for instance, is arranged so as to correspond to the cosmos and its temporal and spatial configurations (Lagerwey, 1987, pp. 3–48). In alchemy, the stages of the compounding of the elixir reproduces in a reverse sequence the cosmological configurations that intervene between the absolute Dao and the domain of relativity.

Communicating with the gods. The supreme Daoist deities are the Three Clarities (*sanzqing*), each of whom rules over one of the many heavens distinguished in Daoist cosmography. They are associated with different precosmic eras and are at the origin of the textual corpora associated with the Three Caverns. Above them some traditions place the Celestial Worthy

of Original Commencement (*Yuanshi tianzun*), who dwells in the supreme Great Canopy Heaven (*Daluo tian*). The unity of the cosmos is represented in a deified form by the Great One (or Great Unity, *Taiyi*); he resides at the symbolic center of the cosmos in the Northern Dipper (*beidou*), whose apparent rotation distributes Original Pneuma to the regions of space and sustains the cycles of time. Several other gods, such as the “emperors” of the five directions (north, south, east, west, and center), also represent cosmological principles. In addition, a multitude of deities, most of whom are the expression of local cults, contribute to form a pantheon with indefinite boundaries that takes different forms according to place and time.

The highest gods, or their representatives, reveal texts, teachings, and practices. The scriptures belonging to the Shangqing and Lingbao corpora are deemed to have taken shape from graphs coagulated from Original Pneuma, or from sounds generated by its vibration, in the early stages of the formation of the cosmos. Those graphs constitute the prototypes of the revealed scriptures, which at first are transmitted from one god to another, undergoing various stages of materialization until they are delivered to humans by a divine being. Just as the gods grant revelations mostly in the form of scriptures, and consistently with the bureaucratic metaphor mentioned above, the typically Daoist form of communicating with the gods is by writing. In Daoist ritual, the priest delivers a “memorial” (or “statement,” *shu*) to the deities to announce that a ceremony will be performed in their honor, declare its purpose, specify its program, and list the names of those who sponsor it. The so-called talismans (*fu*, a word that corresponds almost exactly to Greek *symbolon*) are traced on paper or other supports, including air, in graphs intelligible to the gods. Like the revealed scriptures—some of which, in fact, are deemed to have evolved from them—the talismans have a counterpart in Heaven, and thus serve to identify and authenticate their possessor. Talismans confer power to summon certain deities and to control demons, but they also protect space and heal illnesses; they are worn on one’s body, affixed at the four directions, placed along the path that leads to one’s dwelling, or made into ashes and drunk with water. Another important ritual object that has a written form is the “register” (*lu*), a formal document of investiture that the Daoist priest receives at various stages of his ordination and that defines his rank, the rites that he may perform, and the deities and spirits over which he has control.

The Human Being

Despite significant variations among the different traditions, the basic view of the human being and its potentialities in Daoism reflects its doctrinal principles. Many texts devoted to this subject state that full comprehension of their teachings grants the status of Real Man, or Perfected (*zhenren*). The related practices do not consist in a process of “increase” or “becoming perfect” but vice versa in reducing what obstructs one’s potential for realization, according to the principle of the *Daode jing* that “practising the Dao is called reducing; reduce and then again reduce and thereby attain to non-doing” (sec. 48). Some authors of texts of inner alchemy were aware of the ambiguity involved in the very notion of “doing” a practice in order to attain the state of “non-doing” and emphasized that

the practice operates within the domain that the adept is called to transcend; its final purpose is to reveal the limitations of that domain.

The heart (*xin*) is the symbolic center of the human being. It is the residence of spirit (*shen*) and corresponds to the Northern Dipper in heaven. Just as Oneness takes multiple forms in the cosmos, so the center of the human being reappears in multiple locations. The most important are the three Cinnabar Fields (*dantian*, immaterial loci in the regions of the brain, the heart, and the abdomen) and the five viscera (*wuzang*, namely liver, heart, spleen, lungs, and kidneys). The three Cinnabar Fields and the five viscera represent, respectively, the vertical and horizontal dimensions of the cosmos within the human being.

According to some traditions within Daoism, these and many other loci of the body are also residences of an inner pantheon of major and minor gods. The most important among them correspond to those that dwell in Heaven and perform multiple related roles: they personify the formless Dao or impersonal notions such as Yin and Yang, allow the human being to communicate with the gods of the outer pantheon, and administer the body and its functions. Several texts describe meditation practices in which the visualization of inner deities is combined with channeling essences and pneumas to the residences of the inner gods in order to provide them with nourishment. From the Tang period, these practices were largely replaced by other methods of contemplation and introspection influenced by Buddhism, but the inner gods have continued to perform an important function in ritual when they are summoned forth by the priest in order to submit the memorial to the gods in Heaven.

Alchemy, in its “inner” form (*neidan*), framed its practices in part by drawing from meditation methods and from techniques for “nourishing life” (*yangsheng*). The latter term refers to a large variety of methods that share a physiological foundation, including *daoyin* (a form of gymnastics that is one of the precursors of modern *taiji quan*), breathing, and sexual practices. Using the same word that other sources apply to the cults of common religion, several alchemical texts qualify those techniques as “secular” or “vulgar” (*su*); as other traditions within Daoism do with deities and rites, alchemy incorporates elements of those techniques but grafts them onto its own doctrinal background.

In alchemy and several other traditions, the purpose of the practice is to acquire transcendence or “immortality.” In religious imagery, in both its mystical and popular aspects, “immortality” is a state attained by superior beings, often entirely legendary, through their practices. For others, “immortality” consists in undergoing transformation, in the literal sense of “going beyond the form” and returning to the unconditioned state.

DARWINISM See Evolution

DEATH. The idea of death—the irreversible end to life—has preoccupied, fascinated, and struck fear into human beings through the millennia. In the early twenty-first century, artists continue to sing about death, write about death, and depict it in paintings and photographs. Religious leaders are still talking about how to live a meaningful life in the face of death’s inevitability. Governments go to war in the name of peace and the defense of the living, causing death on a massive scale. Ethicists and activists argue over the right to die, the right to live, the right to kill. Medical personnel strive to prevent it, are often present at the bedside of the dying, and pronounce when death has occurred. Biologists and physiologists puzzle over when it occurs and how it can be measured. Counselors, therapists, relatives, and dear friends help those

who are dying make peace with their death, and help those left behind to live on. Young children wonder what has happened to their loved ones, and families struggle with their grief.

Defining Death

Death is clearly a part of life—every day. And yet, the word defies simple definition, because there are so many aspects to death and so many perspectives. A 1913 edition of *Webster's Dictionary* defined death as “the cessation of all vital phenomena without capability of resuscitation, either in animals or plants.” The current *Concise Oxford Dictionary* defines death both as “dying” (a process) and as “being dead” (a state). As intoned in the Old Testament of the Bible, “All flesh is as grass” (Isaiah 40:6–8). The body dies but in the religious and philosophical traditions of many observers, the soul or spirit lives on.

The Roman Catholic Church, for example, advances the thought that death is the “complete and final separation of the soul from the body.” The church, however, concedes that diagnosing death is a subject for medicine, not the church. In the Zen Buddhist and Shintō religious traditions, mind and body are integrated, and followers have difficulty accepting the brain-death criteria that are now common in Western medical and legal circles. For some Orthodox Jews, Native Americans, Muslims, and fundamentalist Christians, as long as the heart is beating—even artificially—a person is still alive.

Advances in life-supporting technologies in the 1960s spawned the growth of medical ethics as a distinct field, and a new definition for physiological death was needed. For centuries death was indicated by the absence of a pulse or signs of breathing, but new technologies, including the respirator and heart–lung machine, made it possible for physicians to artificially maintain heart and lung function, blurring clear signs of an individual's death. In the United States many states have adopted legislation recognizing brain death—the loss of brain function, which controls breathing and heartbeat—as the certification of death. Canada, Australia, and most of the nations of Europe and Central and South America have broader definitions for death: either loss of all independent lung and heart function, or the permanent, irreversible loss of all brain function.

From a physiological standpoint, somatic death—the death of the organism as a whole—usually precedes the death of individual organs, cells, and parts of cells. The precise time of somatic death is sometimes difficult to determine because transient states, such as coma, fainting, and trance, can closely resemble the signs of death. Several changes in the body that occur after somatic death are used to determine the time of death and circumstances surrounding it. The cooling of the body, called *algor mortis*, is mainly influenced by the air temperature of the surrounding environment of the body. The stiffening of the skeletal muscles, called *rigor mortis*, begins from five to ten hours after death and ends in three or four days. The reddish-blue discoloration that occurs on the underside of the body, called *livor mortis*, is the result of blood settling in the body cavity. Shortly after death, blood clotting begins, along with autolysis, which is the death of the cells. The

decomposition of the body that follows, called putrefaction, is the result of the action of enzymes and bacteria.

Bereavement, Grief, and Mourning

The word *bereavement* comes from a root word meaning “shorn off” or “torn up.” It suggests that one has been deprived or robbed, dispossessed, left in a sad and lonely state. Bereavement is the state of being in which a person has suffered the death of a relative or friend.

Grief refers to the total range of emotions humans feel in response to a loss. The word suggests negative responses, including heartbreak, anguish, distress, guilt, shame, and thoughts of suicide. Grief also encompasses feelings of relief, anger, disgust, and self-pity.

Mourning is the expression of grief over someone's death. It is the process by which people incorporate the experience of loss into their ongoing lives. In mourning, a person searches for answers: How do I carry on in life? How do I survive this? Approaches to mourning are culturally prescribed: Each world culture has certain cultural “rules” for mourning in an appropriate manner. Mourning today is less formal than it was in the past, and so-called modern cultures are less formal in their rituals for mourning than traditional cultures.

Why Must People Die?

A number of answers to this question have been proposed by philosophically oriented biologists such as Sherwin B. Nuland and Basiro Davey and colleagues. The results of tissue cultures indicate that cells are “preprogrammed” by their genetic code to cease the dividing processes after a certain number of divisions have occurred, and then die. A further argument proposes that death is adaptive at the population level, ensuring that individuals do not compete with their offspring for scarce resources and instead channel precious energy into reproduction. Research accounts of the biochemical changes that occur in cells as they age support both these theories and a more straightforward “wear and tear” argument, indicating that death on a biological level can be understood as a combination of a number of factors.

These biological explanations for the occurrence of death focus on the process of aging. The death of younger people, especially one's own child, opens up broader philosophical questions that may be even more difficult to answer: “Why did my baby die, God?” is one of the ways human beings ask this type of question. If God truly is in his heaven and all is right with the world, why do babies die? Human beings have struggled with this type of question through the millennia, and there do not appear to be any definitive, widely accepted answers. Individuals seem to come to grips with such questions in an extraordinarily varied range of ways.

Historical Perspectives

In 1900 the average life expectancy at birth in the United States was 47 years, and this figure increased to a record high of 77.2 years a century later. The gap between female and male life expectancy peaked in 1979 when women outlived men an average of 7.8 years. By 2001 the gap was down to 5.4 years.

That year, women lived an average of 79.8 years and men an average of 74.4 years. White males averaged 75.0 years and black males 68.6 years; white females averaged 80.2 years and black females 75.5 years (Arias and Smith).

In 1900 more than half of the deaths involved young people, age fourteen and younger. By 2001, only 1.6 percent of the total reported deaths occur among young people. Heart disease and cancer are the leading causes of death in the early twenty-first century, together accounting for more than half of all deaths in the United States each year. In order, the top fifteen leading causes of death, comprising fully 83.4 percent of all U.S. deaths in 2001, were: heart disease, cancer, stroke, chronic lower respiratory diseases, accidents (unintentional injuries), diabetes, influenza and pneumonia, Alzheimer's disease, kidney disease, septicemia (infection from microorganisms), intentional self-harm (suicide), chronic liver disease and cirrhosis, assault (homicide), hypertension, and pneumonitis (inflammation of the lungs) due to solids and liquids.

In the past century the experience of death has changed from a time when the typical death was rapid and sudden, often caused by acute infectious diseases such as tuberculosis, typhoid fever, syphilis, diphtheria, streptococcal septicemia, and pneumonia, to a time when the typical death is a slow, progressive process. In 1900 microbial diseases, often striking rapidly, accounted for about 40 percent of all deaths; in the early 2000s accounted for only about 3 percent. In sum, in the past century U.S. society has evolved from one in which many children and young people died to a society in which death has become increasingly associated with older-aged people. The U.S. infant mortality rate reached a record low level in 2001: 6.8 deaths per 1,000 live births.

Observers of this phenomenon have proposed a theory of epidemiologic transition, a three-stage model that describes the decline in mortality levels and the accompanying changes in the causes of death that have been experienced in Western populations. The first stage, called the Age of Pestilence and Famine, is characterized by high death rates that vacillate in response to epidemics, famines, and war. Epidemics and famines often go hand in hand, because malnourished people are susceptible to infectious diseases. The second stage, the Age of Receding Pandemics, describes a time in which death rates decline as a result of the improved nutrition, sanitation, and medical advances that go along with socioeconomic development. The third stage, labeled the Age of Degenerative and (Hu)man-Made Diseases, describes the period in which death rates are low (life expectancy at birth exceeds seventy years) and the main causes of death are diseases related to the process of aging. The biggest challenge to this theory comes from the emergence of new diseases (such as AIDS/HIV, Legionnaires' disease, and Lyme disease) and reemergence of old infectious diseases (such as smallpox and malaria) in the latter part of the twentieth century. HIV/AIDS, for example, took the lives of between 1.9 million and 3.6 million people worldwide in 1999.

According to the Population Reference Bureau, life expectancy at birth for the world's population at the turn of the twenty-first century was 67 years—69 years for females, 65 years

for males. In more developed countries life expectancy averaged 76 years—79 years for females, 72 years for males. In less-developed countries, life expectancy averaged 65 years—66 years for females, and 63 years for males.

Death throughout Art History

Death, an emotionally wrenching idea, has been both a subject for artists and an incentive for artistic production throughout history. Perhaps as much as, perhaps more than, any other subject, artists have dealt with death, dying, the threat of death, escape from death, thoughts of death, and preparation for death through the centuries.

The importance of death as a concept in ancient Egyptian culture is clearly seen in the creation of the pyramids and other burial artifacts. Ancient art in Greece focused on materialistic representations of life in an ideal state, including the physical perfection of its mythological heroes. This can be interpreted as art affirming life as the Greeks experienced it or desired life to be, and the cultural rejection of the finality of death. Looking at art in the Christian tradition with its focus on the death of its central figure, some art historians have described Christianity as a highly developed death cult; the idea of death, mediated through works of Christian art over the centuries, is ultimately affirming of life. Many artists in the period of the Enlightenment of the eighteenth century were commissioned to work in service to the lay aristocracy and eventually the merchant class. The social hierarchy in this time was reinforced through highly developed techniques in portrait painting. Portraiture, seen as self-constructed identity through painting, constitutes a large segment of traditional Western art. Thus, art during the Enlightenment was closely linked to the idea of personal mortality. Major themes in modern art include the importance of self-expression in the face of the forces of mass conformity and antihumanist ideas. The universal theme of mortality is seen in many modern works, and death remains firmly established as a central theme in contemporary art, though the themes surrounding the concept of death are not as likely to reflect religious, romantic, or metaphysical concerns as they were in earlier historical periods.

No one can predict future directions in artists' responses to death, but it is most likely that humankind will continue to look to these visionaries to both document and inform our thinking. Mourners in Greece during the early fifth century were depicted striking their heads, tearing out their hair, beating their breasts, and scratching their cheeks until they bled. Today, many find solace from the largest ongoing community arts project in the world, the AIDS Memorial Quilt. In both instances, artists helped society commemorate the lives of deceased loved ones, and they supported the living in their efforts to find meaning and the strength to endure their tragic feelings of loss.

The Psychology of Dying

The American psychiatrist Elisabeth Kübler-Ross developed a five-stage model of the psychology of dying and grief. In her book titled *On Death and Dying* (1969), she proposed that in response to the awareness of their impending death, individuals move through stages of denial, anger, bargaining, depression,

and acceptance. Other authorities note that these stages do not occur in any predictable order, and feelings of hope, anguish, and terror may also be included in the range of emotions experienced.

Bereaved families and friends also go through stages from denial to acceptance. Grief can begin before a loved one has died, and this anticipatory grief helps lessen later distress. During the next stage of grief, after the death of the loved one, mourners are likely to cry, have trouble sleeping, and lose their appetite. Some feel alarmed, angry, or wounded by being left behind. After formal services for the deceased are over and conventional forms of social support end, depression and loneliness often occur.

Feelings of guilt are quite common, and in some cases individuals think seriously about taking their own life for somehow failing the loved one. This is especially true in response to the loss of a child. Though people often talk about healthy and unhealthy grief, it is very difficult to measure emotional pain in any precise way or advise how long one's grief should last. Many clinicians believe that those who abandon their grief prematurely are living in denial and make healing more difficult; but, on the other hand, it is also possible to become mired in despair. The death of a loved one, thus, threatens to take all the life out of the person who feels left behind.

Research on attitudes toward death and anxiety about death has been conducted mostly by social scientists around the world. There are more than one thousand published studies in this area, and four broad themes emerge from the findings:

1. Most people think about death to some extent and report some fear of death, but only a small percentage exhibit a strong preoccupation with death or fear of death.
2. Women consistently report more fear of death than men, but the difference in levels of fear is typically minor to moderate from study to study.
3. Fear of death does not increase with age among most people.
4. When considering their own death, people are more concerned about potential pain, helplessness, dependency, and the well-being of loved ones than with their own demise.

Death Education

The death-related experiences of most Americans and people in other Western and industrialized societies in the early twenty-first century are markedly different from how people experienced death a century ago. At present, death is much more likely to take place in a medical facility under the control of well-trained strangers. In the past, death more commonly was an intimate family event and usually took place at home with family members caring for the dying person. Loved ones were most likely present when the individual passed, and young children witnessed the events surrounding the death. The loved one's body was washed by the family and prepared

for burial. A local carpenter or perhaps even family members themselves constructed a coffin, and the body lay in state for viewing by family and friends in the parlor of the home. Children kept vigil with adults and sometimes slept in the room with the body. The body was later carried to the gravesite, which might be on the family's land or at a nearby cemetery. The local minister would be present to read Bible verses and say goodbye, and the coffin would be lowered and the grave covered, perhaps by relatives.

In the early 2000s, death has been sanitized and separated from everyday lives. It is likely to happen in a high-tech, multilayered bureaucratic hospital. The body is soon whisked away from view. It is carefully prepared for viewing and subsequent burial by professionals with an artistic flair, and placed in an elaborate and expensive casket. The body is then carried via a dazzling motor coach to the cemetery for interment in a carefully draped burial plot giving little hint that the loved one will actually end up in the earth.

The choreography of the modern death and burial process has become so elaborate that many people react in frustration and dismay and seek more simple, emotionally connected experiences of death. At the same time, the field of death education has grown as colleges and universities create courses on death and dying. These courses include both formal instruction dealing with dying, death, and grief, plus considerable time invested in talking about the participants' personal experiences with death. These developments can all be interpreted as parts of a movement toward bringing death back into people's lives, as a painful and puzzling event to be explored, experienced, and embraced rather than denied and avoided.

DEATH AND AFTERLIFE, ISLAMIC UNDERSTANDING OF. Islamic views of death and the afterlife encompass two broad streams: the individual and the collective or cosmological. The existence of an afterlife for individuals and final judgment of all creation are both central tenets of the faith. The Koran provides the foundation for Muslim views of death, with eschatological imagery leaping out from nearly every page. The Koran is supplemented by hadith, reports of the words and deeds of the prophet Muhammad (c. 570–632), as well as by numerous commentaries and treatises. While the specific beliefs and practices surrounding death and the afterlife display significant sectarian and cultural variety, the following account will focus on the most widely shared views.
