# Preface

---

This reference book presents biographical entries on important scientists – from the earliest times to the present day. It is an updated version of *A Biographical Encyclopedia of Scientists*, which was published by the Institute of Physics in 1993. This in turn was based on earlier editions.

In this new edition, we have updated all the entries and added over 200 new biographies. We have also included a simple pronunciation guide in entries where this is appropriate. The respelling system used is shown on page vi. Another added feature of this edition is the inclusion of a selection of quotations by or about certain people. There are also cross references to other entries in the book – these are indicated by SMALL CAPITALS. In the appendix to the book there is a chronology of key events in science, a list of useful web sites, and a subject index.

In compiling such a book there are several difficult decisions to make on the selection of material. The most general one is that of the scope of the book – what areas of knowledge it should cover. This work concentrates on what might be called the ‘traditional’ pure sciences – physics, chemistry, biology, astronomy, and the earth sciences. It also covers medicine and mathematics, and includes a selection of people who have made important contributions to engineering and technology. A few of the entries cover workers in such fields as anthropology and psychology, and a small number of philosophers have also been allowed in.

Our intention has been to produce a book as much about science itself as about scientists, and this has governed our approach to selecting information: the entries contain basic biographical data – place and date of birth, posts held, etc. – but do not give exhaustive personal details about the subject’s family, prizes, honorary degrees, etc. Most of the space has been given to their main scientific achievements and the nature and importance of these achievements. This has not always been easy; in particular, it has not always been possible to explain in relatively simple terms work in the higher reaches of abstract mathematics or modern theoretical physics.

Perhaps the most difficult problem was compiling the entry list. We have attempted to include people who have produced major advances in theory or have made influential or well-known discoveries. A particular difficulty has been the selection of contemporary scientists, in view of the fact that of all scientists who have ever lived, the vast majority are still alive. In this we have been guided by lists of prizes and awards made by scientific societies. It should also be said that the compilers and editors have used their own judgment in choosing what is important or useful. In some cases entries have been added simply because we found them interesting. We hope that the reader will find all the entries useful and share our interest in them.

JD 2008

# Pronunciation Guide

---

A guide to pronunciation is given for foreign names and names of foreign origin; it appears in brackets after the first mention of the name in the main text of the article.

a <i>as in</i> bat	oh <i>as in</i> home (hohm), post (pohst)
ah <i>as in</i> palm (pahm)	oi <i>as in</i> boil, toy (toi)
air <i>as in</i> dare (dair), pear (pair)	oo <i>as in</i> food, fluke (flook)
ar <i>as in</i> tar	or <i>as in</i> organ, quarter ( <b>kwor</b> -ter)
aw <i>as in</i> jaw, ball (bawl)	ow <i>as in</i> powder, loud (lowd)
ay <i>as in</i> gray, ale (ayl)	s <i>as in</i> skin, cell (sel)
ch <i>as in</i> chin	sh <i>as in</i> shall
e <i>as in</i> red	th <i>as in</i> bath
ee <i>as in</i> see, me (mee)	th <i>as in</i> feather ( <b>feth</b> -er)
eer <i>as in</i> ear (eer)	ts <i>as in</i> quartz (kworts)
er <i>as in</i> fern, layer	u <i>as in</i> buck (buk), blood (blud), one (wun)
f <i>as in</i> fat, phase (fayz)	u(r) <i>as in</i> urn (but without sounding the “r”)
g <i>as in</i> gag	uu <i>as in</i> book (buuk)
i <i>as in</i> pit	v <i>as in</i> van, of (ov)
I <i>as in</i> mile (mIl), by (bI)	y <i>as in</i> yet, menu ( <b>men</b> -yoo), onion ( <b>un</b> -yon)
j <i>as in</i> jaw, age (ayj), gem (jem)	z <i>as in</i> zoo, lose (looz)
k <i>as in</i> keep, cactus ( <b>kak</b> -tus), quite (kwIt)	zh <i>as in</i> treasure ( <b>tre</b> -zher)
ks <i>as in</i> ox (oks)	
ng <i>as in</i> hang, rank (rangk)	
o <i>as in</i> pot	

Names of two or more syllables are broken up into small units, each of one syllable, separated by hyphens. The stressed syllable in a word of two or more syllables is shown in **bold** type.

We have used a simple pronunciation system based on the phonetic respelling of names, which avoids the use of unfamiliar symbols. The sounds represented are as follows (the phonetic respelling is given in parentheses after the example word, if this is not pronounced as it is spelled):

The consonants b, d, h, l, m, n, p, r, t, and w have their normal sounds and are not listed in the table.

In our pronunciation guide a consonant is occasionally doubled to avoid confusing the syllable with a familiar word, for example, -iss rather than -is (which is normally pronounced -iz); -off rather than -of (which is normally pronounced -ov).

## **Abbe, Cleveland** (1838–1916) *American meteorologist*

Abbe (**ab-ee**) was born in New York City and educated there at City College; he later taught at the University of Michigan. He then spent two years (1864–66) in Russia at the Pulkovo Observatory under Otto STRUVE. On his return to America he worked as director of the Cincinnati Observatory (1868–70).

Abbe was the first official weather forecaster in America. He was appointed, in 1871, chief meteorologist with the weather service, which was later formed into the U.S. Weather Bureau (1891), and remained in this organization for the rest of his life. He was one of the first scientists to see the revolutionary role the telegraph had to play in weather forecasting and used reports conveyed to him from all over the country.

Abbe published over 300 papers on meteorology and from 1893 he was in charge of the journals published by the U.S. Weather Bureau. He was also responsible for the division of America into time zones in 1883.

## **Abbe, Ernst** (1840–1905) *German physicist*

Abbe (**ab-ee**), who was born in Eisenach in Germany, came from poor parents but managed to become a lecturer at the University of Jena, where in 1886 he collaborated with Carl Zeiss, a supplier of optical instruments to the university, to improve the quality of microscope production. Up till then, this had been an empirical art without rigorous theory to aid design. Abbe's contribution was his knowledge of optical theory. He is known for the *Abbe sine condition* – a necessary condition for the elimination of spherical aberration in an optical system; such a system he described as aplanatic. He also invented the apochromatic lens system (1886), which eliminated both primary and secondary color distortions, and the *Abbe condenser* (1872) – a combination of lenses for converging light onto the specimen in microscopes.

The partnership between Abbe and Zeiss was a productive combination of Zeiss's practical knowledge and Abbe's mathematical and theoretical ability. After Zeiss's death, Abbe became the sole owner of the Zeiss company.

## **Abegg, Richard** (1869–1910) *German physical chemist*

Abegg (**ah-beg**) was born in the German port of Danzig (now Gdańsk in Poland); he studied chemistry at Kiel, Tübingen, and Berlin. He graduated in 1891 as a pupil of Wilhelm Hofmann. Initially an organic chemist, he was attracted by the advances being made in physical chemistry, and in 1894 moved to Göttingen. Here, he worked on electrochemical and related problems and with G. Bodländer produced an important paper on valence, *Die Elektronaffinität* (1869; Electron Affinity). He is remembered for *Abegg's rule* (partially anticipated by Dmitri Mendeleev), which states that each element has two valences: a normal valence and a contravalence, the sum of which is eight. In 1899 he became a professor at Breslau (now Wrocław in Poland) and was about to become the director of the Physico-Chemical Institute there when he was killed in a ballooning accident.

## **Abel, Sir Frederick Augustus** (1827–1902) *British chemist*

The investigator must associate himself with those who have labored in fields where molecules and atoms rather than multicellular tissues or even unicellular organisms are the units of study.

—Describing chemical research

Abel was born in London, the son of a well-known musician and the grandson of a court painter to the grand duke of Mecklenburg-Schwerin. Despite this artistic background, Abel developed an early interest in science after visiting his uncle A. J. Abel, a mineralogist and pupil of BERZELIUS. In 1845 he was one of the first of the pupils to study at the Royal College of Chemistry, remaining there until 1851. After a brief appointment as chemical demonstrator at St. Bartholomew's Hospital, London, he succeeded Michael FARADAY in 1852 as a lecturer in chemistry at the Royal Military Academy at Woolwich. In 1854 he became ordnance chemist and chemist to the war department.

Abel's career was thus devoted exclusively to the chemistry of explosives. New and powerful explosives, including gun cotton and nitroglycerin, had recently been invented but were unsafe to use. Abel's first achievement was to show

how guncotton could be rendered stable and safe. His method was to remove all traces of the sulfuric and nitric acids used in its manufacture by mincing, washing in soda until all the acid had been removed, and drying. In 1888 he was appointed president of a government committee to find new high explosives. The two existing propellants, Poudre B and ballistite, had various defects, most important of which was a tendency to deteriorate during storage. Together with Sir James DEWAR, Abel introduced the new explosive, cordite, in 1889. This was a mixture of guncotton and nitroglycerin with camphor and petroleum added as stabilizers and preservatives.

Abel was honored for his services by being made a knight in 1891 and a baronet in 1893.

### **Abel, John Jacob** (1857–1938) *American biochemist*

Abel was born in Cleveland, Ohio, the son of a farmer. He was educated at the University of Michigan and Johns Hopkins University. He spent the years 1884–90 in Europe studying at Leipzig, Heidelberg, Würzburg, Vienna, Bern, and Strasbourg, where he gained an MD in 1888. On his return to America he worked briefly at the University of Michigan before being appointed in 1893 to the first chair of pharmacology at Johns Hopkins, a post he retained until his retirement in 1932.

Abel approached biology with a first-rate training in chemistry and with the conviction that the study of molecules and atoms was as important as the observation of multicellular tissues under the microscope. He thus began by working on the chemical composition of various bodily tissues and fluids and, in 1897, succeeded in isolating a physiologically active substance from the adrenal glands, named by him epinephrine, also known as adrenalin. This extract was actually the monobenzoyle derivative of the hormone. It was left to Jokichi TAKAMINE to purify it in 1900.

As early as 1912 Abel clearly formulated the idea of an artificial kidney and in 1914 isolated for the first time amino acids from the blood. He was less successful with his search (1917–24) for the pituitary hormone, being unaware that he was dealing with not one but several hormones. His announcement in 1926 that he had crystallized insulin met with considerable skepticism, especially regarding its protein nature. This work was not generally accepted until the mid 1930s.

After his retirement Abel devoted himself to a study of the tetanus toxin.

### **Abel, Niels Henrik** (1802–1829) *Norwegian mathematician*

By studying the masters and not their pupils.

—In reply to a question about how he gained his expertise

Abel (**ah**-bel) was born in Froland, the son of a poor pastor; he was educated in mathematics at the University of Christiania (Oslo). After the death of his father, Abel had to support a large family; he earned what he could by private teaching and was also helped out by his teacher. He was eventually given a grant by the Norwegian government to make a trip to France and Germany to visit mathematicians. In Germany he met the engineer and mathematician August Crelle, who was to be of great assistance to him. Crelle published Abel's work and exerted what influence he could to obtain him a post in Germany. Tragically Abel died just when Crelle had succeeded in getting him the chair in mathematics at Berlin.

With Evariste GALOIS (whom he never met), Abel founded the theory of groups (commutative groups are known as *Abelian groups* in his honor), and his early death ranks as one of the great tragedies of 19th-century mathematics. One of Abel's first achievements was to solve the longstanding problem of whether the general quintic (of the fifth degree) equation was solvable by algebraic methods. He showed that the general quintic is not solvable algebraically and sent this proof to Karl GAUSS, but unfortunately Gauss threw it away unread, having assumed that it was yet another unsuccessful attempt to solve the quintic.

Abel's greatest work was in the theory of elliptic and transcendental functions. Mathematicians had previously focused their attention on problems associated with elliptic integrals. Abel showed that these problems could be immensely simplified by considering the inverse functions of these integrals – the so-called “elliptic functions.” He also proved a fundamental theorem, *Abel's theorem*, on transcendental functions, which he submitted to Augustin CAUCHY (and unfortunately fared no better than with Gauss). The study of elliptic functions inaugurated by Abel was to occupy many of the best mathematicians for the remainder of the 19th century. He also made very important contributions to the theory of infinite series.

### **Abelson, Philip Hauge** (1913–2004) *American physical chemist*

Part of the strength of science is that it has tended to attract individuals who love knowledge and the creation of it ... Thus, it is the communication process which is at the core of the vitality and integrity of science.

—*The Roots of Scientific Integrity* (1963)

Abelson, who was born in Tacoma, was educated at Washington State College and at the University of California at Berkeley, where he obtained his PhD in 1939. Apart from the war years at the Naval Research Laboratory in Washington, he spent most of his career at the Carnegie Institution, Washington, serving as the director of the geophysics laboratory from

1953, and as president from 1971 to 1978. He subsequently became the editor of a number of scientific journals including the important periodical *Science*, which he edited from 1962 to 1985.

In 1940 he assisted Edwin McMILLAN in creating the first transuranic element, neptunium, by bombardment of uranium with neutrons in the Berkeley cyclotron. Abelson next worked on separating the isotopes of uranium. It was clear that a nuclear explosion was possible only if sufficient quantities of the rare isotope uranium-235 (only 7 out of every 1,000 uranium atoms) could be obtained. The method Abelson chose was that of thermal diffusion. This involved circulating uranium hexafluoride vapor in a narrow space between a hot and a cold pipe; the lighter isotope tended to accumulate nearer the hot surface. Collecting sufficient uranium-235 involved Abelson in one of those massive research and engineering projects only possible in war time. In the Philadelphia Navy Yard, he constructed a hundred or so 48-foot (15-meter) precision-engineered pipes through which steam was pumped. From this Abelson was able to obtain uranium enriched to 14 U-235 atoms per 1,000.

Although this was still too weak a mixture for a bomb, it was sufficiently enriched to use in other separation processes. Consequently a bigger plant, consisting of over 2,000 towers, was constructed at Oak Ridge, Tennessee, and provided enriched material for the separation process from which came the fuel for the first atom bomb.

After the war Abelson extended the important work of Stanley MILLER on the origin of vital biological molecules. He found that amino acids could be produced from a variety of gases if carbon, nitrogen, hydrogen, and oxygen were present. He was also able to show (1955) the great stability of amino acids by identifying them in 300-million-year-old fossils and later (1956) identified the presence of fatty acids in rocks.

**Abrikosov, Alexei A.** (1928– ) *Soviet-born American physicist*

Abrikosov was born in Moscow and in 1951 received his PhD from the Kapitza Institute for Physical Problems, Moscow, for a thesis on the theory of thermal diffusion in plasmas. Four years later the same Institute made him a Doctor of Physical and Mathematical Sciences for his work on quantum electrodynamics at high energies. He worked at several universities and scientific institutions in the Soviet Union and in 1991 he joined the Materials Science Division of the Argonne National Laboratory, Illinois. He is also (since 1965) a professor at Moscow State University.

Most of Abrikosov's work has concerned the theory of solids, including metals, semimetals,

semiconductors, and superconductors. For example, he discovered type-II superconductors (which, unlike type-I, remain superconducting in powerful magnetic fields) and explained their magnetic properties, which involves the so-called *Abrikosov vortex lattice*. He continued his research in Argonne, discovering quantum magnetoresistance in certain silver compounds and studying high-temperature superconductors. Such materials have practical applications in medical magnetic resonance imaging (MRI) equipment and particle accelerators. During his long career in science he has received many honors and awards. In 2003 he shared the Nobel Prize for physics with Vitaly GINZBURG and Anthony LEGGETT for their pioneering work on superconductors and superfluids.

**Adams, John Couch** (1819–1892) *British astronomer*

Adams was born in the small Cornish town of Launceston in the west of England, where his father was a tenant farmer. He developed an early interest in astronomy, constructing his own sundial and observing solar altitudes, and pursuing his astronomical studies in the local Mechanics Institute. He graduated brilliantly from Cambridge University in 1843, and became Lowndean Professor of Astronomy and Geometry in 1858; in 1860 he was appointed director of the Cambridge Observatory.

His fame rests largely on the dramatic events surrounding the discovery of the planet Neptune in 1846. Astronomers had detected a discrepancy between the observed and predicted positions of Uranus and thus it appeared that either NEWTON's theory of gravitation was not as universal as had been supposed, or there was an as yet undetected body exerting a significant gravitational influence over the orbit of Uranus. There is evidence that Adams had decided to work on this problem as early as 1841. He had a general solution to the problem by 1843 and a complete solution by September 1845. It was then that he visited George AIRY, the Astronomer Royal, with a prediction of the exact position of the new planet.

Airy gave little attention to it and was moved to action only when, in June 1846, the French astronomer, Urbain LE VERRIER, also announced the position of a new planet. It was within one degree of the position predicted by Adams the previous year. Airy asked James Challis, director of the Cambridge Observatory, to start looking for the new planet with his large 25-inch (63.5-cm) refractor. Unfortunately Challis decided to cover a much wider area of the sky than was necessary and also lacked up-to-date and complete charts of the area. His start was soon lost and Johann GALLE in Berlin had no difficulty in discovering the planet on his first night of observation. All the fame, prizes, and honors initially went to Le Verrier.

When it was publicly pointed out, by Challis and John HERSCHEL, that Adams's work had priority over Le Verrier's, the shy Adams wanted no part of the controversy that followed. In fact he seemed genuinely uninterested in honors. He declined both a knighthood and the post of Astronomer Royal, which was offered him after Airy's retirement in 1881. He later worked on the planetary perturbations (1866), and on the secular variation of the mean motion of the Moon (1852), both difficult questions of mathematical astronomy. His scientific papers were published by his brother in two volumes, in 1876 and 1901.

**Adams, Roger** (1889–1971) *American organic chemist*

Born in Boston, Massachusetts, Adams studied chemistry at Harvard, where he obtained his PhD in 1912, and at the University of Berlin. After working briefly at Harvard he joined the staff of the University of Illinois in 1916 and later served as professor of organic chemistry from 1919 until his retirement in 1957.

Adams developed a simple but effective method for catalyzing the hydrogenation of unsaturated organic compounds using finely divided platinum or palladium dioxides, which were reduced to the metal. He also worked out the structure of a number of naturally occurring physiologically active compounds, such as chaulmoogra oil (which was used to treat leprosy) and gossypol (a poisonous constituent of animal feedstuffs derived from cotton). In the late 1930s Adams was asked by the American Narcotics Bureau to examine the chemistry of the marijuana alkaloids and he succeeded in isolating and identifying the active ingredient, tetrahydrocannabinol.

**Adams, Walter Sydney** (1876–1956) *American astronomer*

Professor Adams has ... killed two birds with one stone. He has carried out a new test of Einstein's general theory of relativity, and he has shown that matter at least 2,000 times denser than platinum is not only possible, but actually exists in the stellar universe.

—Sir Arthur Eddington, *Stars and Atoms* (1927)

Adams was born in Antioch (now in Turkey). He was the son of missionaries working in Syria, then part of the Ottoman Empire, who returned to America in 1885. Adams graduated from Dartmouth College in 1898 and obtained his MA from the University of Chicago in 1900. After a year in Munich he began his career in astronomy as assistant to George HALE in 1901 at the Yerkes Observatory. He moved with Hale to the newly established Mount Wilson Observatory in 1904 where he served as assistant director, 1913–23, and then as director from 1923 until his retirement in 1946.

At Mount Wilson Adams was able to use first the 60-inch (1.5-m) and from 1917 the 100-inch (2.5-m) reflecting telescopes in whose design and construction he had been closely associated. His early work was mainly concerned with solar spectroscopy, when he studied sunspots and solar rotation, but he gradually turned to stellar spectroscopy. In 1914 he showed how it was possible to distinguish between a dwarf and a giant star merely from their spectra. He also demonstrated that it was possible to determine the luminosity, i.e., intrinsic brightness, of a star from its spectrum. This led to Adams introducing the method of spectroscopic parallax whereby the luminosity deduced from a star's spectrum could be used to estimate its distance. The distances of many thousands of stars have been calculated by this method.

He is however better known for his work on the orbiting companion of Sirius, named Sirius B. Friedrich BESSEL had first shown in 1844 that Sirius must have a companion and had worked out its mass as about the same as our Sun. The faint star was first observed telescopically by Alvan CLARK in 1862. Adams succeeded in obtaining the spectrum of Sirius B in 1915 and found the star to be considerably hotter than the Sun. Adams realized that such a hot body, just eight light-years distant, could only remain invisible to the naked eye if it was very much smaller than the Sun, no bigger in fact than the Earth. In that case it must have an extremely high density, exceeding 100,000 times the density of water. Adams had thus discovered the first "white dwarf" – a star that has collapsed into a highly compressed object after its nuclear fuel is exhausted.

If such an interpretation was correct then Sirius B should possess a very strong gravitational field. According to Einstein's general theory of relativity, this strong field should shift the wavelengths of light waves emitted by it toward the red end of the spectrum. In 1924 Adams succeeded in making the difficult spectroscopic observations and did in fact detect the predicted red shift, which confirmed his own account of Sirius B and provided strong evidence for general relativity.

**Addison, Thomas** (1793–1860) *British physician*

Addison, who was born in Longbenton, near Newcastle upon Tyne, England, graduated in medicine from Edinburgh University in 1815 and soon afterwards moved to practice in London. He entered Guy's Hospital in 1817, was appointed assistant physician in 1824, and later became physician and joint lecturer with Richard BRIGHT, an eminent contemporary.

Addison was the first to describe, in 1849, the disease caused by pathological changes in the adrenal (suprarenal) glands, which is now

known as *Addison's disease*. He described the characteristic anemia, bronzed skin, and other symptoms in his famous paper, *On the Constitutional and Local Effects of Disease of the Supra-Renal Capsules* (1855), and distinguished it from another form of anemia, now called pernicious anemia, which results from other causes entirely. This is sometimes called *Addisonian anemia*.

Addison also wrote papers concerning tuberculosis, skin diseases, the anatomy of the lung, and other topics, which were published in a collected edition in 1868. He collaborated with Bright in writing *Elements of the Practice of Medicine* (1839) of which only the first volume was completed.

An eloquent if rather aloof lecturer, Addison's fame as a physician came largely after his death.

**Adhemar, Alphonse Joseph** (1797–1862)  
*French mathematician*

Adhemar (ad-ay-mar), who was born and died in Paris, France, was a private mathematics tutor who also produced a number of popular mathematical textbooks.

His most important scientific work was his *Les Revolutions de la mer* (1842; *The Upheavals of the Sea*) in which he was the first to propose a plausible mechanism by which astronomical events could produce ice ages on Earth. It had been known for some time that while the Earth moved in an elliptical orbit around the Sun it also rotated about an axis that was tilted to its orbital plane. Because the orbit is elliptical and the Sun is at one focus, the Earth is closer to the Sun at certain times of year. As a result, the southern hemisphere has a slightly longer winter than its northern counterpart. Adhemar saw this as a possible cause of the great Antarctic icesheet for, as this received about 170 hours less solar radiation per year than the Arctic, this could just be sufficient to keep temperatures cold enough to permit the ice to build up.

Adhemar was also aware that the Earth's axis does not always point in the same direction but itself moves around a small circular orbit every 26,000 years. Thus he postulated a 26,000-year cycle developing in the occurrence of glacial periods, but his views received little support.

**Adler, Alfred** (1870–1937) *Austrian psychologist*

It is one of the triumphs of human wit...to conquer by humility and submissiveness...to cause pain to others by one's own suffering...to make oneself small in order to appear great...such are often the expedients of the neurotic.

—*The Neurotic Constitution* (1912)

Adler (ad-ler or ahd-ler) was born in Penzing, Austria, the son of a corn merchant, and was

educated at the University of Vienna, where he obtained his MD in 1895. After two years at the Vienna General Hospital he set up in private practice in 1898.

In about 1900 Adler began investigating psychopathology and in 1902 he became an original member of Sigmund FREUD's circle, which met to discuss psychoanalytical matters. His disagreements with Freud began as early as 1907 – he dismissed Freud's view that sexual conflicts in early childhood cause mental illness – and he finally broke away from the psychoanalytic movement in 1911 to form his own school of individual psychology. Adler tended to minimize the role of the unconscious and sexual repression and instead to see the neurotic as overcompensating for his or her "inferiority complex," a term he himself introduced. His system was fully expounded in his *Practice and Theory of Individual Psychology* (1927). In 1921 Adler founded his first child-guidance clinic in Vienna, which was to be followed by over 30 more before the Nazi regime in Vienna forced their closure in 1932. From 1926 onward he began to spend more and more time in America, finally settling there permanently in 1932 and taking a professorship of psychiatry at the Long Island College of Medicine, New York, a post he retained until his death from a heart attack while lecturing in Aberdeen in Scotland.

**Adrian, Edgar Douglas, Baron Adrian of Cambridge** (1889–1977) *British neurophysiologist*

Adrian, a lawyer's son, was born in London and studied at Cambridge University and St. Bartholomew's Hospital, London, where he obtained his MD in 1915. He returned to Cambridge in 1919, was appointed professor of physiology in 1937, and became the master of Trinity College, Cambridge, in 1951, an office he retained until his retirement in 1965. He was raised to the British peerage in 1955.

Adrian's greatest contribution to neurophysiology was his work on the nerve impulse. When he began it was known that nerves transmit nerve impulses as signals, but knowledge of the frequency and control of such impulses was minimal. The first insight into this process came from Adrian's colleague Keith LUCAS, who demonstrated in 1905 that the impulse obeyed the "all-or-none" law. This asserted that below a certain threshold of stimulation a nerve does not respond. However, once the threshold is reached the nerve continues to respond by a fixed amount however much the stimulation increases. Thus increased stimulation, although it stimulates more fibers, does not affect the magnitude of the signal itself.

It was not until 1925 that Adrian advanced beyond this position. By painstaking surgical techniques he succeeded in separating individ-

ual nerve fibers and amplifying and recording the small action potentials in these fibers. By studying the effect of stretching the sternocutaneous muscle of the frog, Adrian demonstrated how the nerve, even though it transmits an impulse of fixed strength, can still convey a complex message. He found that as the extension increased so did the frequency of the nerve impulse, rising from 10 to 50 impulses per second. Thus he concluded that the message is conveyed by changes in the frequency of the discharge. For this work Adrian shared the 1932 Nobel Prize for physiology or medicine with Charles SHERRINGTON.

**Aganice (Aglaonike or Aglaonice)** (*fl.* ?3rd–1st century BC) *Egyptian sorceress*

Aganice was a natural philosopher and sorceress who is said to have originated from Thessaly in Greece and been associated with the court of the Pharaoh Sesostris III (ruled 1878–1843 BC) in ancient Egypt. However, there is no hard evidence for this, and some modern authors assert that she may have lived much earlier, or simply belong to the canon of ancient mythology. Her status stemmed from a supposed ability to predict lunar and solar eclipses, and to convince gullible audiences that she had the power to make the Moon disappear. According to the Greek biographer Plutarch, she was the daughter of Hegetor and “thoroughly conversant with the periods of the Full Moon when it is subject to eclipse, and knowing beforehand when the Moon was due to be overtaken by the Earth’s shadow, imposed upon audiences of women and made them all believe that she drew down the Moon.” Some modern astronomers have taken this as evidence for a series of dark lunar eclipses in the first century BC, whereas others dispute that such eclipses were common, casting doubt on the credibility of Aganice’s reputation. In any case, her name is lent to a Greek expression for a braggart: “Yes, as the Moon obeys Aganice.”

**Agassiz, Jean Louis Rodolphe** (1807–1873) *Swiss–American biologist*

The world has arisen in some way or another. How it originated is the great question, and Darwin’s theory, like all other attempts to explain the origin of life, is thus far merely conjectural. I believe he has not even made the best conjecture possible in the present state of our knowledge.

—*Evolution and Permanence of Type* (1874)

Generally considered the foremost naturalist of 19th-century America, Agassiz (**ag-a-see**) was born in Motier-en-Vully, Switzerland. He was educated at the universities of Zurich, Heidelberg, and Munich, where he studied under the embryologist Ignaz DÖLLINGER. At the instigation of Georges CUVIER, he cataloged and de-

scribed the fishes brought back from Brazil by C. F. P. von Martius and J. B. von Spix (*Fishes of Brazil*, 1929), following this with his *History of the Freshwater Fishes of Central Europe* (1839–42) and an extensive pioneering work on fossil fishes, which eventually ran to five volumes: *Recherches sur les poissons fossiles* (1833–43; Researches on Fossil Fishes). These works, completed while Agassiz was professor of natural history at Neuchâtel (1832–46), established his reputation as the greatest ichthyologist of his day. Agassiz’s best-known discovery, however, was that of the Ice Ages. Extensive field studies in the Swiss Alps, and later in America and Britain, led him to postulate glacier movements and the former advance and retreat of ice sheets; his findings were published in *Etudes sur les glaciers* (1840; Studies on Glaciers).

A successful series of lectures given at Boston, Massachusetts, in 1846 led to his permanent settlement in America. In 1847 he was appointed professor of zoology and geology at Harvard, where he also established the Museum of Comparative Zoology (1859). Agassiz’s subsequent teachings introduced a departure from established practice in emphasizing the importance of first-hand investigation of natural phenomena, thus helping to transform academic study in America. His embryological studies led to a recognition of the similarity between the developing stages of living animals and complete but more primitive species in the fossil record. Agassiz did not, however, share Darwin’s view of a gradual evolution of species, but, like Cuvier, considered that there had been repeated separate creations and extinctions of species – thus explaining changes and the appearance of new forms. Unfortunately, one of Agassiz’s most influential pronouncements was that there were several species, as distinct from races, of man: an argument used by slavers to justify their subjugation of Black people as an inferior species. His ambitious *Contributions to the Natural History of the United States* (4 vols., 1857–62) remained uncompleted at his death.

**Agre, Peter** (1949– ) *American cell biologist*

Agre was born in Northfield, Minnesota, and in 1970 gained his BA in chemistry from Augsburg College, Minneapolis. He then switched to medicine and attended Johns Hopkins University School of Medicine in Baltimore, where he qualified as MD in 1974. He spent his medical residency at Case Western University and gained a clinical fellowship at the University of North Carolina at Chapel Hill. He then returned to Johns Hopkins for a research fellowship in the cell biology department, becoming a faculty member in the department of medicine in 1984. In 1993 he became professor of bio-

logical chemistry and professor of medicine at Johns Hopkins School of Medicine, specializing in blood disorders.

For body cells to function, there has to be a way in which substances such as water and various ions can pass through the wall of the cell to maintain an even pressure within it – the cell's outer membrane must contain pores. From the mid-1980s Agre's main area of research was to discover the nature of these pores and thus how water molecules cross the cell wall. In 1988 he isolated a protein from the outer membrane of red blood cells, and within two years he demonstrated that this protein forms a channel through which water molecules can travel. Agre named the protein *aquaporin*. The 1991 discovery is now known as aquaporin-1 and various other types of aquaporins have since been found in a wide range of other cells of bacteria, plants, and animals. At last there was an explanation of, for example, how osmosis takes place in plant cells and how blood cells in the kidney reabsorb water from primary urine. The discovery was important in the understanding and possible treatment of kidney disease. For his discovery of water channels in cells, Agre shared the 2003 Nobel Prize for chemistry with the American cell biologist Roderick MACKINNON, who had earlier discovered ion channels.

### **Agricola, Georgius (1494–1555) German metallurgist**

**Agricola** (a-**grik**-o-la) was born Georg BAUER (**bow**-er) but, as was the custom of the day, he Latinized his name (Agricola and Bauer both mean “farmer”). Beyond his place of birth – Glauchau in Germany – little is known about him until his entry into the University of Leipzig in 1514. He later pursued his studies of philosophy and medicine in Italy at Bologna, Padua, and Venice (1523–27). In 1527 he was engaged as physician to the Bohemian city of Joachimsthal – the center of a rich mining area – moving in 1534 to another celebrated mining town, Chemnitz, near his birthplace. Here he became burgomaster in 1545. He wrote seven books on geological subjects but these were also so illuminating of other subjects that he was known in his lifetime as “the Saxon Pliny.”

His most famous work, *De re metallica* (1556; *On the Subject of Metals*), concentrates on mining and metallurgy with a wealth of information on the conditions of the time, such as management of the mines, the machinery used (e.g., pumps, windmills, and water power), and the processes employed. The book is still in print having the unique distinction of being translated and edited (1912) by a president of the United States, Herbert Hoover, with Lou Henry Hoover (his wife).

Agricola is often regarded as the father of

modern mineralogy. In the Middle Ages, the subject was based on accumulated lore from the Orient, the Arabs, and antiquity. Stones were believed to come in male and female form, to have digestive organs, and to possess medicinal and supernatural powers. Agricola began to reject these theories and to provide the basis for a new discipline. Thus in his *De ortu et causis subterraneorum* (1546; *On the Origin and Cause of Subterranean Things*) he introduced the idea of a lapidifying juice (or *succus lapidescens*) from which stones condensed as a result of heat. This fluid was supposedly subterranean water mixed with rain, which collects earthy material when percolating through the ground.

Agricola also, in *De natura fossilium* (1546; *On the Nature of Fossils*), introduced a new basis for the classification of minerals (called “fossils” at the time). Although far from modern, it was an enormous improvement on earlier works. Agricola based his system on the physical properties of minerals, which he listed as color, weight, transparency, taste, odor, texture, solubility, combustibility, and so on. In this way he tried to distinguish between earths, stones, gems, marbles, metals, building stone, and mineral solutions, carefully describing his terms, which should not be assumed to be synonymous with today's terms, in each case.

### **Aiken, Howard Hathaway (1900–1973) American computer pioneer**

Born in Hoboken, New Jersey, Aiken graduated from the University of Wisconsin and began work with the Madison Gas and Engineering Company in 1923. He moved to Westinghouse Electric, Chicago, in 1927 but decided ten years later to pursue an academic career. He was awarded his Harvard PhD in 1939 and was immediately appointed to the faculty, becoming professor of applied mathematics and director of the computation laboratory in 1946, positions he held until his retirement in 1961.

In 1937 Aiken began to look for support to build an electromechanical calculator to reduce the time and effort spent in the numerical solution of differential equations. He obtained backing from IBM in 1939. The result, known as Harvard Mark 1 or ASCC (Automatic Sequence-Controlled Calculator), was completed in 1943. It was 8 feet tall, 50 feet long, weighed 5 tons, and contained 750,000 parts. The Mark 1, which operated decimally, was programmed by punched tape. It was driven by a long metal shaft, which was in turn operated by the main sequence-control mechanism. Consequently, it could calculate no faster than the speed of its mechanical parts. Although essentially obsolete at the time of its appearance, it continued in use. It was employed for calculating mathematical tables for a further sixteen years.

Aiken went on to build a larger Mark II ver-

sion for the U.S. Navy in 1948. Two further machines were built by Aiken. Both of these were operated by electronic circuits, rather than mechanically: the Mark III in 1949, again for the Navy, and the Mark IV in 1952 for the Air Force.

**Airy, Sir George Biddell (1801–1892)**  
*British astronomer*

I had made considerable advance ... in calculations on my favourite numerical lunar theory, when I discovered that, under the heavy pressure of unusual matters (two transits of Venus and some eclipses) I had committed a grievous error in the first stage of giving numerical value to my theory. My spirit in the work was broken, and I have never heartily proceeded with it since.

—Describing his theoretical work on the orbital motion of the Moon

Airy, the son of a tax collector, was born in Alnwick in the north-east of England. He attended school in Colchester before going to Cambridge University in 1819. He met with early success, producing a mathematical textbook in 1826 and numerous papers on optics. He became Lucasian Professor of Mathematics at Cambridge in 1826 and two years later was made Plumian Professor of Astronomy and director of the Cambridge Observatory. In 1835 he was appointed Astronomer Royal, a post he held for 46 years.

Airy was a very energetic, innovative, and successful Astronomer Royal. He reequipped the observatory, installing an altazimuth for lunar observation in 1847, a new transit circle and zenith tube in 1851, and a 13-inch (33-cm) equatorial telescope in 1859. He created a magnetic and meteorological department in 1838, began spectroscopic investigations in 1868, and started keeping a daily record of sunspots with the Kew Observatory heliograph in 1873. In optics he investigated the use of cylindrical lenses to correct astigmatism (Airy was astigmatic) and examined the disklike image in the diffraction pattern of a point source of light (in an optical device with a central aperture) now called the *Airy disk*. Also named for him is his hypothesis of isostasy: the theory that mountain ranges must have root structures of lower density, proportional to their height, in order to maintain isostatic equilibrium.

Despite his many successes he is now mainly, and unfairly, remembered for his lapses. When John ADAMS came to him in September 1845, with news of the position of a new planet, Airy unwisely ignored him, leaving it to others to win fame as the discoverers of Neptune. He also dismissed Michael FARADAY's new field theory.

**Aitken, Robert Grant (1864–1951)**  
*American astronomer*

Born in Jackson, California, Aitken obtained his BA in 1887 and his MA in 1892 from Williams College, Massachusetts. He began his career at the University of the Pacific, then in San Jose, as professor of mathematics from 1891 until 1895 when he joined the staff of Lick Observatory, Mount Hamilton, California. He remained at Lick for his entire career, serving as its director from 1930 until his retirement in 1935.

Aitken did much to advance knowledge of binary stars, i.e., pairs of stars orbiting about the same point under their mutual gravitational attraction. He described over 3,000 binary systems and published in 1932 the comprehensive work *New General Catalogue of Double Stars Within 120° of the North Pole*. He also produced the standard work *The Binary Stars* (1918).

**Akers, Sir Wallace Allen (1888–1954)**  
*British industrial chemist*

Akers, the son of a London accountant, was educated at Oxford University. He first worked for the chemical company Brunner Mond from 1911 to 1924 and, after four years in Borneo with an oil company, returned in 1928. By then Brunner Mond had become part of ICI. From 1931 he was in charge of the Billingham Research Laboratory and from 1944 was the company director responsible for all ICI research.

In World War II Akers worked under Sir John Anderson, the government minister responsible for work on the atom bomb. He was put in charge of Tube Alloys, the Ministry of Supply's front for secret nuclear work. It was Akers who led the mission of British scientists in 1943 to America to work out details of collaboration, although he proved unacceptable to the Americans and was replaced by James CHADWICK. Akers returned to head Tube Alloys in the UK.

After the war one of his main tasks was the setting up of the Central Research Laboratory for ICI at Welwyn near London, later named the Akers Research Laboratory. He was knighted in 1946.

**Al-Battani (or Albategnius) (c. 858–929)**  
*Arab astronomer*

Nobody is known in Islam who reached similar perfection in observing the stars and in scrutinizing their motions.

—Ibn al-Qifti (13th century)

Al-Battani (al-ba-**tah**-nee) was the son of a maker of astronomical instruments in Harran (now in Turkey). He worked mainly in Raqqa on the Euphrates (now ar-Raqqah in Syria) and was basically a follower of PTOLEMY, devoting himself to refining and perfecting the work of his master. He improved Ptolemy's measurement of the obliquity of the ecliptic (the angle

between the Earth's orbital and equatorial planes), the determination of the equinoxes, and the length of the year. He also corrected Ptolemy in various matters, in particular in his discovery of the movement of the solar perigee (the Sun's nearest point to the Earth) relative to the equinoxes. His work was widely known in the medieval period, having been translated by PLATO of Tivoli in about 1120 as *De motu stellarum* (On Stellar Motion), which was finally published in Nuremberg in 1537.

**Albertus Magnus, St.** (c. 1200–1280) *German scholastic philosopher*

Albert Magnus was the son of a German lord, his real name being Count von Bollstädt. Born in the south German town of Lauingen, he studied at the University of Padua and then became, in 1223, a member of the Dominican order against his family's wishes. He continued his studies throughout Europe and then taught theology. From about 1245 he lectured in Paris, where the philosopher and theologian Thomas Aquinas became one of his pupils, and in 1248 he was sent to Cologne to establish a Dominican study center, returning to Paris in 1254.

Albertus Magnus's voluminous writings, including treatises on theology, physics, and natural history, were generally Aristotelian in spirit, though he stressed the importance of direct observation of nature rather than strict adherence to textual authority. He also conducted alchemical experiments and in his *De mineralibus* (1569; On Minerals) he claimed to have tested alchemical gold "and found after six or seven ignitions that it was converted to powder."

He retired, in 1270, to his convent at Cologne. He was made a doctor of the Church and canonized in 1931.

**Albinus, Bernhard Siegfried** (1697–1770) *German anatomist*

Albinus (al-**bi**-nus) was born in Frankfurt an der Oder in Germany and was educated at the University of Leiden, where he subsequently held professorships in anatomy and surgery and later medicine. A popular lecturer on his subject, Albinus also carried out his own studies of human anatomy, and is chiefly known for his detailed classification of contemporary and traditional knowledge in this field. He published, with his former teacher Hermann BOERHAAVE, the complete works of Andreas VESALIUS, and also edited a new edition of the works of Hieronymus FABRICIUS. His own work, in which he emphasized the importance of illustrating the "anatomical norm," was published in 1747 in *Tabulae sceleti et musculorum corporis humani* (Plates of the Skeleton and Muscles of the

Human Body), which contains numerous excellent drawings.

**Albright, Arthur** (1811–1900) *British chemist and industrialist*

Albright came from a Quaker family in the village of Charlbury, near Oxford, England. He was first apprenticed as an apothecary in Bristol and became a partner in the Birmingham firm of John and Edward Sturge, manufacturing chemists. In 1844 the partners established a new plant at Selly Oak to produce white phosphorus for the match industry. This was manufactured from calcium phosphate, derived from imported bones, and sulfuric acid.

White phosphorus was a difficult material to handle, being toxic and spontaneously flammable. Another allotropic form – red phosphorus – was discovered in 1845 by Anton SCHRÖTTER. Albright bought the patents and improved the process for producing red phosphorus. A larger factory was opened at Oldbury. J. E. Lundström of Sweden showed, in 1855, how Albright's phosphorus could be used in the production of safety matches. In this system the chlorate was confined to the tip of the match and the phosphorus was used only on the box.

In 1855 Albright's partnership with the Sturges was dissolved and he joined with J. W. Wilson in the following year, eventually forming the chemical company Albright and Wilson.

**Alcmaeon** (about 450 BC) *Greek philosopher and physician*

Alcmaeon (alk-**mee**-on) was born in Croton (now Crotona in Italy). Details of his work come from the surviving fragments of his book and through references by later authors, including ARISTOTLE. He was probably influenced by the school of thought founded by PYTHAGORAS in Croton and originated the notion that health was dependent on maintaining a balance between all the pairs of opposite qualities in the body, i.e., wet and dry, hot and cold, etc. Imbalance of these qualities resulted in illness. This theory was later developed by HIPPOCRATES and his followers.

Alcmaeon performed dissections of animals and possibly of human cadavers also. He demonstrated various anatomical features of the eye and ear, including their connections with the brain, and correctly asserted that the brain was the control center of bodily functions and the seat of intelligence.

**Alder, Kurt** (1902–1958) *German organic chemist*

Alder (**ahl**-der), who was born in Königshütte, Germany (now Chorzów in Poland), studied chemistry in Berlin and Kiel, receiving his doctorate in 1926 under Otto DIELS. In 1928 Diels

and Alder discovered an important type of organic chemical reaction in which a compound containing two double carbon–carbon bonds separated by a single carbon–carbon bond adds to a compound containing a double carbon–carbon bond. The resulting molecule contains an aromatic ring structure with alternating double and single bonds. Alder was professor of chemistry at Kiel (1934), chemist with I. G. Farben at Leverkusen (1936), and director of the Chemical Institute at the University of Cologne (1940). In 1950 Diels and Alder jointly received the Nobel Prize for chemistry for their discovery of what is now known as the Diels–Alder reaction.

**Aldrovandi, Ulisse (1522–1605)** *Italian naturalist*

Aldrovandi (al-droh-**van**-dee) was educated at Bologna (where he was born and died) and Padua, where he obtained a medical degree in 1553. He was professor of botany and natural history at Bologna and in 1567 founded the Bologna Botanic Gardens. Under the patronage of popes Gregory XIII and Sixtus V, Aldrovandi traveled over a great part of Europe observing natural phenomena and collecting specimens, which he planned to incorporate in a multivolume natural history. Only four volumes appeared during his lifetime, *Ornithologiae* (3 vols., 1599; Ornithology), and *De animalibus insectis* (1602; On Insects). Other volumes appeared posthumously and include works on fish and whales (1613), monsters (1640), serpents and dragons (1640), and quadrupeds (1613; 1616; 1621; 1637).

Aldrovandi was in no sense a modern zoologist. The many-headed hydra and the basilisk appear on his pages along with cows and goats. Further, while he could write at great length about creatures, 31 pages for example on the peacock, little of this would be recognized today as relevant to zoology. Much of the material is linguistic, covering the names of, for example, the peacock in various languages together with synonyms for the bird and its use in proverbs. Much also is concerned with the emblematic appearance and significance as it is found on coins, medals, and coats of arms.

**Alembert, Jean Le Rond d'** See **D'ALEMBERT, JEAN LE ROND.**

**Alferov, Zhores Ivanovich (1930– )** *Russian physicist*

Alferov (al-fe-rof) was born in Vitebsk, Belorussia (then part of the Soviet Union), and educated at the Lenin Electrochemical Institute in St. Petersburg (then Leningrad). Since 1953 he has been a staff member of the A. F. Ioffe Physico-Technical Institute in St. Petersburg, being director from 1987 to the present time.

Since 1995 Alferov has also been a member of the Russian parliament (the Duma), being re-elected in 2007 as a member of the Communist Party.

Since the early 1960s Alferov has been one of the leading figures in the development of the physics and technology of layered semiconductor structures known as semiconductor heterostructures, including applications to lasers, solar cells, and light-emitting diodes (LED). This work has had a major impact on information technology because it has enabled information systems based on semiconductor heterostructures to be built that have the desirable features of being both fast and very small. It is necessary for information systems to be fast because large amounts of information have to be transferred in a short time. It is very useful for information systems to be small so that they can then be used in homes, offices, or even briefcases or pockets.

Fast small transistors based on semiconductor heterostructures have many technological applications, including radio-link satellites and the base stations of mobile telephones. The same type of technology is used in the laser diodes that drive the flow of information in the fiber-optical cables used in the Internet. Other technological applications of semiconductor heterostructures include CD players, bar-code readers, and light-emitting diodes.

Alferov has been awarded many prizes for his pioneering work in semiconductor heterostructures, culminating in the Nobel Prize for physics in 2000, which he shared with Herbert KROEMER and Jack KILBY for their related work.

**Alfvén, Hannes Olof Gösta (1908–1995)** *Swedish physicist*

Alfvén (al-ven), who was born in Norrkoeping, Sweden, was educated at the University of Uppsala where he received his PhD in 1934. He subsequently worked at the Royal Institute of Technology, Stockholm, where he served as professor of the theory of electricity (1940–45), professor of electronics (1945–63), and professor of plasma physics (1963–73).

Alfvén is noted for his pioneering theoretical research in the field of magnetohydrodynamics – the study of conducting fluids and their interaction with magnetic fields. This work, for which he shared the 1970 Nobel Prize for physics with Louis NEEL, was mainly concerned with plasmas, i.e., ionized gases containing positive and negative particles. He investigated the interactions of electrical and magnetic fields and showed theoretically that the magnetic field, under certain circumstances, can move with the plasma. In 1942 he postulated the existence of waves in plasmas; these *Alfvén waves* were later observed in both liquid metals and ionized plasmas.

Alfvén also applied his theories to the motion of particles in the Earth's magnetic field and to the properties of plasmas in stars. In 1942, and later in the 1950s, he developed a theory of the origin of the solar system. This he assumed to have formed from a magnetic plasma, which condensed into small particles that clustered together into larger bodies. His work is also applicable to the properties of plasmas in experimental nuclear fusion reactors. Alfvén's books include *Cosmical Electrodynamics* (1950), which collects his early work, *On the Origin of the Solar System* (1954), and *On the Evolution of the Solar System* (1976, with G. Arhenius).

In his later years Alfvén argued against the current orthodoxy of the big-bang theory of the origin of the universe. Space, he argued, is full of immensely long plasma filaments. The electromagnetic forces produced have caused the plasma to condense into galaxies. As for the expansion of the universe, he attributed this to the energy released by the collision of matter and antimatter. Whereas Alfvén's critics charged him with vagueness, he responded by arguing that cosmologists derive their theories more from mathematical considerations than from laboratory experiments.

**Alhazen (or Abu Ali Al-Hassan Ibn Al Haytham)** (c. 965–1038) *Arabian scientist*

Now the known things are of five kinds: the known in number, the known in magnitude, the known in ratio, the known in position, and the known in species ... In the examples of analysis we give in the present treatise we shall prove the known things used, whether or not we have found them in other works.

—*Opticae Thesaurus* (1572; The Treasury of Optics)

Born in Basra (now in Iraq), Alhazen (al-ha-zen) was one of the most original scientists of his time. About a hundred works are attributed to him; the main one was translated into Latin in the 12th century and finally published in 1572 as *Opticae Thesaurus* (The Treasury of Optics). This was widely studied and extremely influential. It was the first authoritative work to reject the curious Greek view that the eye sends out rays to the object looked at. Alhazen also made detailed measurements of angles of incidence and refraction. He studied spherical and parabolic mirrors, the camera obscura, and the role of the lens in vision. While the Greeks had had a good understanding of the formation of an image in a plane mirror, Alhazen tackled the much more difficult problem of the formation of images in spherical and parabolic mirrors and offered geometrical solutions. It is difficult to think of any other writer who had surpassed the Greeks in any branch of the exact sciences by the 14th let alone the 11th century. He was, however, unfortunate in his relationship with the deranged caliph al-Hakim.

Having rashly claimed that he could regulate the flooding of the Nile, he was forced to simulate madness to escape execution until the caliph died in 1021.

**Al-Khwarizmi, Abu Ja'far Muhammad Ibn Musa** (c. 800–c. 847) *Arab mathematician, astronomer, and geographer*

With my two algorithms, one can solve all problems – without error, if God wills it!

—*Algebra*

Al-Khwarizmi (al-**kwah**-riz-mee) takes his name from his birthplace, Khwarizm (now Khiva in Uzbekistan). His importance lies chiefly in the knowledge he transmitted to others. Very little is known about his life except that he was a member of the academy of sciences in Baghdad, which flourished during the rule (813–33) of caliph al-Ma'mun. Al-Khwarizmi's main astronomical treatise and his chief mathematical work, the *Algebra*, are dedicated to the caliph. The *Algebra* enlarged upon the work of DIOPHANTUS and is largely concerned with methods for solving practical computational problems rather than algebra as the term is now understood. Insofar as he did discuss algebra, al-Khwarizmi confined his discussion to equations of the first and second degrees.

His astronomical work, *Zij al-sindhind*, is also based largely on the work of other scientists. As with the *Algebra*, its chief interest is as the earliest Arab work on the subject still in existence.

Al-Khwarizmi's other main surviving works are a treatise on the Hindu system of numerals and a treatise on geography. The Hindu number system, with its epoch-making innovations, for example the incorporation of a symbol for zero, was introduced to Europe via a Latin translation (*De numero indorum*; On the Hindu Art of Reckoning) of al-Khwarizmi's work. Only the Latin translation remains but it seems certain that al-Khwarizmi was the first Arab mathematician to expound the new number system systematically. The term "algorithm" (a rule of calculation) is a corrupted form of his name. His geographical treatise marked a considerable improvement over earlier work, notably in correcting some of the influential errors and misconceptions that had gained currency owing to PTOLEMY'S *Geography*.

**Allbutt, Sir Thomas Clifford** (1836–1925) *British physician and medical historian*

Allbutt was born in Dewsbury in Yorkshire, England, and studied natural sciences at Cambridge University, graduating in 1860. He then studied medicine at St. George's Hospital, London, gaining his MB in 1861. He was appointed physician to Leeds General Infirmary in 1864

where, in 1866, he invented the short clinical thermometer, which was a great advance on previous highly cumbersome instruments. His major interest was cardiology and he was the first to describe the effects of syphilis on the cerebral arteries. His *System of Medicine* (8 vols. 1896–99) became an important medical text. In 1892 he was appointed professor of medicine at Cambridge, where he lectured and wrote several notable works on the history of medicine, including *Greek Medicine in Rome* (1921).

**Allen, Edgar** (1892–1943) *American endocrinologist*

Allen, the son of a physician, was born in Canon City, Colorado, and educated at Brown University. After war service he worked at Washington University, St. Louis, before being appointed (1923) to the chair of anatomy at the University of Missouri. In 1933 he moved to a similar post at Yale and remained there until his death.

In 1923 Allen, working with Edward DOISY, began the modern study of the sex hormones. It was widely thought that the female reproductive cycle was under the control of some substance found in the corpus luteum, the body formed in the ovary after ovulation. Allen thought rather that the active ingredient was probably in the follicles surrounding the ovum. To test this he made an extract of the follicular fluid and found that on injection it induced the physiological changes normally found only in the estrous cycle. Allen had in fact discovered estrogen although it was only identified some six years later by Adolf BUTENANDT.

**Allen, James Alfred Van** See VAN ALLEN, JAMES ALFRED.

**Alpher, Ralph Asher** (1921–2007) *American physicist*

Alpher was born in Washington, DC, and educated there at George Washington University; he obtained his BS in 1943 and his PhD in 1948. He spent the war as a physicist with the U.S. Navy's Naval Ordnance Laboratory in Washington followed by a period (1944–55) with the applied physics laboratory of Johns Hopkins University, Baltimore. In 1955 Alpher joined the staff of the General Electric Research and Development Center, Schenectady, New York, remaining with them until his retirement in 1986.

At George Washington, Alpher came under the influence of the physicist George GAMOW with whom he collaborated in a number of papers. They produced, with Hans BETHE, a major paper on the origin of the chemical elements, sometimes called the *Alpher–Bethe–Gamow theory*, which was incorporated into Gamow's modern form of the big-bang theory of the ori-

gin of the universe, published in 1948. It is said that Bethe's name was added to make the title sound like "alpha-beta-gamma," the first three letters of the Greek alphabet. In the theory it was supposed that the universe was initially very hot and dense and was composed entirely of neutrons. The neutrons decayed to protons (hydrogen nuclei), which could then capture neutrons to form deuterium nuclei. A further series of reactions produced helium. It was also proposed that a further succession of reactions, mainly the capture of neutrons, could produce other elements. Calculations on the abundance of the elements as predicted by the theory were performed by Alpher and Robert C. Herman. Although it is accepted that hydrogen and helium were indeed formed in the primitive universe by such a process, heavier elements are now known to be synthesized in the stars.

The same year, 1948, saw the publication of a remarkable paper by Alpher and Herman in which they predicted that the big bang should have produced intense radiation that gradually lost energy as the universe expanded and by now would be characteristic of a temperature of about 5 kelvins (–268°C). Unlike its later and independent formulation by Robert DICKE in 1964, the 1948 paper had surprisingly little impact. Alpher did approach a number of radar experts but was informed that it was then impossible to detect such radiation. When it was discovered by Arno PENZIAS and Robert WILSON in 1964–65 its effect was to initiate a major revolution in cosmology and astrophysics.

In 1953 Alpher and James FOLLIN performed calculations that took account of the change in the relative numbers of protons and neutrons in the early Universe. This has been described as one of the first modern attempts to analyze the early history of the Universe. In 2001 Alpher and Herman published a book, *Genesis of the Big Bang*, on their work together and with Gamow on this topic.

**Alpini, Prospero** (1553–1617) *Italian botanist and physician*

Alpini (al-**pee**-nee), who was born in Venice, Italy, studied medicine at Padua University, receiving his MD in 1578. He became physician to Giorgio Emo, the Venetian consul in Egypt, and between 1580 and 1583 traveled widely in Egypt and the Greek Islands. This enabled him to make an extensive study of the Egyptian and Mediterranean floras, and he was the first European to describe the coffee and banana plants and a genus of the ginger family, later named *Alpinia*. He also studied the date palm and was the first to fertilize dates artificially, having realized that this palm has separate male and female trees. In 1593 Alpini was appointed professor of botany at Padua and he also became director of the Botanic Gardens there, introducing many Egyptian plants.

**Alter, David** (1807–1881) *American inventor and physicist*

Alter was born in Westmoreland County, Pennsylvania. Largely self-taught, he graduated from the Reformed Medical College in New York in 1831. During his lifetime Alter experimented at home using apparatus constructed by himself. He worked on a wide range of subjects but was little recognized for his achievements. His best work was on spectrum analysis, suggesting that each element had its own characteristic spectrum that would enable qualitative analysis to be carried out. This was later proved correct by Gustav KIRCHHOFF and Robert BUNSEN. Alter's inventions included a new method for purifying bromine, a process for obtaining oil from coal, an electric clock, and an electric telegraph that would spell out words with the aid of a pointer.

**Altman, Sidney** (1939– ) *American chemist*

Born in Montreal, Canada, Altman was educated at the University of Colorado, Boulder, where he obtained his PhD in 1967. He moved to Yale in 1971, becoming professor of biology in 1980 and a naturalized U.S. citizen in 1984.

In 1982 Thomas CECH at Colorado had shown that RNA sometimes served as a biocatalyst – a role previously thought to be exclusive to protein enzymes. Cech's work was on a reaction in which the RNA was a self-catalyst. Altman set out to investigate other catalytic activity of RNA.

He worked with ribonuclease-P, an enzyme composed of both RNA and a protein, which catalyzes the processing of transfer RNA (tRNA). For the enzyme to work at the cellular level, it was thought that both protein and RNA were needed. It could, however, be possible that the RNA was merely a kind of structural support for the protein enzyme. Altman found that, *in vitro*, ribonuclease-P alone could splice the tRNA molecule at the correct place; the unaccompanied protein displayed no such activity.

Final proof came when a recombinant DNA template was used to produce only the RNA part of the ribonuclease-P. The artificial RNA still catalyzed the appropriate activity without any associated protein whatsoever. Altman had thus helped to break down the previously unquestioned dogma that molecules could either carry information, like RNA, or catalyze chemical reactions, like proteins, but they could not do both. The discovery could also throw light on the puzzle that if proteins are needed to assemble RNA, and RNA to assemble proteins, then how did the process ever get started? The answer could lie in the catalytic activity of RNA itself.

For his work on ribonuclease-P Altman shared the 1989 Nobel Prize for chemistry with Thomas Cech.

**Alvarez, Luis Walter** (1911–1988) *American physicist*

There is no democracy in physics. We can't say that some second-rate guy has as much right to opinion as Fermi.

—Quoted by D. S. Greenberg in *The Politics of Pure Science* (1967)

Alvarez, the son of a research physiologist, was born in San Francisco and educated at the University of Chicago where he gained his PhD in 1936. He moved soon after to the University of California, Berkeley. Apart from wartime work on radar at the Massachusetts Institute of Technology Radiation Laboratory (1940–43) and on the Manhattan Project at Los Alamos (1943–45), Alvarez spent his entire career at Berkeley, serving as professor of physics from 1945 until his retirement in 1978.

In 1938 Alvarez reported his first major discovery, namely, the phenomenon of orbital electron capture. In 1936 Hans BETHE had argued that an excited nucleus could decay by capturing one of its own orbiting electrons, a process known as K-capture as the electron is taken from the innermost (K) electron shell. Alvarez succeeded in detecting the process experimentally by identifying the characteristic x-rays emitted during K capture as a result of electrons moving from outer orbits into the vacant K orbit.

Alvarez followed this by making (1939) the first measurement, with Felix BLOCH, of the neutron's magnetic moment. He also demonstrated that hydrogen-3 (tritium) was radioactive, work which proved to be of significance in the later development of the hydrogen bomb.

While working on radar during the war Alvarez had what he later described as one of his most valuable ideas. If radar could be used to track approaching aircraft then, he argued, the same information should be adequate to guide a pilot to a safe landing in bad weather. There were many obstacles to be overcome before GCA (Ground Controlled Approach) could be adopted. By early 1943, however, Alvarez was able to talk down a distant plane he could follow only on radar.

Soon after he moved to Los Alamos where he worked on the problem of detonating the bomb. It was necessary for 32 detonators to fire simultaneously. Alvarez was an observer in a follow-up plane of the Hiroshima bomb.

After the war Alvarez remained as creative as ever. His most important work was in the field of particle physics. By the early 1950s experimentalists had begun to find it difficult to track particles. Cloud chambers took too long to operate, emulsions could only pick up charged particles, and consequently much was being missed. In April 1953 Alvarez was introduced by Donald GLASER to the idea that particles passing through a small glass bulb containing diethyl ether would produce bubble tracks. The

chamber operated by suddenly reducing the pressure causing the liquid to “boil” and leave a bubble track where a particle had passed.

Alvarez immediately began to design a much larger bubble chamber using liquid hydrogen as a fluid. After a few test runs with some small chambers Alvarez proposed to build a 72-inch model at a cost of \$2.5 million. It first came into operation in March 1959 and was used to discover a large number of elementary particles. For his work in this field Alvarez was awarded the 1968 Nobel Prize for physics.

In 1962 Alvarez first saw the Giza pyramids in Egypt. Ever capable of seeing a problem calling for scientific analysis, he wondered if there were any hidden chambers in the Cephren pyramid as there were in the other Giza structures. If the pyramid was radiated with muons, more muons would pass through the less dense plane of a hidden chamber and would show up clearly on a scatter plot. After several years’ persuasion of politicians and officials Alvarez’s team made the appropriate measurement in 1968. At first it seemed that the pyramid contained a massive chamber and Alvarez excitedly made plans to tunnel into the tomb. Calculations quickly showed, however, that no such chamber could exist as it would have caused a collapse long ago. Eventually a computer error was detected. After several years’ work Alvarez conceded that the Cephren pyramid was quite solid.

Pyramid archaeology was not the only excursion taken by Alvarez outside conventional physics. In 1977 his son Walt, a geologist, showed him a rock from Gubbio in the Italian Apennines. It was aged 65 million years and consisted of two layers of limestone, one from the Cretaceous, the other from the Tertiary, separated by a thin clay strip. During the rock’s formation the dinosaurs had flourished and passed into extinction.

Alvarez was intrigued by the presence in the clay of unusually high concentrations of iridium. No more than about 0.03 parts per billion are normally to be found in the Earth’s crust. The geologists, however, reported that there was 300 times as much iridium in the clay layer than in the surrounding limestone samples (an example of what is now known as the “iridium anomaly”). The clay, it was calculated, had formed over a mere 1,000 years, and was located in time at the KT boundary (K = *Kreide*, German for Cretaceous, T = Tertiary). Could the thin strip of clay and its iridium content throw any light on the mass extinctions that were taking place during its formation?

He first suggested that the iridium could have come from a nearby supernova explosion. This was soon rejected after a fruitless search in the clay for traces of plutonium-244, another supernova byproduct. Alvarez began to consider another possibility, namely, a collision with a large asteroid. It would certainly bring

along with it the observed iridium, but it was not immediately apparent how the asteroid could produce a global extinction. Further reflection suggested that an asteroid 10 kilometers in diameter would throw sufficient dust into the atmosphere to darken the sky for several years. This in turn would prevent photosynthesis, destroy plant life and, along the way, all other dependent creatures.

Alvarez published his theory in 1980 and spent much of the remaining decade of his life explaining and defending his views. Some geologists objected that dinosaurs had become extinct some 20,000 years before the iridium layer was deposited. Others claimed that prolonged darkness would have been as damaging to marine as to terrestrial life, whereas marine life suffered no comparable mass extinction. Despite these and other objections Alvarez’s impact theory survived the 1980s as the most favored account of the death of the dinosaurs.

Alvarez left a vivid account of his life in his *Alvarez, Adventures of a Physicist* (1987).

### **Alzheimer, Alois** (1864–1915) *German psychiatrist*

Alzheimer (**ahlts**-hl-mer or **awlts**-hl-mer) was born in Markbreit in Germany and studied medicine at the universities of Würzburg and Berlin. After working in hospitals in Frankfurt and Heidelberg, he joined the Munich Psychiatric Clinic of Emil Kraepelin (1856–1926) as head of the anatomy department. He worked in Munich from 1904 until 1912 when he was appointed professor of psychiatry and neurology at the University of Breslau (now Wrocław in Poland).

In 1907 Alzheimer treated a 51-year-old woman with a growing memory loss. Her condition rapidly deteriorated into severe dementia. On autopsy, he identified a number of pathological conditions including shrinking of the cortex and the presence of neurofibrillary tangles and neuritic plaques. The plaques and tangles were distinctive enough to warrant a diagnosis of senile dementia or, as it later became known, *Alzheimer’s disease*.

### **Amagat, Emile Hilaire** (1841–1915) *French physicist*

Born at Saint-Satur, Amagat (am-a-ga) obtained his doctorate in 1872 from Paris and became a professor of physics at the Faculté Libre des Sciences at Lyons and eventually a full member of the French Academy of Sciences.

He is noted for his work on the behavior of gases. He started work plotting isotherms of carbon dioxide at high pressures, expanding the results of Thomas Andrews; this research was published in 1872 as his doctoral thesis. In 1877 followed a publication on the coefficient of compressibility of fluids, showing conclusively

that this decreased with an increase in pressure, a result contradicting the results of other scientists. Between 1879 and 1882 Amagat investigated a number of gases, publishing data on isotherms and reaching the limit of pressures obtainable using glass apparatus – about 400 atmospheres. To get yet further Amagat invented a hydraulic manometer that could produce and measure up to 3200 atmospheres. (This manometer was later used in firearms factories for testing purposes.)

**Amaldi, Edoardo** (1908–1989) *Italian physicist*

Amaldi (am-al-dee) was born in Carpaneto in Italy; in 1929 he graduated from the University of Rome, where he had studied under Enrico FERMI. Together with Fermi and others he discovered that fast-moving neutrons are slowed down (moderated) by substances containing hydrogen, and can thus be brought to energies at which they more easily interact with nuclei. He also contributed to the study of tau mesons, hyperons, and antiprotons.

In 1937 he was made professor of general physics at the University of Rome, and from 1952 until 1954 he was secretary-general of the European Organization for Nuclear Research. He also served as president of the International Union of Pure and Applied Physics (1957–60) and president of the Istituto Nazionale di Fisica Nucleare (1960–65).

Amaldi played a key role in the creation and development of CERN (Conseil européen pour la Recherche nucléaire; European Laboratory for Particle Physics). On a visit to Europe in 1948 Luis ALVAREZ had asked Amaldi why the Europeans did not “do physics jointly” and build, as several American universities had done, a large accelerator. Amaldi began to lobby for such a project and persuaded a reluctant UK to enter, having overcome, in a stormy meeting, the strong objections of Lord Cherwell. When, in 1952, eleven governments set up CERN Amaldi was offered the post of director general. He refused, accepting instead the position of vice director in charge of administration, returned to his university post in 1954, and concentrated on research into the detection of gravitational waves.

**Ambartsumian (or Ambartsumyan), Viktor Amazaspovich** (1908–1996) *Armenian astrophysicist*

Ambartsumian (am-bart-soo-mee-an) was born in Tbilisi (now in Georgia), the son of a distinguished Armenian philologist. He graduated from the University of Leningrad in 1928 and did graduate work at Pulkovo Observatory, near Leningrad, from 1928 to 1931. He was professor of astrophysics from 1934 to 1946 at Leningrad and held the same post at the State

University at Yerevan in Armenia from 1947 until his death. In 1946 he organized the construction, near Yerevan, of the Byurakan Astronomical Observatory, having been appointed its director in 1944. He remained as director until 1988.

Ambartsumian’s work was mainly concerned with the evolution of stellar systems, both galaxies and smaller clusters of stars, and the processes taking place during the evolution of stars. The idea of a stellar “association” was introduced into astronomy by Ambartsumian in 1947. Associations are loose clusters of hot stars that lie in or near the disk-shaped plane of our galaxy. They must be young, no more than a few million years old, as the gravitational field of the galaxy will tend to disperse them. This must mean that star formation is still going on in the galaxy.

He also argued in 1955 that the idea of colliding galaxies proposed by Rudolph MINKOWSKI and Walter BAADE to explain such radio sources as Cygnus A would not produce the required energy. Instead, he proposed that the source of energy was gigantic explosions occurring in the dense central regions of galaxies and these would be adequate to provide the  $10^{55}$  joules emitted by the most energetic radio sources.

**Amdahl, Gene Myron** (1922– ) *American computer engineer*

The son of a South Dakota farmer, Amdahl was educated at South Dakota State College and, following war service, the University of Wisconsin, where he received his doctorate in 1952. Shortly after, he joined IBM to work on the design of their new mainframe computers, the 701, 704, and 709. Amdahl left IBM in 1955 in a disagreement over the minor role he had been assigned in the development of their new model, the 7030. He returned to IBM in 1960, after working for the Ford subsidiary Aeronautics on systems design, and began work on the IBM 360 series. This was one of the first models to incorporate integrated circuits and proved to be one of the most successful mainframes ever produced.

In 1965 Amdahl was made an IBM Fellow, a five-year appointment allowing him to work on any project he chose. During this period he founded the IBM Advanced Computing Systems Lab in Menlo Park, California.

Before the expiry of his fellowship Amdahl resigned once more. This time the disagreement arose over IBM’s traditional policy of pricing mainframes on the basis of their computing power rather than their cost. Such an approach, Amdahl argued, gave IBM no incentive to build more powerful machines. In 1970 he founded the Amdahl Corporation with the aim of designing IBM-compatible mainframes. Large-scale integration chips were just coming into use and, while previously designers had strug-

gled to link 25–30 circuits on a chip, Amdahl aimed to have 100. Within three years Amdahl's new computer, the Amdahl 470, three times more powerful than the IBM 360s but no more expensive at \$3.5 million, had created sales of \$320 million. IBM responded with price cuts and Amdahl consequently sold his company in 1979 to Fujitsu.

He immediately started his second company, Trilogy, using the new technology of wafer-scale integration which, in theory, should allow 2,000 chips to be replaced by 20 wafers. Amdahl was predicting sales of \$1 billion within two years. The technology, however, was too new and the models proved to be less powerful than expected. They also had a tendency to short-circuit and came onto the market three years behind schedule. Amdahl left the mainframe business and conceded the market to IBM. Trilogy merged with Elxsi in 1985.

Amdahl subsequently founded other companies: Amdor International (in 1987) and Commercial Data Servers (in 1995). Since 2004 he has been on the board of advisors of Massively Parallel Technologies.

**Amici, Giovanni Battista (1786–1863)**  
*Italian astronomer and instrument maker*

Amici (a-**mee**-chee) was professor of mathematics at the University of Modena and in 1835 became the director of the observatory at the Royal Museum in Florence. He made great improvements in the design of parabolic mirrors for reflecting telescopes, and constructed and designed prismatic spectrosopes. In 1840 he made two achromatic objective lenses with diameters of 9.5 and 11 inches (24 and 28 cm), which were used by Giovanni DONATI. He also made advances in microscopy, improving the compound microscope and using it to study plant reproduction.

**Amontons, Guillaume (1663–1705)**  
*French physicist*

Amontons (a-mon-**ton**), a Parisian, who had been deaf since childhood, invented and perfected various scientific instruments. In 1687 he made a hygrometer (an instrument for measuring moisture in the air); in 1695 he produced an improved barometer; and in 1702–03 a constant-volume air thermometer. In 1699 he published the results of his studies on the effects of change in temperature on the volume and pressure of air. He noticed that equal drops in temperature resulted in equal drops in pressure and realized that at a low enough temperature the volume and pressure of the air would become zero – an early recognition of the idea of absolute zero. These results lay largely unnoticed and the relationship between temperature and pressure of gases was not reexamined

until the next century (by scientists such as Jacques CHARLES).

Amontons also published in 1699 the results of his studies on friction, which he considered to be proportional to load.

**Ampère, André Marie (1775–1836)**  
*French physicist and mathematician*

Ampère (ahm-**pair**) was born in Lyons, France, where his father was a wealthy merchant. He was privately tutored, and to a large extent self-taught. His genius was evident at an early age. He was particularly proficient at mathematics and, following his marriage in 1799 he was able to make a modest living as a mathematics teacher in Lyons. In 1802 he moved first to Bourg-en-Bresse to take up an appointment, then to Paris as professor of physics and chemistry at the Ecole Centrale.

His first publication was on the statistics of games of chance *Considérations sur la théorie mathématique de jeu* (1802; Considerations on the Mathematical Theory of Games) and his work at Bourg led to his appointment as professor of mathematics at the Lyceum of Lyons, and then in 1809 as professor of analysis at the Ecole Polytechnique in Paris. His talents were recognized by Napoleon, who in 1808 appointed him inspector general of the newly formed university system – a post Ampère held until his death.

Ampère's most famous scientific work was in establishing a mathematical basis for electromagnetism. The Danish physicist Hans Christian OERSTED had made the important experimental discovery that a current passing through a wire could cause the movement of a magnetic compass needle. Ampère witnessed a demonstration of electromagnetism by François ARAGO at the Academy of Science on 11 September 1820. He set to work immediately on his own investigations, and within seven days was able to report the results of his experiments.

In a succession of presentations to the academy in the next four months, he developed a mathematical theory to explain the interaction between electricity and magnetism, to which he gave the name “electrodynamics” (now more commonly: electromagnetism) to distinguish it from the study of stationary electric forces, which he christened “electrostatics.”

Having recognized that electric currents in wires caused the motion of magnets, and that a magnet can affect another magnet, he looked for evidence that electric currents could influence other electric currents. The simplest example of this interaction is found by arranging for currents to flow through two parallel wires. Ampère discovered that if the currents passed in the same direction the wires were attracted to each other, but if they passed in opposite directions the wires were repelled. From this he went on to consider more complex configura-

tions of closed loops, helices, and other geometrical figures, and was able to provide a mathematical analysis that allowed quantitative predictions.

In 1825 he had been able to deduce an empirical law of forces (*Ampère's law*) between two current-carrying elements, which showed an inverse-square law (the force decreases as the square of the distance between the two elements, and is proportional to the product of the two currents). By 1827 he was able to give a precise mathematical formulation of the law, and it was in this year that his most famous work *Mémoires sur la théorie mathématique des phénomènes électrodynamiques uniquement déduite de l'expérience* (Notes on the Mathematical Theory of Electrodynamical Phenomena, Solely Deduced from Experiment) was published.

Besides explaining the macroscopic effects of electromagnetism, he attempted to construct a microscopic theory that would fit the phenomenon, and postulated an electrodynamic molecule in which electric-fluid currents circulated, giving each molecule a magnetic field.

In his honor, the unit of electric current is named for him, and in fact the ampere is defined in terms of the force between two parallel current-carrying wires.

### **Anaxagoras of Clazomenae** (about 500 BC–428 BC) *Greek philosopher*

Anaxagoras (an-ak-sag-o-rus) left his birthplace in Asia Minor (now Turkey) in about 480 BC and taught in Athens during its most brilliant period under Pericles, who was himself one of Anaxagoras's pupils. In about 450 BC he was exiled to Lampsacus after being prosecuted for impiety by the enemies of Pericles.

Although he wrote a book, *On Nature*, only fragments of his writings survive; his work is known through later writers, notably ARISTOTLE and SIMPLICIUS, and is open to contradictory interpretations. The difficulty consists in reconciling his principle of homoeomereity, which states that matter is infinitely divisible and retains its character on division, with his statement "there is a portion of everything in everything." His work can be seen as a criticism of the Eleatic school of PARMENIDES and ZENO of Elea, who had argued against plurality and even motion.

Anaxagoras's astronomy was more rational than that of his predecessors; he stated that the Sun and stars were incandescent stones, that the Moon derived its light from the Sun, and he gave the modern explanation for eclipses of the Sun and Moon.

### **Anaximander of Miletus** (c. 611 BC–c. 547 BC) *Greek philosopher*

Anaximander...said that a certain infinite

nature is first principle of the things that exist. From it come the heavens and the worlds in them.

—Hippolytus, *Refutation of All Heresies* (2nd century AD)

Anaximander (a-nak-si-man-der), who was born and died in Miletus (now in Turkey), belonged to the first school of natural philosophy and was the pupil of THALES. He wrote one of the earliest treatises but none of his writings survive and his work is known only through later writers, notably ARISTOTLE and THEOPHRASTUS.

Anaximander criticized Thales's idea that water was the basic element of the universe by pointing out that no one element gains the upper hand and that "they make retribution and pay the penalty to one another ... according to the ordering of time." From this he deduced that the primal matter was what he called the *apeiron* or the indefinite. This idea was later developed by the atomists. He was the first to realize that the Earth did not have to float on water or be supported in any way; he stated that it was in equilibrium with the other bodies in the universe.

Anaximander was the first philosopher to speculate on the origin of man. He is also credited with the first determinations of the solstices and equinoxes and the production of the first map of the world as he knew it. He was the first to recognize that the Earth's surface is curved but believed it was curved only in the north-south direction and consequently represented the Earth as a cylinder.

### **Anaximenes of Miletus** (about 546 BC) *Greek philosopher*

Anaximenes (an-ak-sim-e-nee) was the last of the great Milesian philosophers. He was probably a pupil of ANAXIMANDER of Miletus and, like THALES before him, he identified one of the tangible elements as the primal substance. For Anaximenes this was air, which by processes of condensation and rarefaction could produce every other kind of matter. He used the rather mystical argument that since air is the breath of life for man it must also be the main principle of the universe.

### **Anderson, Carl David** (1905–1991) *American physicist*

Anderson, the son of Swedish immigrants, was born in New York City and educated at the California Institute of Technology where he obtained his PhD in 1930 and where he remained for his entire career, serving as professor of physics from 1939 until his retirement in 1978.

Anderson was deeply involved in the discovery of two new elementary particles. In 1930 he began to study cosmic rays by photographing their tracks in a cloud chamber and noted that

particles of positive charge occurred as abundantly as those of negative charge. The negative particles were clearly electrons but those of positive charge could not be protons (the only positive particles known at the time) as they did not produce sufficient ionization in the chamber. Eventually Anderson concluded that such results “could logically be interpreted only in terms of particles of a positive charge and a mass of the same order of magnitude as that normally possessed by a free negative electron.” It was in fact the positron or positive electron, whose existence he announced in September 1932. In the following year his results were confirmed by Patrick BLACKETT and Giuseppe OCCHIALINI and won for Anderson the 1936 Nobel Prize for physics.

In the same year Anderson noted some further unusual cosmic-ray tracks. As they appeared to be made by a particle more massive than an electron but lighter than a proton it was at first thought to be the particle predicted by Hideki YUKAWA that was thought to carry the strong nuclear force and hold the nucleus together. The particle was initially named the “mesotron” or “yukon.” However, this identification proved to be premature, as its interaction with nucleons was found to be so infrequent that it could not possibly perform the role described by Yukawa. From 1938 the particle became known as the meson, and the confusion was partly dispelled in 1947 when Cecil POWELL discovered another and more active meson, to be known as the pi-meson or pion to distinguish it from Anderson’s mu-meson or muon. While the role of the pion is readily explained, that of Anderson’s muon is still far from clear.

### Anderson, Philip Warren (1923– ) *American physicist*

Anderson was born in Indianapolis and obtained his BS (1943), MS (1947), and PhD (1949) at Harvard University, doing his doctoral thesis under John VAN VLECK. The period 1943–45 was spent at the Naval Research Laboratory working on antenna engineering. Upon receiving his doctorate, Anderson joined the Bell Telephone Laboratories at Murray Hill, New Jersey, where he worked until 1984. He is currently Joseph Henry Professor of Physics at Princeton.

Anderson’s main research has been in the physics of the solid state, incorporating such topics as spectral-line broadening, exchange interactions in insulators, the JOSEPHSON effect, quantum coherence, superconductors, and nuclear theory. Under Van Vleck he worked initially on elucidating the phenomenon of pressure broadening of lines in microwave, infrared, and optical spectroscopy. In 1959 he developed a theory to explain “superexchange” – the coupling of spins of two magnetic atoms in

a crystal through their interaction with a non-magnetic atom located between them. He went on to develop the theoretical treatments of antiferromagnetics, ferroelectrics, and superconductors.

In 1961 Anderson conceived a theoretical model to describe what happens where an impurity atom is present in a metal – now widely known and used as the *Anderson model*. Also named for him is the phenomenon of *Anderson localization*, describing the migration of impurities within a crystal. In the 1960s Anderson concentrated particularly on superconductivity and superfluidity, predicting the existence of resistance in superconductors and (with Pierre Morel) pointing out the nature of the possible superfluid states of  $^3\text{He}$ . In 1971 he returned to disordered media, working on low-temperature properties of glass and later studying spin glasses and high-temperature superconductivity.

Along with his Harvard tutor Van Vleck and the British physicist Nevill MOTT, Anderson shared the 1977 Nobel Prize for physics “for their fundamental theoretical investigation of the electronic structure of magnetic and disordered systems.”

In the late 1980s Anderson became a controversial figure in the physics community by arguing before Congress that the proposed SSC (Superconducting Super Collider) to be built in Texas at a cost of \$8 billion would yield neither practical benefits nor any fundamental truths that could not be gained elsewhere and more cheaply. When Congress killed the plan in 1993 Anderson commented that he was only sorry that Congress had allowed the project to go on so long.

### Anderson, Thomas (1819–1874) *British organic chemist*

Born in the port of Leith in Scotland, where his father was a physician, Anderson also studied medicine, gaining his MD from Edinburgh in 1841. His main interest, however, lay in chemistry which he pursued in 1842 with BERZELIUS in Sweden and with LIEBIG in 1843 in his famous Giessen Laboratory. Anderson was appointed Regius Professor of Chemistry at the University of Glasgow in 1852.

Anderson’s most important work was concerned with the chemistry of pyridine ( $\text{C}_5\text{H}_5\text{N}$ ), a heterocyclic compound, which he extracted in 1851 from bone oil. He had earlier (1849) extracted the related substances, lutidine ( $\text{C}_5\text{H}_3\text{N}$ ), picoline ( $\text{C}_5\text{H}_4\text{N}$ ), and collidine ( $\text{C}_5\text{H}_2\text{N}$ ). Anderson went on to suggest that he had discovered an homologous series in which the radical  $\text{C}_5\text{H}_n$  was being substituted for  $\text{H}_3$  in the ammonia molecule. The pyridines are used as powerful and versatile organic solvents capable of dissolving fats, mineral oils, and rubber.

Anderson also did much to introduce the "agricultural chemistry" of Liebig into Scotland. He worked from 1848 as a chemist with the Highland and Agricultural Society, for which he determined the chemical composition of such staples as turnip, wheat, and beans. Anderson wrote one of the earliest texts on the subject in his *Elements of Agricultural Chemistry* (1860).

**Andrade, Edward Neville da Costa** (1887–1971) *British physicist*

Born in London, Andrade was educated at University College, London, and at Heidelberg where he obtained his PhD in 1911. He then worked with Ernest RUTHERFORD at Manchester before joining the Royal Artillery in 1914. After the war he was appointed professor of physics at the Artillery College, Woolwich, and moved to a similar chair at University College, London, in 1928. Andrade resigned in 1950 to take up the directorship of the Royal Institution, a post he held until his retirement in 1952.

Andrade worked mainly on the physics of metals and the viscosity of liquids. On the former subject he made the first serious scientific study of creep in metals while on the latter subject he investigated the effect of an electric field on viscosity. In addition to writing a number of popular works on science, Andrade was also widely known as a student of 17th-century physics. He was an expert on Robert HOOKE and as chairman in 1947 of the Royal Society Newton letters committee he played an important role in beginning the monumental task of the publication of Newton's letters, a task requiring 40 years for its completion (from 1938).

**Andreessen, Marc** (1971– ) *American computer scientist*

Andreessen (**an-dree-sen**) was born in New Lisbon, Wisconsin, and was educated at the University of Illinois at Urbana.

In his senior year at Illinois he worked at the National Center for Supercomputer Applications (NCSA), a high-tech think tank, where he came across the Internet, then in its early days. He immediately realized that a browser that could be easily used would be very useful. In a few weeks Andreessen, together with Eric BINA and some colleagues from NCSA, produced an operational browser called *Mosaic*.

In 1994 Andreessen and Jim Clark founded a company called Mosaic Corp. with the intention of making Internet browsers. They soon changed the name to Netscape Communications after legal objections to the previous name by the University of Illinois. Andreessen and his team, including Bina, produced an improved version of Mosaic, which they called *Navigator*.

Navigator was initially very successful but was eclipsed when Microsoft introduced its own browser *Internet Explorer*. In 1998 Andreessen became technology officer of America Online (AOL), which had bought out Netscape. He left AOL in 1999 with the intention of playing a more direct role in the development of the Internet. He is currently involved in a number of projects including Ning, a platform for creating social websites and networks.

**Andrews, Roy Chapman** (1884–1960) *American naturalist and paleontologist*

Andrews was born in Beloit, Wisconsin, and was educated there at Beloit College. After graduating, he took up a post at the American Museum of Natural History, New York. His early interest lay in whales and other aquatic mammals, and these he collected assiduously on a number of museum-sponsored expeditions to Alaska, North Korea, and the Dutch East Indies (Indonesia) between 1908 and 1913. It was largely through Andrews's efforts that the collection of cetaceans at the American Museum of Natural History became one of the most complete in the world.

Andrews is best known for his discovery of previously unknown Asiatic fossils. Most of his findings were made on three expeditions to Asia, which he led as chief of the Asiatic Exploration Division of the American Museum of Natural History. The first of these was to Tibet, southwestern China, and Burma (1916–17); he then visited northern China and Outer Mongolia (1919), and central Asia (1921–22 and 1925). The third Asian expedition produced major finds of fossil reptiles and mammals, including remains of the largest known land mammal, the Paraceratherium (formerly called Baluchitherium), an Oligocene relative of the modern rhinoceros, which stood some 17–18 feet (5.5 m) at the shoulder. In Mongolia, Andrews discovered the first known fossil dinosaur eggs. He was also able to trace previously unknown geological strata, and unearthed evidence of primitive human life on the central Asian plateau.

Andrews was appointed director of the American Museum of Natural History in 1935, but resigned in 1942 in order to devote himself entirely to writing about his travels and discoveries.

**Andrews, Thomas** (1813–1885) *Irish physical chemist*

There exists for every liquid a temperature at which no amount of pressure is sufficient to retain it in the liquid form.

—Quoted by W. A. Miller in *Elements of Chemistry* (1863)

The son of a linen merchant from Belfast (now in Northern Ireland), Andrews studied chem-

istry under Thomas Thomson at Glasgow, under Jean DUMAS in Paris, and under Justus von LIEBIG at Giessen. He also studied medicine at Edinburgh and obtained his MD in 1835. He practiced medicine in Belfast before becoming vice-president of Queen's College, Belfast, in 1845 and professor of chemistry in 1849.

Andrews made experimental studies on the heat evolved in chemical reactions and also showed that ozone is an allotrope of oxygen. He was a brilliant experimentalist and his work on the liquefaction of gases brought order to a confused subject. Andrews performed a famous series of experiments on the variation of the volume of carbon dioxide gas with pressure. He studied the behavior of the gas at different temperatures, and showed that there was a certain temperature – the critical temperature – above which the gas could not be liquefied by pressure alone. This work, which was published as *On the Continuity of the Liquid and Gaseous States of Matter* (1869) led to the liquefaction of those gases previously held to be “permanent” gases.

### **Anfinsen, Christian Boehmer** (1916–1995) *American biochemist*

Anfinsen was a true pioneer in the field of protein structure and protein folding.  
—Daniel Nathans

Born in Monessen, Pennsylvania, Anfinsen was educated at Swarthmore College, the University of Pennsylvania, and Harvard, where he obtained his PhD in 1943. He taught at Harvard Medical School from 1943 to 1950, when he moved to the National Heart Institute at Bethesda, Maryland, where from 1952 to 1962 he served as head of the laboratory of cellular physiology. In 1963 Anfinsen joined the National Institute of Arthritis and Metabolic Diseases at Bethesda, where he was appointed head of the laboratory of chemical biology. In 1982 he became professor of biology at Johns Hopkins University.

By 1960 Stanford MOORE and William STEIN had fully determined the sequence of the 124 amino acids in ribonuclease, the first enzyme to be so analyzed. Anfinsen, however, was more concerned with the shape and structure of the enzyme and the forces that permit it always to adopt the same unique configuration. The molecule of ribonuclease – a globular protein – consists of one chain twisted into a ball and held together by four disulfide bridges. By chemical means, the sulfur bridges can be separated so that the enzyme becomes a simple polypeptide chain with no power to hydrolyze ribonucleic acid, i.e., it becomes denatured. Once the bridges are broken they can be reunited in any one of 105 different ways. Anfinsen found that the minimum of chemical intervention – merely putting the enzyme into a favorable environment – was sufficient to induce the ribonucle-

ase to adopt the one configuration that restores enzymatic activity.

The important conclusion Anfinsen drew from this observation was that all the information for the assembly of the three-dimensional protein must be contained in the protein's sequence of amino acids – its primary structure. He went on to show similar behavior in other proteins. For this work Anfinsen shared the 1972 Nobel Prize for physiology or medicine with Moore and Stein.

### **Ångström, Anders Jonas** (1814–1874) *Swedish physicist and astronomer*

Ångström (**ang**-strom or **awng**-stru(r)m) was born the son of a chaplain in Lögdö, Sweden. He studied and taught physics and astronomy at the University of Uppsala, where he obtained his doctorate (1839) and later became professor of physics (1858), a position he held up to his death.

Ångström was one of the pioneers of spectroscopy. His most important work was *Optiska Undersökningar* (1853; *Optical Investigations*), in which he published measurements on atomic spectra, particularly of electric sparks. He noted spectral lines that were characteristic of both the gas and the electrodes used. Ångström applied EULER'S theory of resonance to his measurements and deduced that a hot gas emits light at precisely the same wavelength at which it absorbs light when it is cool. In this he anticipated the experimental proof of Gustav KIRCHHOFF. He was also able to show the composite nature of the spectra of alloys.

Having established the principles of spectroscopy in the laboratory, Ångström turned his attention to the Sun's spectrum, publishing *Recherches sur le spectre solaire* (1868; *Researches on the Solar Spectrum*) in which he made the inference that hydrogen was present in the Sun. In this work he also reported the wavelengths of some 1,000 FRAUNHOFER lines measured to six significant figures in units of  $10^{-8}$  centimeters. Since 1905 his name has been officially honored as a unit of length used by spectroscopists and microscopists; 1 angstrom (Å) =  $10^{-8}$  centimeters. His map of the *Normal Solar Spectrum* (1869) became a standard reference for some 20 years. Ångström was also the first to examine the spectrum of the aurora borealis and to measure the characteristic bright yellow-green light sometimes named for him.

### **Anning, Mary** (1799–1847) *British fossil hunter*

Anning was born in Lyme Regis, Dorset, on the south coast of England, the daughter of a cabinetmaker. Her father died in 1810, leaving his widow and two surviving children in debt. To make a meager living, the family turned to

hunting for fossils along the cliffs bordering the small seaside town, and selling them to collectors and museums. From this modest beginning, and in spite of her poverty and low social class, Mary Anning defied the conventions of her age to become well known and respected among the male-dominated scientific community. In 1817 Lieutenant-Colonel Thomas Birch, an affluent amateur collector of fossils, became the family's patron, and he arranged to sell his own collection for the benefit of the Anning family. During this time, Mary was effectively running the family fossil business, acquiring a wealth of anatomical knowledge about the specimens she gathered and prepared for sale, and becoming a prominent figure in Lyme and beyond. She is credited with several major discoveries of prehistoric marine reptiles, including the first fossil ichthyosaur (in about 1809–1811; now in the Natural History Museum, London), and also the first plesiosaur (in 1821). Although many of Anning's finds were sold on with little or no credit given to their discoverer, her reputation grew, and with it came scientific recognition and reward. From 1838 she received an annuity from the British Association for the Advancement of Science, and shortly before her death she was named as the first honorary member of the newly founded Dorset County Museum.

**Antoniadi, Eugène Michael** (1870–1944)  
*Greek–French astronomer*

Antoniadi (an-ton-yah-dee) was born in Constantinople (now Istanbul, Turkey). He established quite early a reputation as a brilliant observer and in 1893 was invited by Camille FLAMMARION to work at his observatory at Juvisy near Paris. From 1909 he worked mainly with the 33-inch (84-cm) refracting telescope at the observatory at Meudon. He became a French citizen in 1928.

In his two works *La Planète Mars* (1930; The Planet Mars) and *La Planète Mercure* (1934; The Planet Mercury), Antoniadi published the results of many years' observations and presented the best maps of Mars and Mercury to appear until the space probes of recent times. With regard to Mars he took the strong line: "Nobody has ever seen a genuine canal on Mars," attributing the "completely illusory canals," "seen" by astronomers such as Percival LOWELL and Flammarion, to irregular natural features of the Martian surface. Antoniadi also observed the great Martian storms of 1909, 1911, and 1924 noting, after the last one, that the planet had become covered with yellow clouds and presented a color similar to Jupiter.

On Mercury his observations made between 1914 and 1929 seemed to confirm Giovanni SCHIAPARELLI's rotation period of 88 days, identical with the planet's period of revolution

around the Sun. The effect of this would be for Mercury always to turn the same face to the Sun, in the same way as the Moon always turns the same face to the Earth. Antoniadi cited nearly 300 observations of identifiable features always in the same position, as required by the 88-day rotation period.

However, radar studies of Mercury in 1965 revealed a 59-day rotation period for Mercury. This time is however very close to half the synodic period of Mercury (116 days) so that when the planet returns to the same favorable viewing position in the sky, at intervals of 116 days, it does present the same face to observers.

Antoniadi also wrote on the history of astronomy, publishing *L'Astronomie Egyptienne* (Egyptian Astronomy) in 1934.

**Apker, Leroy** (1915–1978) *American physicist*

Apker was born in Rochester, New York, and educated there at the University of Rochester; he obtained his PhD in 1941. He later joined the staff of General Electric where he worked as a research associate.

Apker worked on the photoelectric effect applied to semiconductors and ionic crystals. A particular aspect of his work was photoemission from the alkali-metal halides, such as potassium iodide. Crystals of these compounds can contain a type of defect involving a missing negative ion replaced by an electron – called a "color center" (because such defects color the crystal). Apker studied the photoemission from such crystals, and the interaction of excitons with color centers causing the ejection of electrons.

**Apollonius of Perga** (c. 262 BC–c. 190 BC)  
*Greek mathematician and geometer*

Apollonius (ap-o-loh-nee-us) moved from his birthplace Perga (now in Turkey) to study in the Egyptian city of Alexandria, possibly under pupils of EUCLID. Later he taught in Alexandria himself. One of the great Greek geometers, Apollonius's major work was in the study of conic sections and the only one of his many works to have survived is his eight-book work on this subject, the *Conics*. Apollonius's work on conics makes full use of the work of his predecessors, notably Euclid and CONON of Samos, but it is a great advance in terms of its thoroughness and systematic treatment. The *Conics* also contains a large number of important new theorems that are entirely Apollonius's creation. He was the first to define the parabola, hyperbola, and ellipse. In addition, he considered the general problem of finding normals from a given point to a given curve (i.e., lines at right angles to a tangent at a point on the curve).

Apart from the geometrical work that has

**CONIC SECTIONS** Apollonius showed that the circle, ellipse, parabola, and hyperbola could be generated by different sections of a conical surface.

survived, Apollonius is known to have contributed to optics – in particular to the study of the properties of mirrors of various shapes. This work, however, is now lost.

**Appel, Kenneth** (1932– ) *American mathematician*

Appel, who was born in Brooklyn, New York City, was educated at the University of Michigan, where he completed his PhD in 1959. After working for two years at the Institute for Defense Analysis at Princeton, he joined the faculty of the University of Illinois, Urbana, where he served as professor of mathematics from 1991 to 1993. He then took up the chairmanship of the mathematics department at the University of New Hampshire until 2002.

In 1976, in collaboration with Wolfgang HAKEN, Appel announced the solution to one of mathematics long-standing unsolved problems, the four-color map problem. In 1852 Francis Guthrie had noticed that it seemed to be possible to color any map, assuming countries with common borders were colored differently, with no more than four colors. Guthrie was sufficiently intrigued by the point to raise it with the mathematician de Morgan and ask for a proof of the conjecture. De Morgan found the problem unexpectedly difficult, as did succeeding generations of mathematicians.

Appel and Hagen used a variation of a method first tried by Arthur Kempe in 1879. It depends on the fact that maps must contain certain unavoidable configurations – Appel and Hagen recognized 1,482 of these. They then used a computer to show that all of these could be reduced to four-color configurations. They began work in 1972, but it was not until 1976 that they were satisfied with their analysis and their program. It took more than 1,200 hours of computer time to prove the theorem.

**Appert, Nicolas-François** (1749–1841) *French inventor*

Appert (a-**PAIR**), who was born in Chalons-sur-Marne, France, was a chef, confectioner, and distiller who invented the canning of food. In 1795 he started to experiment with sealed containers, using corked glass sealed with wax. He succeeded in preserving fruits, soups, marmalades, etc., for several years. To claim a 12,000-franc award in 1810 he published his findings in *L'art de conserver, pendant plusieurs années, toutes les substances animal et végétales* (The Art of Preserving All Kinds of Animal and Vegetable Substances for Several Years). He used the money to set up the first commercial cannery in the world, the House of Appert, at Massy, which was open from 1812 to 1833.

**Appleton, Sir Edward Victor** (1892–1965) *British physicist*

Appleton was born in Bradford, England, and studied physics at Cambridge University from 1910 to 1913. During World War I, while he was serving in the Royal Engineers, he developed the interest in radio that was to influence his later research. After the war he returned to Cambridge and worked in the Cavendish Laboratory from 1920. In 1924 he was appointed Wheatstone Professor of Experimental Physics at King's College, London.

Here, in his first year, he used a BBC transmitter to conduct a famous experiment, which established beyond doubt the presence of a layer of ionized gas in the upper atmosphere capable of reflecting radio waves. The existence of such a layer had been postulated by Oliver HEAVISIDE and Arthur KENNELLY to explain MARCONI's transatlantic radio transmissions. By varying the frequency of a transmitter in Bournemouth and detecting the signal some 140 miles (225 km) away in Cambridge, he showed that interference occurred between direct (ground) waves and waves reflected off the

layer (sky waves). Furthermore, the experiment measured the height of the layer, which he estimated at 60 miles (96 km). He proceeded to do theoretical work on the reflection or transmission of radio waves by an ionized layer and found, using further measurements, a second layer above the Heaviside–Kennelly layer. The *Appleton layer* undergoes daily fluctuations in ionization and he established a link between these variations and the occurrence of sunspots.

In 1936 he became the Jacksonian Professor of Natural Philosophy at Cambridge, and during the war years until 1949 he was secretary of the department of scientific and industrial research, in which period he led research into radar and the atomic bomb.

For his great achievements in ionospheric physics he was knighted in 1941 and in 1947 won the Nobel Prize for physics. From 1949 until his death he was principal of Edinburgh University.

**Arago, Dominique François Jean** (1786–1853) *French physicist*

To get to know, to discover, to publish – this is the destiny of a scientist.  
—Quoted by A. L. MacKay in *A Harvest of a Quiet Eye* (1977)

Born in Estagel, France, Arago (a-ra-goh or a-ra-goh) was educated at the Ecole Polytechnique in Paris and then spent some years in Spain, where he accompanied Jean Baptiste BIOT on a measurement of an arc of meridian. On his return to Paris in 1809 he was elected to the Académie des Sciences and received the chair of analytical geometry at the Ecole Polytechnique. In 1830 he succeeded J. B. J. FOURIER as the permanent secretary of the Ecole Polytechnique. Arago worked in a number of branches of physics.

His first investigations concerned the polarization of light and in 1811 he discovered chromatic polarization. He was a vigorous defender of A. J. FRESNEL'S wave theory of light against the criticisms of LAPLACE and Biot, who both supported the corpuscular theory. In 1838 he described an experiment to decide the issue by comparing the speed of light in air with that in a denser medium. Shortly before Arago's death, Léon FOUCAULT and Armand FIZEAU proved that the experiment supported the wave theory.

Arago also worked on electromagnetism, showing that a coil of wire carrying a current could act as a magnet. He also found that a rotating copper disk could deflect a magnetic needle suspended above it. (This arrangement, known as *Arago's disk*, depends on magnetic induction.)

In astronomy, Arago discovered the Sun's chromosphere. He also played a part in the discovery of Neptune by Urbain LE VERRIER.

Arago was a fierce republican and, from 1830 onward, he was involved in political life as

deputy for the Pyrénées Orientales. In 1848 he became a government minister and, among other measures, abolished slavery in the French colonies.

**Arber, Werner** (1929– ) *Swiss microbiologist*

Arber (ar-ber), who was born in Gränichen, Switzerland, graduated from the Swiss Federal Institute of Technology in 1953 and gained his PhD from the University of Geneva in 1958. He spent a year at the University of Southern California before returning to Geneva where he became professor of molecular genetics in 1965. In 1971 Arber moved to Basel to take the chair of molecular biology.

In the early 1950s Giuseppe Bertani reported a phenomenon he described as “host-controlled variation” in which phages (the viruses that infect bacteria) successfully growing on one host found it difficult to establish themselves on a different bacterium. In 1962, he proposed that bacteria possess highly specific enzymes capable of destroying invading phages by cutting up their DNA. The existence of such “restriction enzymes,” as they came to be called, was later established by Hamilton SMITH.

It turned out that, as Arber had proposed, the enzymes attack the invading DNA at a specific site, always cutting them at exactly the same place. It was this property that endowed restriction enzymes with such interest for if strands of DNA could be so manipulated to be cut at particular known points, it only needed the power to join such strands together in desired combinations for genetic engineering to be a reality. As restriction enzymes were found to leave DNA strands “sticky” and ready to combine with certain other “sticky” strands it was soon apparent to molecular biologists that genetic engineering was at last a practical proposition.

For his work on restriction enzymes Arber shared the 1978 Nobel Prize for physiology or medicine with Smith and Daniel NATHANS.

**Archimedes** (287 BC–212 BC) *Greek mathematician*

Give me a lever long enough, and a firm place to stand on, and with my own weight I will move the Earth.  
—*On the Lever*

The father of Archimedes (ar-ki-mee-deez) was an astronomer and he himself inherited an interest in the subject. He was educated in Alexandria and spent most of the rest of his life in his birthplace, Syracuse, under the patronage of King Hieron. Archimedes was without question the greatest mathematician and scientist that classical Greek civilization produced and is usually considered to be one of the greatest mathematicians of all time. He was held in

very high regard even by his contemporaries, and Karl Friedrich GAUSS thought that only Isaac NEWTON was Archimedes's equal as a mathematician. Archimedes was as much an applied mathematician as a pure mathematician. He was very much interested in putting his theoretical discoveries to practical use and is known to have been skilled in making his own equipment and carrying out his own experiments. It is no exaggeration to describe Archimedes as the creator of the science of mechanics. Naturally before his time many isolated facts had been discovered, but it was only with him that mechanics became a unified body of theory capable of yielding new and unexpected practical applications.

Archimedes was able to find methods for determining the center of gravity of a variety of bodies. He also gave the first general theory of levers, and organized a practical demonstration to show how, with a suitable series of levers, a very small force is capable of moving a very large weight. He amazed his contemporaries by arranging for the king of Syracuse to move a large ship simply by pressing a small lever. In connection with his work on levers Archimedes made one of his famous statements, "Give me a firm place to stand on and I will move the Earth." Archimedes also had a practical interest in optics, although no writings of his on the subject have come down to us. He put all this newfound theoretical knowledge to deadly effect when Syracuse was besieged by the Romans, by designing and building a variety of war machines. Among these were enormous mirrors to focus the Sun's rays and set fire to the Roman ships, and a variety of catapults.

Archimedes also successfully applied his scientific discoveries in hydrostatics. He designed all sorts of pumps, and the Archimedean water-screw is still widely used. But his most famous practical success was in solving a problem presented to him by King Hieron. Hieron wished to know whether a newly made crown, which was supposed to be of pure gold was, as he suspected, partly silver. Archimedes solved the problem by grasping the concept of relative density. By immersing successively the crown itself and pieces of gold and silver of equal weight in full containers of water and observing the amount of water each displaced, Archimedes was able to show that the crown was indeed not made of pure gold. One of the famous stories associated with Archimedes tells how this occurred to him when he was getting into his bath and observed how the more of his body was immersed the more water overflowed from the bath. He saw instantly how to solve his problem, leaped from the bath, and rushed through the streets, stark naked, shouting "Eureka!" (I have found it).

Archimedes's work in applied mathematics and science ensured his great contemporary

fame, but some of his greatest work was probably in his more esoteric researches in pure mathematics. Like all Greek mathematicians, his interest was primarily concentrated on geometry. Arithmetic was greatly hampered by a very cumbersome system of notation. Although Archimedes himself invented a much improved system for notation of very large numbers, algebra had yet to be invented, in Europe at least. Archimedes's most profound achievement was to perfect the "method of exhaustion" for calculating the areas and volumes of curved figures. The method involves successively approximating the figure concerned by inscribed and circumscribed polygons. This method essentially used the concept of limit – a concept that took some time for later European mathematicians to grasp. Archimedes used this method to determine an approximate value for  $\pi$ , which was not to be improved on for many centuries.

Archimedes was put to death by a Roman soldier when the Romans, under general Marcellus, finally successfully besieged Syracuse. The killing was against the orders of Marcellus who respected Archimedes and wished for him to be protected. Archimedes was apparently drawing mathematical symbols in the sand when killed.

### **Argelander, Friedrich Wilhelm August** (1799–1875) *German astronomer*

Born in the Baltic port of Memel (now Klaipeda in Lithuania), Argelander (ar-ge-lahn-der) was the son of a wealthy Finnish merchant and a German mother. He was educated at Königsberg, where his interest in astronomy was aroused by the lectures of Friedrich BESSEL. Argelander began his career in 1820 as an assistant in Bessel's Königsberg Observatory. In 1823 he moved to the Åbo Observatory in Finland, then part of Russia. The observatory burned down in 1827 and Argelander began the design and construction of a new observatory in Helsinki, which was completed in 1832. In 1836 he was appointed professor of astronomy at Bonn. Here Friedrich Wilhelm IV built for Argelander an impressive new observatory. They were in fact old friends. In 1806, following Prussia's defeat by Napoleon, Friedrich Wilhelm, then the crown prince, had sought refuge in the Argelander home in Memel, East Prussia.

Argelander's name continues to be known by astronomers for his compilation of the *Bonner Durchmusterung* (1859–63; 3 vols; Bonn Survey), still the largest and most comprehensive of prephotographic catalogs. Under Bessel he had begun a survey of the sky from 15°S to 45°N. This was extended at Bonn to an area from 90°N to 2°S and when complete listed the positions of 324,198 stars down to the ninth magnitude. His work was continued by his suc-

cessor, E. Schonfeld, who in the *Southern Bonner Durchmusterung* (1886; Southern Bonn Survey) added a further 133,659 stars taken from the southern skies (2°S–23°S).

**Aristarchus of Samos** (c. 320 BC–c. 250 BC) *Greek astronomer*

Little is known of the life of Aristarchus (a-ri-star-kus), but ARCHIMEDES reported that Aristarchus had proposed that, while the Sun and the fixed stars are motionless, the Earth moves around the Sun on the circumference of a circle. Just what led Aristarchus to this view and how firmly he held it is not known. It received no support until the late medieval period.

One short work of Aristarchus has survived – *On the Sizes and Distances of the Sun and Moon*. In this work he calculated that the Earth is about 18 times further away from the Sun than from the Moon. His method was to use the fact that when the Moon is exactly in the second quarter it will form a right-angled triangle with the Earth and the Sun, and the relative lengths of the sides of the triangle can be determined by angular measurement. Aristarchus's method is correct, but his measurement was inaccurate (the Sun is roughly 400 times further away). Despite the size of the error it was nevertheless the first attempt to come to grips with astronomical distances by something more sophisticated than revelation or guesswork.

**Aristotle** (384 BC–322 BC) *Greek philosopher, logician, and scientist*

Every science and every inquiry, and similarly every activity and pursuit, is thought to aim at some good.

—*The Nicomachean Ethics*, Bk I

Aristotle (a-ri-stot-el), the son of Nicomachus, physician at the court of Mayntas II of Macedon, was born in Chalcis and moved to Athens in 367 BC, where he was a member of the academy until PLATO's death in 347. For the next 12 years he worked in Assos in Asia Minor, Mytilene on Lesbos, and, from 342 until 335, in Macedon as the tutor of the young Alexander the Great. Unfortunately little is known of this legendary relationship apart from the fact that Alexander took with him on his campaigns a copy of Homer's *Iliad* annotated by Aristotle. Also, Plutarch quotes a letter from Alexander rebuking his former tutor for publishing his *Metaphysics* and revealing to all what had been privately and, he assumed, exclusively taught to him. Following Alexander's accession to the throne of Macedon in 335 Aristotle returned to Athens to found his own school, the Lyceum. When, however, Athens, with little cause to love the power of Macedon, heard of the death of Alexander (323) they turned against Aristotle

and accused him, as they had SOCRATES earlier in the century, of impiety. To prevent Athens from "sinning twice against philosophy" he moved to Chalcis where he died the following year.

Aristotle not only developed an original and systematic philosophy but applied it in a deliberate manner to most areas of the knowledge of his day. The resulting treatises on such subjects as physics, cosmology, embryology, and mineralogy acquired a considerable authority, becoming for medieval scholars if not the last word on any subject then invariably the first. Aristotelian science was not overthrown until the great scientific revolution of the 16th and 17th centuries.

In cosmology Aristotle basically accepted the scheme in which the Earth was at the center of the universe with the planets and fixed stars moving around it with uniform speed in perfectly circular orbits. (He also believed, on empirical grounds, that the Earth was round.) But Aristotle was not content simply to construct models of the universe and faced the problem of how to account for the various forms of motion. He began by accepting that matter was composed of the four elements of EMPEDOCLES – earth, water, fire, and air. Left to themselves the elements would either fall freely, like earth and water, or rise naturally like air and fire. This for Aristotle was natural motion, self-explanatory and consisting simply of bodies freely falling or rising to their natural place in the universe. For a stone to fall to the ground no one had to push or pull it but merely to remove all constraints for it to fall in a straight line to the Earth.

But the heavenly bodies do not move up or down in straight lines. Therefore, Aristotle concluded, they must consist of a fifth element, aether (or *quinta essentia* to the medieval schoolmen), whose natural motion was circular. Thus in the Aristotelian universe different bodies obey different laws; celestial and terrestrial bodies move differently because the laws of motion are different in the heavens from those operating below the Moon. Nor was this the only distinction. For Aristotle the heavens were, with their supposed regularity, incorruptible, without change or decay; such processes were only too apparent on the Earth.

Aristotle also produced a number of volumes on biological problems. In particular his *De partibus animalium* (On the Parts of Animals) and his *De generatione animalium* (On the Generation of Animals) show a detailed knowledge of the fauna of the Mediterranean world and a concern to understand their anatomy and physiology. Over 500 species of animal are referred to by Aristotle. He was also a keen observer and had obviously made empirical investigations on the development of the chick embryo for example, noting the appearance of its heart on the fourth day. In fact some of his observations were only confirmed by zoologists in the

19th century and had for long been thought to be as erroneous as his physics.

In embryology he was also able to refute by dissection the view that the sex of the embryo is determined by its site in the womb. He also argued against the doctrine of pangenesis, that the seed comes from the whole of the body, as he also did against the classical version of preformationism, that the embryo contains all parts already preformed. His physiology, which could not be obtained so readily from simple dissection, was less acute. Respiration was thought to cool the body, an exercise unnecessary for fish who could cool themselves merely by drawing water through their gills.

He, further, produced a rudimentary taxonomy that went to some length to show that divisions based on number of limbs turned out to be obviously arbitrary. Instead, he proposed that mode of reproduction be used. This gave him the basic division between viviparous (exclusively mammalian) and the oviparous, subdivided into birds and reptiles laying proper eggs and the fishes laying "imperfect eggs." He added the insects, who lay no eggs at all but simply produce larvae.

If Aristotle had produced only his *Organon* – works on logic – he would have been considered a prolific and powerful thinker. His style of logic lasted unchallenged even longer than his physics for it was not until 1847 that George BOOLE laid the foundations of a more modern logic and it was not until the present century that non-Aristotelian logics were systematically developed.

**Arkwright, Sir Richard** (1732–1792)  
*British inventor*

In the evening I walked to Cromford and saw the children coming from their work out of one of Mr. Arkwright's manufactories. I was glad to see them look in general very healthy and many with fine, rosy complexions.

—Joseph Farington, *Diary of Joseph Farington* (ed. James Greig 1922)

Arkwright was born in the town of Preston in northern England. Apprenticed to a barber at the age of 18, he became a wigmaker. Through travel and self-education he developed an interest in spinning machinery and in 1769 he patented a water-powered machine that, unlike previous machines, produced a cotton yarn strong enough for use as warp. This machine was used in the horse-driven mill he established at Nottingham (1768) to produce machine-spun yarn. In 1771 he set up a water-powered mill in Cromford, Derbyshire, and in the following years established a number of factories employing machinery for all processes of textile manufacture from carding to spinning. This established the cotton industry as the main industry in the north of Eng-

land. He was knighted in 1786 and died a wealthy man.

**Armstrong, Henry Edward** (1848–1937)  
*British chemist and teacher*

The son of a London provisions merchant, Armstrong studied under FRANKLAND at the Royal College of Chemistry and completed his doctorate in 1870 under Adolph KOLBE at Leipzig. A man of great energy and wide interests, he was a pioneer of British technical education, a prolific researcher, and leader of a major school of chemical research. After various teaching posts in London, he was appointed (1884–1911) professor at the Central Technical College in London (forerunner of the Imperial College of Science and Technology). He served on many committees and was secretary (1883–93) and later president (1893–95) of the Chemical Society.

Armstrong's research work covered many fields, including aromatic substitution, crystallography, stereochemistry, terpenes, and enzymes. He proposed the quinone theory of color and the work carried out by his school on orientation and isomeric change in naphthalene derivatives, although little regarded in Britain, was of fundamental importance to the German dyestuffs industry.

**Arnald of Villanova** (c. 1235–1313) *Spanish alchemist*

Arnald (ar-nald), who was born in Valencia, Spain, was educated in Paris and Montpellier, and studied medicine at Naples. He became a famous physician much in demand by popes and monarchs. In 1285 he became a professor at the University at Montpellier, but came into conflict with the Church in 1299 and was charged with heresy in Paris. He was imprisoned but finally released about 1303 and died at sea between Naples and Genoa in about 1313.

Arnald was one of the first scholars to mention alcohol. In medicine he used it to extract the "virtues of herbs," which became known as tinctures. Some of his other medical ideas were less progressive: he wrote at length on the efficacy of seals and amulets claiming to be able to provide one that would defend its wearer from witchcraft, storms, quinsy, inflammation of the brain, and financial difficulties.

He produced many works on medicine, most notably *Medicinalium introductionum speculum* (An Introductory View of Medicine), and also works on theology and chemistry. The many alchemical works, including *Rosarium philosophorum* (A Rose Garden of Philosophers), that were attributed to him and that had considerable influence in the following centuries are now thought not to be his work.

**Arrhenius, Svante August** (1859–1927)  
*Swedish physical chemist*

These new theories [of Arrhenius] ... suffered from the misfortune that nobody really knew where to place them. Chemists would not recognize them as chemistry; nor physicists as physics. They have in fact built a bridge between the two.

—Per Theodor Cleve (1903)

Arrhenius (ar-**ray**-ni-us) was born in Wijk, near Uppsala, Sweden. He originally went to Uppsala University to study chemistry, changing later to physics. Finding the standard mediocre, he transferred to Stockholm in 1881 to do research under the physicist Erik Edlund, working initially on electrical polarization and then on the conductivity of solutions (electrolytes).

At the time it was known that solutions of certain compounds conduct electricity and that chemical reactions could occur when a current was passed. It was thought that the current decomposed the substance. In 1883 Arrhenius proposed a theory that substances were partly converted into an active form when dissolved. The active part was responsible for conductivity. In the case of acids and bases, he correlated the strength with the degree of decomposition on solution. This work was published as *Recherches sur la conductibilité galvanique des électrolytes* (1884; *Researches on the Electrical Conductivity of Electrolytes*) and submitted as his doctoral dissertation. The paper's great merit was not recognized by the Swedish authorities and he was awarded only a fourth-class doctorate. Arrhenius sent his work to several leading physical chemists, including Jacobus VAN'T HOFF, Friedrich OSTWALD, and Rudolf CLAUSIUS, who were immediately impressed. This led to a period of travel and work in various European laboratories in the period 1885–91.

In 1887 van't Hoff showed that although the gas law ( $pV = RT$ ) could be applied to the osmotic pressure of solutions, certain solutions behaved as if there were more molecules than expected. Arrhenius immediately realized that this was due to dissociation – a conclusion confirmed by further experimental work and published in the classic paper *Über die Dissociation der in Wasser gelösten Stoffe* (1887; *On the Dissociation of Substances in Water*). The idea that electrolytes were dissociated even without a current being passed proved difficult for many chemists but the theory has stood the test of time.

This work won Arrhenius a high international reputation but only limited acclaim in Sweden. Despite this he returned to Stockholm in 1891 as lecturer at the Technical Institute and in 1895 became professor there. In 1903 he was awarded the Nobel Prize for chemistry, and in 1905 he became the director of the Nobel Institute, a post he held until shortly before his death.

Arrhenius is also remembered for the *Arrhenius equation*, which relates the rate of a chemical reaction to the temperature. He was a man of wide-ranging intellect and besides developing his work on solutions, he worked on cosmogony and on serum therapy, being especially interested in the relation between toxins and antitoxins. He also investigated the greenhouse effect by which carbon dioxide regulates atmospheric temperature and calculated the changes that would have been necessary to have produced the Ice Ages.

**Aschoff, Karl Albert Ludwig** (1866–1942)  
*German pathologist*

Educated at Bonn, Berlin (his birthplace), and Strasbourg, Aschoff (**ah**-shoff) was later professor of pathological anatomy, firstly at Marburg (1903–06) and then at Freiburg, where he remained for the rest of his career. He carried out investigations of a number of human pathological conditions, including jaundice, appendicitis, cholecystitis, tuberculosis, and thrombosis. In 1904 he described the inflammatory nodules located in the muscle of the heart and associated with rheumatism (*Aschoff's bodies*). He recognized the bacteri-engulfing activity of the phagocytes in various tissues and named them the reticuloendothelial system. The pathological institute that Aschoff built up at Freiburg-im-Breisgau was attended by students from all over the world.

**Aselli, Gaspare** (c. 1581–1625)  
*Italian anatomist*

Aselli (**ah**-sel-ee), who was born into a prosperous family in Cremona, Italy, was educated at the University of Pavia, where he later served as professor of anatomy and surgery.

In 1622 while dissecting a recently fed dog he noticed various white vessels spread throughout the intestines. As they exuded a milky fluid when pricked he called them the “lacteals” or the “albas venas.” He claimed to trace them to the liver and not unnaturally assumed them to be the vessels transporting the chyle, broken down food products, to the liver to be changed into blood – a process demanded by the current physiology of GALEN. Aselli's observations were fully described in the posthumously published work, *De lactibus* (1627; *On the Lacteals*), a work that also contained the first colored anatomical illustrations.

It was not until 1651 that Jean PECQUET showed that lacteals did not go to the liver.

**Aspect, Alain** (1947– )  
*French physicist*

Alain Aspect was educated at the École Normale Supérieure de Cachan. In 1981–82 at Orsay in Paris, Aspect and his coworkers performed a series of experiments involving coincidence measurements on polarizing photons,

designed to check the inequalities put forward by John BELL in 1964. Bell's inequalities allow for an experimental test of whether there are local hidden variables in quantum mechanics. It is generally believed by physicists that the *Aspect experiment* provided proof that hidden variables are not involved. Aspect is currently working on Bose–Einstein condensates.

**Astbury, William Thomas** (1889–1961)  
*British x-ray crystallographer and molecular biologist*

[Molecular biology] is concerned particularly with the forms of biological molecules and with the evolution, exploitation, and ramification of these forms in the ascent to higher and higher levels of organization.

—Harvey Lectures, 1950–1951

William Astbury was born in Longton, England, were his father was a potter. In 1916 he won a scholarship to Cambridge University, to study chemistry, physics, and mathematics, and graduated in 1921 after spending two years of the war doing x-ray work for the army. He then joined William Henry BRAGG's brilliant group of crystallographers, first at University College, London, and from 1923 at the Royal Institution. In 1945 Astbury was appointed to the new chair of biomolecular structure at Leeds.

Astbury's early structural studies were carried out on tartaric acid but in 1926 Bragg asked him to prepare some x-ray photographs of fibers for his lectures. The results stimulated an interest in biological macromolecules that Astbury retained for the rest of his life. In 1928 he moved to the University of Leeds as lecturer in textile physics and by 1930 had produced an explanation of the extensibility of wool in terms of two keratin structures:  $\alpha$ -keratin in which the polypeptides were hexagonally folded (unextended wool) and  $\beta$ -keratin in which the chain was drawn out in zigzag fashion. A popular account of this work was given in *Fundamentals of Fibre Structure* (1933).

The keratin structure established his reputation, and he quickly extended his studies to other fibers and proteins. He showed that the globular proteins consisted of three-dimensionally folded chains that could be denatured and drawn out into protein fibers. This work laid the foundation for the x-ray structural investigations of hemoglobin and myoglobin. The hexagonal  $\alpha$ -keratin structure dominated British crystallographic protein studies until 1951, when it was shown to be incorrect by Linus PAULING who demonstrated the  $\alpha$ -helical structure of polypeptide chains.

In 1935 Astbury began to study nucleic acids by x-ray crystallography, and in 1938 he and his research student Florence Bell produced the first hypothetical structure of DNA.

**Aston, Francis William** (1877–1945)  
*British chemist and physicist*

Aston was born in Harborne, England, the son of a metal merchant. He was educated at Mason College, the forerunner of Birmingham University, where he studied chemistry. From 1898 until 1900 he did research on optical rotation. He left Birmingham in 1900 to work in a Wolverhampton brewery for three years. During this time he continued with scientific research in a home laboratory, where he worked on the production of vacua for x-ray discharge tubes. This work came to the notice of J. H. POYNTING of the University of Birmingham who invited Aston to work with him. He remained at Birmingham until 1910 when he moved to Cambridge as research assistant to J. J. THOMSON. He became a research fellow at Cambridge in 1920 and stayed there for the rest of his life, apart from the war years spent at the Royal Aircraft Establishment, Farnborough. Aston's main work, for which he received the Nobel Prize for chemistry in 1922, was on the design and use of the mass spectrograph, which was used to clear up several outstanding problems and became one of the basic tools of the new atomic physics.

Thomson had invented an earlier form of spectrograph in which a beam of positive rays from a discharge tube passed through a magnetic and an electric field, which deflected the beam both horizontally and vertically. All particles (ions) with the same mass fell onto a fluorescent screen in a parabola. Aston improved the design by using a suitable magnetic field, so that ions of the same mass were focused in a straight line rather than a parabola. Different ions were deflected by different amounts, and the spectrograph produced a photographic record of a series of lines, each corresponding to one type of ion. The deflections allowed accurate calculation of the mass of the ions.

Aston's first spectrograph was ready in 1919 and with it he was soon able to throw light on one outstanding problem about the nature of the elements. In 1816 William PROUT had put forward his hypothesis that all elements are built up from the hydrogen atom and that their atomic weights are integral multiples of that of hydrogen. Although receiving considerable support it was eventually rejected when it was found that many elements have nonintegral weights (e.g., chlorine: 35.453). Frederick SODDY in 1913 had introduced the idea of isotopes, that is, the same chemical element in different forms having differing weights. Aston established that isotopes are not restricted to radioactive elements but are common throughout the periodic table. He also saw that they could explain Prout's hypothesis. Thus he found that neon was made from the two isotopes  $^{20}\text{Ne}$  and  $^{22}\text{Ne}$  in the proportion of 10 to 1. This will give a weighted average of 20.2 for a large number

of neon atoms. The value of 35.453 for chlorine can be similarly explained. The whole-number rule is his principle that atoms have a mass that is equivalent to a whole number of hydrogen atoms.

Aston then went on to determine as many atomic weights as accurately as his instruments would allow. His first spectrograph was only suitable for gases but by 1927 he had introduced a new model capable of dealing with solids. From 1927 to 1935 he resurveyed the atomic weights of the elements with his new instrument.

In the course of this activity he found some minor discrepancies with the whole-number rule. Thus the atomic weight of hydrogen is given not as 1 but 1.008, of oxygen-16 as 15.9949 and of oxygen-17 as 16.99913. Aston attempted to show why these values are so tantalizingly close to the integral values of Prout – why the isotopes of oxygen are not simple 16 and 17 times as massive as the hydrogen atom. He argued that the missing mass is in fact, by the mass-energy equivalence of EINSTEIN, not really missing but present as the binding energy of the nucleus. By dividing the missing mass by the mass number and multiplying by 10,000, Aston went on to calculate what was later called the “packing fraction” and is a measure of the stability of the atom and the amount of energy required to break up or transform the nucleus.

Thus contained in Aston’s work were the implications of atomic energy and destruction and he believed in the possibility of using nuclear energy – he also warned of the dangers. He lived just long enough to see the dropping of the first atomic bomb in August 1945.

### **Atanasoff, John Vincent (1904–1995)** *American physicist and computer pioneer*

Atanasoff was born in Hamilton, New York, and educated at the universities of Florida, Iowa, and Wisconsin, where he gained his PhD in 1930. He taught at the Iowa State University from 1930 until 1942, when he moved to the Naval Ordnance Laboratory at White Oak, Maryland. After World War II, Atanasoff worked for various technical companies, eventually serving as president of Cybernetics Inc. from 1961 until 1982.

The son of a Bulgarian immigrant who was an electrical engineer, Atanasoff was introduced to calculation at the age of nine when his father gave him a slide rule. This was of little use when, in 1930, he was trying to complete his thesis on the electrical properties of helium. Not even a desk calculator could significantly lighten the extensive computations. He began to think about how things could be improved. By 1937 he had opted for a machine that operates digitally, uses capacitors to store binary numbers, and calculates by logic circuits. Work-

ing with his assistant, Clifford Berry, Atanasoff built a prototype in 1939 of the suitably named ABC (Atanasoff–Berry Computer). This was good enough to raise sufficient funds to build an operating machine, which was completed in 1942.

Although the ABC was the first device to incorporate a number of key notions, it was unsatisfactory as a working machine. It was slow, could not be programmed, had to be controlled at all times, and suffered from a number of systematic errors. Clearly, it could be improved but the outbreak of war in 1942 took Atanasoff away to other duties. By the time he was free to work on the ABC other workers had seized the initiative. Atanasoff’s work long lay forgotten.

This was corrected in a 1973 court case involving two American companies. Sperry Rand had bought the patent to ENIAC and was seeking to charge royalties to other computer manufacturers. Honeywell Inc. resisted, claiming that ENIAC was derived from the ABC and from information passed to ENIAC’s designer, John MAUCHLY, by Atanasoff in the early 1940s. Atanasoff gave evidence and the judge found that ENIAC was not the first “automatic electronic digital computer,” and that it was “derived from one Dr. John Vincent Atanasoff.”

### **Audubon, John James (1785–1851)** *American ornithologist and naturalist*

The illegitimate son of a French sea captain and his Creole mistress, Audubon (**aw**-de-bon) was born in Les Cayes on the Caribbean island of Haiti and was brought up in Nantes in his father’s family. He studied painting in Paris, spending six months in the studio of Jacques Louis David. In 1803, to escape conscription into Napoleon’s army, Audubon was sent to Pennsylvania where his father owned a farm. Neither the farm nor any of Audubon’s other business interests flourished and he was declared bankrupt in 1819 and imprisoned.

No doubt one cause of Audubon’s commercial failure was the time spent hunting and observing birds and other animals in the wild. The first hint that his skills as an artist and naturalist could be combined to make money came in 1810 when Alexander Wilson passed through Louisville, Louisiana, where Audubon was operating a general store. Wilson was looking for subscribers to his lavishly illustrated *American Ornithology* (9 vols; 1808–14).

By 1820 Audubon had decided to publish his own collection of animals and birds. He spent a further four years traveling through Louisiana and Mississippi shooting specimens. As no American publisher appeared to be interested in his work, Audubon took his paintings to Britain in 1826. He eventually found a printer in Edinburgh willing to work on his “double elephant size” engravings (39” × 29”). Sets of five plates were sold to subscribers for about

\$10 to finance the next set. In this way 200 full sets of *Birds of America* (1827–38) were published in Britain in 87 parts with 435 plates. Full sets are rarely available for sale – when auctioned they are unlikely to raise less than a million dollars.

Audubon returned to America in 1839, where he bought an estate on the Hudson and began to prepare his *Viviparous Quadrupeds of North America* (3 vols; 1845–48).

### **Auenbrugger von Auenbrugg, Joseph Leopold** (1722–1809) *Austrian physician*

Born in Graz in Austria, Auenbrugger (**ow-en-broo-ger**) learned medicine at the University of Vienna and subsequently worked (1751–62) at the Spanish Hospital, Vienna, where he became chief physician. In the course of his work, he noticed how the note made by tapping the chest altered between healthy and diseased patients and described how this technique of chest percussion could be used to diagnose congestion of the lungs and other conditions. Auenbrugger published his findings in *Inventum novum* (1761; *A New Discovery*) but their value was slow in gaining recognition. Only after a French translation by Jean-Nicholas CORVISART in 1808 did chest percussion achieve widespread application. It is still used today.

Auenbrugger became one of Vienna's most celebrated physicians and was ennobled by Emperor Joseph II in 1784.

### **Auer, Karl, Baron von Welsbach** (1858–1929) *Austrian chemist*

Auer (**ow-er**) was born in Vienna, the son of the director of the Imperial Printing Press. He was educated at the Vienna Polytechnic and at Heidelberg University, where he was a pupil of Robert BUNSEN.

In 1885 he made a major contribution to knowledge of the lanthanoid (rare-earth) elements. In 1840, Carl MOSANDER had isolated a new "element" called didymium. Auer showed (1885) that this contained, on fractionation, green and rose-red portions. He named them *praseodymia* ("green twin") and *neodymia* ("new twin").

Auer was also one of the first to find some use for the rare-earth elements. Gas had been in use as an illuminant since the beginning of the century and, although an improvement on the early oil lamps, it had many disadvantages of its own. It was expensive, hot, smoky, and smelly. Auer realized that it would be better to use the gas to heat a solid that would itself provide light, rather than use the luminosity of the flame. He used a mantle over the flame, impregnated with thorium oxide and a small amount of cerium. The *Welsbach mantle*, patented in 1885, delayed the end of gas lighting for a few years. Unfortunately for Auer, his

invention was too late for, in 1879, EDISON had managed to burn an electric bulb for 40 continuous hours.

Later, in 1898, Auer tried to improve the electric lamp by replacing its carbon filament by metallic osmium, which has a melting point of 2,700°C. Once more he failed, for the future lay with tungsten, which has a higher melting point of 3,410°C.

He was more successful with the so-called *Auer metal* – an alloy consisting mainly of cerium with other lanthanoid elements. It is also called Mischmetal (German: mixed metal) and is used for flints in cigarette lighters.

### **Auger, Pierre Victor** (1899–1993) *French physicist*

Auger (**ow-zher** or **ow-ger**) was born in Paris and educated there at the Ecole Normale Supérieure, where he obtained his doctorate in 1926. He was later appointed to the staff of the University of Paris and after serving there as professor of physics from 1937 became director of higher education for France in 1945. From 1948 until 1960 he was director of the science department of UNESCO; he left UNESCO to become president of the French Space Commission but in 1964 he took the post of director-general of the European Space and Research Organization, a post he retained until his retirement in 1967.

Auger worked mainly on nuclear physics and cosmic rays. In 1925 he discovered the *Auger effect* in which an excited atom emits an electron (rather than a photon) in reverting to a lower energy state. In 1938 Auger made a careful study of "air showers," a cascade of particles produced by a cosmic ray entering the atmosphere and later known as an *Auger shower*. Auger had an interest in the popularization of science. He also published volumes of poetry.

### **Averroës** (1126–1198) *Spanish-Muslim physician and philosopher*

Knowledge is the conformity of the object and the intellect.

—*Destructio destructionum* (Refuting Refutations)

Averroës (**a-ve-roh-eez**), also known simply as The Commentator to the Latin West, or Ibn Rushd (from his full name, Abu Al-Walid Muhammad Ibn Ahmad Ibn Rushd), came from a family of jurists and was born in Cordoba in Moorish Spain. He himself trained in law and medicine and later served as *qadi* or judge in Seville and Cordoba. In 1182 he was appointed physician to the court of caliph Abu Ya'qub Yusuf in Marrakesh and to his son, Abu Yusuf Ya'qub, in 1195 but was recalled shortly before his death.

In the field of medicine Averroës produced his *Kulliyat fi al tib* (General Medicine) be-

tween 1162 and 1169. He is however better known for his great commentaries on ARISTOTLE but, above all, for his *Tahafut al-Tahafut* (The Incoherence of the Incoherence), a strong attack on the Muslim philosopher al-Ghazzali's *Tahafut al-Falasifah* (The Incoherence of the Philosophers). The work was more influential in the Latin Christian West than in the Muslim East, and its contents paved the way for the medieval separation of faith and reason.

**Avery, Oswald Theodore** (1877–1955)  
*American bacteriologist*

Avery was born in Halifax, the capital of Nova Scotia, Canada. Educated at Colgate University, he received his BA in 1900 and his medical degree in 1904. After a time at the Hoagland Laboratory, New York, as a lecturer and researcher in bacteriology, he joined the Rockefeller Institute Hospital (1913–48). While investigating the pneumococcus bacteria responsible for causing lobar pneumonia, Avery found that the bacteria produced soluble substances, derived from the cell wall and identified as polysaccharides, that were specific in their chemical composition for each different type of pneumococcus. This work provided a basis for establishing the immunologic identity of a cell in biochemical terms.

In 1932 Avery started work on the phenomenon of transformation in bacteria. It had already been shown that heat-killed cells of a virulent pneumococcus strain could transform a living avirulent strain into the virulent form. In 1944 Avery and his colleagues Maclyn McCARTY and Colin MACLEOD extracted and purified the transforming substance and showed it to be deoxyribonucleic acid (DNA). Previously it had been thought that protein was the hereditary material and thus Avery's work was an important step toward the eventual discovery, made nine years later by James WATSON and Francis CRICK, of the chemical basis of heredity.

**Avicenna (or Abu-'Ali Al-Husayn Ibn-Sina)** (980–1037) *Persian physician and philosopher*

Writing about erotics is a perfectly respectable function of medicine, and about the way to make the woman enjoy sex; these are an important part of reproductive physiology.  
—*Canon*

Avicenna (av-i-sen-a), whose works span the entire spectrum of arts and sciences, is one of the most famous figures of Persian culture. Born in Bokhara (now in Uzbekistan), he was a child prodigy, learning and practicing medicine in his teens and gaining the position of court physician to Prince Nuh ibn Mansur when still only 18. This gave Avicenna access to the library of the Samanid court, of which he took full advantage. However, the Samanid

rulers were overthrown by Turkish forces and Avicenna was forced to flee. After a period spent traveling and in several short-lived posts, he became physician to Prince Shams ad-Dawlah in Hamadan. Here he started on a massive medical textbook, the *Canon (Al Qanun)*. In this, Avicenna collated virtually all preceding medical knowledge and set down his own ideas. Comprising five books, the *Canon* deals with anatomy, physiology, etiology, diagnosis, obstetrics, drugs, and so on, and runs to over one million words. It subsequently became a standard text throughout Europe and the Middle East until the 17th century, being translated into Hebrew and Latin. During this period, he also wrote his *Book of Healing*, a comprehensive encyclopedia covering mathematics, logic, natural sciences, and metaphysics and based largely on the ideas of ARISTOTLE and other Greek philosophers.

In 1022, the death of prince ad-Dawlah led Avicenna to leave Hamadan. He found refuge at the court of Prince 'Ala ad-Dawlah, where his immense output of writings continued. This included his account of the paths to spiritual enlightenment, the *Book of Directives and Remarks*. He also composed some notable works of poetry and wrote on many other topics, including astronomy, physics, and chemistry.

Avicenna was frequently involved in the political turmoil of warring Persian states and on several occasions had to escape possible capture and imprisonment. He was fond of wine, women, and, doubtless, song too and prescribed himself a glass of wine to combat fatigue. He died while accompanying the prince on a campaign, evidently of colic and exhaustion.

**Avogadro, Amedeo** (1776–1856) *Italian physicist and chemist*

Avogadro (av-oh-gah-droh) was born in Turin in northern Italy and came from a long line of lawyers. He too was trained in law and practiced for some years before taking up the study of mathematics and physics in 1800. His early work was carried out in the field of electricity, and in 1809 he became professor of physics at the Royal College at Vercelli. He was professor of mathematical physics at Turin from 1820 until 1822 and from 1834 to 1850.

His fame rests on his paper *Essai d'une manière de déterminer les masses relatives des molécules des corps et les proportions selon lesquelles entrent dans ces combinaisons* (1811; On a Way of Finding the Relative Masses of Molecules and the Proportions in Which They Combine), published in the *Journal de Physique*. This states the famous hypothesis that equal volumes of gases at the same temperature and pressure contain equal numbers of molecules. It follows from the hypothesis that relative molecular weights can be obtained

from vapor densities and that the proportion by volume in which gases combine reflects the combining ratio of the molecules. Using this theory, Avogadro showed that simple gases such as hydrogen and oxygen are diatomic ( $H_2$ ,  $O_2$ ) and assigned the formula  $H_2O$  to water, whereas John DALTON had arbitrarily assumed that the simplest compound of two elements would have the formula  $HO$ .

Avogadro's work provided the essential link between Gay Lussac's law of combining volumes and Dalton's atomic theory. This was not, however, realized at the time and, as a consequence, the determination of a self-consistent set of atomic weights was delayed for 50 years. The French physicist André AMPERE was one of the few who accepted the theory and for many years it was taken to be Ampère's own.

Avogadro's contribution to chemistry was not appreciated in his own lifetime. The importance and truth of the theory was unrecognized until 1860 when his fellow Italian, Stanislao CANNIZZARO, forcefully restated it at the Karlsruhe Conference and demonstrated that it was the key needed to unlock the problem of atomic and molecular weights. The number of particles in one mole of a substance was named *Avogadro's constant* in his honor. It is equal to  $6.022\ 52 \times 10^{23}$ .

### **Axel, Richard** (1946– ) *American neuroscientist*

Born in New York, Axel attended Columbia University, graduating AB in 1967, and then studied medicine at Johns Hopkins University School of Medicine, obtaining his MD in 1970. He returned to Columbia University to study pathology, and in 1978 was appointed professor in the pathology and biochemistry department. He became investigator in the Howard Hughes Medical Institute in 1984, and university professor in 1999. He was professor at Harvard Medical School (2001–02) and in 2003 he became affiliate professor in the Department of Physiology and Biophysics at the University of Washington, Seattle.

Axel is best known for his work on the sense of smell, or olfaction. In 1991 he published, jointly with Linda BUCK, a landmark paper that described a large family of genes for receptors of odor molecules. The scientists discovered about a thousand such genes in the mouse, each encoding a receptor protein with unique binding properties, and thus capable of responding to just one or a few odorant molecules. The receptors are anchored in the cell membrane of olfactory receptor cells within the nose. Axel and Buck showed that binding of an odor molecule to its corresponding receptor causes the receptor to activate a G protein inside the cell, which in turn stimulates the formation of cyclic AMP (cAMP). This acts as a second messenger, causing the opening of ion channels in the cell mem-

brane and triggering electrical signals from the cell to the brain via long slender cellular processes. Hence, this work established that odor receptors belong to the class known as G protein-coupled receptors.

Axel and Buck subsequently pursued independent but often complementary lines of enquiry into olfactory reception. They showed that each olfactory receptor cell bears only one type of odor receptor molecule on its surface. However, odor molecules typically can bind to several different receptor types. Thus a single odor will elicit a characteristic pattern of signals from the olfactory receptor cells. This is why an animal such as the mouse can discriminate between as many as 10,000 different smells, even with only 1,000 or so types of receptor cells.

Subsequently, Axel's team at Columbia used genetically engineered mice to reveal that the processes of all olfactory sensory cells carrying the same receptor type converge on the same relay station, or glomerulus, in the olfactory bulb in the brain. Hence, any given odor will trigger signals to a particular set of glomeruli, creating a corresponding spatial "map" in the brain; different odors trigger overlapping but nonidentical combinations of glomeruli. Signals from the glomeruli are transmitted to higher regions of the brain, where the information is processed to produce a conscious experience, and memories of smells are stored.

Axel's attention then turned to the fruit fly *Drosophila* as a simple experimental model. The team confirmed that the fly brain follows the same principles of spatial patterning in olfaction as seen in mice, and that this has both functional and behavioral significance. For example, Axel's team could abolish the normal aversive response to an alarm substance ( $CO_2$ ) by engineering flies in which the specific glomerulus for  $CO_2$  was inhibited.

For his work on "odorant receptors and the organization of the olfactory system," Axel was awarded the 2004 Nobel Prize for physiology or medicine, jointly with his erstwhile colleague, Linda Buck.

### **Axelrod, Julius** (1912–2005) *American neuropharmacologist*

Axelrod was born in New York City, becoming a student at New York University in 1929, and, after a year, transferring to the City College, where he took a degree in chemistry and biology. He wanted to study medicine but was turned down by several medical schools, despite his qualifications. Axelrod felt that his rejection was influenced by anti-Semitism. From 1933 to 1935 he was a laboratory assistant at the Department of Bacteriology, New York University Medical School. From 1935 to 1945 he had a job as a technician in a laboratory of industrial hygiene that had just been set up in New York. But still with an ambition for a ca-

reer in scientific research, and after some years at the Goldwater Memorial Hospital and the National Heart Institute, he took a year off in 1955, obtained a PhD from George Washington University, and moved to the National Institute of Mental Health (NIMH) as chief of the pharmacology section. He held this post until his retirement in 1984, while also continuing to work in the cell biology laboratory at the NIMH.

Axelrod's research involved the mechanisms underlying the transmission between nerve cells, in particular, the action of the catecholamines, the neurotransmitters of the sympathetic nervous system. The most important of these is norepinephrine, first identified as a neurotransmitter by Ulf VON EULER in 1946. Axelrod realized that once the molecule had interacted with its target cell some mechanism must come into action to switch it off. Later he was able to describe the role of two enzymes, catechol-o-methyltransferase (COMT) and monoamine oxidase (MAO), which degrade the catecholamines.

However, studies with radioactive norepinephrine showed its persistence in the sympathetic nerves for some hours. This led Axelrod to propose that norepinephrine is taken up into, as well as released from, sympathetic nerves. This recapture inactivates the neurotransmitter. In general, Axelrod's research led to the development of drugs designed to affect neurotransmitters, in particular antidepressants that inhibit the uptake of serotonin. Axelrod also worked on a number of other topics, including the metabolism of the hallucinogenic drug LSD and the working of the pineal gland.

For work on the catecholamines Axelrod shared the 1970 Nobel Prize for physiology or medicine with von Euler and Bernard KATZ.

**Ayala, Francisco José** (1934– ) *Spanish–American biologist*

Ayala (ah-yah-la), who was born in Madrid, Spain, began his higher education there at the University of Madrid, moved to America in 1961, and obtained his PhD from Columbia in 1964. He worked initially at Rockefeller before joining the Davis campus of the University of California in 1971, where he was later appointed professor of genetics in 1974. He was professor of biology at the University of California, Irving, from 1987 to 1989, when he became Donald Bren Professor of Biological Sciences.

Ayala has worked extensively in the field of molecular evolution. He has also sought to measure genetic variation in natural populations, rates of evolution, and the amount of genetic change needed to produce new species. Many of his results were published in his *Molecular Evolution* (1976) and in a work he coauthored in 1977 entitled *Evolution*. He has written a number of other books including *Molecular Genetics* (1984). Ayala has campaigned against government restrictions on stem-cell research.

**Ayrton, William Edward** (1847–1908) *British physicist*

Ayrton was born in London, where his father was a lawyer. After attending University College, London, and Glasgow University, he worked for the Indian Telegraph Company, and in 1873 was appointed to teach natural philosophy and telegraphy at the Imperial Engineering College, Tokyo, Japan. He returned to London in 1879 and became a professor at the City and Guilds College and later at Finsbury Technical College (1881). In 1884 he became a professor at the Central College.

## **Baade, Wilhelm Heinrich Walter** (1893–1960) *German–American astronomer*

Almost every one of Baade's papers turned out to have far-reaching consequences.

—Sir Fred Hoyle

Baade (**bah**-de), born the son of a schoolteacher in Schröttinghausen, Germany, was educated at the universities of Münster and Göttingen, where he obtained his PhD in 1919. He worked at the University of Hamburg's Bergedorf Observatory from 1919 to 1931, when he moved to America. He spent the rest of his career at the Mount Wilson and Palomar Observatories, retiring in 1958.

In 1920 Baade discovered the minor planet Hidalgo, whose immense orbit extends to that of Saturn. He was also, in 1949, to detect the minor planet Icarus, whose orbit, which lies within that of Mercury, can bring it very close to Earth. In the 1930s he did important work with Fritz ZWICKY on supernovae, with Edwin HUBBLE on galactic distances, and with his old Hamburg colleague, Rudolph MINKOWSKI, on the optical identification of radio sources.

Baade's most significant work however began in 1942. As he was of German origin he was precluded from the general induction of scientists into military research, being allowed to spend the war observing the heavens. In early 1943 he was blessed with ideal viewing conditions. Los Angeles was blacked out because of wartime restrictions and, for a short while, the air was calm and the temperature constant. Under these near-perfect conditions Baade took some famous photographs with the 100-inch (2.5-m) reflecting telescope of the central region of the Andromeda galaxy. To his great excitement he was able to resolve stars in the inner region where Hubble before him had found only a blur of light.

These observations allowed Baade to introduce a fundamental distinction between types of stars. The first type, Population I stars, he found in the spiral arms of the Andromeda galaxy. They were young hot blue stars as opposed to the Population II stars of the central part of the galaxy, which were older and redder with a lower metal content. This distinction, now much expanded, has played a crucial role in theories of galactic evolution.

Some of the stars that Baade observed in the

Andromeda galaxy were Cepheid variables, stars that vary regularly in brightness. His realization that there were two kinds of Cepheids had an immediate impact. The relationship between period and luminosity of Cepheids had been discovered by Henrietta LEAVITT in 1912 and put into a quantified form by Harlow SHAPLEY so that it could be used in the determination of stellar distances of great magnitude. In the 1920s Hubble had found Cepheids in the outer part of the Andromeda galaxy, and, using the period–luminosity rule, had calculated its distance as 800,000 light-years. Since then the relationship had been used by many astronomers.

Baade, by 1952, was able to show that the original period–luminosity relationship was valid only for Population II Cepheids whereas Hubble's calculation involved Population I Cepheids. Baade worked out a new period–luminosity relationship for these Cepheids and found that the Andromeda galaxy was two million light-years distant.

The distance to the Andromeda galaxy had been used by Hubble to estimate the age of the universe as two billion years. Baade's revised figure gave the age as five billion years. This result was greeted with considerable relief by astronomers as Hubble's figure conflicted with the three to four billion years that the geologists were demanding for the age of the Earth. Further, with Baade's revision of the distance of the Andromeda galaxy without any change in its luminosity, it was now clear that its size must also be increased together with the size of all the other galaxies for which it had been a yardstick. Baade was thus able to establish that while our galaxy was somewhat bigger than normal it was not the largest, as Hubble's work had implied.

## **Babbage, Charles** (1792–1871) *British mathematician*

The whole of the development and operations of analysis are now capable of being executed by machinery.... As soon as an Analytical Engine exists, it will necessarily guide the future course of science.

—*Passages from the Life of a Philosopher* (1864)

From church we went, by his special invitation, to see Babbage's calculating

machine; and I must say, that during an explanation which lasted between two and three hours, given by himself with great spirit, the wonder at its incomprehensible powers grew upon us every moment.

—George Ticknor, *Life, Letters, and Journals of George Ticknor* (1876)

Babbage, whose father was a banker, was born in Teignmouth in southwest England and studied at Cambridge. He played a major role in ending the isolationist attitudes prevalent in British mathematical circles in the early 19th century. In 1815 he helped to found the Analytical Society, which aimed to make the work of Continental mathematicians better known in Britain. Babbage's interest in stimulating British scientific activity was by no means confined to mathematics. In 1820 he was a founder of the Royal Astronomical Society and in 1834 of the Statistical Society, and he continued to attack the British public for their lack of interest in science. Among his inventions were a speedometer and the locomotive "cowcatcher." Babbage also did mathematical work that contributed to the setting up of the British postal system in 1840. From 1828 to 1839 he was Lucasian Professor of Mathematics at Cambridge University.

Babbage is best known for his work in designing and attempting to build three mechanical computers. He had been struck by the discrepancies found in mathematical tables and the persistence of error. "I wish to God these calculations had been executed by steam," he lamented in 1821. Mechanical execution, he argued, would eliminate error. Consequently he began work in 1823 on the machine later known as his Difference Engine No. 1. It operated by the method of finite differences and thus allowed values of functions to be obtained by addition rather than by multiplication. The engine was an analog decimal machine in which numbers were represented by the rotation of various wheels. After a decade of work the project was abandoned when Babbage's credit ran out. It had cost the equivalent of about \$85,000, was 8-foot high, and was made from 25,000 parts.

He later designed a simpler version, Difference Engine No. 2, with only a third of the number of parts. Plans were drawn up in 1847 and offered to an uninterested government in 1852. Without financial support Babbage never saw the project develop beyond the design stage.

The more ambitious analytical engine, first described in 1834, was similarly unsuccessful. Unlike the Difference Engine, this was to be a general computing machine in the manner of a modern computer, and was intended to be programmed with punched cards. One of Babbage's more enthusiastic supporters in this work was Ada, Countess of Lovelace.

In 1985, Doron Swade and his colleagues at the Science Museum in London set out to build

a full-size Babbage computer based upon his original designs. They chose to work on No. 2 and hoped to have it ready for Babbage's bicentenary in 1992. The construction was carried out in full public view on the floor of the museum. It was completed in May 1991, cost \$500,000 to build, and has worked satisfactorily ever since.

Babbage was influential in a number of other areas. His *Reflections on the Decline of Science in England* (1830) began the move to the professionalization of British science. In his *On the Economy of Machinery and Manufactures* (1832), a work closely studied by Marx, Babbage argued that industry could only flourish by adopting a scientific approach to both technical and commercial matters. He also campaigned against street noises and was largely responsible for "Babbage's Bill" of 1864, restricting the rights of street musicians. The subject was sufficiently important to him to form a chapter in his revealing *Passages from the Life of a Philosopher* (1864).

### **Babcock, Harold Delos** (1882–1968) *American astronomer*

Babcock, who was born in Edgerton, Wisconsin, was educated at the University of California, Berkeley, where he graduated in 1907. In 1908 he joined the staff of the Mount Wilson Observatory where he remained until his retirement in 1948. After his formal retirement he continued to work for many years with his son Horace Babcock.

When he first joined the observatory George HALE had just discovered the presence of strong magnetic fields in sunspots by noting the splitting of their spectral lines, the so-called "Zeeman effect" first described by Pieter ZEEMAN in 1896. Babcock's first task was to supply the basic laboratory data on the effects of strong magnetic fields on various chemical elements.

Many years later, in collaboration with his son, he used their joint invention, the magnetograph, to detect the presence of weak and more generalized magnetic fields on the Sun. They also, in 1948, revealed the existence of strong magnetic fields in certain stars.

### **Babcock, Horace Welcome** (1912–2003) *American astronomer*

Babcock was born in Pasadena, California, the son of Harold Delos Babcock, a distinguished American astronomer who spent a lifetime observing at the Mount Wilson Observatory. Horace Babcock graduated in 1934 from the California Institute of Technology (Cal Tech) and obtained his PhD in 1938 from the University of California. He worked initially at Lick Observatory from 1938 to 1939 and at the Yerkes and McDonald observatories from 1939 to 1941. He then engaged in war work at the ra-

diation laboratory at the Massachusetts Institute of Technology (1941–42) and at Cal Tech (1942–45). In 1946 Babcock returned to astronomy and joined his father at Mount Wilson where they began an enormously profitable collaboration. Babcock later served from 1964 until his retirement in 1978 as director of the Mount Wilson and Palomar Observatories, which became known in 1969 as the Hale Observatories.

In 1908 George Hale had detected splitting of the spectral lines in the light from sunspots. Such an effect results from the presence of a magnetic field, an effect first described by Pieter ZEEMAN in 1896. The fields observed by Hale were of considerable strength, ranging up to some 4,000 gauss. The field of the Earth by contrast is less than one gauss. The question then arose as to whether the Sun itself possessed a general magnetic field distinct from fields associated with sunspots. The problem facing early investigators was how to detect weak fields and this was not overcome until 1948 when the Babcocks successfully developed their magnetograph, permitting them to measure and record the Zeeman effect continuously and automatically. By the late 1940s they were able to report the presence of weak magnetic fields on the Sun, about one gauss in strength and restricted to latitudes greater than 55°. Further unexpected features were changes in polarity discovered in the 1950s: when examined in 1955 the north solar pole possessed positive polarity, the south negative polarity; by 1958 the situation was completely reversed.

In 1948 the Babcocks announced the further major discovery of stellar magnetic fields. By 1958 they had established the presence of magnetic fields in some 89 stars. The fields tended to be strong, of the order of several thousand gauss, and seemed to belong mainly to stars of spectral types O and B. Attempts to explain the presence of such fields were made considerably more difficult by the realization that some stars were “magnetic variables”: the field of the brighter component of the binary star Alpha Canes Venatici was found to vary, with reversing polarity, from +5,000 to –4,000 gauss in 5.5 days. Such studies have done much to stimulate work on magnetohydrodynamics.

### **Babcock, Stephen Moulton** (1843–1931) *American agricultural chemist*

A farmer's son from New York State, Babcock gained his BA degree from Tufts College, Massachusetts, in 1866 and after a period of farming became a chemistry assistant and (from 1875) instructor at Cornell University. In 1879 he gained his doctorate under Hans Hübner at Göttingen, Germany. After a further spell at Cornell on his return, he became chemist at the New York Agricultural Station in 1882, where he worked on the analysis of milk.

In 1888 Babcock became professor of agricultural chemistry at the University of Wisconsin. Here, in 1890, he devised an efficient test (the *Babcock test*), which quickly became standard, for measuring the butterfat content of milk. Studies followed on rennet, fermentation, metabolic water, and animal nutrition. In 1907 Babcock's associates began studies in which cattle were fed balanced diets derived from a single source – corn, wheat, or oats. The results obtained provided further evidence for the existence of accessory food factors and Babcock's school played an important part in the vitamin studies that followed.

### **Babinet, Jacques** (1794–1872) *French physicist*

Babinet (ba-bee-nay), who was born in Lusignan, France, studied in Paris at the Ecole Polytechnique and from 1820 he was a professor at the Collège Louis le Grand. He was elected to the Académie des Sciences in 1840.

His major work was devoted to the diffraction of light; he used diffraction to measure wavelengths more accurately than before, and did theoretical work on general diffraction systems. The *Babinet theorem* states that there is an approximate equivalence between the diffraction pattern of a large system and that of the complementary system, which is opaque where the original system is transparent and vice versa.

Furthermore he showed an interest in the optical properties of the minerals, developing new instruments for the measurement of angles and polarizations. He also studied meteorological phenomena, especially those of an optical nature, investigating rainbows and the polarization of skylight. Babinet was the first to suggest (1829) that the wavelength of a given spectral line could be used as a fundamental standard of length. The idea was adopted in 1960, when the meter was defined as 1,650,763.73 wavelengths of the radiation emitted by an atom of krypton-86 in a specified transition. (This definition was changed in 1983 to the distance traveled by light in a certain fraction of a second.)

### **Babo, Lambert Heinrich Clemens von** (1818–1899) *German chemist*

Babo (bah-boh) was born in Ladenberg, Germany, and studied at Giessen under Justus von LIEBIG. He was appointed as an assistant professor at Freiburg University in 1845, later being appointed professor of chemistry in 1859.

In 1847 he showed that the vapor pressure of a liquid can be lowered by dissolving substances in it. He also succeeded in demonstrating that the degree of depression of the vapor pressure is, in general, proportional to the concentration of the solution (known as *Babo's*

law). François RAOULT was able to use Babo's discovery in 1886 to establish some general rules and to determine molecular weights.

**Bache, Alexander Dallas** (1806–1867)  
*American geophysicist*

Bache (baych), the great-grandson of Benjamin FRANKLIN, was born in Philadelphia and graduated from West Point in 1825. After two years in the army he became professor of natural science and chemistry (1828–41) at the University of Pennsylvania. He spent the period 1836–38 studying the European educational system, publishing his findings in *Education in Europe* (1839).

In 1840 Bache founded the first American magnetic observatory at Girard College. He became, in 1843, superintendent of the U.S. Coast Survey, which he built up into a major institution. He had the entire coastline surveyed during his lifetime, his own particular research being into the Gulf Stream, an area also studied by his great-grandfather.

Dissatisfied with the American Association for the Advancement of Science he gathered around himself a group of scientists known as the "Lazzorconi," or beggars. He was successful in persuading Congress to create, in 1863, the National Academy of Sciences "to investigate, examine, experiment, and report upon any question of science and art." Bache was made its first president.

**Backus, John** (1924–2007) *American computer scientist*

Backus was born in Philadelphia. After graduating from Columbia University, New York, he joined the staff of IBM in 1952 and remained with them until his retirement in 1991. From 1959 until 1963 he worked at the IBM Research Center, Yorktown Heights, New York, and thereafter as an IBM Fellow at the IBM Research Laboratory, San Jose, California.

Backus has reported on the state of programming when he joined IBM. It was, he noted, "a black art, a private arcane matter." All programming was done using machine or assembly language. There were no compilers, no index registers, and the programmer spent most of his time debugging the program and feeding it into the computer. The programmers actually cost more than the computer. Backus commented, "They dismissed as foolish plans to make programming accessible to a larger population"; it was inconceivable "that any mechanical process could possibly perform the mysterious feats of invention required to write an efficient program."

In 1954 Backus led an IBM team determined to free computer programming from the professional élite. As the speed of computers increased it made no sense to have them standing

idle while a programmer struggled to operate them. The problem was made more pressing by the development of the new and more powerful IBM 704. By late 1954 some of the main details of the high-level language Fortran (from *Formula Translation*) had been established. Backus defined his aim as "to design a language which would make it possible for engineers and scientists to write programs for the 704." The language itself was available in 1957 and soon became the most widely used programming language of the time.

**Bacon, Francis** (1561–1626) *British philosopher*

They are ill discoverers that think there is no land, when they can see nothing but sea.  
—*The Advancement of Learning* (1605)

I have taken all knowledge to be my province.  
—Letter to Lord Burleigh, 1592

Francis Bacon, Baron Verulam and Viscount St. Albans, was born in London into the Elizabethan ruling class; his father was Sir Nicholas Bacon, lord keeper of the Seal, and his uncle was Lord Burleigh. He entered Cambridge University in 1573 to study law, qualified in 1582, and entered parliament in 1584. His political career was noted for his ability both to attach himself to the side of royal favorites (and thereby rise) and to make sure that he was on the opposing side when they fell from favor (and thereby rise further). He held many state offices including those of attorney general (1613) and lord chancellor (1618).

Bacon's first work of philosophy was *The Advancement of Learning* (1605), a review of the current state of knowledge. He planned an encyclopedia of all knowledge, the *Instauratio Magna* (Great Renewal), but this was never completed, the most substantial fragment being the *Novum organum* (1620; New Organum alluding to the *Organum* of ARISTOTLE concerning logic). Bacon rejected completely deference to the authority of the ancients, in particular the deductive logic of Aristotle, in dealing with science and the investigation of the world. He asserted that nature could be understood and even controlled by man. Bacon's method to accomplish this was induction, by which he understood a method of proceeding from the particular to the general by a process of exclusions, generalizing from particular experiments and investigations. Bacon had a great influence on the first generation of British experimental scientists. Despite his urge toward completeness, Bacon's knowledge of the science of his day was inadequate. In one field, however, he was highly prescient: by induction he concluded that heat was a form of motion.

In 1621 Bacon was accused of bribery, imprisoned for a few days, fined, and banished from parliament and the Court. He retired to his estate in Hertfordshire and in this last pe-

riod of his life he wrote a revision of *The Advancement of Learning* known by its Latin title *De augmentis scientiarum* (1623). He also produced some fragments of the *Instauratio* and *The New Atlantis*, a utopia that foreshadowed the scientific societies founded later in the century.

Bacon's death was brought on by his last scientific experiment. He had the idea that snow might preserve flesh and to test this he stuffed a chicken with snow, which he himself collected. It is said that as a result he caught a chill and died soon after.

**Bacon, Roger** (1220–1292) *English philosopher and alchemist*

All science requires mathematics.

—*Opus majus* (1733; Major Work)

Without experience nothing can be known sufficiently.

—As above

Bacon, who was born in Ilchester, southwest England, studied at Oxford and then at Paris (1234–50) under Petrus Peregrinus. In about 1257 he joined the Franciscan Order and from about 1250 until 1277 he was at Oxford, where he studied under Grosseteste. He is supposed to have been confined in Paris from 1277.

Bacon was often in disgrace with the authorities but he had a considerable reputation as a philosopher and alchemist, being called *Doctor Mirabilis* (Miraculous Teacher). From about 1247 until 1257 he concentrated on re-

search in mathematics, optics, alchemy, and astronomy and during this developed a magnifying glass, defined reflection and refraction, and also mentioned gunpowder in his writings. Bacon distinguished two kinds of alchemy, speculative and operative, and he believed firmly in the practical benefits of science. His writings, the *Opus majus* (Major Work, published in 1733), *Opus secundus* (Second Work), and *Opus tertius* (Third Work), include a number of predictions, of powered cars, aircraft, and ships, and of machines for extending the powers of man. He was committed to the belief that the Earth was round, and suggested that it could be circumnavigated. He stressed that experimentation was essential to the progress of science.

**Baekeland, Leo Hendrik** (1863–1944) *Belgian–American industrial chemist*

Baekeland (**bayk**-land) was born in Ghent and educated at the university there, graduating in 1884. He was professor of physics and chemistry at Bruges in 1887 and returned to Ghent the next year as assistant professor of chemistry. But Baekeland grew impatient with academic life and in 1889 a honeymoon tour took him to America where he settled.

Baekeland worked at first as a photographic chemist and in 1891 he opened his own consulting laboratory. In 1893 he began to manufacture a photographic paper, which he called Velox, and six years later his company was bought out by the Kodak Corporation for one

**BAKELITE** *The polymeric structure of bakelite.*

million dollars. Now financially independent, Baekeland returned to Europe to study at the Technical Institute at Charlottenburg.

On his return to America, Baekeland began to investigate, as a synthetic substitute for shellac, the phenol–formaldehyde resins discovered by BAEYER in 1871. Since nothing remotely like shellac emerged, he began to look for other uses for this material. By choosing suitable reaction conditions he produced a hard amberlike resin, which could be cast and machined and which had excellent durability and electrical properties. Bakelite was finally unveiled in 1909, when Baekeland set up the General Bakelite Corporation.

In 1922 Baekeland's company merged with two rivals and in 1939 it became a subsidiary of the Union Carbide and Carbon Corporation. Baekeland continued to produce scientific papers throughout this period. He received many honors and held many professional posts, including that of president of the American Chemical Society.

**Baer, Karl Ernst von** (1792–1876) *German–Estonian biologist, comparative anatomist, and embryologist*

Baer (bair) is generally considered the father of modern embryology. He was born on his family's estate in Piep, Estonia, and received private tutoring and schooling before entering Dorpat University to study medicine. He graduated in 1814 and then studied comparative anatomy at the University of Würzburg, where he was introduced to embryology by Ignaz DÖLLINGER. In 1817 Baer became professor of zoology at Königsberg and in 1834 was appointed academician and librarian of the Academy of Sciences at St. Petersburg.

It was prior to his move to St. Petersburg that Baer did most of his pioneering work in laying the foundation of comparative embryology as a separate discipline. In distinguishing the mammalian ovum within the Graafian follicle he established that all mammals, including man, develop from eggs. He also traced the development of the fertilized egg and the order in which the organs of the body appear and develop, showing that similar (homologous) organs arise from the same germ layers in different animals, thus extending the work of Kaspar WOLFF and the German anatomist Christian Pander. His expounding of the "biogenetic law," demonstrating the increasing similarity and lack of specialization in the embryos of different animals as one investigates younger and younger embryos, provided DARWIN with basic arguments for his evolutionary theory. Baer was, however, opposed to the idea of there being a common ancestor for all animal life, although he conceded that some animals and some races of man might have had common ancestry. His other notable discoveries included

the mammalian notochord and the neural folds as the precursors of the nervous system. Baer intended his embryological work to be, at least partly, a means of improving animal classification by demonstrating vertebrate affinities. Indeed modern zoological classification is now based partly on biogenetic principles. His great work on the mammalian egg, *De ovi mammalium et hominis genesi* (1827; *On the Origin of the Mammalian and Human Ovum*) was followed (1828–37) by *Über Entwicklungsgeschichte der Tiere* (*On the Development of Animals*), in which he surveyed all existing knowledge of vertebrate development.

A man of wide interests, Baer did much work in other scientific disciplines. He was instrumental in founding the German Anthropological Society and helped to found the Russian Geographical and Entomological Societies.

**Baeyer, Johann Friedrich Adolph von** (1835–1917) *German organic chemist*

Baeyer (bay-er) was the son of a member of the Prussian General Staff and his mother was the daughter of a celebrated jurist and literary historian. Born in Berlin, Baeyer went to Heidelberg in 1856 to study chemistry with Robert BUNSEN. Here he met August KEKULE, who had a profound influence on his development as a chemist and gave him the theoretical foundation for his work. After obtaining his PhD (1858) Baeyer took up a teaching position in 1860 at a small technical school, the Gewerbe-Institut, in Berlin. In 1872 he was appointed professor of chemistry at Strasbourg and in 1875 succeeded LIEBIG as professor of chemistry at Munich, where he remained for the rest of his life.

In 1864, continuing the work of WÖHLER, Liebig, and Schlieper on uric acid, Baeyer characterized a related series of derivatives including alloxan, parabanic acid, hydantoin, and barbituric acid. In 1871 he discovered the phthalein dyes, phenolphthalein and fluorescein, by heating phenols with phthalic anhydride. In the course of this work he discovered the phenol–formaldehyde resins, which were later developed commercially by BAEKELAND. The centerpiece of Baeyer's prolific researches, however, was his work on indigo, which started in 1865 and lasted for 20 years.

The first step consisted of the reduction of indigo to its parent substance, indole, which Baeyer accomplished by the new method of heating with zinc dust. The first synthesis was a lengthy one, starting from phenylacetic acid. This was soon followed by shorter methods starting from *o*-nitrocinnamic acid and *o*-nitrophenylpropionic acid. In 1883 he gave a structure of indigo that was correct except for the stereochemical arrangement of the double bond, which was later shown to be *trans* by x-ray crystallography (1928). Baeyer's syntheses

proved too costly for commercial manufacture and he took no part in the industrial development of indigo, terminating his work in 1885. Commercial synthetic indigo was eventually produced in 1890. Baeyer's work also led to the production of many other new dyes.

From indigo Baeyer turned to the polyacetylenes, compounds whose explosive properties led him to consider the stability of carbon-carbon bonds in unsaturated and ring compounds. He formulated the *Baeyer strain theory*, stating that compounds are less stable the more their bond angles depart from the ideal tetrahedral arrangement. Baeyer's other researches included work on oxonium compounds; on the reduction of aromatic compounds, in which he observed a loss of aromaticity on reduction; and on terpenes, including the first synthesis of a terpene in 1888.

The strain theory was one of Baeyer's few theoretical contributions; he was a virtuoso of test-tube chemistry at a time when this could produce extraordinary results. In 1905 he received the Nobel Prize for chemistry for his work on indigo and aromatic compounds.

**Bahcall, John Noris** (1934–2005) *American physicist*

Bahcall was born in Shreveport, Louisiana, and educated at the universities of California, Chicago, and Harvard, where he obtained his PhD in 1961. He immediately moved to the faculty of the California Institute of Technology, and remained there until 1971 when he was appointed to the Institute of Advanced Studies, Princeton.

In the 1960s Bahcall began to consider the emission of neutrinos from the Sun. One of the apparent early triumphs of nuclear physics was the light it threw on the internal workings of the Sun. Theorists such as Hans BETHE had proposed the existence of a number of cyclic fusion reactions producing vast amounts of energy, heavier elements, and a certain number of neutrinos. As neutrinos have a low probability of interacting with other particles, some solar neutrinos should be received at the Earth's surface. Bahcall calculated that there occurs one event per second for every  $10^{36}$  target atoms, for which one solar neutrino unit (SNU) should be detectable. The matter was put to the test by Raymond DAVIS, who used a detector consisting of a tank of 100,000 gallons of cleaning fluid in a one-mile-deep mine.

Bahcall predicted that Davis would observe a flux of about 8 SNU. In fact, from 1967 onwards, Davis recorded a flux of about 2 SNU. The burden was placed upon the theorists to account for the anomalous results, or to revise the theory in ways that would make the results acceptable. This is the *solar neutrino problem*.

A number of options were considered by Bah-

call. Perhaps, the Sun was passing through a quiet phase and over long periods of time neutrino output would agree with theory. It was also thought that the issue would eventually be resolved when the abundance of radioactive technetium, produced by interactions deep in the Earth between neutrinos and molybdenum, has been accurately measured.

Or, perhaps, our solar model is wrong. This, Bahcall pointed out, leads nowhere. Alternative solar models agree with the standard model in the rate of neutrino production. Other theorists have challenged generally accepted physical principles. Bahcall considered the possibility that *neutrino oscillations* occurred, i.e., the transition from one type of neutrino to another type. This process is only possible if neutrinos have nonzero masses. This is necessarily the case in most grand unified theories. Since there is evidence from other sources that neutrinos do have nonzero masses, the current consensus is that these neutrino oscillations explain the solar neutrino problem, although this has not been conclusively demonstrated.

As a number of new and more sensitive detectors are being built, theorists seem inclined to await fresh data before judging between competing theories. Until then, as Bahcall noted, physicists will dismiss the problem as a matter of astronomy while astronomers will attribute the anomaly to the failings of physics.

**Baillie, Matthew** (1761–1823) *British physician*

Baillie, who was born in Scotland, studied classics, mathematics, and philosophy at Glasgow University and then arts and medicine at Oxford University. He graduated MD in 1787 and was appointed physician to St. George's Hospital, London. A nephew of William and John HUNTER, he inherited William Hunter's house and medical school at Windmill Street in 1783. Baillie's major work was the *Morbid Anatomy of Some of the Most Important Parts of the Human Body* (1793). This was a pioneering work, illustrated by a series of engravings, that helped establish pathology as a separate subject. From 1810 onward he was a physician to the royal family, attending George III during his final illness.

His sister was the poet and dramatist, Joanna Baillie.

**Baily, Francis** (1774–1844) *British astronomer*

Born in Newbury in southern England, Baily was a prosperous stockbroker who, on retirement, devoted himself to astronomy. During the total eclipse of the Sun in 1836 he noted that immediately before and after totality a number of bright points of light appear around the edge of the Moon. This effect, known as

*Baily's beads*, is caused by light from the Sun shining through the lunar valleys.

**Baird, John Logie** (1888–1946) *British inventor*

Baird, who was born in Helensburgh, Scotland, studied electrical engineering at the Royal Technical College in Glasgow and then went to Glasgow University. His poor health prevented him from active service during World War I and from completing various business enterprises in the years following the war.

After a breakdown in 1922 he retired to Hastings and engaged in amateur experiments on the transmission of pictures. Using primitive equipment he succeeded in transmitting an image over a distance of a couple of feet, and in 1926 he demonstrated his apparatus before a group of scientists. Recognition followed, and the next year he transmitted pictures by telephone wire between London and Glasgow. In the same year he set up the Baird Television Development Company. He continued to work on improvements and on 30 September 1929 gave the first experimental BBC broadcast. Synchronization of sound and vision was achieved a few months later. In 1937, however, the Baird system of mechanical scanning was ousted by the all-electronic system put forward by Marconi–EMI. Baird was at the forefront of virtually all developments in television and continued research into color, stereoscopic, and big-screen television until his death.

**Baird, Spencer Fullerton** (1823–1887) *American biologist*

Baird was born in Reading, Pennsylvania, and educated at Dickinson College. From 1845 to 1850 he was professor of natural sciences at the college, making immense collections of North American fauna from several expeditions. In 1874 he was appointed United States Commissioner of Fish and Fisheries. He was assistant secretary and then full secretary (1878–87) of the Smithsonian Institution and in 1857 was one of the founders of the Institution's National Museum. Baird was also one of the principal founders of the Woods Hole Marine Laboratory. A colleague of Louis AGASSIZ and John J. Audubon, Baird did much to introduce field study in botany and zoology in the United States, in ornithology in particular, stressing the importance of extreme accuracy in descriptions. From 1853 to 1884 he published several accounts of North American reptiles, birds, and mammals.

**Bakewell, Robert** (1725–1795) *British stock breeder*

Little is known about Bakewell's early life except that he helped his father on their 440-acre rented farm at Dishley in Leicestershire in cen-

tral England, which he took over in 1760 on the death of his father. Bakewell's aim was to "get beasts to weigh where you want them to weigh." His most impressive achievement was the production of his Leicester breed of sheep. Within 50 years the breed had spread throughout the world and Bakewell apparently succeeded in producing two pounds of mutton where there had only been one before. He also introduced the custom of letting out his rams for breeding. He was, however, less successful with his Leicester long horn cattle, which, though good meat-producers, did not yield much milk.

**Bakker, Robert** (1945– ) *American paleontologist*

Let dinosaurs be dinosaurs. Let the Dinosauria stand proudly alone, a class by itself. They merit it. And let us squarely face the dinosauriness of birds and the birdness of the Dinosauria.

—*The Dinosaur Heresies* (1986)

The son of an electrical engineer, Bakker was born in Ridgewood, New Jersey, and educated at Yale and at Harvard, where he completed his PhD in 1976. After teaching for eight years at Johns Hopkins University, Baltimore, he moved to Boulder, Colorado, in 1984 to work as an independent paleontologist.

In the early 1970s, while still a graduate student, Bakker argued that traditional views on the nature of dinosaurs were misguided. Dinosaurs, he claimed, were warm-blooded, like mammals, and not cold-blooded like reptiles. In support Bakker offered three main arguments derived from comparative anatomy, latitudinal zonation, and ecology.

Anatomically the bones of endotherms (warm-blooded creatures) are rich in blood vessels and show no growth rings. Precisely these features are found in mammals, birds, and, Bakker noted, dinosaurs as well. They are lacking in cold-blooded reptiles (ectotherms).

Further, endotherms can cope with most temperature variations and can be found in temperate, arctic, and equatorial zones. Large reptiles, however, cannot survive cool winters. Yet, during the Cretaceous, dinosaurs could have been found in the far north of Canada, well within the Arctic Circle.

Finally Bakker points to predator–prey ratios. The Komodo dragon, the largest living lizard, consumes its own weight every 60 days, a lion in only eight days. Such are the demands of endothermy. As a consequence a community can support fewer warm-blooded predators than cold-blooded predators. The predator–prey ratio, Bakker argued, is a constant characteristic of the predator's metabolism. Calculations revealed that a given biomass can support a warm-blooded predator biomass of 1–3% and a cold-blooded predator biomass of up to 40%. Given that some fossil deposits yield thousands

of individuals, their predator–prey ratio should be measurable. And Bakker did find that among the reptiles of the Permian (285–225 million years ago) the ratio was very high (35–60%), while the dinosaurs of the Triassic (225–195 million years) had a ratio of only 1–3%.

Bakker's work called for a revision of vertebrate systematics. In traditional classifications birds and dinosaurs are seen as collateral descendants of thecodonts, that is, animals with teeth set in sockets. Bakker, however, has proposed that birds are descended from dinosaurs. Such views, vigorously and frequently expressed, have made Bakker a controversial and well-known figure. It is often said that Bakker was the inspiration for the main character in the popular film *Jurassic Park*.

Bakker has sought to reach an even wider public with his *Raptor Red* (1995), a popular novel dealing with a year in the life of a large predatory dinosaur. He now lives in Wyoming, where he conducts guided digs.

**Balard, Antoine-Jérôme** (1802–1876)  
*French chemist*

Balard (ba-lar) was born in Montpellier in southern France, and studied there at the School of Pharmacy. After graduating in 1826, he remained at Montpellier as a demonstrator in chemistry. In 1825, while investigating the salts contained in seawater, he discovered a dark red liquid, which he proved was an element with properties similar to chlorine and iodine. Balard proposed the name “muride” but the editors of the journal *Annales de chimie* (Annals of Chemistry) preferred “brome” (because of the element's strong odor, from the Greek for “stink”) and the element came to be called bromine. Balard also (1834) discovered dichlorine oxide (Cl<sub>2</sub>O) and chloric(I) acid (HClO).

In 1833 he became professor at Montpellier and in 1843 succeeded Louis Thenard at the Sorbonne as professor of chemistry. In 1854 he was appointed professor of general chemistry at the Collège de France, where he remained until his death.

**Balfour, Francis Maitland** (1851–1882)  
*British zoologist*

The younger brother of the British statesman Earl Balfour, Francis Balfour's career was cut short when, while convalescing from typhoid fever in Switzerland, he died attempting an ascent of the Aiguille Blanche, Mont Blanc. Balfour, who was born in Edinburgh, Scotland, held the position of animal morphologist at the Naples Zoological Station and in 1882 was appointed to the specially created post of professor of animal morphology at Cambridge University. Much influenced by the work of

Michael FOSTER, with whom he wrote *Elements of Embryology* (1883), Balfour showed the evolutionary connection between vertebrates and certain invertebrates, both of which have a notochord (a flexible rod of cells extending the length of the body) in their embryonic stages. Similar research was being conducted at that time by Aleksandr KOVALEVSKI. Balfour proposed the term Chordata for all animals possessing a notochord at some stage in their development, the Vertebrata (backboned animals) being a subphylum of the Chordata. He was an early exponent of recapitulation – the theory that ancestral forms are repeated in successive embryonic stages undergone by modern species. Balfour also did pioneer work on the development of the kidneys and related organs, as well as the spinal nervous system. His other important publications include *On the Development of Elasmobranch Fishes* (1878) and *Comparative Embryology* (1880–81) published in two volumes (invertebrates and vertebrates), the latter forming the basis of modern embryological study.

**Balmer, Johann Jakob** (1825–1898)  
*Swiss mathematician*

Born in Lausanne, Switzerland, Balmer (bah-mer) was not a professional scientist but worked as a school teacher in Basel from 1859. In 1885 he discovered that there was a simple mathematical formula that gave the wavelengths of the spectral lines of hydrogen – the *Balmer series*. This formula proved to be of great importance in atomic spectroscopy and in developing the atomic theory. Balmer arrived at his result purely from empirical evidence and was unable to explain why it yielded correct answers. Not until the further development of the atomic theory by Niels BOHR and others was this possible.

**Baltimore, David** (1938– ) *American molecular biologist*

Baltimore was born in New York City and studied chemistry at Swarthmore College. He continued with postgraduate work at the Massachusetts Institute of Technology, and at Rockefeller University, where he obtained his PhD in 1964. After three years at the Salk Institute in California, he returned to MIT in 1968 where, in 1972, he became professor of biology.

Francis CRICK had formulated what came to be known as the Central Dogma of molecular biology, namely, that information could flow from DNA to RNA to protein but could not flow backward from protein to either DNA or RNA. Although he had not actually excluded the passage of information from RNA to DNA it became widely assumed that such a flow was equally forbidden. In June 1970 Baltimore and,

quite independently, Howard TEMIN announced the discovery of an enzyme later to be known as reverse transcriptase, which is capable of transcribing RNA into DNA. Apparently certain viruses, like the RNA tumor viruses used by Baltimore, could produce DNA from an RNA template. For this work Baltimore shared the 1975 Nobel Prize for physiology or medicine with Temin and Renato DULBECCO. A few years later their work took on an added significance when GALLO and MONTAGNIER identified a retrovirus as the cause of AIDS.

Earlier (1968) Baltimore had done important work on the replication of the polio virus. He revealed that the RNA of the virus first constructed a "polyprotein" (or giant protein molecule), which then split into a number of smaller protein molecules. Two of these polymerized further RNA while the remainder formed the protein coat of the new viral particles.

In 1982 Baltimore became founding director of the Whitehead Institute, Cambridge, Massachusetts, a research biomedical foundation backed by the industrialist E. C. Whitehead. While at Whitehead, in collaboration with D. Schatz, he identified two antibody genes, RAG-1 and RAG-2. In 1990 Baltimore was appointed president of Rockefeller University; it was not to prove a fruitful or happy time. Many staff opposed the appointment and Baltimore became involved in a bitter controversy. It had been claimed that a paper coauthored by Baltimore and published in 1986 in the journal *Cell* was based on falsified data. Although Baltimore withdrew his name from the paper, the public controversy persisted in Congressional hearings and the correspondence columns of the British scientific journal *Nature*. Baltimore resigned the presidency in 1992 and returned to MIT in 1994 as professor of molecular biology. He was appointed president of the California Institute of Technology in 1997, resigning in 2006. Baltimore is currently president of the American Association for the Advancement of Science.

### **Bamberger, Eugen** (1857–1932) *German chemist*

Bamberger (**bahm-ber-ger**) studied at Breslau, Heidelberg, and in his native city of Berlin, where he graduated. After working as an assistant, first to Karl Rammelsberg in Berlin (1882) and then to Adolf von BAEYER in Munich (1883), he became professor of chemistry at the Federal Institute of Technology in Zurich in 1893.

Bamberger worked on a number of topics in organic chemistry, including the synthesis of nitroso compounds and quinols, the conversion of sulfonic acids into sulfanilic acids, and the production of diazonium anhydrides. He also extended Baeyer's ideas on benzene structure

to naphthalene and first proposed the term "alicyclic" to describe unsaturated organic ring compounds.

### **Banach, Stefan** (1892–1945) *Polish mathematician*

Banach (**bah-nak**) was born into a poor family in Krakow, Poland, and was largely self-educated. Although he attended the Lwow Institute of Technology he did not graduate. He taught mathematics privately for some years before being appointed in 1922 to the University of Lwow, where he was elected professor of mathematics in 1927. Lwow was occupied by the Germans in 1941 and although Banach managed to survive the war years he died from lung cancer in 1945.

Banach is one of the few mathematicians, along with EUCLID and HILBERT, who have given their name to a space. A *Banach space* is a type of vector space more general than a Hilbert space.

In 1924, Banach, with A. TARSKI, proved an apparently nonsensical theorem. The *Banach-Tarski paradox* claims that it is possible to dissect a sphere into a finite number of pieces which can be reassembled to form two spheres the same size as the original. It was later shown that the sphere must be dissected into at least five pieces.

### **Banks, Sir Joseph** (1743–1820) *British botanist*

He [Banks] stopped and, looking round, involuntarily exclaimed, "How beautiful!" After some reflection he said to himself, "It is surely more natural that I should be taught to know all these productions of Nature, in preference to Greek and Latin; but the latter is my father's command and it is my duty to obey him; I will however make myself acquainted with all these different plants for my own pleasure and gratification."

—Sir Everard Home, *Hunterian Oration* (1822)

The son of William Banks of Revesby Abbey, Lincolnshire, Joseph Banks inherited a large fortune when he came of age, and later used this money to finance his scientific expeditions. Born in London, he studied botany at Oxford, graduating in 1763, and three years later traveled abroad for the first time as naturalist on a fishery-protection vessel heading for Labrador and Newfoundland. On the voyage he was able to collect many new species of plants and insects and, on his return, was elected a fellow of the Royal Society.

In London Banks learned that the Royal Society was organizing a voyage to the South Pacific to observe the transit of Venus across the Sun. In 1768 James COOK set sail in the *Endeavour* and Banks, together with a team of artists and the botanist Daniel Solander, accompanied him. Cook landed in Australia, a

continent with a flora and fauna different from any found elsewhere. Banks found that most of the Australian mammals were marsupials, which are more primitive, in evolutionary terms, than the placental mammals of other continents.

After three years with the *Endeavour* Banks returned, with a large collection of unique specimens, to find himself famous. George III, interested in hearing a first-hand account of Banks's travels, invited him to Windsor. This visit was the start of a long friendship with the king, which helped Banks establish many influential contacts – possibly a factor in his election as president of the Royal Society in 1778, a post that he held until his death.

Throughout his life Banks retained his interest in natural history and in the specimens collected on the many expeditions mounted during that period. As honorary director of Kew Gardens he played a major part in establishing living representatives of as many species as possible at Kew and in providing a center for advice on the practical use of plants. He initiated many successful projects, including the introduction of the tea plant to India from its native China and the transport of the breadfruit from Tahiti to the West Indies. By George III's request, he also played an active role in importing merino sheep into Britain from Spain.

The British Museum (Natural History) now houses Banks's library and herbarium, both regarded as major collections.

### **Banting, Sir Frederick Grant** (1891–1941) *Canadian physiologist*

Banting, a farmer's son from Alliston, Ontario, began studying to be a medical missionary at Victoria College, Toronto, in 1910. During his studies he concentrated increasingly on medicine and graduated MD in 1916, whereupon he immediately joined the Canadian Army Medical Corps. In 1918 he was awarded the Military Cross for gallantry in action and was invalided out of the army.

Banting then returned to Toronto and worked for a time studying children's diseases before setting up practice in London, Ontario, in 1920. He also began work at the London Medical School, specializing in studies on the pancreas, particularly the small patches of pancreatic cells known as the islets of Langerhans. Earlier work had shown a connection between the pancreas and diabetes and Banting wondered if a hormone was produced in the islets of Langerhans that regulated glucose metabolism. In 1921 he approached John Macleod, professor of physiology at Toronto University, who was initially skeptical. Feeling that Banting needed help in physiological and biochemical methods, Macleod suggested the assistance of a young research student, Charles BEST, and eventually merely granted Banting and Best

some laboratory space during the vacation, while he went abroad.

Over the next six months Banting and Best devised a series of elegant experiments. They tied off the pancreatic ducts of dogs and made extracts of the islets of Langerhans free from other pancreatic substances. These extracts, called "isletin," were found to have some effect against diabetes in dogs. Prior to trials on humans, Macleod asked a biochemist, James Collip, to purify the extracts and the purification method for what was now known as insulin was patented by Banting, Best, and Collip in 1923. They allowed manufacturers freedom to produce the hormone but required a small royalty to be paid to finance future medical research.

The pharmaceutical firm Eli Lilly began industrial production of insulin in 1923 and in the same year Banting was awarded the chair of medical research at Toronto University and a government annuity of \$7,000. The Nobel Prize for physiology or medicine was awarded jointly to Banting and Macleod in 1923; Banting was furious that Best had not been included in the award and shared his part of the prize money with him. Macleod shared his portion with Collip. In 1930 the Banting and Best Department was opened at the University of Toronto and Banting became its director. Under Best's guidance, it became the center of medical research in Canada. His own later researches were into cancer and also the function of the adrenal cortex.

Banting was knighted in 1934. When war broke out in 1939 he joined an army medical unit and worked on many committees linking Canadian and British wartime medical research. His bravery was much in evidence at this time, particularly his personal involvement in research into mustard gas and blackout problems experienced by airmen. In 1941 on a flight from Gander, Newfoundland, to Britain his plane crashed and he died in the snow.

### **Bárány, Robert** (1876–1936) *Austro-Hungarian physician*

Bárány (**bah**-rah-nee) was born in Vienna and educated at the university there, graduating in medicine in 1900. After studying at various German clinics, he returned to Vienna to become an assistant at the university's ear clinic. In 1909 he was appointed lecturer in otology. Through his work at the clinic he devised a test, now called the *Bárány test*, for diagnosing disease of the semicircular canals of the inner ear by syringing the ear with either hot or cold water. For this he was awarded the 1914 Nobel Prize in physiology or medicine. At this time he was being held as a prisoner of war in Siberia, but through the offices of the Swedish Red Cross he was released for the presentation.

In 1917 Bárány was appointed professor at

Uppsala University, where he continued his investigations on the inner ear and the role of the cerebellum in the brain in controlling body movement. *Bárány's pointing test* is used to test for brain lesions.

**Barcroft, Sir Joseph** (1872–1947) *Irish physiologist*

Barcroft was born in Glen Newry in Northern Ireland. As professor of physiology at Cambridge University (1926–37) and director of animal physiology for the Agricultural Research Council (1941–47), he carried out extensive research into human embryology, physiology, and histology. He investigated the oxygen-carrying role of hemoglobin, and devised (1908) an apparatus for the analysis of blood gases.

Barcroft led three high-altitude expeditions – to Tenerife (1910); Monte Rosa, Italy (1911); and the Peruvian Andes (1922) – in order to study acclimatization and the effects of rarefied atmospheres on respiration. He found that, at low oxygen pressures, the human lung is not able to secrete oxygen into the blood at a higher pressure than the pressure of the inhaled air.

During World War I, Barcroft was chief physiologist at the Experimental Station at Porton, Wiltshire, where he studied the effects of poisonous gases. Elected a fellow of the Royal Society in 1910 and knighted in 1935, Barcroft wrote the famous text *Respiratory Function of the Blood* (1914), as well as publications on the brain and its environment and on prenatal conditions.

**Bardeen, John** (1908–1991) *American physicist*

Bardeen, the son of a professor of anatomy, was born in Madison, Wisconsin, and studied electrical engineering at the University of Wisconsin. He obtained his PhD in mathematical physics at Princeton in 1936. Bardeen began work as a geophysicist with Gulf Research and Development Corporation, Pittsburgh, in 1931 but in 1935 entered academic life as a junior fellow at Harvard, moving to the University of Minnesota in 1938. He spent the war years at the Naval Ordnance Laboratory, followed by six creative years from 1945 until 1951 at the Bell Telephone Laboratory, after which he was appointed professor of physics and electrical engineering at the University of Illinois, a post he held until 1975.

Bardeen is remarkable as a recipient of two Nobel Prizes for physics. The first, awarded in 1956, he shared with Walter BRATTAIN and William SHOCKLEY for their development of the point-contact transistor (1947), thus preparing the way for the development of the more efficient junction transistor by Shockley.

Bardeen's second prize was awarded in 1972

for his formulation, in collaboration with Leon COOPER and John SCHRIEFFER, of the first satisfactory theory of superconductivity – the so-called BCS theory. In 1911 Heike KAMERLINGH-ONNES had discovered that mercury lost all electrical resistance when its temperature was lowered to 4.2 kelvins. Superconductivity was also shown to be a property of many other metals, yet despite much effort to understand the phenomenon, a full explanation was not given until 1957. The basic innovation of the BCS theory was that the current in a superconductor is carried not by individual electrons but by bound pairs of them, later known as *Cooper pairs*. The pairs form as a result of interactions between the electrons and vibrations of the atoms in the crystal. The scattering of one electron by a lattice atom does not change the total momentum of the pair, and the flow of electrons continues indefinitely.

The success of the BCS theory led to an enormous revival of interest in both the theory of superconductors and their practical application. Beginning in the 1970s, there began to emerge a new industry capable of exploiting superconducting materials, especially in devices based on the effects discovered by Brian JOSEPHSON.

**Barger, George** (1878–1939) *British organic chemist*

Barger, of Anglo-Dutch parentage, was born in Manchester, England, attended school in Holland, and studied natural sciences at Cambridge University, where he graduated with equal distinction in chemistry and botany.

While a demonstrator in botany at the University of Brussels (1901–03) Barger discovered a method of determining the molecular weight of small samples by vapor-pressure measurements. From 1903 to 1909 he was a researcher at the Wellcome Physiological Research Laboratories, where he worked mainly on ergot, isolating ergotoxine in collaboration with Francis Carr (1906).

In the course of the work on ergot Barger and Henry DALE isolated a series of related amines, derived from tyramine, which had sympathomimetic activity. This work led to a better understanding of the nervous system and to the development of new drugs. The work on active amines was collected in *The Simpler Natural Bases* (1914) and the work on ergot culminated in the definitive monograph on every facet of the subject, *Ergot and Ergotism* (1931).

From 1909 to 1919 Barger worked in London, as head of chemistry at Goldsmiths' College, professor of chemistry at Royal Holloway College, and from 1914 as chemist with the National Institute of Medical Research. In 1919 he was elected a fellow of the Royal Society and appointed to the new chair of chemistry in relation to medicine at Edinburgh. The most

notable researches of this period were Charles Harington's structural elucidation and synthesis of thyroxine, in which Barger collaborated, and Barger's synthesis of methionine. His school did important work on physostigmine, cholinesterase, and vitamin B<sub>1</sub>. In 1938 Barger became professor of chemistry at the University of Glasgow. He was a pioneer of medicinal chemistry, an excellent linguist, and a tireless ambassador for science.

**Barkhausen, Heinrich Georg** (1881–1956) *German physicist*

After attending the gymnasium and engineering college in his native city of Bremen, Barkhausen (**bark**-how-zen) gained his PhD in Göttingen and in 1911 became professor of electrical engineering in Dresden. Here he formulated the basic equations governing the coefficients of the amplifier valve.

In 1919 he discovered the *Barkhausen effect*, observing that a slow continuous increase in the magnetic field applied to a ferromagnetic material gave rise to discontinuous leaps in magnetization, which could be heard as distinct clicking sounds through a loudspeaker. This effect is caused by domains of elementary magnets changing direction or size as the field increases.

In 1920, with K. Kurz he developed an ultrahighfrequency oscillator, which became the forerunner of microwave-technology developments. After World War II he returned to Dresden to aid the reconstruction of his Institute of High-Frequency Electron-Tube Technology, which had been destroyed by bombing, and remained there until his death.

**Barkla, Charles Glover** (1877–1944) *British x-ray physicist*

Barkla was born in Widnes in the northwest of England. After taking his master's degree in 1899 at Liverpool, Barkla went to Trinity College, Cambridge but, because of his passion for singing, he transferred to King's College to sing in the choir. At King's College he started his important research on x-rays. In 1902 he returned to Liverpool as Oliver Lodge Fellow and in 1909 became Wheatstone Professor at King's College, London. From 1913 onward he was professor of natural philosophy at Edinburgh University.

His scientific work, for which he received the 1917 Nobel Prize for physics, concerned the properties of x-rays – in particular, the way in which they are scattered by various materials. He showed in 1903 that the scattering of x-rays by gases depends on the molecular weight of the gas. In 1904 he observed the polarization of x-rays – a result that indicated that x-rays are a form of electromagnetic radiation like light. Further confirmation of this was obtained

in 1907 when he performed certain experiments on the direction of scattering of a beam of x-rays as evidence to resolve a controversy with William Henry BRAGG who argued, at the time, that x-rays were particles.

Barkla also demonstrated x-ray fluorescence, in which primary x-rays are absorbed and the excited atoms then emit characteristic secondary x-rays. The frequencies of the characteristic x-rays depend on the atomic number of the element, as shown by Henry Mosely, who could well have shared Barkla's Nobel Prize but for his untimely death.

From about 1916, Barkla became isolated from modern physics with an increasingly dogmatic attitude, a tendency to cite only his own papers, and a concentration on untenable theories.

**Barnard, Christiaan Neethling** (1922–2001) *South African surgeon*

The prime goal is to alleviate suffering and not to prolong life. And if your treatment does not alleviate suffering but only prolongs life, that treatment should be stopped.

Barnard, who was born in Beaufort West, South Africa, was awarded his MD from the University of Cape Town in 1953 and joined the Medical Faculty as a research fellow in surgery. After three years at the University of Minnesota (1955–58), where he studied heart surgery, he returned to Cape Town as director of surgical research. He concentrated on improving techniques for artificially sustaining bodily functions during surgery and for keeping organs alive outside the body. On 2 December 1967 Barnard performed the first heart-transplant operation on a human patient, a 54-year-old grocer named Louis Washkansky. He received the heart of Denise Duvall, a traffic accident victim. The heart functioned but the recipient died of pneumonia 18 days after the operation. The body's immune system had broken down following the administration of drugs to suppress rejection of the new heart as foreign tissue.

Barnard subsequently performed further similar operations with improved postoperative treatment giving much greater success. In 1974 he performed the first successful double heart-transplant operation. His pioneering work generated worldwide publicity for heart-transplant surgery and it is now widely practiced. In 1984 he became professor emeritus at the University of Cape Town. He wrote a number of books, including his interesting autobiography *One Life* (1970).

**Barnard, Edward Emerson** (1857–1923) *American astronomer*

Although Barnard was born into a poor family in Nashville, Tennessee, and received little for-

mal education, he developed a great interest in astronomy and also became familiar with photographic techniques from his work in a portrait studio. He managed both to study and instruct at Vanderbilt University from 1883 to 1887. From 1888 he worked at the Lick Observatory until in 1895 he became professor of astronomy at Chicago and was thus able to work at the newly established Yerkes Observatory.

Barnard was a keen observer and had detected more than ten comets by 1887 and several more in subsequent years. In 1892 he became the first astronomer after GALILEO to discover a new satellite of Jupiter, subsequently named Amalthea, which lay inside the orbits of the four Galilean satellites and was much smaller and fainter. In 1916 he discovered a nearby red star with a very pronounced proper motion of 10.3 seconds of arc per year: in 180 years it will appear to us to have moved a very considerable distance, equal to the diameter of the Moon. The star is now called *Barnard's star*.

Barnard's other discoveries included various novae, variable stars, and binary stars. He was also one of the first to appreciate that dark nebulae were not areas of the sky containing no stars at all (as William HERSCHEL had thought) but, as Barnard and Max WOLF demonstrated, were enormous clouds of dust and gas that shielded the stars behind them from our view. By 1919 he had discovered nearly 200 such nebulae.

**Barnard, Joseph Edwin (1870–1949)**  
*British physicist*

While working in his father's business, Barnard used his spare time to study at the Lister Institute, King's College, London, where he developed an interest in microscopy, especially photomicrography, which led to his receiving a chair at the Charing Cross Medical School. He was a fellow and three times president of the Royal Microscopical Society and in 1920 became honorary director of the applied-optics department at the National Institute for Medical Research.

His research and experience in photomicrography led him to write *Practical Photomicrography* (1911), which became a standard work. Later he developed a technique for using ultraviolet radiation, which is of shorter wavelength than visible light, and therefore gives greater resolution. With W. E. Gye he used this method to identify several ultramicroscopic organisms connected with malignant growths that were too small to see using standard microscopy.

**Barr, Murray Llewellyn (1908–1995)**  
*Canadian geneticist and anatomist*

Barr was born in Belmont, Ontario, and was educated at the University of Western Ontario,

gaining his BA in 1930, MD in 1933, and MSc in 1938. His association with Western Ontario was continued with his appointment as an instructor in 1936. He subsequently became professor of microscopical anatomy (1952), professor of anatomy and head of the anatomy department (1964), and emeritus professor (1979).

Barr is best known for his discovery, made in 1949 in conjunction with Ewart Bertram, of the densely staining nuclear bodies present in the somatic cells of female humans and other female mammals. These are called sex chromatin or *Barr bodies*. Later studies by Barr and others revealed that the single Barr body in normal cells is one of the two X-chromosomes in a highly condensed and genetically inactive state. The other X-chromosome is in the diffuse state and is genetically active.

Their discovery enabled Barr and his coworkers to devise a relatively simple diagnostic test for certain genetic abnormalities, in which cells rubbed from the lining of the mouth cavity (a buccal smear) were stained and examined microscopically. For instance, individuals suffering from Turner's syndrome, which usually affects females, have only one X-chromosome and lack Barr bodies. In contrast, males affected by Klinefelter's syndrome possess an extra X-chromosome and exhibit Barr bodies in their cells.

Besides his work in cytogenetics and inherited human disorders, Barr is also noted for his descriptions of nervous-system anatomy. His publications included *The Human Nervous System: an Anatomical Viewpoint* (1972; 5th edition, with J. A. Kiernan, 1988).

**Barringer, Daniel Moreau (1860–1929)**  
*American mining engineer and geologist*

Barringer, who was born in Raleigh, North Carolina, graduated from Princeton in 1879 and then studied law at Pennsylvania, geology at Harvard, and chemistry and mineralogy at the University of Virginia. In 1890 he established himself as a consulting mining engineer and geologist; he was the author of the standard work *Law of Mines and Mining in the U.S.* (1907).

Barringer is remembered for his investigation of the massive Diabolo Crater in Arizona, which is nearly 600 feet (200 m) deep and over 4,000 feet (1,200 m) in diameter. The cause of such a gigantic hole was a matter of speculation, most considering it to be of volcanic origin. Barringer, finding numerous nickel-iron rocks in the area, became convinced that the remains of an enormous meteorite lay buried at the center of the crater. He began drilling in 1902 but failed to find anything of significance. He later concluded that a meteorite would have been unlikely to enter vertically; after experimenting with projectiles he established that it probably entered at an angle of 45° and would therefore

be embedded to one side. In 1922 drilling began again but rapid flooding of the shafts caused Barringer to abandon the search. After his death the crater became known as the *Bar-ringer Meteor Crater*.

**Barrow, Isaac** (1630–1677) *British mathematician*

Born the son of a prosperous London linen draper, Barrow was educated at Cambridge University. Because of his royalist sympathies he was rejected, on Cromwell's instructions, as a candidate for the professorship of Greek. Consequently he began in 1655 an extensive tour of Europe. With the restoration of Charles II, he returned to Britain in 1660 and was finally elected professor of Greek at Cambridge. In 1663 he accepted the newly created Lucasian Professorship of Mathematics, a post he resigned from in 1669.

The claim has often been made that Barrow resigned his chair in favor of his pupil, Isaac NEWTON. In reality Newton was not the pupil of Barrow and, while he appreciated Newton's mathematical genius and saw to it that Newton succeeded him, Barrow was more interested in advancing his own career. He was appointed chaplain to Charles II in 1669 and in 1673 returned to Cambridge as Master of Trinity College, an office in the gift of the king. He died soon after in 1677 from, according to John Aubrey, an overdose of opium, an addiction that he had acquired in Turkey.

Barrow is best known for his *Lectiones opticae* (1669; Lectures on Optics) and *Lectiones geometricae* (1670; Lectures on Geometry), both edited by Newton, and the posthumously published *Lectiones mathematicae* (1683; Lectures on Mathematics). Unfortunately for Barrow's reputation, his work in both optics and mathematics was soon overshadowed by Newton's own publications.

**Bartholin, Erasmus** (1625–1698) *Danish mathematician*

Bartholin (bar-**too**-lin), the son of Caspar and brother of Thomas Bartholin, who were both distinguished anatomists, was born in Roskilde, Denmark, and educated in Leiden and Padua, where he obtained his MD in 1654. After further travel in France and England he returned to Denmark in 1656 and held chairs in mathematics and medicine at the University of Copenhagen from 1657 until his death.

Bartholin worked on the theory of equations and with Ole RØMER made an unsuccessful attempt to calculate the orbits of the comets prominent in the late 1660s. He is however best remembered for his discovery of double refraction announced in his *Experimenta crystalli Islandici disdiacastici* (1669; Experiments on Icelandic Double-Refracting Crystal). In it he

described how Icelandic feldspar (calcite) produces a double image of objects observed through it. This discovery greatly puzzled scientists and was much discussed by NEWTON and Christiaan HUYGENS, who tried unsuccessfully to incorporate the strange phenomenon into their respective theories of light.

Double refraction proved remarkably recalcitrant to all proposed explanations for well over a century and it was only with the work of Etienne MALUS on polarized light in 1808, and that of Augustin FRESNEL in 1817, that Bartholin's observations could at last be understood.

**Bartlett, Neil** (1932– ) *British-American chemist*

Bartlett was born in Newcastle upon Tyne in northeast England and educated at the University of Durham, where he obtained his PhD in 1957. He taught at the University of British Columbia, Canada, and at Princeton before being appointed to a chemistry professorship in 1969 at the University of California, Berkeley. Bartlett retired in 1993. He became a naturalized American citizen in 2000.

Bartlett was studying metal fluorides and found that the compound platinum hexafluoride ( $\text{PtF}_6$ ) is extremely active. In fact it reacted with molecular oxygen to form the novel compound  $\text{O}_2^+\text{PtF}_6^-$ . This was the first example of a compound containing the oxygen cation. At the time it was an unquestioned assumption of chemistry that the noble gases – helium, neon, argon, krypton, and xenon – were completely inert, incapable of forming any compounds whatsoever. Further, there was a solid body of valence theory that provided good reasons why this should be so. So struck was Bartlett with the ability of  $\text{PtF}_6$  to react with other substances that he tried, in 1962, to form a compound between it and xenon. He knew that the ionization potential of xenon was not too much greater than the ionization potential of the oxygen molecule. To his and other chemists' surprise xenon fluoroplatinate ( $\text{XePtF}_6$ ) was produced – the first compound of a noble gas. Once the first compound had been detected xenon was soon shown to form other compounds, such as xenon fluoride ( $\text{XeF}_4$ ) and oxyfluoride ( $\text{XeOF}_4$ ). Krypton and radon were also found to form compounds although the lighter inert gases have so far remained inactive.

**Bartlett, Paul Doughty** (1907–1998) *American chemist*

Bartlett was born in Ann Arbor, Michigan, and educated at Amherst College and Harvard, where he obtained his PhD in 1931. After teaching briefly at the Rockefeller Institute and the University of Minnesota he returned to Harvard in 1934 and served there as professor of

chemistry from 1948 until his retirement in 1975.

Bartlett worked mainly on the mechanisms involved in organic reactions; for example, the behavior of free radicals and the kinetics of polymerization reactions. He also investigated the chemistry of elemental sulfur and the terpenes (a family of hydrocarbons found in the essential oils of plants).

**Barton, Sir Derek Harold Richard** (1918–1998) *British chemist*

Barton was born in the port of Gravesend in southeast England, and was educated at Imperial College, London, where he obtained his PhD in 1942. After doing some industrial research he spent a year as visiting lecturer at Harvard before being appointed reader (1950) and then professor (1953) in organic chemistry at Birkbeck College, London. Barton moved to a similar chair at Glasgow University in 1955 but returned to Imperial College in 1957 and held the chair of chemistry until 1978, when he became director of the Institute for the Chemistry of Natural Substances at Gif-sur-Yvette in France. In 1986 he became a distinguished professor at Texas Agricultural and Mechanical University.

In 1950 Barton published a fundamental paper on conformational analysis in which he proposed that the orientations in space of functional groups affect the rates of reaction in isomers. Barton discussed six-membered organic rings, particularly, following the earlier work of Odd HASSELL, the “chair” conformation of cyclohexane, and explained its distinctive stability.

This was done in terms of the distinction between equatorial conformations, in which the hydrogen atoms lie in the same plane as the carbon ring, and axial conformations, where they are perpendicular to the ring. He confirmed these notions with further work on the stability and reactivity of steroids and terpenes.

It was for this work that he shared the 1969 Nobel Prize for chemistry with Hassell. Barton's later work on oxyradicals and his predictions about their behavior in reactions helped in the development of a simple method for synthesizing the hormone aldosterone.

**Basov, Nikolai Gennediyevich** (1922–1998) *Russian physicist*

Basov (**bah**-sof), who was born in Voronezh in western Russia, served in the Soviet army in World War II, following which he graduated from the Moscow Institute of Engineering Physics (1950). He studied at the Lebedev Institute of Physics of the Soviet Academy of Sciences in Moscow, gaining his doctoral degree in 1956 and going on to become deputy director (1958) and later director (1973). In 1989 he be-

came director of the quantum radiophysics division.

Basov's major contribution was in the development of the maser (*microwave amplification by stimulated emission of radiation*), the forerunner of the laser. From 1952 he had been researching the possibility of amplifying electromagnetic radiation using excited atoms or molecules. His colleague at the Lebedev Institute, Aleksandr PROKHOROV, was involved in the microwave spectroscopy of gases, with the aim of creating a precise frequency standard, for use in very accurate clocks and navigational systems. Their work led to theories and experiments designed to produce a state of “population inversion” in molecular beams, through which amplification of radiofrequency radiation became possible.

Together Basov and Prokhorov in 1955 developed a generator using a beam of excited ammonia molecules. This was the maser, developed simultaneously but independently in America by Charles TOWNES. Basov, Prokhorov, and Townes received the 1964 Nobel Prize for physics for this work.

The first masers used a method of selecting the more excited molecules from a beam, but a more efficient method was proposed by Basov and Prokhorov in 1955, the so-called “three-level” method of producing population inversion by “pumping” with a powerful auxiliary source of radiation. The next year the method was applied by Nicolaas BLOEMBERGEN in America in a quantum amplifier.

Basov went on to develop the laser principle, and in 1958 introduced the idea of using semiconductors to achieve laser action. In the years 1960–65 he realized many of his ideas in practical systems. He subsequently did considerable theoretical work on pulsed ruby and neodymium-glass lasers, which are now in common use, and on the interaction of radiation with matter. In particular, he worked on the production of short powerful pulses of coherent light.

**Bassi, Agostino** (1773–1856) *Italian microbiologist*

Bassi (**bah**-see), who was born in the northern Italian town of Lodi and educated at the University of Pavia, conducted valuable research into animal diseases. Anticipating PASTEUR, he suggested that certain diseases are caused by minute animal or plant parasites. Some of his most important studies were concerned with cholera and with pellagra, a deficiency disease of the skin. In 1835 he was able to show that the disease of silkworms known as muscardine was caused by a fungus, subsequently named *Botrytis bassiana* in his honor. He demonstrated that muscardine is contagious and formulated methods to prevent and eliminate the disease. Bassi also published accounts of work

on potato cultivation, cheese-making, and vinification.

**Bates, Henry Walter** (1825–1892) *British naturalist and explorer*

The son of a stocking-factory owner in the central English town of Leicester, Bates left school at 13 and was apprenticed to a hosiery manufacturer, but still found time for indulging his hobby of beetle collecting. In 1844 he met Alfred WALLACE and stimulated the latter's interest in entomology. This led, three years later, to Wallace suggesting they should travel together to the tropics to collect specimens and data that might throw light on the evolution of species.

In May 1848 they arrived at Pará, Brazil, near the mouth of the Amazon. After two years collecting together they split up, and Bates spent a further nine years in the Amazon basin. By the time he returned to England in 1859, he estimated he had collected 14,712 species, 8,000 of which were new to science.

While collecting Bates had noted startling similarities between certain butterfly species – a phenomenon later to be termed *Batesian mimicry*. He attributed this to natural selection, since palatable butterflies that closely resembled noxious species would be left alone by predators and thus tend to increase. His paper on this, *Contributions to an Insect Fauna of the Amazon Valley, Lepidoptera: Heliconidae* (1861) provided strong supportive evidence for the Darwin–Wallace evolutionary theory published three years earlier.

DARWIN persuaded Bates to write a book on his travels, which resulted in the appearance of *The Naturalist on the River Amazon* (1863), an objective account of the animals, humans, and natural phenomena Bates encountered. Although one of the best and most popular books of its kind, Bates was to comment that he would rather spend a further 11 years on the Amazon than write another book. He became assistant secretary of the Royal Geographic Society in 1864.

**Bates, Leslie Fleetwood** (1897–1978) *British physicist*

Bates was educated at the university in his native city of Bristol and at Cambridge University, where he obtained his PhD in 1922. After teaching first at University College, London, he moved to Nottingham, where he served as professor of physics from 1936, apart from wartime duties on the degaussing of ships, until his retirement in 1964.

Most of Bates's work was on the magnetic properties of materials. He was the author of a widely used textbook, which went through many editions, *Modern Magnetism* (1938).

**Bateson, William** (1861–1926) *British geneticist*

Born in the coastal town of Whitby in northeast England, Bateson graduated in natural sciences from Cambridge University in 1883, having specialized in zoology. He then traveled to America, where he studied the embryology of the wormlike marine creature *Balanoglossus*. He discovered that, although its larval stage resembles that of the echinoderms (e.g., starfish), it also has gill slits, the beginnings of a notochord, and a dorsal nerve cord, proving it to be a primitive chordate. This was the first evidence that the chordates have affinities with the echinoderms.

Back at Cambridge Bateson began studying variation within populations and soon found instances of discontinuous variation that could not simply be related to environmental conditions. He believed this to be of evolutionary importance, and began breeding experiments to investigate the phenomenon more fully. These prepared him to accept MENDEL's work when it was rediscovered in 1900, although other British scientists were largely skeptical of the work. Bateson translated Mendel's paper into English and set up a research group at Grantchester to investigate heredity in plants and animals.

Through his study of the inheritance of comb shape in poultry, Bateson demonstrated that Mendelian ratios are found in animal crosses (as well as plants). He turned up various deviations from the normal dihybrid ratio (9:3:3:1), which he rightly attributed to gene interaction. He also found that certain traits are governed by two or more genes, and in his sweet-pea crosses showed that some characters are not inherited independently. This was the first hint that genes are linked on chromosomes, but Bateson never accepted T. H. MORGAN's explanation of linkage or the chromosome theory of inheritance.

In 1908 Bateson became the first professor of the subject he himself named – genetics. However, he left Cambridge only a year later and in 1910 became director of the newly formed John Innes Horticultural Institution at Merton, Surrey, where he remained until his death. He was the leading proponent of Mendelian genetics in Britain and became involved in a heated controversy with supporters of biometrical genetics such as Karl PEARSON. The views of both sides were later reconciled by the work of Ronald FISHER. Bateson wrote a number of books, including the controversial *Materials for the Study of Variation* (1894) and *Mendelian Heredity – A Defence* (1902); he also founded, with R. C. Punnett, the *Journal of Genetics* in 1910.

**Bauer, Georg** See [AGRICOLA](#), [GEORGIUS](#).

**Bawden, Sir Frederick Charles** (1908–1972) *British plant pathologist*

Bawden was born in North Tawton, England, and was educated at Cambridge University, receiving his MA in 1933. From 1936 to 1940 he worked in the virus physiology department at Rothamsted Experimental Station, becoming the head of the plant pathology department in 1940. He was director of the station from 1958 until his death.

In 1937 Bawden discovered that the tobacco mosaic virus (TMV) contains ribonucleic acid, this being the first demonstration that nucleic acids occur in viruses. With Norman PIRIE, Bawden isolated TMV in crystalline form and made important contributions to elucidating the structure of viruses and the ways in which they multiply. Bawden's work also helped in revealing the mechanisms of protein formation.

**Bayer, Johann** (1572–1625) *German astronomer*

Born in Rhain in Germany, Bayer (**bi**-er) was an advocate (lawyer) by profession. In 1603 he published *Uranometria* (Measurement of the Heavens), the most complete catalog of pre-telescopic astronomy. To Tycho BRAHE's catalog of 1602, he added nearly a thousand new stars and twelve new southern constellations. The catalog's main importance, however, rests on Bayer's innovation of naming stars by letters of the Greek alphabet. Before Bayer, prominent stars were given proper names, mainly Arabic ones such as Altair and Rigel. If not individually named, they would be referred to by their position in the constellation. Bayer introduced the scheme, which is still used, of referring to the brightest star of a constellation by "alpha," the second brightest by "beta," and so on. Thus Altair, which is the brightest star in the constellation Aquila, is systematically named Alpha Aquilae. If there were more stars than letters of the Greek alphabet, the dimmer ones could be denoted by letters of the Roman alphabet and, if necessary, numbers.

Bayer's other proposed innovation – to name constellations after characters in the Bible – was less successful.

**Bayliss, Sir William Maddock** (1860–1924) *British physiologist*

Bayliss was the son of a wealthy iron manufacturer in the industrial town of Wolverhampton in central England. In 1881 he entered University College, London, as a medical student but when he failed his second MB exam in anatomy he gave up medicine to concentrate on physiology. He graduated from Oxford University in 1888, then returned to University College, London, where he worked for the rest of his life, holding the chair of general physiology from 1912. Bayliss was elected

a fellow of the Royal Society in 1903 and was knighted in 1922.

He was chiefly interested in the physiology of the nervous, digestive, and vascular systems, on which he worked in association with his brother-in-law, Ernest STARLING. Their most important work, published in 1902, was the discovery of the action of a hormone (secretin) in controlling digestion. They showed that in normal digestion the acidic contents of the stomach stimulate production of the hormone secretin when they reach the duodenum. Secretin is transported in the bloodstream to initiate secretion of digestive juices by the pancreas. In 1915 Bayliss produced a standard textbook on physiology, *Principles of General Physiology*, which treated the subject from a physicochemical point of view.

**Beadle, George Wells** (1903–1989) *American geneticist*

Beadle was born in Wahoo, Nebraska, and graduated from the University of Nebraska in 1926; he gained his PhD from Cornell University in 1931. He then spent two years doing research in genetics under T. H. MORGAN at the California Institute of Technology. Beadle was a professor at the California Institute of Technology from 1946 until 1961 and was president of the University of Chicago from 1961 until 1968. In 1937 Beadle went to Stanford University, where in 1940 he began working with Edward TATUM on the mold *Neurospora*. They used nutritional mutants, which were unable to synthesize certain essential dietary compounds, to determine the sequence of various metabolic pathways. Substances similar to the missing compound were added to the mutant mold cultures to find whether or not they could substitute for the lacking chemical. If the culture survived then it could be assumed that the mold could convert the substance into the chemical it needed, showing that the nutrient was likely to be a precursor of the missing chemical.

From this and similar work Beadle and Tatum concluded that the function of a gene was to control the production of a particular enzyme and that a mutation in any one gene would cause the formation of an abnormal enzyme that would be unable to catalyze a certain step in a chain of reactions. This reasoning led to the formulation of the one gene–one enzyme hypothesis, for which Beadle and Tatum received the 1958 Nobel Prize for physiology or medicine, sharing the prize with Joshua LEDERBERG, who had worked with Tatum on bacterial genetics.

**Beaufort, Sir Francis** (1774–1857) *British hydrographer*

Beaufort was born in Navan in Ireland; his father was a cleric of Huguenot origin who took

an active interest in geography and topography, publishing in 1792 one of the earliest detailed maps of Ireland. Beaufort joined the East India Company in 1789 and enlisted in the Royal Navy the following year, remaining on active service until 1812.

He proposed, in 1806, the wind scale named for him. This was an objective scale ranging from calm (0) up to storm (13) in which wind strength was correlated with the amount of sail a full-rigged ship would carry appropriate to the wind conditions. It was first used officially by Robert FITZROY in 1831 and adopted by the British Admiralty in 1838. When sail gave way to steam the scale was modified by defining levels on it in terms of the state of the sea or, following George SIMPSON, wind speed.

In 1812 Beaufort surveyed and charted the Turkish coast, later writing his account of the expedition, *Karamania* (1817). He was appointed hydrographer to the Royal Navy in 1829. In this office Beaufort commissioned voyages to survey and chart areas of the world, such as those of the *Beagle* with Charles DARWIN and the *Erebus* with Joseph HOOKER. The sea north of Alaska was named for him.

### Beaumont, Elie de (1798–1874) *French geologist*

Beaumont (**boh-mon**), who was born and died in Canon, France, was educated at the Ecole Polytechnique and the School of Mines, Paris, and taught at the School of Mines from 1827, later becoming professor of geology there (1835). He is remembered chiefly for his theory on the origin of mountains. He published his views in 1830 in his *Revolutions de la surface du globe*, in which he argued that mountain ranges came into existence suddenly and were the result of distortions produced by the cooling crust of the Earth. Such a view fitted in well with the catastrophism of such zoologists as Georges CUVIER. Beaumont summarized his theories in his *Notice sur les systèmes des montagnes* (1852; *On Mountain Systems*).

Beaumont served as engineer-in-chief of mines for the period 1833–47. He also collaborated with Ours Pierre Dufrenoy in compiling the great geological map of France, published in 1840.

### Beaumont, William (1785–1853) *American physician*

Born in Lebanon, Connecticut, Beaumont started out as a farmhand and then a school-teacher before becoming a doctor's apprentice. He received his license to practice medicine in 1812 and joined the army as a surgeon's mate. While serving as post surgeon at Fort Mackinac, Michigan, he treated a Canadian trapper, Alexis St. Martin, for wounds caused by a close-range shotgun blast. His patient recovered but

was left with an opening (fistula) in his stomach wall. Beaumont took this opportunity to conduct pioneering experiments on the process of digestion in the human stomach, sampling its contents through the fistula and studying the rates of digestion of various foods and the effects of emotional changes on digestion. His *Experiments and Observations on the Gastric Juice and the Physiology of Digestion* (1833) helped trigger further research in this field.

### Beche, Sir Henry Thomas de la See DE LA BECHE, SIR HENRY THOMAS.

### Becher, Johann Joachim (1635–1682) *German chemist and physician*

Becher (**bek-er**), a pastor's son from Speyer in southwest Germany, was largely self-taught. After traveling throughout Europe he gained his MD from the University of Mainz in 1661 and became professor of medicine there in 1663. Short spells as court physician in Mainz (1663–64) and physician to the elector of Bavaria (1664) were followed by a period in Vienna from 1665, where he attempted to realize several economic projects, including a Rhine–Danube canal. He fell from favor and was forced to flee via Holland to England, where he died.

Becher is a transitional figure between alchemy and modern chemistry. He claimed to have a process for producing gold from silver and sand and his chemical system was an extension of the Paracelsian *Tria prima* of sulfur, salt, and mercury. He stated that all inorganic bodies were a mixture of water and three earthy principles: vitreous earth (*terra fusilis*), combustible earth (*terra pinguis*), and mercurial earth (*terra fluida*). *Terra pinguis* was identified as the cause of combustion and this became the phlogiston of Georg STAHL's later theory. Becher's most influential work was *Physicae subterraneae* (1669; *Subterranean Physics*), which was republished by Stahl in 1703. This work contained his theories on the nature of minerals and experiments.

### Beckmann, Ernst Otto (1853–1923) *German organic and physical chemist*

Beckmann (**bek-man**) was born in the German industrial city of Solingen in the Ruhr. His father was an industrial chemist who independently discovered the pigment Paris green. Ernst served an apprenticeship as a pharmacist before studying chemistry at the University of Leipzig, where he graduated in 1878. In 1886, while *Privatdozent* at Leipzig, he discovered the *Beckmann rearrangement* whereby ketoximes are converted into amides. This reaction was soon to be used by Arthur HANTZSCH to determine the stereochemistry of the oximes.

Needing an efficient method for finding mo-

lecular weights, Beckmann devised the *Beckmann thermometer*, suitable for measuring changes in temperature over a small range. It is used in finding the elevation in boiling point or depression of freezing point for a solution – which can then be used to calculate the molecular weight of the solute. His other research included work on terpenes and the chlorides of sulfur and selenium. Beckmann was professor at Giessen (1891), Erlangen (1892), and Leipzig (1897). In 1912 he became the first director of the Kaiser Wilhelm Institute at Dahlem, a post with opportunities that never materialized owing to the demands of World War I.

**Becquerel, Antoine Henri** (1852–1908)  
*French physicist*

Becquerel (bek-er-el) was born in Paris, France; his early scientific and engineering training was at the Ecole Polytechnique and the School of Bridges and Highways, and in 1876 he started teaching at the Polytechnique. From 1875 he researched into various aspects of optics and obtained his doctorate in 1888. In 1899 he was elected to the French Academy of Sciences, continuing the family tradition as his father and grandfather, both renowned physicists, had also been members. He held chairs at the Ecole Polytechnique, the Museum of Natural History, and the National Conservatory of Arts and Crafts, and became chief engineer in the department of bridges and highways.

Becquerel is remembered as the discoverer of radioactivity in 1896. Following Wilhelm RÖNTGEN's discovery of x-rays the previous year, Becquerel began to look for x-rays in the fluorescence observed when certain salts absorb ultraviolet radiation. His method was to take crystals of potassium uranyl sulfate and place them in sunlight next to a piece of photographic film wrapped in black paper. The reasoning was that the sunlight induced fluorescence in the crystals and any x-rays present would penetrate the black paper and darken the film.

The experiments appeared to work and his first conclusion was that x-rays were present in the fluorescence. The true explanation of the darkened plate was discovered by chance. He left a plate in black paper next to some crystals in a drawer and some time later developed the plate. He found that this too was fogged, even though the crystals were not fluorescing. Becquerel investigated further and discovered that the salt gave off a penetrating radiation independently, without ultraviolet radiation. He deduced that the radiation came from the uranium in the salt.

Becquerel went on to study the properties of this radiation; in 1899 he showed that part of it could be deflected by a magnetic field and thus consisted of charged particles. In 1903 he shared the Nobel Prize for physics with Pierre and Marie CURIE.

**Beddoes, Thomas** (1760–1808) *British chemist and physician*

Beddoes, who was born in Shifnal, England, studied classics at Oxford and medicine and chemistry at Edinburgh, where he was the pupil of Joseph BLACK. After obtaining his MD in 1787 he returned to Oxford as reader in chemistry.

When, in 1792, Beddoes lost his Oxford post because of his sympathy for the French Revolution, he approached the Lunar Society of Birmingham, which included Josiah Wedgwood, Joseph PRIESTLEY, Matthew BOULTON, and James WATT, with the idea of forming an institute to investigate the medicinal uses of the gases discovered in the previous 20 years. As a result one of the first specialized research institutes, the Pneumatic Medical Institute, was opened at Clifton, Bristol, in 1799 with Humphry DAVY, then 19 years old, as Beddoes's assistant. The work proved disappointing except in the case of dinitrogen oxide (nitrous oxide, N<sub>2</sub>O), the euphoriant properties of which provided Davy with his first serious chemical paper.

Beddoes's work on gases was published as *Considerations on the Medicinal Use of Factitious Airs* (1794–96). Beddoes later moved to London where he built up a successful medical practice.

**Bednorz, Johannes Georg** (1950– )  
*German physicist*

Bednorz (**bed-norts**) was educated at the Federal Institute of Technology, Zurich, where he gained his PhD in 1982. He immediately joined the staff of the IBM Research Center in Zurich, where he now leads the high-temperature superconductivity research group.

Here he was invited by his senior colleague, Alex MULLER, to collaborate in a search for superconductors with higher critical temperatures. Little progress had been made in this area for a decade and, as a young unknown scientist, Bednorz's decision to work in such an unpromising field appeared to many to be somewhat rash. Success, however, came relatively quickly and in 1986 Bednorz and Muller found a mixed lanthanum, barium, and copper oxide that had a critical temperature of 35 K (–238°C), which was significantly higher than that of any other superconductor known at the time. Their work was quickly recognized and in 1987 Muller and Bednorz were awarded the Nobel Prize for physics.

**Beebe, Charles William** (1887–1962)  
*American naturalist*

Beebe (**bee-bee**) was born in New York City and graduated from Columbia University in 1898. The following year, he began organizing and building up the bird collection of the New

York Zoological Park. After serving as a fighter pilot in World War I he became, in 1919, director of the Department of Tropical Research of the New York Zoological Society.

Beebe is noted as one of the pioneers of deep-sea exploration. His first observation capsule was a cylinder; later collaboration with the geologist and engineer Otis Barton resulted in the design of a spherical capsule (the bathysphere). Various dives were made and in August 1934 Beebe and Barton were lowered to a (then) record depth of 3,028 feet (923 m) near Bermuda. Beebe made many interesting observations, such as the absence of light at 2,000 feet (610 m), phosphorescent organisms, and an apparently unknown animal estimated to be some 20 feet (6.1 m) long. He abandoned deep-sea exploration after making thirty dives. Descents to even greater depths were subsequently made by Auguste PICCARD and others.

**Beer, Wilhelm** (1797–1850) *German astronomer*

Beer (bayr) was born in Berlin, where he spent his whole adult life working as a banker. Like his friend Johann Heinrich von Mädler, Beer was a very competent amateur observer of Mars and the Moon. In 1830 they published the first reasonable map of Mars. It did not show the canals that Giovanni SCHIAPARELLI and others were later to “observe.” In 1836 they published a large map of the Moon that was the most comprehensive of its time. Beer also measured the heights of the larger lunar mountains.

**Béguyer de Chancourtois, Alexandre Emile** (1820–1886) *French mineralogist*

The Parisian Béguyer de Chancourtois (bay-gee-ay de shahng-kor-twah), who was inspector-general of mines in France, is remembered for his work on the classification of the elements. In 1862 he proposed his system, known as the “telluric screw,” in which the elements were arranged in order of atomic weight and then plotted on a line descending at an angle of 45° from the top of a cylinder. It was found that elements on the same vertical line resembled each other.

The proposal received little attention, largely because it was published without the explanatory diagram, which made the article virtually impossible to understand. As with John NEWLANDS’s system of classifying the elements, Béguyer de Chancourtois’s proposal was overshadowed by that of Dmitri MENDELEEV, first published in 1869.

**Behring, Emil Adolf von** (1854–1917) *German immunologist*

For hundreds of thousands of years, the wisest physicians and scientists have studied the properties of blood and its relation to health

and illness, without ever suspecting the specific antibodies appearing in the blood as a result of an infectious disease, which are capable of rendering infectious toxins harmless.

—Describing his work on immunization

Behring (**bay**-ring) was born in Hansdorf in Germany. He graduated in medicine at Berlin University and entered the Army Medical Corps before becoming (in 1888) a lecturer in the Army Medical College, Berlin. In 1889 he moved to Robert KOCH’s Institute of Hygiene and transferred to the Institute of Infectious Diseases in 1891, when Koch was appointed its chief.

In 1890, working with Shibasaburo KITASATO, Behring showed that injections of blood serum from an animal suffering from tetanus could confer immunity to the disease in other animals. Behring found that the same was true for diphtheria and this led to the development of a diphtheria antitoxin for human patients, in collaboration with Paul EHRLICH. This treatment was first used in 1891 and subsequently caused a dramatic fall in mortality due to diphtheria.

Behring’s success brought him many prizes, including the first Nobel Prize in physiology or medicine, awarded in 1901. He was appointed professor of hygiene at Halle University in 1894 and one year later moved to a similar post at Marburg. In 1913 he introduced toxin–antitoxin mixtures to immunize against diphtheria, a refinement of the immunization technique already in use. He also devised a vaccine for the immunization of calves against tuberculosis.

**Beilby, Sir George Thomas** (1850–1924) *British industrial chemist*

Beilby (**beel**-bee), the son of a clergyman, was born in the Scottish capital of Edinburgh and educated at the university there. He began work with an oil-shale company as a chemist in 1869 and increased the yield of paraffin and ammonia from oil shales by improving the process of their distillation. He also worked on cyanides, patenting, in 1890, a process for the synthesis of potassium cyanide in which ammonia was passed over a heated mixture of charcoal and potassium carbonate. This had wide use in the gold-extracting industry.

From 1907 to 1923 Beilby was chairman of the Royal Technical College, Glasgow, later the University of Strathclyde. He became interested in the economic use of fuel and smoke prevention, submitting evidence to the Royal Commission on Coal Supplies in 1902. In 1917 he was appointed as the first chairman of the Fuel Research Board. He was knighted in 1916.

**Beilstein, Friedrich Konrad** (1838–1906) *Russian organic chemist*

Born to German parents in the Russian city of

St. Petersburg, Beilstein (**bil**-shtIn) studied chemistry in Germany under BUNSEN, LIEBIG, and WURTZ and gained his PhD under WÖHLER at Göttingen (1858). He was lecturer at Göttingen (1860–66) and from 1866 professor of chemistry at the Technological Institute at St. Petersburg.

Beilstein's many researches in organic chemistry included work on isomeric benzene derivatives. He is better remembered, however, for his monumental *Handbuch der organischen Chemie* (1880–82; Handbook of Organic Chemistry), in which he set out to record systematically all that was known of every organic compound. He produced the second (1886) and third (1900) editions, after which the work was assigned to the Deutsch Chemische Gesellschaft, who have published it ever since.

### **Békésy, Georg von** (1899–1972) *Hungarian-American physicist*

Békésy (**bay**-ke-shee), the son of a diplomat in the Hungarian capital, Budapest, studied chemistry at the University of Bern and physics at Budapest University, where he obtained his PhD in 1923. He immediately joined the research staff of the Hungarian Telephone Laboratory where he remained until 1946 while simultaneously holding the chair of experimental physics at Budapest University from 1939. He left Hungary in 1947, via the Swedish Karolinska Institute, for America, where he served first as a senior fellow in psychophysics at Harvard from 1949 to 1966 and finally as professor of sensory science at the University of Hawaii from 1966 until his death.

Békésy first worked on problems of long-distance telephone communication before moving to the study of the physical mechanisms of the cochlea within the inner ear. When he began this study it was generally thought, following the work of Hermann von HELMHOLTZ, that sound waves entering the ear selectively stimulated a particular fiber of the basilar membrane; this in turn stimulated hairs of the organ of Corti resting on it, which transferred the signal to the auditory nerve.

Using the techniques of microsurgery, Békésy was able to show that a different mechanism is involved. He found that when sound enters the cochlea, a traveling wave sweeps along the basilar membrane. The wave amplitude increases to a maximum, falling sharply thereafter; it is this maximum point to which the organ of Corti is sensitive. For this insight into the mechanism of hearing, Békésy was awarded the 1961 Nobel Prize for physiology or medicine.

### **Bell, Alexander Graham** (1847–1922) *British inventor*

Mr Watson come here; I want you.

—Speaking to his assistant Thomas Watson in

the world's first telephone conversation, 10 March 1876

Bell's family were practitioners in elocution and speech correction and he himself trained in this. Born in Edinburgh, as a child he was taught mainly at home. For a short time he attended Edinburgh University and University College, London, after which he taught music and elocution at a school in Elgin, Scotland. It was in Elgin that he carried out his first studies on sound.

From 1868 Bell worked in London as his father's assistant, but after the death of his two brothers from tuberculosis, the family moved to Canada, where Alexander, who had also become ill, recovered. In 1871 he went to Boston where he gave lectures on his father's method of "visible speech" – a system of phonetic symbols for teaching the deaf to speak. A year later he opened a school for teachers of the deaf. In 1873 he became professor of vocal physiology at Boston University.

With financial help from two of his deaf students, Bell experimented with the transmission of sound by electricity, aided by Thomas Watson, his technician. His multiple telegraph was patented in 1875 and, in 1876, the patent for the telephone was also granted. Bell's wife Mabel Hubbard, whom he married in 1877, was deaf. Later she founded the Aerial Experiment Association.

In 1880 he received the Volta Prize from France and the money was used to fund the laboratories in which an improved form of the gramophone was invented by Thomas EDISON. Although best known as the inventor of the telephone, Bell investigated a wide range of related technical subjects, including sonar and various equipment for the deaf. In 1885 he bought land and established laboratories and a summer home on Cape Breton Island.

### **Bell, Sir Charles** (1774–1842) *British physician*

Bell, who was born in Edinburgh, Scotland, studied under his elder brother John, a surgeon, and attended lectures at Edinburgh University. In 1804, Charles moved to London, where he started his own surgical practice and began his investigations into the nervous system. In *A New Idea of the Anatomy of the Brain* (1811), Bell described how nerves are not single structures but bundles of many nerve fibers. He also showed that the anterior and posterior roots of each spinal nerve carry different types of nerve fibers, which he later clarified as being respectively excitatory (motor) and sensory in function. The French physiologist, François MAGENDIE, is also credited with this discovery and the functional differentiation of the spinal nerve roots is sometimes called the *Bell-Magendie law*. In *The Nervous System of the Human Body* (1830), Bell amplified his find-

ings, establishing that a nerve fiber can carry impulses in one direction only and that each muscle must be supplied with both excitatory and sensory fibers.

Bell also contributed to knowledge of facial paralysis and to other surgical fields besides lecturing at the Great Windmill Street School of Anatomy and the Middlesex Hospital. In addition, he wrote *Essays on the Anatomy of Expression in Painting* (1806). He received the first medal awarded by the Royal Society in 1829 and was knighted two years later.

### **Bell, John Stuart** (1928–1990) *British physicist*

I think that when we have solved the problem of the interface between the classical and the quantum-mechanical worlds, there will be something different in the theory.

—Quoted by J. Bernstein in *Quantum Profiles*

Born into a poor family in the Northern Irish capital of Belfast, Bell was encouraged by his mother to continue his education after leaving school at sixteen. Consequently, after working for a year as a laboratory assistant in the physics department of Queen's University, Belfast, he enrolled as a student and graduated in 1949. Rather than pursue a PhD and burden his family further, Bell began work immediately at the Atomic Energy Research Establishment at Harwell. He worked initially on the design of the first accelerator at CERN (Conseil Européen pour la Recherche Nucléaire; European Organization for Nuclear Research), the Proton Synchrotron. He was also given a year's leave of absence to work on a doctorate at Birmingham University. On his return to Harwell he turned to the theoretical study of elementary particles. Bell moved to CERN in Geneva in 1960 where he remained for the rest of his life. He was accompanied by his wife, Mary Bell, also a physicist, who worked at CERN on accelerator design.

In 1964 Bell published what for many has become the single most important theoretical paper in physics to appear since 1945; it was entitled *On the Einstein Podolsky Rosen Paradox*. The title referred to a thought experiment proposed by Einstein and others in 1935 sharply challenging the basis of quantum theory. He proposed a principle of reality stating that: "If, without in any way disturbing a system we can predict with certainty ... the value of a physical quantity then there exists an element of physical reality corresponding to this physical quantity." For example, electrons have a spin that can take one of two values, conveniently classed as positive or negative. Spin, like angular momentum, is conserved. Consequently, if a particle with zero spin decays into an electron/positron ( $e^-/p^+$ ) pair, the two particles must have equal and opposite spins. Knowing, for example, that the

electron has a negative spin, it can be inferred that the positron must have a positive spin.

But this, according to Einstein, gives us a way to measure the spin of a particle without disturbance. If the  $p^+$  spin is measured and found to be positive, the measurement may well disturb the  $p^+$ , but on this basis the spin of the  $e^-$  can be concluded to be negative without in any way disturbing the  $e^-$ . It follows from Einstein's reality principle that the negative spin of  $e^-$  is a real property of the electron. This view, however, conflicts with the usual interpretation of quantum mechanics, which sees the spin of the electron as a superposition of both spin states, a condition only resolved when the electron is observed and the wave function collapses. Nor can it be said that the state of the electron is in any way influenced by the outcome of the observation of the positron's spin for, as no signal can travel faster than the speed of light, instantaneous communication between separated particles is impossible.

The theoretical physicist is therefore presented with an uncomfortable choice. He or she can accept that electrons have intrinsic spin, in accordance with the reality principle and against quantum mechanics, or adopt what Einstein scornfully termed a "spooky action at distance." One weekend in 1964 Bell saw a way in which the matter could be resolved.

The spin of a particle is complicated in that it can be independently measured along three coordinates  $x$ ,  $y$ , and  $z$  at right angles to each other. Further, a measurement of the electron's spin in the  $x$  direction will influence the spin of the positron in the  $x$  direction also; it will, however, have no effect on measurements along the  $y$  and  $z$  directions. Similar rules apply to measurements along the  $y$  and  $z$  axes. Bell argued that, if the reality principle is correct, then one would expect to find for a large number of observations:

$$x^+y^+ < (x^+z^+ + y^+z^+)$$

That is, the number of particles with a positive spin along the  $x$  and  $y$  axes is smaller than the number found on both the  $x^+z^+$  and  $y^+z^+$  axes. The result is known variously as *Bell's inequality* and *Bell's theorem*. Although it proved impossible to test Bell's inequality in terms of the reactions described in the 1964 paper, later workers have produced equivalent formulations that are testable. The most convincing of these, the *Aspect experiment* performed by Alain Aspect of the Institute of Optics at the University of Paris in 1982, using correlations between polarized photons, established that the inequality did not hold. The conclusion seemed to be that nature preferred to act "spookily" at a distance rather than using Einstein's reality principle.

At first Bell's five-page paper was ignored. Only when experimentalists such as John Clauser at Berkeley in 1969 took his work up did Bell's argument become widely known.

Bell's views on his own work, more tentative and less extreme than those of many of his followers and popularizers, were collected in his *Speakable and Unspeakeable in Quantum Mechanics* (1987).

**Bell Burnell, Dame Susan Jocelyn** (1943– ) *British astronomer*

A bit of scruff.

—Referring to the pen-recorder trace of the first recorded pulsar

Born in Belfast, Northern Ireland, the daughter of the architect who designed the Armagh planetarium, Jocelyn Bell developed an early interest in radioastronomy. She was advised by Bernard LOVELL to study physics first and consequently found herself the only woman in a class of 50 physics students at Glasgow University. After graduating from Glasgow she moved to Cambridge, where she completed her PhD in 1969.

As part of her duties she visited the Mullard Radio Astronomy Laboratory each day, filled the inkwells and monitored the 100-foot length of paper chart produced daily by the 4.5-acre telescope. The sky was scanned every four days and, with little computer power available at that time, the data had to be analyzed by hand. One day she identified a strange signal. As it meant nothing to her, Bell simply put a question mark next to it. When she noticed it again she drew it to the attention of her supervisor, Antony HEWISH. But nothing more was seen for a month. Perhaps, Hewish suggested, it had been a one-time event, a flare that had been and gone.

But after a month it reappeared. On examination Bell found the signals were equally spaced out at intervals of about 1.3 seconds. It was soon established that the signal was genuine and not an instrumental malfunction; nor was it produced by satellites or any terrestrial interference. The source was shown to lie outside the solar system and to have a sidereal motion. A more detailed examination of the signals revealed a regular sequence of pulses at intervals of 1.33730113 seconds with an accuracy better than one part per hundred million. Bell discovered a second signal coming from a different part of the sky in December, and a third and fourth the following month.

Once it had been decided that no LGMs, or "Little Green Men," were involved in the signals, Hewish made the discovery public in 1968. The name "pulsar" was soon coined and soon after Thomas GOLD proposed that the signals were emitted by a small, rapidly rotating neutron star. In an earlier age the first pulsar would have been known as *Bell's Star*; today it carries number CP 1919. Bell's work helped Hewish to gain the 1974 Nobel Prize for physics.

Bell herself married and became Bell Burnell

and was appointed in 1968 to a research fellowship at the University of Southampton, where she worked on gamma rays. In 1973 she moved to the Mullard Space Science Laboratory in London to work on x-ray astronomy. Bell moved again in 1982 to head the James Clerk Maxwell Telescope project at the Royal Observatory, Edinburgh. In 1991 she was appointed professor of physics at the Open University, Milton Keynes, a position she held for ten years. In 2001 she became Dean of Science at the University of Bath, retiring in 2004. At present she is Visiting Professor of Astrophysics at Oxford University. She became a Dame in 2001.

**Belon, Pierre** (1517–1564) *French naturalist*

Belon (be-lon) was born in Le Mans, France, and studied medicine in Paris. In 1540 he went to Germany to study botany, becoming a leading figure in the 16th-century revival of natural history that followed the great voyages, the invention of printing, and the new artistic realism of the Renaissance.

Between 1546 and 1549 Belon traveled in the eastern Mediterranean countries, comparing the animals and plants he observed with their descriptions by classical authors. The results were published as *Les Observations des plusieus singularitez et choses mémorables trouvées en Grèce, Asie, Judée, Egypte, Arabie et autre pays étranges* (1553; *Observations of Many Singularities and Memorable Items in Greece, Asia, Judea, Egypt, Arabia, and Other Foreign Countries*). On his travels, Belon was in the habit of investigating the birds and fishes that came to market, and in England he met the Venetian Daniel Barbaro, who had made many drawings of Adriatic fishes. From these sources Belon produced two books on fishes: *L'Histoire naturelle des étranges poissons marins* (1551; *The Natural History of Foreign Sea Fish*) and *De aquatilibus* (1553; *On Water Creatures*). The first is notable for its dissertation on the dolphin, in which he identified the common Atlantic species with the dolphin of the ancients and distinguished it from the porpoise.

Belon's principal achievement is a history of birds, *L'Histoire de la nature des oyseaux* (1555; *The Natural History of Birds*). An illustrated book of the kind inspired by the drawings of Albrecht Dürer and Leonardo da Vinci, it describes about 200 birds, mostly of European origin. He drew attention to the correspondence between the skeletons of birds and man, an early hint of the discipline of comparative anatomy.

Belon was also interested in geology and botany and is reputed to have introduced the cedar of Lebanon into western Europe. He also established two botanical gardens in France and suggested that many exotic plants might be

acclimatized and grown in temperate regions. In many ways a typical figure of the Renaissance, Belon's end was all too typical of that time, for he was murdered in the Bois de Boulogne in 1564.

**Belousov, Vladimir Vladimirovich** (1907–1990) *Russian geologist and geophysicist*

Belousov (byel-oo-sof), a Muscovite by birth, became head of the department of geodynamics at the Soviet Academy of Sciences, Moscow, in 1942 and was later (1953) made professor of geophysics at Moscow University. His main work concentrated on the structure and development of the Earth's crust. In 1942 he put forward his theory on Earth movements, in which he proposed that the Earth's material has gradually separated according to its density and this is responsible for movements in the crust. He at first rejected theories on continental drift.

Belousov became chairman of the Soviet Joint Geophysical Committee in 1961. His works include *Principles of Geotectonics* (1975).

**Benacerraf, Baruj** (1920– ) *American immunologist*

Benacerraf (bay-nah-se-raf), who was born in the Venezuelan capital of Caracas, was brought up in France but moved to America in 1940, becoming naturalized in 1943. He studied at Columbia and the University of Virginia where he obtained his MD in 1945. He worked first at the Columbia Medical School before spending the period 1950–56 at the Hospital Broussais in Paris. He returned to America in 1956 to the New York Medical School where he served from 1960 to 1968 as professor of pathology. After a short period at the National Institute of Allergy and Infectious Diseases at Bethesda, Maryland, Benacerraf accepted the chair of comparative pathology at Harvard in 1970. From 1980 until 1992 he was president of the Dana-Farber Cancer Institute, Boston.

In the 1960s, working with guinea pigs, Benacerraf began to reveal some of the complex activity of the H-2 system, described by George SNELL. In particular he identified the Ir (immune response) genes of the H-2 segment as playing a crucial role in the immune system. This was achieved by injecting simple, synthetic, and controllable "antigens" into his experimental animals and noting that some strains responded immunologically while others were quite tolerant. Such differential responses have so far indicated there are over 30 Ir genes in the H-2 complex.

Later work began to show how virtually all responses of the immune system, whether to grafts, tumor cells, bacteria, or viruses, are under the control of the H-2 region. Benacerraf and his colleagues continued to explore its ge-

netic and immunologic properties and also to extend their work to the analogous HLA system in humans. This work may well be important in the study of certain diseases, such as multiple sclerosis and ankylosing spondylitis, which have been shown to entail defective immune responses.

In 1980 Benacerraf was awarded for this work, together with George Snell and Jean DAUSSET, the Nobel Prize for physiology or medicine.

**Beneden, Edouard van** (1846–1910) *Belgian cytologist and embryologist*

Beneden (be-nay-den) was born in Louvain, Belgium, the son of the zoologist Pierre-Joseph van Beneden. Edouard followed his father's footsteps, taking charge of zoology teaching at Liège University in 1870. Here he extended Walther FLEMMING's work on cell division. Working with the horse intestinal worm, *Ascaris megalcephala*, Beneden had demonstrated by 1887 that the chromosome number in all the body cells is constant, but that this number is halved in the germ cells. This halving is achieved because the two successive divisions preceding ova and spermatozoa formation are accompanied by only one chromosome doubling. Such a reduction division (meiosis) is necessary to prevent chromosome numbers from doubling on fertilization.

Beneden also made important contributions to embryology from his studies on the cleavage and gastrulation of the fertilized egg.

**Bennet, Abraham** (1750–1799) *British physicist*

Bennet's scientific work was in electrostatics, the study of stationary electric charges and their effects, and he contributed many experiments and observations to the early development of this field. He was the inventor of the gold-leaf electrometer (an instrument for detecting and measuring electric charges) and did various experiments on electrostatic induction (the effect by which one body induces a charge on a nearby uncharged body). He also tried, though unsuccessfully, to demonstrate that light has momentum by focusing light rays on a sheet of paper hanging free in a vacuum.

**Bentham, George** (1800–1884) *British botanist*

Bentham, son of the naval architect Samuel Bentham, was born in the southwestern English county of Devon; he first became interested in botany at the age of 17, while living in France with his parents. There he read Augustin Pyrame de CANDOLLE's revision of J. B. LAMARCK's *Flore Française* (French Flora) and was much impressed with its analytical keys for plant identification. Thus began his consum-

ing interest in plant taxonomy, on which he consistently worked during his leisure time.

From 1826 to 1832 he was secretary to his uncle, the famous jurist and philosopher, Jeremy Bentham, and studied for the bar at Lincoln's Inn. However, in 1833 he abandoned law for his growing botanical collection and library, which he generously presented to the Royal Botanic Gardens, Kew, in 1854. He then worked at Kew for the rest of his life.

His first botanical work, *Catalogue des plantes indigènes des Pyrénées et du bas Languedoc* (Catalog of the Indigenous Plants of the Pyrenees and Lower Languedoc), was published in Paris in November 1826. On his return to England he published *Outlines of a New System of Logic* (1827). Then in the early 1830s, Bentham turned his attention more to botany and his first important work in this field, *Labiatum Genera et Species* (Genera and Species of the Labiatae), appeared between 1832 and 1836. While at Kew he published his popular *Handbook of the British Flora* (1858) and contributed to the Kew series of colonial floras with his *Flora Hongkongensis* (1861; Flora of Hong Kong) and the seven-volume *Flora Australiensis* (1863–78; Flora of Australia). In collaboration with Joseph HOOKER he produced his greatest work, the *Genera Plantarum* (1862–83; Plant Genera), which remains a standard in plant classification.

**Benz, Karl Friedrich** (1844–1929) *German engineer*

Benz was born in the city of Karlsruhe in southwest Germany, where his father was a railway engineer. After training in mechanical engineering (1853–64), he opened his own machine-tools works in Mannheim and in 1877 began experimenting with a two-cycle engine. In 1885 he ran his first Benz car, a three-wheeled vehicle now preserved in Munich, which was the first practical automobile powered by an internal-combustion engine. The vehicle was not patented until January 1886. The company founded by Benz to manufacture the vehicle, Benz & Cie., produced its first four-wheeled automobile in 1893 and its first series of racing cars in 1899. Benz left the company in about 1906; it later merged to form Daimler-Benz (1926), the makers of Mercedes-Benz automobiles.

**Benzer, Seymour** (1921–2007) *American geneticist*

Benzer was born in New York City, graduated from Brooklyn College in 1942, and gained his PhD in physics from Purdue University in 1947. He spent the years 1948–52 at various research institutes to familiarize himself with biological techniques, returning to Purdue as assistant professor in biophysics.

Benzer hoped to disprove the theory that the gene is an indivisible unit by demonstrating that recombination can occur within genes. However, such recombinations would be expected to occur so rarely that huge numbers of organisms would need to be studied to find one. In 1954 Benzer found a suitable organism to work on – the virus T4, a bacteriophage that infects the bacterium *Escherichia coli*. It multiplies approximately 100 fold in 20 minutes, giving millions of phage in a relatively short period.

Benzer found various mutants of T4, termed rII mutants, that had lost the ability to multiply on a specific strain of *E. coli*. He mixed together mutants that had mutated in different parts of the same gene and placed the mixture on a dish of *E. coli*. Any recombination within the gene that restored its function (and thus its ability to multiply in and destroy the bacteria) could be easily identified as clear areas in the *E. coli* dish. Such areas were indeed found, which proved that the gene can be split into recombining elements and verified James WATSON's and Francis CRICK's model of the gene as consisting of many nucleotide pairs.

Benzer went on to show that the number of distinguishable mutation sites corresponds with the estimated number of nucleotide pairs for that gene and that the sites are arranged linearly. He identified functionally independent units within the gene, naming these "cistrons."

Benzer also did important work on chemical mutagens and on the degeneracy of the genetic code. More recently he concentrated on the genetic control of behavior and the application of molecular biology to brain function. He moved from Purdue University to the California Institute of Technology in 1965, becoming professor of biology in 1967 and Boswell Professor of Neuroscience in 1975.

**Berg, Paul** (1926– ) *American molecular biologist*

Berg was born in New York City and educated at Pennsylvania State University and Case Western Reserve University, where he obtained his PhD in 1952. He taught first at the School of Medicine at Washington University, St. Louis, moving to Stanford University in California in 1959, where he was professor of biochemistry from 1959 to 1970 and Willson Professor of Biochemistry from 1970. From 1985 until 2000 he was director of the Center for Molecular and Genetic Medicine. Berg is professor emeritus at Stanford. He ceased his research work in 2000.

In 1955 Francis CRICK proposed his adaptor hypothesis, in which he argued that amino acids did not interact directly with the RNA template but were brought together by an adaptor molecule. Crick offered little informa-

tion on the nature of such molecules, merely arguing that they were unlikely to be large protein molecules and suggesting that there might well be a specific adaptor for each of the 20 amino acids. In 1956 Berg successfully identified such an adaptor, later known as transfer RNA, even though he was then unaware of Crick's hypothesis. He found a small RNA molecule that appeared to be quite specific to the amino acid methionine.

Berg's name later became known to a much wider public with the publication in *Science* (24 July 1974) of the "Berg letter," written with the backing of many leading molecular biologists, in which he gave clear warning of the dangers inherent in the uncontrolled practice of recombinant DNA experiments. It had become possible, Berg stated, to excise portions of DNA from one organism, using specialized enzymes, and to insert them into the DNA of another organism. For example, the harmless microorganism *Escherichia coli*, found in all laboratories, could be implanted with active DNA from the tumor-causing virus SV 40 and perhaps allowed to spread throughout a human population with quite unpredictable results. Berg consequently proposed an absolute voluntary moratorium on certain types of experiments and strict control on a large number of others. An international conference was held in Asilomar, California, followed by the publication of strict guidelines by the National Institutes of Health in 1976. That such agreement could be reached and maintained, it has been claimed, was largely a result of the integrity and authority of Berg. Ironically Berg was awarded the Nobel Prize for chemistry in 1980 for the large part he played in developing the splicing techniques that made recombinant DNA techniques possible in the first place.

**Berger, Hans** (1873–1941) *German psychiatrist*

Berger (**bair-ger**) was born in Neuses, Germany, and studied medicine at the University of Jena; having joined the university psychiatric clinic in 1897 as an assistant, he eventually served as its director and professor of psychiatry (1919–38). In his early work, he attempted to correlate physical factors in the brain, such as blood flow and temperature, with brain function. Disappointing results in this area made Berger turn to investigating the electrical activity of the brain. In 1924 he made the first human electroencephalogram by recording, as a trace, the minute changes in electrical potential measured between two electrodes placed on the surface of the head. Berger subsequently characterized the resultant wave patterns, including alpha and beta waves, and published his findings in 1929. The technique of electroencephalography is now used to diagnose such diseases as brain tumors and

epilepsy. It is also used in psychiatric research and in diagnosing brain death.

**Bergeron, Tor Harold Percival** (1891–1977) *Swedish meteorologist*

Bergeron (**bair-ger-on**), who was born in Stockholm, studied at the universities of Stockholm and Leipzig. During the period 1925–28 he worked at the famous Geophysical Institute at Bergen before taking a teaching appointment at Oslo University (1929–35). He held various appointments in the Swedish Meteorological Institute and was elected to the chair of meteorology at Uppsala in 1947.

Bergeron is best known for his work on cloud formation and in 1935 published the fundamental paper *On the Physics of Clouds and Precipitation*. Clouds consist of minute drops of water, but these drops will only fall as rain when they coalesce to form sufficiently large drops. Bergeron considered various processes, such as electric attraction and collisions caused by turbulence, but dismissed these as being too slow and inefficient. He therefore proposed a mechanism in which both ice crystals and water droplets are present in clouds. The water droplets tend to evaporate and the vapor then condenses onto the crystals. These fall, melt, and produce rain. Thus all rain, according to Bergeron, begins as snow and without the presence of ice crystals in the upper reaches of clouds there can be no rain. This theory was supported by the experimental and observational work of Walter Findeisen in 1939 and became known as the *Bergeron-Findeisen theory*. It does not explain precipitation from tropical clouds where temperatures are above freezing point.

Bergeron also produced important work on weather fronts, methods of weather forecasting, and the growth of ice sheets.

**Bergius, Friedrich Karl Rudolph** (1884–1949) *German industrial chemist*

The son of a chemicals industrialist, Bergius (**bair-gee-uus**), who was born in Goldschmieden, Poland, obtained his doctorate at Leipzig (1907) and worked with Hermann NERNST at Berlin and Fritz HABER at Karlsruhe, where he became interested in high-pressure chemical reactions. He was a professor at the Technical University at Hannover (1909–14) and then worked for the Goldschmidt Organization until 1945.

He is noted for his development of the *Bergius process* – a method of treating coal or heavy oil with hydrogen in the presence of catalysts, so as to produce lower-molecular-weight hydrocarbons. The process was important as a German source of gasoline in World War II. After the war Bergius lived in Austria and Spain before settling in Argentina as a techni-

cal adviser to the government, working on the production of sugar, alcohol, and cattle feed from wood. He shared the Nobel Prize for chemistry with Carl BOSCH in 1931.

**Bergman, Torbern Olaf** (1735–1785)  
*Swedish chemist*

Bergman (**baig**-man), who was born in Katrineberg, Sweden, studied at the University of Uppsala, at first reading law and theology before turning to science and mathematics. He was a prolific scientist, working in physics, mathematics, and physical geography as well as chemistry. After graduating with a master's degree in 1758, he became professor of mathematics at Uppsala in 1761 and later professor of chemistry and pharmacy in 1767.

Bergman carried out many quantitative analyses, especially of minerals, and he extended the chemical classification of minerals devised by Axel CRONSTEDT. He remained an adherent of the phlogiston theory and although he firmly supported the doctrine of constant composition his analyses were not as solidly based as those of his later compatriot Jöns BERZELIUS. His most influential work was probably *Disquisitio de Attractionibus Electivis* (1785; A Dissertation on Elective Attractions). He compiled extensive tables listing relative chemical affinities of acids and bases. Bergman gave early encouragement to Karl SCHEELE, some of whose work he published.

**Bergmann, Max** (1886–1944) *German organic chemist and biochemist*

Bergmann (**baig**-mahn), who was born in Fuerth in Germany, studied in Munich and Berlin and gained his PhD under Emil FISCHER in 1911. He worked as Fischer's assistant in Berlin until the latter's death in 1919. From 1921 to 1934 he was director of the Kaiser Wilhelm Institute for Leather Research, Dresden, from which he resigned on Hitler's coming to power. He then emigrated to America where he worked as a member of the Rockefeller Institute for Medical Research.

Bergmann's research interests were those of his teacher, Fischer: carbohydrates and amino acids. In 1932 he discovered the carbobenzoxy method of peptide synthesis, the greatest advance in this field since Fischer's first peptide synthesis in 1901. In this method the amino group of amino acids is "protected" by the carbobenzoxy group during condensation to form the peptide linkage and later freed by hydrolysis. Following Bergmann's work, many other protective groups have been used in peptide syntheses.

In America Bergmann investigated the specificity of proteinase enzymes and discovered (1937) that enzymes like papain were capable of splitting quite small peptides at precise link-

ages. The last three years of his life were devoted mainly to problems connected with the war.

**Bergström, Sune** (1916–2004) *Swedish biochemist*

Bergström (**baig**-stru(r)m) was born in Stockholm and educated at the Karolinska Institute there, where he obtained his MD in 1943. In 1947 he was appointed to the chair of biochemistry at Lund. In 1958 he moved to a comparable position at the Karolinska Institute, which he left in 1981.

In the 1930s Ulf VON EULER found an active substance in human semen capable of lowering blood pressure and causing muscle tissue to contract. He named it *prostaglandin* on the assumption that it came from the prostate gland. It soon became clear that there was not one such substance but a good many closely related ones with a variety of important physiological roles, but as they were produced in small quantities and rapidly broken down by enzymatic action, they proved to be very difficult to isolate and analyze. From 100 kilograms of rams' seminal vesicles, Bergström was able to extract a minute dose. To his surprise, however, he found the prostaglandin "extraordinarily active in virtually nonexistent doses."

In the 1950s Bergström succeeded in extracting the prostaglandins referred to as PGD<sub>2</sub>, PGE<sub>2</sub>, and PGF<sub>2</sub>. He went on to demonstrate that they were derived from arachidonic acid (C<sub>20</sub>H<sub>36</sub>O<sub>2</sub>), a fatty acid present in the adrenal gland, liver, and brain. Bergström's discovery opened up the study of prostaglandins by allowing them to be produced in the laboratory. For his pioneering work in this field he shared the 1982 Nobel Prize for physiology or medicine with John VANE and Bengt SAMUELSSON.

**Beringer, Johann Bartholomaeus Adam** (1667–1740) *German geologist*

Beringer (**bay**-ring-er) was a native of Würzburg, Germany, where his father was the dean of medicine at the university. He obtained his doctorate from Würzburg in 1693 and was appointed professor in 1694 – a position he held for the rest of his life.

He is largely remembered today for his extreme gullibility. Some colleagues, knowing him to be a keen fossil collector, decided to see if he could recognize artificial "fossils." They therefore prepared and scattered on the local hillside "fossils" of an increasingly unlikely nature. Nothing seemed to alert the suspicions of Beringer and indeed, the more bizarre the figure, the more excited he became. He published an account of them in 1726 with full illustrations despite warnings that he was dealing with fakes. Finally, the story goes although there is

no documentary evidence for this, he found a stone with his own name on it and spent the rest of his life trying to buy up copies of his book.

**Bernal, John Desmond** (1901–1971)  
*British crystallographer*

Life is a partial, continuous, progressive, multiform and conditionally interactive self-realization of the potentialities of atomic electron states.

—*The Origin of Life* (1967)

The full area of ignorance is not mapped: we are at present only exploring its fringes.

—Quoted by Sagittarius and George in *The Perpetual Pessimist*

Bernal's family were farmers in Nenagh, now in the Republic of Ireland; his mother was an American journalist. He was educated at Cambridge University, where his first work on crystallography was done as an undergraduate on the mathematical theory of crystal symmetry. William BRAGG offered him a post at the Royal Institution, which he joined in 1922.

Bernal was one of the most influential scientists of his generation. He had decided early in his career that x-ray crystallography would turn out to be the most likely tool to reveal details of the structure of matter. In addition to his intellectual mastery of the subject, he also possessed the ability to transmit his own enthusiasm to others and to attract around him a large number of highly talented and ambitious colleagues. To this group he was always known as "Sage."

His first success came in 1924 when he worked out the structure of graphite. He also began to work on bronze. In 1927 Bernal moved to Cambridge to a newly created lectureship in structural crystallography. While at Cambridge he worked on the structure of vitamin B<sub>1</sub> (1933), pepsin (1934), vitamin D<sub>2</sub> (1935), the sterols (1936), and the tobacco mosaic virus (1937).

Much of this research came not from Bernal alone; in most of his Cambridge studies he collaborated closely with Dorothy HODGKIN and many others came to work with Bernal, including Max PERUTZ, Francis CRICK, and Rosalind FRANKLIN.

In 1937 he was appointed professor of physics at Birkbeck College, London. With the outbreak of war in 1939 he joined the Ministry of Home Security and carried out with Solly ZUCKERMAN an important analysis of the effects of enemy bombing. Later in the war he served as scientific adviser to Lord Mountbatten, the Chief of Combined Operations. Bernal's main duties were connected with the planned Normandy landings. He spent much time establishing the physical condition of the beaches the Allies would land on in 1944. Maps, he soon discovered, were inaccurate. "Do you realize," he

would tell his staff, "no one knows where France is?" He was one of the first to land on the Normandy beaches on D-day.

Bernal's duties were performed despite the fact that he was one of Britain's best known communists, having joined the party in 1924. While many of his friends abandoned the party at some stage of their life, some because of the Stalinist purges, others because of the Molotov pact, and most of those remaining because of the Hungarian uprising, Bernal remained with the party throughout his life. He traveled frequently in Eastern Europe, Russia, and China, and he was probably the only significant Western scientist to give permanent support to the work of LYSENKO.

In 1963 Bernal suffered the first of several serious strokes. He became progressively less mobile and in the last two years of his life, unable to speak, he was confined to a wheelchair.

**Bernard, Claude** (1813–1878) *French physiologist*

Science allows no exceptions; without this there would be no determinism in science, or rather, there would be no science at all.

—*Leçons de la pathologie expérimentale* (1871; Lessons on Experimental Pathology)

Bernard (bair-**nar**), the son of a poor wine grower from St. Julien, began writing plays to earn money but turned to medicine on the advice of a literary critic. His first experiences of medicine were discouraging but, following his appointment as assistant to François MAGENDIE at the Collège de France, he began a period of extremely productive research. He drew attention to the importance of the pancreas in producing secretions for breaking down fat molecules into fatty acid and glycerine and showed that the main processes of digestion occur in the small intestine and not, as was previously thought, in the stomach. In 1856 he discovered glycogen, the starchlike substance in the liver, whose role is to build up a reserve of carbohydrate, which can be broken down to sugars as required; normally the sugar content of the blood remains steady as a result of this interaction. The digestive system, he found, is not just catabolic (breaking down complex molecules into simple ones), but anabolic, producing complex molecules (such as glycogen) from simple ones (such as sugars).

Bernard also did valuable work on the vasomotor system, demonstrating that certain nerves control the dilation and constriction of blood vessels; in hot weather blood vessels of the skin expand, releasing surplus heat, contracting during cold to conserve heat. The body is thus able to maintain a constant environment separate from outside influences. Apart from elucidating the role of the red blood corpuscles in transporting oxygen, Bernard's investigation of the action of carbon monoxide on

the blood proved that the gas combines with hemoglobin, the effect being to cause oxygen starvation. He also carried out important work on the actions of drugs, such as the opium alkaloids and curare (curarine), on the sympathetic nerves.

Bernard's health deteriorated from 1860 and he spent less time in the laboratory. He thus turned to the philosophy of science and in 1865 published the famous *Introduction à la médecine expérimentale* (An Introduction to the Study of Experimental Medicine). The book discusses the importance of the constancy of the internal environment, refutes the notion of the "vital force" to explain life, and emphasizes the need in planning experiments for a clear hypothesis to be stated, which may then be either proved or disproved. On the strength of this work he was elected to the French Academy in 1869.

**Berners-Lee, Sir Timothy John** (1955– ) *British computer scientist*

Berners-Lee was born in London and educated at Oxford University, graduating in 1976. When he was at Oxford, he built his first computer. After graduating, he worked for two years with Plessey Telecommunications and in 1978 he joined D. G. Nash, where he wrote software. During a spell of a year and a half that he spent as an independent consultant he was at CERN for six months as a consultant software engineer. Here he wrote a program called *Enquire*, which was never published, to store information. Between 1981 and 1984 he was at John Poole's Image Computer Systems Ltd., working on technical design.

In 1984 Berners-Lee started a fellowship at CERN, where he worked on systems for the acquisition of scientific data. In 1989 he built on his previous work on *Enquire* by proposing a system now known as the World Wide Web, which would enable people to combine information in a web of hypertext documents. This vision was realized with the release of the World Wide Web program, initially internally at CERN in 1990 and then on the Internet in 1991. Berners-Lee continued developing the Web between 1991 and 1993.

He joined the Laboratory for Computer Science at the Massachusetts Institute of Technology (MIT) in 1994 and was a founder of the World Wide Web Consortium, the organization that coordinates the development of the Web. In 2004 he was appointed to the chair of computer science at Southampton University. Berners-Lee is currently working on the Semantic Web – an extension of the World Wide Web in which information content is expressed in both natural language and in a form that can be understood by software. Berners-Lee was knighted in 2004.

**Bernoulli, Daniel** (1700–1782) *Swiss mathematician*

Daniel was a son of Johann I Bernoulli (ber-noo-lee). Of all the Bernoulli family he was probably the most outstanding mathematician and certainly the one with the widest scientific interests. Daniel, who was born in Groningen in the Netherlands, studied at the universities of Basel, Strasbourg, and Heidelberg. His studies, which reflected his already wide interests, included logic, philosophy, and medicine in addition to mathematics.

In 1724 Daniel produced his first important piece of mathematical research – a work on differential equations, which sufficiently impressed the European scientific community to earn him an invitation to the St. Petersburg Academy of Sciences as a professor of mathematics. Once installed in Russia he continued to pursue his varied interests and obtained a post at the academy for his friend Leonhard EULER. In 1733 he left Russia to return to Switzerland to take up a chair in mathematics at Basel. Bernoulli's wide interests continued to occupy him and during his time at Basel he also held posts in botany, anatomy, physiology, and physics.

In Switzerland Daniel did the work for which he is best known, namely his virtual founding of the modern science of hydrodynamics using Isaac NEWTON's laws of force. He published these ideas in his *Hydrodynamica* (1738; Hydrodynamics). Apart from his work in fluid dynamics Daniel made distinguished contributions to probability theory and differential equations in mathematics, and to electrostatics in physics.

He also laid the basis for the kinetic theory of gases. Like his uncle, Jakob I Bernoulli, Daniel corresponded voluminously with many scholars throughout Europe, thus extensively disseminating his new ideas.

**Bernoulli, Jakob I** (1654–1705) *Swiss mathematician*

Jakob I (or Jacques) was the first of the Bernoulli family of scientists to achieve fame as a mathematician. As with the two other particularly outstanding Bernoullis – his brother, Johann I, and nephew, Daniel – Jakob I played an important role in the development and popularization of the then recently invented integral and differential calculus of Isaac NEWTON and Gottfried LEIBNIZ. His particular contribution to the calculus consisted in showing how it could be applied to a wide variety of fields of applied mathematics.

Jakob I, who was born in Basel, Switzerland, began studying theology and in 1676 traveled through Europe where he met many of the important scientists of the day, such as Robert BOYLE in England. He returned to Basel in 1682 where he began lecturing on mechanics and

held a chair in mathematics at Basel University from 1687 until his death. Apart from his mathematical work he was an influential figure in the European scientific community through his voluminous correspondence.

His most important contributions to mathematics were in the fields of probability and in the calculus of variations. His work on probability is contained in his treatise the *Ars conjectandi* (1713; *The Art of Conjecturing*) in which he made numerous important contributions to the subject, among which was his discovery of what is now known as the "law of large numbers." The law has a number of forms. In effect it says that for an event of probability  $P$  in a large number of trials  $n$  the number of actual events approaches  $nP$  as  $n$  increases. *Ars conjectandi* also contains Bernoulli's work on permutations and combinations.

The Bernoulli family were always prone to rivalry and Jakob I and his younger brother, Johann I, became involved in a controversy over the problem of finding the shortest path between two points of a particle moving solely under the influence of gravity. The result of this vigorous dispute was the creation of the calculus of variations, a field that Leonhard EULER was later to develop. In addition to this Jakob I did important and useful work in the study of the catenary, which he applied to the design of bridges.

### **Bernoulli, Johann I** (1667–1748) *Swiss mathematician*

Johann I (or Jean) was the brother of Jakob I Bernoulli and was born in Basel, Switzerland. As in the case of several of the Bernoulli family Johann I's father did not encourage him to make a career of mathematics and he graduated in medicine in 1694.

Once he had abandoned medicine for mathematics he became chiefly interested in applying the calculus to physical problems. He played an important role as a propagandist for the calculus in general and in particular as a champion of Gottfried LEIBNIZ's priority over Isaac NEWTON. Johann I held a chair in mathematics at Groningen, Holland, from 1695 and returned to Switzerland to take up a chair in mathematics at Basel on the death of his brother in 1705. Johann I's interests ranged over many fields outside mathematics including physics, chemistry, and astronomy. His mathematical work also included particularly important contributions to optics, to the theory of differential equations, and to the mathematics of ship sails.

### **Bert, Paul** (1833–1886) *French physiologist and politician*

Bert (bair), who was born in Auxerre in eastern France, initially studied engineering and law but turned to medicine, becoming a pupil of the

eminent physiologist, Claude Bernard, at the Sorbonne, Paris. From his studies of the effects of low and high pressures on the human body, Bert showed how deep-sea divers and others working at high external pressure could avoid the condition known as the bends by returning gradually to normal pressure conditions. In this way, the nitrogen gas that dissolves in blood at high pressure is removed slowly instead of forming bubbles in the blood and causing agonizing and possibly fatal cramps. Bert wrote *La Pression barométrique* (1878; *Barometric Pressure*), which was translated into English in 1943 for the benefit of aircrews flying at high altitudes during World War II.

Bert entered politics in 1876 as deputy for Yonne and served briefly as minister of education and welfare (1881–82). He was staunchly anticlerical and left-wing in his views. In 1886 he was appointed governor-general to the Annam and Tonkin provinces in Indochina but died of dysentery in the same year.

### **Berthelot, Pierre Eugène Marcellin** (1827–1907) *French chemist*

The Parisian-born son of a doctor, Berthelot (bair-te-**loh**) studied medicine at the Collège de France but became interested in chemistry, becoming assistant to Antoine-Jérôme BALARD in 1851. He was professor of organic chemistry at the Ecole Supérieure de Pharmacie (1859–76) and professor of chemistry at the Collège de France (1864–1907).

Alcohols were Berthelot's early research interest and he introduced the terms mono-, di-, and polyatomic alcohols. He showed that glycerin was a triatomic alcohol and in 1854 he synthesized fats from glycerin and fatty acids. He carried out a great deal of work on sugars, which he recognized as being both polyhydric alcohols and aldehydes. Berthelot was one of the pioneers of organic synthesis. Before his time, organic chemists had mainly been concerned with degradations of natural products but Berthelot, in keeping with his logical systematic nature, began with the simplest molecules; his syntheses included methane, methanol, formic acid, ethanol, acetylene, benzene, naphthalene, and anthracene. His favored techniques were reduction using red-hot copper and the silent electric discharge. His methods were somewhat crude and the yields were low. Berthelot's work on organic synthesis was published as *Chimie organique fondée sur la synthèse* (1860; *Organic Chemistry Based on Synthesis*).

Arising from his interest in esterification, Berthelot studied the kinetics of reversible reactions. In 1862, working with Péan de Saint Gilles, he produced an equation for the reaction velocity. This was incorrect but it inspired Cato GULDBERG and Peter WAAGE to enunciate the law of mass action (1864).

In 1864 Berthelot turned to thermochemistry. In his book *Mécanique chimique* (1879; Chemical Mechanics) he introduced the terms “endothermic” and “exothermic” to describe reactions that respectively absorb and release heat. He also introduced the bomb calorimeter for the determination of heats of reaction and investigated the kinetics of explosions.

Berthelot's interest in agricultural chemistry was stimulated by his discovery of nitrogen uptake by plants in the presence of an electrical discharge. In 1883 he established an agricultural station at Meudon, where fundamental work on the nitrogen cycle was carried out. He looked forward to the day when poverty and squalor would be eradicated by the application of synthetic chemistry and new sources of energy.

Berthelot was a pioneer of historical studies in chemistry. In this he was influenced by his friend, the scholar Renan. In later life he became increasingly involved in affairs of state, mostly concerned with education, and in 1895–96 he served as foreign minister.

### **Berthollet, Comte Claude-Louis** (1748–1822) *French chemist*

Born in Talloires, France, Berthollet (bair-to-lay) studied medicine at Turin and gained his MD in 1768. He went to Paris in 1772 where he began publishing chemical researches in 1776 and was elected a member of the Académie Française in 1780. His Italian medical degree was not recognized in France so he obtained a Parisian degree in 1778.

When Berthollet published his important paper on chlorine (which came from sea water), *Mémoire sur l'acide marin déphlogistique* (1785; Memoir on a Marine Dephlogistonated Acid), he was the first French chemist to accept Antoine LAVOISIER's new system. Unfortunately, he also accepted Lavoisier's erroneous idea that chlorine contains oxygen. In 1784 Berthollet became inspector of a dyeworks and he discovered and developed the use of chlorine as a bleach. He published a standard text on dyeing *Éléments de l'art de la teinture* (1791; Elements of the Art of Dyeing).

Berthollet was neither a great manipulator nor a persuasive lecturer, but he did original work in many fields. He analyzed ammonia (1785), prussic acid (hydrogen cyanide, 1787), hydrogen sulfide (1798), and discovered potassium chlorate (1787). Although a convert, he remained skeptical about Lavoisier's oxygen theory of acidity: his analyses showed no oxygen in prussic acid or hydrogen sulfide, despite their undoubted acidity. Berthollet attempted to use his newly discovered potassium chlorate in gunpowder but it proved too unstable, destroying a powder mill at Essones in 1788. More productive were his analyses of iron and steel, which resulted in better quality steel.

After the French Revolution of 1789 Berthollet was a member of various commissions and in 1795 he became a director of the national mint. In 1798 he was entrusted by Napoleon with the organization of scientific work on the expedition to Egypt and he established an Institute of Egypt. On his return to Paris in 1799 Berthollet bought a large house at Arcueil in the suburbs of Paris, where he set up a laboratory and subsequently founded the Société d'Arcueil, which included Pierre de LAPLACE, Alexander von HUMBOLDT, Jean BIOT, Louis Thenard, and Joseph GAY-LUSSAC. At Arcueil, Berthollet produced his magnum opus, the *Essai de statique chimique* (1803; Essay on Chemical Statics), in which he propounded a theory of indefinite proportions. By 1808, following the work of John DALTON, Jöns BERZELIUS, and Gay-Lussac, indefinite proportions was decisively rejected, but Berthollet's idea that mass influences the course of chemical reactions was eventually vindicated in the law of mass action of Cato GULDBERG and Peter WAAGE (1864).

Berthollet was made a senator in 1804 and in his later years was regarded as the elder statesman of French science.

### **Berzelius, Jöns Jacob** (1779–1848) *Swedish chemist*

I ... have seldom experienced a moment of such pure and deep happiness as when the glowing stick which was thrust into it [oxygen] lighted up and illuminated with unaccustomed brilliancy my windowless laboratory.

—*Autobiographical Notes*

Born in Väversunda, Sweden, Berzelius (ber-zee-lee-us) struggled to obtain a satisfactory education. In 1796 he entered the University of Uppsala but his studies were interrupted because of lack of funds. He began his chemical experiments without any official encouragement and from 1799 he worked during the summers as a physician at Medevi Springs where he analyzed the waters. He finally obtained his MD degree in 1802 with a dissertation on the medical uses of the voltaic pile.

After graduating Berzelius moved to Stockholm where he did research with Wilhelm HISINGER, a mining chemist. Their first success came in 1803 with the isolation of cerium but they were anticipated in this by Martin KLAPROTH. Berzelius later discovered selenium (1817), thorium (1828), and his coworkers discovered lithium (1818) and vanadium (1830). In 1807 Berzelius was appointed professor at the School of Surgery in Stockholm (later the Karolinska Institute), and he was soon able to abandon medicine and to concentrate on chemistry.

Berzelius was a meticulous experimenter and systemizer of chemistry. His early work was on electrochemistry and he formed a “du-

alistic" view of compounds, in which they were composed of positive and negative parts. He was an ardent supporter of John DALTON's atomic theory, but, like LAVOISIER, believed in the importance of oxygen – thus he argued for many years that chlorine contained oxygen.

In 1810 Berzelius began a long series of studies on combining proportions that established Dalton's atomic theory on a quantitative basis. This work led to tables of atomic weights that were generally very accurate, but he never accepted Amedeo AVOGADRO's hypothesis and this led to some confusion. He was a prolific author with about 250 papers to his credit. His *Lärbok i kemien* (1808–1818; Textbook of Chemistry) subsequently passed through many editions and was translated into most languages except English. Pupils who came to study with him included Friedrich WÖHLER, Leopold GMELIN, and Eilhardt MITSCHERLICH. His ideas on chemical proportions and electrochemistry are set out in *Essai sur la théorie des proportions chimiques et sur l'influence chimique de l'électricité* (1819; Essay on the Theory of Chemical Proportions and on the Chemical Effects of Electricity).

Berzelius's work in organic chemistry was less fruitful than the rest of his work but he improved organic analysis by introducing a tube of calcium chloride for the collection of water and the use of copper(II) oxide as an oxidizing agent. From 1835 Berzelius's rigid adherence to the dualistic theory proved obstructive to progress in organic chemistry, although it was given a certain plausibility by Wöhler and Justus von LIEBIG's discovery of the benzoyl radical (1832).

Berzelius introduced much of the familiar chemical apparatus, including rubber tubing and filter paper, and the modern chemical symbols, although these were little used in his lifetime. He had a knack of coining words for phenomena and substances – "catalysis," "protein," and "isomerism" were all introduced by him.

### **Besicovitch, Abram Samoilovich** (1891–1970) *Ukrainian–British mathematician*

Born in the Ukrainian town of Berdjansk, Besicovitch (be-sik-o-vich) graduated in 1912 from the University of St. Petersburg, having studied under A. A. MARKOV. In 1917 he became professor of mathematics at Perm (later Molotov University) and then taught at the Leningrad Pedagogical Institute and Leningrad University. He left the Soviet Union in 1924 to work briefly in Copenhagen before moving to England. G. H. HARDY was sufficiently impressed by Besicovitch's analytical powers to secure him a lectureship at Liverpool University. After a year he became a lecturer at Cambridge and in 1950

became Rouse Ball Professor of Mathematics, a post that he held for eight years.

Besicovitch was primarily an analyst. The subject with which he is most associated is that of almost periodic functions, an interest stemming from his collaboration with Bohr. 1932 saw the publication of his book *Almost Periodic Functions*. He also did important work on the "Karkeya problem," general real analysis, complex analysis, and various geometric problems. His other main work was on geometric measure theory.

### **Bessel, Friedrich Wilhelm** (1784–1846) *German astronomer*

Bessel (bes-el) was born into a poor family in Minden, Germany, and started work as a clerk. His interest in and aptitude for astronomy brought him to the attention of Heinrich OLBERS, who obtained a position for him in the observatory at Lilienthal. Four years later he was entrusted with the construction of the observatory at Königsberg and appointed its director.

Bessel made many advances in astronomy. He cataloged the position of 50,000 stars down to the ninth magnitude between 15°S and 45°N and, using James BRADLEY's results, achieved new levels of accuracy. He also made careful observations of 61 Cygni and was able to detect a parallax of 30 arc seconds and to calculate the star's distance – the first such determination – as 10.3 light years. (The distance is now known to be 11.2 light-years.) Although Bessel was the first to announce the detection of parallax (1838), Thomas HENDERSON had in fact measured it in 1832 in his observations of Alpha Centauri.

Bessel's other great discovery came after observing a slight displacement in the proper motion of Sirius, which he explained as the effect of an orbit around an unseen star, and announced in 1844 that Sirius was a double star system having a dark companion. Sirius B was detected optically by Alvan CLARK in 1862. Bessel made a similar claim for Procyon whose companion was discovered optically in 1895. He also noted irregularities in the motion of Uranus and suggested that they were caused by an unknown planet, but died just before the discovery of Neptune.

In mathematics Bessel worked on the theory of the functions, named for him, that he introduced to determine motions of bodies under mutual gravitation and planetary perturbations. They still have a wide application in modern physics.

### **Bessemer, Sir Henry** (1813–1898) *British inventor and engineer*

Bessemer was the son of a mechanical engineer who had fled from the French Revolution. After leaving the village school in Charlton,

England, where he was born, he worked as a type-caster, until the family moved to London in 1830. At the age of 17 he set up his own business to produce metal alloys and bronze powder. In 1843 he had an idea that made his fortune. On purchasing some "gold" paint (made of brass) for his sister he was horrified at its high price. He designed an automatic plant to manufacture the paint and made sufficient money to pursue a career as a professional inventor.

During the Crimean War (1853–56) Bessemer invented a new type of gun with a rifled barrel. To manufacture the gun he needed a strong metal that could be run into a mold in a fluid state. At that time cast iron (pig iron) contained carbon and silicon impurities, which made it brittle. Wrought iron, which was relatively pure, was made by a laborious process of refining pig iron. The temperature of the furnace, while sufficient to melt the pig iron, was not sufficient to keep the purer iron molten. The refined metal was extracted in lumps after which it was "wrought." Bessemer proposed burning away the impurities by blowing air through the molten metal. The *Bessemer converter* that he invented is a cylindrical vessel mounted in such a way that it can be tilted to receive a charge of molten metal from the blast furnace. It is then brought upright for the "blow" to take place. Air is blown in through a series of nozzles at the base and the carbon impurities are oxidized and carried away by the stream of air.

Bessemer announced his discovery in 1856. At first his idea was accepted enthusiastically and within weeks he obtained the equivalent of about \$135,000 in license fees. However, though the process had worked for him, elsewhere it failed dismally because of excess oxygen trapped in the metal, and because of the presence of phosphorus in the ores. (By chance Bessemer's ore had been phosphorus-free.) His invention was dropped and Bessemer found himself the subject of much ridicule and criticism. Bessemer established his own steelworks in Sheffield (1859) using imported phosphorus-free iron ore.

Robert Mushet (about 1856) solved the problem of the excess oxygen by the addition of an alloy of iron, manganese, and carbon to the melt. Bessemer's process then worked provided nonphosphoric ores were used, but it took much time and determination to convince ironworkers after the initial failure. The invention eventually reduced the price of steel to a fifth of its former cost, made it possible to produce it in large quantities, and made possible its use in a variety of new products. The problem of dealing with the phosphorus impurities was solved in 1878 by Sydney Gilchrist THOMAS and Percy Carlyle GILCHRIST. Bessemer retired a rich man in 1873.

### **Best, Charles Herbert** (1899–1978) *American–Canadian physiologist*

Best, who was born in West Pembroke, Maine, graduated in physiology and biochemistry from the University of Toronto in 1921. In the summer of that year he gave up a lucrative holiday playing professional football and baseball to begin work with Frederick BANTING. Together they isolated the hormone insulin, and showed its use in the treatment of diabetes. Banting was furious when Best was not awarded a share in the 1923 Nobel Prize for physiology or medicine for the discovery of insulin.

Best remained at the University of Toronto and gained his MB in 1925. He was made head of the physiology department in 1929 and became director of the Banting and Best Department of Medical Research when Banting was killed in 1941. He continued the work on insulin throughout these years and in an important paper published in 1936 he suggested the administration of zinc along with insulin to reduce its rate of absorption and make it more effective over a longer time. He also studied cardiovascular disease and established the clinical use of heparin as an anticoagulant for blood in the treatment of thrombosis. He discovered the vitamin choline, which prevents liver damage, and the important enzyme histaminase, which takes part in local inflammation reactions, breaking down histamine.

### **Bethe, Hans Albrecht** (1906–2005) *German–American physicist*

Bethe (**bay-te**), the son of an academic, was born in Strasbourg in France and educated at the universities of Frankfurt and Munich, where he obtained his doctorate in 1928. He taught in Germany until 1933 when he moved first to England and, in 1935, to America. In America he held the chair of physics at Cornell from 1937 until his retirement in 1975, serving in the war as director of theoretical physics at Los Alamos from 1943 to 1946.

Bethe soon established a reputation for his impressive knowledge of nuclear reactions. This was, in part, based on three review articles on nuclear physics he published in 1936 and 1937, which have been described as the first presentation of this field as a branch of science and which are sometimes known as "Bethe's Bible."

In 1938 Bethe was invited by Edward TELLER to contribute a paper on astrophysics for a conference he was organizing. Bethe at first pleaded ignorance of the subject but, under pressure from Teller, he finally agreed to search for a relevant topic. He noted that most astrophysicists seemed to be puzzling over the origin of the chemical elements. He therefore decided to consider another issue, namely, the sources of stellar energy. He managed to find, as he reported in his 1939 paper *Energy Production in Stars*, "... the only nuclear reaction which gives

the correct rate of stellar energy production within the limits of the theory.”

Bethe was referring to the carbon cycle (or CNO cycle). The cycle begins with a hydrogen nucleus or proton ( $^1\text{H}$ ) and a carbon-12 atom; it has six stages:

Here,  $\gamma$  is a gamma ray,  $\text{e}^+$  a positron, and  $\nu$  a neutrino. The net result of the cycle is to convert four protons ( $4^1\text{H}$ ) into a helium nucleus ( $\text{He}^4$ ), while the carbon-12-atom remains available after step 6 to repeat the cycle once more. In the process 27 MeV (million electron volts) are released.

Although the amount of energy produced per cycle is modest, the large amount of stellar matter involved is sufficient to generate the enormous energies met with inside stars. Bethe's CNO cycle, however, gives no indication of the origin of the carbon-12 that starts the cycle. It was left to Fred HOYLE and his colleagues to resolve this issue in the 1950s. Bethe did, however, contribute, with Ralph ALPHER, to George GAMOW's famous 1948 alpha-beta-gamma paper on the origin of the elements and the big bang. Unfortunately their paper advanced no further than the isotopes of hydrogen and helium.

Bethe also played a significant part in public affairs. He quarreled in the 1940s with Teller on the need to build the hydrogen bomb, and in the 1980s over the viability of the U.S. Strategic Defense Initiative (known as “Star Wars”). In 1958 he served as a delegate to the Geneva Conference that negotiated the first test-ban treaty. He also worked for the 1963 ban on atmospheric testing. More recently, in 1992, Bethe called upon the United States and Russia to reduce their nuclear arsenals to a thousand warheads each.

Bethe also worked in other branches of physics. In 1929 he published a classic paper initiating crystal-field theory, and in 1949 he made a pragmatic calculation of the LAMB shift. He also continued to work at physics in his retirement. He collaborated with John BAHCALL on several papers dealing with the solar-neutrino problem. He also began to tackle the problem of explaining how stars explode. Modern computer models, he complained, lead to moderate explosions when compared with the massive eruptions of a supernova.

For his earlier work on the theory of nuclear reactions, and for his contributions to astrophysics, Bethe was awarded the 1967 Nobel Prize for physics.

**Bevan, Edward John** (1856–1921)  
*British industrial chemist*

Bevan, who was born at Birkenhead in Lancashire, northwest England, was educated privately and in 1873 began employment with the Runcorn Soap and Alkali Company. From 1877 to 1879 he studied chemistry at Owens College, Manchester, where he met Charles CROSS with whom he went into partnership in 1885 as consulting chemists.

Their main interest was cellulose and in 1892 they patented the viscose process of rayon manufacture in which cellulose (woodpulp) is dissolved in carbon disulfide and alkali. The cellulose is regenerated by acid, either in the form of yarn (rayon) or film (cellophane). He wrote several books, including *Cellulose* (1895), which he coauthored with Cross.

**Bichat, Marie François Xavier** (1771–1802)  
*French pathologist*

Life is the ensemble of functions that resist death.

—*Recherches physiologiques sur la vie et la mort* (1800; Physiological Researches on Life and Death)

Bichat (bee-*sha*), the son of a physician, was born at Thoirette, France, and studied humanities at Montpellier and philosophy at Lyons. He switched to studies in surgery and anatomy and moved in 1793 to Paris, where he worked for some years under the patronage of Pierre Desault, the leading French surgeon. He was appointed physician at the Hôtel-Dieu in 1800 shortly before his death from tuberculous meningitis.

Despite his short life Bichat produced two highly influential works, *Traité des membranes* (1800; Treatise on Membranes) and *Anatomie générale* (1801; General Anatomy). He revealed the inadequacies of Giovanni MORGAGNI's claim that disease resided in the organs of the body, and instead stressed the role of the component tissues in determining health and disease. He consequently went on to make a detailed investigation of the tissues of the body, distinguishing 21 different types. He argued that in an organ made up of a number of tissues it is often found that while one tissue type is diseased the remainder are healthy.

This work was significant in bridging the gap between the organ pathology of Morgagni and the cell pathology of Rudolf VIRCHOW.

**Biela, Wilhelm von** (1784–1856)  
*Austrian astronomer*

Born in Rossia, Austria, Biela (bee-la) was an army officer and an amateur astronomer. In 1826 he observed a comet with a short period of 6.6 years. When *Biela's comet* reappeared in 1845 it had split into two parts. It was last seen in 1852 when it presumably broke up, for in No-

vember 1872 what was probably its remains was seen as a fantastic meteor shower, which caused a worldwide sensation. The shower can still be seen faintly in Andromeda in late November. The meteors are sometimes called the Bielids or, alternatively, the Andromedids.

**Biffen, Sir Rowland Harry** (1894–1949)  
*British geneticist and plant breeder*

Biffen was born in Cheltenham in Gloucestershire, England; after graduating in natural sciences from Cambridge in 1896, he joined a team investigating rubber production in Mexico, the West Indies, and Brazil. On his return he was appointed lecturer in botany at Cambridge and patented a method for handling rubber latex.

Biffen was inclined more toward applied than pure botany and joined the Cambridge School of Agriculture shortly after its foundation in 1899. He began conducting cereal trials in order to select improved types, and when Gregor MENDEL's laws of inheritance were re-discovered in 1900, he realized immediately that they could be applied to improving plant-breeding methods. Biffen speculated that physiological as well as morphological traits would prove to be inherited in Mendelian ratios, and in 1905 demonstrated that this was true for resistance to yellow rust, a fungal disease of wheat.

Little Joss and Yeoman, two wheat varieties bred by Biffen, were unequaled for many years. In 1912 Biffen became director of the Plant Breeding Institute at Trumpington, a newly formed research center established by the government to promote Biffen's work and the application of scientific principles to plant breeding. Biffen was also professor of agricultural botany at the university from 1908 to 1931 and was instrumental in setting up the National Institute of Agricultural Botany at Cambridge. He was knighted for his services to agriculture in 1925.

**Billroth, Christian Albert Theodor** (1829–1894)  
*Austrian surgeon*

Billroth (**bil-roht**), who was born in Bergen, Germany, first studied natural sciences and later medicine at the University of Göttingen and subsequently in Berlin, becoming qualified to practice in 1852. In the following year he was appointed to the surgical clinic at Berlin University and in 1860 became director of a similar clinic at the University of Zurich, where he wrote his *Allgemeine chirurgische Pathologie und Therapie* (1863; General Surgical Pathology and Therapy). However, it was as professor of surgery at the University of Vienna (1867–94) that Billroth made his greatest contributions to surgery. Here, he introduced the new antiseptic methods in abdominal surgery, thus enabling hitherto impossibly dangerous opera-

tions. Billroth was the first to perform the removal of a section of the esophagus (1872), to undertake a complete laryngectomy (1873), and to excise the lower half of the stomach, rejoining the upper half to the duodenum. This is sometimes called *Billroth's operation*.

Apart from being an eminent surgeon of international repute, Billroth was also a gifted musician and like Theodor ENGELMANN a friend of Johannes Brahms.

**Bina, Eric** (1964– )  
*American computer scientist*

Bina (**bee-na**) worked at the National Center for Supercomputer Applications (NCSA) at the University of Illinois at Urbana in the early 1990s. While there, he collaborated with Marc ANDREESSEN and some other colleagues in producing a prototype Internet browser called *Mosaic*.

After Andreessen founded Mosaic Corp. with Jim Clark in 1994, Bina joined the new company, subsequently named Netscape Communications, and helped to develop an improved version of *Mosaic*, which was called *Navigator*. This invention was a key development in the very rapid growth of the Internet.

**Binnig, Gerd** (1947– )  
*German physicist*

Binnig was born in Frankfurt, Germany, and educated at the Goethe University there, where he obtained his PhD in 1978. He immediately joined the staff of the IBM Research Laboratory at Roschliken, Zurich.

One limitation of the conventional electron microscope developed in the 1930s by E. RUSKA was its failure to reveal much information about the surface of a material. Overall surface structure can be distinguished by the techniques of low-energy electron diffraction (LEED) and some indication of the detailed structure can be gained from the field-emission and field-ion microscopes developed by Erwin MUELLER. Binnig, in collaboration with Heinrich ROHRER, began work on a high-resolution *scanning tunneling microscope* (STM) in 1978. By 1981 they were able to resolve details on the surface of some calcium-iridium-tin crystals.

The STM employs a small conducting probe which is held close to the surface and slowly scanned across it. Electrons tunnel between the surface and the probe, and the probe is raised or lowered so as to keep the signal constant. A computer-generated map of the surface is produced. Like the similar *atomic force microscope* (ATM), the device can, under suitable conditions, resolve individual atoms or molecules on the surface.

For their work in this field Binnig and Rohrer shared the 1986 Nobel Prize for physics.

**OPTICAL ACTIVITY** Biot showed that compounds such as tartaric acid could rotate polarized light in solution. The explanation was later given by Le Bel and van't Hoff, who suggested that carbon molecules have a three-dimensional tetrahedral structure. Tartaric acid (above) has two isomers that are mirror images of each other. One rotates the light to the left (*levo*); the other to the right (*dextro*).

**Biot, Jean Baptiste** (1774–1862) *French physicist*

Biot (**bi**-oh), a Parisian by birth, grew up during the French Revolution and at the age of 18 he joined the army as a gunner. He left a year later to study mathematics at the Ecole Polytechnique in Paris. On leaving he taught at a school in Beauvais but soon returned to Paris to become a professor of physics at the Collège de France.

In 1804 Biot made an ascent in a balloon with Joseph GAY-LUSSAC. They reached a height of three miles and made many observations, including the fact that the Earth's magnetism was not measurably weaker at that height.

For the next few years Biot collaborated with François ARAGO in many fields of research and they traveled to Spain together to measure the length of an arc of meridian, in order to calibrate a standard unit of length. Biot later went on a number of other important expeditions.

His most famous work was on optical activity, for which, in 1840, he was awarded the Rumford medal of the Royal Society. He was the first to show that certain liquids and solutions, as well as solids, can rotate the plane of polarized light passing through them. Biot suggested that this is due to asymmetry in the molecules. From this idea grew the technique of polarimetry as a method of measuring the concentration of solutions.

**Birkeland, Kristian Olaf Bernhard** (1867–1917) *Norwegian physicist and chemist*

Birkeland (**beer**-ke-lan) was born in the Norwegian capital, Christiania (now Oslo), and studied in Paris, Geneva, and Bonn where he was a pupil of Robert BUNSEN. In 1898 he was appointed to the chair of physics in Oslo University. He is remembered today for his discovery of a means for the fixation of nitrogen (the *Birkeland-Eyde process*).

Energy crises are not monopolies of the 1970s. In 1898 William CROOKES in his presi-

dential address to the British Association had pointed out that, given the world demand for nitrogenous fertilizers, the deposits of nitrates would rapidly be exhausted. As there is a virtually unlimited supply of nitrogen in the atmosphere the obvious solution was to find some way in which it could be used. Birkeland, in collaboration with Samuel EYDE, solved the problem in 1903 by passing air through an electric arc to form oxides of nitrogen, which could then be absorbed in water to give nitric acid. This was mixed with lime to give calcium nitrate. The process is particularly useful in regions (as in Scandinavia) where there is a plentiful supply of hydroelectric power, although the Haber process is now the main industrial method of fixing nitrogen.

Birkeland also spent much time studying the aurora borealis, making several expeditions and establishing a geophysical laboratory as far north as 70°. In 1896 he was the first to suggest the correct explanation that the aurora borealis could be the result of charged rays emitted by the Sun and trapped in the Earth's magnetic field near the poles. He derived this idea from the resemblance between the newly discovered cathode rays and the aurora.

**Birkhoff, George David** (1884–1944) *American mathematician*

Birkhoff, who was born in Overisel, Michigan, studied at the Lewis Institute (now the Illinois Institute of Technology) from 1896 to 1902, and subsequently at the University of Chicago and at Harvard. In 1907 he obtained his PhD from Chicago and took up a teaching post at the University of Wisconsin, moving to Princeton in 1909. In 1912 he became assistant professor at Harvard and, in 1919, professor there, a post he held until 1939.

Birkhoff's mathematical interests were wide, and among the many areas to which he made notable contributions were differential equations, celestial mechanics, difference equations, and the three-body problem. His main field of research was mathematical analysis, especially

applied to dynamics. In the course of his work on dynamical systems Birkhoff obtained a famous proof of a conjecture made by Henri POINCARÉ in topology, usually known as Poincaré's last geometric theorem. In 1923 he proved a result, now known as *Birkhoff's theorem*, for spherically symmetric systems in General Relativity Theory. This has turned out to be important in the theory of black holes and cosmology. The ergodic theorem, a result concerned with the formal mathematics of probability theory that Birkhoff proved in 1931, is another of his outstanding achievements. Modern dynamics received an enormous impetus from Birkhoff's work, and he also worked on the foundations of relativity and quantum mechanics.

**Bíró, Ladislao José** (1899–1985) *Argentinian inventor*

Throughout the 1930s Bíró (bl-roh) worked as a journalist and artist in Budapest, the capital of his native Hungary. While thus engaged he noticed how quickly printer's ink dried and began to think of a new type of pen. Before Bíró the alternatives were expensive and unreliable fountain pens, or steel nibs with bottles of ink. To meet the demand Birmingham was producing nearly 200 million nibs each year. Bíró saw that a ball rotating in an ink supply would write when pushed along a sheet of paper. The ink bottle and leaking fountain pen could be dispensed with. In 1938, with his brother Georg, a chemist, Bíró applied for a patent.

Europe, however, was no place to develop a new product in 1938. Bíró had happened to meet president Justo of Argentina while on holiday in Yugoslavia. Intrigued by the new pen, the president invited Bíró to come and work in Argentina. Bíró accepted the invitation and soon found backers in return for a substantial share in any future profits. In 1944 the North American rights were sold for \$2 million. But Bíró had little taste for business and resigned from the company in 1947 to devote more time to art. He also continued to invent and produced, among other items, a heat-proof tile and a pick-proof lock.

The durability of Bíró's work can be seen partly in the billions of ballpoint pens that are made and thrown away each year, and partly in the fact that in most of the world's languages a ballpoint pen is also known as a "biro."

**Bishop, John Michael** (1936– ) *American immunologist and microbiologist*

Bishop attended Gettysburg College and studied medicine at Harvard University. In 1962 he secured an internship at Massachusetts General Hospital in Boston, and in 1964 he moved to the National Institutes of Health, Washington, DC, as research associate in vi-

rology, later becoming senior investigator (1966) and assistant professor (1968). He was appointed professor of microbiology and immunology at the University of California Medical Center, San Francisco, in 1972, and in 1981 he became director of the G. W. Hooper Research Foundation. He became chancellor of the University of California in 1998.

Bishop, working in collaboration with Harold VARMUS, demonstrated for the first time that cancer-causing genes (*oncogenes*) carried by certain viruses are derived from normal genes present in the cells of their host, known as *proto-oncogenes*. This work by the team at the University of California, published in 1976, led to the discovery of many more such cellular genes, and represented a major advance in cancer research. In recognition of this, Bishop and Varmus were jointly awarded the 1989 Nobel Prize for physiology or medicine.

**Bittner, John Joseph** (1904–1961) *American experimental biologist*

Bittner, who was born in Meadville, Pennsylvania, gained his doctorate at the University of Michigan and spent the greater part of his academic life involved in cancer research. He was George Chase Christian Professor of Cancer Research at the University of Michigan and director of cancer biology of the University of Minnesota's medical school (1942–57), and later professor of experimental biology.

While working at Ben Harbor Research Station, Maine (1936), Bittner found that some strains of mice were highly resistant to cancer, while others were very prone to it. If the young of cancer-resistant mice were transferred to cancer-prone mothers they became cancerous, apparently via the mothers' milk, whereas cancer-resistant parents induced resistance in cancer-prone young. Bittner's discovery of viruslike organisms in the milk of cancer-prone parents suggested that these organisms are the cause of the cancer. Bittner's findings followed, and may be linked with, those of Francis ROUS, who made the controversial finding that other viruslike organisms are, perhaps, the cause of sarcomas (tumors originating in connective tissue) in chickens. Such work does not, of course, suggest that all cancers are caused by viruses or viruslike organisms, merely that some forms may be.

**Bjerknes, Jacob Aall Bonnevie** (1897–1975) *Norwegian meteorologist*

Bjerknes (*byairk-nays*), the son of Vilhelm Bjerknes, followed the example of his father in studying meteorology. Born in the Swedish capital, Stockholm, he was educated at the University of Oslo, where he obtained his PhD in 1924, and worked at the Geophysical Institute

at Bergen with his father from 1917, remaining there when Vilhelm moved to Oslo in 1926.

During World War I Bjerknes worked with his father in establishing a series of weather observation stations throughout Norway. From the data collected, and working with other notable meteorologists, including Tor BERGERON, they developed their theory of polar fronts, also known as the *Bergen theory* or the *frontal theory*. They had established that the atmosphere is composed of distinct air masses possessing different characteristics and applied the term "front" to the boundary between two air masses. The polar front theory showed how cyclones (low-pressure centers) originated from atmospheric fronts over the Atlantic Ocean where a warm air mass met a cold air mass.

In 1939 Bjerknes moved to America and, unable to return to occupied Norway, became professor of meteorology at the University of California where he continued to study atmospheric circulation. In 1952 he became one of the first to use space techniques for meteorological research when he used photographs of cloud cover taken by research rockets for weather analysis.

### **Bjerknes, Vilhelm Friman Koren** (1862–1951) *Norwegian meteorologist*

Bjerknes was born in the Norwegian capital, Christiania (now Oslo), where his father, Carl, was professor of mathematics at the university. In 1890 Vilhelm traveled to Germany and became assistant to Heinrich HERTZ. He was made professor of applied mechanics and mathematical physics at the University of Stockholm in 1895. He returned to Norway in 1907 and in 1912 moved to the University of Leipzig to become professor of geophysics.

Bjerknes's important contributions to meteorology and weather forecasting include his mathematical models (1897) of atmospheric and oceanic motions, which later led to the theory of air masses. In 1904 he produced a program for weather prediction based on physical principles. He returned to Norway in 1907 and in 1912 moved to the University of Leipzig to become professor of geophysics.

During World War I he founded the famous Bergen Geophysical Institute, gathering there a group of notable meteorologists, including his son, Jacob Bjerknes, Tor BERGERON, and Carl-Gustaf ROSSBY. In 1921 he produced an important work, *On the Dynamics of the Circular Vortex with Applications to the Atmospheric Vortex and Wave Motion*.

### **Bjerrum, Niels** (1879–1958) *Danish physical chemist*

The son of a professor of ophthalmology, Bjerrum (**byair**-um), who was born in the Danish capital, Copenhagen, received his master's de-

gree in 1902 and doctorate in 1908, becoming professor at the Royal Veterinary and Agricultural College (1914–49).

His first notable work was an extensive study of chromium complexes by means of conductivity, equilibrium constant, and absorption spectrum measurements. In 1909 he proposed (contrary to Svante ARRHENIUS's original dissociation theory) that strong electrolytes are completely dissociated. In 1911, working with Hermann NERNST, he applied the quantum theory of a harmonic oscillator to the temperature dependence of the specific heats of gases. This led to work on molecular rotation and vibration and hence to pioneer work on the infrared spectra of polyatomic molecules.

### **Black, Sir James Whyte** (1924– ) *British pharmacologist*

Black graduated from St. Andrews University, Scotland, in 1946, and, after a number of academic posts, joined ICI as a pharmacologist (1958–64). After working for Smith, Kline, and French he became professor of pharmacology at University College, London (1973–77), before joining Wellcome as Director of Therapeutic Research (1978–84). From 1984 until 1992 he was professor of analytical pharmacology at King's College Hospital, London. From 1992 to 2006 he was chancellor of the University of Dundee. Black was knighted in 1991.

Black has been associated with two important advances in pharmacology. In the 1950s he isolated the first beta blockers. These are compounds that prevent the stimulation of certain nerve endings (beta receptors) in the sympathetic nervous system, thus reducing heart activity. Beta blockers are widely used to treat hypertension and angina. His subsequent work has been concerned with the control of gastric ulcers and his discovery of the drug cimetidine, which reduces acid secretion in the stomach and is used to treat ulcers in the stomach and duodenum. For this work and his work on beta blockers he was awarded the 1988 Nobel Prize for physiology or medicine.

### **Black, Joseph** (1728–1799) *British physician and chemist*

Upon the whole, Chymistry is as yet but an opening science, closely connected with the usefull and ornamental Arts, and worthy the attention of a liberal mind ... While our knowledge is imperfect, it is apt to run into error: but Experiment is the thread that will lead us out of the labyrinth.

Black, the son of a wine merchant, was born in Bordeaux, France, and studied languages and natural philosophy, and later, medicine and chemistry at Glasgow University (1746–50). He moved to Edinburgh in 1751, where he presented his thesis in 1754. Black published very little and the thesis, expanded and published as

*Experiments upon Magnesia Alba, Quicklime, and some other Alkaline Substances* (1756), contained his most influential work. The paper in fact marked the beginning of modern chemistry. Black investigated quantitatively the cycle of reactions:

limestone → quicklime → slaked lime →  
limestone

and showed that the gas evolved (“fixed air” or carbon dioxide) is distinct from and a constituent of atmospheric air, and is the cause of the effervescence of limestone with acids. He proved that mild alkalis will become more alkaline when they lose carbon dioxide and they are converted back to mild alkalis through reabsorption of the gas.

Black’s other great discovery was that of latent heat (the heat required to produce a change of state). The concept of latent heat came to him in 1757 and the experimental determination of the latent heat of fusion of ice was made in 1761. The next year he determined the latent heat of formation of steam. Black also distinguished the difference between heat and temperature and conceived the idea of specific heat.

Black was professor of medicine and lecturer in chemistry at Glasgow (1756–66) and then professor of chemistry at Edinburgh for the rest of his life. Black’s lectures, which he gave for over 30 years, were immensely popular and were published in 1803.

### **Blackett, Patrick Maynard Stuart** (1897–1974) *British physicist*

Blackett, the son of a London stockbroker, attended the Royal Naval College at Dartmouth. After serving with the navy in World War I, during which he fought at the Battle of the Falklands and Jutland, he entered Cambridge University, resigned his commission, and decided to become a scientist. He worked in the 1920s with Ernest RUTHERFORD at the Cavendish Laboratory and, in 1933, was appointed professor of physics at London University. In 1937 he moved to Manchester, returning to London in 1953 to take the chair at Imperial College where he remained until his retirement in 1963. During World War II he worked on numerous advisory bodies and from 1942 to 1945 was director of operational research at the admiralty.

Just as Blackett was beginning his research career Rutherford had announced his discovery of the atomic transmutation of nitrogen into oxygen by bombardment with alpha particles. Blackett, using a cloud chamber, took some 23,000 photographs containing some 400,000 alpha particle tracks in nitrogen and found in 1925 just eight branched tracks in which the ejected proton was clearly separated from the newly formed oxygen isotope.

Blackett continued with the Wilson cloud chamber and began, in collaboration with Giuseppe OCCHIALINI, to use it to detect cosmic rays. As the appearance of cosmic rays is unpredictable it was standard practice to set up the chamber to take a photograph every 15 seconds, producing a vast amount of worthless material for analysis. To avoid this Blackett introduced in 1932 the counter-controlled chamber. Geiger counters were so arranged above and below the chamber that when a cosmic ray passed through both, it activated the expansion of the chamber and photographed the ion tracks produced by the ray. Using this device they confirmed in 1933 Carl ANDERSON’S discovery of the positron. They also suggested that the positron was produced by the interaction of gamma rays with matter, such that a photon is converted into an electron–positron pair. The phenomenon is known as pair production.

After the war Blackett’s research interests moved from cosmic rays to terrestrial magnetism. Using new sensitive magnetometers his group began a major survey of the magnetic history of the Earth. By 1960 they could report that there had been considerable change in the relative positions of the continents over the past 500 million years, thus providing further support for the doctrine of continental drift.

Blackett was also active in public affairs and a noted opponent of nuclear weapons. In 1948 he was awarded the Nobel Prize for physics for “his development of the Wilson cloud chamber and his discoveries therewith in the field of nuclear physics and cosmic radiation.” He was raised to the British peerage as Baron Blackett in 1969.

### **Blackman, Frederick Frost** (1866–1947) *British plant physiologist*

Blackman, born in London the son of a doctor, studied medicine at St. Bartholomew’s Hospital there and natural sciences at Cambridge University. He remained in Cambridge for the whole of his career where he served as head of plant physiology until his retirement in 1936.

Blackman is mainly remembered for his classic 1905 paper, *Optima and Limiting Factors*, in which he demonstrated that where a process depends on a number of independent factors, the rate at which it can take place is limited by the rate of the slowest factor. This paper was stimulated by the research of one of his students, who showed that raising the temperature only increased the rate of photosynthesis if the level of illumination was high. Increased temperatures had no effect at low light intensities.

He had earlier, in 1895, provided convincing experimental support for the long held view that gaseous exchange between the leaves and

the atmosphere takes place through the stomata, the pores on the leaf's surface.

**Blackwell, Elizabeth** (1821–1910)  
*British–American physician*

Blackwell is best remembered for being the first woman to receive a medical degree in the United States, in 1849. However, she also did much in promoting women's health and training for women physicians. She was born in Bristol, England, and emigrated to America as a child. The early death of her father forced her into teaching to support the family, but she soon determined on a career in medicine. Yet formidable obstacles faced her; apart from lack of money to finance her preliminary studies, no woman had ever been admitted to a medical school. While continuing to teach she arranged to lodge in the house of a physician, Samuel Henry Dickson of Charleston, where she could acquire some basic medical knowledge. She was turned down by all the major medical colleges, and was accepted by just one of the minor medical schools, Geneva Medical College, New York State. She overcame the initial skepticism and embarrassment of staff at the college, and the hostility of the townspeople, to complete her course and graduate first in her class. To continue her medical training she then went to Europe, initially to La maternité lying-in hospital in Paris, where she contracted an eye disease that left her blind in one eye. Thereafter she studied at St. Bart's Hospital in London, where she was generally welcomed by the teaching staff, an exception being the professor of midwifery: according to Blackwell, "[he told me that] his neglecting to give me aid was owing to no disrespect for me as a lady, but to his condemnation of my object!" Blackwell returned to America in 1851 and settled in New York, where she opened a free part-time dispensary for poor women and children. In 1857 she founded the New York Infirmary for Indigent Women and Children. Apart from medical care, an important aspect was the training for women medical and nursing students. In 1859, while on a lecture tour of Britain, Blackwell became the first woman to be included in the United Kingdom's Medical Register. Back in America, in the face of continuing hostility to women from the established medical schools, Blackwell opened a Women's Medical College in 1868, with an initial intake of 15 students and nine faculty members. The following year she returned to live in England, leaving her sister Emily in charge of the College. Elizabeth went on to promote medical education in England, helping to set up the National Health Society and founding the London School of Medicine for Women. In 1875 she was appointed professor of gynecology at the London School of Medicine for Children.

**Blaeu, Willem Janszoon** (1521–1638)  
*Dutch cartographer*

Blaeu (blow), who was born in Alkmaar, Holland, began work as a carpenter. In 1595 he spent a year with Tycho BRAHE at his observatory at Hven. He opened his cartographic shop in Amsterdam soon after his return to Holland and specialized in producing globes. He published his first world map in 1605 and his first atlas in 1633.

After his death the business was carried on by his sons, Jan and Cornelis. In 1648 they produced their world map, which contained much that was new including the coastline of north and west Australia and parts of New Zealand and the Antarctic. It also abandoned the great southern continent previously believed to exist.

**Blagden, Sir Charles** (1748–1820)  
*English physician and chemist*

Blagden, born in Wotton under Edge in England, studied medicine at Edinburgh, where one of his professors was Joseph BLACK, and graduated in 1768. He became a medical officer in the British army in the same year and theoretically remained in that post until 1814. From 1782 to 1789 Blagden was assistant to Henry CAVENDISH, a post that involved him in the so-called "water controversy," a dispute between James WATT, Cavendish, and Antoine LAVOISIER concerning the priority of the discovery of the synthesis of water from its elements. Blagden was friendly with the great French scientists of the day, especially Claude BERTHOLLET, and on a visit to Paris in 1783 he told Lavoisier of Cavendish's synthesis, an experiment that Lavoisier repeated in Blagden's presence. Blagden became secretary of the Royal Society soon afterward, in which capacity he published Watt's papers on the same subject. The dispute was largely artificial because the three men drew different conclusions from their work.

Blagden's own scientific work was concerned with the freezing of mercury, the supercooling of water, and the freezing of salt solutions. He discovered, in 1788, that the lowering of the freezing point of a solution is proportional to the concentration of the solute present. This became known as *Blagden's law*. Blagden was knighted in 1792.

**Blakeslee, Albert Francis** (1874–1954)  
*American botanist and geneticist*

Blakeslee was born at Geneseo in New York State and educated at Wesleyan University, Connecticut, graduating in 1896. He taught science for four years before entering Harvard to do postgraduate research, gaining his PhD in 1904. In this year he discovered that the bread molds (*Mucorales*) exhibit heterothallism (self-sterility) and spent the next two years in Ger-

many making further investigations on the fungi.

From 1907 to 1914 Blakeslee was professor of botany at Connecticut Agricultural College. In 1915 he moved to the department of genetics at the Carnegie Institution, where he remained until 1941. In 1924 he began work on the alkaloid colchicine, which is found in the autumn crocus, and 13 years later he discovered that plants soaked in this alkaloid had multiple sets of chromosomes in their cells. Such plants, termed polyploids, often exhibit gigantism and this discovery proved of immediate use in the horticultural industry in producing giant varieties of popular ornamentals. More importantly, however, colchicine often converts sterile hybrids into fertile polyploids and is therefore an invaluable tool in crop-breeding research.

Other contributions made by Blakeslee to plant genetics include his study of inheritance in the jimson weed and his research on embryo culture as a method of growing hybrid embryos that would abort if left on the parent plant.

**Blane, Sir Gilbert** (1749–1834) *British physician*

Blane was born in Blane, Scotland, and studied medicine at Edinburgh and Glasgow, receiving his MD in 1778. In the following year he sailed with the fleet as personal physician to Admiral Lord Rodney and later as physician to the fleet. While in the West Indies, he made intelligent use of James LIND's results and introduced the provision of lime juice and other citrus fruits to combat scurvy among the seamen. He also generally improved the standards of hygiene on board ship.

He returned to London in 1783 and became a physician at St. Thomas's Hospital, London, and later attended both George IV and William IV as physician-in-ordinary. He was instrumental in enforcing his health regulations throughout the Royal Navy and helped draft the Quarantine Act of 1799. He was made a baronet in 1812.

His rather grave manner earned him the nickname of "chilblaine" among his colleagues.

**Blau, Marietta** (1894–1970) *Austrian-American physicist*

Noted for her pioneering work in the photographic detection of subatomic particles, Blau was born in Vienna, Austria, and attended the university there, receiving a PhD in 1919. After working briefly in Berlin and at the University-Institute of Frankfurt-am-Main, she returned to Vienna to work unpaid at the Radiuminstitut and the Second Physical Institute, from 1923 until 1938. During this time she relied on the financial support of her family, apart from a grant (1933–34) from the Aus-

trian Association of University Women, which permitted her brief spells working in Göttingen and at the Curie Institute, Paris. In the face of growing anti-Jewish feeling, Blau left Vienna just before the Nazis annexed Austria; initially she went to Oslo, then, on the recommendation of Albert EINSTEIN, to the Technical University, Mexico City (1939–44). She subsequently worked in the metallurgical industry (1944–48) in North America, and as a physicist at Columbia University (1948–50) and the Brookhaven National Laboratory (1950–55) before being appointed associate professor at the University of Miami (1955–60).

As early as 1925 in Vienna, Blau created photographic emulsions that could detect the tracks of high-energy protons, and in collaboration with Hertha WAMBACHER was the first (in 1932) to expose emulsions to neutron beams to determine the spectrum of neutrons arising from reactions in the emulsion. In 1937 the two women showed how cosmic rays cause the disintegration of heavy nuclei in photographic emulsions, producing so-called Blau-Wambacher stars. In North America, after World War II, Blau was involved in the early development of photomultiplier tubes, and continued her researches into elementary particles. In 1962 she was awarded the Erwin Schrödinger Prize, shared (posthumously) with Wambacher.

**Bliss, Nathaniel** (1700–1764) *British astronomer*

Bliss was born in Bisley, Gloucestershire, in western England and was educated at Oxford. In 1736 he was appointed rector of St. Ebbe's church, Oxford, and succeeded HALLEY in 1742 as Savilian Professor of Geometry, also in Oxford. He left Oxford in 1762 when he was appointed fourth Astronomer Royal in succession to James BRADLEY.

The tenure of his position at Greenwich was too short for Bliss to leave much of a mark on the Royal Observatory. He did, however, observe in 1761 that rare astronomical event, a transit of Venus, enabling him to calculate the horizontal parallax of the Sun as 10.3" (compared with the modern figure of 8.8").

**Blobel, Günter** (1936– ) *German-born American cell biologist*

Blobel (**blo**-bel) was born in Waltersdorf, Silesia, Germany (now in Poland). He graduated in medicine from the University of Tübingen in 1960, and in 1962 secured a fellowship at the University of Wisconsin, Madison, to study oncology. After gaining his PhD in 1967, Blobel moved to the Cell Biology Laboratory at Rockefeller University, New York. He became assistant professor in 1969, associate professor in 1973, and professor in 1976.

Blobel's work has focused on how the many

different proteins made by living cells are sorted and distributed to their correct destinations. He followed on from pioneering studies of cell structure and protein secretion undertaken by his Rockefeller colleague and mentor George PALADE, helping to unravel some of the fundamental mechanisms of cell biology.

In 1971, Blobel proposed the “signal hypothesis,” which postulated that proteins destined for transport out of the cell are given a special tag, rather like a baggage label, that directs the protein to its destination. His subsequent work described how this tag consists of a short sequence of amino acids – the signal peptide – that transiently forms part of the protein.

Proteins are assembled from amino acids by particles called ribosomes, which are associated with an intracellular network of membranous chambers called the endoplasmic reticulum (ER). The signal peptide instructs the ribosome to attach to the ER membrane over a membrane channel. The signal peptide leads the growing chain of amino acids (polypeptide) through the channel, until eventually the signal peptide is removed and the complete polypeptide is released into the lumen of the ER. From here it is ultimately transported out of the cell.

Blobel’s team, as well as other research groups, went on to show that similar signal peptides are employed in targeting proteins to organelles (miniorgans) within the cell, such as mitochondria and chloroplasts. In 1980 Blobel proposed the general principle that proteins contain specific amino acid sequences (topogenic sequences) that determine not only whether they are exported from the cell or retained, but also their position and orientation in a particular target membrane. Subsequent work by various groups has revealed a variety of topogenic sequences, and established their universal importance to protein targeting in all cell types.

Blobel’s work has provided insights into how certain diseases are caused by proteins having faulty address tags, which means that they fail to reach their proper destinations. It also paves the way for the development of drugs that can be targeted more precisely to particular cell locations.

For his discovery that proteins have intrinsic signals that govern their transport and localization in the cell, Blobel was awarded the 1999 Nobel Prize for physiology or medicine.

### **Bloch, Felix** (1905–1983) *Swiss–American physicist*

Bloch (blok) was born in Zürich, Switzerland, and educated at the Federal Institute of Technology there and at the University of Leipzig, where he obtained his PhD in 1928. He taught briefly in Germany and in 1933 moved to America, via various institutions in Italy, Denmark,

and Holland. In 1934 he joined the Stanford staff, remaining there until his retirement in 1971 and serving from 1936 onward as professor of physics. He also served briefly as first director of the international laboratory for high-energy physics in Geneva, known as CERN (1954–55).

In 1946, Bloch and Edward PURCELL independently introduced the technique of nuclear magnetic resonance (NMR). This utilizes the magnetic property of a nucleus, which will interact with an applied magnetic field such that it takes certain orientations in the field (a quantum mechanical effect known as space quantization). The different orientations have slightly different energies and a nucleus can change from one state to another by absorbing a photon of electromagnetic radiation (in the radiofrequency region of the spectrum). The technique was used initially to determine the magnetic moment (i.e., the torque felt by a magnet in a magnetic field at right angles to it) of the proton and of the neutron. It has since, however, been developed into a powerful tool for the analysis of the more complex molecules of organic chemistry. The energy states of the nucleus are affected slightly by the surrounding electrons, and the precise frequency at which a nucleus absorbs depends on its position in the molecule. In 1952 Bloch shared the Nobel Prize for physics with Purcell for this work on NMR.

Bloch worked extensively in the field of solid-state physics developing a detailed theory of the behavior of electrons in crystals and revealing much about the properties of ferromagnetic domains.

### **Bloch, Konrad Emil** (1912–2000) *German–American biochemist*

Born in Neisse (now Nysa in Poland), Bloch (blok) was educated at the Technical University, Munich, and – after his emigration to America in 1936 – at Columbia University, New York, where he obtained his PhD in 1938. He then taught at Columbia until 1946, when he moved to the University of Chicago, becoming professor of biochemistry there in 1950. In 1954 Bloch accepted the position of Higgins Professor of Chemistry at Harvard, a post he retained until his retirement in 1978.

In 1940 the important radioisotope carbon-14 was discovered by Martin KAMEN and Samuel Ruben. Bloch was quick to see that it could be used to determine the biosynthesis of such complex molecules as cholesterol, a basic constituent of animal tissues characterized by four rings of carbon atoms. Thus in 1942, in collaboration with David Rittenberg, Bloch was able to confirm the earlier supposition that cholesterol was partly derived from the two-carbon acetate molecule.

The many steps through which acetate develops into the 27-carbon cholesterol took years

of analysis to establish. The breakthrough came in 1953, when Bloch and R. Langdon identified squalene as an intermediate in cholesterol synthesis. Squalene, a terpene with an open chain of 30 carbon atoms, initiates the folding necessary to produce the four rings of cholesterol. For this work Bloch shared the 1964 Nobel Prize for physiology or medicine with Feodor LYNEN.

**Bloembergen, Nicolaas** (1920– )  
*Dutch–American physicist*

Bloembergen (**blom**-ber-gen) was born in Dordrecht in the Netherlands and was educated at the universities of Utrecht and Leiden, where he obtained his PhD in 1948. He moved to America soon afterward, joined the Harvard staff in 1949, and served from 1957 as Gordon McKay Professor of Applied Physics; from 1974 to 1980 he was also Rumford Professor of Physics. He became Gerhard Gade university professor in 1980, a post he held until his retirement in 1990.

In the mid 1950s Bloembergen introduced a simple yet effective modification to the design of the maser. First built by Charles TOWNES in 1953, the early maser could only work intermittently: once the electrons in the higher energy level had been stimulated they would fall down to the lower energy level and nothing further could happen until they had been raised to the higher level once more. Bloembergen developed the three-level and multilevel masers, which were also worked on by Nikolai BASOV and Aleksandr PROKHOROV in the Soviet Union. In the three-level maser, electrons are pumped to the highest level and stimulated. They consequently emit microwave radiation and fall down to the middle level where they can once more be stimulated and emit energy of a lower frequency. At the same time more electrons are being pumped from the lowest to the highest level making the process continuous. Bloembergen has worked extensively on nonlinear optics – i.e., on effects produced by high intensities of radiation. He has particularly investigated the use of lasers to excite or break particular bonds in a chemical reaction. For his work he shared the 1981 Nobel Prize for physics with Arthur SCHAWLOW (and Kai Siegbahn).

Bloembergen wrote *Nuclear Magnetic Relaxations* (1948) and *Nonlinear Optics* (1965).

**Blumberg, Baruch Samuel** (1925– )  
*American physician*

Blumberg was born in New York City and studied physics and mathematics at Union College, Schenectady, and at Columbia, where, after a year, he changed to medical studies. He received his MD from Columbia in 1951 and his PhD in biochemistry from Oxford University in 1957. After working at the National Institutes of

Health in Bethesda from 1957 until 1964 Blumberg was appointed professor of medicine at the University of Pennsylvania, a position he held until his retirement in 1994.

In 1963, while examining literally thousands of blood samples in a study of the variation in serum proteins in different populations, Blumberg made the important discovery of what soon became known as the “Australian antigen.” He found in the blood of an Australian aborigine an antigen that reacted with an antibody in the serum of an American thalassemia patient. It turned out that the antigen was found frequently in the serum of those suffering from viral hepatitis, hepatitis B, and was in fact a hepatitis B antigen.

It was hoped that from this discovery techniques for the control of the virus would develop. It certainly made it easier to screen blood for transfusion for the presence of the hepatitis virus; it also permitted the development of a vaccine from the serum of those with the Australian antigen. Blumberg has also suggested that the virus is involved in primary liver cancer.

For his work on the Australian antigen Blumberg shared the 1976 Nobel Prize for physiology or medicine with Carleton GAJ-DUSEK.

**Blumenbach, Johann Friedrich** (1752–1840)  
*German anthropologist*

Blumenbach (**blou**-men-bahk), the son of an assistant headmaster of the local gymnasium, was born in Gotha, Germany, and educated at the universities of Jena and Göttingen, where he obtained his MD in 1775. He remained at Göttingen for the whole of his career, serving as professor of medicine from 1778 onward.

In his *De generis humani variatate nativa* (1776; Concerning the Natural Diversity of the Human Race) Blumenbach took up the problem posed by LINNAEUS in 1747, which challenged scientists to find a generic character that would distinguish between men and apes. Blumenbach’s solution was to attribute two hands to humans and four hands to monkeys. This enabled him to form a separate order, Bimanus, for man alone while including apes, monkeys, and lemurs in the Quadrumana.

In Bimanus he included five races – Caucasian, Ethiopian, Mongolian, Malayan, and American Indian – insisting that they were “all related and only differing from each other in degree.” Nonetheless he favored a monogenetic view of mankind, which led him to see the Caucasian race as primary, with the other four races existing as “degenerate” forms. Blumenbach’s version of this common 18th-century view was relatively mild. He argued that the degeneration was an acquired trait, the result of climatic and dietary influences. The rampant racism found in some of his contemporaries is

on the whole absent from the works of Blumenbach. To show that “degenerate” forms were not the same as inferior forms he produced in 1799 a paper in which he provided biographies of those African poets, philosophers, and jurists who had established themselves in European society.

**Bode, Johann Elert** (1747–1826) *German astronomer*

Born in Hamburg, Germany, Bode (**boh**-de) was the director of the Berlin Observatory and popularized a discovery made earlier in 1772 by Johann Titius of Wittenberg. This was a simple but inexplicable numerical rule governing the distance of the planets from the Sun measured in astronomical units (the mean distance of the Earth from the Sun). The rule, known as *Bode’s law*, is to take the series 0, 3, 6, 12, 24 ... , add 4 to each member, and divide by 10. The result is the distance in astronomical units of the planets from the Sun. The law and its application can be tabulated and, provided that the asteroids are counted as a single planet, quite an impressive fit can be achieved. It breaks down for Neptune and is hopelessly wrong for Pluto. It played a role in the discovery of Neptune by Urbain LE VERRIER in 1846. It is not known whether the law is simply a pure coincidence, or whether it is a consequence of the way in which the solar system formed.

**Bodenstein, Max Ernst August** (1871–1942) *German physical chemist*

Bodenstein (**boh**-den-shtIn), who was born in Magdeburg, Germany, gained his doctorate at Heidelberg (1893). He subsequently worked with Wilhelm OSTWALD at Leipzig before becoming a professor at Hannover (1908–23) and at the Institute for Physical Chemistry, Berlin (1923–36). He made a series of classic studies on the equilibria of gaseous reactions, especially that of hydrogen and iodine (1897). His technique was to mix hydrogen and iodine in a sealed tube, which he placed in a thermostat and held at a constant high temperature. The reaction eventually reached an equilibrium, at which the rate of formation of hydrogen iodide (HI) was equal to the rate of decomposition to the original reactants:

The equilibrium mixture of  $\text{H}_2$ ,  $\text{I}_2$ , and HI was “frozen” by rapid cooling, and the amount of hydrogen iodide present could be analyzed. Using different amounts of initial reactants, Bodenstein could vary the amounts present at equilibrium and verify the law of chemical equilibrium proposed in 1863 by Cato GULDBERG and Peter WAAGE.

Bodenstein also worked in photochemistry and was the first to show how the large yield per quantum for the reaction of hydrogen and

chlorine could be explained by a chain reaction.

**Boerhaave, Hermann** (1668–1738) *Dutch physician and chemist*

It will now perhaps be universally granted that our professor [Boerhaave] has indeed supplied us with the best system from an unparallel’d fund of medical learning happily digested.

—W. Burton, *An Account of the Life and Writings of Hermann Boerhaave* (1743)

Boerhaave (**bor**-hah-ve) was born at Voorhout, near Leiden, in the Netherlands, and studied philosophy at the University of Leiden. He was intended to enter the Church, but an accusation of impiety turned him from theology to medicine and he obtained his MD in 1693 at Harderwijk. Boerhaave returned to Leiden where he began to teach medicine and chemistry and practiced medicine privately. Boerhaave was a polymath, learned in medicine, botany, and chemistry. His lectures were immensely successful and he occupied the chairs of medicine and botany (1709), practical medicine (1714), and chemistry (1718). Boerhaave was celebrated during his life for his medical works, *Institutiones medicae* (1708; Institutions of Medicine), and *Aphorismi de cognoscendis et curandis morbis* (1709; The Book of Aphorisms) but posthumously he exerted great influence as a chemist through his excellent work *Elementia chemiae* (1723; Elements of Chemistry). Boerhaave made no great discoveries but he had unerring judgment in selecting that which was most valuable in the work of others. He tried to apply the mechanistic philosophy of NEWTON and Robert BOYLE to both medicine and chemistry. His early work on calorimetry was the foundation on which Joseph BLACK subsequently built. He was elected a fellow of the Royal Society and during his lifetime was as famous as Newton.

**Boethius, Anicius Manlius Severinus** (c. 480–524) *Roman philosopher*

Boethius (**boh**-ee-thee-us), a member of the noble Anicii family, was born in a Rome conquered and ruled by the Ostrogoths. He flourished under the Ostrogothic king Theodoric, being appointed consul in 510 and *magister officiorum*, the head of the Imperial civil administration, in about 520. For reasons that are not clear Boethius was imprisoned in Pavia, tortured, and finally put to death.

As a scholar Boethius had expressed a wish to translate “the whole work of ARISTOTLE into the Roman idiom” but only succeeded in dealing with the logical works. He also produced works on arithmetic, geometry, astronomy, and music, later to form the basis for the teaching of the “quadrivium” (the course of studies in medieval universities), a term he may well have

introduced. Such works were based closely on earlier Greek works of Nichomachus and EUCLID. Boethius is historically important for keeping the tradition of Greek thought and science alive in Europe until the works of the great Arab scholars were translated some six centuries later.

**Bogoliubov, Nikolai Nikolaevich (1909–1992)** *Russian mathematician and physicist*

Born in Nizhny Novgorod in Russia, Bogoliubov (bu-gu-lyoo-bof) was accepted for graduate work at the Academy of Sciences of the Ukrainian SSR, and subsequently worked there and at the Soviet Academy of Sciences.

His main contribution was in the application of mathematical techniques to theoretical physics. He developed a method of distribution-function for nonequilibrium processes, and also worked on superfluidity, quantum field theory, and superconductivity. His work was partly paralleled by the work of John BARDEEN, Leon COOPER, and John Robert SCHRIEFFER.

He was also active in founding scientific schools in nonlinear mechanics, statistical physics, and quantum-field theory. Bogoliubov was a prolific author, with many of his books on these topics translated into English. From 1963 he was academician-secretary of the Soviet Academy of Sciences and was made director of the Joint Institute for Nuclear Research in Dubna in 1965. The next year he was also made a deputy to the Supreme Soviet. He was honored by scientific societies throughout the world, and in his own country received the State Prize three times (1947, 1953, and 1984) and the Lenin Prize (1958).

**Bohm, David Joseph (1917–1992)** *American physicist*

There are no things, only processes.  
—Quoted by C. H. Waddington in *The Evolution of an Evolutionist* (1975)

Bohm's father, an Austrian immigrant, ran a successful furniture business. Born in Wilkes-Barre, Pennsylvania, Bohm attended The Pennsylvania State University before moving to the University of California, Berkeley, where he gained his PhD in 1943. After a period working on the development of the atomic bomb under the supervision of OPPENHEIMER at the Radiation Laboratory, Berkeley, Bohm joined the Princeton physics faculty in 1947. Here he ran into political trouble; called to testify before the House Un-American Activities Committee he pleaded the Fifth Amendment and refused to give evidence against his colleagues. He was cited for contempt and threatened with prison. When his Princeton position expired in 1951, Bohm found himself unemployable in the U.S. Oppenheimer advised him to leave the country and he worked in Brazil at São Paulo Univer-

sity (1951–55) and in Israel at Haifa (1955–57). He then settled in Britain, working first at Bristol University as a research fellow before being appointed professor of theoretical physics at Birkbeck College, London (1961), a post he held until his retirement in 1983.

In 1951 Bohm published a much respected textbook, *Quantum Theory*. He was, however, unhappy with the traditional account of quantum theory. His concern lay not with its lack of determinism, but with the fact that “it had no place in it for an adequate notion of an independent actuality.” Electrons could be both wave and particle and, because of HEISENBERG'S uncertainty principle, we can never simultaneously know an electron's position and momentum. One way around this difficulty is to suppose that quantum theory presents an imperfect view of nature, with a more complete and deterministic underlying reality. Such approaches, it was widely believed, had been shown by VON NEUMANN in 1932 to be incompatible with quantum theory. Against this Bohm argued that von Neumann's proof was entirely mathematical and consequently based on axioms and presuppositions that were always open to question. In the 1950s he began to seek for the “hidden variables,” which would allow him better to understand quantum theory.

He proposed that the electron is a real particle with a definite position and momentum, but it is also connected with a “pilot wave.” Bohm regarded this new wave as real and known only by its effects on the electron. Electrons, of course, in Bohm's theory still display wave-particle duality because of the effect of the pilot wave. As the wave reacts with both the electron and the environment, the wave-particle complex responds accordingly to a particular type of measurement. It is a necessary consequence of this view that signals can be conveyed instantaneously from the pilot wave to the electron.

In a later work, *Wholeness and the Implicate Order* (1980), Bohm sought to establish a more general position. Bohm was inspired by an analogy with a device that he saw at a science exhibition. Two concentric glass cylinders have a layer of glycerine between them. If a localized spot of ink is placed in the glycerine and one cylinder is rotated with respect to the other, the ink is smeared out and the spot of ink disappears (in Bohm's terminology, it is “enfolded” or “implicated”). Turning the cylinder in the opposite direction brings the ink back into a spot (it is “unfolded” or “explicate”). Thus while order may appear to have been lost in a system, it may in fact be enfolded in the system, and could be unfolded under the right conditions.

Bohm appears to have been the first person to suggest in a general way that holography might be a key feature of fundamental physics. He also made important contributions to the

theory of collective effects of ions in plasmas and electrons in metals (in collaboration with David Pines) and, together with Yakir Aharonov, predicted an effect, known as the *Aharonov–Bohm effect*, which demonstrated the physical reality of vector potentials in electrodynamics (and more generally gauge theories).

**Bohn, René** (1862–1922) *German organic chemist*

Born in Dornach, France, Bohn (bohn) studied chemistry at the Federal Institute of Technology at Zürich and obtained his doctorate from the University of Zürich in 1883. From 1884 he was a chemist with the Badische Anilin und Soda Fabrik at Ludwigshafen, becoming a director in 1906. He worked mainly on the synthesis of anthraquinone dyes and his most notable synthesis was that of the blue vat dye, indanthrone (1901), the first nonindigo vat dye. He also did important work on the red alizarin dyes.

**Bohr, Aage Niels** (1922– ) *Danish physicist*

Bohr (bor), the son of Niels Bohr, was born in the Danish capital, Copenhagen, and educated at the university there. After postgraduate work at the University of London from 1942 to 1945 he returned to Copenhagen to the Institute of Theoretical Physics, where he served as professor of physics from 1958 to 1981.

When Bohr began his research career the shell model of the nucleus of Maria GOEPPERT-MAYER and Hans JENSEN had just been proposed in 1949. Almost immediately Leo James RAINWATER produced experimental results at odds with the predictions derived from a spherical shell model, and proposed that some nuclei were distorted rather than perfectly spherical.

Bohr, in collaboration with Benjamin MOTTELSON, followed Rainwater's work by proposing their collective model of nuclear structure (1952), so called because it was argued that the distorted nuclear shape was produced by the participation of many nucleons. For this work Bohr shared the 1975 Nobel Prize for physics with Rainwater and Mottelson.

**Bohr, Niels Hendrik David** (1885–1962) *Danish physicist*

When it comes to atoms, language can be used only as in poetry. The poet too is not nearly so concerned with describing facts as with creating images.

—Quoted by J. Bronowski in *The Ascent of Man* (1975)

Niels Bohr came from a very distinguished scientific family in Copenhagen, Denmark. His father, Christian, was professor of physiology at Copenhagen and his brother Harald was a mathematician of great distinction. (His own

son, Aage, was later to win the 1975 Nobel Prize for physics.) Bohr was educated at the University of Copenhagen where he obtained his PhD in 1911. After four productive years with Ernest RUTHERFORD in Manchester, Bohr returned to Denmark becoming in 1918 director of the newly created Institute of Theoretical Physics.

Under Bohr (who after Albert EINSTEIN was probably the most respected theoretical physicist of the century) the institute became one of the most exciting research centers in the world. A generation of physicists from around the world were to pass through it and eventually it was to bestow on the orthodox account of quantum theory the apt description of the “Copenhagen interpretation.”

In 1913 Bohr published a classic paper, *On the Constitution of Atoms and Molecules*, in which he used the quantum of energy introduced into physics by Max PLANCK in 1900, to rescue Rutherford's account of atomic structure from a vital objection and also to account for the line spectrum of hydrogen. The first problem Bohr faced was to explain the stability of the atom. Rutherford's 1911 model of the atom with electrons orbiting a central nucleus (the so-called planetary model) was theoretically unstable. This was because, unlike planets orbiting the Sun, electrons are charged particles, which, according to classical physics, should radiate energy and consequently spiral in toward the nucleus.

Bohr began by assuming that there were “stationary” orbits for the electrons in which the electron did not radiate energy. He further assumed that such orbits occurred when the electron had definite values of angular momentum, specifically values  $h/2\pi$ ,  $2h/2\pi$ ,  $3h/2\pi$ , etc., where  $h$  is Planck's constant. Using this idea he was able to calculate energies  $E_1$ ,  $E_2$ ,  $E_3$ , etc., for possible orbits of the electron. He further postulated that emission of light occurred when an electron moved from one orbit to a lower-energy orbit; absorption was accompanied by a change to a higher-energy orbit. In each case the energy difference produced radiation of energy  $h\nu$ , where  $\nu$  is the frequency. In 1913 he realized that, using this idea, he could obtain a theoretical formula similar to the empirical formula of Johann BALMER for a series of lines in the hydrogen spectrum. Bohr received the Nobel Prize for physics for this work in 1922. The Bohr theory was developed further by Arnold SOMMERFELD.

Bohr also made other major contributions to this early development of quantum theory. The “correspondence principle” (1916) is his principle that the quantum-theory description of the atom corresponds to classical physics at large magnitudes.

In 1927 Bohr publicly formulated the “complementarity principle.” This argued against continuing attempts to eliminate such supposed difficulties as the wave–particle duality of light

**BOHR THEORY** In the Bohr theory of the atom, initially the atom has an electron in its inner orbit and a vacant outer orbit (top). In absorbing a photon, the electron moves to an outer orbit and the atom is in an excited state. Emission (bottom) is the opposite process. The photon energy  $\nu$  is given by  $h\nu = E_2 - E_1$ .

and many other atomic phenomena. His starting point was the impossibility to distinguish satisfactorily between the actual behavior of atomic objects and their interaction with the measuring instruments that serve to define the conditions under which the phenomena appear. Examine light with one instrument, the argument went, and it undulates like a wave; select another and it scatters like a particle. His conclusion was that evidence obtained under different experimental conditions cannot be comprehended within a single picture, but must be regarded as complementary in the sense that only the totality of the phenomenon exhausts the possible information about the objects. It was a principle Bohr remained faithful to, even representing it on his coat of arms in 1947 with the motto *Contraria sunt complementa* (Opposites are complements) above the Yin/Yang symbols. Together with the indeterminacy principle of Werner HEISENBERG and the probability waves of Max BORN, this principle emerged from the 1930 Solvay conference (the last one Einstein attended) as the most authoritative and widely accepted theory to describe atomic phenomena.

Bohr also made major contributions to the work on radioactivity that led to the discovery and exploitation of nuclear fission. Bohr's liquid-drop model of the nucleus, which was published in 1936, provided the basis for the first theoretical account of fission worked out in col-

laboration with John WHEELER in 1939. It was also Bohr who, in 1939, made the crucial suggestion that fission was more likely to occur with the rarer isotope uranium-235 than the more common variety uranium-238.

In 1943 Bohr, who had a Jewish mother, felt it necessary to escape from occupied Denmark and eventually made his way to Los Alamos in America where he served as a consultant on the atomic bomb project. He was quick to appreciate the consequences of using such weapons and in 1944 made an early approach to Roosevelt and Churchill proposing that such obvious danger could perhaps be used to bring about a rapprochement between Russia and the West. Scientists were in a unique position, he argued, in having the Soviet contacts and the knowledge to make the first approach. Much of Bohr's time after the war was spent working, among scientists, for adequate controls of nuclear weapons and in 1955 he organized the first Atoms for Peace conference in Geneva.

**Bok, Bart Jan** (1906–1983) *Dutch–American astronomer*

Bok (bok), who was born at Hoorn in the Netherlands, studied at the universities of Leiden (1924–27) and Groningen (1927–29) and obtained his PhD from Groningen in 1932. He had moved to America in 1929, becoming nat-

uralized in 1938, and served at Harvard from 1929 to 1957 with the appointment of professor of astronomy from 1947 onward. Bok spent the period 1957–66 in Australia as director of the Mount Stromlo Observatory, Canberra, and professor of astronomy at the Australian National University. He returned to America in 1966 to become director of the Steward Observatory, Arizona, until 1970 and professor of astronomy (from 1974 emeritus professor) at the University of Arizona, Tucson.

Bok's major interest was the structure of our galaxy, the Milky Way. With his wife, Priscilla, he published a survey of the subject: *The Milky Way* (1941). Although it had been long assumed that the Milky Way had a spiral structure it was not until Walter BAADE identified in the 1940s the hot young O and B stars of the Andromeda galaxy as spiral markers that such a conjecture could be confirmed. The actual structure was first worked out in some detail by William MORGAN. The existence of 21-centimeter radio signals from clouds of neutral hydrogen in the galaxy was predicted by Hendrik VAN DE HULST and their discovery in 1951 provided a second tracer. It was clear to Bok by the late 1950s that the radio data, which were expected to support the optical picture, instead contradicted it. He consequently attempted to harmonize the two structures by modifying Morgan's somewhat elliptical arms, making them much more spherical, and giving more emphasis to the Carina–Centaurus arm.

Bok's name is also associated with his discovery in 1947 of small dark circular clouds visible against a background of stars or luminous gas and since known as *Bok globules*. Since they are thought to be precursors of stars, as Bok himself conjectured, they have received considerable attention in recent years.

### **Boltwood, Bertram Borden** (1870–1927) *American chemist and physicist*

Boltwood, the son of a lawyer, was born in Amherst, Massachusetts, and educated at Yale and the University of Munich. Apart from the period 1900–06, when he served as a private consultant, and the year 1909–10, which he spent with Ernest RUTHERFORD at the University of Manchester, England, he devoted the whole of his academic career to Yale. He occupied the chair of physics (1906–10), the chair of radioactivity (1910–18), and the chair of chemistry from 1918 until his death by suicide in 1927.

Boltwood made a number of contributions to the study of radioactivity. The radioactivity of uranium and radium had been discovered in the 1890s by Henri BECQUEREL and Marie CURIE. Starting in 1902 Rutherford and Frederick SODDY had shown that radium, uranium, and other radioactive elements broke down in a quite complicated sequence into other el-

ements. Boltwood worked on the breakdown of uranium into radium, a process that Soddy had not found easy to demonstrate. Soddy had tried to obtain radium directly from uranium in 1904 and failed. Boltwood postulated that this was because uranium did not decay directly into radium but into some intermediate element, and began to search for it. After much effort Boltwood eventually found what he was looking for in "actinium X," which, as it appeared different from anything else, he felt confident enough to claim as a new element and named it "ionium" in 1907. This claim ran into trouble when ionium was found to behave very much like thorium and in 1908 it was shown by B. Keetman that if ionium and thorium are mixed together no chemical technique can separate them. Soddy decided the matter in 1913 when he was able to obtain a spectrograph of ionium and found it to be the same as thorium. Although he was wrong in detail, the general picture Boltwood had developed of the decay of uranium to radium was valid until superseded by Soddy's idea of the isotope.

One important byproduct of Boltwood's work was his demonstration in 1905 that lead was always found in uranium and was probably the final stable product of its decay. He argued that in minerals of the same age the lead–uranium ratio would be constant, and in minerals of different ages the ratio would be different. He calculated some estimates of the ages of several rocks based on the estimates then accepted for decay rates and came up with some good results. This was the beginning of attempts to date rocks and fossils by radiation measurements and other physical techniques, which have revolutionized geology and archeology.

### **Boltzmann, Ludwig Edward** (1844–1906) *Austrian theoretical physicist*

Who sees the future? Let us have free scope for all directions of research; away with all dogmatism, either atomistic or antiatomistic!  
—*Lectures on the Theory of Gases*, Vol. I (1896)

In my opinion it would be a great tragedy for science if the theory of gases were temporarily thrown into oblivion because of a momentary hostile attitude toward it, as was for example the wave theory because of Newton's authority.  
—*Lectures on the Theory of Gases*, Vol. II (1898)

Boltzmann (**bohts**-mahn) studied at the university in his native city of Vienna, where he received his doctorate in 1866. He held professorships in physics or mathematics at Graz (1869–73; 1876–79), Vienna (1873–76; 1894–1900; 1902–06), Munich (1889–93), and Leipzig (1900–02).

Boltzmann made important contributions to the kinetic theory of gases. He developed the law of equipartition of energy, which states that the total energy of an atom or molecule is, on

average, equally distributed over the motions (degrees of freedom). He also produced an equation showing how the energy of a gas was distributed among the molecules (called the *Maxwell–Boltzmann distribution*).

Boltzmann also worked on thermodynamics, in which he developed the idea that heat, entropy, and other thermodynamic properties were the result of the behavior of large numbers of atoms, and could be treated by mechanics and statistics. In particular, Boltzmann showed that entropy – introduced by Rudolf CLAUSIUS – was a measure of the disorder of a system. *Boltzmann's equation* (1896) relates entropy ( $S$ ) to probability ( $p$ ):  $S = k \log p + b$ . The constant  $k$  is known as *Boltzmann's constant* and has the value  $1.38054 \times 10^{-23}$  joule per kelvin. The equation is engraved on his gravestone.

Boltzmann's work in this field was heavily criticized by opponents of atomism, particularly Wilhelm OSTWALD. It did however lead to the science of statistical mechanics developed later by Josiah Willard GIBBS and others. Boltzmann also worked on electromagnetism. He is further noted for a theoretical derivation of the law of radiation discovered by Josef STEFAN.

Toward the end of his life he suffered from illness and depression, and committed suicide in 1906.

**Bolyai, Janos** (1802–1860) *Hungarian mathematician*

I have created a new and different world out of nothing.

—Describing his discovery of non-Euclidean geometry in a letter to his father, Farkas Bolyai (1823)

Bolyai (**boh**-lyoi), who was born in Koloszvár (now Cluj) in Romania, was the son of Farkas Bolyai, a distinguished mathematician who had an obsession with the status of EUCLID's famous parallel postulate and devoted his life to trying to prove it. Despite his father's warnings that it would ruin his health, peace of mind, and happiness, Janos too started working on this axiom until, in about 1820, he came to the conclusion that it could not be proved. He went on to develop a consistent geometry in which the parallel postulate is not used, thus establishing the independence of this axiom from the others. His discovery was published in an appendix to a treatise by his father, Farkas Bolyai, dated 1829 but appearing in 1832. Although his discovery had been anticipated by Nikolai LOBACHEVSKY and Karl GAUSS he was unaware of their work.

The discovery of the possibility of non-Euclidean geometries had a tremendous impact on both mathematics and philosophy. In mathematics it opened the way for a far more general and abstract approach to geometry than had previously been pursued, and in philosophy it

settled once and for all the arguments about the supposed privileged status of Euclid's geometry. Bolyai also did valuable work in the theory of complex numbers.

**Bond, George Phillips** (1825–1865) *American astronomer*

There is nothing, then, so extravagant in predicting a future application of photography on a most magnificent scale ... What more admirable method can be imagined for the study of the orbits of the fixed stars and for resolving the problem of their annual parallax.  
—Diary entry, 1857

George Bond, who was born in Dorchester, Massachusetts, spent most of his early life assisting his father, William Bond, whom he succeeded as director of the Harvard Observatory. He therefore contributed to most of his father's observational and photographic work. Apart from the joint discovery of Hyperion with his father he is best known for showing how stellar magnitude could be calculated from photographs. In 1857 he noted that the size of the image is relative to the brightness of the star and the length of the exposure. It is this basic fact that has been used by the compilers of the *Astrographic Catalog* to record measurements of stellar magnitudes. He was also the first to photograph a double star, Mizar, in 1857.

**Bond, William Cranch** (1789–1859) *American astronomer*

Bond, who was born in Portland, Maine, was probably the first American astronomer to make a European reputation for himself. He was a watchmaker whose passion for astronomy was awakened by an eclipse, witnessed in 1806. He built his own observatory, which soon became one of the best in America. In 1847 the self-educated craftsman was invited to be director of the Harvard Observatory.

Bond's achievements were mainly observational and photographic. He made the first photograph of a star (Vega) in 1850, and was also the first to photograph the Moon. In 1848 with his son George Bond he discovered the eighth satellite of Saturn, Hyperion, and in 1850 he detected the third ring of Saturn between the two brighter ones – the so-called “crepe” ring. He was succeeded by his son as director of the observatory.

**Bondi, Sir Hermann** (1919–2005) *British–Austrian mathematician and cosmologist*

Science is above all a cooperative enterprise.  
—*Nature* (1977)

Bondi (**bon**-dee) was born in Vienna, Austria, and studied at Cambridge University, where he later taught. In 1954 he moved to London to take up the chair in mathematics at King's Col-

lege. Bondi was always actively interested in the wider implications of science and the scientific outlook; he was a member of the British Humanist Association and the Science Policy Foundation. He served as chief scientific adviser to the Ministry of Defence (1971–77), chief scientist at the Department of Energy (1977–80), and chairman of the Natural Environment Research Council (1980–84). He was knighted in 1973 and served as master of Churchill College, Cambridge, from 1983 to 1990.

Bondi's most important work was in applied mathematics and especially in cosmology. In collaboration with Thomas GOLD, he propounded, in 1948, a new version of the steady-state theory of the universe. This, among other topics, forms the substance of Bondi's book *Cosmology* (1952). The idea of a steady-state theory had first been suggested by Fred HOYLE, the purpose being to devise a model of the universe that could accommodate both the fact that the universe is the same throughout, and yet is expanding. Bondi and Gold's model was innovative in postulating that there is continuous creation of matter in order to maintain the universe's homogeneity despite its expansion. Although it enjoyed considerable popularity, Bondi and Gold's steady-state model is now considered to have been decisively refuted by observational evidence and the big-bang theory is favored.

**Bonner, James Frederick** (1910–1996)  
*American biologist*

Born at Ansley, Nebraska, Bonner graduated in chemistry from the University of Utah in 1931 but turned to biology under the influence of Theodosius DOBZHANSKY. He received his PhD from the California Institute of Technology (Cal Tech) in 1934, which was then becoming known as the main center for molecular biology. Here he became interested in developmental biology and the question of why only some genes of the chromosome complement of an organism are expressed in any one cell. He discovered that histone, a protein that is found associated with the chromosomes, is responsible for shutting off gene activity, and that if the histone is removed then the repressed genes become functional again. He also discovered that certain hormones act by repressing and derepressing genes.

Bonner in addition conducted research on the artificial synthesis of ribonucleic acid and studied ribosomes and mitochondria. From 1946 to 1981 he was professor of biology at Cal Tech, becoming Professor Emeritus in 1981. He wrote many books, including *The Nucleohistones* (1964) and *The Molecular Biology of Development* (1965).

**Bonnet, Charles** (1720–1793) *Swiss naturalist*

Insects held my attention for some years. The strenuousness with which I worked on this study strained my eyes to such an extent that I was forced to interrupt it. Deprived thus of what had so far been my greatest pleasure, I tried to console myself by changing subjects. I then turned toward the physics of plants – a matter less animated, less fertile in discoveries, but of a more generally recognized usefulness.

—*Recherches sur l'usage des feuilles dans les plantes* (1754; *Researches on the Use of Leaves in Plants*)

Born in Geneva, Switzerland, Bonnet (bo-nay) studied law, gaining his doctorate in 1743. In the same year he was elected a fellow of the Royal Society for his work on regeneration in lower animals and his demonstration of breathing pores (stigmata or spiracles) in caterpillars and butterflies. He is chiefly remembered however for discovering parthenogenesis (reproduction without fertilization) in the spindle-tree aphid and for the ideas on evolution he proposed following this observation.

Bonnet believed all organisms are preformed and that the germs of every subsequent generation are contained within the female. Such thinking implied that species remain constant, leaving Bonnet to explain how species become extinct as evidenced by fossil remains. He argued that the Earth had experienced periodic catastrophes, each destroying many life forms, but the remaining species all evolved to some degree. (Bonnet was the first to use the term "evolution" in a biological context.) Thus after the next catastrophe apes progress to men, and men become angels. The catastrophism theory was adopted by Georges CUVIER, and strongly influenced geological thinking until the 1820s.

**Boole, George** (1815–1864) *British mathematician*

Pure mathematics was discovered by Boole in a work which he called "The Laws of Thought"... His work was concerned with formal logic and this is the same thing as mathematics.

—Bertrand Russell

Boole came from a poor background in the English city of Lincoln and was virtually self-taught in mathematics. He discovered for himself the theory of invariants. Before he obtained an academic post Boole spent several years as a school teacher, first in Yorkshire and later at a school he opened himself. In 1849 he became professor of mathematics at Queen's College, Cork, Ireland.

Boole's main work was in showing how mathematical techniques could be applied to the study of logic. His book *The Laws of Thought* (1854) is a landmark in the study of logic. Boole laid the foundations for an axiomatic treatment of logic that proved essential for the further fundamental developments soon to be made in

the subject by such workers as Gottlob FREGE and Bertrand Russell.

Boole's own logical algebra is essentially an algebra of classes, being based on such concepts as complement and union of classes. His work was an important advance in considering algebraic operations abstractly – that is, studying the formal properties of operations and their combinations without reference to their interpretation or “meaning.” Fundamental formal properties like commutativity and associativity were first studied in purely abstract terms by Boole.

Boole's work led to the recognition of a new and fundamental algebraic structure, the *Boolean algebra*, alongside such structures as the field, ring, and group. The study of Boolean algebras both in themselves and their application to other areas of mathematics has been an important concern of modern mathematics. Boolean algebras find important applications in such diverse fields as topology, measure theory, probability and statistics, and computing.

**Boot, Henry Albert Howard** (1917–1983)  
*British physicist*

Born in the industrial city of Birmingham, England, the son of an electrical engineer, Boot was educated at the university there, completing his PhD in 1941. He was immediately recruited by his head of department, Marcus OLIPHANT, to work on the generation of microwaves for use in radar sets.

Radar operates by reflecting radio waves off objects, but only a tiny part of the radiation transmitted was reflected back, and only a tiny part of this was picked up by the receiving antenna. For the system to work, high power must be transmitted. Moreover, to ensure that the direction of the target can be precisely identified a narrow beam must be used. Some early transmitters used a wavelength as long as 15 meters and spread the signal over a 100° sector. The demand was for “centrimetric radar”; that is, a high-intensity radar beam with a wavelength of a centimeter or two.

The solution came from Boot and his colleague John RANDALL in November 1939 with the *cavity magnetron*, later to be described as the most important invention of the war. The device consists of a block of copper with accurately machined cavities, such that electrons can circulate in a magnetic field through the cavities and thereby generate electromagnetic radiation. When tested, the magnetron delivered 400 watts on a wavelength of 9 centimeters. It was passed to the research department of General Electric who increased its power to 10 kW. Magnetron radar was used first by Bomber Command but soon became available to fighters and convoy escorts.

Boot remained in the Scientific Civil Service after the war. He worked mainly on microwaves

at SERL, the Services Electronics Research Laboratory at Baldock, Hertfordshire, until his retirement in 1977.

**Bopp, Thomas** (1949– ) *American astronomer*

Thomas Bopp was born in Denver, Colorado. His interest in astronomy led him to join a local informal group of amateur astronomers in the Phoenix area. Here, on July 22, 1995, he was the first to see a new comet, now known as *Hale-Bopp*. The comet was independently found by the astronomer Alan HALE.

**Borda, Jean-Charles de** (1733–1791)  
*French mathematician and nautical astronomer*

Born in Dax, France, Borda (bor-**da**) was educated at La Flèche and entered the army as a military engineer. He entered the navy in 1767 and participated in a number of scientific voyages. In 1782 he was captured by the English while participating in the American War of Independence.

His main scientific work was in such practical areas of science as fluid mechanics and in the design of instruments for geodesy and navigation. His work in fluid mechanics had a strongly experimental slant and he applied his discoveries to such practical military problems as the design of artillery, ships, and pumps. He is notable for having shown that the theory of fluid resistance put forward by NEWTON was erroneous. Borda was also involved in instituting the metric system of weights and measures and introduced the term “meter.” He made contributions to the calculus of variations and was notable for his hostility to religion.

**Bordet, Jules Jean Baptiste Vincent** (1870–1961) *Belgian immunologist*

Bordet (bor-**day**) was born in Soignies, Belgium, and graduated in medicine from Brussels University in 1892. In 1894 joined the Pasteur Institute, Paris, where he worked under the bacteriologist Elie METCHNIKOFF. In collaboration with Octave Gengou, Bordet discovered that in an immunized animal the antibodies produced by the immune response work in conjunction with another component of blood (which Bordet termed “alexin” but which is now called “complement”) to destroy foreign cells that invade the body. This component, Bordet found, was present in both immunized and non-immunized animals and was destroyed by heating to over 55°C. This work formed the basis of the *complement-fixation test*, a particularly sensitive means of detecting the presence of any specific type of cell or its specific antibody. A notable application of this was the test to detect syphilis devised by August von Wasserman.

In 1901 Bordet left Paris to found and direct

the Pasteur Institute in Brussels and in 1907 he was appointed professor of pathology and bacteriology at Brussels University. In 1906 Bordet isolated the bacterium responsible for whooping cough, which is named after him: *Bordetella (Haemophilus) pertussis*. For his discovery of complement and other contributions to medicine, he was awarded the 1919 Nobel Prize in physiology or medicine.

**Borelli, Giovanni Alfonso (1608–1679)**  
*Italian mathematician and physiologist*

Borelli (bo-rel-ee) was born in Naples. His mathematical training – he was professor at Messina and Pisa – led him to apply mathematical and mechanical laws to his two main interests, astronomy and animal physiology. He rightly explained muscular action and the movements of bones in terms of levers, and also carried out detailed studies of the flight mechanism of birds. However, his extension of such principles to internal organs, such as the heart, stomach, and lungs, overlooked the essential chemical actions that take place in these organs. Borelli's *De motu animalium* (1680; On the Movement of Animals), which includes his theory of blood circulation, is thus in part erroneous.

In astronomy, in his *Theoricæ medicorum planetarum* (Theory of the Medicean Planets; 1666), Borelli presented a novel and influential account of the motions of the Medicean satellites around their parent planet Jupiter. He accounted for their elliptical orbits in terms of two distinct motions. The first, “perpetual and uniform,” whereby the satellite is attracted rectilinearly to Jupiter as iron moves in a straight line to a magnet; the second, and “directly contrary ... continually decreasing,” arises from the manner in which the satellite “is driven out from the sun by the force of its circular motion.” NEWTON was aware of Borelli's work and appreciated the originality of his approach in the use of elliptical orbits and also his appreciation that orbital motion was complex.

Borelli was also one of the first astronomers, in his *Del movimento della cometa di Dicembre 1664* (1665; The Motion of the Comet of December 1664), to propose, on the basis of observations and calculations, that comets also move in elliptical orbits. Earlier workers, including KEPLER, had taken comets to be transient visitors passing through the solar system in a straight line. As the church opposed such views, Borelli chose to publish under the pseudonym Pier Maria Mutoli.

**Borlaug, Norman Ernest (1914– )**  
*American agronomist and plant breeder*

Dr Borlaug has saved more lives than any person who has ever lived....

—Congressional Tribute to Dr Norman E.

Borlaug Act, passed unanimously by the US Senate in 2006.

Borlaug (**bor-lawg**) was born in Cresco, Iowa, and graduated in forestry from Minnesota University in 1937, gaining his doctorate in plant pathology in 1941. He then spent three years with the Du Pont Chemical Company, testing the effects of chemicals on plants and plant diseases. In 1944 he joined the newly formed International Maize and Wheat Improvement Center in Mexico and began the breeding work that was to produce the highly adaptable dwarf wheats that played so large a part in the “Green Revolution” of the late 1960s and early 1970s.

Borlaug's high-yielding cereals increased agricultural production in the developing countries to the extent that many became self-sufficient for grain. For his major role in temporarily alleviating world famine, Borlaug was awarded the Nobel Peace Prize in 1970. He is still actively campaigning for agricultural improvement in the developing world, despite some criticisms from environmentalists. In 2007 he was presented with the US Congressional Gold Medal.

**Born, Max (1882–1970)** *German physicist*

I am now convinced that theoretical physics is actual philosophy.

—*Autobiography*

Born (born) was the son of an embryologist, a professor of anatomy at the University of Breslau (now Wrocław) in Poland. He was educated at the university in his native city of Breslau, and at the universities of Heidelberg, Zurich, and Göttingen, where he obtained his PhD in 1907. From 1909 until 1933 he taught at Göttingen, being appointed professor of physics in 1921. With the rise of Hitler he moved to Britain, and from 1936 served as professor of natural philosophy at the University of Edinburgh, returning to Germany on his retirement in 1953.

Born's early work was on crystals, particularly the vibrations of atoms in crystal lattices. The *Born-Haber cycle* is a theoretical cycle of reactions and changes by which it is possible to calculate the lattice energy of ionic crystals. He is noted for his role in the development of the new quantum theory. Together with Pascual JORDAN, he developed (1925) the matrix mechanics introduced by Werner HEISENBERG. He also showed how to interpret the theoretical results of Louis de BROGLIE and the experiments of such people as Clinton J. DAVISSON, which showed that particles have wavelike behavior.

At the time, it was known that in some circumstances light, electrons, etc., behaved as waves whereas in others they acted like particles. (William BRAGG once suggested using the corpuscular (particle) theory on Monday, Wednesday, and Friday, and the undulatory

(wave) theory on Tuesday, Thursday, and Saturday.) Mathematical treatments could be used to predict behavior, but there was a problem in finding some accepted physical picture of how electrons, for instance, could act in this way. Erwin SCHRÖDINGER, who developed wave mechanics, interpreted particles as “wave packets,” but this was unsatisfactory because such packets would dissipate in time. Born’s interpretation was that the particles exist but are “guided” by a wave. At any point, the amplitude (actually the square of the amplitude) indicates the probability of finding a particle there.

An essential part of this idea of electrons, atoms, etc., is that it depends on probability – there is no predetermined way in which absolute predictions can be made, as in classical physics. A similar result is embodied in the uncertainty principle of Werner Heisenberg. EINSTEIN, among others, could never accept this and Born corresponded with him on the subject (the *Born–Einstein letters* were published in 1971).

After the development of quantum mechanics Born returned to the study of lattice dynamics and explained it fully in quantum mechanical terms. He was a prolific author and produced classic works on atomic physics, lattice dynamics, quantum mechanics, and optics as well as several popular books and an autobiography.

Born shared (with Walter Bothe) the 1954 Nobel Prize for physics. He is buried in Göttingen, where his tombstone displays his fundamental equation of matrix mechanics:

$$pq - qp = h/2\pi i$$

### **Borodin, Aleksander Porfirevich** (1834–1887) *Russian chemist and musician*

Born the illegitimate son of a Russian prince in St. Petersburg, Borodin (**bor**-o-deen) was educated at the Medical Academy there from 1850 to 1856, where he showed a strong preference for chemistry over medicine. He traveled widely in Europe for several years and attended, with MENDELEEV, the famous First International Congress of Chemists at Karlsruhe in 1860 as a member of the Russian delegation. On his return to Russia, he was appointed to the faculty of the St. Petersburg Academy where he became professor of chemistry in 1864.

Although known as a composer, Borodin actually spent most of his time working as an organic chemist. In 1861 he developed a method for the fluorination of organic compounds. He later, in 1876, devised a widely used method for the quantitative determination of urea. His musical works include two symphonies, the tone poem *In the Steppes of Central Asia* (1880), and the opera *Prince Igor*, which was finished after his death by Rimsky-Korsakov and Glazunov.

### **Bosch, Carl** (1874–1940) *German industrial chemist*

Born in Cologne, Germany, Bosch (bosh) was trained as both metallurgist and chemist and gained his doctorate under Johannes WISLIZENUS at Leipzig (1898). He joined the large German dyestuffs company, Badische Anilin und Soda Fabrik (BASF), in 1899. Following Fritz HABER’s successful small-scale ammonia synthesis in 1909, Bosch began to develop a high-pressure ammonia plant at Oppau for BASF. The plant was opened in 1912 – a successful application of the Haber process on a large scale. Bosch also introduced the use of the water-gas shift reaction as a source of hydrogen for the process:

After World War I the large-scale ammonia fertilizer industry was established and the high-pressure technique was extended by BASF to the synthesis of methanol from carbon monoxide and hydrogen in 1923. Bosch was chairman of BASF’s successor, IG Farben (1935–40) and concurrently director of the Kaiser Wilhelm institutes. He shared the Nobel Prize for chemistry with Friedrich BERGIUS in 1931.

### **Bose, Sir Jagadis Chandra** (1858–1937) *Indian plant physiologist and physicist*

Bose (bohs), who was born in Mymensingh (which is now in Bangladesh), began his studies in London as a medical student. He then won a scholarship to Cambridge University, from where he graduated in natural sciences in 1884. He was appointed professor of physical science at Presidency College, Calcutta, in 1885 and retained this post until 1915. In 1917 he founded and became director of the Bose Research Institute, Calcutta. He was knighted in 1917 and in 1920 became the first Indian to be elected a fellow of the Royal Society.

Bose’s early research was on the properties of very short radio waves – work in which he showed their similarity to light. He also designed an improved version of Oliver LODGE’s coherer, then used to detect radio waves, and as a result was able to put forward a general theory of the properties of contact-sensitive materials.

His most famous work concerned his investigations into plant physiology and the similarities between the behavioral response of plant and animal tissue. By devising extremely sensitive instruments he was able to demonstrate the minute movements of plants to external stimuli and to measure their rate of growth. While his experimental skill was widely admired, this work did not at the time gain universal acceptance.

**Bose, Satyendra Nath** (1894–1974) *Indian physicist*

Bose was educated at Presidency College, in his native Calcutta. Among his teachers was the eminent Indian physicist Jagadis Chandra Bose. Bose held the post of lecturer at the Calcutta University College of Science from 1917 until he left in 1921 to become a reader in physics at the new University of Dacca in East Bengal. His work ranged over many aspects of physics, among them statistical mechanics, the electromagnetic properties of the ionosphere, theories of x-ray crystallography, and unified field theory. However it is for his work in quantum statistics that he is best known.

Bose attracted the attention of Albert EINSTEIN and other European physicists by publishing a paper in 1924 in which he was able to derive Max PLANCK's black body radiation law, but without using the classical electrodynamics as Planck himself had done. On the strength of this work Bose was able to get two years' study leave in Europe and during his visit he came into contact with many of the great physicists of the day, such as Louis de BROGLIE, Max BORN, and Einstein. Einstein's generalization of Bose's work led to the system of statistical quantum mechanics now known as *Bose–Einstein statistics* and the prediction of a phase transition at low temperatures to a state known as a *Bose–Einstein condensate*. This state was first observed in the late 20th century. The Bose–Einstein system of statistics contrasts with the rival Fermi–Dirac statistics in that it applies only to particles not limited to single occupancy of the same state, i.e., particles (known as bosons) that do not obey the Pauli exclusion principle.

**Boss, Lewis** (1846–1912) *American astronomer*

The standard positions and proper motions of all stars brighter than the seventh magnitude, extending from the north to the south pole, and some thousands of additional fainter stars promising to yield reasonably accurate proper motions.

—Describing the contents of the *General Catalogue* (1937)

Boss, who was born in Providence, Rhode Island, studied at Dartmouth College where he graduated in 1870. In 1872 he was appointed assistant astronomer to the 49th parallel survey for the American–Canadian boundary, accurately locating stations from which the surveyors could work with confidence. In 1876 Boss was appointed director of the Dudley Observatory, Albany, a post he held until his death in 1912.

While working on the parallel survey Boss became aware of the many errors made in the measurement of stellar positions, which thus caused the current catalogs to be inaccurate. He

consequently made his own observations, publishing the positions of 500 stars in 1878. He then undertook the observation and reduction of a zone for the Leipzig *Astronomische Gesellschaft* and also began work on his own catalog. This was published in 1910 as the *Preliminary General Catalogue* containing the position and proper motion of 6,188 of the brighter stars. His work was extended by his son, Benjamin Boss, who published in 1937 the *General Catalogue* containing comparable details of 33,342 stars.

**Bothe, Walther Wilhelm Georg Franz** (1891–1957) *German atomic physicist*

Bothe (**boh**-te), who was born in Oranienburg, Germany, studied at the University of Berlin under Max PLANCK and received his PhD in 1914. For the next few years, he was a prisoner of war in Russia but, on his return to Germany in 1920, he started teaching at Berlin and worked in Hans GEIGER's radioactivity laboratory.

He devised the “coincidence method” of detecting the emission of electrons by x-rays in which electrons passing through two adjacent Geiger tubes at almost the same time are registered as a coincidental event. He used it to show that momentum and energy are conserved at the atomic level. In 1929 he applied the method to the study of cosmic rays and was able to show that they consisted of massive particles rather than photons. For this research he shared the 1954 Nobel Prize for physics with Max BORN.

By 1930 his reputation was established and he was appointed professor of physics at Giessen. The same year he observed a strange radiation emitted from beryllium when it was exposed to alpha particles. This radiation was later identified by CHADWICK as consisting of neutrons.

While director of the Max Planck Institute in Heidelberg, Bothe supervised the construction of Germany's first cyclotron. This work was finished in 1943 and during World War II he led German scientists in their search for atomic energy. When the war ended he was given the chair of physics at Heidelberg, which he retained until his death.

**Boucher de Crevecoeur de Perthes, Jacques** (1788–1868) *French archeologist*

Boucher de Perthes (**boo-shay** de pairt) was born in Rethel, France, the son of a customs official, and followed in his father's profession. In 1825 he was appointed director of the Abbeville customs, a post he occupied for his entire career.

His hobby was investigating the fossil-rich beds of the nearby Somme Valley and in *Antiquités celtiques et antédiluviennes* (3 vols. 1847–64; Celtic Antediluvian Antiquities) Boucher de Perthes first revealed the existence

of a prehistoric world occupied by man. He reported finding such objects as polished stone axes, which he attributed to the people he called "celtiques," and also older tools linked with the remains of extinct mammalian species. These he claimed must have belonged to "homme antédiluvien."

Inevitably such revolutionary ideas initially received little support in France where Georges CUVIER's views still dominated evolutionary thinking. British scientists were more sympathetic, and in 1859 Boucher de Perthes's views were publicly and authoritatively acknowledged before the Royal Society by two British geologists, Joseph PRESTWICH and Hugh Falconer. Later evidence that some of the finds at Abbeville were forgeries tended to discredit Boucher de Perthes's early work, even though it was never satisfactorily established whether or not he played a part in producing the fakes.

**Bouguer, Pierre** (1698–1758) *French physicist and mathematician*

Bouguer (boo-gair), the son of a hydrographer and mathematician, was born in Le Croisic, France, and followed into his father's profession. He was a child prodigy and obtained a post as professor of hydrography at the remarkably early age of 15. The study of the problems associated with navigation and ship design was his chief interest. Bouguer took part in an extended expedition to Peru led by Charles de la Condamine to determine the length of a degree of the meridian near the equator. While on this expedition Bouguer also did a great deal of other valuable experimental work.

One of Bouguer's most successful inventions was the heliometer to measure the light of the Sun and other luminous bodies. Although it was not his chief interest the research for which Bouguer is now best remembered was on photometry. Here too he did much valuable experimental work and one of his major discoveries was of the law now named for him. This states that in a medium of uniform transparency the intensity of light remaining in a collimated beam (i.e., a beam of light in which all the rays are parallel) decreases exponentially with the length of its path in the medium. The law is sometimes unjustly attributed to Johann LAMBERT. Bouguer's work in optics can be seen as the beginning of the science of atmospheric optics.

**Boulton, Matthew** (1728–1809) *British engineer*

I shall never forget Mr. Boulton's expression to me: "I sell here, Sir, what all the world desires to have – POWER." He had about seven hundred people at work. I contemplated him as an iron chieftain, and he seemed to be a father to his tribe.

—James Boswell, *The Life of Samuel Johnson* (1791)

Boulton, who was born in the industrial city of Birmingham in central England, was the manufacturer who supported and financed James WATT's steam engine. He had founded a small factory at Soho near Birmingham (1762), which produced metal articles, and realized that better power sources were needed. He met James Watt in 1768 and recognized the potential of Watt's engine. They became partners in 1775. In 1786 he designed steam-powered coining machinery, which was patented in 1790, and supplied machinery to the Royal Mint and coins to the East India Company.

**Bourbaki, Nicolas** *French group of mathematicians*

Structures are the weapons of the mathematician.

"Bourbaki" (**bor**-ba-kee) is the collective *nom de plume* of a group of some of the most outstanding of contemporary mathematicians. The precise membership of Bourbaki, which naturally has changed over the years, is a closely guarded secret but it is known that most of the members are French.

Since 1939, Bourbaki has been publishing a monumental work, the *Eléments de mathématique* (Elements of Mathematics), of which over thirty volumes have so far appeared. In this Bourbaki attempts to expound and display the architecture of the whole mathematical edifice starting from certain carefully chosen logical and set-theoretic concepts. The emphasis throughout the *Eléments* is on the interrelationships to be found between the various structures present in mathematics, and to a certain extent this means that Bourbaki's exposition cuts across traditional boundaries, such as that between algebra and topology. Indeed for Bourbaki, pure mathematics is to be thought of as nothing other than the study of pure structure.

Since the members of Bourbaki are all working mathematicians, rather than pure logicians, in contrast to other foundational enterprises (e.g., those of Gottlob FREGE, Bertrand RUSSELL, and A. N. Whitehead) the influence of Bourbaki's writings on contemporary mathematicians and their conception of the subject has been immense.

**Boussingault, Jean Baptiste** (1802–1887) *French agricultural chemist*

Born in Paris, France, Boussingault (boo-sang-goh) began his career as a mineralogist after studying at the mining school there. He spent several years in Latin America, where he is reported to have fought in the wars of independence under Bolívar. He returned to France in 1832 and shortly afterward became professor of chemistry at Lyons. In 1839 he moved to the

Sorbonne in Paris. Boussingault entered politics in 1848 but returned to chemistry after the coup of 1851. Between 1860 and 1874 he published a comprehensive eight-volume work on agricultural chemistry.

His most important work was on the role of nitrogen in plants. In 1837 he began a series of experiments proving that leguminous plants (peas, clover, etc.) are capable of using atmospheric nitrogen. By growing a wide variety of plants in nitrogen-deficient soils he was able to show that grains could not support themselves but that the legumes could survive (he was not sure how the nitrogen was taken up by the plants). He further demonstrated that animals could not utilize atmospheric nitrogen when living on nitrogen-free diets.

In 1864 Boussingault made the fundamental discovery that the volume of carbon dioxide absorbed by a plant is equal to the volume of oxygen given out.

**Boveri, Theodor Heinrich** (1862–1915)  
*German zoologist*

Boveri (boh-vay-ree) was born in Bamberg, Germany, and graduated in medicine from Munich in 1885. He remained at Munich to do cytological research until his appointment as professor of zoology and comparative anatomy at Würzburg in 1893. In 1888, he coined the term *centrosome* for the region of the cell that contains the centriole, first discovered by Edouard van BENEDEN. Boveri also proved Beneden's theory that equal numbers of chromosomes are contributed by the egg and the sperm to the zygote. Boveri accurately described the formation of the polar bodies following meiosis in the egg cell, and made pioneering studies of sperm formation (spermatogenesis), introducing a diagrammatic representation of the process (1892), which is still in use today.

**Bovet, Daniel** (1907–1992) *Swiss-Italian pharmacologist*

Bovet (boh-vay) was born in Neuchâtel, Switzerland. In 1929 he gained a DSc in zoology and comparative anatomy from the University of Geneva where his father was professor of pedagogy. He continued research work at the Pasteur Institute in Paris, serving as director from 1936 until 1947 and following up the discoveries of Gerhard DOMAGK on prontosil. He and his coworkers were able to show that the sulfonamide group is responsible for the antibacterial action of prontosil. The drug is only active *in vivo* as the animals metabolize the parent drug into sulfanilamide, which is the antibacterial compound.

Prontosil was a dye, protected by patents and expensive. Sulfanilamide was colorless, freely available, cheap to manufacture, and

equally as effective as a bactericide. Many analogs, known as sulfa-drugs, have been made and these are widely used against streptococcal infections such as pneumonia, meningitis, and scarlet fever.

These researches led Bovet to develop the earlier ideas of Paul EHRlich, Emil FISCHER, and Juda Quastel into a more refined "antimetabolite hypothesis," which is one of the fundamental lines of approach in modern drug research. It is based on the idea that a chemical compound whose properties and molecular shape resemble those of a normal body metabolite may affect the functions of that metabolite. Just as a lock (a metabolic reaction) is opened by just one shape of key (a metabolite) so another slightly different shape of key (an antimetabolite) may jam the lock and prevent the new key from fitting. These ideas led Bovet to develop the antihistamine drug "933F" in 1937 and this gave rise to a series of drugs that are useful for asthma and hay fever.

Later, after a trip to Brazil, Bovet became interested in the Indian nerve poison curare. The structure of curare had already been worked out and in 1946 Bovet began work on analogs, which led to the use of succinylcholine as a muscle relaxant in surgical operations.

In 1947 Bovet became head of pharmacology and chemotherapeutics at the Superior Institute of Health in Rome, where he remained until 1964, when he was appointed professor of pharmacology at the University of Sassari. He became an Italian citizen and in his later years carried out research work on tranquilizers and anesthetics. In 1971 he accepted the chair of psychobiology at the University of Rome, finally retiring in 1982. He was awarded the Nobel Prize for physiology or medicine in 1957 for his work on curare and antihistamines.

**Bowen, Edmund John** (1898–1980)  
*British physical chemist*

Bowen, who was born in Worcester, England, spent his entire career at Oxford University, beginning in 1915 as a student at Balliol College and continuing after graduation as a fellow of University College from 1922 until his retirement in 1965.

He worked mainly on photochemistry, investigating a large number of photochemical reactions and producing a survey of the subject, *Chemical Aspects of Light* (1942). He also produced, with F. Wokes, the more specialized *The Fluorescence of Solutions* (1953) and edited and contributed to *Luminescence in Chemistry* (1968).

**Bowen, Ira Sprague** (1898–1973) *American astronomer*

Bowen, who was born in Seneca Falls, New York, graduated from Oberlin College, Chicago

in 1919 and gained his PhD from the California Institute of Technology, Pasadena, in 1926. He taught physics at Cal Tech from 1921 to 1945, serving from 1931 as professor. In 1946 he was made director of the Mount Wilson Observatory and in 1948 of the newly opened Palomar Observatory, posts he continued to hold until his retirement in 1964.

In 1928 Bowen tackled the problem of the strange lines first observed by William HUGGINS in the 1860s in the spectrum of planetary nebulae and the Orion nebula. The difficulty was, according to Bowen, that the strong lines had not been reproduced in the laboratory. Spectrographic evidence showed that such lines must be emitted by an element of low atomic weight. Talk of a new element, known as "nebulium," that could produce the observed spectral lines was however dismissed by Bowen as nonsense.

Bowen was able to show that the lines were in fact due to radiation emitted from ionized atoms of oxygen and nitrogen as they decayed into more stable lower-energy levels. Specifically he was able to show that triply and doubly ionized oxygen as well as doubly ionized nitrogen would radiate at the wavelengths attributed to "nebulium" but only in the highly rarefied conditions of nebulae where collisions between atoms are very infrequent. It is this radiation that contributes to the green and red colors observed in emission and planetary nebulae.

**Bowman, Sir William** (1816–1892)  
*British physician*

Bowman, who was born at Nantwich, Cheshire, in England, studied medicine at King's College, London, and in 1840 was appointed assistant surgeon at the newly founded King's College Hospital. His main interest was the investigation of the microscopic structure of tissues (histology). Although he studied voluntary (striated) muscle and liver, it is for his work on the kidney that Bowman is best known. He showed that the capsule (now called Bowman's capsule) that surrounds the bunch of blood capillaries (glomerulus) in each Malpighian corpuscle is continuous with the renal tubule, which in turn leads to the collecting ducts and ultimately to the ureter. This piece of structural evidence prompted him to propose that fluid passed from the glomerulus into the tubule. He reported his findings in his famous paper, *On the Structure and Use of the Malpighian Bodies of the Kidney* (1842).

In the following years, he increasingly devoted his attentions to eye surgery and in 1846 became assistant surgeon at the Royal London Ophthalmic Hospital (now Moorfields Eye Hospital) and full surgeon in 1851. One of the most celebrated eye surgeons of his day, he introduced the newly invented ophthalmoscope into

his practice and described many anatomical features of the eye including the basement membrane of the cornea and the radial fibers of the ciliary muscle, both of which bear his name. He also advanced techniques in eye surgery.

Bowman's *The Physiological Anatomy and Physiology of Man* (5 vols. 1845–56), which he wrote with his teacher, Robert Todd, was one of the first texts in which histology assumed real significance in medicine and testifies to the valuable contribution of its author. A popular lecturer with his students, Bowman was also a methodical and kindly practitioner. In 1880 he founded the Ophthalmological Society and was its first president. He was knighted in 1884.

**Boyd, William Clouser** (1903–1984)  
*American biochemist*

Boyd was born in Dearborn, Missouri, and educated at Harvard and Boston, where he obtained his PhD in 1930. He later taught in the medical school there, serving as professor of immunochemistry from 1948 until his retirement in 1969.

Karl LANDSTEINER's discovery of blood groups in 1902 and subsequent studies of their global distribution permitted a far more accurate estimate of racial types than had previously been possible. To this end Boyd began the systematic collection and analysis of blood samples from all over the world.

Eventually, in the 1950s, in such works as *Genetics and the Races of Man* (1950) he began to present evidence for the existence of 13 races – early European, northern and eastern European, Lapp, Mediterranean, African, Asian, Dravidian, Amerind, Indonesian, Melanesian, Polynesian, and Australian aborigine.

**Boyer, Herbert Wayne** (1936– )  
*American biochemist*

Boyer was born in Pittsburgh, Pennsylvania, and educated at St. Vincent College, Latrobe, and the University of Pittsburgh where he obtained his PhD in 1963. He joined the faculty of the University of California, San Francisco, shortly afterward in 1966 and served as professor of biochemistry from 1976 to 1991.

Much of Boyer's work has been concerned with developing some of the basic techniques of recombinant DNA, known more popularly as genetic engineering. Thus in 1973 he succeeded with Robert Helling, and independently of the work of Stanley COHEN and Annie Chang, in constructing functional DNA from two different sources. Such chimeras, as they became called, were initially engineered by splicing together segments from two different plasmids (extrachromosomal DNA found in some bacteria) from the *Escherichia coli* bacillus. The chimera was then inserted into *E. coli* and was found to

replicate and, equally significant, to express traits derived from both plasmids.

Development after 1973 was so rapid that by 1976 it had occurred to Boyer and a number of other workers that recombinant DNA could be used to produce such important proteins as insulin, interferon, and growth hormone in commercial quantities. Consequently in 1976 he joined with financier Robert Swanson to invest \$500 each to form the company Genentech, which went public in 1980.

Despite successfully developing techniques for the production of somatostatin in 1977, insulin in 1978, and growth hormone in 1979, the position of Genentech was far from secure at the beginning of 1981 with the emergence of competition from a number of rival companies and legal problems concerned with the ownership of genes.

In 2004 Boyer and Stanley Cohen received the Albany Medical Center Prize in Medicine and Biomedical Research for their pioneering work in gene splicing and recombination.

**Boyer, Paul D.** (1918– ) *American biochemist*

Boyer was born in Provo, Utah, and educated at Brigham Young University. He obtained his PhD in 1943 from the University of Wisconsin-Madison and worked first at Stanford and later at the University of Minnesota. In 1963 he became professor of chemistry and biochemistry at the University of California, Los Angeles. His main research has been on the elucidation of the enzyme mechanism for the synthesis of adenosine triphosphate. For this research, Boyer shared the 1997 Nobel Prize for chemistry with John WALKER. The prize was also shared with Jens SKOU.

**Boyle, Robert** (1627–1691) *British chemist and physicist*

... to beget a good understanding 'twixt the chymists and the natural philosophers.

—The stated aim of his *Essay on Nitre* (1664)

The son of the Earl of Cork, and born at Lismore Castle, now in the Republic of Ireland, Boyle was a member of an aristocratic and wealthy family. He spent four years at Eton College and from 1638 studied at Geneva, returning to London in 1644. He then retired to his estate at Stalbridge, Dorset, where he took up the life of a scientific “virtuoso.”

In 1654 Boyle moved to Oxford, where he worked on pneumatics. In 1658–59 he had an air pump built for him by Robert HOOKE, after the type invented by Otto von GUERICKE in 1654. Boyle was ably assisted by Hooke in various pioneering experiments in which he showed that air was essential for the transmission of sound, and for respiration and com-

bustion – and that the last two processes exhausted only part of the air.

In Boyle's most famous experiment he took a U-shaped tube with a shorter closed end, and a longer open end into which he poured mercury, thus isolating a given volume of air in the shorter end. When the mercury was level in both “limbs” the air was under atmospheric pressure, and by adding more mercury to the longer limb the pressure could be increased. Boyle found that the volume was halved if the pressure was doubled, reduced to a third if the pressure was tripled, and so on – and that this process was reversible. Boyle's work on the compressibility of air was published in *New Experiments Physico-Mechanicall, Touching the Spring of the Air and its Effects* (1660) but the famous law stating that the pressure and volume of air are inversely proportional was not stated explicitly until the second edition (1662). The law, known as *Boyle's law* in America and Britain but in Europe as *Mariotte's law*, can be expressed (where  $C$  is a constant) as  $p \times V = C$ ; that is, the product of the pressure and volume of a gas remains constant if, as Edmé Mariotte noted, the temperature remains constant. This law (together with its companion gas law, that of Jacques CHARLES) is true only for ideal gases, but approximately holds for real gases at very low pressures and at high temperatures.

Boyle developed a mechanical corpuscular philosophy of his own, derived from the Greek tradition and the work of GALILEO and Pierre GASSENDI. In Boyle's conception all physical phenomena could be explained by corpuscles of different shapes, sizes, and motions, this corpuscular matter being capable of infinite transformations (which allowed the possibility of alchemy and excluded the existence of elements).

However, in *The Sceptical Chymist* (1661) Boyle proposed a view of matter that presaged modern views and certainly disposed effectively of the Aristotelian doctrine of the four elements. He supposed that all matter was composed of primary particles, some of which joined together to form semi-indivisible corpuscles and whose organization and motion explained all qualities of matter.

Boyle's main contribution to chemistry was his insistence on experiment, precision, and accurate observation. He devised many analytical tests including the use of vegetable dyes as acid–base indicators and of flame tests to detect metals. The chemist's concern for the purity of his materials began with Boyle. Although he prepared hydrogen by the action of acids on iron and observed the oxidation of mercury and its subsequent regeneration on further heating, the “fixation” of gases in bodies remained unexplained in his work. Likewise, he observed the increase in weight of metals on calcination but attributed this to heat, which he sometimes regarded as material.

Boyle left Oxford for London in 1668 where, despite his scholarly nature and poor health, he was very much at the center of scientific life as a founder member of the Royal Society. He believed, like his hero Francis BACON, that science could be put to practical use.

**Boys, Sir Charles Vernon (1855–1944)**  
*British physicist*

The son of a clergyman, Boys was born in Wing in the eastern English county of Rutland and educated at the Royal School of Mines, London. He later taught at the Royal College of Science, South Kensington. Boys left the College in 1897 to take up the appointment of Metropolitan gas referee, a post that he held until 1939 when the job was abolished. The post was something of a sinecure, and required Boys to do little more than supervise the work of his assistants and to monitor methods used to test the quality of the gas the Board supplied to its customers. Boys also found time to establish himself as an expert witness, appearing in numerous patent and other technical disputes.

Boys is best known for his determination of the gravitational constant in 1897. The measurement was first made by Henry CAVENDISH in 1797 and was expressed in terms of the Earth's density. NEWTON had proposed a density between five and six in 1687; Cavendish found experimentally a density of 5.448.

Whereas Cavendish had used a six-foot beam in his torsion rod experiment, Boys opted for a mere nine inches. The decrease in size was made possible by using some exceedingly fine quartz fibers in the torsion balance. Boys drew these fine filaments by attaching the end of an arrow to a piece of molten quartz and firing it with a crossbow. As a result uniform temperatures were easier to maintain, and convection current disturbances were minimized. Boys calculated on the basis of his measurements that two 1-gram point masses 1 centimeter apart would attract each other with a force of  $6.6576 \times 10^{-8}$  dyne, and consequently the density of the Earth would be  $5.527 \text{ g/cm}^3$ , figures which compare well with the modern figure of  $6.670 \times 10^{-8}$  dyne, and  $5.517 \text{ g/cm}^3$ .

There are a number of other instruments linked to Boys. Among these are an integrator (1881) for mechanical integration, a radiometer (1890) for measuring stellar radiation, a rotating lens camera (1900) for photographing the flight of a bullet, and, in his capacity as gas referee, an improved calorimeter to measure the calorific value of gas (1905).

**Brachet, Jean Louis Auguste (1909–1998)**  
*Belgian cell biologist*

Brachet (bra-shay) was educated at the Free University in his native city of Brussels where his father, an embryologist, was rector. After

gaining his MD in 1934 he joined the faculty as an anatomy instructor and in 1943 was appointed professor of general biology.

Brachet began his career by studying the then poorly understood nucleic acids. It had been thought that plant cells contain RNA and animal cells DNA but, in 1933, Brachet demonstrated that both types of nucleic acid occur in both plant and animal cells. He proved this by developing a cytochemical technique that made it possible to localize the RNA-containing structures in the cell. Brachet also noted that cells rich in RNA tend to be those actively engaged in protein synthesis. On this basis Brachet was led in 1942 to propose the important hypothesis that ribonucleoprotein granules could be the agents of protein synthesis. Such granules, later termed ribosomes, were indeed shown to function in this way by George PALADE in 1956.

Later experiments, in which Brachet removed the nucleus from the cell, showed that although protein synthesis continued for a while the amount of RNA in the cytoplasm decreased until there was none left. This indicated that the production of RNA occurs in the nucleus and that it is then transported from the nucleus to the cytoplasm.

**Braconnot, Henri (1781–1855)**  
*French naturalist and biochemist*

Born in Commercy, France, and educated at Strasbourg and at Paris, Braconnot (bra-con-noh) became professor of natural history at the Lyceum, Nancy, and director of the botanical gardens. Braconnot was interested in the chemical makeup of plants and discovered (1819) a means of obtaining glucose from various plant products lacking in starch, such as tree bark and sawdust. (Until then, glucose had been obtained by boiling starch with acid.) The nonstarch material was later isolated and named cellulose by Anselme PAYEN. Braconnot also did work on saponification and discovered some of the acids occurring in plants.

**Bradley, James (1693–1762)**  
*British astronomer*

Bradley was born in Sherborne in Dorset, England, and educated at Oxford University. He was taught astronomy by his uncle, the Rev. James Pound, who was also an astronomer. In 1721 Bradley became Savilian Professor of Astronomy at Oxford and in 1742 he succeeded Edmond HALLEY as Astronomer Royal. His astronomical career began with a determined effort to detect parallax – the angular displacement of a body when viewed from spatially separate positions (or, more significantly, one position on a moving Earth). He fixed a telescope in as vertical a position as possible to minimize the effects of atmospheric refraction and began to observe the star Gamma Draco-

nis. He soon found that the star had apparently moved position but prolonged observation convinced him that it could not be parallax he had measured, for he found the greatest shift in position in September and March and not in December and June as it should have been if he was observing parallax. However, the change in position was so regular (every six months) that it could be due only to the observer being on a moving Earth. It took him until 1729 to find the precise cause of the change in position. He realized that as light has a finite speed it will therefore take some time, however small, to travel down the length of the telescope. While it is traveling from the top to the bottom of the telescope the bottom of the instrument will have been carried by the orbital motion of the Earth. The image of the star will therefore be slightly displaced. Bradley realized that he had at last produced hard observational evidence for the Earth's motion, for the finite speed of light, and for a new aberration that had to be taken into account if truly accurate stellar positions were to be calculated. He worked out the constant of aberration at between  $20''$  and  $20''.5$  – a very accurate figure. He also discovered another small displacement, which, because it had the same period as the regression of the nodes of the Moon, he identified as the result of the  $5^\circ$  inclination of the Moon's orbit to the ecliptic. This caused a slight wobble of the Earth's axis, which he called *nutation*. Friedrich BESSEL later used Bradley's observations to construct a catalog of unprecedented accuracy.

### **Bragg, Sir William Henry** (1862–1942) *British physicist*

Physicists use the wave theory on Mondays, Wednesdays, and Fridays, and the particle theory on Tuesdays, Thursdays, and Saturdays.

—Quoted by A.L. Mackay in *The Harvest of a Quiet Eye* (1977)

Bragg's father was a merchant seaman turned farmer. William Henry Bragg was born in Westwood in England and educated at a variety of schools before going as a scholar to Cambridge University. He graduated in 1884 and after a year's research under J. J. THOMSON took the chair of mathematics and physics at the University of Adelaide, Australia, in 1886. He returned to England as professor of physics at Leeds University in 1909, moving from there to University College, London, in 1915.

In Australia, Bragg concentrated on lecturing and started original research late in life (in 1904). He first worked on alpha radiation, investigating the range of the particles. Later he turned his attention to x-rays, originally believing (in opposition to Charles Barkla) that they were neutral particles. With the observation of x-ray diffraction by Max VON LAUE, he ac-

cepted that the x-rays were waves and constructed (1915) the first x-ray spectrometer to measure the wavelengths of x-rays. Much of his work was on x-ray crystallography, in collaboration with his son, William Lawrence Bragg. They shared the Nobel Prize for physics in 1915.

During the war Bragg worked on the development of hydrophones for the admiralty. In some ways his most significant work was done at the Royal Institution, London, where he was director from 1923. Under James DEWAR's directorship the research functions of the Royal Institution had virtually disappeared. Bragg recruited several young and brilliant crystallographers who shared with him a commitment to applying the new technique to the analysis of organic compounds. There was no reason to suppose there was much chance of success but as early as the 1920s Bragg was planning to investigate biological molecules with x-rays. His first attempts were made on anthracene and naphthalene in 1921.

### **Bragg, Sir William Lawrence** (1890–1971) *British physicist*

The important thing in science is not so much to obtain new facts as to discover new ways of thinking about them.

—Quoted by A. Koestler and J. R. Smithies in *Beyond Reductionism* (1958)

William Lawrence Bragg was the son of William Henry Bragg. Born in Adelaide, Australia, he was educated at the university there and at Cambridge University, where he became a fellow and lecturer. After the war, in 1919, he was appointed professor of physics at Manchester University. He succeeded Ernest RUTHERFORD in 1938, after a short period in 1937 as director of the National Physical Laboratory, as head of the Cavendish Laboratory and Cavendish Professor at Cambridge. Finally, in 1953, he became director of the Royal Institution, London, a post his father had held previously and which he held until his retirement in 1961.

Success came very early to Bragg, who shared the Nobel Prize for physics with his father in 1915. Following Max VON LAUE's discovery of x-ray diffraction by crystals in 1912, Lawrence Bragg in the same year formulated what is now known as the *Bragg law*:

$$n\lambda = 2d \sin \theta$$

which relates the wavelength of x-rays ( $\lambda$ ), the angle of incidence on a crystal  $\theta$ , and the spacing of crystal planes  $d$ , for x-ray diffraction.  $n$  is an integer (1, 2, 3, etc.).

Bragg collaborated with his father in working out the crystal structures of a number of substances. Early in this work they showed that sodium chloride does not have individual molecules in the solid, but is an array of sodium

and chloride ions. In 1915 the Braggs published their book *X-rays and Crystal Structure*.

Lawrence Bragg later worked on silicates and on metallurgy. He was responsible for setting up a program for structure determinations of proteins.

### **Brahe, Tycho** (1546–1601) *Danish astronomer*

Now it is quite clear to me that there are no solid spheres in the heavens, and those that have been devised by the authors to save the appearances, exist only in the imagination, for the purpose of permitting the mind to conceive the motion which the heavenly bodies trace in their courses.

—*De mundi aetherei recentioribus phaenomenis* (1588; On the Most Recent Phenomena of the Aetherial World)

Tycho (**tee**-koh), whose father Otto was the governor of Helsingborg castle, was born in Knudstrup, Denmark. Kidnapped by and brought up by his uncle Jörgen, an admiral in the Danish navy, he was sent to Leipzig University in 1562 to study law. However, his interest in astronomy had already been kindled. He witnessed a partial solar eclipse in 1560 in Copenhagen whose predictability so impressed him that he began a serious study of PTOLEMY'S *Almagest*. He was allowed to continue with the formal study of astronomy and began a tour of the universities of northern Europe. It was while at Rostock in 1566 that, according to tradition, he became involved in a dispute with another young Danish nobleman over who was the better mathematician. The dispute led to a duel in which Tycho lost part of his nose. This he replaced with a mixture of gold, silver, and wax; the nose is clearly visible in contemporary engravings.

Tycho became aware that the successful solar-eclipse prediction of 1560 was not a typical index of the state of 16th-century astronomy. For instance, a conjunction of Jupiter and Saturn predicted by current tables was wrong by ten days. Tycho therefore began his long apprenticeship, traveling through northern Europe meeting the astronomers, instrument makers, and patrons who would support him later on.

His international reputation was made with the dramatic events that centered upon the nova of 1572 – ever since known as *Tycho's star*. Not since the days of HIPPARCHUS (second century BC) had a new star visible to the naked eye appeared in the sky. In *De nova stella* (1573; On the New Star), Tycho was able to demonstrate that the new star showed no parallax and therefore truly belonged to the sphere of the fixed stars. This was important cosmologically because according to ARISTOTLE no change could take place in the heavens, which were supposed to be eternal and incorruptible; change could take place only in the sublunary

sphere. By demonstrating that the new star of 1572 and the great comet of 1577 were changes in the heavens, Tycho was providing new evidence against the traditional Aristotelian cosmology.

In order to induce him to stay in Denmark, Tycho's monarch, Frederick II, offered him the island of Hven and unlimited funds to build an observatory there at Uraniborg. Tycho moved there in 1577, building an observatory/castle stocked with the best instruments then in existence, and constructing enormous quadrants and sextants. He became the greatest observational astronomer of the pretelescopic age. Before Tycho, astronomers tended to work with observations many centuries old. COPERNICUS would be more likely to use the tables of Ptolemy (second century AD) than to make his own observations. When modern tables, such as the *Prutenic Tables* of Erasmus REINHOLD, were constructed, although based on the Copernican system, they were scarcely more reliable. Tycho changed all this. Twenty years' careful observation using accurate instruments enabled him to determine the positions of 777 stars with unparalleled accuracy. He did not, however, accept the Copernican heliocentric system. Instead he proposed a compromise between that and the Ptolemaic, suggesting that the Earth remains at the center, immobile; the Sun and Moon move round the Earth; and all other bodies move round the Sun. His system received hardly any support.

After the death of Frederick II in 1588, Tycho quarreled with his successor, Christian IV, on his coming of age. The last recorded observation made at Hven was on 15 March 1596. Tycho set off once more on his travels, this time encumbered by his enormous instruments. Eventually he found a new patron, one even stranger than himself, the mad Holy Roman Emperor Rudolph II. Tycho was made Imperial Mathematician in 1599, given yet another castle at Benatek outside Prague, and, more important, given the young Johannes KEPLER as an assistant. Although the relationship was a stormy one, both benefited enormously. Tycho died suddenly in 1601 after a short illness leaving Kepler to publish Tycho's *Rudolphine Tables* posthumously in 1627. His last words were: "Let me not seem to have lived in vain." That such a fear was groundless is witnessed on the title page of Kepler's great work, *Astronomia nova* (New Astronomy):

"Founded on observations of the noble Tycho Brahe."

### **Brahmagupta** (c. 598–c. 665) *Indian mathematician and astronomer*

Brahmagupta (brah-ma-**guup**-ta) was the director of the observatory at Ujjain, a town in central India. In 628 he wrote the *Brahmasphuta-siddhānta* (The Opening of the Universe)

half of which is about mathematics and half about astronomy. He introduced negative numbers into India, gave a satisfactory rule for the solution of quadratic equations, and attempted to apply algebra to astronomy. He discovered the formula for the area of a cyclic quadrilateral:

$$A = \sqrt{[s(s-a)(s-b)(s-c)(s-d)]}$$

where  $s$  is half the perimeter and  $a$ ,  $b$ ,  $c$ , and  $d$  are the lengths of the sides. One innovation introduced by him was the use of oval epicycles for Mars and Venus. He rejected the view that the stars are stationary and the Earth moves, on the grounds that any such movement would cause high buildings to fall.

**Braid, James** (1795–1860) *British physician*

Braid was born in Rylaw House, Scotland, and educated at Edinburgh University before becoming apprenticed to a doctor in Leith. On obtaining his medical diploma, he became a surgeon to colliery workers but later moved to Manchester where he established in practice as a surgeon. It was here that he began his scientific study of mesmerism – the induction of a trancelike state in a patient, first made famous by Anton MESMER. Braid discovered that by concentrating on a moving pendulum or similar object, a patient could enter into a state of what he termed “neurohypnotism,” which he later shortened to “hypnosis.” In his paper, *A Practical Essay on the Curative Agency of Neuro-Hypnotism* (1842), Braid suggested several therapeutic applications for his techniques, including the alleviation of pain and anxiety and the treatment of certain nervous diseases.

Although his work encountered criticism from some quarters, Braid undoubtedly influenced his successors, notably the French school of neuropsychiatry.

**Bramah, Joseph** (1748–1814) *British engineer and inventor*

A former cabinetmaker who was born in Stainborough, England, Bramah designed and built many of the machine tools that facilitated the expansion of British manufacturing in the 19th century. In order to make a pick-proof lock, he developed very precisely engineered tools, many of which were made by Henry MAUDSLAY, then a young blacksmith. Bramah displayed the lock in his shop window (1784) offering a prize to whoever could pick it. This was not achieved until 67 years later when a mechanic took 51 hours to open it.

Bramah also invented a hydraulic press, an improved toilet, a wood-planing machine, and a machine for numbering banknotes.

**Brambell, Francis William Rogers** (1901–1970) *British zoologist*

Brambell, who was born in Sandycove, now in the Republic of Ireland, gained both his BA and PhD from Trinity College, Dublin. He then worked successively at University College and King's College, London. In 1930 he became professor of zoology at Bangor University, remaining there until his retirement in 1968.

Brambell's work on prenatal mortality in wild rabbits led to his discovery that protein molecules are transferred from mother to fetus not through the placenta as previously supposed but by the uterine cavity and fetal yolk sac. He further found that this process is selective; for example the gamma globulins are transferred more readily than other serum proteins. Such work is important in studies of resistance to disease in the newborn and of hemolytic diseases of infants. For this work Brambell received the Royal Medal of the Royal Society of London in 1964.

**Brand, Hennig** (about 1670) *German alchemist*

Brand (brant) is remembered as the discoverer of phosphorus, probably in 1669 in Hamburg, Germany, and as such the first known discoverer of an element. The discovery was of particular importance because few new elements had been discovered since classical times. True to the traditions of alchemy, Brand kept his method secret but samples and hints on the method were obtained by Johann Daniel Kraft and Johann Kunckel. The latter prepared phosphorus independently in 1676 by the distillation of concentrated urine with sand but still the method remained unpublished. Eventually, Robert BOYLE, having obtained a sample from Kraft, repeated the isolation; naming the substance *aerial noctiluca* (substance that shines by night in air), he published his findings in a book of the same title (1680).

**Brandt, Georg** (1694–1768) *Swedish chemist*

Brandt (brant) was the son of an ironworker and former apothecary in Riddarhyta, Sweden, and from an early age he helped his father with metallurgical experiments. He studied medicine and chemistry at Leiden, and gained his MD at Rheims in 1726. He was later made warden of the Stockholm mint (1730), and professor of chemistry at the University of Uppsala.

In 1733 he systematically investigated arsenic and its compounds. He invented the classification of semimetals (now called metalloids), in which he included arsenic, bismuth, antimony, mercury, and zinc.

In 1735 Brandt postulated that the blue color of the ore known as smalt was due to the presence of an unknown metal or semimetal. He

named this “cobalt rex” from the Old Teutonic “kobold,” originally meaning “demon,” later applied to the “false ores” that did not yield metals under the traditional processes. In 1742 Brandt isolated cobalt, and found it was magnetic and alloyed readily with iron. His results were confirmed in 1780 by Torbern BERGMAN, who first obtained fairly pure cobalt.

Brandt also, in 1748, experimented with the dissolution of gold in hot concentrated acid, and with its precipitation from solution. These experiments clarified some of the alleged transmutations of silver into gold. Indeed, Brandt devoted his later years to exposing fraudulent transmutations of metals into gold, and it was said of him that no chemist did more to combat alchemy.

**Brans, Carl Henry** (1935– ) *American mathematical physicist*

Brans was born in Dallas, Texas, and graduated in 1957 from Loyola University, Louisiana. Having obtained his PhD from Princeton in 1961, he returned to Loyola in 1960 and in 1970 was appointed professor of physics.

Brans has worked mainly in the field of general relativity. He is best known for his production with Robert DICKE in 1961 of a variant of EINSTEIN's theory in which the gravitational constant varies with time. A number of very accurate measurements made in the late 1970s has failed to detect this and some of the other predictions made by the *Brans-Dicke theory*.

**Brattain, Walter Houser** (1902–1987) *American physicist*

Brattain, who was born in Amoy, China, was brought up on a cattle ranch. He was educated at Whitman College, at the University of Oregon, and at Minnesota, where he obtained his PhD in 1929. He immediately joined the Bell Telephone Company with which he worked as a research physicist until his retirement in 1967. After leaving Bell, Brattain taught at Whitman College doing research there on phospholipids.

Brattain's main field of work was the surface properties of semiconductors. It was known that a junction at a semiconductor would rectify an alternating current and that this effect was a surface property. Brattain was particularly interested in using semiconductors to amplify signals. Working with John BARDEEN, he investigated various arrangements for achieving this – originally studying silicon in contact with electrolytes, but later using germanium in contact with gold. Their first efficient point-contact transistor (1947) consisted of a thin wafer of germanium with two close point contacts on one side and a large normal contact on the other. It had a power amplification of 18. Bardeen and Brattain shared the 1956 Nobel

Prize for physics with William SHOCKLEY for their development of the transistor.

**Braun, Karl Ferdinand** (1850–1918) *German physicist*

Braun (brown), who was born in Fulda, Germany, studied at Marburg and, in 1872, received a doctorate from the University of Berlin. He taught in various university posts. In 1885 he became professor of experimental physics at Tübingen and in 1895 he became professor of physics at Strasbourg.

In 1874, Braun observed that certain semi-conducting crystals could be used as rectifiers to convert alternating to direct currents. At the turn of the century, he used this fact in the invention of crystal diodes, which led to the crystal radio. He also adapted the cathode-ray tube so that the electron beam was deflected by a changing voltage, thus inventing the oscilloscope and providing the basic component of a television receiver. His fame comes mainly from his improvements to MARCONI's wireless communication system and, in 1909, they shared the Nobel Prize for physics. Braun's system, which used magnetically coupled resonant circuits, was the main one used in all receivers and transmitters in the first half of the 20th century.

Braun went to America to testify in litigation about radio patents but, when the United States entered World War I in 1917, he was detained as an alien and died in New York a year later.

**Bredt, Konrad Julius** (1855–1937) *German organic chemist*

Bredt (bret) was born in Berlin and studied in Leipzig and Frankfurt before gaining his doctorate at Strasbourg in 1880 under Rudolph FITTIG. He became professor at the technical institute at Aachen in 1897. His most important research was the structural elucidation of camphor in 1893. The empirical formula had been determined by Jean DUMAS in 1833 and over 30 formulae were proposed before Bredt deduced the correct structure.

**Breit, Gregory** (1899–1981) *Russian-American physicist*

Although born in Nicholaev, Russia, Breit (brIt) moved to America in 1915 and became a naturalized citizen in 1918. He studied at Johns Hopkins University, gaining his PhD in 1921. From 1921 until 1924 he worked successively at the universities of Leiden, Harvard, and Minnesota, before joining the Carnegie Institution, Washington (1924–29).

At Carnegie, Breit worked in the department of terrestrial magnetism as a mathematical physicist, and it was there that he conducted, with Merle A. TUVE, some of the earliest exper-

iments to measure the height and density of the ionosphere. Their technique was to transmit short bursts of radio waves and analyze the reflected waves received. Their work is now seen as a significant step in the historical development of radar.

Besides his pioneering work on the ionosphere, Breit researched quantum theory, nuclear physics, and quantum electrodynamics. In particular, he and Eugene WIGNER were able to show that the experimental observations of the interactions of neutrons and protons indicated that the particles differed only in their charge and other electrical properties, and not in their nuclear forces. The *Breit-Wigner formula* is a formula for the energy dependence of the absorption cross-section of a compound nucleus in a nuclear reaction.

Between 1929 and 1973 Breit held professorial posts at the universities of New York, Wisconsin, and Yale, and the State University of New York, Buffalo.

### **Brenner, Sydney** (1927– ) *South African-British molecular biologist*

The son of a Lithuanian exile, Brenner was born in Germiston, South Africa, and educated at the universities of Witwatersrand and Oxford, where he obtained his DPhil in 1954. In 1957 he joined the staff of the Medical Research Council's molecular biology laboratory in Cambridge, and later served as its director (1979–86). In 1996 he founded the Molecular Sciences Institute, Berkeley, California. He is presently involved with a number of organizations including the Salk Institute.

Brenner's first major success came in 1957 when he demonstrated that the triplets of nucleotide bases that form the genetic code do not overlap along the genetic material (DNA). The basic idea was that the amino-acid sequence of a protein is determined by the sequence of the four nucleotides – A, T, C, and G – in the DNA, with a specific amino acid being specified by a sequence of three nucleotides. Thus in an *overlapping* code the sequence:

A T T A G T A C G T C G A...

would yield the following triplets, ATT, TTA, TAG, AGT, GTA, etc., each of which specified a particular amino acid.

Brenner, however, pointed out that such a code imposed severe restrictions on the permitted order of bases. ATT, for example, in an overlapping code, could be followed by the four base triplets TTA, TTT, TTC, and TTG only. This was relatively easy to test without in any way understanding the true nature of the code, and it was soon shown that such implied restrictions were frequently broken.

A greater triumph followed in 1961 when Brenner, in collaboration with Francis CRICK and others, reported the results of careful ex-

periments with the bacteriophage T4, which clearly showed that the code did consist of base triplets that neither overlapped nor appeared to be separated by “punctuation marks.”

The same year also saw Brenner, this time in collaboration with François Jacob and Matthew MESELSON, introducing a new form of RNA, messenger RNA (mRNA). With this came one of the central insights of molecular biology – an explanation of the mechanism of information transfer whereby the protein-synthesizing centers (ribosomes) play the role of nonspecific constituents that can synthesize different proteins, according to specific instructions, which they receive from the genes through mRNA. In 1963 Brenner turned his attention to the tiny nematode (roundworm) *Caenorhabditis elegans*. He realized that this simple multicellular animal, consisting of about 1000 cells, had potential to serve as a model system for studying genetic control systems in complex organisms. By his example, Brenner convinced others that genetic experimentation on *C. elegans* would reveal insights into processes such as development, behavior, aging, and disease in humans and other animals. Among his colleagues in Cambridge was John E. SULSTON, who later discovered the importance of programmed cell death during the development of the worm's embryo. Brenner's work paved the way for the sequencing of the entire *C. elegans* genome during the 1980s and 1990s, and enabled further discoveries about genetic control of developmental processes, notably those made by another of Brenner's collaborators, Robert HORVITZ. In 2002, Brenner was awarded the Nobel Prize in physiology or medicine, jointly with Sulston and Horvitz, for discoveries concerning “genetic regulation of organ development and programmed cell death.”

### **Bretonneau, Pierre Fidèle** (1778–1862) *French physician*

Bretonneau (bre-ton-oh) was born in St. Georges-sur-Cher, France. A surgeon's son, he went to clinical lectures at the Ecole de Santé in Paris, graduated in 1815, and later practiced in Tours, where he served for some time as the chief physician at the Tours hospital. Bretonneau carefully studied a particular disease, which, beginning in 1818, reached epidemic proportions in Tours. In 1821 he proposed to call it diphtheria, from the Greek word for leather, as the disease was characterized by the formation of a membrane over the mucosa of the throat. He realized it was contagious despite his failure to transmit it to animals. He did however distinguish it from scarlet fever and, in 1825, performed the first successful tracheotomy (incision of the trachea through the neck muscles to prevent asphyxiation) on a diphtheria patient.

He further made an early attempt to describe

typhoid and distinguished it from typhus. His theories on infectious diseases partly anticipated the germ theory of PASTEUR.

**Brewster, Sir David** (1781–1868) *British physicist*

Brewster, who was born in Jedburgh, Scotland, started by studying for the ministry at Edinburgh University but, after completing the course, he abandoned the Church for science. He earned his living by editing various journals and spent much time popularizing science.

Brewster published almost 300 papers, mainly concerning optical measurements. He was an early worker in spectroscopy, obtaining (1832) spectra of gases and of colored glass. His most famous work was on the polarization of light. In 1813 he discovered *Brewster's law*, which states that if a beam of light is split into a reflected ray and a refracted ray at a glass surface, then they are polarized, and the polarization is complete when the two rays are at right angles. The angle of incidence at which this occurs is called the *Brewster angle*. He is also known for his invention, in 1816, of the kaleidoscope.

Brewster was knighted in 1832. From 1859 he was principal of Edinburgh University.

**Bricklin, Daniel** (1951– ) *American computer engineer*

Bricklin graduated in electrical engineering and computer science from MIT in 1973. Before entering the Harvard Business School in 1977 he spent some years at Digital, where he helped to develop their earliest word-processing system. While working for his Harvard MBA he became aware how frustrating and tedious business planning could be, particularly when any small correction or change in one minor item could call for thousands of necessary recalculations.

Bricklin began to develop what has now become a familiar item, namely, the spreadsheet program. It was written in Basic for an Apple II. Initially it took 20 seconds to recalculate 100 cells and would not scroll. A company, Software Arts, was set up in 1979 with two colleagues, Robert Frankston and Dan Fylstra, to produce the spreadsheet they named VisiCalc.

Bricklin's invention was most opportune. Personal computers (PCs), most notably the Apple II, had already appeared. Initially, however, they appealed only to the hobbyist – there was very little anyone could do with an early PC; it had no applications and no software to run. Bricklin's VisiCalc filled this gap to the extent that some customers would buy an Apple II in order to run VisiCalc.

Bricklin's idea was enormously successful and other companies developed spreadsheet programs of their own. By 1986 over seven mil-

lion spreadsheet programs had been bought. Software Arts was sold to Lotus in 1985 and Bricklin went on to set up his own mail-order business, Software Gardens Inc., to sell his own software programs on a much smaller scale. He is also involved in the development of a web-based spreadsheet (WikiCalc).

**Bridgman, Percy Williams** (1882–1961) *American physicist*

Doubtless the most influential single discovery was that of a method of producing high hydrostatic pressure without leak. The discovery of the method had a strong element of accident.

—Reply to the National Academy of Sciences questionnaire “Discoveries Which You Regard as Most Important”

It is the merest truism, evident at once to unsophisticated observation, that mathematics is a human invention.

—*The Logic of Modern Physics* (1927)

Bridgman, the son of a journalist, was born in Cambridge, Massachusetts, and educated at Harvard where he obtained his PhD in 1908. He immediately joined the faculty, leaving only on his retirement in 1954 after serving as professor of physics from 1919 to 1926, professor of mathematics and natural philosophy from 1926 to 1950, and as Huggins Professor from 1950 to 1954.

Most of Bridgman's research was in the field of high-pressure physics. When he began he found it necessary to design and build virtually all his own equipment and instruments. In 1909 he introduced the self-tightening joint and, with the appearance of high-tensile steels, he could aim for pressures well beyond the scope of earlier workers. With his equipment, Bridgman was regularly able to attain pressures of 100,000 kg/cm<sup>2</sup>.

Bridgman used such pressures to explore the properties of numerous liquids and solids. In the course of this work he discovered two new forms of ice, freezing at temperatures above 0°C. He also, in 1955, transformed graphite into synthetic diamond. Bridgman was awarded the 1946 Nobel Prize for physics for his work on extremely high pressures.

He was also widely known as a philosopher of science and in his book *The Logic of Modern Physics* (1927) formulated his theory of “operationalism” in which he argued that a concept is simply a set of operations. In his seventies Bridgman developed Paget's disease, which gave him considerable pain and little prospect of relief. He committed suicide in 1961.

**Briggs, Henry** (1561–1630) *English mathematician*

The mirror of the age for excellent skill in geometry.

—William Oughtred (17th century)

Born in Warley Wood, England, Briggs became a fellow of Cambridge University in 1588 and was later made a lecturer (1592) and a professor (1596) of geometry at Gresham College, London.

He is remembered chiefly for the modifications he made to John NAPIER's logarithms, which were first published in 1614. Napier had produced these to base *e* (natural logarithms) but Briggs considerably improved their convenience of use by introducing the base 10 (common logarithms). He also introduced the modern method of long division. Briggs became Savilian Professor of Geometry at Oxford in 1619.

**Bright, Richard** (1789–1858) *British physician*

Born in Bristol and educated at Edinburgh University and Guy's Hospital, London, Bright received his MD from Edinburgh in 1813. After a period spent traveling in Europe, he was appointed assistant physician to Guy's Hospital in 1820, becoming full physician four years later. One of Bright's major interests was kidney disease. He was able to correlate symptoms in his patients with the results of postmortem examinations, and described how the presence of albumin in urine (albuminuria) and the accumulation of fluid in the body (dropsy) were caused by pathological changes in the kidneys. The term *Bright's disease* is now used for several renal diseases all sharing the above symptoms.

Bright also studied and wrote on subjects such as abdominal tumors, jaundice, and nervous diseases, and collaborated with his famous contemporary at Guy's, Thomas ADDISON, in writing *Elements of the Practice of Medicine* (vol. 1, 1839). An amiable and distinguished consultant, Bright also did much to develop teaching methods at Guy's and helped found the *Guy's Hospital Reports*, in which he published much of his work.

**Broca, Pierre Paul** (1824–1880) *French physician and anthropologist*

Broca (bro-**kah**), who was born in Sainte-Foula-Grande, France, studied at the University of Paris and received his MD in 1849. In 1853 he was appointed assistant professor in the faculty of medicine. His specialty was the brain and, through surgical work and postmortem examination, he was able to demonstrate that damage to one particular region (the left inferior frontal gyrus, now also known as Broca's convolution) of the cortex was associated with impairment or loss of speech. This was one of the first conclusive demonstrations that control of different bodily functions resides in localized regions of the cerebral cortex.

Broca applied his knowledge of the brain to

anthropology. He devised techniques of accurately measuring skulls to enable comparison between the different races of modern man and skulls unearthed at prehistoric sites. Broca's findings supported the then highly contentious theory of Charles DARWIN that man, like other living things, had evolved from primitive ancestors. Broca helped found several notable anthropological institutions, including the Société d'Anthropologie de Paris (1859) and the Ecole d'Anthropologie (1876), thus helping to establish anthropology as a respectable branch of science.

**Brockhouse, Bertram Neville** (1918–2003) *Canadian physicist*

Brockhouse gained his PhD from the University of Toronto in 1950. He worked initially with the Atomic Energy Commission of Canada at the Chalk River Nuclear Laboratory, Ontario. In 1962 he moved to MacMaster University, Hamilton, Ontario, where he remained until his retirement in 1984.

The construction of nuclear reactors in Canada and the United States in the 1940s allowed physicists, once the war had ended, to use neutron beams to explore atomic structure. Neutrons are more effective probes than protons because they are electrically neutral and consequently do not interact with the orbiting electrons. Because neutrons can behave as waves they produce diffraction patterns as a result of collisions with their target atomic nuclei. The effect is similar to that of x-ray diffraction, in which the crystal lattice acts as a diffraction grating for the particles. Neutron diffraction from crystals can be used to select beams of neutrons with the same energy. These "monochromatic" beams can then be used in neutron-scattering experiments.

Brockhouse chose to study the inelastic scattering of neutrons as they bombarded atoms bound in a crystal lattice. In this procedure neutrons give up or gain energy from the atoms they collide with. Monochromatic neutron beams were directed at a crystal target and the energies of the scattered neutrons measured as they emerged. It was thus possible to determine how much energy had been gained or lost. With these data Brockhouse was able to obtain information about the vibration of atoms in the crystal and such important properties as the ability of the crystal to conduct heat and electricity.

For his work on atomic structure Brockhouse shared the 1994 Nobel Prize for physics with Clifford SHULL.

**Brodie, Sir Benjamin Collins** (1783–1862) *British physician*

Born in Wintersloy, England, Brodie learned medicine in London, first as apprentice to an

apothecary and then at the Windmill Street School of Anatomy. He later studied at St. George's Hospital, where he was subsequently appointed house surgeon (1805) and assistant surgeon (1808). Between 1809 and 1814 he contributed six papers to the Royal Society in which he challenged the prevailing contemporary view that body heat was caused, more or less, by simple chemical combustion. Brodie argued that it was a complex process under the influence of the brain, which controlled the functioning of vital organs, such as the heart. This brought Brodie to prominence and he was elected a fellow of the Royal Society in 1810.

Brodie soon had a large and lucrative practice. He wrote *Diseases of the Joints* (1818), which ran to several editions, and in 1819 he was appointed professor of comparative anatomy and physiology at the Royal College of Surgeons, of which he later (1844) became president. A surgeon to both George IV and William IV, Brodie was made a baronet in 1834. As one of the most prominent members of the medical establishment, he was chosen (1858) to be the first president of the newly formed General Medical Council, which administered the registration of all persons qualified to practice medicine.

**Brodie, Bernard Beryl** (1909–1989)  
*American pharmacologist*

Born in Liverpool in northwest England, Brodie was educated at McGill University in Canada and at New York University, where he obtained his PhD in 1935. He worked at the Medical School there from 1943 to 1950 when he moved to the National Institutes of Health at Bethesda, Maryland, where he served as chief of the chemical pharmacology laboratory until 1970.

Brodie worked in a wide variety of fields including chemotherapy, anesthesia, drug metabolism, and neuropharmacology. In 1955 Brodie and his colleagues produced some results that once more raised the possibility of a chemical basis of mental disease. Basically they showed that the tranquilizer reserpine – an alkaloid extracted from the roots of *Rauwolfia* – can produce a profound fall in the level of serotonin, a naturally occurring monoamine in the brain. The question then arose as to whether the tranquilizing effect of reserpine is due to its reduction of too high a level of serotonin.

It was further shown that some of the actions of serotonin could be neutralized by the presence of the hallucinogen LSD. As the structures of the two molecules are somewhat similar the possibility arose that LSD could monopolize the enzyme that normally breaks down serotonin and thus permit the accumulation of unusually high levels of serotonin. It is perhaps this action that causes the hallu-

cinogenic state and which, it has been argued, mimics the schizophrenic state.

In reality the speculations arising from Brodie's work have turned out to be surprisingly difficult to confirm or reject.

**Brogie, Prince Louis Victor de** See **DE BROGLIE, PRINCE LOUIS VICTOR**.

**Brongniart, Alexandre** (1770–1847)  
*French geologist and paleontologist*

Brongniart (bro-nyar) was the son of an architect. He was born in Paris and educated at the School of Mines there, serving in the army as an engineer before being appointed director of the Sèvres porcelain factory (1800–47). He also served as professor of natural history at the Ecole Centrale des Quatre Nations, Paris, from 1797. In 1822 he succeeded René HAÛY to the chair of mineralogy at the Natural History Museum, Paris.

Brongniart's early work included his *Essai d'une classification naturelle des reptiles* (1800; Essay on the Classification of Reptiles) in which he divided the Reptilia into the Chelonia, Sauria, Ophidia, and Batrachia. In 1822 he published the first full-length account of trilobites, the important paleozoic arthropods.

His most significant work was done in collaboration with Georges CUVIER on the geology of the Paris region, published jointly by them in 1811 as *Essai sur la géographie minéralogique des environs de Paris* (Essay on the Mineralogical Geography of the Environs of Paris). In this monograph they were among the first geologists to identify strata within a formation by their fossil content; earlier geologists had tended to rely on the characteristics of the rocks rather than their content. They were able to show a constant order of fossil sequence, mainly of mollusks, over the whole Paris region.

They also produced evidence that counted strongly against the neptunism of Abraham WERNER in their discovery of alternate strata of fresh- and sea-water mollusks. The solution to the problem of how fresh- and sea-water strata could alternate was crucial for the new science of geology and was to lead to the catastrophism of Cuvier and the evolution theory of Charles DARWIN.

Outside science his major achievement was the revival of the Sèvres factory which, when he took over in 1800, was at a particularly low point in its history. He abandoned the production of soft-paste ware and developed a new range of colors, producing works as richly colored as paintings.

His son, Adolph, was a distinguished botanist who, in 1828, published a history of fossil plants.

**Bronk, Detlev Wulf** (1897–1975) *American physiologist*

Bronk, the son of a Baptist minister, came from Dutch stock: the family name survives in the Bronx district of New York City, where he was born. He was educated at Swarthmore, Pennsylvania, and at Michigan, where he obtained his PhD in 1922. Bronk spent some time in England working with Edgar ADRIAN in Cambridge before accepting, in 1929, the post of director of the Johnson Institute, attached to the University of Pennsylvania, where he was already serving as professor of biophysics and director of the Institute of Neurology. In 1949 Bronk became president of Johns Hopkins University but left there in 1953 to take the presidency of the Rockefeller Institute (later Rockefeller University) in New York, where he remained until his retirement in 1968.

Bronk established an early reputation with his fundamental work with Edgar Adrian on nerve impulses (1928–29). They demonstrated that both motor and sensory nerves transmit their messages by varying the number of impulses sent rather than by using impulses of different intensities. By careful experiments they established that the range of the impulses is between 5 and 150 per second, with greater stimuli producing higher frequencies.

In the 1930s Bronk worked mainly on the autonomic nervous system. He is, however, mainly remembered for his crucial role in organizing the institutional structure of American science.

**Brønsted, Johannes Nicolaus** (1879–1947) *Danish physical chemist*

Born in Varde, Denmark, Brønsted (**bron**-sted or **bron**-steth) studied at the Polytechnic Institute, Copenhagen, from 1897, obtaining degrees in engineering (1899) and chemistry (1902), and a doctorate (1908). The same year he became professor of chemistry at Copenhagen.

Brønsted worked mainly in thermodynamics, especially in the fields of electrochemistry and reaction kinetics. In 1923 he proposed, concurrently with Thomas LOWRY, a new definition of acids and bases. This, the *Lowry–Brønsted theory*, states that an acid is a substance that tends to lose a proton and a base is a substance that tends to gain a proton. In 1924, working with V. K. La Mer on the activity coefficients of dilute solutions, he confirmed the theoretical expression of Peter DEBYE and Erich HÜCKEL for electrolytes.

**Broom, Robert** (1866–1951) *British–South African morphologist and paleontologist*

Broom, who was born in Paisley, Scotland, graduated in medicine from Glasgow University in 1889. He traveled to Australia in 1892 and in

1897 settled in South Africa where he practiced medicine, often in remote rural communities, until 1928. He also held posts as professor of geology and zoology (1903–10) at Victoria College, now Stellenbosch University, South Africa, and curator of paleontology at the Transvaal Museum, Pretoria, from 1934 until his death.

Apart from studies of the embryology of Australian marsupials and monotremes, Broom's major contributions to science have been concerned with the evolutionary origins of mammals, including man. He excavated and studied the fossils of the Karroo beds of the Cape, and in the 1940s discovered numbers of Australopithecine skeletons in Pleistocene age quarries at Sterkfontein, Transvaal. These latter have proved of considerable importance in investigations of man's ancestry and Broom's account of their discovery is given in *Finding the Missing Link* (1950).

**Brouncker, William, Viscount** (1620–1685) *English mathematician and experimental scientist*

Brouncker (**brung**-ker) graduated from Oxford University in 1647 with a degree in medicine. He held a variety of official posts, including serving as member of parliament and president of Gresham's College. He was a friend of the eminent mathematician John WALLIS and his own most notable work was also in mathematics. He was a founder and first president of the Royal Society (1662–77) and as such carried out experimental work. Brouncker usually contented himself with solving problems arising from the work of other mathematicians rather than doing creative work himself but was the first to use continued fractions. He was a friend of Samuel Pepys and frequently figures in Pepys's *Diary*. Apart from science Brouncker had a lively interest in music.

**Brouwer, Dirk** (1902–1966) *Dutch–American astronomer*

Brouwer (**brow**-er), the son of a civil servant from Rotterdam in the Netherlands, studied at the University of Leiden where he obtained his PhD under Willem de SITTER in 1927. He then moved to America to do postdoctoral research at the University of California at Berkeley. He joined the Yale faculty in 1928, serving from 1941 until his death as professor of astronomy and director of the Yale Observatory.

Brouwer worked mainly in celestial mechanics, particularly in the analysis of observations concerning orbiting bodies and on planetary theory, providing new methods by which the motion of a planet could be determined and by which the very long-term changes in orbits could be calculated. He collaborated with Gerald CLEMENCE and W. J. Eckert in the

production in 1951 of the basic paper in which the accurate orbits of the outer planets were given for the years 1653–2060. Brouwer's other major contribution was to astrometry, or positional astronomy, where he introduced new techniques and initiated programs for the measurement of stellar positions, especially in the southern sky.

He was also involved in the decision to adopt a new time scale, known as Brouwer's suggestion as "Ephemeris Time" (ET). This became necessary when the rotation rate of the Earth, on which time measurements had been based, was found to vary very slightly. Ephemeris Time is derived from the orbital motions of the Moon and the Earth and is perfectly uniform. It is only used by astronomers however; more general timekeeping now involves atomic clocks.

**Brouwer, Luitzen Egbertus Jan** (1881–1966) *Dutch mathematician and philosopher of mathematics*

Born in Overschie in the Netherlands, Brouwer took his first degree and doctorate at the University of Amsterdam, where he became successively *Privatdozent* and professor in the mathematics department. From 1903 to 1909 he did important work in topology, presenting several fundamental results, including the fixed-point theorem. This is the principle that, given a circle (or sphere) and the points inside it, then any transformation of all points to other points in the circle (or sphere) must leave at least one point unchanged. A physical example is stirring a cup of coffee – there will always be at least one particle of liquid that returns to its original position no matter how well the coffee is stirred.

Brouwer's best-known achievement was the creation of the philosophy of mathematics known as *intuitionism*. The central ideas of intuitionism are a rejection of the concept of the completed infinite (and hence of the transfinite set theory of Georg Cantor) and an insistence that acceptable mathematical proofs be constructive. That is, they must not merely show that a certain mathematical entity (e.g., a number or a function) *exists*, but must actually be able to construct it. This view leads to the rejection of large amounts of widely accepted classical mathematics and one of the three fundamental laws of logic, the law of excluded middle (either  $p$  or not- $p$ ; a proposition is either true or not true).

Brouwer was able to re-prove many classical results in an intuitively acceptable way, including his own fixed-point theorem.

**Brown, Alexander Crum** See CRUM BROWN, ALEXANDER.

**Brown, Herbert Charles** (1912–2004) *American chemist*

Brown moved from London, where he was born, to Chicago with his family when he was two years old. His father, originally a cabinet maker, ran a hardware store but Brown had to leave school to help support his mother and three sisters. When he finally did get to college, Crane Junior, it was forced to close in 1933 for lack of funds. He eventually made it to the University of Chicago where he obtained his doctorate in 1938. Brown then worked at Wayne University, Detroit, from 1943 until 1947, when he moved to Purdue University, Indiana, where he served as professor of inorganic chemistry until his retirement in 1978.

Brown was particularly noted for his work on compounds of boron. He discovered a method of making sodium borohydride ( $\text{NaBH}_4$ ), a reagent used extensively in organic chemistry for reduction. He also found a simple way of preparing diborane ( $\text{B}_2\text{H}_6$ ). By reacting diborane ( $\text{B}_2\text{H}_6$ ) with alkenes (unsaturated hydrocarbons containing a double bond) he produced a new class of compounds, organoboranes, which are also useful in organic chemistry. Brown also used addition compounds of amines with boron compounds to investigate the role of steric effects in organic chemistry. He received the 1979 Nobel Prize for chemistry.

**Brown, Michael Stuart** (1941– ) *American medical biochemist and geneticist*

Born in New York, Brown gained his BA from the University of Pennsylvania in 1962, and was awarded his MD in 1966. His first post was as an intern at Massachusetts General Hospital, Boston (1966–68), after which he joined the National Institutes of Health as a clinical associate (1968–71). In 1971 he was appointed assistant professor at the University of Texas Southwestern Medical School, Dallas, and in 1977 he became professor of genetics and director of the Center of Genetic Diseases.

Brown's research interests have included digestive enzymes, particularly their role in the metabolism of cholesterol. However, he is perhaps best known for his studies of lipid receptors on body cells and their importance in removing cholesterol from the blood. This work was done in conjunction with Joseph GOLDSTEIN, with whom Brown has had a long and fruitful scientific partnership dating from 1966 when they met as interns at Massachusetts General Hospital. Most notably, their work on familial hypercholesterolemia, an inherited disorder of cholesterol metabolism, earned them the 1985 Nobel Prize for physiology or medicine.

**Brown, Robert** (1773–1858) *British botanist*

He [Brown] seemed to me to be chiefly

remarkable for the minuteness of his observations and their perfect accuracy ... His knowledge was extraordinarily great, and much died with him, owing to his excessive fear of never making a mistake.

—Charles Darwin, *Autobiography*

Brown, a clergyman's son from Montrose, Scotland, studied medicine at Edinburgh University. He joined the Fifeshire Regiment of Fencibles in 1795 and served five years in Ireland as a medical officer. During a visit to London in 1798 he was introduced to Sir Joseph BANKS. This led, two years later, to his being recommended by Banks for the post of naturalist on the *Investigator* in an expedition to survey the coast of New Holland (Australia) under the command of Matthew Flinders. Brown accepted the appointment and the *Investigator* set sail for the Cape of Good Hope and Australia in 1801. During his five years with the expedition Brown collected 4,000 plant specimens, and on his return to England spent another five years classifying these. Rather than use LINNAEUS's artificial classification, he followed Antoine de JUSSIEU's more natural system, adding his own modifications and using microscopic characters to help delimit species. By 1810 he had described 2,200 species, over 1,700 of which were new (including 140 new genera). He intended to produce an extensive treatise on Australian plants but the poor sales of the first volume, which appeared in 1810, led him to discontinue publication of the remainder.

In the course of his painstaking work Brown became very familiar with plant morphology, which led him to make many important observations. He found that in conifers and related plants the ovary around the ovule is missing, thus establishing the basic difference between these plants and flowering plants or between the gymnosperms and the angiosperms, as the two groups of seed-bearing plants were later named. He also observed and named the nucleus, recognizing it as an essential part of living cells.

In 1827, while examining a suspension of pollen grains in water, under a microscope, Brown observed that the grains were in continuous erratic motion. Initially he believed that this movement was caused by some life force in the pollen, but when he extended his observations to inanimate particles suspended in water he found the same effect. This phenomenon was named *Brownian motion* and remained unexplained until the kinetic theory was developed.

From 1806 to 1822 Brown was librarian of the Linnean Society; in 1810 he also became librarian and curator at Banks's Soho Square residence. Banks stipulated in his will that on his death Brown should take charge of his house, library, and herbarium. In 1820 Brown duly inherited this responsibility and in 1827

he donated Banks's library and herbarium to the British Museum on the understanding that the trustees established an independent botany department in the museum. Thus a botanical collection became accessible to the general public for the first time in Britain.

### **Brown, Robert Hanbury** (1916–2002) *British radio astronomer*

Brown, the son of a British army officer, was born in Aruvankadu, India, and educated at the City and Guilds College, London. From 1936 to 1942 he worked on the development of radar at the Air Ministry Research Station, Bawdsey. This was followed by three years in Washington with the British Air Commission and two years with the Ministry of Supply. Brown published an account of his war work in *Boffin* (1991). By the late 1940s Brown was keen to enter academic research and persuaded Bernard LOVELL to admit him as a research student at the Jodrell Bank radio observatory. Brown later served there as professor of radio astronomy from 1960 to 1963 when he was appointed to a professorship in physics at the University of Sydney, a post he held until his retirement in 1981.

In 1950 Brown plotted the first radio map of an external galaxy, the spiral nebula in Andromeda. This was followed by the identification of emissions from four other extragalactic nebulae. Brown further proposed radical changes in the design of standard interferometers that allowed him to measure in 1952 a radio source in Cygnus with a diameter of only 30 seconds of arc. Further work produced in 1954 a new type of interferometer – the so-called optical intensity interferometer.

### **Brown-Séquard, Charles-Edouard** (1817–1894) *British-French physiologist and neurologist*

Brown-Séquard (brown-say-**kar**) was born in Port Louis, Mauritius, and studied medicine in Paris, graduating in 1846. He was professor of physiology and pathology at Harvard (1864–68) and in 1878 succeeded Claude Bernard as professor of experimental medicine at the Collège de France. The intervening years were spent in a variety of posts in New York, London, and Paris. He is perhaps best known for his work on the adrenal gland. In his experiments on hormonal secretions, he demonstrated the connection between excision of the adrenal glands and ADDISON's disease.

Continuing the work of GALEN on dissection of the spinal cord, he discovered the *Brown-Séquard syndrome* (crossed hemiplegia), a condition of motor nerve paralysis resulting from the lesion of one side of the spinal cord. This produces an absence of sensation on the opposite side of the body to the nerve paralysis.

Brown-Séguard also investigated the possibility of prolonging human life by the use of extracts prepared from the testes of sheep. The majority of his research findings were published as papers in the journal *Archives de physiologie* (Archives of Physiology), of which he was one of the founders.

**Bruce, Sir David** (1855–1931) *British bacteriologist*

We are all children of one Father. The advance of knowledge in the causation and prevention of disease is not for the benefit of any one country, but for all ...

—Address to the British Association, Toronto (1924)

Bruce was a one-time colleague of Robert KOCH in Berlin but spent the greater part of his career as a military physician. Born in Melbourne, Australia, he was educated at Edinburgh University. He was assistant professor of pathology at the Army Medical School, Netley (1889–94), and then commandant of the Royal Army Medical College, Millbank, where he was also director of research on tetanus and trench fever (1914–18). He undertook royal commissions of enquiry into various diseases of man and domestic animals in Malta and central Africa. In Malta he was able to trace the cause of Malta fever (brucellosis or undulant fever found in the milk of goats) to a bacterium later named for him as *Brucella melitensis*. Bruce also investigated the cause of nagana, a disease of horses and cattle in central and southern Africa, and found it to be transmitted by a trypanosome parasite carried by the tsetse fly. This work was of great help in his later research on sleeping sickness (trypanosomiasis), which he also proved to be transmitted by the tsetse fly. The recipient of many honors for his humanitarian work, Bruce was chairman of the War Office's Pathological Committee during World War I. He was knighted in 1908.

**Brunel, Isambard Kingdom** (1806–1859) *British engineer*

Brunel's father, Marc Brunel (1769–1849), a French emigré and distinguished engineer, arrived in England in 1799. He sent his son to Paris in 1820 to learn mathematics and engineering. Brunel returned to England in 1822 to work for his father and in 1825 they began the construction of the Rotherhithe–Wapping tunnel underneath the Thames. Here Brunel quickly learned of the unpredictability of great engineering projects. He also learned about their danger when the tunnel flooded in 1828 and Brunel nearly drowned.

While convalescing, he heard that the city of Bristol was considering building a bridge across the River Avon. A competition was to be held with Thomas TELFORD as the judge. Brunel submitted plans for a suspension bridge at Clifton,

a span still standing and, perhaps, his most durable monument, even though it remained uncompleted during his lifetime. Telford rejected Brunel's design and proposed instead that he himself should build something more appropriate. The selection committee, however, preferred Brunel's plans. Although work began in 1831 it was not until 1864, well after Brunel's death, that the bridge was opened.

While in the Bristol region other commissions came his way. In 1833 he was invited to build the Great Western Railway (GWR) to run between London and Bristol. He decided to adopt a 7-foot gauge rather than the 4 foot 8 1/2-inch gauge introduced by George STEPHENSON at the beginning of the railway age. The broad gauge enabled trains to run faster and more comfortably. It did not, however, allow the GWR to link up easily with the rest of the growing railway network. The line was opened in 1841 and extended to Exeter by 1844. It was insisted, however, in the interest of establishing a unitary railway system, that after 1846 no more broad-gauge track could be laid down. The last of the track was removed in 1896.

Not all Brunel's projects were as successful or as durable – in particular, the atmospheric railway that he built in south Devon between Exeter and Newton Abbot in the 1840s. The idea was to eliminate the locomotive. A continuous pipe was laid between the rails and attached to the carriages by a suspended piston. Air was evacuated from the pipe by pumping engines located along the route. In practice, it proved too difficult to maintain the leather seal along the pipe through which the connecting rod emerged; it was either eaten by rats, or made brittle by the sea air, or it froze in winter. Whatever the reason, once breached, the train was brought to a halt. The line was opened in November 1847 and closed the following year, having incurred enormous losses.

Brunel's vision could not be limited by the Atlantic. Why not, he asked, continue the line over the ocean with an equally comfortable liner. This was, for the time, a bold decision. The first Atlantic steam crossing had been accomplished by the American *Savannah* in 1819 using steam as well as sail. Conventional wisdom held that to cross the Atlantic on steam alone would require so much coal as to leave no room for freight. Brunel calculated otherwise and dispelled this myth forever with his *Great Western* (1837; 2,340 tons), a timber ship driven by paddles. It crossed the Atlantic in 15 days with 200 tons of coal unused in its bunkers.

Brunel went on to build the equally revolutionary *Great Britain* (1843; 3,676 tons) with an iron hull and screw propeller, which continued in service for 30 years. His final work was the incredible *Great Eastern* (1858; 32,000 tons) with its double iron hull, screws, and paddles; it was later used to lay the first transatlantic cable.

The struggle to complete the *Great Eastern* against considerable financial and engineering difficulties seems to have ruined Brunel's health and probably caused the stroke he suffered soon after his great ship had been finally launched. He died soon after.

**Brunhes, Jean** (1869–1930) *French geographer*

Brunhes (**broo-ne**) came from an academic background in Toulouse, France, with both his father and brother being professors of physics. He was educated at the Ecole Normal Supérieure, Paris, (1889–92) and taught at the University of Fribourg from 1896 until 1912, when he moved to the Collège de France, Paris, as professor of human geography.

His most important work was his three-volume *Géographie humaine* (1910; Human Geography), which was translated into English in 1920. Following his teacher, Vidal de la Blache, he argued against the geographical determinism implicit in the work of Friedrich RATZEL. Instead he was more concerned to reveal the complicated interplay between man, society, and the environment.

**Brunner, Sir John Tomlinson** (1842–1919) *British industrialist*

Brunner's father had traveled to England from Switzerland in 1832 and settled in Liverpool. Brunner began working in the office of a shipping clerk in 1857 and in 1861 joined a chemical firm in Widnes and became chief cashier. There he met Ludwig MOND, a research chemist who had acquired the rights to Ernest SOLVAY's new ammonia–soda process. The two entered into a partnership in 1875 and established a firm in Cheshire to produce soda. Within a few years they had converted an initial loss into a profit, which continued to grow in the succeeding years. In 1881 the partnership was converted into a limited company with capital assets of £600,000. Brunner, Mond, and Company merged with other companies in 1926 to form Imperial Chemical Industries (ICI).

Brunner was made a baronet in 1895 and served as a member of parliament (1885–1910).

**Bruno, Giordano** (1548–1600) *Italian philosopher*

Perhaps your fear in passing judgment on me is greater than mine in receiving it.  
—To his judges on the last day of his trial, 8 February 1600

The son of a soldier from Nola in Italy, Bruno (**broo-noh**) entered the Dominican Order in 1565 but was forced to leave in 1576 for unspecified reasons. The following 15 years were spent traveling in France, England, and Germany before visiting Venice in 1591 where he was arrested and handed over to the Inquisi-

tion (1592). He was extradited by the Roman Inquisition in 1593. As details of the trial have been destroyed it is no longer known which eight heretical propositions he refused to recant. The results of his action are not however in any doubt: he was gagged and burned alive.

The exact role of Bruno in 16th-century intellectual history remains a matter of considerable controversy and he was clearly a man of many parts. He was first an expert on the art of mnemonics (memory), a renaissance “science” long extinct, and he was also involved with a revival of the occult mystical philosophical system of hermeticism. More importantly Bruno was also a keen supporter of the heliocentric system of Nicolaus COPERNICUS and in his *Cena de le Ceneri* (1584; The Ash Wednesday Supper) added to some rather implausible arguments in defence of Copernicus's claims for the infinity of the universe. His championing of the then unorthodox heliocentric theory was certainly considered heretical and his unhappy end may well have influenced GALILEO's actions before the Inquisition.

**Buch, Christian Leopold von** See [VON BUCH, CHRISTIAN LEOPOLD](#).

**Buchner, Eduard** (1860–1917) *German organic chemist and biochemist*

Buchner (**book-ner**) studied chemistry under Adolf von BAEYER and botany in his native city of Munich, gaining his doctorate in 1888. In 1897, while associate professor of analytical and pharmaceutical chemistry at Tübingen, he observed fermentation of sugar by cell-free extracts of yeast. Following PASTEUR's work (1860), fermentation had been thought to require intact cells, and Buchner's discovery of zymase was the first proof that fermentation was caused by enzymes and did not require the presence of living cells. The name “enzyme” came from the Greek *en* = in and *zyme* = yeast. Buchner also synthesized pyrazole (1889). He was professor of chemistry at the University of Berlin from 1898 and won the Nobel Prize for chemistry in 1907 for his work on fermentation. He was killed in Romania, while serving as a major in World War I.

**Buchner, Hans Ernst Angass** (1850–1902) *German bacteriologist*

Buchner, the brother of Eduard Buchner, was born in Munich, Germany, and gained his MD from the University of Leipzig in 1874. He later worked at Munich University serving as professor of hygiene from 1894 until his death.

In 1888 George Nuttall had shown that the ability of blood to destroy invading bacteria lay in the serum. Buchner followed up his work and went on to demonstrate that the bacteriolytic power was lost when the serum was

heated to 56°C. He therefore concluded that serum possessed a heat labile substance that he proposed to name alexin. This work was soon extended by Jules BORDET and the alexins were later renamed complement by Paul EHRLICH. Buchner also did basic work on gamma globulins and developed techniques to study anaerobic bacteria.

**Buck, Linda B.** (1947– ) *American neurobiologist*

Buck initially studied psychology and microbiology in her native Seattle, at the University of Washington, obtaining her BS in 1975. After gaining a PhD at the University of Texas in 1980, she worked at Columbia University, first as a postdoctoral fellow (1980–84) then as an associate. In 1991 she joined Harvard Medical School as assistant professor in the neurobiology department, subsequently becoming associate professor (1996) and professor (2001). Throughout this period she was also affiliated to the Howard Hughes Medical Institute at Columbia University. In 2002 she moved to the Fred Hutchinson Cancer Research Center in Seattle. Since 2003 she has been affiliate professor in the Department of Physiology and Biophysics, University of Washington, Seattle.

While at Columbia in the 1980s, Buck made groundbreaking discoveries about the nature of olfaction, or the sense of smell. Working on the mouse as a model organism, in collaboration with Richard AXEL, Buck identified a family of some one thousand genes that encoded the odor receptor molecules found on sensory cells of the olfactory epithelium inside the nose. She and Axel established that these were G protein-coupled receptors. In subsequent work, independently of Axel, Buck demonstrated that each sensory cell carries on its surface just one type of receptor molecule, and that each type of receptor cell sends its electrical signals to a specific relay station, or glomerulus, in the olfactory bulb of the brain.

Buck's later studies showed how this specificity of information from smell receptors is maintained as signals travel from the glomeruli via mitral cells to higher levels of the brain. Micro-regions of the brain cortex receive impulses from mitral cells and combine these to form patterns that are characteristic for the corresponding odors. Here the information is processed to create the perception of smell and relate it to experiences stored as memory.

Buck has also discovered that pheromones – chemical signals released into the environment from other individuals or other species – are sensed by distinct families of G protein-coupled receptors in separate parts of the olfactory epithelium. Her latest work is concerned with instinctive behaviors, and also the possible influence of the brain on aging and lifespan.

She was awarded the 2004 Nobel Prize for

physiology or medicine, jointly with Axel, for discoveries of “odorant receptors and the organization of the olfactory system.”

**Buckland, Francis Trevelyan** (1826–1880) *British surgeon and naturalist*

Buckland was born in Oxford, the son of William (Dean) Buckland, founder of the Oxford University Museum of Geology. Educated at Oxford and at St. George's Hospital, London, Buckland practiced medicine and was an army surgeon from 1852 to 1863. Buckland was an authority on pisciculture, investigating the economic aspects of artificial salmon supply, devising ladders to assist the salmon in reaching their marine spawning beds, and observing the preponderance of male as opposed to female trout. He also carried out research into the homing instinct of salmon, deducing that the fish were able to recognize rivers by chemotactile (taste/smell) means. A popular science writer, Buckland is perhaps best known for his many volumes of *Curiosities of Natural History* (1857–72). Buckland also did much to secure international agreement to prevent the extermination of the North Atlantic fur seal.

**Budd, William** (1811–1880) *British physician*

A man of the highest genius, [whose] doctrines are now everywhere victorious, each succeeding discovery furnishing an illustration of his marvellous prescience.

—John Tyndall (19th century)

Budd, the son of a surgeon from North Tawton, England, was the fifth of nine sons, six of whom became doctors. He studied medicine at the Ecole de Médecine in Paris and at the University of Edinburgh where he obtained his MD in 1838. He then practiced in Bristol where he also served as physician at the Royal Infirmary and lectured in medicine at the medical college.

From observations on an outbreak of typhoid fever in North Tawton in 1839 Budd developed a clearly argued case against the view that such outbreaks were due to a generalized atmospheric miasma. He published a number of studies over the years, collected later in his *Typhoid Fever* (1873). He argued that the causative factor could not be atmospheric and stressed that poor sanitary conditions did not of themselves generate typhoid but were important in spreading it. The cause was related to the movement of people, as could be demonstrated by its spread from village to village, and Budd postulated the existence of infective agents, released in the excreta of typhoid sufferers. He thus emphasized the importance of disinfection and a clean water supply. Such views however had little impact on the leading typhoid expert of the day, Charles Murchison,

who in his *Treatise on the Continued Fevers* (1873) continued to insist that disease arose spontaneously from dirt and excrement.

Budd also wrote on cholera and in *Malignant Cholera* (1849) narrowly missed anticipating the claim of John SNOW that the disease was waterborne.

### **Buffon, Comte Georges Louis Leclerc de (1707–1788) French naturalist**

The noblest conquest man has ever made.

—Of the horse. *L'Histoire des mammifères* (The History of Mammals)

The son of wealthy Burgundian landowners, Buffon (boo-**fon**) was born in Montbard; he studied law at Dijon and medicine at Angers. After traveling in Italy and England, he inherited his mother's estate upon her death in 1732. The estate flourished under his direction, benefiting from Buffon's knowledge of silviculture and the ironworks he installed, thus allowing him to concentrate upon scientific matters.

He began by translating S. HALE'S *Vegetable Statics* (1735) and NEWTON'S *The Method of Fluxions* (1740) into French. In 1739 he was appointed keeper of the Jardin du Roi, a post he occupied until his death. Buffon restored, extended, and embellished the institution, which was renamed as the Natural History Museum during the Revolution.

Buffon began work on his *Histoire naturelle* (Natural History), a work that would dominate the rest of his life and which would eventually run to 44 volumes. The completed *Histoire* consisted of:

Vols. 1–15. *Quadrupeds*, 1749–67, with the assistance of Louis Daubenton who provided the anatomical details.

Vols. 16–24. *Birds*, 1770–83, with the assistance of the Abbé Bexon and G. de Montbeillard.

Vols. 25–31. *Supplementary Volumes*. These deal mainly with the quadrupeds, but Vol. 5 (1778) contains Buffon's important *Epochs of Nature*.

Vols. 32–36. *Minerals*, 1783–88.

The final 8 volumes, *Reptiles* (2 vols., 1788–89), *Fish* (5 vols., 1798–1803), and *Cetacea* (1804) were prepared by E. de Lacepede.

Vol. 1 contained an influential *Preliminary Discourse*. Nature, Buffon argued, was a continuum, and any attempts to divide it into apparently natural classes such as cats and dogs were misguided. Only individuals existed in nature; the rest, genera, species, classes, and orders, were bogus. In accordance with such views Buffon moved in the *Histoire*, quite artificially, from the familiar to the unfamiliar. He began with Man and familiar domestic animals such as dogs, horses, and cows, before moving on to savage animals. The horse was followed by the dog, not the zebra.

In later volumes of the *Histoire* Buffon mod-

ified these initial extreme views. He conceded that "two animals belong to the same species as long as they can perpetuate themselves," and also accepted that there did seem to be, beneath superficial differences, "a single plan of structure" present in all quadrupeds. This did not, however, imply a common descent. If, he argued, the ass was derived from the horse, where were the intermediate forms?

Buffon took a bolder line in his *Epochs of Nature*. He argued against the traditional Biblical chronology of about 6,000 years for the Earth's age, claiming instead a period of 78,000 years between the formation of the solar system and the emergence of Man. The estimates were based upon assumptions concerning the rate at which hot bodies of known size and temperature cooled. His calculations allowed him to go further and predict that temperatures will continue to fall, and when they reach 1/25th of the present temperature after 93,000 years, life on Earth will be extinguished.

### **Bullard, Sir Edward Crisp (1907–1980) British geophysicist**

Bullard was born in Norwich and educated at Cambridge University, England. After war service in naval research he returned to Cambridge as a reader in geophysics before accepting a post as head of the physics department of the University of Toronto (1948) and visiting the Scripps Institute of Oceanography, California (1949). After a five-year spell as director of the National Physical Laboratory, he returned to Cambridge as a reader and later, in 1964, professor of geophysics and director of the department of geodesy and geophysics. Here he remained until his retirement in 1974.

Bullard made a number of contributions to the revolution in the Earth sciences that took place in the 1950s and 1960s. He carried out major work on the measurement of the heat flow from the Earth. It had been assumed that as the ocean floor was less rich in radioactive material than the continental crust, it would be measurably cooler. The technical difficulties of actually measuring the temperature of the ocean floor were not overcome until 1950, and in 1954 Bullard was able to announce that there was no significant temperature difference between the continental crust and the ocean floor. This led Bullard to reintroduce the idea of convection currents.

In 1965 Bullard studied continental drift, using a computer to analyze the fit between the Atlantic continents. An excellent fit was found for the South Atlantic at the 500-fathom contour line. However, a reasonable fit could only be made for the North Atlantic if a number of assumptions, such as deformation and sedimentation since the continents drifted apart, were taken into account. Later, when independent evidence for these assumptions was

obtained, it gave powerful support for the theory of continental drift.

Bullard was knighted in 1953.

**Bullen, Keith Edward** (1906–1976) *Australian applied mathematician and geophysicist*

Bullen, the son of Anglo-Irish parents, was born in Auckland, New Zealand; he was educated at the universities of Auckland, Melbourne, and Cambridge, England. He began his career as a teacher in Auckland then lectured in mathematics at Melbourne and Hull, England. In 1946 he became professor of applied mathematics at the University of Sydney.

Bullen made his chief contributions to science from his mathematical studies of earthquake waves and the ellipticity of the Earth. In 1936 he gave values of the density inside the Earth down to a depth of 3,100 miles (5,000 km). He also determined values for the pressure, gravitation intensity, compressibility, and rigidity throughout the interior of the Earth as a result of his mathematical studies. From the results on the Earth's density he inferred that the core was solid and he also applied the results to the internal structure of the planets Mars, Venus, and Mercury and to the origin of the Moon.

Bullen conducted some of his early work in collaboration with Harold JEFFREYS on earthquake travel times. This resulted in the publication of the *Jeffreys–Bullen (JB) tables* in 1940.

**Bunsen, Robert Wilhelm** (1811–1899) *German chemist*

Bunsen (**bu**-sen or **buun**-zen), the son of a professor of linguistics, gained his doctorate at the university in his native city of Göttingen (1830) with a thesis on hygrometers. After an extensive scientific tour in Europe, he became a lecturer at Göttingen in 1834. He was professor of chemistry at Kassel (1836), Marburg (1841), and Heidelberg (1852–89).

Bunsen carried out one great series of researches in organic chemistry, *Studies in the Cacodyl Series* (1837–42), after which he abandoned organic for analytical and inorganic chemistry. During his research on the highly toxic cacodyl compound he lost one eye in an explosion and twice nearly killed himself through arsenic poisoning. He prepared various derivatives of cacodyl (tetramethylarsine,  $(\text{CH}_3)_2\text{As}_2(\text{CH}_3)_2$ ), including the chloride, iodide, fluoride, and cyanide, and his work was eagerly welcomed by Jöns BERZELIUS as confirmation of his theory that organic chemistry mirrored inorganic, the “radical theory.”

Bunsen was a great experimentalist, an expert in gas analysis and glass blowing, and a pioneer of photochemistry and spectroscopy. He also worked in electrochemistry, devising an

improved version of the Grove cell. At Heidelberg he used his new cell to produce metals by electrodeposition. The classic paper *Chemical Analysis through Observation of the Spectrum* (1860) by Bunsen and Gustav KIRCHHOFF ushered in the era of chemical spectroscopy. The spectroscope was an extremely sensitive analytical instrument. With it Bunsen discovered two new elements: rubidium and cesium.

The famous *Bunsen burner* was introduced by him in 1855, although a similar burner, used by Michael FARADAY, did exist before Bunsen and the regulating collar was a later refinement. He greatly refined gas analysis and wrote a standard treatise on the subject, *Gasometrische Methoden* (1857, *Methods in Gas Measurement*).

Bunsen was a great teacher and at Heidelberg he became a legend. Chemists who came to study with him included Adolph KOLBE, Edward FRANKLAND, Victor and Lothar MEYER, Friedrich BEILSTEIN, and Johann BAEYER.

**Burbank, Luther** (1849–1926) *American plant breeder*

Burbank was brought up on a farm in Lancaster, Massachusetts, and received only an elementary education. He began breeding plants in 1870, when he bought a 7-hectare (17.3-acre) plot of land. After about a year he had developed the Burbank potato, which was introduced to Ireland to help combat the blight epidemics. By selling the rights to this potato he made \$150, which he used to travel to California, where three of his brothers had already settled.

Burbank established a nursery and experimental farm in Santa Rosa, where the climate was especially conducive to fruit and flower breeding – his occupation for the next 50 years. He worked by making multiple crosses between native and introduced strains, using his remarkable skill to select commercially promising types. These were then grafted onto mature plants to hasten development, so that their value could be rapidly assessed. In this way he produced numerous new cultivated varieties of plums, lilies, and many other ornamentals and fruits.

The works of Charles DARWIN, particularly *The Variation of Animals and Plants under Domestication*, greatly influenced Burbank. However his success in varying plant characters reinforced his belief in the inheritance of acquired characteristics, even though he knew of Gregor MENDEL's research.

**Burbidge, Eleanor Margaret** (1919– ) *British astronomer*

Born Margaret Peachey in Davenport, England, Burbidge studied physics at the University of London. After graduation in 1948 she joined

the University of London Observatory where she obtained her PhD and served as acting director (1950–51). She then went to America as a research fellow, first at the Yerkes Observatory of the University of Chicago (1951–53) and then at the California Institute of Technology (1955–57). The period 1953–55 was spent in highly productive work at the Cavendish Laboratory in Cambridge, England. She returned to Yerkes in 1957, serving as associate professor of astronomy from 1959 to 1962 and then transferred to the University of California, San Diego, where she was professor of astronomy from 1964 until 1990 and emeritus professor from 1990. She also served (1979–88) as director of the Center for Astrophysics and Space Sciences.

Burbidge returned briefly to England in 1972 on leave of absence to become director of the Royal Greenwich Observatory, now situated at Herstmonceux Castle in Sussex. She declared her aim to be to strengthen optical astronomy in Britain. But as the 98-inch (2.5-m) Isaac Newton telescope at Herstmonceux was only a few hundred feet above sea level and sited above a marsh her opportunities for observation at the Royal Observatory were somewhat limited. A little over a year later, in October 1973, Burbidge resigned amid much speculation declaring simply that she preferred “to return to her own research work rather than devote a major part of her time to administrative matters.”

In 1948 she married Geoffrey Burbidge, a theoretical physicist, and began a highly productive partnership. They collaborated with Fred HOYLE and William FOWLER in 1957 in publishing a key paper on the synthesis of the chemical elements in stars. They also produced one of the first comprehensive works on quasars in their *Quasi-Stellar Objects* (1967). She had earlier recorded the spectra of a number of quasars with the 120-inch (3-m) Lick reflector and discovered that their spectral lines displayed different red shifts, probably indicating the ejection of matter at very high speeds.

The first accurate estimates of the masses of galaxies were based on Margaret Burbidge’s careful observation of their rotation. She was awarded the Bruce Medal in 1999, with her husband Geoffrey Burbidge.

### **Burbidge, Geoffrey** (1925– ) *British astrophysicist*

Born at Chipping Norton in central England, Burbidge graduated in 1946 from the University of Bristol and obtained his PhD in 1951 from the University of London. In the period 1950–58 he held junior university positions at London, Harvard, Chicago, Cambridge (England), and the Mount Wilson and Palomar Observatories in California. He became associate

professor at Chicago (1958–62) before being appointed associate professor (1962), then professor of physics (1963) at the University of California, San Diego. Burbidge was director of the Kitt Peak National Observatory, Arizona, from 1978 until 1984, when he moved to the University of California, San Diego, as professor of astronomy.

Burbidge began his research career studying particle physics but after his marriage in 1948 to Margaret Peachey, who was to become one of the world’s leading optical astronomers, he turned to astrophysics and began a productive research partnership with his wife. The Burbidges worked on the mysterious quasars, first described by Allan SANDAGE in 1960, and produced in their *Quasi-Stellar Objects* (1967) one of the earliest surveys of the subject. Geoffrey Burbidge was far from convinced that quasars were “cosmologically distant” in accordance with the orthodox interpretation of their massive red shifts. In 1965 he proposed with HOYLE that they were perhaps comparatively small objects ejected at relativistic speeds from highly active radio galaxies such as Centaurus A. The effect of this would be to place the main body of quasars only 3–30 million light years from our Galaxy and not the 3 billion light years or more demanded by the generally accepted view.

He was equally reluctant to accept without reservation that other emerging orthodoxy of the 1960s, the big-bang theory on the origin of the universe. In 1971 he published a paper in which he maintained that we still do not know whether the big-bang occurred and that much more effort must be devoted to cosmological tests. Although such views have found little favor, Burbidge has continued, like Hoyle, to be highly productive, rich in new ideas, and yet to remain outside and somewhat skeptical of prevailing cosmological and astrophysical orthodoxy. He was awarded the Bruce Medal in 1999, with his wife Margaret Burbidge.

### **Buridan, Jean** (1300–1358) *French philosopher and logician*

Buridan (**byoo-ri-dan** or **boo-ree-dan**) was born in Béthune, France, and studied at the University of Paris under William of Ockham before being appointed professor of philosophy there. It is likely that he remained there all his life as a secular cleric as he is reported to have served as rector of the university in 1328 and 1340.

In his physical works Buridan developed a devastating critique of ARISTOTLE’S account of motion. In its place he proposed an impetus theory in which an enforced motion such as the spinning of a millstone is explained by something being impressed into it by the original motive force. Without any external resistance, according to Buridan, the stone would continue spinning forever. The greater the mass and

speed of a body the greater its impetus. With such an explanatory framework Buridan and later theorists could begin to tackle some of the basic problems of motion.

Buridan was also an acute logician with his *Sophismata* (Fallacies) containing argument sufficiently subtle to interest contemporary logicians. The animal known as *Buridan's ass* (which was unable to choose between two equidistant bundles of hay) does not, however, appear in any of his works. A similar example does occur in Buridan's commentary on Aristotle's *De caelo* (On the Heavens) where the ass is in fact a dog.

### **Burkitt, Denis Parsons (1911–1993)** *British surgeon*

Born in Enniskillen, now in Northern Ireland, Burkitt attended Dublin University, receiving his BA in 1933 and MB in 1935. Having become a fellow of Edinburgh's Royal College of Surgeons in 1938, Burkitt served in the Royal Army Medical Corps during World War II (1941–46). After the war he worked in Uganda as government surgeon (1946–64), being appointed senior consultant surgeon to the Ugandan Ministry of Health in 1961.

In the late 1950s, Burkitt began studying a form of lymphoma that affected children in his part of Africa. Typically these patients had malignant swellings of the facial bones, although tumors could also be found in the ovaries and abdominal lymph nodes. Burkitt demonstrated that all cases were characterized by infiltration of the affected tissues by lymphocytes, and that the various clinical manifestations were all part of the same cancerous condition, now

known as *Burkitt's lymphoma*. With his colleagues Edward Williams and Clifford Nelson, Burkitt undertook a geographical survey of the incidence of the disease and found it to be correlated with the same temperature and rainfall zones as malaria. This suggested that the occurrence of the disease may be linked with the distribution of certain insect carriers, as with malaria. Also, an association has now been established between the disease and Epstein-Barr virus, which is isolated from many cases. Burkitt's lymphoma survey is regarded as one of the pioneering studies of geographical pathology.

In later life, and drawing on his experiences of the contrasting diets of developed and developing countries, Burkitt did much to promulgate the benefits to health of a high-fiber diet, and argued that certain diseases of affluent societies, such as bowel cancer and appendicitis, are attributable to dietary fiber deficiency. His publications include *Burkitt's Lymphoma* (1970), *Refined Carbohydrate Foods and Disease* (1975), and *Western Diseases, Their Emergence and Prevention* (1981).

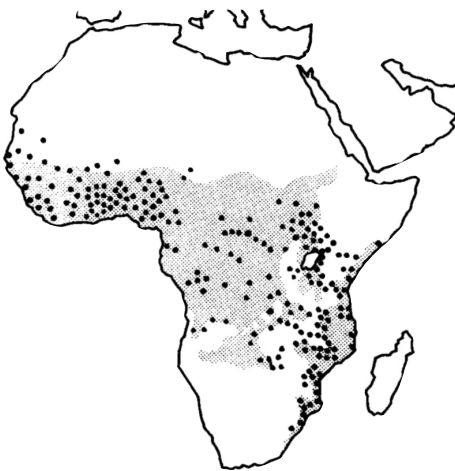

### **Burnet, Sir Frank Macfarlane (1899–1985)** *Australian virologist*

There is virtually nothing that has come from molecular biology that can be of any value to human living in the conventional sense of what is good, and quite tremendous possibilities of evil, again in the conventional sense.

—*Changing Patterns* (1968)

Burnet's father, a bank manager, had emigrated to Australia from Scotland as a young man. Burnet was born in Traralgon and studied medicine at Melbourne University, gaining his MD in 1924. After a period abroad at the Lister Institute, London, where he gained his PhD in 1928, Burnet returned to Melbourne to work at the Walter and Eliza Hall Institute; he remained here until his retirement in 1965, having been its director since 1944.

From 1932 until 1933 Burnet worked with the Medical Research Council virology unit in London on influenza. He continued to work with the flu virus in Melbourne, searching for something more convenient than ferrets in which to cultivate the virus. Following the lead of Ernest GOODPASTURE, Burnet showed (1935) that flu virus could be grown in chick embryo (hen's eggs). While developing this new technique Burnet made an unexpected discovery. Adult hens could be infected with flu and, as was well known, develop antibodies against the virus. Yet the chicks born from the eggs used to grow the flu virus failed to develop any flu antibodies. It appeared that there was a period in development before which an organism was "immunologically illiterate"; it could not dis-

**BURKITT'S LYMPHOMA** Map showing how the incidence of the disease correlates with the incidence of malaria in Africa.

tinguish between its own tissue and alien tissue.

In 1949 Burnet drew the immunological conclusions from his work. If an antigen were injected into an animal before birth it should develop an immunological tolerance to that antigen, and consequently fail to produce antibodies if ever exposed later in life. But, Burnet discovered, this did not happen. While a young chick exposed to the antigen as an embryo would fail to develop antibodies, such chicks in adulthood display the usual intolerance and produce antibodies to the appropriate antigen. Burnet had failed to realize that the exposure to the antigen must be continuous for tolerance not only to develop but be maintained. The point was later established by Peter MEDAWAR and his colleagues in 1953. It was for this work that Burnet shared the 1960 Nobel Prize for physiology or medicine with Medawar.

Burnet himself found his work on antibodies more satisfying. How, he asked, are organisms able to respond so quickly and so effectively to antigens never before encountered? In 1957, in a paper entitled *Antibody Production Using the Concept of Clonal Selection*, Burnet argued that antibodies, or more accurately the lymphocytes that produce the antibodies, are so comprehensive in their diversity that there is likely to be an antibody in circulation to match any conceivable antigen. The lymphocytes are specialized cells and can respond to just one kind of antigen by producing the appropriately matching antibodies. Once stimulated, however, the lymphocytes will pump out vast numbers of antibodies indefinitely.

Burnet described his work on his clonal selection theory in his autobiography, *Changing Patterns* (1968).

### **Burnet, Thomas** (1635–1715) *English cleric and geologist*

Burnet was born at Croft in England and was educated at Cambridge University, becoming a fellow of Christ's College in 1657. After a period as tutor to various noblemen he was appointed master of Charterhouse School in 1685. He was also appointed chaplain to William III in 1686 but was later forced to resign (1692) because of his controversial account of the history of the Earth.

In 1681 he published his *Telluris theoria sacra*, which was published in an English version as *The Sacred Theory of the Earth* in 1684 and revised and extended in 1691. In this he tackled the problem that was to face all geologists until the last century – how to write a history of the Earth that was consistent with the account given in Genesis. His aim was to take the facts of scripture and show how they could be used to give a rational account of the development of the Earth.

His theory was that the Earth had once been

entirely smooth, trapping beneath its shell a large volume of water. Owing to the action of the Sun this shell – the Earth's crust – cracked and released the flood of water; parts of the shattered crust remaining formed the mountains.

Burnet's attempt to explain the history of the Earth in natural terms met a torrent of opposition, both theological and scientific. The strongest argument against this explanation was the presence of marine fossils in mountains for, if the Earth's crust from which the mountains were formed was created before the flood, how could it have come to contain evidence of marine life?

### **Burt, Cyril Lodowic** (1883–1971) *British psychologist*

The son of a London physician, Burt was educated at Oxford University where he studied classics and philosophy. He was introduced to psychology by Oxford's single psychologist, William McDougall. After a period of study in Germany, Burt was appointed to a lectureship in experimental psychology at Liverpool University in 1908. He returned to London in 1912 and remained there for the rest of his career, first as educational psychologist to the London County Council, and from 1932 until his retirement in 1950 as professor of psychology at University College, London.

Much of Burt's life was devoted to the study of intelligence. The statistician Charles Spearman had claimed in 1905 to be able to measure "g," the factor of general intelligence, objectively. In this he was followed by Burt, who further insisted that intelligence was innate as well as general. The surest way to establish this would be, Burt realized, to measure the intelligence quotients of identical twins separated at birth. If intelligence really was inherited, then the IQ of separated twins should show a high degree of correlation, even though they would have been raised in different homes, and educated in different ways. Consequently, he began to collect data from 1912 onwards. By 1966 Burt had collected a sample of 53 identical separated pairs and the correlation of their IQs was the high figure of 0.771.

Soon after, the journalist Oliver Gillie and the psychologist L. J. Kamin began to raise questions about Burt's work. Not only could research collaborators not be found, but their very existence could not be established. Again, the correlation figure of 0.771 appeared to remain constant over the years, despite changes in sample size, a most unlikely statistical outcome. Further, it turned out that much of Burt's work was based not on measurement, but on estimates of home background and intelligence that he made at a distance. For these and other reasons, Burt's work in this field has been largely discounted.

**Butenandt, Adolf Friedrich Johann** (1903–1995) *German organic chemist and biochemist*

Butenandt (**boo-te-nant**), who was born at Bremerhaven-Lehe (now Wesermünde) in Germany, took his first degree in chemistry at the University of Marburg and gained his doctorate in 1927 under Adolf WINDAUS at Göttingen. He remained at Göttingen as *Privatdozent* until 1933. Following the work of Windaus on cholesterol, Butenandt investigated the sex hormones and in 1929 he isolated the first pure sex hormone, estrone, from the urine of pregnant women (the compound was also discovered independently by Edward Doisy). A search for the male sex hormone resulted in the isolation in 1931 of 15 milligrams of androsterone from 3,960 gallons of urine.

In 1933 he became professor of organic chemistry at the Danzig Institute of Technology and here he demonstrated the similarities between the molecular structures of androsterone and cholesterol. His proposed structure for androsterone was confirmed by Leopold RUŽIČKA's synthesis in 1934. The male hormone testosterone was synthesized by Butenandt and Ružička only months after its isolation in 1935. Butenandt and Ružička were jointly awarded the Nobel Prize for chemistry in 1939 but Butenandt was forbidden to accept it by the Nazi government. Butenandt was also the first to crystallize an insect hormone, ecdysone, and found that this too was a derivative of cholesterol. Later he led research on the isolation and synthesis of the pheromones.

From 1936 to 1945 Butenandt was director of the Max Planck Institute for Biochemistry at Tübingen and from 1945 to 1956 professor of physiological chemistry there. He retained these posts when the institute moved to Munich in 1956, and in 1960 he succeeded Otto HAHN as president of the Max Planck Society, becoming honorary president in 1972.

**Butlerov, Aleksandr Mikhailovich** (1828–1886) *Russian chemist*

Butlerov (**boot-lyer-of**), who was born in Chistopol in Russia, studied at the University of Kazan, graduating as a master of chemistry in 1851. He received his doctorate in 1854 at Moscow and then worked at Kazan, as lecturer (1852) and professor (1857). Russian chemistry, which had been largely dominated by Germans, was backward and Butlerov spent the period 1857–58 traveling in Europe, where he met Friedrich KEKULÉ, Justus von LIEBIG, Friedrich WÖHLER, and Archibald COUPER, and worked in Charles WURTZ's laboratory in Paris.

Butlerov was mainly a theoretician and he extended Kekulé's concepts of organic structure. He proposed that each organic compound has a unique configuration and he invented the term "chemical structure." In 1864 he predicted

the existence of tertiary alcohols and in 1876 first introduced the idea of isomers in chemical equilibrium (tautomerism). He wrote *An Introduction to the Full Study of Organic Compounds* (1864). Butlerov was appointed rector of the University of Kazan in 1860 but amid student unrest and clashes between the Russian and German factions he resigned, was reinstated, and finally resigned in 1863. In 1867 he became professor of chemistry at St. Petersburg, where he became increasingly involved in other activities, such as beekeeping and spiritualism.

**Buys Ballot, Christoph Hendrik Diederik** (1817–1890) *Dutch meteorologist*

Buys Ballot (BIs ba-lot) was the son of a minister from Kloetinge in the Netherlands. He was educated at the University of Utrecht, obtaining his PhD in 1844, and became professor of mathematics in 1847 and professor of physics in 1867. He did much to organize the observation and collection of meteorological data in the Netherlands and founded, in 1854, the Netherlands Meteorological Institute.

He is best remembered for the law on wind direction he formulated in 1857. This states that an observer facing the wind in the northern hemisphere has the lower pressure on his right and the higher pressure on his left; in the southern hemisphere this is reversed. Its justification is clearer if stated in the equivalent form: in the northern hemisphere winds circulate counterclockwise around low-pressure areas and clockwise around high-pressure ones.

**Byrd, Richard Evelyn** (1888–1957) *American polar explorer*

Born in Winchester, Virginia, Byrd graduated from the U.S. Naval Academy in 1912. Forced in 1916 to resign from the navy with an injured leg, he joined the air force. After the end of World War I he became interested in polar aviation. He joined the MacMillan expedition to the Arctic (1924) and, with Floyd Bennett, reportedly made the first flight over the North Pole on 9 May 1926.

Byrd then became interested in Antarctic exploration, leading his first expedition there in 1928. He established his base camp, Little America, on the Ross Ice Shelf and, in 1929, flew over the South Pole. The Antarctic was the largest remaining unmapped and unexplored area of the world and Byrd contributed greatly to opening up and mapping the continent. A more extensive expedition was undertaken in 1933–35, during which Byrd spent five months alone at an Antarctic weather station in 1934, followed by three more, the last in 1955–56.

A large section of the Antarctic was named Marie Byrd Land, after his wife.

**Byron, Augusta Ada, Countess of Lovelace** (1815–1852) *British computer pioneer*

Ada Lovelace was the daughter of Annabella Millbanke and the poet Lord Byron. Ada's mother left her husband after a month of marriage and Ada never saw her father. Born in London, she was educated privately, studying mathematics and astronomy in addition to the more traditional topics. She seems to have developed an early ambition to be a famous scientist. Her correspondence, however, with Mary SOMERVILLE and Augustus De MORGAN, two of her informal teachers, shows that her formal

skills were very limited. De Morgan saw her as a talented beginner who could have become an original mathematician if given the chance to receive a rigorous formal Cambridge-style training. Such routes were not open to young Victorian women.

In 1834 she heard Charles BABBAGE lecture on his famous "difference engine." She offered Babbage her support and they became good friends. In 1842 she translated from French an account of Babbage's analytical engine by the Italian engineer, L. F. Manabrea. At Babbage's suggestion she added some explanatory notes. They constitute one of the primary sources of his work.

## **Cagniard de la Tour, Charles** (1777–1859) *French physicist*

Ferments ... are composed of very simple organized microscopic bodies ... brewer's yeast is a mass of small globulous bodies capable of reproducing themselves ... it is very probably through some effect of their growth that they release carbon dioxide and ... convert [a sugary solution] into a spirituous liquor.

—Describing the role of yeast in fermentation

Born in Paris, France, Cagniard de la Tour (ka-nyar de la toor) was educated at the Ecole Polytechnique and then spent his time as an amateur inventor. In 1819 he invented the disk siren, in which the sound is produced by air blowing through holes in a rotating disk, the pitch being determined by the speed of rotation. He made his most famous discovery in 1822; when he heated certain liquids in sealed tubes he observed that at a particular temperature and pressure the meniscus dividing liquid from vapor disappeared. Under these conditions – known as the *critical state* – the densities of liquid and vapor become the same and the two are identical.

In the field of biology Cagniard de la Tour discovered, independently of Theodor SCHWANN, the role of yeast in alcoholic fermentation. He also studied the physics of the human larynx and the sounds produced by it and invented a machine for studying bird flight.

## **Cahours, August André Thomas** (1813–1891) *French organic chemist*

These classic works [Cahours's] have become one of the solid foundations on which we today base the fundamental proposition that as a perfect gas the [gram] molecular weight of most substances occupies the same volume in the vapor state.

—Armand Gautier (1891)

Cahours (ka-hor), who was born in Paris, France, was professor at the Ecole Polytechnique there (1871) and warden of the Paris mint. He made many notable discoveries, including methyl salicylate, amyl alcohol in fusel oil, anisole and phellandrene in fennel oil, and the alkyl compounds of aluminum, arsenic, and beryllium.

## **Cailletet, Louis Paul** (1832–1913) *French physicist*

Born in Chatillon-sur-Seine in France, the son of a metallurgist, Cailletet (ka-ye-tay) studied in Paris and then became a manager at his father's foundry.

He is most famous for his work on the liquefaction of gases. Cailletet realized that the failure of others to liquefy the permanent gases, even under enormous pressures, was explained by Thomas Andrew's concept of critical temperature. In 1877 he succeeded in producing liquid oxygen by allowing the cold, compressed gas to expand. This technique, depending on the effect discovered by JOULE and THOMSON, cooled the gas to below its critical temperature. In later experiments he liquefied nitrogen and air. Raoul PICTET, working independently, used a similar technique. In 1884 Cailletet was elected to the Paris Academy for his work. He is also the inventor of the altimeter and the high-pressure manometer.

## **Callippus** (c. 370 BC–c. 300 BC) *Greek astronomer*

Callippus (ka-lip-us), who was born in Cyzicus (now in Turkey), was possibly a pupil of EUDOXUS. He is also known to have had discussions on astronomy with ARISTOTLE in Athens. Although none of his works have survived he is known to have reformed the Eudoxan system. Callippus is also reported as suggesting improvements in the Metonic cycle, the period – of 19 years or 235 synodic (lunar) months – after which the phases of the Moon recur on the same days of the year. He proposed taking a period of 76 years (4 Metonic cycles) made from 940 lunar months, 28 of which would be intercalary (inserted). This would give a solar year of precisely 365 $\frac{1}{4}$  days. The Greeks never actually adopted any of these cycles but they do give some indication of how accurately their astronomers had worked out the length of the year.

## **Calvin, Melvin** (1911–1997) *American chemist and biochemist*

Born in St. Paul, Minnesota, Calvin studied chemistry at the Michigan College of Mining and Technology and gained his BS degree in

1931. After obtaining his PhD from the University of Minnesota in 1935 he spent two years at the Victoria University of Manchester, England, working with Michael POLANYI. Here he became interested in chlorophyll and its role in the photosynthetic process in plants. Calvin began a long association with the University of California at Berkeley in 1937. From 1941 to 1945 he worked on scientific problems connected with the war, including two years on the Manhattan Project (the atomic bomb).

In 1946 Calvin became director of the Bio-organic Division of the Lawrence Radiation Laboratory at Berkeley, where he used the new analytical techniques developed during the war – ion-exchange chromatography, paper chromatography, and radioisotopes – to investigate the “dark reactions” of photosynthesis, i.e., those reactions that do not need the presence of light. Plant cells were allowed to absorb carbon dioxide labeled with the radioisotope carbon-14, then immersed at varying intervals in boiling alcohol so that the compounds they synthesized could be identified. In this way the cycle of photosynthetic reactions (known as the *Calvin cycle*) was elucidated and shown to be related in part to the familiar cycle of cell respiration. This work, which was collected in *The Path of Carbon in Photosynthesis* (1957), earned Calvin the Nobel Prize for chemistry in 1961.

Calvin remained at Berkeley, as director of the Laboratory of Chemical Biodynamics (1960–63), professor of molecular biology (1963–71), and professor of chemistry (1971). He continued to work on problems of photosynthesis (especially on the role of chlorophyll in quantum conversion) and on the evolution of photosynthesis.

### **Campbell, Keith** (1954– ) *British cell biologist*

Campbell initially qualified as a medical technician, and then studied microbiology at Queen Elizabeth College, London, where he obtained a BSc. He worked briefly in the Yemen as a chief medical laboratory technician and, on returning to the UK, embarked on a project to help control Dutch elm disease. In 1983 he joined the University of Sussex, where he was subsequently awarded a DPhil. Following two postdoctoral positions he joined the Roslin Institute, near Edinburgh, in 1990. He left the Institute in 1997 to become head of embryology at a biotech company, PPL Therapeutics, and in 1999 he was appointed professor of animal development at Nottingham University.

From the outset, Campbell's main scientific interest was the cell cycle and its control mechanisms. From the time it is formed to the time it divides, every cell goes through a sequence of events known as the *cell cycle*. For his doctoral thesis at Sussex University, Campbell investigated the control exerted on nuclear division in

yeast and *Xenopus* (a toad) by factors in a cell's cytoplasm.

At the Roslin Institute, Campbell collaborated with the embryologist Ian WILMUT, who was refining the technique of nuclear transfer for cloning mammals. This technique, employed by cloning pioneers such as Steen WILLADSEN, involved taking a donor cell from an early embryo and fusing it with a recipient unfertilized egg cell from which the nucleus had been removed. The fused cell was then implanted in a surrogate mother and allowed to develop. Campbell devised a new method of synchronizing the cell cycles of the donor and recipient cells, as a means of reducing the high failure rate. He initially placed the donor cells in a low-nutrient medium, thereby starving them into a state of quiescence in which all but their most essential genes were switched off. This coordinated their cell cycle with that of the recipient egg cells. As a result of this modification, in 1995 Wilmut and Campbell successfully cloned two sheep from embryo cells – Megan and Morag – and in 1996 came their most famous arrival – another sheep named Dolly, the first mammal to be cloned from fully differentiated body cells.

After moving to PPL Therapeutics, a company with close ties to the Roslin Institute, Campbell focused on applying cloning technology to developing transgenic livestock with potential medical applications, for example as a source of stem cells or tissue for human transplants. He continues to research mechanisms of development and differentiation, and the cell cycle.

### **Camerarius, Rudolph Jacob** (1665–1721) *German botanist*

Born the son of a professor of medicine at Tübingen in Germany, Camerarius (kam-er-aree-uus) was himself educated there and received his doctorate in 1687. He joined the staff at Tübingen and following his father's death in 1695 was appointed professor of medicine and director of the botanic gardens, posts he occupied until his death from TB in 1721.

In 1694 in *De sexu plantarum* (On the Sex of Plants) Camerarius produced clear experimental evidence for the sexuality of plants first proposed by John RAY and Nehemiah Grew. By isolating pistillate (female) dioecious plants from staminate (male) plants (dioecious referring to plant species where the male and female flowers are borne on separate plants), he was able to show that although the pistillate plants produced fruit, they lacked seeds. With monoecious plants (those that bear separate unisexual male and female flowers on the same plant, e.g., corn) he found that removing the male inflorescence also resulted in sterile fruit.

In his description of plant anatomy Camerarius identified the stamens as the male organ

and the style and stigma as the female part. He also described the role of pollination.

**Cameron, Sir Gordon Roy (1899–1966)**  
*Australian pathologist*

Born at Echuca, Australia, the son of a Methodist minister, Cameron studied medicine at Melbourne University, graduating in 1922. He worked first at the university and then at the Walter and Eliza Hall Institute before leaving for Europe in 1927 to do postgraduate work at Freiburg. Shortly afterward he was appointed to the staff of University College Hospital, London, where he served as professor of morbid anatomy from 1937 until his retirement in 1964.

Cameron worked on a wide range of problems including pulmonary edema, inflammation, and the pathology of the spleen and liver. He also produced a major survey of all aspects of the field with his *Pathology of the Cell* (1952).

**Candolle, Augustin Pyrame de (1778–1841)**  
*Swiss botanist*

Candolle (kan-dol), who was born in Geneva, Switzerland, studied medicine for two years at the academy there before moving to Paris in 1796 to study both medicine and natural sciences. In Paris he met many distinguished naturalists, including Georges CUVIER and Jean Baptiste LAMARCK, and quickly established his own reputation through the publication of many outstanding monographs on plants. He received his MD from the University of Paris in 1804 and, at the request of the French government, made a botanical and agricultural survey of France between 1806 and 1812.

In 1813 he published his famous *Théorie élémentaire de la botanique* (Elementary Theory of Botany), in which he introduced the term “taxonomy” to mean classification. This work was based on the natural classificatory systems of Cuvier and Antoine JUSSIEU, and in it Candolle maintained that relationships between plants could be established through similarities in the plan of symmetry of their sexual parts. He realized that the symmetry could be disguised by fusion, degeneration, or loss of sexual organs, making structures with a common ancestry appear different. Candolle thus formulated the idea of homologous parts – a concept that lends much weight to the theory of evolution, but surprisingly he continued to believe in the immutability of species. Candolle’s classification replaced that of LINNAEUS and was used widely until George BENTHAM and Joseph HOOKER produced their improved system 50 years later.

Candolle also made important contributions to plant geography, realizing that the distribution of vegetation can be profoundly influenced by soil type. The relationships he described be-

tween plants and soil were backed up by personal observations from his travels in Brazil, East India, and North China.

From 1808 to 1816 Candolle was professor of botany at Montpelier University, after which he returned to Geneva to take the chair of natural history at the Academy. On his arrival in Geneva he completely reorganized the gardens. Between 1824 and 1839 he published the first seven volumes of his huge *Prodromus Systematis Naturalis Regni Vegetabilis* (Guide to Natural Classification for the Plant Kingdom), an encyclopedia of the plant kingdom. His son, Alphonse de Candolle, saw to the publication of the remaining ten volumes after his father’s death and also carried on many of his father’s other schemes.

**Cannizzaro, Stanislao (1826–1910)**  
*Italian chemist*

Born the son of a magistrate in Palermo, Sicily, Cannizzaro (kan-i-zah-roh) studied physiology in his native city and at Naples. He turned to organic chemistry after realizing the importance of chemical processes in neurophysiology, and from 1845 to 1847 worked as a laboratory assistant to R. Piria at Pisa. Cannizzaro was an ardent liberal and in 1847 he returned to Sicily to fight as an officer in the insurrection against the ruling Bourbon regime. Following the abortive revolution of 1848 he went into exile and returned to chemistry, working with Michel Eugène CHEVREUL in Paris (1849–51).

Cannizzaro returned to Italy in 1851 as professor of chemistry and physics at the Collegio Nazionale at Alessandria. In 1853 he discovered the reaction known as *Cannizzaro’s reaction*, in which an aromatic aldehyde is simultaneously oxidized and reduced in the presence of concentrated alkali to give an acid and an alcohol.

In 1855 Cannizzaro moved to Genoa as professor of chemistry and here he produced the work for which he is chiefly remembered. His pamphlet *Sunto di un corso di filosofia chimica* (1858; Epitome of a Course of Chemical Philosophy) finally resolved more than 50 years of confusion about atomic weights. In 1860 a conference was held at Karlsruhe, Germany, to discuss the problem. No agreement was reached but Cannizzaro’s pamphlet was circulated and soon after was widely accepted. In it Cannizzaro restated the hypothesis first put forward by Amedeo AVOGADRO, clearly defined atoms and molecules, and showed that molecular weights could be determined from vapor-density measurements.

Politics intervened once more in Cannizzaro’s life and in the struggle to reunite Italy he returned to Palermo in 1860 to join Garibaldi. He was professor of inorganic and organic chemistry at Palermo until 1870, when he went to Rome to found the Italian Institute of Chem-

istry. The most notable research of this last period was that on santonin, a compound derived from species of *Artemisia* (wormwoods) that is active against intestinal worms, which Cannizzaro showed to be a derivative of naphthalene. He was widely honored and became a senator in 1871.

**Cannon, Annie Jump** (1863–1941) *American astronomer*

Miss Cannon was not given to theorizing; it is probable that she never published a controversial word or a speculative thought.

That was the strength of her scientific work – her classification was dispassionate and unbiased.

—Cecilia Payne-Gaposchkin, “Miss Cannon and Stellar Spectroscopy,” *The Telescope*, No. 8 (1941)

Annie Cannon was the daughter of a Delaware state senator and was born in Dover in that state. She was one of the first girls from Delaware to attend university, being a student at Wellesley College from 1880 to 1884. After a decade spent at home, where she became deaf through scarlet fever, she entered Radcliffe College in 1895 to study astronomy. In 1896 she was appointed to the staff of the Harvard College Observatory, as it was the practice of the observatory, under the directorship of Edward PICKERING, to employ young well-educated women to do calculations. She worked there for the rest of her career, serving from 1911 to 1932 as curator of astronomical photographs. In 1938, after nearly half a century of distinguished service, she was appointed William Cranch Bond Astronomer.

One of the main programs of the observatory was the preparation of the *Henry Draper Catalogue* of a quarter of a million stellar spectra. Stars were originally to be classified into one of the 17 spectral types, A to Q, which were ordered alphabetically in terms of the intensity of the hydrogen absorption lines. Cannon saw that a more natural order could be achieved if some classes were omitted, others added, and the total reordered in terms of decreasing surface temperature. This produced the sequence O, B, A, F, G, K, M, R, N, and S. Cannon showed that the great majority of stars can be placed in one of the groups between O and M. Her classification scheme has since only been slightly altered.

Cannon developed a phenomenal skill in cataloging stars and at the height of her power it was claimed that she could classify three stars a minute. Her classification of over 225,000 stars, brighter than 9th or 10th magnitude, and the compilation of the *Catalogue* took many years. It was finally published, between 1918 and 1924, as volumes 91 to 99 of the *Annals of Harvard College Observatory*. She continued the work unabated, later publications including an additional 47,000 classifications in the

*Henry Draper Extension* (*Annals*, vol. 100, 1925–36). Even as late as 1936 when she was over 70 she undertook the classification of 10,000 faint stars submitted to her by the Cape of Good Hope Observatory.

**Cannon, Walter Bradford** (1871–1945) *American physiologist*

Only the moral degenerate is capable of inflicting the torment that the anti-visionist imagines. No one who is acquainted with the leaders in medical research who are responsible for the work done in the laboratories can believe for a moment that they are moral degenerates.

—*Journal of the American Medical Association*, No. 51 (1908)

Cannon, who was born in Prairie du Chien, Wisconsin, graduated from Harvard in 1896 and was professor of physiology there from 1906 to 1942. His early work included studies of the digestive system, in particular the use of x-rays to study stomach disorders. For this he introduced the *bismuth meal*. Most of his working life, however, was spent studying the nervous system, particularly the way in which various body functions are regulated by hormones. As early as 1915 he showed the connection between secretions of the endocrine glands and the emotions. In the 1930s he worked on the role of epinephrine in helping the body to meet “fight or flight” situations. He also studied the way hormone-like substances are involved in transmitting messages along nerves.

**Canton, John** (1718–1772) *British physicist*

Canton, who was born in Stroud in western England, was a schoolmaster in London and a gifted amateur physicist. He invented a new technique for making artificial magnets in 1749 and was elected to the Royal Society, which gave him a medal for this work in 1751.

He followed Benjamin FRANKLIN's theories of electrostatics and was the first in England to repeat Franklin's experiments with lightning. He also discovered a few more properties of electrostatic induction, including the fact that both glass and clouds could become negatively charged instead of, as was usual, positively. In 1757, he made the first observations of fluctuations in the Earth's magnetic field, which, at the end of the next century, led to the discovery of charged layers in the atmosphere. In 1762 he demonstrated that – in spite of scientific opinion to the contrary – water was compressible.

**Cantor, Georg Ferdinand Ludwig Philipp** (1845–1918) *German mathematician*

The son of a prosperous merchant of St. Pe-

tersburg, at that time the capital of Russia, Cantor (**kan-tor** or **kahn-tor**) was educated at the University of Berlin where he completed his PhD in 1868. In 1870 he joined the faculty of the University of Halle and was appointed professor of mathematics in 1879. He spent his entire career at Halle, although it was a career repeatedly interrupted after 1884 by mental illness; he was a manic depressive and was hospitalized first in 1899 and several times thereafter. After 1897 he made no further contribution to mathematics and died of heart failure in 1918 in a mental institution.

Although Cantor's earliest work was concerned with FOURIER series, his reputation rests upon his contribution to transfinite set theory. He began with the definition of infinite sets proposed by DEDEKIND in 1872: a set is infinite when it is similar to a proper part of itself. Sets with this property, such as the set of natural numbers, are said to be "denumerable" or "countable."

In 1874, Cantor published a remarkable paper in Crelle's *Journal*. Here he first showed that the rational numbers (numbers that can be expressed by dividing one integer by another: 1/2, 1/3, 1/4, 2/3, etc.) are denumerable – they can be put in a one-to-one correspondence with the natural numbers (1, 2, 3, etc.). The usual method of demonstrating this is to set up an array in which the first line contains all the rationals in which the denominator is 1 (1/1, 2/1, 3/1, etc.), the second line has all the rationals with a denominator 2 (1/2, 2/2, 3/2, etc.), and so on. It is then possible to "count" all the fractions in the array by moving diagonally backwards and forwards through the array, and it is clear that every rational number can be put in one-to-one correspondence with an integer. This technique, known as *Cantor's diagonal procedure*, is not the one Cantor used in the 1874 paper, although he did give the diagonal demonstration later. The set of rational numbers and the set of natural numbers are said to have the same "power."

Cantor then went on to show that the set of all real numbers is not denumerable. He did this by a *reductio ad absurdum* method. First he assumed that all the real numbers between 0 and 1 are denumerable and expressed as infinite decimal fractions (e.g., 1/3 = 0.333...). They are arranged in denumerable order:

$$a_1 = 0.a_{11} a_{12} a_{13} a_{14} \dots$$

$$a_2 = 0.a_{21} a_{22} a_{23} a_{24} \dots \text{ etc.}$$

Here,  $a_1$  is the first real number and  $a_{11}$  the first digit,  $a_{12}$  the second, etc. The first digit of the second number  $a_2$  is  $a_{21}$ , etc. Cantor then showed that it is possible to construct an infinite decimal that is not in the above set by taking the diagonal containing  $a_{11}$ ,  $a_{22}$ ,  $a_{33}$ , etc., and changing the digit to 9 if it is 1 and changing the digit to 1 for all other digits. This gives

**CANTOR'S METHOD** The diagonal procedure for demonstrating that the rational numbers are countable.

a number that is a real number between 0 and 1, yet is not in the above set. In other words, the real numbers are not denumerable – there is a sense in which there are "more" real numbers than rational numbers or natural numbers. The set of real numbers has a higher power than the set of natural numbers.

Cantor designated the set of natural numbers, the smallest transfinite set, with the symbol  $\aleph_0$  and the set of real numbers by the letter  $c$ , the number of the continuum.  $\aleph$  is the first letter of the Hebrew alphabet, called "aleph." Cantor's symbol  $\aleph_0$  is referred to as "aleph nul."

Cantor went on to show that there were in fact an infinite number of transfinite sets. The power set of a set  $S$  consists of the subsets of  $S$ . Thus let  $S = (1,2)$ , the power set of  $S$ ,  $P(S) = \{(1), (2), (1,2), (\emptyset)\}$ , bearing in mind that every set is a member of itself, and that the empty set ( $\emptyset$ ) belongs to every set. In general Cantor demonstrated that if a set  $S$  has  $n$  members then  $P(S)$  will have  $2^n$  members, that  $P(S) > S$ , a result since known as *Cantor's theorem*.

The theorem applies to all sets, infinite as well as finite. Thus the power set of  $\aleph_0$  will be greater than  $\aleph_0$  and the process can be continued with the power set of the power set of  $\aleph_0$ , and so on indefinitely. Cantor had shown that the set of natural numbers had a cardinality of  $\aleph_0$ , and the real numbers,  $c$ , had a cardinality of  $2^{\aleph_0}$ . This enabled him to pose in 1897 the hypothesis that  $2^{\aleph_0} = \aleph_1$ , or, that the continuum ( $c$ ) is the next highest infinite number after  $\aleph_0$ . Cantor made little progress with the continuum problem. It remained for GODEL and COHEN to illuminate the issue many years later.

**Capecci, Mario R. (1937– )** American geneticist

Born in Verona, Italy, Capecchi had a turbulent childhood. His mother was arrested by the Gestapo in 1941 and deported to Dachau concentration camp; the young Capecchi lived with a local peasant family in the Italian Alps, but after a year was forced to set off alone and live

off his wits. Despite numerous hardships, he survived, and after the war was reunited with his mother while being treated for malnutrition in a children's hospital. Mother and son sailed for the USA and Capecchi lived with his aunt and uncle near Philadelphia. Despite his lack of formal education, he made rapid progress at high school and, subsequently, at Antioch College, where he obtained a BS in 1961. He then moved to Harvard University, and the laboratory of James D. WATSON, of Watson and CRICK fame. Following the award of a PhD in 1967 he became assistant professor of biochemistry (1969) and then associate professor (1971). He joined the University of Utah, as professor of biology, in 1973, becoming professor of human genetics in 1989, and distinguished professor of human genetics and biology in 1993. In 1988 he was also appointed investigator for the Howard Hughes Medical Institute.

As early as 1977, Capecchi was developing the techniques that would be crucial for his groundbreaking work in the targeted mutation of genes, using the mouse as an experimental model. He demonstrated that DNA containing functional genes could be injected into the nucleus of a cell using an ultrafine glass needle controlled by micromanipulators, and that the genes would be stably inherited by the progeny cells on subsequent cell division. However, such injected genes were integrated at random into the host chromosome. What was needed was a more precise method of controlling where an introduced gene would be incorporated. This came with the discovery by Capecchi's team that somatic cells (i.e. body cells) were capable of performing homologous recombination, a process hitherto assumed to be confined to germline cells during the production of eggs or sperm. By this process, a mutant gene introduced into a nucleus can, at a low frequency, find and swap places with its homologue, a counterpart gene with the same sequence of bases in its DNA. Hence, appropriate modification of the introduced gene can be used to alter or disable that particular gene in the cell and in all its progeny.

Capecchi and colleagues initially reported their findings in 1982, and by 1984 were confident that the technique offered a viable strategy for gene targeting of cultured mammalian cells. However, was it possible to extend the technique to entire animals, to obtain strains of mice carrying the altered gene? To attempt this Capecchi made use of cultured embryonic stem cells. The British geneticist Martin EVANS had shown that such cells could be genetically modified, and then injected into a developing mouse embryo at the blastocyst stage, ultimately giving rise to various tissues in the adult animal. Such an organism, containing body cells of different genetic makeup, is called a chimera. Capecchi now selected a particular gene, the *Hprt* gene, encoding the enzyme hypoxanthine

phosphoribosyltransferase (HPRT), and disabled it by inserting a gene conferring resistance to the antibiotic neomycin. Embryonic stem (ES) cells transfected with the mutant gene were shown to have lost the ability to make the HPRT enzyme and gained resistance to neomycin, proving that the targeted modification was successfully incorporated. These findings were complemented by the work of Oliver SMITHIES, who had been exploring the potential of gene targeting in attempts to repair defective genes in cultured human tissue cells.

The following year, in 1988, Capecchi and colleagues reported an improved method for selecting ES cells carrying a desired genetic modification. This was the positive-negative selection strategy, which used a vector containing two 'reporter' genes in addition to the 'foreign' gene. Such a strategy enabled researchers to distinguish cells in which the foreign gene had recombined at the target site from cells in which it had integrated at random. This was another significant step toward producing mouse strains with precisely targeted mutations transmitted stably in the germline cells, and ushered in a new era.

The results from Capecchi's team encouraged many others to enter the field. By 1989 the first 'knockout' mouse strains had been bred, with specific genes disabled using the new gene targeting technique. These allowed researchers to identify the effects of targeted mutations on the development or health of the animals, and gave a much clearer insight into the function of the genes concerned. Subsequent developments brought the ability to knockout a gene only in particular tissues or at certain stages of development, and to replace a gene with another, different gene – creating so-called 'knockin' mice.

Capecchi has continued to investigate the effect of targeted mutations on mouse development, and to unravel the roles of various genes, notably Hox genes, in patterning the early mammalian embryo and in adult life. Through such work his team has produced mouse models of certain human genetic disorders, such as synovial sarcoma and alveolar rhabdomyosarcoma, both of which are aggressive childhood cancers in humans.

In 2001 Capecchi was awarded the Albert Lasker Award for basic medical research, jointly with Evans and Smithies. The trio were honoured again in 2007, by receiving the Nobel Prize for physiology or medicine, for discovering principles for introducing specific gene modifications in mice by the use of embryonic stem cells.

**Cardano, Girolamo (1501–1576)** *Italian mathematician, physician, and astrologer*

Oh, the madness of men to give heed to vanity rather than the fundamental things of life!

—*Ars Magna* (1545; The Great Skill)

The work of Cardano (kar-**dah**-noh) constitutes a landmark in the development of algebra and yet in his own time he was chiefly known as a physician. He studied medicine at the University of Pavia, the city of his birth, and at the University of Padua, receiving his degree in 1526. He spent much of his life as a practicing physician, becoming professor of medicine at Pavia in 1543. One of his notable nonmathematical achievements was to give the first clinical description of typhus fever.

It was however in mathematics that Cardano's real talents lay. His chief work was the *Ars magna* (1545; The Great Skill) in which he gave ways of solving both the general cubic and the general quartic. This was the first important printed treatise on algebra. The solution of the general cubic equation was revealed to him by Niccolò TARTAGLIA in confidence and Cardano's publication aroused a bitter controversy between the two. Cardano's former servant, Lodovico Ferrari, had discovered the solution of the general quartic equation. In his later *Liber de ludo aleae* (Book on Games of Chance) Cardano did some pioneering work in the mathematical theory of probability.

Cardano's interests were not, however, limited to mathematics and medicine. He also indulged in philosophical and astrological speculation and this had the unfortunate consequence that in 1570 he was charged with heresy by the Church. He was briefly jailed but was soon released after the necessary recantation. As a result of this episode Cardano lost his post as a professor at the University of Bologna, which he had held since 1562.

### **Carlson, Chester Floyd** (1906–1968) *American inventor and entrepreneur*

The son of a barber from Seattle, Washington, Carlson studied physics at the California Institute of Technology. After graduating in 1930 he began to work for Bell Telephones. Soon after, however, Carlson opted for a change of career, took a law degree, and began to work in the patent department of a New York electronics firm. While there he worked with a refugee German physicist, Otto Kornei.

Carlson was struck by repeated demands for copies of patent applications and the difficulty of meeting this demand rapidly and accurately. Typing could not cope with complex diagrams, and other methods of reproduction were far too slow for a busy legal office. Consequently Carlson and Kornei began to consider what they initially called "electro-photography." The first patent was taken out in 1937 and the first actual electrostatic copy made the following year when Carlson made a clear copy of the date

and site of their achievement, namely, "10-22-38 Astoria."

Carlson's aim was to produce dry, clear, multiple, black-and-white copies of almost any material, rapidly, accurately, and cheaply. Shunning traditional photographic methods as too slow and costly, Carlson began to look at electrostatic forms of reproduction. He began by coating a rotating drum with positively charged selenium, and focusing an image on to the drum. As selenium is photoconductive, exposure to light will remove all charge except in the areas covered by the focused image. The charged image can then be made to pick up the toner, a special black carbon dust, which can in turn be transferred to specially charged paper. After passing through a heating stage to fuse the toner on the paper, and under a brush to remove excess dust, the copy was ready for use.

Once the formidable problem of ensuring the machine's reliability had been overcome, Carlson faced the even greater difficulty of selling his product. After having been turned down by all the leading office-equipment manufacturers, the Batelle Memorial Institute, a research organization in Columbus, Ohio, offered to back Carlson. In 1947 the Haloid Company of Rochester, New York, bought the rights to produce Carlson's new copier. They became Haloid Xerox in 1958, and just plain Xerox in 1961. The term *xerography*, from the Greek word *xeros*, dry, first appeared on 23 October 1948, in the *New York Times*.

With the introduction of the 914 series, the first push-button copier, Xerox was about to conquer the world and turn Carlson into a multimillionaire in the process.

### **Carlsson, Arvid** (1923– ) *Swedish pharmacologist*

Carlsson was born in Uppsala, Sweden. He graduated MD in 1951 from the University of Lund, where in the same year he was appointed assistant professor, becoming associate professor in 1956. In 1959 he moved to Göteborg University as professor of pharmacology.

Carlsson's main interest has been the nature and role of signaling molecules (neurotransmitters) in the nerve cells of the brain. In the late 1950s he discovered that dopamine is a neurotransmitter in the brain, particularly in parts of the brain called the basal ganglia, which play an important role in controlling muscular activity.

Using experimental animals, Carlsson showed that if dopamine was depleted, the animals developed signs similar to those of Parkinson's disease in humans. These signs could be alleviated, and levels of dopamine could be restored, by administering the dopamine precursor L-dopa. Subsequently it was found that sufferers of Parkinson's disease do indeed have unusually low levels of

dopamine in their basal ganglia. As a result, L-dopa was developed as a drug to treat the symptoms of the disease in humans.

Carlsson's findings have also contributed to the development of more effective drugs for the treatment of depression, notably the new generation of antidepressive drugs known as selective serotonin uptake blockers.

For his work on signal transduction in the nervous system, Carlsson was awarded the 2000 Nobel Prize for physiology or medicine, jointly with Paul GREENGARD and Eric R. KANDEL.

### **Carnap, Rudolf** (1891–1970) *German philosopher and logician*

Carnap (**kar**-nap) had a rigorous scientific and philosophical education, which was reflected in the style and content of all his later work. Born in Ronsdorf, Germany, he studied mathematics, physics, and philosophy at the universities of Jena and Freiburg (1910–14) and obtained a doctorate from Jena with a thesis on the concept of space in 1921.

In 1926 Carnap was invited to take up a post at the university of Vienna where he became a major figure in the Vienna Circle – a group of philosophers and mathematicians founded by Moritz Schlick. This group had an empiricist outlook, i.e., that all our ideas, concepts, and beliefs about the external world derive from our immediate sensory experience. Out of this evolved the logical empiricist or logical positivist school of thought, which states that the meaningful statements we can make are just those that have logical consequences that are observably verifiable. That is, meaningful statements must be testable by experience; those that are not, like the propositions of metaphysics and religion, are, strictly, meaningless.

Throughout his life Carnap used the tools of symbolic logic to bring a greater precision to philosophical inquiry, including investigations into the philosophy of language and into probability and inductive reasoning. He produced his first major work in 1928, *Der Logisch Aufbau der Welt*, translated into English in 1967 as *The Logical Structure of the World*. In this he developed a version of the empiricist reducibility thesis, holding that scientific theories and theoretical sentences must be reducible to sentences that describe immediate experiences, which are observably verifiable. His other works included *Logische Syntax der Sprache* (1934; *The Logical Syntax of Language*) and *Logical Foundations of Probability* (1950).

He emigrated to America in 1936 becoming professor of philosophy at Chicago until 1952 and at UCLA until 1961.

### **Carnot, Nicolas Leonard Sadi** (1796–1832) *French physicist*

Carnot (**kar-noh**) came from a distinguished Parisian political family; his father, Lazare, was a leading politician under Napoleon Bonaparte. He studied at the Ecole Polytechnique, from which he graduated in 1814. For the next few years he worked as a military engineer, but the political climate had changed with the fall of Bonaparte and, in 1819, he transferred to Paris and concentrated on scientific research.

The fruits of this work ripened in 1824 in the form of a book called *Réflexions sur la puissance motrice de feu* (On the Motive Power of Fire). The main theme of this masterpiece was an analysis of the efficiency of engines in converting heat into work. He found a simple formula depending only on the temperature differences in the engine and not on intermediate stages through which the engine passed. He also introduced the concept of reversibility in the form of the ideal *Carnot cycle*. Using these ideas he derived an early form of the second law of thermodynamics, stating that heat always flows from hot to cold. It became an inspiration, many years later, for Rudolf CLAUSSIUS's formulations of thermodynamics. Carnot died of cholera at the age of 36.

### **Caro, Heinrich** (1834–1910) *German organic chemist*

Caro (**kah-roh**), who was born in Posen (now Poznan in Poland), studied at the University of Berlin (1852–55) before entering the dyestuffs industry, first in Mülheim then in Manchester, England, where he worked on mauveine, the first synthetic dye. He joined the Badische Anilin und Soda Fabrik in 1866, becoming a director in 1868. In 1869 Caro, GRAEBE, and Liebermann synthesized alizarin, the first natural dye to be synthesized (also discovered simultaneously by William Perkin). Caro made many subsequent discoveries, including methylene blue (1877) and Fast Red A, the first acidic azo dye (1878). He discovered *Caro's acid*, a powerful oxidizing agent (H<sub>2</sub>SO<sub>5</sub>), in 1898.

### **Carothers, Wallace Hume** (1896–1937) *American industrial chemist*

Carothers, the son of a teacher, was born in Burlington, Iowa, and gained a BS degree from Tarkio College, Missouri (1920), after working his way through college. He gained his PhD in 1924 from the University of Illinois and was an instructor in chemistry at Illinois and Harvard before joining the Du Pont company at Wilmington, Delaware, as head of organic chemistry research in 1928.

Carother's early work was in the application of electronic theory to organic chemistry but at du Pont he worked on polymerization. His first great success was the production of the synthetic rubber neoprene (1931). Working with acetylenes he discovered that the action of hy-

drochloric acid on monovinylacetylene produced 2-chloro-buta-1,3-diene (chloroprene), which polymerized very readily to give a polymer that was superior in some respects to natural rubber.

In a systematic search for synthetic analogs of silk and cellulose he prepared many condensation polymers, especially polyesters and polyethers. In 1935 one polyamide, produced by condensation of adipic acid and hexamethylenediamine, proved outstanding in its properties and came into full-scale production in 1940 as Nylon 66. But Carothers did not live to see the results of his achievements; despite his brilliant successes he suffered from fits of depression and took his own life at the age of 41.

**Carrel, Alexis** (1873–1944) *French surgeon*

Intelligence is almost useless to the person whose only quality it is.

—*Man, the Unknown* (1935)

Carrel (ka-**rel**) received his medical degree from the university in his native city of Lyons in 1900. In 1902 he started to investigate techniques for joining (suturing) blood vessels end to end. He continued his work at the University of Chicago (1904) and later (1906) at the Rockefeller Institute for Medical Research, New York. Carrel's techniques, which minimized tissue damage and infection and reduced the risk of blood clots, were a major advance in vascular surgery and paved the way for the replacement and transplantation of organs. In recognition of this work, Carrel was awarded the 1912 Nobel Prize for physiology or medicine.

During World War I, Carrel served in the French army. With the chemist Henry Dakin, he formulated the Carrel–Dakin antiseptic for deep wounds. Returning to the Rockefeller Institute after the war, Carrel turned his attention to methods of keeping tissues and organs alive outside the body. He maintained chick embryo heart tissue for many years on artificial nutrient solutions and with the aviator Charles Lindbergh he devised a so-called artificial heart that could pump physiological fluids through large organs, such as the heart or kidneys.

In *Man, the Unknown* (1935), Carrel published his controversial views about the possible role of science in organizing and improving society along rather authoritarian lines. During World War II he founded and directed the Carrel Foundation for the Study of Human Problems under the Vichy government, in Paris. Following the Allied liberation, Carrel faced charges of collaboration but died before a trial was arranged.

**Cartan, Elie Joseph** (1869–1951) *French mathematician*

Cartan (kar-**tan**) is now recognized as one of the most powerful and original mathematicians

of the 20th century, but his work only became widely known toward the end of his life. Cartan, who was born in Dolomieu, France, studied at the Ecole Normale Supérieure in Paris and held teaching posts at the universities of Montpellier, Lyons, Nancy, and, from 1912 to 1940, Paris.

Cartan's most significant work was in developing the concept of analysis on differentiable manifolds, which now occupies a central place in mathematics. He began his research career with a dissertation on LIE groups – a topic that led him on to his pioneering work on differential systems. The most important innovation in his work on Lie groups was his creation of methods for studying their global properties. Similarly his work on differential systems was distinguished by its global approach. One of his most useful inventions was the “calculus of exterior differential forms,” which he applied to problems in many fields including differential geometry, Lie groups, analytical dynamics, and general relativity. Cartan's son Henri is also an eminent mathematician.

**Carter, Brandon** (1942– ) *British physicist*

Born in Sydney, Australia, Carter was educated at the University of St. Andrews, Scotland, and at Cambridge University, where he completed his PhD in 1968. He remained in Cambridge as a research fellow at the Institute of Astronomy until 1973. Carter then moved to France to join the Centre National de la Recherche Scientifique (CNRS), working from 1986 as director of research at the Paris-Meudon Observatory.

In 1974 Carter formulated what is known as the *anthropic principle*. The argument began with COPERNICUS whose heliocentric system is often thought to have removed man from any special privileged position in the universe. Carter, however, insisted that it is privileged to the extent that our location in the universe must be compatible with our existence as observers. That is, if the universe had differed significantly in its size, age, and character then intelligent life would not now be present to observe it. If, for example, the strength of the gravitational force differed by just one part in  $10^{40}$  all stars would be either blue giants or red dwarves; with no Sun-like stars to nourish life, the universe would be without observers. The fact that it has observers, therefore, presupposes that the nuclear, gravitational, and electromagnetic forces all fall within some very narrow limits.

This is sometimes known as the “weak form” of the anthropic principle. Carter advanced from this to the strong version with his claim that “The universe must have those properties which allow life to develop within it at some stage in its history.” While some physicists have seen in the anthropic principle a profound key

to the secrets of nature, others have dismissed it on the grounds that it is immune to falsification, makes no significant predictions, and offers all its explanations after the event.

**Cartwright, Edmund** (1743–1823)  
*British inventor*

Cartwright, who was born in Marnham, England, began his career as a clergyman. However, after visiting Richard ARKWRIGHT's cotton-spinning mills in Derbyshire in 1784, he became interested in developing machinery for the textile industry. He built a simple form of power loom, which was patented in 1785, and set up a weaving and spinning factory in Doncaster the same year. In 1789 he patented a wool-carding machine. He was not financially successful – his factory went bankrupt in 1794 – but in 1809 he was awarded £10,000 by the House of Commons in recognition of the benefit to the nation from his invention of the power loom.

**Carty, John Joseph** (1861–1932) *American telephone engineer*

Carty was born and went to school in Cambridge, Massachusetts, but because of eye trouble was delayed in entering college. During this delay his imagination was captured by the invention of the telephone (1875) by Alexander Graham BELL in neighboring Boston. He consequently joined the Bell System in 1879, eventually becoming chief engineer there. He served as chief engineer of the New York Telephone Company (1889–1907) and of the American Telephone and Telegraph Company (1907–19), and finally became vice president of the latter company until his retirement in 1930.

Carty was responsible for a number of technical innovations in the development of the commercial use of the telephone. These included the introduction of the “common” battery, which, by providing current from a central source to a number of interconnected telephones, allowed the development of a complex urban network. He also directed the project to provide the first transcontinental telephone wire line, completing in 1915 the 3,400-mile (5,400-km) link between New York and San Francisco.

**Carver, George Washington** (1864–1943)  
*American agricultural chemist*

Carver was born a slave in Diamond Grove, Missouri. Nevertheless, he managed to acquire some elementary education and went on to study at the Iowa State Agricultural College from which he graduated in 1892. He taught at Iowa until 1896, when he returned to the South to become director of the department of agricultural research at the Tuskegee Institute, Alabama. There he stayed despite lucrative offers to work for such magnates as Henry Ford and Thomas EDISON.

His main achievement was to introduce new crops into the agricultural system of the South, in particular arguing for large-scale plantings of peanuts and sweet potatoes. He saw that such new crops were vital if only to replenish the soil, which had become impoverished by the regular growth of cotton and tobacco.

But he did much more than introduce new crops for he tried to show that they could be used to develop many new products. He showed that peanuts contained several different kinds of oil. So successful was he in this that by the 1930s the South was producing \$60 million worth of oil a year. Peanut butter was another of his innovations. In all he is reported to have developed over 300 new products from peanuts and over 100 from sweet potatoes.

**Casimir, Hendrik Brugt Gerhard** (1909–2000) *Dutch physicist*

Born in the Dutch capital city, The Hague, Casimir (**kaz-i-meer**) studied at the universities of Leiden, Copenhagen, and Zurich, and held various research positions between 1933 and 1942.

He published many papers in the fields of theoretical physics, applied mathematics, and low-temperature physics. His most notable work was in the theory of the superconducting state. Following the work of W. MEISSNER, Casimir and his colleague, Cornelis Gorter, advanced a “two-fluid” model of superconductivity in 1934 in which a fraction of the electrons were regarded as superconducting, while the rest remained “normal” electrons. They were successful in explaining the high degree of interrelationship between the magnetic and thermal properties of superconductors.

Casimir is also known for the *Casimir effect*, which he predicted in 1948. This is the occurrence of a very small attractive force between two parallel metal plates, caused by quantum fluctuations in the vacuum state in quantum electrodynamics. The effect was first observed in 1958. Casimir also did related work on intermolecular forces.

From 1942, Casimir pursued a highly successful career with the Philips company, becoming director of the Philips Research Laboratories in 1946, and a member of the board of management (1957–72). He supervised Philips's research activities in several countries.

**Caspersson, Torbjörn Oskar** (1910–1997) *Swedish cytochemist*

Caspersson (**kas-per-son**), who was born in Motala, Sweden, gained his MD from Stockholm University in 1936. He then joined the staff of the Nobel Institute serving as professor of medical cellular research and genetics from 1944 to 1977. In 1977 he was appointed professor and head of the medical cell research and gen-

etics department at the Kungliga Karolinska Mediko-Kirurgiska Institutet in Stockholm.

In the late 1930s Caspersson spent a few years working on DNA. In 1936 with the Swiss chemist Rudolf Signer he made fundamental measurements of the molecule that suggested a molecular weight between 500,000 and a million, so showing the nucleic acids to be larger than protein molecules.

Further important data were collected by a photoelectric spectrophotometer developed by Caspersson. This allowed the movement of RNA in the cell to be followed by its characteristic absorption peak in the ultraviolet at 2,600 angstroms and to establish that protein synthesis in the cell was associated with an abundance of RNA. Despite this Caspersson remained committed to the orthodox view that genes were proteins and believed nucleic acids to be a structure-determining supporting substance.

In 1970 Caspersson made a major breakthrough in the study of chromosomes. Before 1970 the only way to identify a chromosome was by its length. Caspersson argued that if genes differed in their concentration of the four bases (guanine, adenine, cytosine, and thymine), then they would be distributed differently in each chromosome. If a dye could be found that bound to one of the bases only, then a characteristic chromosomal pattern would be displayed. Precisely this happened when Caspersson found a quina-acrine mustard with an affinity for guanine. When illuminated with ultraviolet the now familiar pattern of bright and dark bands was displayed with startling clarity. Within a year Caspersson had used distinctive banding patterns to characterize all human chromosomes.

**Cassegrain, N.** (about 1672) *French telescope designer*

Little is known about the life of Cassegrain (**kas**-e-gran). He was apparently a physician in Chartres and was credited, in 1672, as the inventor of a reflecting telescope, which is named for him. James Short was one of the first to use

the design, producing his telescopes in about 1740.

**Cassini, Giovanni Domenico** (1625–1712) *Italian–French astronomer*

Born in Perinaldo, Italy, Cassini (**ka-see-nee**) was educated in Genoa and at the age of 25 became professor of astronomy at Bologna. He remained there until 1669 when he moved to France in order to take charge of Louis XIV's new Paris Observatory. He became a French citizen in 1673.

While still at Bologna he worked out, fairly accurately, the rotational periods of Jupiter and Mars. In 1668 he constructed a table of the movements of the Medici planets – the satellites of Jupiter discovered by GALILEO. It was this table that allowed Ole RØMER to calculate the speed of light. In Paris, using aerial telescopes up to 150 feet (45.7 m) long, he discovered four new satellites of Saturn – Iapetus in 1671, Rhea in 1672, and Dione and Tethys in 1684. In 1675 he discovered the gap that divides Saturn's rings into two parts and has since been called *Cassini's division*.

Cassini's most important work concerned the size of the solar system. Using data collected by Jean RICHER in Cayenne, together with his own observations in Paris, he was able to work out the parallax of Mars and thus calculate the astronomical unit (AU) – the mean distance between the Earth and the Sun. His figure of 87 million miles (140 million km) may have been 7% too low, but compared with earlier figures of Tycho BRAHE (5 million miles) and Johannes KEPLER (15 million miles) his results gave mankind a realistic picture of the size of the universe for the first time. Cassini also made fundamental measurements on the size and shape of the Earth concluding, erroneously, that it was a prolate spheroid. He became blind in 1710 and was succeeded in the directorship of his observatory by both his son, Jacques Cassini, and his grandson, César François Cassini.

**Castner, Hamilton Young** (1858–1898) *American chemist*

**CASSEGRAINIAN TELESCOPE** *The ray path in Cassegrain's reflecting telescope.*

Born in New York City, Castner studied at Brooklyn Polytechnic and at Columbia University, New York. He started as a chemical consultant in 1879 and moved to Britain in 1886 when he failed to gain any backing in America for his process for the production of sodium.

Henri Sainte-Claire DEVILLE had developed a system in which caustic soda could be reduced to sodium with charcoal at high temperatures. However he ran into a variety of practical difficulties, which were satisfactorily cleared up by Castner. Castner intended to use the sodium for producing aluminum by reduction of aluminum chloride – at the time aluminum was a very expensive metal. A factory was opened in 1888 at Oldbury, Birmingham, England, to manufacture 100,000 pounds of aluminum per annum. But it was too late for, two years earlier, Charles HALL in America and Paul HÉROULT in France had independently discovered a cheap way to produce aluminum by electrolysis. Castner quickly had to invent some uses for his sodium, for which there was little demand at the time. One was the manufacture of sodium peroxide (by burning sodium in air), used as a bleach. By passing ammonia over molten sodium and charcoal he produced sodium cyanide, which was used in the extraction of gold.

By the early 1890s, with the growing demand for his products, his problem was an inability to produce enough sodium. He solved this with a new method of making sodium by the electrolysis of brine using a mercury cathode. The process had been anticipated by Karl KELLNER in Austria; rather than litigate the two chemists cooperated and in 1897 set up the Castner–Kellner Alkali Company in Runcorn, Cheshire, England, where there was a cheap and abundant supply of salt. In the year of his death it was already producing 20 tons of caustic soda a day with a production of 40 tons of bleaching powder daily as a byproduct.

### Cauchy, Baron Augustin Louis (1789–1857) *French mathematician*

Men pass away, but their deeds abide.  
—Attributed

Cauchy (koh-shee) showed great mathematical talent at an early age and came to the attention of Joseph LAGRANGE and Pierre LAPLACE, who encouraged him in his studies. Born in Paris, France, he was educated at the Ecole Polytechnique, where he later lectured and became professor of mechanics in 1816, and worked briefly as an engineer in Napoleon's army. He held extreme conservative views in religion and politics, typical of which was the strong allegiance to the Bourbon dynasty that caused him to follow Charles X (who had ennobled Cauchy) into exile in 1830. Cauchy then became professor of mathematics at Turin, but returned to France

in 1838 and resumed his post at the Ecole Polytechnique.

Cauchy was an extremely prolific mathematician who made outstanding contributions to many branches of the subject, ranging from pure algebra and analysis to mathematical physics and astronomy. He was also an outstanding teacher. His greatest achievements were in the fields of real and complex analysis in which he was one of the first mathematicians to insist on the high standards of rigor now taken for granted in mathematics. He gave the first fully satisfactory definitions of the fundamentally important concepts of limit and convergence.

### Cavalieri, Francesco Bonaventura (1598–1647) *Italian mathematician and geometer*

Few, if any, since Archimedes, have delved as far and as deep into the science of geometry.  
—Galileo Galilei, letter to Cesare Marsili (1629)

Born in the Italian city of Milan, Cavalieri (ka-val-yaair-ee) joined the Jesuits as a boy. He became interested in mathematics while studying EUCLID's works and met GALILEO, whose follower he became.

Cavalieri's fame rests chiefly on his work in geometry in which he paved the way for the development of the integral calculus by Isaac NEWTON and Gottfried LEIBNIZ. In 1629 Cavalieri became professor of mathematics at Bologna, a post he held for the rest of his life. At Bologna he developed his "method of indivisibles," published in his *Geometria indivisibilibus continuorum nova quadam ratione promota* (1635; A Certain Method for the Development of a New Geometry of Continuous Indivisibles), which had much in common with the basic ideas of integral calculus.

Cavalieri also helped to popularize the use of logarithms in Italy through the publication of his *Directorium generale uranometricum* (1632; A General Directory of Uranometry).

### Cavalli-Sforza, Luigi Luca (1922– ) *Italian geneticist*

Cavalli-Sforza (ka-val-ee-sfort-za), who was born in Genoa, Italy, was educated at the University of Pavia where he gained his MD in 1944. After working on bacterial genetics at Cambridge (1948–50) and Milan (1950–57) he has held chairs in genetics at Parma (1958–62) and Pavia (1962–70). In 1970 he was appointed professor of genetics at Stanford University, a position he held until his retirement in 1992. He is still actively working as emeritus professor at Stanford.

Cavalli-Sforza has specialized mainly in the genetics of human populations, producing with Walter Bodmer a comprehensive survey of the

subject in their *Genetics, Evolution and Man* (1976).

He has also done much to show how genetic data from present human racial groups could be used to reconstruct their past separations. This reconstruction, based on the analysis of 58 genes, yields a bifurcated evolutionary tree with Caucasian and African races in one branch and Orientals, Oceanians, and Amerinds in the other. The main division appeared, according to Cavalli-Sforza, some 35–40,000 years ago.

**Cavendish, Henry** (1731–1810) *English chemist and physicist*

Cavendish, who was born in Nice in the south of France, was the son of Lord Charles Cavendish, himself a fellow of the Royal Society and administrator of the British Museum. Henry was educated at Cambridge University (1749–53), but left without a degree. Following this he devoted the rest of his life to science. He inherited from his uncle a vast fortune with which he built up a large library and financed his scientific interests. Throughout his life he was an eccentric recluse, appearing only rarely in public and then chiefly at scientific meetings. He communicated with his housekeeper by a system of notes and was such a misogynist that he ordered all his female domestics to keep out of his sight.

Cavendish's first published work was *Three Papers containing Experiments on Factitious Airs* (1766). In these he clearly distinguished hydrogen ("inflammable air") and carbon dioxide ("fixed air") as gases separate from common air. Some of the work on fixed air duplicated that of Joseph BLACK, little of which had been published, but Cavendish was the first to weigh gases accurately.

Much of Cavendish's work remained unpublished in his lifetime and he is now known to have anticipated or come very close to several major discoveries. His electrical studies, which were edited by Clerk MAXWELL in 1879, following the discovery of his notebooks and manuscripts, included the clear distinction between electrical quantity and potential, the measurement of capacitance, and the anticipation of OHM's law (1781). He had the concept of specific heat in 1765 but the work was not published. In 1778, working on the effect of water vapor on the compressibility of air, he arrived at what is essentially the law of partial pressures. One important physical investigation that was published was the determination of the mean density of the Earth (1798) by means of the torsion balance in what became known as the *Cavendish experiment*.

In his chemical work Cavendish came close to the concepts of equivalent weights and multiple proportions but he was not a generalizer and the concepts only became explicit in the works of others. His most illustrious and con-

troversial work was his synthesis of water. The paper *Experiments on Air* (1784) reported his researches on exploding hydrogen with oxygen and air. He concluded that air consisted of a mixture of oxygen and nitrogen in a ratio of 1:4 and that hydrogen and oxygen mixed in proportions of 2:1 yielded their own weight of water. This work was carried out in 1781, and although Cavendish's priority is quite clear a dispute ensued between James WATT, Antoine LAVOISIER, and Cavendish. It was discovered from this work that water is not an element but a compound.

The reason for Cavendish's three-year delay in publishing his work on water was the persistent discovery of nitric acid (then called nitrous acid) in the water after sparking hydrogen and air. In further experiments he accomplished the conversion of nitrogen to nitric acid by sparking over alkali, which then formed potassium nitrate. This synthesis was the basis of the commercial production of nitric acid until 1789. In the course of his work on gases Cavendish refined the eudiometer and his measurements of the oxygen content of air showed it to be the same everywhere.

On his death Cavendish left over a million pounds sterling to his relatives. From this the endowment of the famous Cavendish Laboratory was made to Cambridge University in 1871.

**Cavendish, Margaret, Duchess of Newcastle** (1623–1673) *British natural philosopher*

The daughter of a wealthy landowner, Margaret was born at St. John's, Colchester, in the eastern English county of Essex and inherited £10,000 on his death. She received a scant education from "an ancient decayed gentlewoman." With the outbreak of the civil war the family lost its estates, two brothers died fighting for the king, and in 1641 Margaret entered the royal court as a maid of honor to Henrietta Maria, wife to Charles I. In 1643 she fled with the queen to Paris and spent the next eighteen years in impoverished exile in Europe.

In 1645 she married William Cavendish, Duke of Newcastle. While in exile in Paris and in Antwerp she moved in circles where the ideas of Hobbes, DESCARTES, and GASSENDI were frequently discussed. From such discussions Margaret was introduced to mechanical philosophy.

While in exile she began to write on topics in natural philosophy, producing her *Philosophical and Physical Opinions* (1655). She continued to write about science after her return from exile with the restored Charles II in 1660, publishing her *Observations upon Natural Philosophy* (1666). She was highly critical of the new science. Her main objection was the familiar one that not all natural phenomena could be

explained by “the Dusty motion of Atoms.” Consequently, she argued, every atom must be “animated with life and knowledge.” She was also critical of the newly invented microscope, claiming that it distorted nature.

Much of her later life was spent in seclusion at Welbeck writing verse and plays as well as concerning herself with natural philosophy. She did, however, pay a well-documented visit to London in 1667 when she visited the Royal Society and witnessed experiments performed by BOYLE and HOOKE. But membership would remain closed to her or any other woman for a further three centuries.

**Caventou, Jean Bienaimé (1795–1877)**  
*French pharmacist and organic chemist*

Caventou (ka-vahn-**too**), the son of an army apothecary from St. Omer in France, studied pharmacy in Paris, eventually becoming professor of toxicology at the Ecole de Pharmacie (1835–60); he also had a pharmacy business. He learned the technique of solvent extraction of alkaloids from plants from Joseph PELLETIER, with whom (1817–20) he isolated the alkaloids strychnine, brucine, cinchonine, quinine, veratrine, and colchicine. Caventou and Pelletier are regarded as the founders of alkaloid chemistry. Curiously, until 1823 they believed that alkaloids contained no nitrogen when in fact they are now defined as nitrogenous substances. Caventou’s early success was not repeated in later life and after Pelletier’s death in 1842 he published nothing.

**Cayley, Arthur (1821–1895)** *British mathematician*

As for everything else, so for a mathematical theory: beauty can be perceived but not explained.

—Quoted by J. R. Newman (editor) in *The World of Mathematics*

Born in Richmond in southern England, Cayley studied mathematics at Cambridge University, but before becoming a professional mathematician spent 14 years working as a barrister. He was forced to do this since he was unwilling to take holy orders – at that time a necessary condition of continuing his mathematical career at Cambridge. When this requirement was dropped, Cayley was able to return to Cambridge and in 1863 became Sadlerian Professor there.

Cayley was an extremely prolific mathematician. His greatest work was the creation of the theory of invariants, in which he worked closely with his friend James Joseph SYLVESTER. Cayley developed this theory as a branch of pure mathematics but it turned out to play a crucial role in the theory of relativity, as it is important in the calculation of space–time relationships in physics. He also developed the

theory of matrices and made major contributions to the study of  $n$ -dimensional geometry. He went a considerable way toward unifying the study of geometry. Cayley also did important work in the theory of elliptic functions.

One of Cayley’s notable nonmathematical achievements was playing a large role in persuading the University of Cambridge to admit women as students.

**Cayley, Sir George (1773–1857)** *British inventor*

Cayley, a man of independent means, was born in the northern English coastal town of Scarborough and succeeded to the family estates on the death of his father in 1797. He had been educated at schools in York and Nottingham and had learned some science from a nonconformist clergyman who was also a fellow of the Royal Society.

Cayley is recognized as the founder of the science of aerodynamics. As early as 1799, in a design engraved on a small silver disk, he made an important step in the history of aeronautics by separating for the first time the system providing power from that contributing lift. He realized that man would never fly by flapping his arms but only by building a rigid wing to which he could attach an external power source. This was followed by a series of papers produced during the period 1804–55 in which he worked out many of the details implicit in his original idea.

Cayley designed an undercarriage fitted with tension wheels (later to find use on the bicycle) in 1808, streamlining in 1809, and a glider that was capable of lifting him up for a few yards. In the same year he produced his important paper *On aerial navigation*, which introduced the cambered wing, followed by his designs for a hot-air airship in 1816 and a helicopter in 1818. In the 1840s and 1850s he designed a large number of powered gliders, culminating in his construction of the first man-carrying glider in 1853, which was reluctantly tested by his coachman on the first successful manned glider flight in the same year.

In addition to his aeronautical works Cayley produced designs for the caterpillar tractor and for artificial limbs, and was interested in land reclamation and railway engineering. He also founded the Regent Street Polytechnic Institution, London, in 1839.

**Cech, Thomas Robert (1947– )** *American chemist*

Chicago-born Cech (chek) was educated at the University of California, Berkeley, where he gained his PhD in 1975. He then joined the faculty of the University of Colorado, Boulder, where he became professor of chemistry in 1983. In 2000 he became president of the

Howard Hughes Medical Institute in Maryland and also works at the Institute in Boulder, Colorado (the Cech Laboratory).

In 1977 Phillip SHARP discovered long stretches of noncoding DNA, later called "introns." In 1982 Cech began to investigate how these supposedly redundant sequences could be removed from the RNA molecule after it had been copied from the DNA template. For such a complex process to happen so rapidly it must, it seemed, be catalyzed by an enzyme. Since the first enzyme to be synthesized (by James SUMNER in 1926) had turned out to be a protein, and since all of the hundreds of other cellular enzymes had also turned out to be proteins, Cech confidently began to search for the protein enzyme responsible for snipping introns from RNA molecules.

He worked with ribosomal RNA (rRNA) of the protozoan *Tetrahymena thermophila*. He began with some unspliced rRNA and some protozoa nuclei mixed together *in vitro*. He assumed that the nuclear enzymes would catalyze the splicing. But, although the RNA introns were indeed neatly snipped away, none of the nuclear enzymes appeared to have been used. At first Cech assumed that the RNA itself harbored the protein enzyme responsible. To eliminate this possibility Cech synthesized his own pre-rRNA from a recombinant DNA template. The result was a viable but artificial rRNA, which, never having been in contact with a cell, could not possibly contain any cellular splicing enzymes. Despite this the introns were still removed.

RNA, Cech concluded in 1982, must be self-splicing. It acted like an enzyme in catalyzing a specific reaction, at a greatly accelerated rate, yet, unlike an enzyme, it operated upon itself. To mark the difference Cech proposed the name "ribozyme."

Confirmation of Cech's researches soon came from the work of Sidney ALTMAN on ribonuclease. For this work, Cech and Altman shared the 1989 Nobel Prize for chemistry.

**Celsius, Anders** (1701–1744) *Swedish astronomer*

Celsius (**sel**-see-us), the son of a mathematician, became professor of astronomy at the university in his native city of Uppsala, where he opened an observatory in 1740. In 1742 he devised a temperature scale in which the temperature of melting ice was taken as 100° and the temperature of boiling water was taken to be 0°. The modern *Celsius* (or *centigrade*) scale has the opposite fixed points (ice point 0°; steam point 100°C).

**Celsus, Aulus Cornelius** (b. c. 10 BC) *Roman encyclopedist*

Celsus (**sel**-sus), a member of a noble Roman

family, was the author of a comprehensive encyclopedia of knowledge covering many topics, including agriculture, military art, and philosophy. However, only the part dealing with medicine has survived, and it is for this work, *De medicina*, that he is remembered. Comprising eight sections, it covers medical history, diet, symptoms and treatments of various diseases, surgical techniques, and drugs. Celsus's work was rediscovered by Pope Nicholas V and became, in 1478, one of the first medical texts to be printed. Its lucid and elegant Latin prose made it widely acclaimed during the Renaissance period.

**Cerenkov, Pavel Alekseyevich** *See* CHERENKOV, PAVEL ALEKSEYEVICH.

**Cerf, Vinton G.** (1943– ) *American computer scientist*

Cerf (serf) was educated at Stanford University, where he obtained a BSc in mathematics, and at the University of California at Los Angeles (UCLA), where he obtained MSc and PhD degrees in computer science. It was during his time as a graduate student at UCLA between 1967 and 1972 that he started the work that led to the introduction of the Internet. Cerf is frequently referred to as the "Father of the Internet" because, together with Robert KAHN, he published in 1974 papers on Transmission Control Protocol/Internet Protocol (TCP/IP) for networking computers.

Cerf worked at the US Department of Defense's Research Projects Agency (DARPA) between 1976 and 1982 on Internet-related technology. Between 1982 and 1986 he was vice president of MCI Digital Information. While there he was responsible for the engineering of MCI mail, which was the first commercial email system to be connected to the Internet. Between 1986 and 1994 Cerf was vice president of the Corporation for Research Initiatives (CNRI). He rejoined MCI in 1994.

Cerf was the founding president of the Internet Society between 1992 and 1995 and was chairman of the board from 1998 to 1999. Cerf and Robert Kahn were awarded the US Medal of Technology in 1997 for their role in founding the Internet.

**Cesalpino, Andrea** (1519–1603) *Italian physician and botanist*

Born at Arezzo in Italy, Cesalpino (chay-zal-pee-noh) studied anatomy and medicine at the University of Pisa, where he graduated in 1551; in 1555 he became professor of medicine and director of the botanic garden there. In 1592 he became physician to Pope Clement VIII and professor at the Sapienza University.

He is most famous for his plant classification based on fruit and seed characteristics, which

is described in his work, *De plantis* (1583; *On Plants*). This work also discusses the whole of theoretical botany and had great influence on later botanists.

Cesalpino also wrote a number of anatomical books in which he partly anticipated the theory of the circulation of the blood proposed by William HARVEY.

### **Chadwick, Sir James** (1891–1974) *British physicist*

Chadwick was born in Macclesfield in northern England and was educated at the University of Manchester, where he graduated in 1911 and remained as a graduate student under Ernest RUTHERFORD. In 1913 he went to Leipzig to work under Hans GEIGER and found himself interned in 1914 near Spandau as an enemy alien. There he remained for the duration of the war, cold and hungry but permitted, with the help of Walther NERNST, to carry out rudimentary research.

On his return to England in 1919 he was invited by Rutherford to accompany him to Cambridge University where, from 1922 until 1935, he served as assistant director of research at the Cavendish Laboratory. It was during this period that Chadwick, in 1932, made his greatest discovery – the neutron. Before this, physicists had accepted the existence of only two elementary particles: the proton (p) with a positive charge, and the electron (e) with a negative charge. It was however clear to all that these two particles could not account for all the atomic phenomena observed. The helium atom, for example, was thought to consist of four protons; that it only possessed a positive charge of two was due to the nucleus also containing two “internal electrons” which neutralized the charge on two of the protons. The difficulty of such a view was the failure of a disintegrating nucleus to produce the electrons supposedly contained within it.

In 1920 Rutherford had provided an alternative solution by introducing the possibility of “an atom of mass 1 which has zero nuclear charge.” Chadwick attempted unsuccessfully to discover such a particle in the 1920s by bombarding aluminum with alpha particles (helium nuclei). More promising, however, was the report in 1930 that the bombardment of beryllium with alpha particles yielded a very penetrating radiation. In 1932 Irène and Frédéric JOLIOT-CURIE found that this radiation could eject protons with considerable velocities from matter containing hydrogen. They thought such radiation consisted of gamma rays – electromagnetic radiation of very short wavelength. Chadwick showed that the gamma rays would not eject protons, but that the result was explained if the particles had nearly the same mass as protons but no charge, i.e., the particles were neutrons. It was for this work that Chad-

wick was awarded the 1935 Nobel Prize for physics.

By 1936 a certain amount of friction had begun to appear between Chadwick, who wished to build a cyclotron at the Cavendish Laboratory, and Rutherford, who initially was violently opposed to any such project. It was therefore with some relief that Chadwick decided in 1935 to accept the offer of the chair of physics at Liverpool University. There he built Britain's first cyclotron and was on hand at the outbreak of war to support the claims made by Otto FRISCH and Rudolph PEIERLS on the feasibility of the atomic bomb. Chadwick consequently spent most of the war in America as head of the British mission to the Manhattan project.

For this service he was knighted in 1945. He returned to Cambridge in 1958 as Master of Gonville and Caius College, in which office he remained until his retirement in 1958.

### **Chain, Ernst Boris** (1906–1979) *German–British biochemist*

Chain, born the son of a chemist in Berlin, Germany, graduated in 1930 from the Friedrich-Wilhelm University with a degree in chemistry. He left Germany for England in 1933 and, after two years' research at Cambridge University, joined Howard FLOREY at Oxford. Here his brilliance as a biochemist was put to good use in the difficult isolation and purification of penicillin – work that Alexander FLEMING had been unable to carry out. He shared the 1945 Nobel Prize for physiology or medicine with Florey and Fleming for this achievement.

After 1945 he was professor of biochemistry at the Superior Institute of Health in Rome, returning to England in 1961 for the chair of biochemistry at Imperial College, London. During this time he discovered penicillinase – an enzyme that some bacteria can synthesize and so destroy the drug. He also worked on tumor metabolism and the mode of action of insulin in diabetes.

### **Chamberlain, Owen** (1920–2006) *American physicist*

The son of the prominent radiologist Edward Chamberlain, Owen Chamberlain followed his father's interest in physics. Born in San Francisco, he graduated from Dartmouth College in 1941 and gained his doctorate in physics from the University of Chicago in 1949. From 1948 until 1950 he was an instructor in physics at the University of California at Berkeley, becoming associate professor in 1954, professor in 1958, and emeritus professor from 1989.

The onset of America's involvement in World War II interrupted his university studies, and he spent the years 1942–1946 under the leadership of Emilio SEGRÉ working on the Man-

hattan atom-bomb project at Los Alamos. There he investigated spontaneous fission of the heavy elements and nuclear cross-sections. Later he worked with Enrico FERMI on neutron diffraction by liquids.

At Berkeley, Chamberlain experimented with the bevatron particle accelerator of the Lawrence Radiation Laboratory, and in 1955 (together with Segrè, C. Weigand, and T. Ypsilantis) discovered the antiproton – a particle with the same mass as the proton, but of opposite (negative) charge. For their discovery, Chamberlain and Segrè received the 1959 Nobel Prize for physics. The existence of antiparticles had been predicted by Paul DIRAC's theory of 1926, and the first of these, the positive electron (or positron) had been found by Carl David ANDERSON in cosmic radiation in 1931.

Chamberlain's later research involved working on the development and construction of the Time-Projection-Chamber at the Stanford Linear Accelerator Center.

**Chamberlin, Thomas Chrowder** (1843–1928) *American geologist*

Chamberlin came from a farming background in Mattoon, Illinois. His discovery of fossils in a local limestone quarry aroused his interest in geology, which he pursued at the University of Michigan. He worked for the Wisconsin Geological Survey from 1873, serving as chief geologist for the period 1876–82. From 1881 until 1904 he was in charge of the glacial division of the U.S. Geological Survey. After a period as president of the University of Wisconsin (1887–92) he became professor of geology at the University of Chicago (1892–1918).

Apart from his work on the geological surveys, Chamberlin's most significant work was in the field of glaciation. Early work on glaciation had assumed that there had been one great ice age but James Geikie, in his *The Great Ice Age* (1874–84), had begun collecting evidence that there had been several ice ages separated by nonglacial epochs. Chamberlin contributed the chapter on North America to Geikie's work. He showed that drift deposits are composed of at least three layers and went on to establish four major ice ages, which were named the Nebraskan, Kansan, Illinoian, and Wisconsin after the states in which they were most easily studied.

Together with the astronomer Forest MOULTON, Chamberlin formulated, in 1906, the planetismal hypothesis on the origin of the planets in the solar system. They supposed that a star had passed close to the Sun causing matter to be pulled out of both. Within the gravitational field of the Sun this gaseous matter would condense into small planetesimals, and eventually into planets. The theory was published in *The Two Solar Families* (1928) but it has little sup-

port today as it cannot account for the distribution of angular momentum in the solar system.

**Chambers, Robert** (1802–1871) *Scottish geologist and writer*

The son of a cotton manufacturer from Peebles in Scotland, Chambers was largely self-educated, drawing much of his learning from the *Encyclopaedia Britannica*. After the family moved to Edinburgh, Chambers set up as a bookseller at the age of 16. Soon after he formed the partnership W. & R. Chambers with his brother William and thus created a publishing house still active in Edinburgh today.

Chambers himself published a number of works on Scottish antiquities and history. None, however, had the impact of his *Vestiges of Creation* (1844), which by 1860 had been through eleven British editions, none of which Chambers ever acknowledged as his own. It was only with the posthumous twelfth edition that the author's name appeared on the title page. The work, dealing with the “development” of the animal kingdom, was highly controversial and rumors about its anonymous author abounded, extending as far as the unlikely Prince Albert.

Chambers began by showing how physics could account for the origin and development of the solar system in terms of the nebular hypothesis of LAPLACE. If the inorganic world developed in accordance with physical law, it could not be absurd to suppose that the organic world followed a similar pattern. Chambers then presented a history of the Earth in which there had been a general progression from lower to higher forms. It was, he argued, no credit to God to suppose that each species must have been created separately. Life, he thought, could arise from a “chemico-electric reaction.”

And how is one form transmuted into another? Here he turned to the views of Von BAER and argued that, influenced by external conditions, the embryonic stage could be prolonged until it developed into the next higher stage. For example, a fish that remains an embryonic fish longer than the norm develops into a reptile.

The savage reception the work received must have justified the decision of Chambers to remain anonymous. Asked to defend his decision in later life, he replied to a close friend, referring to his eleven children, that he had eleven good reasons for his secrecy. Nevertheless, unable to tolerate references by the geologist Adam SEDGWICK to “the inner deformity and foulness of the work,” Chambers replied in his anonymous *Explanations* (1845).

**Chamisso, Adelbert von** (1781–1838) *French–German naturalist and poet*

Born in Champagne in northeastern France,

Chamisso (shah-**mis**-oh) studied medicine and botany at Berlin. From 1815 to 1818 he accompanied Otto Kotzebue as naturalist on his Russian scientific expedition in which an attempt was made to find a sea passage through the Arctic. In 1819 he was appointed curator of the Berlin Botanic Gardens, and in the same year studies of tunicates (primitive vertebrates) and mollusks led him to observe the occurrence of both sexual and asexual forms in their life cycles.

Chamisso is however better known as a talented lyricist and wrote a number of well-known stories, ballads, and poems.

**Chance, Alexander Macomb** (1844–1917) *British chemical industrialist*

Chance was the son of a Birmingham glassmaker who had branched out into the manufacture of soda to guarantee his supply of raw materials. In 1868 he became manager of an alkali works.

During the latter half of the 19th century the **LEBLANC** process for producing soda was facing competition from newer methods, such as the ammonia–soda process of Ernest **SOLVAY**. Chance extended the Leblanc process, making it commercially viable, by finding a way of recovering sulfur from calcium sulfide, which was one of the waste products. His method was to pump carbon dioxide through the calcium sulfide solution, freeing hydrogen sulfide, which was then partially oxidized to sulfur.

**Chance, Britton** (1913– ) *American biophysicist*

Chance was born an engineer's son in Wilkes-Barre, Pennsylvania; he was educated at the University of Pennsylvania, where he obtained his PhD in 1940 and where he served as Eldridge Reeves Johnson Professor of Biophysics from 1949 to 1983. He is still professor emeritus at Pennsylvania.

In 1943 he carried out a spectroscopic analysis that provided firm evidence for the enzyme–substrate complex whose existence had been confidently assumed by biochemists since the beginning of the century. Working with the iron-containing enzyme peroxidase, which strongly absorbs certain wavelengths of light, he found that variations in light absorption could be precisely correlated with rates of production of the enzyme–substrate complex. This was seen as confirming the important work of Leonor **MICHAELIS**.

Chance has also contributed to one of the great achievements of modern biochemistry, namely the unraveling of the complicated maze through which energy is released at the cellular level. He found that the concentration of ADP (adenosine diphosphate), as well as the oxygen concentration, determined the oxida-

tion and reduction states of the proteins in the respiratory (electron-transport) chain. His studies of changes in ADP concentration led to a better understanding of how glucose is used in the body.

**Chandler, Seth Carlo** (1846–1913) *American astronomer*

Chandler, who was born in Boston, Massachusetts, graduated from Harvard in 1861 and then acted as assistant to Benjamin **GOULD**, an astronomer with the U.S. Coast Survey, from 1861 to 1864. He remained with the Survey until 1870 when he started work as an actuary, returning to scientific work with the Harvard Observatory in 1881. From 1885 he devoted himself to private research.

Chandler is best known for his discovery of the variation in the location of the geographic poles – and, hence, of the variation in latitude of points on the Earth's surface. In 1891 he announced the discovery of a 428-day cycle during which latitude varied by 0.3 second. This variation in the Earth's rotation became known as the *Chandler wobble* and was soon confirmed by the International Latitude Service, established in 1900.

**Chandrasekhar, Subrahmanyan** (1910–1995) *Indian–American astrophysicist*

Chandrasekhar (chan-dra-**see**-ker), who was born in Lahore, which is now in Pakistan, studied at the Presidency College, Madras, gaining his MA in 1930. He then went to Cambridge University, England, where in 1933 he both obtained his PhD and was elected to a fellowship. In 1936 he moved to America and worked from 1937 at the University of Chicago and the Yerkes Observatory, serving as the Morton D. Hull Distinguished Service professor of Theoretical Astrophysics from 1952 to 1986, and as professor emeritus from 1986. He became an American citizen in 1953.

Chandrasekhar's major fields of study were stellar evolution and stellar structure and the processes of energy transfer within stars. It was known that stars could end their life either dramatically and explosively as a supernova or as an extremely small dense star of low luminosity known as a white dwarf. But what decided the particular path a star took was answered by Chandrasekhar in his *Introduction to the Study of Stellar Structure* (1939). He showed that when a star has exhausted its nuclear fuel, an inward gravitational collapse will begin. This will eventually be halted in most stars by the outward pressure exerted by a degenerate gas, i.e., a gas that is completely ionized, with the electrons stripped away from the atomic nuclei, and that is very highly compressed. The star will therefore have shrunk into an object composed of material so dense

that a matchbox of it would weigh many tons.

Chandrasekhar showed that such a star would have the unusual property that the larger its mass, the smaller its radius. There will therefore be a point at which the mass of a star is too great for it to evolve into a white dwarf. He calculated this mass to be 1.4 times the mass of the Sun. This has since become known as the *Chandrasekhar limit*. A star lying above this limit must either lose mass before it can become a white dwarf or take a different evolutionary path. In support of Chandrasekhar's theoretical work, it has been established that all known white dwarfs fall within the predicted limit.

In the 1970s Chandrasekhar devoted much time to the mathematical theory of black holes, publishing a classic book on the subject in 1983. He also made a detailed study of NEWTON's work and published his results in his *Newton's Principia for the Common Reader*.

For his numerous contributions to astrophysics, Chandrasekhar shared the 1983 Nobel Prize for physics with William FOWLER.

**Chang, Min Chueh (1908–1991)** *Chinese-American biologist*

Chang, who was born in T'ai-yüan in China, was educated at the Tsinghua University in Peking, and at Cambridge, England, where he obtained his PhD in 1941. He emigrated to America in 1945 and joined the Worcester Foundation in Shrewsbury, Massachusetts, where he subsequently remained. From 1961 he also served as professor of reproductive biology at Boston University.

Chang carried out a number of major research projects from which emerged not only greater understanding of the mechanisms of mammalian fertilization, but also such practical consequences as oral contraceptives and the transplantation of human ova (eggs) fertilized *in vitro* (Latin meaning literally "in glass," or in a test tube) by Robert Edwards and Patrick Steptoe in 1978. In 1951, at the same time as Colin Austin, Chang discovered that a "period of time in the female tract is required for the spermatozoa to acquire their fertilizing capacity," a phenomenon known later as capacitation. He further demonstrated, in 1957, that there is a decapacitation factor in the seminal fluid, which, although it can be removed by centrifugation, has resisted further attempts at identification.

Chang also made the important advance in 1959 of fertilizing rabbit eggs *in vitro* and transplanting them into a recipient doe. This was followed in 1964 by comparable work for the first time with rodents. It was also Chang who provided much of the experimental basis for Gregory PINCUS's 1953 paper showing that injections of progesterone into rabbits could

serve as a contraceptive by inhibiting ovulation.

**Chang Heng (78–142 AD)** *Chinese astronomer, mathematician, and instrument maker*

Chang Heng was the Astronomer Royal at the court of the emperors of the Later Han. Although none of his works have survived there are detailed reports of his achievements, which are, by any standard, numerous and impressive. As a mathematician he is reported to have given 3.1622 or the square root of 10 as the value of  $\pi$ , which was as good as any other attempt of that period, apart from that of ARCHIMEDES. In astronomy he gave a detailed description of the figure of the universe in which the Earth lies at the center of a large sphere like the yolk of an egg, which was an improvement on the earlier conception of a hemispherical heaven standing over the Earth like an umbrella.

His real originality however lay in the introduction and design of scientific instruments. Thus he introduced a complete armillary sphere at about the same time as his western contemporary, PTOLEMY. This was used to determine positions of celestial bodies and consisted of an interconnected set of such main circles of the celestial sphere as the equator, ecliptic, horizon, and meridian. Chang Heng went much further and constructed one that rotated by the force of flowing water in such a way that its movement coincided with the rising and setting of the stars. What is intriguing about this is whether he had devised some primitive form of clockwork – some early escapement, preparing the way for SU SUNG's water clock of the 11th century – 1,200 years before Giovanni de DONDI was to introduce it into Europe.

Even more impressive is his construction of the world's first seismograph. It is clearly described as consisting of a vessel on the outside of which were eight dragon heads containing a ball. When an earthquake occurred the ball was propelled out of a dragon's mouth and caught by a bronze toad waiting underneath. Inside there was, presumably, some pendulum mechanism, which would release just one ball selectively giving the direction of the shock. It is interesting to note that the first seismograph recorded in the west, depending on the spilling of an overfilled saucer of mercury, was in 1703.

**Chapman, Sydney (1888–1970)** *British mathematician and geophysicist*

Born in Eccles in northern England, Chapman entered Manchester University in 1904 to study engineering. After graduating in 1907, his interest was diverted into more strictly mathematical areas, and he went to Cambridge

to study mathematics, graduating in 1910. His first post was as chief assistant at the Royal Observatory, Greenwich, and his work there sparked off his lasting interest in a number of fields of applied mathematics, notably geomagnetism. In 1914 Chapman returned to Cambridge as a lecturer in mathematics, and in 1919 he moved back to Manchester as professor of mathematics, remaining there for five years. From 1924 to 1946 he was professor of mathematics at Imperial College, London. After working at the War Office during World War II he moved to Oxford to take up the Sedleian Chair in natural philosophy, from which he retired in 1953. However, his retirement meant no lessening in his teaching and research activity, which continued for many years at the Geophysical Institute, Alaska, and at the High Altitude Observatory at Boulder, Colorado.

The two main topics of Chapman's mathematical work were the kinetic theory of gases and geomagnetism. In the 19th century James Clerk MAXWELL and Ludwig BOLTZMANN had put forward ideas about the properties of gases as determined by the motion of the molecules of the gas. Chapman's work, which he began in 1911, was the next major step in the development of a full mathematical treatment of the kinetic theory. The Swedish mathematician Enskog had been working, independently of Chapman, along similar lines, and the resulting theory is now generally known as the *Chapman-Enskog theory of gases*. While working in 1917 on mixtures of gases Chapman predicted the phenomenon of gaseous thermal diffusion. His subsequent work on the upper atmosphere was a practical application of his earlier more theoretical study of gases.

Highlights of Chapman's work on geomagnetism are his work on the variations in the Earth's magnetic field in periods of a lunar day (27.3 days) and its submultiples. This he showed to be the result of a small tidal movement set up in the Earth's atmosphere by the Moon. He also developed, in 1930, in collaboration with one of his students, what has become known as the *Chapman-Ferraro theory* of magnetic storms. In collaboration with Julius Bartels, Chapman wrote *Geomagnetism* (2 vols. 1940), which soon established itself as a standard work.

### **Chappe, Claude** (1763–1805) *French engineer*

Chappe (shap), a former cleric who was born in Brûlon in France, invented the semaphore arm-signaling system that was first used during the French Revolution to signal between Lille and Paris. His brother was a member of the Legislative Assembly and put forward Claude's idea for building a series of towers equipped with telescopes and two-arm semaphores. In 1794 it took less than an hour to semaphore to

Paris the news that Condé-sur-l'Escaut had been taken from the Austrians. After others challenged his claim to be the inventor of semaphore, Chappe killed himself in a fit of depression.

### **Chaptal, Jean Antoine Claude** (1756–1832) *French chemist*

It is possible to dye a beautiful scarlet without being a chemist; but the operations ... of the dyer are not the less founded upon invariable principles, the knowledge of which would be of infinite utility to the artist.

—*Éléments de chimie* (1790–1803; *Elements of Chemistry*)

Chaptal (shap-tal), the son of an apothecary from Nogaret, France, studied medicine at Montpellier, graduating in 1777. He later switched to chemistry, becoming professor at Montpellier in 1781. During the French Revolution he was arrested but then released to manage the saltpeter works at Grenelle. He also helped to organize the introduction of the metric system and published a textbook, *Éléments de chimie* (1790–1803; *Elements of Chemistry*).

Chaptal is mainly remembered as an industrial chemist; he was the first to produce sulfuric acid commercially in France at his factory at Montpellier. His early paper on bleaching (1787) was translated and published in England in 1790 by Robert Kerr. In 1800 he proposed a new method of bleaching using vapor from a boiling alkaline liquor, which was soon introduced into England. Chaptal also wrote one of the first books on industrial chemistry, *Chimie appliquée aux arts* (1807; *Chemistry Applied to the Arts*).

### **Charcot, Jean-Martin** (1825–1893) *French neurologist*

Parisian-born Charcot (shar-koh) studied medicine in his native city and received his MD in 1853. His interest in disease of the nervous system led to his appointment, in 1862, to the Salpêtrière Hospital for nervous and mental disorders. This marked the beginning of a long and distinguished association. Charcot described the pathological changes associated with several degenerative conditions of the nervous system, including the disintegration of ligaments and joint surfaces (known as *Charcot's disease*) that occurs in advanced stages of locomotor ataxia. His studies of brain damage in cases of speech loss (aphasia) and epilepsy supported the findings of his contemporary, Paul Broca, that is, different bodily functions are controlled by different regions of the cerebral cortex.

In 1872, Charcot was appointed professor of pathological anatomy at the faculty of medicine and later (1882) became professor of neurology at the Salpêtrière. He was increasingly

concerned with the link between mind and body in cases of hysteria and trauma. With his eloquent manner and a dramatic presentation of his lectures on a small stage, he became a widely celebrated teacher. Among many famous students was Sigmund FREUD, who was influenced by Charcot's use of hypnosis on patients.

Charcot's son, Jean, became a famous polar explorer.

### **Chardonnet, Hilaire Bernigaud, Comte de** (1839–1924) *French chemist*

Chardonnet (shar-don-ay), who was born at Besançon in eastern France, acted as an assistant to Louis PASTEUR while he was working on silk worms. This stimulated his interest in the chemistry of fibers and led him to search for means to produce a synthetic fiber.

In 1884 Chardonnet took out a patent for a process for producing the world's first artificial fiber, which he made by dissolving nitrocellulose in alcohol and ether, and then forcing the solution through tiny holes leaving thin threads once the solvent had evaporated. Products of the fiber, called "Chardonnet silk" or rayon, were first exhibited in the Paris Exposition of 1889. Despite the fiber's origin in nitrocellulose it was not actually explosive but was highly flammable. Modifications to the process that made rayon less flammable enabled it to be manufactured for a mass market.

### **Chargaff, Erwin** (1905–2002) *Austrian-American biochemist*

Chargaff (char-gaf), who was born at Czernowitz (now Chernovtsy in Ukraine), gained his PhD from the University of Vienna in 1928 and then spent two years at Yale University. He returned to Europe, working first in Berlin and then at the Pasteur Institute, Paris, before returning permanently to America in 1935.

Initially Chargaff's work covered a range of biochemical fields, including lipid metabolism and the process of blood coagulation. Later his attention became concentrated on the DNA molecule, following the announcement in 1944 by Oswald AVERY that the factor causing the heritable transformation of bacteria is pure DNA. Chargaff reasoned that, if this were so, there must be many more different types of DNA molecules than people had believed. He examined DNA using the recently developed techniques of paper chromatography and ultraviolet spectroscopy and found the composition of DNA to be constant within a species but to differ widely between species. This led him to conclude that there must be as many different types of DNA as there are different species. However, some interesting and very important consistencies emerged. Firstly the number of purine bases (adenine and guanine) was always equal to the number of pyrimidine bases

(cytosine and thymine), and secondly the number of adenine bases is equal to the number of thymine bases and the number of guanine bases equals the number of cytosine bases. This information, announced by Chargaff in 1950, was of crucial importance in constructing the Watson–Crick model of DNA.

From 1935 Chargaff worked at Columbia University, as professor of biochemistry from 1952 and as emeritus professor from 1974.

### **Charles, Jacques Alexandre César** (1746–1823) *French physicist and physical chemist*

Born in Beaugency, France, Charles (sharl or charlz) was a clerk in the finance ministry who developed an interest in science, especially in the preparation of gases. Eventually he became professor of physics at the Conservatoire des Arts et Métiers in Paris. He constructed the first hydrogen balloons, making an ascent to over 3,000 meters (1.9 mi) in 1783. This feat brought him popular fame and royal patronage.

His name is chiefly remembered, however, for his discovery of *Charles's law*, which states that the volume of a fixed quantity of gas at constant pressure is inversely proportional to its temperature. Hence all gases, at the same pressure, expand equally for the same rise in temperature. Strictly speaking, the law holds only for ideal gases but it is valid for real gases at low pressures and high temperatures. Charles deduced the law in about 1787, working with oxygen, nitrogen, carbon dioxide, and hydrogen, but he did not publish it. He communicated his results to Joseph GAY-LUSSAC, who published his own experimental results in 1802, six months after DALTON had also deduced the law. The priority, as Gay-Lussac himself pointed out, belongs to Charles but Gay-Lussac's figures were more accurate (and thus the law is sometimes referred to as *Gay-Lussac's law*). This law and that formulated by Robert BOYLE comprise the gas laws.

### **Charpak, Georges** (1924– ) *French physicist*

Charpak (shar-pak or shar-pak), who was born in Dabrovia, Poland, was educated at the Ecole des Mines, Paris. He was imprisoned at Dachau from 1943 until 1945. He then worked in France on nuclear research, mainly at the Centre National de la Recherche Scientifique (CNRS). He moved in 1959 to CERN (Conseil Européen pour la Recherche Nucléaire; European Laboratory for Particle Physics), in Geneva, retiring in 1991.

By the time Charpak arrived at CERN nuclear physicists had begun to search for evermore-elusive particles. To detect their fleeting and rare appearances could require the examination of thousands of particle tracks. Yet the

older particle detectors – bubble chamber, cloud chamber, etc. – could handle only a small proportion of the data pouring from the newer and more powerful accelerators.

In 1968 Charpak described his newly designed drift chamber in which charged wires are strung 1.2 millimeters apart, layer on layer, in a gas-filled container. A voltage is applied to the wires in such a way that the central wires are charged positively, and the outer ones negatively. If a charged particle enters the detector, it ionizes atoms of gas, and the ions drift to the central wires, triggering a signal. As the wires criss-cross through the chamber it is possible to reconstruct a three-dimensional picture of the ion's tracks from the signals obtained.

When linked to computers the drift chamber can handle a million nuclear events per second. It played a vital role in the 1983 discovery of the W and Z bosons by Carlo RUBBIA. It also won for Charpak the 1992 Nobel Prize for physics. In more recent times Charpak turned his attention to biochemical reactions. In 2001 he published *Megawatts and Megatons: A Turning Point in the Nuclear Age* (with Richard L. Garvin).

**Charpentier, Jean de (1786–1885)** *Swiss geologist and glaciologist*

Charpentier (shar-pahn-tyay) studied under Abraham WERNER at the Mining Academy in his native city of Freiberg, where his father was also a professor. He worked as an engineer in the Silesian mines before being appointed director of the Bex salt mines in 1813.

He studied the problem of the widely scattered and impressively large erratic boulders and soon rejected the current theories of their origin. The theory that such boulders were meteorites was unlikely for they were identical in composition with other Alpine rocks. The flood theory, supported by Charles LYELL, supposed that they had been distributed by boulder-laden icebergs. However, this raised the problems of where the water had come from and where it had gone to.

Charpentier concluded that the agent responsible was glaciation and first presented his glacial theory publicly in Lucerne in 1835. He gained little support but did attract the attention of Louis AGASSIZ. In 1841 Charpentier published his results in his *Essai sur les glaciers* (Essay on Glaciers) but was anticipated by Agassiz's earlier publication, in 1840, of his *Etudes sur les glaciers* (Studies on Glaciers).

**Châtelet, Emilie Le Tonnelier de Breteuil, Marquise du (1706–1749)** *French physicist, mathematician, philosopher, and translator*

Long-overlooked as a scholar in her own right, and caricatured as merely the long-standing

mistress of French writer VOLTAIRE, du Châtelet (**shah-te-lay**) is now regarded as one of the great scientific minds of the 18th century. She was born into a wealthy aristocratic family in Paris, where her father held a prominent position at court. Emilie spurned typical girlish interests, and her father arranged for tutors to provide her with a wide-ranging private education. She quickly became a skilled linguist and mathematician, was well versed in science, and listened avidly to scholarly visitors to the court at Versailles. In 1725 she made an arranged marriage to an army officer, and subsequently bore him three children. du Châtelet met Voltaire in 1733, and they fell in love. The following year, with Voltaire in trouble with the authorities for his criticism of the French state, the two sought refuge at Chateau de Cirey, near the German border, a dilapidated mansion belonging to Emilie's husband. Here, they embarked on a fruitful collaboration, with du Châtelet publishing scientific papers and corresponding with leading scientists. However, it is their mutual interest in the works of Isaac NEWTON that would transform science in France and beyond. In 1738 Voltaire published *Element's of Newton's Philosophy*, a clear exposition of Newton's discoveries in astronomy and optics that introduced these ideas to the wider French public. Although cited as sole author, Voltaire emphasized in the preface the crucial role of du Châtelet's scientific expertise in writing the book. Fired with enthusiasm for Newtonianism, du Châtelet then wrote *Institutions de Physique* (Foundations of Physics; 1740), in which she attempted to reconcile conflicts in the astronomical systems of DESCARTES, LEIBNIZ, and Newton. But her greatest achievement was a translation from the original Latin of Newton's *Principia Mathematica*. She augmented the original text with her own interpretations and examples, algebraic commentary, and contemporary experimental confirmations, thus demonstrating to French scholars the full significance of Newtonian mechanics. Published in 1759, this remains the standard French translation of Newton's great work. In 1748 du Châtelet started an affair with a poet and much younger man, the Marquis de Saint-Lambert, and the following year found she was pregnant. In spite of this, Voltaire remained a steadfast friend, and du Châtelet persevered to finish her *Principia* translation. Both she and her newborn daughter died shortly after the birth. Voltaire wryly observed that du Châtelet "was a great man whose only fault was being a woman."

**Chatelier, Henri Louis Le** See [LE CHATELIER, HENRI LOUIS](#).

**Cherenkov (or Cerenkov), Pavel Alekseyevich (1904–1990)** *Soviet physicist*

Cherenkov (che-**reng**-kof) came from a peasant family in Voronezh, Russia, and was educated at the university there, graduating in 1928. From 1930 he was a member of the Lebedev Institute of Physics in Moscow, serving there from 1953 as professor of experimental physics.

In 1934 Cherenkov was investigating the absorption of radioactive radiation by water when he noticed that the water was emitting an unusual blue light. At first he thought it was due simply to fluorescence but was forced to reject this idea when it became apparent that the blue radiation was independent of the composition of the liquid and depended only on the presence of fast-moving electrons passing through the medium.

It was later shown by Ilya FRANK and Igor TAMM in 1937 that the radiation was caused by electrons traveling through the water with a speed greater than that of light in water (though not of course greater than that of light in a vacuum). This *Cherenkov radiation* can be produced by other charged particles and can be used as a method of detecting elementary particles. Cherenkov, Frank, and Tamm shared the Nobel Prize for physics in 1958.

### Chauvin, Yves (1930– ) *French chemist*

Chauvin is Directeur de recherché honoraire à l'Institut Français du Pétrole, Rueil-Malmaison, France. He is noted for elucidating the mechanism of metathesis, a type of reaction in organic chemistry with many applications.

The word metathesis comes from the Greek word *meta*, meaning change, and *thesis*, meaning position. A simple example of metathesis occurs in inorganic chemistry – for example, silver nitrate with potassium chloride gives silver chloride and potassium nitrate. In inorganic chemistry, metathesis is often called “double decomposition.” In organic chemistry, metathesis reactions occur in organic compounds with double bonds, which are broken and remade in such a way that groups of atoms change places. A metathesis reaction is frequently compared to a dance in which the couples change partners. In organic chemistry, this type of reaction requires certain complex metal compounds to act as a catalyst.

This type of reaction was discovered in the 1950s. However, the molecular mechanism by which it worked was not known, thus making it impossible to utilize this type of reaction in organic synthesis in any systematic way. In 1971 Chauvin proposed a mechanism for metathesis reactions and with a consequent understanding of what types of catalysts were effective, thus paving the way for systematic investigation into suitable catalysts. Together with his student Jean-Louis Hérrison, Chauvin postulated that the catalyst is a metal carbene (subsequently called metal alkylide), i.e., a compound in which a metal atom is attached to a carbon

atom by a double bond. Unlike previous attempts to explain metathesis reactions, the mechanism which Chauvin proposed was in accord with experimental results and subsequent investigations have confirmed that his proposed mechanism is correct.

The importance of Chauvin's work to organic synthesis, both in academic and industrial research, was rewarded by his share in the 2005 Nobel Prize for chemistry, along with Robert GRUBBS and Richard SCHROCK.

### Chevreul, Michel Eugène (1786–1889) *French organic chemist*

Where the eye sees at the same time two contiguous colours, they will appear as dissimilar as possible, both in their optical composition and in the height of their tone. We have then, *at the same time*, simultaneous contrast of colour properly so called, and contrast of tone.

—*The Principles of Harmony and Contrast of Colours* (1839)

One of the longest-lived of all chemists, Chevreul (she-**vrū**(r)l), who was born at Angers in France, studied at the Collège de France (1803). He was an assistant to Antoine François de FOURCROY (1809), assistant at the Musée d'Histoire Naturelle (1810), then professor of physics at the Lycée Charlemagne (1813–30).

In 1810 Chevreul began a great program of research into fats, which was published in his book *Recherches chimiques sur les corps gras d'origine animale* (1823; *Chemical Researches on Animal Fats*). By acidification of soaps derived from animal fats and subsequent crystallization from alcohol he was able to identify for the first time various fatty acids: oleic acid, “margaric acid” (a mixture of stearic and palmitic acids), butyric acid, capric and caproic acids, and valeric acid. He recognized that fats are esters (called “ethers” in the nomenclature of the day) of glycerol and fatty acids and that saponification produces salts of the fatty acids (soaps) and glycerol. In 1825 Chevreul and Joseph GAY-LUSSAC patented a process for making candles from crude stearic acid. Other fats investigated by Chevreul were spermaceti, lanolin, and cholesterol.

In 1824 Chevreul became director of the dye-works for the Gobelins Tapestry, where he did important work on coloring matters, discovering hematoxylin in logwood, quercetin in yellow oak, and preparing the reduced colorless form of indigo. He also investigated the science and art of color with special application to the production of massed color by aggregations of small monochromatic “dots,” as in the threads of a tapestry.

Chevreul's later appointments were professor of chemistry at the Musée d'Histoire Naturelle (1830) and director there (1864). His other work included the discovery of creatine (1832) and studies on the history of chemistry.

**Chittenden, Russell Henry** (1856–1943)  
*American physiologist and biochemist*

As part of his undergraduate course at Yale, Chittenden, who was born in New Haven, Connecticut, was asked to investigate why scallops taste sweeter when reheated from a previous meal than when freshly cooked. This project led to his discovery of glycogen and glycine in the muscle tissue – the first demonstration of the free occurrence of glycine (or glycocholl as it was then known) in nature. The work attracted the attention of Wilhelm KÜHNE at Heidelberg who invited Chittenden to his laboratory. Later collaboration between Chittenden (at New Haven) and Kühne (in Heidelberg) provided a strong foundation for studies in enzymology.

Chittenden also did important work in toxicology and on the protein requirements of man, showing that the so-called Voit standard, which recommended 118 grams of protein per day, was a vast overestimate, and that good health could be maintained on 50 grams a day. He played a major part in the establishment of physiological chemistry (biochemistry) as a science in its own right.

**Chladni, Ernst Florens Friedrich**  
(1756–1827) *German physicist*

Born in Wittenberg in Germany, Chladni (**klad-nee**) was forced to study law by his father and obtained his degree from Leipzig in 1782. When his father died, Chladni turned to science. He is noted for his work on acoustics, being the first to analyze sound in a rigorous mathematical way. For this he invented the sand-pattern technique, in which thin metal plates covered in sand are made to vibrate. The sand collects in the nodal lines producing symmetrical patterns (called *Chladni's figures*).

Chladni also had a great interest in music and designed two musical instruments: the euphonium and the clavicylinder. He also measured the speed of sound in gases other than air by filling organ pipes with the gas and measuring the change in pitch.

Chladni was one of the first scientists to believe that meteorites fell from the sky but his opinion was treated with disdain until Jean Baptiste BIOT proved him to be correct in 1803.

**Chou Kung** (about 12th century BC) *Chinese mathematician*

Chou Kung (chou kuung), or the duke of Chou, was the brother of Wu Wang, the founder of the Chou dynasty. He served briefly as regent on his brother's death.

He is remembered for his name in the *Chou li* (Rites of Chou), one of the earliest Chinese mathematical works, in which he supposedly takes part in a dialog with someone called Shang Kao. The dialog was thought to date back to the time of Chou Kung but scholars

now think this extravagant. Although they are prepared to accept some parts as going back to the sixth century BC, the bulk of it they assign to the Han dynasty (200 BC – AD 200). The work is important in providing hard evidence for the state of early Chinese mathematics.

The most significant feature of the work is a demonstration of the truth of PYTHAGORAS's theorem for triangles with sides of 3, 4, and 5 units. The "proof," described as "piling up the rectangles," is purely diagrammatic. The work also shows knowledge of the multiplication and division of fractions, the finding of common denominators, and the extraction of square roots. Compared with Greek works of a comparable period, such as ARCHIMEDES, the work is unimpressive.

**Christie, Sir William Henry Mahoney**  
(1845–1922) *British astronomer*

Christie, a Londoner, was the grandson of the founder of the firm of London auctioneers and the son of a mathematician. He graduated from Cambridge University in 1868 and immediately joined the staff of the Royal Greenwich Observatory. He later served from 1881 to 1910 as Astronomer Royal and was knighted in 1904.

During Christie's period of office the observatory saw considerable expansion and refurbishment. The Physical Observatory, later known as the South Building, was built at Greenwich between 1891 and 1899 and equipped with new telescopes: a 28-inch (71-cm) refractor for visual use and a 26-inch (66-cm) for photographic purposes were provided in the 1890s.

The Observatory agreed to cooperate in an international project, involving 18 observatories, to produce the first photographic chart of the heavens. The ambitious project was proposed by the director of the Paris Observatory, Admiral E. Mouchez, in 1887 and the chart became known as the "Carte du Ciel." The Observatory was made responsible for the necessary observations and measurements for the large area of the sky from the north celestial pole to 65°N declination. This work was completed and published by 1909, long after the estimated time but before the other participants had finished.

Christie's own research was spent mainly on sunspot activity in collaboration with Edward MAUNDER and on unsuccessful attempts to measure stellar radial velocities.

**Chu, Paul Ching-Wu** (1941– ) *American physicist*

Chu was born in Hunan, China, but his parents were members of the Nationalist Party and the family fled to Taiwan in 1949 for political reasons. After graduating in physics from Chengkung University, Chu moved to America

in 1963 and gained his PhD in 1968 from the University of California, San Diego. After spending some time working for the company AT & T, Chu entered academic life, first at Cleveland State University, and since 1979 as professor of physics at the University of Houston. Since 1987 he has been director of the Texas Center for Superconductivity at Houston. He has also served as president of the Hong Kong University of Science and Technology (since 2001).

Much of Chu's work has been in the field of superconductivity. A major breakthrough had been achieved in 1986 when Alex MULLER had discovered some materials that become superconductive below the relatively high critical temperature of 35 K ( $-238^{\circ}\text{C}$ ). This temperature was still too low to be economic. The vital temperature was 77.4 K ( $-195.8^{\circ}\text{C}$ ) – the temperature below which nitrogen becomes liquid. The aim was to find materials that could be cooled to a superconducting state using relatively cheap liquid nitrogen, rather than the extremely expensive liquid helium (b.p.  $-268.9^{\circ}\text{C}$ ). Chu was determined that his Houston laboratory would be the first to find a superconductor with a critical temperature above 77.4 K.

The superconductor found by Muller was a ceramic material composed of barium, lanthanum, and copper oxide ( $\text{Ba-La-CuO}$ ). Chu began by reproducing Muller's work. He next developed new methods of synthesis for this type of compound and began first to vary the ratio of elements in the compound. Initial results obtained by reducing the amount of copper were encouraging, but could not be repeated. However, at high pressures of 10,000 atmospheres it was possible to increase the critical temperature to about 40 K. Changing the proportions of the elements could raise the temperature to 52.5 K, but this was still at high pressures.

The original Muller compound contained three metals in the ratio 2:1:4. Many researchers concentrated on substituting other metals in the same ratio. Copper seemed to play a special bonding role and was judged by Chu to be indispensable. Chu decided to replace the lanthanum with other related lanthanoid elements. One he chose to work with was yttrium (Y). Finally, in January 1987, just a year after Muller's breakthrough, Chu found that the critical temperature of  $\text{Y}_{1.2}\text{Ba}_{0.8}\text{CuO}_4$  was 93 K and that the effect was stable and permanent.

**Chu, Steven** (1948– ) *American physicist*

Chu was born in St Louis, the second son of Chinese immigrants, and moved to New York in 1950. He attended the University of Rochester, majoring in mathematics and physics and grad-

uating AB and BS in 1970. Graduate studies under Eugene Commins at the University of California, Berkeley, earned Chu his PhD in 1976. After a spell as postdoctoral research fellow at Berkeley, he moved to the Bell Laboratories, Murray Hill (1978–83), and in 1983 became head of the Quantum Electronics Research Department, Holmdel. In 1987 Chu moved to Stanford University as professor of physics and applied physics, and in 2004 was appointed director of the Lawrence Berkeley National Laboratory.

While at Bell Laboratories, in 1982 Chu and his colleague, Allen Mills, achieved the feat of accurately measuring the energy levels of positronium, the bound state of an electron and positron, using laser spectroscopy. Then, in 1985, he led a group that developed a pioneering technique for cooling and trapping atoms using laser beams. This technique can also be adapted as "optical tweezers," to trap microscopic particles, including DNA or other biomolecules, in water. Chu's team arranged three pairs of opposed laser beams at right angles so they trapped sodium atoms, in a vacuum, at the intersection of the six beams. Photons of the appropriate energy pushed back the sodium atoms as they tended to move out of the area, so confining them in the form of a pea-sized cloud consisting of about one million atoms. In this way the atoms cooled to within a few millionths of a degree of absolute zero, a phenomenon known as DOPPLER cooling. In the cloud the atoms move as if in a thick liquid, described as "optical molasses." Chu went on to demonstrate that the sodium atoms could be effectively trapped by the laser beams in combination with magnetic coils, forming a magneto-optical trap (MOT). William D. PHILLIPS subsequently demonstrated Doppler cooling to temperatures lower than had been theoretically predicted; this led to a reappraisal of the entire theory of Doppler cooling. For this work, Chu was awarded the 1997 Nobel Prize for physics, jointly with Phillips and Claude COHEN-TANNOUDJI.

The laser-cooling technique inspired Chu to develop the atomic fountain, in which laser-cooled atoms are sprayed like the jets of a water fountain in a vacuum-filled chamber. Essentially, cooling the atoms decreases their velocity, and improves the accuracy of the device. This now forms the basis of atomic clocks with much greater accuracy than their predecessors. Chu and his Stanford team continue to develop methods of laser cooling and trapping, and to investigate applications for laser-based optical tweezers, for example in studying the behavior of RNA and proteins during translation at ribosomes in biological systems.

**Ciechanover, Aaron** (1947– ) *Israeli biochemist*

Born in Haifa, Ciechanover studied medicine at the Hebrew University School of Medicine, Jerusalem, obtaining his MD in 1974. After service in the Israeli Defense Forces (1974–77) he joined the Israel Institute of Technology (Technion) in Haifa, and gained a PhD in medicine in 1981. He moved to the USA as a post-doctoral fellow at Massachusetts Institute of Technology (1982–84) before returning to the Technion, where he was subsequently appointed associate professor (1987) and professor (1992). He is currently director of the Rappaport Family Institute for Research in Medical Sciences at the Technion.

While still a postgraduate student, Ciechanover collaborated with his colleague at the Technion, the Israeli biochemist Avram HERSHKO, in investigating energy-dependent protein degradation mechanisms in living cells. The duo worked with cell-free extracts obtained from immature red blood cells, and discovered that a crucial component of the process was a polypeptide of approximate molecular mass 9000, later named ubiquitin. Ciechanover and Hershko took sabbatical leave to visit the laboratory of US biochemist Irwin ROSE in Philadelphia. Here the three scientists were able to show that ubiquitin molecules bind covalently to various proteins. They went on to describe the enzymes involved in this ubiquitination of proteins, and how this ubiquitin tagging marks proteins for degradation by the cell. Ciechanover subsequently studied various aspects of protein ubiquitination, and its relevance to the cell cycle and other cellular activities.

In 2004 he was awarded the Nobel Prize for chemistry, jointly with Rose and Hershko, “for the discovery of ubiquitin-mediated protein degradation.”

### Clairaut, Alexis Claude (1713–1765) *French mathematical physicist*

I intended to go back to what might have given rise to geometry; and I attempted to develop its principles by a method natural enough so that one might assume it to be the same as that of geometry's first inventors, attempting only to avoid any false steps that they might have had to take.

—*Elémens de géométrie* (1741; Elements of Geometry)

The Parisian-born son of a mathematics teacher, Clairaut (kle-roh) was introduced to the subject at an early age. By the age of ten he was studying L'Hôpital's work on conic sections and two years later he read a paper to the French Académie des sciences. He was elected to the Académie at the age of 18 following the publication in 1731 of his *Recherches sur les courbes à double courbes* (Researches on the Curves of Double Curves).

Soon after, in 1736, he accompanied MAURTIUS on an expedition to Lapland to deter-

mine the length of 1° of a meridian within the Arctic circle. The aim of the expedition was to determine the shape of the Earth by measuring its curvature at the places where it differed most – the equator and poles. A similar expedition under the direction of LA CONDAMINE measured the equatorial curvature in the Andes. Behind the expeditions lay a crucial test of Newtonian mechanics that the Earth's rotation should cause it to bulge at the equator and flatten at the poles. Cartesian science predicted that the reverse position should hold. As Clairaut revealed in his *Théorie de la figure de la terre* (1743; Theory of the Shape of the Earth) the Earth had, as NEWTON had claimed, a larger diameter through the equator than through the poles, a shape known to geometers as an “oblate spheroid.”

In 1747 Clairaut turned his attention to the Moon and once again the issue was the accuracy of Newtonian mechanics. The motion of the lunar apogee – the point in the lunar orbit furthest away from the Earth – differed from Newton's predicted value by a factor of two. At first Clairaut was tempted to question the validity of Newton's inverse square law, but in 1749 he discovered that no such drastic step need be taken; several factors of the lunar orbit had been ignored. When these were included in Newton's lunar equations the correct value for the motion of the lunar apogee was obtained.

Clairaut was also involved in the dramatic events surrounding the return of HALLEY's comet. Halley had claimed that the comet of 1682 would return in 1758. Clairaut realized that if Newtonian mechanics was to be an exact science it must make a more precise prediction. He informed the Académie in November 1758 that the comet would be at perihelion on 13 April 1759; the actual date was 13 March, just within the allowed-for margins of error.

Clairaut also collaborated with the Marquise du CHÂTELET in her French translation of Newton's *Principia*.

### Claisen, Ludwig (1851–1930) *German organic chemist*

Claisen (kli-sen), who was born at Cologne in Germany, gained his PhD under Friedrich KEKULÉ at Bonn, later becoming professor at Kiel (1897–1904) and honorary professor at Berlin.

He is best known for the condensation reactions that bear his name. The *Claisen–Schmidt condensation* is a method of synthesizing  $\alpha,\beta$ -unsaturated aldehydes and ketones, by reaction of an aldehyde with another aldehyde or a ketone. This type of reaction was first discovered by J. Gustav Schmidt in Zurich (1880). The *Claisen condensation* (1890) involves condensation between similar or different esters, or esters and ketones, in the presence of sodium ethoxide to give unsaturated esters. The

*Claisen flask*, used for vacuum distillation, was developed in 1893. Claisen also made an important contribution to the study of tautomerism by isolating (simultaneously with Johannes Wislicenus) the keto-and enol-forms of acetyldibenzoylmethane and dibenzoylacetone.

**Clark, Alvan Graham (1832–1897)** *American astronomer and instrument-maker*

Clark, the son of the instrument-maker Alvan Clark, was born at Fall River, Massachusetts. He started life as a portrait painter but soon joined his father's firm and became a lens grinder, preparing the mirrors and lenses for some of the best telescopes of the late 19th century. In 1861 he had made a lens for Edward BARNARD at the University of Mississippi. Testing it before parting with it he looked through it at Sirius and to his surprise observed a faint image near the star. It was, in fact, Sirius B, the famous companion predicted by Friedrich BESSEL in 1844. Clark made many more observations, and discovered 16 double stars.

The Clark firm provided Simon NEWCOMB, head of the U.S. Naval Observatory, with a 26-inch (66-cm) refractor. It was with this that the very small satellites of Mars, Phobos and Deimos, were detected by Asaph HALL in 1877. In 1888 Clark built the 36-inch (91-cm) refractor for the Lick Observatory and his final achievement, just before his death, was to install his 40-inch (101-cm) refractor in the Yerkes Observatory. A practical limit is reached in using lenses larger than this and after Clark's death astronomers put their faith in mirrors rather than lenses. For this reason the Yerkes 40-inch and the Lick 36-inch are still the largest and the second largest refractors in the world.

**Clarke, Sir Cyril Astley (1907–2000)** *British physician*

Clarke, who was born in Leicester in eastern England, was educated at the University of Cambridge and Guy's Hospital, London, where he qualified in 1932. He remained at Guy's until 1936 when he engaged in life-insurance work before spending the war years in the Royal Navy. From 1946 Clarke worked as a consultant physician in Liverpool until 1958, when he joined the staff of the university. Here he later served as professor of medicine from 1965 to 1972 and also, from 1963 to 1972, as director of the Nuffield unit of medical genetics.

Although a consultant physician, Clarke was also a skilled amateur lepidopterist. In 1952 he became interested in the genetics of the wing colors of swallowtail butterflies and began a collaboration with Philip Sheppard, a professional geneticist who later became a colleague at Liverpool University. In particular, they

worked on the inheritance of mimicry in the wing patterns of certain swallowtails. They noted that the gene controlling the wing pattern is actually a group of closely linked genes behaving as a single unit – a supergene. They also found that even though the males also carry such supergenes, the patterns only show in the females.

At this point Clarke was struck by certain striking parallels between the inheritance of swallowtail wing patterns and human blood types. Above all it aroused his interest in Rhesus babies. This condition arises when an Rh-negative mother, that is someone whose blood lacks the Rh factor or antigen, and an Rh-positive father produce an Rh-positive child. Occasionally the fetus's blood leaks from the placenta into the mother's blood and stimulates the production of Rh antibodies. This will cause her to destroy unwittingly the red cells of any subsequent Rh-positive babies she may carry.

Clarke and Sheppard puzzled over how to prevent the mother producing the destructive Rh antibodies. The answer eventually came from Clarke's wife who, in an inspired moment, told him to inject the Rh-negative mothers with Rh antibodies. As this is what destroys the blood of the fetus in the first place, the answer initially sounds absurd. However, the Rh antibodies should destroy incompatible Rh-positive cells before the mother's own antibody machinery acted, that is, before the mother could become sensitized to Rh-positive blood.

In 1964 Clarke and his colleagues were able to announce a major breakthrough in preventive medicine. Since then thousands of women have received injections of Rh antibodies with only a few failures.

**Claude, Albert (1898–1983)** *Belgian–American cell biologist*

Claude (klohd), who was born at Longlier in Belgium, was educated at the University of Liège where he obtained his doctorate in 1928. He joined the staff of the Rockefeller Institute, New York, in 1929 and in 1941 adopted American citizenship. Claude returned to Belgium in 1948 to serve as director of the Jules Bordet Research Institute, a post he retained until his retirement in 1972.

In the 1930s Claude attempted to purify Peyton ROUS's chicken sarcoma virus (RSV) using a centrifuge. He succeeded in producing a fraction with an enhanced sarcogenic power, noting that small granules containing nucleoprotein were present. Suspecting these granules to be the cause of the RSV, he was somewhat surprised to find similar granules present in centrifuged cells taken from uninfected chicken embryo.

Over the next 20 years, using electron microscopes as well as improved centrifuges,

Claude began to chart the constitution of the protoplasm. Although the mitochondria had first been described as early as 1897, Claude was able to distinguish them from what he originally termed “microsomes.” Among such microsomes he could make out a “lacelike reticulum” spread throughout the cytoplasm, a structure later named the endoplasmic reticulum. Another member of Claude’s laboratory, George PALADE, went on to identify the ribosome.

For his work in opening up the study of cell structures Claude shared the 1974 Nobel Prize for physiology or medicine with Palade and Christian de DUVE.

### **Claude, Georges (1870–1960)** *French chemist*

Born in Paris, France, Claude was educated at the Ecole de Physique et Chimie after which he worked as an engineer in various industries. Claude made a number of important contributions to technology, including the discovery (1886) that acetylene (ethyne) could be handled with safety if dissolved in acetone, and a method of liquefying air (1902), which he used for the large-scale production of nitrogen and oxygen. In 1910 he introduced neon lighting, using neon gas at low pressure excited by an electric discharge to emit a bright red light.

The latter part of his life was, however, less successful. From 1926 onward he worked on new sources of energy. In particular, he tried to show how it could be extracted from the temperature difference between the surface and the bottom of the sea. Although his argument was sound he never overcame the formidable engineering difficulties.

Although an old man of 75 when World War II ended Claude was imprisoned as a Vichy sympathizer.

### **Clausius, Rudolf Julius Emmanuel (1822–1888)** *German physicist*

Clausius (**klow-zee-uus**), who was born in Köslin (now Koszalin in Poland), studied at the University of Berlin and obtained his doctorate from Halle in 1848. He was professor of physics at the Royal Artillery and Engineering School, Berlin (1850–55) and professor of mathematical physics at Zurich (1855–67). He then transferred to the University of Würzburg (1867) and, from there, moved to Bonn (1869).

He is noted for his formulation of what is now known as the second law of thermodynamics. Clausius arrived at this by considering the theorem of Sadi CARNOT on heat engines and attempting to reconcile this with the mechanical theory of heat, which was developing at the time. In 1850 he published a famous paper *Über die bewegende Kraft der Wärme* (On the Motive Force of Heat), in which he first in-

troduced the principle that “it is impossible by a cyclic process to transfer heat from a colder to a warmer reservoir without net changes in other bodies.” An alternative statement of this, the second law, is “heat does not flow spontaneously from a colder to a hotter body.” The second law of thermodynamics was independently recognized by Lord KELVIN.

Clausius gave the law a mathematical statement in 1854 and published a number of papers on the topic over the next few years. In 1865 he introduced the term “entropy” as a measure of the availability of heat. The change in entropy of a system is the heat absorbed or lost at a given temperature divided by the temperature. An increase in entropy corresponds to a lower availability of heat for performing work.

The second law of thermodynamics is one of the fundamental principles of physics. It describes the fact that, although the total energy in a system is conserved, the availability of energy for performing work is lost. Clausius showed that in any nonideal (irreversible) process the entropy increased. The first and second laws of thermodynamics are encapsulated in his famous statement, “The energy of the universe is a constant; the entropy of the universe always tends toward a maximum.”

Clausius also followed the work of James JOULE on the kinetic theory of gases, introducing the ideas of effective diameter and mean free path (the average distance between collisions). A contribution to electrochemistry was his idea that substances dissociated into ions on solution. In the field of electrodynamics he produced a theoretical expression for the force between two moving electrons – a formula later used by Hendrik LORENTZ.

### **Clemence, Gerald Maurice (1908–1974)** *American astronomer*

Clemence, who was from Smithfield, Rhode Island, studied mathematics at Brown University, Rhode Island. After graduating he joined the staff of the U.S. Naval Observatory in 1930 where he remained until 1963, serving as head astronomer and director of the Nautical Almanac from 1945 to 1958 and science director of the Observatory from 1958. In 1963 he was appointed senior research associate and lecturer at Yale, becoming professor of astronomy in 1966, a post he held until his death.

Clemence’s work was primarily concerned with the orbital motions of the Earth, Moon, and planets. In 1951, in collaboration with Dirk BROUWER and W. J. ECKERT, Clemence published the basic paper *Coordinates of the Five Outer Planets 1653–2060*. This was a considerable advance on the tables for the outer planets calculated by Simon NEWCOMB and George W. Hill 50 years earlier. Clemence and his colleagues calculated the precise positions of the outer planets at 40-day intervals over a period

of 400 years. It was the first time that the influence of the planets on each other was calculated at each step instead of the prevailing custom of assuming that the paths of all except one were known in advance.

Such an ambitious scheme was only made possible by the emergence of high-speed computers, one of which was made available to them by IBM from 1948. For each step some 800 multiplications and several hundred other arithmetical operations were required and would, Clemence commented, have taken a human computer 80 years if he could have completed the work without committing any errors en route.

Clemence also conceived the idea that Brouwer named "Ephemeris Time," by which time could be determined very accurately from the orbital positions of the Moon and the Earth. This followed the discovery that the Earth's period of rotation was not constant and should not therefore be used in the measurement of time. Ephemeris Time eventually came into use in 1958, although it has been superseded for most purposes by the more convenient and even more accurate atomic time scale.

### **Cleve, Per Teodor (1840–1905) *Swedish chemist***

Cleve (**klay**-ve), who was born in the Swedish capital Stockholm, became assistant professor of chemistry at the University of Uppsala in 1868 and was later made professor of general and agricultural chemistry there. He is mainly remembered for his work on the rare earth elements.

In 1874 Cleve concluded that didymium was in fact two elements; this was proved in 1885 and the two elements named neodymium and praseodymium. In 1879 he showed that the element scandium, newly discovered by Lars NILSON, was in fact the eka-boron predicted by Dmitri MENDELEEV in his periodic table. In the same year, working with a sample of erbia from which he had removed all traces of scandia and ytterbia, Cleve found two new earths, which he named holmium, after Stockholm, and thulium, after the old name for Scandinavia. Holmium in fact turned out to be a mixture for, in 1886, Lecoq de Boisbaudran discovered that it also contained the new element dysprosium.

Cleve is also remembered as the teacher of Svante ARRHENIUS.

### **Coblentz, William Weber (1873–1962) *American physicist***

Coblentz, the son of a farmer from North Lima, Ohio, was educated at the Case Institute of Technology and at Cornell, where he obtained his PhD in 1903. In 1904 he joined the National Bureau of Standards in Washington and in the following year founded the radiometry

section of the bureau, where he remained until his retirement in 1945.

Coblentz worked mainly on studies of infrared radiation. At the Lick Observatory he began, in 1914, a series of measurements aimed at determining the heat radiated by stars. He was also one of the pioneers of absorption spectroscopy in the infrared region as a technique for identifying compounds.

### **Cockcroft, Sir John Douglas (1897–1967) *British physicist***

Cockcroft, who was born at Todmorden in northern England, entered Manchester University, England, in 1914 to study mathematics, but left the following year to join the army. After World War I he was apprenticed to the engineering firm Metropolitan Vickers, which sent him to read electrical engineering at the Manchester College of Technology. He later went to Cambridge University, graduated in mathematics, and joined Ernest RUTHERFORD's team at the Cavendish Laboratory.

Cockcroft soon became interested in designing a device for accelerating protons and, with E. T. S. WALTON, constructed a voltage multiplier. Using this, Cockcroft and Walton bombarded nuclei of lithium with protons and, in 1932, brought about the first nuclear transformation by artificial means:  ${}^7_3\text{Li} + {}^1_1\text{H} \rightarrow {}^4_2\text{He} + {}^3_2\text{He} + 17.2 \text{ MeV}$ .

For this work Cockcroft and Walton received the 1951 Nobel Prize for physics. During World War II Cockcroft played a leading part in the development of radar. In 1940 he visited America as a member of the Tizard mission to negotiate exchanges of military, scientific, and technological information. In 1944 he became director of the Anglo-Canadian Atomic Energy Commission. He returned to Britain in 1946 to direct the new Atomic Energy Research Establishment at Harwell and remained there until 1959, when he was appointed master of Churchill College, Cambridge, a new college devoted especially to science and technology. Cockcroft received a knighthood in 1948.

### **Cocker, Edward (1631–1675) *English engraver and mathematician***

Cocker was famous for writing and engraving a very influential and popular textbook, the *Arithmetic* (1678). He was also a teacher of arithmetic and writing. Cocker produced notable textbooks on other subjects, including several writing manuals and an English dictionary but none of these rivaled in popularity his book on arithmetic, which went through over 100 editions. Cocker is mentioned by Samuel Pepys who thought his skill as an engraver sufficient to comment favorably on it in his *Diary*.

**Cockerell, Sir Christopher Sydney** (1910–1999) *British engineer and inventor*

Cockerell was born in Cambridge and educated at Cambridge University, graduating in engineering in 1931. Initially he joined a small engineering firm, then returned to Cambridge to study electronics, and in 1935 he joined the Marconi Company as an electronics engineer. Here he worked on the development of airborne navigational equipment and on radar.

In 1950 he left Marconi to set up his own boat-hire business on the Norfolk broads. As an amateur yachtsman, Cockerell was interested in the effect of water drag on the hull of a boat and had the idea of raising the boat above the water on a cushion of air. In 1954 he performed a crucial experiment using kitchen scales, tin cans, and a vacuum cleaner to show that a properly directed stream of air could produce the required lift. The next year he built a working model out of balsa wood, powered by a model-aircraft engine.

He was granted a patent on his idea in 1955 and in 1957 the Ministry of Supply commissioned a full-size craft from the company Saunders Roe. The first prototype, SR-N1, weighed 7 tons and was capable of 60 knots. It crossed the English Channel in 1959 (with Cockerell aboard). Hovercraft entered regular cross-channel service in 1968.

Cockerell was a consultant to Hovercraft Development Ltd. until 1979. He was also interested in the development of wave-power generators.

**Cohen, Paul Joseph** (1934–2007) *American mathematician*

Cohen, who was born at Long Branch, New Jersey, was educated at Brooklyn College and at the University of Chicago, where he obtained his PhD in 1958. He spent a year at the Massachusetts Institute of Technology and two years at the Institute for Advanced Studies, Princeton, before moving to Stanford. He was appointed professor of mathematics at Stanford from 1959 to 2004, when he became an emeritus professor.

Mathematicians had been introduced to transfinite arithmetic by Georg CANTOR from the 1870s onwards. Cantor had identified two distinct infinite sets, namely the set of natural numbers and the set of real numbers, represented by  $\aleph_0$  and  $c$  respectively. He had also proved that there were an infinite number of infinite numbers, that following  $\aleph_0$ , there came  $\aleph_1$ ,  $\aleph_2$ ,  $\aleph_3$ , ... indefinitely. Where did  $c$  fit into this sequence? Cantor answered by proposing that  $c = \aleph_1$ , a supposition since known as the "continuum hypothesis." It was the first member on David HILBERT's 1900 list of outstanding unsolved mathematical problems.

Little progress was made upon the problem before 1938 when Kurt GÖDEL demonstrated

that set theory remains consistent if the continuum hypothesis is added as an axiom. This did not, however, constitute a proof of the hypothesis, for set theory's own absolute consistency has never been proved. Nonetheless, Gödel's work did show that the continuum hypothesis could not be shown to be false within set theory.

In 1963 Cohen proposed to develop a non-Cantorian set theory that contained not the continuum hypothesis but its negation. He showed that no contradiction ensued and it seemed to follow that the continuum hypothesis was quite independent of set theory and that it could be neither proved nor disproved within any standard system of set theory.

**Cohen, Seymour Stanley** (1917– ) *American biochemist*

Cohen was educated in his native New York, at the City College and at Columbia, where he obtained his PhD in 1941. He joined the University of Pennsylvania in 1943, serving as professor of biochemistry from 1954 until 1971, when he moved to the University of Denver, Colorado, as professor of microbiology. Cohen returned to New York in 1976 to take the chair of pharmaceutical sciences at the State University, Stony Brook, becoming emeritus professor in 1985.

In 1946 Cohen began a series of studies in molecular biology using the technique of radioactive labeling. The common microorganism *Escherichia coli* could be infected in the laboratory with the bacteriophage known as T2. Within a matter of minutes the bacterial cell would burst releasing several hundred replicas of the invading T2. The problem was to understand the process. It was known that phages were nucleoproteins consisting of a protein coat surrounding a mass of nucleic acid (DNA in the case of T2). But, as Cohen realized, nucleic acid differed from protein in containing measurable amounts of phosphorus. This could in theory be traced through any biochemical reaction by labeling it with the radioactive isotope phosphorus-32.

Cohen used this technique in a number of experiments in the late 1940s that suggested rather than demonstrated the vital role of DNA in heredity. It was not until 1952, when Alfred HERSHEY and Martha Chase used Cohen's labeling technique, that more substantial results were available.

**Cohen, Stanley** (1922– ) *American biochemist*

A native New Yorker, Cohen was educated at Brooklyn and Oberlin colleges and at the University of Michigan, where he was appointed teaching fellow in the department of biochemistry in 1946. He moved to the University of

Colorado School of Medicine in 1948, and in 1952 he took up the post of American Cancer Society postdoctoral fellow at Washington University, St. Louis. His long association with the Vanderbilt University School of Medicine, Nashville, began in 1959, with his appointment as assistant professor of biochemistry. He subsequently became associate professor (1962), professor (1967), and distinguished professor (1986).

Cohen's appointment to Washington University in 1952 marked the start of a fruitful collaboration with the Italian cell biologist, Rita LEVI-MONTALCINI, who had discovered a chemical produced by a culture of mouse tumor cells that influenced the number of nerve cells growing in chick embryos. Cohen set about trying to characterize this growth factor (later termed "nerve growth factor"), and found the same chemical in snake venom and in the salivary glands of adult male mice.

His findings led Cohen to investigate another growth factor that influences the embryological development of such tissues as those of eyes and teeth, which are derived from epidermis. He was able to identify a receptor on the cell membrane that was responsive to this epidermal growth factor. This was of great significance, suggesting a mechanism by which cells are able to interact with chemical messengers such as hormones, which control their growth or normal functions. Such cell-surface receptors are also a crucial element in the abnormal uncontrolled growth of cells in cancer.

For his work on growth factors and membrane receptors, Cohen was awarded the 1986 Nobel Prize for physiology or medicine, jointly with Levi-Montalcini.

### **Cohen-Tannoudji, Claude** (1933– ) *Algerian-born French physicist*

Cohen-Tannoudji was educated at the Ecole Normale Supérieure. In 1973 he was appointed professor of atomic and molecular physics at the Collège de France, Paris.

Cohen-Tannoudji, following on from the work of William PHILLIPS and Steven CHU, sought to understand and improve the process of optical cooling of single atoms. He proposed that laser traps operate by a process of what has since been called Sisyphus cooling. The laser beams, he argued, produce a series of standing waves of light polarized in different directions. As the atoms pass through the various fields their energy levels and thereby temperature are lowered.

Early efforts at cooling had found that laser traps unfortunately also tend to agitate atoms causing them to move out of the beam. One solution proposed by Cohen-Tannoudji allowed helium atoms to be cooled to 0.18 microkelvins. The method exploited the fact that atoms could occupy a particular combination of two distinct

quantum states with different velocities, in which they remain invisible to any additional photons. Thus, once in this state, their energy cannot be increased by any further photon collisions.

For his work in this field Cohen-Tannoudji shared the 1997 Nobel Prize for physics with Chu and Phillips.

### **Cohn, Ferdinand Julius** (1828–1898) *German botanist and bacteriologist*

Its perusal makes one feel like passing from ancient history to modern times.

—On Cohn's 1872 treatise *Untersuchungen über Bacterien* (Researches on Bacteria).

William Bulloch, *The History of Bacteriology* (1938)

Cohn (kohn), who was born in Breslau (now Wrocław in Poland), was an extremely intelligent child and progressed through school rapidly, being admitted to the philosophy department at Breslau University at the early age of 14. He later developed an interest in botany but was prevented from graduating at Breslau by the university's anti-Semitic regulations. He therefore moved to Berlin, where he received his doctorate in botany in 1847.

Cohn returned to Breslau, becoming professor of botany there in 1872. He had long argued that the state should be responsible for the establishment of botanical research institutes, and as a result of his campaign the world's first institute for plant physiology was set up in Breslau in 1866. Cohn was director of this institute until his death and in 1870 he founded the journal *Beiträge zur Biologie der Pflanzen* (Contributions to Plant Biology), mainly for the purpose of publishing work carried out at Breslau.

Cohn's early research concentrated on the morphology and life histories of the microscopic algae and fungi, which led to his demonstration that the protoplasm of plant and animal cells is essentially similar. Later, stimulated by the work of Louis PASTEUR, he became increasingly interested in bacteria. His classic treatise *Untersuchungen über Bacterien* (Researches on Bacteria), published in his journal in 1872, laid the foundations of modern bacteriology. In it he defined bacteria, used the constancy of their external form to divide them into four groups, and described six genera under these groups. This widely accepted classification was the first systematic attempt to classify bacteria and its fundamental divisions are still used in today's nomenclature.

Although Cohn did not believe in the theory of spontaneous generation he was aware that bacteria could develop in boiled infusions kept in sealed containers. He postulated the existence of a resistant developmental stage and through careful observation was able to demon-

strate the formation of heat-resistant spores by *Bacillus subtilis*.

Through his book *Die Pflanze* (1872; *The Plant*) and the printing of many of his popular lectures, Cohn presented the study of biology to a wide and appreciative public. He was also responsible for the publication of Robert KOCH's important work on the life cycle of the anthrax bacillus.

**Cohnheim, Julius** (1839–1884) *German pathologist*

Born in Demmin in Germany, Cohnheim (**kohn**-hIm) graduated from the University of Berlin in 1861, remaining there as assistant to the pathologist Rudolf VIRCHOW. He later held chairs of pathological anatomy at Kiel, Breslau, and, from 1878, at Leipzig, until his death from gout complications.

Cohnheim threw considerable light on the process of inflammation. He inflicted relatively minor wounds on the tongue and intestines of frogs and observed the consequences. He noted that at the site of injury large numbers of white blood cells (leukocytes) pass through the walls of the veins to produce the swelling characteristic of inflammation. This disproved Virchow's theory that pus corpuscles originate at the point of wounding and showed them instead to be disintegrated leukocytes.

Cohnheim also did important work on tuberculosis, confirming Jean VILLEMINS theory that the disease is contagious by injecting tuberculous material into the chamber of a rabbit's eye and watching its development through the transparent cornea.

Cohnheim's technique of freezing material before sectioning is now a standard laboratory practice.

**Colombo, Matteo Realdo** (c. 1516–1559) *Italian anatomist*

Born in Cremona, Italy, Colombo (**ko-lohm**-boh) became a pupil of the famous anatomist Andreas VESALIUS and succeeded his teacher to the chair of anatomy at Padua University. His book, *De re anatomica* (*On Anatomy*), published after his death in 1559, contained descriptions of the pleura, peritoneum, and other organs that were more accurate than preceding ones. However, his most important contribution to medicine was to demonstrate that blood from the lungs returns to the heart via the pulmonary vein.

**Compton, Arthur Holly** (1892–1962) *American physicist*

Compton came from a distinguished intellectual family in Wooster, Ohio. His father, Elias, was a professor of philosophy at Wooster College while his brother, Karl, also a physicist, became president of the Massachusetts Institute

of Technology. He was educated at Wooster College and at Princeton, where he obtained his PhD in 1916. He began his career by teaching at the University of Minnesota and, after two years with the Westinghouse Corporation in Pittsburgh, he returned to academic life when in 1920 he was appointed professor of physics at Washington University, St. Louis, Missouri. The main part of his career however was spent at the University of Chicago where he served as professor of physics from 1923 to 1945. Compton then returned to the University of Washington first as chancellor and then (1953–61) as professor of natural philosophy.

Compton is best remembered for the discovery and explanation in 1923 of the effect named for him for which, in 1927, he shared the Nobel Prize for physics with Charles T. R. WILSON. He was investigating the scattering of x-rays by light elements such as carbon, and found that some of the scattered radiation had an increased wavelength, an increase that varied with the angle of scattering. According to classical physics there should be no such change, for it is difficult to see how the scattering of a wave can increase its wavelength, and Compton was led to seek its explanation elsewhere.

He thus assumed that the x-rays also exhibited particle-like behavior. Hence they could collide with an electron, being scattered and losing some of their energy in the process. This would lead to a lowering of the frequency with a corresponding increase in the wavelength. Compton went on to work out the formula that would predict the change of wavelength produced in the secondary x-rays and found that his precise predictions were fully confirmed by measurements made of cloud-chamber tracks by Wilson. Significantly, this was to provide the first hard experimental evidence for the dual nature of electromagnetic radiation; that is, that it could behave both as a wave and a particle. This would be developed much further in the 1920s as one of the cornerstones of the new quantum physics.

In the 1930s Compton concentrated on a major investigation into the nature of cosmic rays. The crucial issue, following the work of Robert MILLIKAN, was whether or not a variation in the distribution of cosmic rays with latitude could be detected. Such an effect would show that the rays were charged particles, deflected by the Earth's magnetic field, and not electromagnetic radiation. As a result of much travel and the organization of a considerable amount of the research and measurements of others Compton was by 1938 able to establish conclusively that there was a clearly marked latitude effect.

During the war Compton was an important figure in the manufacture of the atomic bomb as a member of the committee directing research on the Manhattan project. He also set up at Chicago the Metallurgical Laboratory, which

acted as a cover for the construction of the first atomic pile under the direction of Enrico FERMI and took responsibility for the production of plutonium. Compton later wrote a full account of this work in his book *Atomic Quest* (1956).

**Comte, Auguste Isidore** (1798–1857)  
*French positivist philosopher*

To understand a science it is necessary to know its history.

—*Cours de philosophie positive* (1830–1842; Treatise on Positive Philosophy)

The son of a government official from Montpellier in southern France, Comte (kont) started his education at the Ecole Polytechnique, Paris; after only two years he was expelled in 1816 for challenging the authorities. Soon after, he met Henri Saint-Simon (1760–1825), a political sociologist, and became his secretary. However, always unstable, Comte soon quarreled with his mentor and resigned in 1824. There then followed a bout of insanity, a suicide attempt by throwing himself into the Seine, and his marriage to a former prostitute, Caroline Massin.

By this time Comte had started lecturing on his “positive philosophy” and he earned some money from tutoring and examining. Later in his career the English philosopher John Stuart Mill ensured that sufficient private funds were available to meet Comte’s needs.

Between 1830 and 1842 Comte published six volumes of his *Cours de philosophie positive* (Treatise on Positive Philosophy), covering the application of positivism to mathematics, astronomy, physics, chemistry, history, and social studies. All subjects, he noted, pass through three stages. In the first theological stage, phenomena are explained by reference to divine beings. The second, metaphysical stage substitutes abstract forces for gods. Finally, in the positive stage, the inadequacy of all underlying causes comes to be recognized, and positivists seek only for relations of constant conjunction between phenomena.

In later life Comte sought to go much further and establish what some saw as “Catholicism without Christianity.” He proposed to introduce a Positivist Calendar in which new patron saints such as NEWTON and GALILEO would replace Christian figures. There would be a catechism and a chief priest.

Despite such excesses Comte’s work proved to be enormously influential. The rejection of metaphysics and the emphasis on expressing laws of nature in terms of experience found later echoes in the work of Ernst MACH and the early work of EINSTEIN. Comte is also remembered for his presumption in claiming that there are some things, such as the chemistry of the stars, which will always lie outside our experience. Shortly afterwards, in 1859, Gustav Kirchoff demonstrated that the chemical com-

position of stars could be inferred from their spectral lines.

**Conant, James Bryant** (1893–1978)  
*American chemist*

Science owes more to the steam engine than the steam engine owes to science.

—*Science and Common Sense* (1961)

Conant, who was born in Dorchester, Massachusetts, studied at Harvard, gaining his PhD in 1916; he was subsequently professor of chemistry there (1919–33), and then president (1933–53). Conant had a multifaceted career as a research chemist, administrator, diplomat, and educationalist. In the research phase he worked on organic reaction mechanisms and he also showed that oxyhemoglobin contains ferrous iron (1923). During World War II he was head of the National Defense Research Committee and deputy head of the Office of Scientific Research and Development; he played an important role in the development of the atomic bomb. On retiring from Harvard he became commissioner and then ambassador to Germany (1953–57) and wrote many controversial books on education.

**Connes, Alain** (1947– ) *French mathematician*

Connes was born in Draguignan, France, and educated at the Ecole Normale Supérieure between 1966 and 1970. He was a research fellow at the Centre National de la Recherche Scientifique (CNRS) between 1970 and 1974, followed by a year as a visiting research fellow at Queen’s University, Kingston, Canada. He was an associated professor, and subsequently professor at the University of Paris VI between 1976 and 1980 and became the director of research at CNRS in 1981. Since 1979 he has been long-term professor and Léon Motchane professor at the Institut des Hautes Etudes Scientifiques (IHES). Since 1984 he has also been a professor at the Collège de France. In 1982 Connes was awarded the Fields Medal for his work on the abstract algebras associated with sets of operators.

Connes is best known for developing the branch of mathematics known as noncommutative geometry, i.e., geometry in which the fundamental entities are noncommuting objects such as matrices, and applying it to theoretical physics. He summarized the early part of his work on this topic in a lengthy book entitled *Noncommutative Geometry*, the English translation of which was published in 1994. This book included his work of the early 1990s in which he expressed the Standard Model of elementary particle theory in terms of noncommutative geometry. He later extended this work to include gravity. Subsequently he has applied noncommutative geometry to superstring

theory and the process of renormalization in quantum field theory.

**Conon of Samos** (about 245 BC) *Greek mathematician and astronomer*

He discerned all the lights of the vast universe, and disclosed the risings and settings of the stars, how the fiery brightness of the sun is darkened, and how the stars retreat at fixed times.

—Catullus (1st century BC)

Conon (**koh**-non) settled in Alexandria and was employed as court astronomer to the Egyptian monarch Ptolemy III. None of Conon’s own writings survive and what is known of his work is through secondhand references to him by other Greek mathematicians. For example, Conon’s work on conics was made use of by APOLLONIUS of Perga in his famous treatise on conics.

Among Conon’s activities as an astronomer was the compilation of tables of the times of the rising and setting of the stars, known as the *parapegma*. He was also responsible for naming a constellation of stars. The consort of Ptolemy III, Berenice II, presented her hair as an offering at the temple of Aphrodite. This disappeared and Conon claimed that the hair now hung as a new constellation of stars, which he named Coma Berenices (“Berenice’s Hair”).

Conon was known to have been a friend of ARCHIMEDES and it is probable that the “Spiral of Archimedes,” a mathematical curve, was in fact Conon’s discovery.

**Conway, John Horton** (1937– ) *British mathematician*

Born in the city of Liverpool in the northwest of England, Conway was educated at Cambridge where he obtained his PhD in 1964. He was appointed professor of mathematics at Cambridge in 1983. In 1988 he moved to America to become John von Neumann Professor of Mathematics at Princeton.

Conway’s name became familiar to a large number of nonmathematicians through his invention of the “game of life” in 1970. The game is played on an infinite two-dimensional cellu-

lar array. Each cell has eight immediate neighbors, and can be in one of two states: on or off, occupied or empty, alive or dead. Two simple rules govern the outcome of any initial state:

1. A live cell will remain alive in the next generation if it has either two or three live neighbors.
2. An empty or dead cell will be occupied or come to life in the next generation if it has exactly three live neighbors.

In all other situations living cells die and dead cells remain dead. The game starts with an initial pattern of live cells and proceeds by a series of discrete changes – at each change all the cells change simultaneously to give a new pattern in the next generation.

Is there a general way, Conway asked, to determine the fate of any pattern? He also offered a \$50 prize to anyone who could produce a pattern that grew indefinitely, or demonstrated that no such pattern could exist. The problem so intrigued computer operators that the search for interesting *Life* forms is thought to have cost millions of dollars in unauthorized computer time. The prize was awarded to a group at the Massachusetts Institute of Technology which discovered a pattern known as a “glider,” which every thirty generations produced another glider. Conway used gliders to demonstrate in 1982 that there are patterns that behave like self-replicating animals. The snag is that spontaneous creations of such patterns would require a computer screen larger than the solar system.

Conway has also made major contributions to group theory and knot theory. Is it possible to classify all finite simple groups? These are groups which, in the manner of prime numbers, cannot be decomposed into smaller groups. While many groups fitted into clearly defined classes, several others, known as “sporadic groups,” fitted into no recognized class. Five such groups were identified by Mathieu in the 1860s. A sixth was discovered in 1965 and Conway identified a further three in 1968. By 1975 twenty-six sporadic groups were known. This completed the classification theorem, also known as the “Enormous Theorem,” which clas-

GAME OF LIFE Successive generations of a simple starting pattern.

sifies all finite simple groups and has been estimated to be 15,000 pages long.

One aim of knot theorists is to distinguish between different types of knots. This can be done by calculating the crossing number, that is, the number of points the string crosses itself. Unfortunately, many different knots can have the same crossing number, and the number itself may be difficult to calculate. In 1960 Conway introduced a new and simpler way to find crossing numbers. It allowed him to establish, for example, that there are at least 801 distinct knots with a crossing number no higher than 11.

Conway is also the author, along with E. Burkelpamp and R. Guy, of a book on mathematics and games – *Winning Ways* (1982).

**Conybeare, William Daniel (1787–1857)**  
*British geologist*

Conybeare, the son of a clergyman from St. Botolph, England, was educated at Oxford University. He entered the Church himself and was vicar of Axminster, Devon, before being made dean of Llandaff in Wales in 1844.

He became interested in geology and was an early member of the Geological Society, founded in 1807. His most significant work was *Outlines of the Geology of England and Wales*, which was published in collaboration with William PHILLIPS in 1822. In this influential work fossils were used to date sedimentary strata and the stratigraphy of British rocks was outlined beginning with the 350-million-year-old Carboniferous, which they named from its abundant carbon deposits.

Conybeare also wrote on the geology of the coalfields of the Bristol area with William Buckland and was one of the first to use geological cross-sections. He participated in the dramatic discoveries of the remains of giant reptiles and was instrumental in the naming of Gideon MANTELL's iguanodon from the Tilgate Forest in Sussex and of Buckland's *Megalosaurus*. In 1824 he succeeded in reconstructing the plesiosaur from its remains, claiming it as a link between the ichthyosaur and the crocodiles.

In theory, he largely followed his friend Buckland in attempting to explain the structure of the Earth and the disappearance of species in terms of a series of catastrophes. He thus argued strongly against Charles LYELL.

**Cook, James (1728–1778)** *British navigator and explorer*

The great quantity of new plants etc. Mr Banks and Dr Solander collected in this place occasioned my giving it the name of *Botany Bay*. It is situated in the latitude of 34°0'S, longitude 208°37'W; it is capacious safe and commodious, it may be known by the land on the sea-coast which is of a pretty even and moderate height....

—*The Journals of Captain James Cook* (1770)

Cook, the son of a Scottish farm laborer, was born at Marston in England. He was educated at the local village school and joined the Royal Navy as an able seaman in 1755. He became a ship's master in 1759, spending eight years on survey work before being appointed by the Royal Society to take command of the *Endeavour* in 1768 on its voyage to the islands of Tahiti. He made two further major voyages of discovery in 1772–75 and in 1776.

In many ways Cook's journeys were the first modern voyages. His voyage in 1768 was to be the first of the great scientific expeditions that were to become so common in the following century. One of his main duties was to carry Royal Society observers to Tahiti to watch the transit of Venus across the Sun; such transits of planets were valuable for determining the distance between the Earth and the Sun. The scientists on board included the distinguished naturalists Joseph Banks and his assistant, Daniel Solander, and the expedition also carried artists to maintain a visual record.

The voyage's second main objective was to discover the southern continent, Terra Australis, which was believed to exist. It was assumed that the northern land mass of Eurasia must be symmetrically balanced by a southern land mass. Cook found New Zealand and extensively charted this over a period of six months and then, continuing his voyage, sighted the southeast coast of Australia on 19 April 1770. He continued up the east coast of Australia successfully navigating the treacherous Great Barrier Reef. The *Endeavour* returned to England with a vast collection of scientific observations. Cook also won fame for preventing any of his crew members from dying of scurvy by insisting on a diet that included forms of fresh fruit and vegetables.

Cook led a second expedition (1772–75) to the South Seas in the *Resolution* and the *Adventure* in which he circumnavigated the high latitudes and traveled as far south as latitude 72°. He discovered new lands, including New Caledonia and the South Sandwich Islands, but found no trace of the "great southern continent." It was also on the second voyage that the chronometer was used as a standard issue after its successful testing. Before 1772 navigators determined their longitude either by guesswork or by some very complicated calculations based on the Moon. Now, merely by noting the time and making comparatively simple calculations, it was possible to determine positions east or west of Greenwich. On his return he was made a fellow of the Royal Society and, for his paper on scurvy and its prevention, was awarded the Copley Medal.

Cook's third voyage (1776), again in the *Resolution*, ended in disaster. In trying to recover one of the ship's boats, which had been stolen by Polynesian islanders, Cook was attacked and

killed by the natives on the beach of Kealakekua Bay.

**Cooke, Sir William Fothergill** (1806–1879) *British physicist*

William Cooke was the son of a London surgeon. After a period spent at Durham and Edinburgh Universities he joined the Indian Army and, on his return, started to study medicine at Heidelberg, but his interest was caught by the practical potential of the electric telegraph.

Returning to England in 1837, he entered into partnership with Charles WHEATSTONE and, together, they patented many telegraphic alarm systems for use on the railroads. Cooke received his knighthood in 1869.

**Cooper, Leon Neil** (1930– ) *American physicist*

Cooper, who was born in New York City, was educated at Columbia where he obtained his PhD in 1954. After brief spells at the Institute for Advanced Study, Princeton, the University of Illinois, and Ohio State University, he moved in 1958 to Brown University, Providence, and was later (1962) appointed to a professorship of physics.

Cooper's early work was in nuclear physics. In 1955 he began work with John BARDEEN and John Robert SCHRIEFFER on the theory of superconductivity. In 1956 he showed theoretically that at low temperatures electrons in a conductor could act in bound pairs (now called *Cooper pairs*). Bardeen, Cooper, and Schrieffer showed that such pairs act together with the result that there is no electrical resistance to flow of electrons through the solid. The resulting BCS theory stimulated further theoretical and experimental work on superconductivity and won its three authors the 1972 Nobel Prize for physics.

Cooper has also worked on the superfluid state at low temperatures and, in a different field, on the theory of the central nervous system.

**Cope, Edward Drinker** (1840–1897) *American vertebrate paleontologist and comparative anatomist*

Educated in his home town of Philadelphia, Cope displayed an interest in natural history from earliest youth. From 1864 to 1867 he was professor of comparative zoology and botany at Haverford College, Pennsylvania. In 1872 Cope joined the U.S. Geological Survey, and was subsequently professor of geology and mineralogy (1889–95) and of zoology and comparative anatomy (1895–97) at the University of Pennsylvania.

Cope's early studies were mainly concerned with living fishes, reptiles, and amphibians, and in 1861 he went to Washington to study the

Smithsonian Institution's herpetological collections. Having resigned from his Haverford College professorship in order to be free to study and collect North American animals, Cope's interests gradually began to turn to fossils, and it was during his long association with the U.S. Geological Survey that he made the valuable contributions to paleontological knowledge associated with his name. During explorations of western America, from Texas to Wyoming, Cope discovered a great many new species of extinct (Tertiary) vertebrates (fishes, reptiles, mammals, etc.). Like his rival Othniel MARSH he is credited with the discovery of about 1,000 species of fossils new to science. With Joseph Leidy he described those fossils collected by the Ferdinand Hayden Survey in Wyoming. He also traced the evolutionary history of the horse and other mammals, proposed a theory for the origin and evolution of mammalian teeth (since somewhat modified), and made important contributions to knowledge of the stratigraphy of North America, indicating parallels with European strata.

Cope was a leading paleontological protagonist for the revival of Jean Baptiste LAMARCK's theory of the inheritance of acquired characters, based on his own experience and theory of kintogenesis, which suggested that the limbs and other moving parts of an animal were altered and modified according to their use or disuse. Cope's Lamarckian views were elaborated in *The Origin of the Fittest* (1886) and *Primary Factors in Organic Evolution* (1896).

In 1878 Cope became editor of the *American Naturalist* but soon resigned owing to differences with Marsh, head of the U.S. Geological Survey.

**Copernicus, Nicolaus** (1473–1543) *Polish astronomer*

Mathematics is written for mathematicians.

—*De Revolutionibus orbium coelestium* (1543; On the Revolution of the Celestial Spheres)

Following the death of his father, a merchant of Torun, Poland, in 1484, Copernicus (koh-**per**-nikus) was brought up by his maternal uncle Lucas, the bishop of Ermeland. In 1491 he entered the University of Cracow where he became interested in astronomy. He went to Italy in 1496, studying law and medicine at the universities of Bologna and Padua and finally taking a doctorate in canon law at the University of Ferrara in 1503. By this time he had become, through a literal case of nepotism, a canon of Frauenburg, a post he was to hold until his death. In 1506 Copernicus returned home to serve his uncle as his doctor and secretary at Heinsberg castle. When his uncle died in 1512 Copernicus moved to Frauenburg to take up his modest duties as a canon.

Copernicus's pursuit of his interest in astronomy both brought him a distinguished rep-

utation and led to a dissatisfaction with the prevailing system of astronomy. However his first statement of his revolutionary views, the *Commentariolus* (Commentary), written between about 1510 and 1514, was circulated privately in manuscript form. The system Copernicus was rebelling against goes back to the Greece of PLATO and received its fullest development in the *Almagest* of PTOLEMY in the second century AD. It assumed that the Earth, unmoving, was at the center of the universe around which not only the Moon but the Sun and the other known planets revolved with perfect uniform circular motion. However, in order to fit the complicated movements of the planets into such a simple scheme, all kinds of compromises had to be made and complications brought in. Hence the introduction of such concepts as epicycles, eccentrics, and equants into the basically simple system. The second weakness was its failure to predict at all accurately the movement of the planets. Thus a conjunction of the major planets in 1503 predicted by the almanacs of the day was as much as ten days off. Copernicus, unlike Tycho BRAHE, seemed unworried about the second point and, in all his writings, emphasized the urgency of a return to uniform circular motion. How, he asked himself in the *Commentariolus*, could this be achieved? It is at this point that he came up with his revolutionary hypothesis, "All the spheres revolve about the Sun as their midpoint and therefore the Sun is the center of the universe."

Copernicus then worked his system out in detail. His great work *De revolutionibus orbium coelestium* (On the Revolution of the Celestial Spheres) although finished by the early 1530s was to be published only in the month of his death in 1543. Why Copernicus withheld his masterpiece from the world is a matter for speculation. News of his system seems to have spread quite widely. The popes Leo X and Clement VII refer to it without any obvious hostility although Luther makes an abusive reference to it. The publication of *De revolutionibus* was due to a young professor of mathematics from Wittenberg, RHETICUS. Having heard of Copernicus's system and wishing to study it at first hand he turned up in Frauenburg bearing the typical gifts of the humanist scholar, the first printed editions of EUCLID and Ptolemy. But Copernicus was still reluctant to publish and would only agree to Rheticus writing a description of the new system, which appeared as *Narratio prima* (1539; First Narrative). Copernicus finally agreed, under strong pressure from Rheticus and his friends, to Rheticus's copying and publishing his manuscript. Rheticus went to Nuremberg intending to see the work through the press, but before its completion he had to leave to take up a new appointment at Leipzig. The task of seeing the work through the press was left with Andreas

Osiander, a Nuremberg theologian who added to the work a famous and unauthorized preface asserting that the heliocentric hypothesis was not intended to be a true description of the universe but was merely a useful supposition. He was presumably trying to avoid any church opposition. It was finally published in March 1543. It is recorded by a friend of Copernicus's that "he only saw his completed book at the last moment, on the day of his death." The book did meet opposition from theologians who found that it conflicted with the Bible. The Aristotelians were opposed to it and to many it seemed simply absurd that the Earth could be flying through space. Even professional astronomers like Tycho found it unacceptable. A moving Earth ought to imply apparent movement in the fixed stars, but none could be observed. Acceptance of Copernicus's explanation – that the stars were too far away for parallax to be observed – would involve a radical change in the accepted size of the universe. Moreover, although the heliocentric theory explained the movements of the Moon and the planets in a much more elegant way than the Ptolemaic system, Copernicus's insistence on perfect circular orbits involved nearly as much complexity as was found in Ptolemy.

However, there was no real official opposition to *De revolutionibus* and the system outlined in it until it was placed on the index of those books banned by the Catholic Church in 1616 (from which it was not removed until 1835). But it did find acceptance with many mathematicians and astronomers, so that by the end of the century the issue had switched from whether to accept Ptolemy or Copernicus, to how one should accept Copernicus – as a true description or a useful mathematical trick.

**COPERNICAN SYSTEM** The epicyclic motion of a planet. The center C is the Earth; S is the position of the Sun.

**Corey, Elias James** (1928– ) *American chemist*

Born in Methuen, Massachusetts, Corey was educated at the Massachusetts Institute of Technology, where he originally intended to train as an electrical engineer. He switched to chemistry after attending a lecture course on organic chemistry. He obtained his doctorate in 1950 and, after a period at the University of Illinois, moved to Harvard in 1959 as professor of chemistry.

Corey is a synthetic chemist with over a hundred first syntheses to his credit. These include a number of substances used medicinally, such as ginkgolide B (a compound extracted from the ginkgo tree and used to treat asthma) and the synthetic prostaglandins (hormonelike compounds used to induce labor and to treat infertility).

Yet Corey has done much more than synthesize any number of complex molecules. He has also worked out and described in detail a new and fruitful systematic approach to synthetic chemistry. The difficulty facing the chemist presented with the problem of making a known complex compound is to determine which of several possible routes are worth pursuing.

Corey proposed a systematic scheme known as “retrosynthetic analysis.” In this the targeted compound is broken in stages into smaller and smaller subunits, at the same time ensuring that all the steps could be reversed at each stage. The starting point is a catalog of the main features of the compound in terms of chains, rings, branches, etc. Molecular complexity is then reduced by, for example, breaking chains and removing branches to obtain a set of rules that leads from compound to reactants and back to compound again.

Corey has given an account of his method in his book, *The Logic of Chemical Synthesis* (1989). He has also devised a computer program, LHASA (Logic and Heuristics Applied to Synthetic Analysis), to generate synthetic paths. For his work on retrosynthetic analysis Corey was awarded the 1990 Nobel Prize for chemistry.

**Cori, Carl Ferdinand** (1896–1984) *Czech-American biochemist*

Cori (**kor-ee**), who was born in the Czech capital of Prague, was educated at the gymnasium in Trieste, where his father was director of the Marine Biological Station, and at the University of Prague Medical School. He graduated in 1920, the year he married Gerty Radnitz, a fellow student who was to become his collaborator until her death in 1957. The Coris moved to America in 1922, taking up an appointment at the New York State Institute for the Study of Malignant Diseases in Buffalo. In 1931 they both transferred to the Washington University Medical School, where Cori was successively

professor of pharmacology and of biochemistry until his retirement in 1966.

The great French physiologist Claude Bernard had shown as long ago as 1850 that glucose is converted in the body into the complex carbohydrate glycogen. This is stored in the liver and muscle, ready to be converted back into glucose as the body needs a further energy supply. Just what steps are involved in this process was the fundamental problem the Coris began to tackle in the mid 1930s.

The first clue came in 1935, when they discovered an unknown compound in minced frog muscle. This was glucose-1-phosphate, in which the phosphate molecule is joined to the glucose 6-carbon ring at the standard position (1). It was next established that when this new compound, or *Cori ester* as it was soon called, was added to a frog or rabbit muscle extract, it was converted rapidly to glucose-6-phosphate by an enzyme that was named phosphoglucomutase, a process that was reversible. As only glucose itself can enter the cells of the body, glucose-6-phosphate must be converted to glucose by the enzyme phosphatase.

Although the actual pathway of glycolysis is much more detailed and took several years to elucidate, the value of the Coris' work is undeniable. Above all they pointed the way to the crucial role of phosphates in the provision of cellular energy, the details of which were soon to be worked out by Fritz LIPMANN.

For their work the Coris shared the 1947 Nobel Prize for physiology or medicine with Bernardo HOUSSAY.

**Cori, Gerty Theresa Radnitz** (1896–1957) *Czech-American biochemist*

Gerty Radnitz was born in the Czech capital of Prague and graduated from the Medical School there in 1920, the year in which she married her lifelong collaborator Carl Cori. She moved with him to America, taking a post in 1922 at the New York State Institute for the Study of Malignant Diseases in Buffalo. In 1931 she went with her husband to the Washington University Medical School, where she became professor of biochemistry in 1947.

In 1947 the Coris and Bernardo HOUSSAY shared the Nobel Prize for physiology or medicine for their discovery of how glycogen is broken down and resynthesized in the body.

**Coriolis, Gustave-Gaspard** (1792–1843) *French physicist*

Coriolis (**kor-i-oh-lis**), a Parisian by birth, studied and taught at the Ecole Polytechnique, becoming assistant professor of analysis and mechanics in 1816. He was the first to give precise definitions of work and kinetic energy in his work *Du calcul de l'effet des machines* (1829; On the Calculation of Mathematical Action)

and he particularly studied the apparent effect of a change in the coordinate system on these quantities.

From this latter research grew his most famous discovery. In 1835, while studying rotating coordinate systems, he arrived at the idea of the *Coriolis force*. This is an inertial force which acts on a rotating surface at right angles to its direction of motion causing a body to follow a curved path instead of a straight line. This force is of particular significance to astrophysics, ballistics, and to earth sciences, particularly meteorology and oceanography. It affects terrestrial air and sea currents; currents moving away from the equator will have a greater eastward velocity than the ground underneath them, and so will appear to be deflected. The idea was developed independently by William FERREL in America.

In 1838 Coriolis stopped teaching and became director of studies at the Polytechnique, but his poor health grew worse and he died five years later.

**Cormack, Allan Macleod (1924–1998)**  
*South African physicist*

Born in Johannesburg in South Africa, Cormack was educated at the University of Cape Town. He became interested in x-ray imaging at the Groote Schuur Hospital in Johannesburg, where he worked as a physicist in the radioisotopes department. In 1956 he moved to America, where he served as professor at Tufts University, Massachusetts, until his retirement in 1994.

Cormack was the first to analyze theoretically the possibilities of developing a radiological cross-section of a biological system. Independently of the British engineer Godfrey HOUNSFIELD, he developed the mathematical basis for the technique of computer-assisted x-ray tomography (CAT), describing this in two papers in 1963 and 1964, and provided the first practical demonstration. X-ray tomography is a process by which a picture of an imaginary slice through an object (or the human body) is built up from information from detectors rotating around the body. The application of this technique to medical x-ray imaging was to lead to diagnostic machines that could provide very accurate pictures of tissue distribution in the human brain and body. Hounsfield was unaware of the work of Cormack when he developed the first commercially successful CAT scanners for EMI in England.

Cormack also pointed out that the reconstruction technique might equally be applied to proton tomography, or to gamma radiation from positron annihilations within a patient, and he investigated these as possible imaging techniques.

Cormack shared the 1979 Nobel Prize for

physiology or medicine with Hounsfield for the development of CAT.

**Cornell, Eric A. (1961– )**  
*American physicist*

Cornell was born in Palo Alto, California. He was educated at Stanford University and gained his PhD in physics at MIT in 1990. He did postdoctoral research at the Joint Institute for Laboratory Astrophysics (JILA), Boulder, from 1990 to 1992. Since 1992, he has been in the physics department at the University of Colorado, Boulder, and at the National Institute of Standards and Technology (NIST), Boulder, and, since 1994, also at JILA.

In 1995 Cornell and Carl WIEMAN succeeded in obtaining a type of matter known as a Bose–Einstein condensate. Wolfgang KETTERLE also obtained a Bose–Einstein condensate in 1995, independently of Cornell and Wieman.

In 1924 Satyendra Nath BOSE discovered Bose–Einstein statistics in the course of calculations in which he put the law of black-body radiation, found by Max PLANCK in 1900, on a firm theoretical footing. He sent his work to EINSTEIN, who arranged for it to be published. Einstein subsequently extended the work of Bose. In a paper published in 1925 Einstein predicted that if a gas of a certain type of atom was cooled to a very low temperature near absolute zero then all the atoms would form a single quantum state together, with the transition to this state, now known as a Bose–Einstein condensate, being analogous to the formation of a liquid from a gas.

In 1995 Cornell and Wieman succeeded in producing a Bose–Einstein condensate in the form of 2000 atoms of rubidium at the extremely low temperature of 20 nK (nanokelvin), which is 0.000 000 02 degrees above the absolute zero temperature.

It may well turn out to be the case that the discovery of Bose–Einstein condensates will have important technological applications in areas such as precision measurement and nanotechnology. Cornell, Ketterle, and Wieman shared the 2001 Nobel Prize for physics for their work.

**Corner, Edred John Henry (1906–1996)**  
*British botanist*

Corner, a Londoner, graduated from Cambridge University in 1929. He then spent 20 years overseas, first as assistant director of the Gardens Department of the Straits Settlements (Singapore) and from 1947 to 1948 as a field officer for UNESCO in Latin America. He returned to Cambridge in 1949 and later, from 1966 until his retirement in 1973, served as professor of tropical botany.

Although Corner originally began as a mycologist (someone who studies fungi), such was

the general level of knowledge of tropical plants that he felt compelled to work in a less specialized field. He produced a large number of books on the subject, of which his *Life of Plants* (1964) and *Natural History of Palms* (1966) have become widely known.

**Cornforth, Sir John Warcup** (1917– )  
*Australian chemist*

For him [the scientist], truth is so seldom the sudden light that shows new order and beauty; more often, truth is the uncharted rock that sinks his ship in the dark.

—Nobel Prize address, 1975

Cornforth was educated at the university in his native city of Sydney and at Oxford University, where he obtained his DPhil in 1941. He spent the war in Oxford working on the structure of penicillin before joining the staff of the Medical Research Council in 1946. In 1962 Cornforth moved to the Shell research center at Sittingbourne in Kent to serve as director of the Milstead Laboratory of Chemical Enzymology. In 1975 he accepted the post of Royal Society Research Professor at Sussex University, where he served until 1982.

In 1951 the American chemist Robert WOODWARD had succeeded in synthesizing the important steroid, cholesterol; Cornforth was interested in how the molecule is actually synthesized in the cell. Using labeled isotopes of hydrogen, he traced out in considerable detail the chemical steps used to form the  $C_{27}H_{45}OH$  molecule of cholesterol from the initial  $CH_3COOH$  of acetic acid. It was for this work that he shared the 1975 Nobel Prize for chemistry with Vladimir PRELOG. He was knighted in 1977. Cornforth has also synthesized alkenes, oxazoles, and the plant hormone abscisic acid.

**Correns, Karl Erich** (1864–1933) *German botanist and geneticist*

Correns (**kor**-rens), the only child of the painter Erich Correns, was born in Munich, Germany. He studied at Tübingen University, where he began his research on the effect of foreign pollen in changing the visible characters of the endosperm (nutritive tissue surrounding the plant embryo). In some of his crossing experiments Correns used varieties of pea plants, following the ratios of certain characters in the progeny of these. After four generations he had gathered sufficient evidence to formulate the basic laws of inheritance. Not until he searched for relevant literature did he find that Gregor MENDEL had reached the same conclusion a generation earlier. Correns's own work, published in 1900, thus only provided further proof for Mendel's theories. His later research concentrated on establishing how widely Mendel's laws could be applied. Using variegated plants he obtained, in 1909, the first conclusive evi-

dence for cytoplasmic, or non-Mendelian, inheritance, in which certain features of the offspring are determined by the cytoplasm of the egg cell. Other contributions to plant genetics include his proposal that genes must be physically linked to explain why some characters are always inherited together. Correns was also the first to relate Mendelian segregation (the separation of paired genes, or alleles) to meiosis and the first to obtain evidence for differential fertilization between gametes. From 1914 until his death he was director of the Kaiser Wilhelm Institute for Biology in Berlin.

**Cort, Henry** (1740–1800) *British metallurgist and inventor*

Cort, who was born in Lancaster in northern England, worked as a navy agent in London before taking over an ironworks near Gosport (1775). He experimented with ways of improving wrought iron and in 1783 he patented a method of piling and rolling iron into bars using grooved rollers. The following year he patented his dry-puddling process for converting pig iron into wrought iron. Although his techniques of ironworking were an important contribution to the Industrial Revolution, Cort was financially ruined by the debts of a partnership and lost his patents.

**Corvisart, Jean-Nicolas** (1755–1821)  
*French physician*

I do not believe in medicine, but I do believe in Corvisart.

—Napoleon Bonaparte

Corvisart (**kor**-vee-**sar**), the son of an attorney from Dricourt in France, entered medicine against strong opposition from his family, who wished him to pursue a legal career. He nevertheless graduated in medicine in 1785 and later held posts at the Charité and the Collège de France. He was then appointed personal physician to Napoleon.

Corvisart, who emphasized the importance of thorough clinical examinations, did much to introduce the new technique of percussion, first described by Leopold AUENBRUGGER. He not only practiced it himself but also, in 1808, produced a French translation of Auenbrugger's classic work. He was less receptive, though, to the introduction by his pupil René Laennec of the stethoscope, an instrument he seems not to have used.

He also produced *Essais sur les maladies organiques du coeur et des gros vaisseaux* (1806; *Essays on the Organic Diseases of the Heart and Large Vessels*), one of the earliest works devoted to diseases of the heart.

**Coster, Dirk** (1889–1950) *Dutch physicist*

Coster (**kos**-ter), who was born in Amsterdam in the Netherlands, was educated at the Uni-

versity of Leiden where he obtained his doctorate in 1922. From 1924 to 1949 he was professor of physics at the University of Groningen. In 1923, in collaboration with Georg von HEVESY, he discovered the element hafnium. The element was named for Hafnia, an old Roman name for Copenhagen. Copenhagen was the home of Niels BOHR, who had suggested to them that the new element would most likely be found in zirconium ores.

**Cottrell, Sir Alan Howard (1919– )**  
*British physicist and metallurgist*

Cottrell, who was born in the English Midlands city of Birmingham, studied at the university there, gaining his BSc in 1939 and PhD in 1949. After leaving Birmingham in 1955, he took the post of deputy head of the metallurgy division of the Atomic Energy Research Establishment at Harwell until 1958, when he became Goldsmiths Professor of Metallurgy at the University of Cambridge. From 1965 he held a number of posts as a scientific adviser to the British government. In 1974 he became master of Jesus College, Cambridge, and subsequently vice-chancellor of the University of Cambridge (1977–79).

Cottrell's most notable research was in the study of dislocations in crystals. In experiments on the yield points of carbon steels he discovered that, because of the interactions of the carbon atoms with dislocations in the steel, a region enriched with carbon atoms develops around the dislocations (the *Cottrell atmosphere*). This leads to an increase in yield stress compared to the value in the pure material.

Cottrell's analysis of the forces between impurity atoms is basic to dislocation theories of yield point and strain aging. In 1949 Cottrell and B. A. Bilby correctly predicted the time law of strain aging from the rate of diffusion of impurity atoms to dislocations. Cottrell also worked on the effect of radiation on crystal structure – work that was important in design changes to the fuel rods in early nuclear reactors.

**Coulomb, Charles Augustin de (1736–1806)**  
*French physicist*

Coulomb's contributions to the science of friction were exceptionally great. Without exaggeration, one can say that he created this science.

—I. V. Kragelsky and V. S. Schedrov,  
*Development of the Science of Friction – Dry Friction* (1956)

Coulomb (koo-**lomb**), who was born in Angoulême, France, was educated in Paris and then joined the army, serving as an engineer. He spent nine years in Martinique designing and building fortifications, returning to France because of ill health. On his return he accepted several public offices but with the coming of

the revolution he withdrew from Paris, spending his time quietly and safely at Blois and devoting himself to science. He returned to public life under Napoleon, serving as an inspector of public instruction from 1802.

He made an early reputation for himself by publishing work on problems of statics and friction. Some of the concepts that he introduced and analyzed are still used in engineering theory, for example, the notion of a thrust line. This describes how a building must be constructed if it is to control the oblique force arising from such items as roof members. Coulomb gave a general solution to the problem.

He is however most widely remembered for his statement of the inverse square laws of electrical and magnetic attraction and repulsion published in 1785. The secret of his work was the invention of a simple but successful torsion balance, which he used with great experimental skill. It was so sensitive that a force equivalent to about 1/100,000 of a gram could be detected. The balance consisted of a silken thread carrying a carefully balanced straw covered with wax. The straw, to which a charged sphere could be fixed, was free to rotate in a large glass tube that was marked in degrees around its circumference. He could now bring another charged ball within various distances of the rotatable straw and measure the amount of twist produced. By varying the distances involved and the nature and amount of the charge, Coulomb was able to deduce a number of laws. He stated his “fundamental law of electricity” as “the repulsive forces between two small spheres charged with the same sort of electricity is in the inverse ratio of the squares of the distances between the centers of the two spheres.” That is, two like charged bodies will repel each other and the force of that repulsion will fall off with the square of the distance separating them: if a body moves twice as far away the repulsive force will be four times weaker, if the body moves three times as far away the repulsive force will be nine times weaker, and so on for any distance between them. Coulomb went on to show that the same form of law applies to magnetic as well as electrical attraction and repulsion. What is surprising about Coulomb (and his contemporaries) was an inability to see any relationship between electricity and magnetism. Despite having demonstrated that the two phenomena obey basically the same laws he insisted that they consisted of two distinct fluids.

Coulomb was immortalized by having the unit of electric charge named in his honor: the quantity of electricity carried by a current of one ampere in one second is a *coulomb*.

**Coulson, Charles Alfred (1910–1974)**  
*British theoretical chemist, physicist, and mathematician*

Coulson was born in Dudley in the English Midlands and his father was principal of a local technical college. He was educated at Cambridge University, where he obtained his PhD in 1935, and afterward taught mathematics at the universities of Dundee and Oxford. Coulson then successively held appointments as professor of theoretical physics at King's College, London (1947–52), Rouse Ball Professor of Mathematics at Oxford (1952–72), and, still at Oxford, professor of theoretical chemistry from 1972 until his death in 1974.

As a physicist Coulson wrote the widely read *Waves* (1941) and *Electricity* (1948). His most creative work however was as a theoretical chemist. In 1933 he did early work on calculating the energy levels in polyatomic molecules and in 1937 he provided a theory of partial bond order (e.g., chemical bonding intermediate between double and single bonding). He also worked on aromatic molecules (benzene, naphthalene, etc.) with Christopher LONGUET-HIGGINS. His book *Valence* (1952) covers the application of quantum mechanics to chemical bonding. Later Coulson turned to theoretical studies of carcinogens, drugs, and other topics of biological interest.

Coulson was also one of the leading Methodists of his generation and, from 1965 to 1971, chairman of Oxfam, the third-world charity. He produced a number of works on the relationship between Christianity and science of which *Science and Christian Belief* (1955) is a typical example.

### **Couper, Archibald Scott** (1831–1892) *British organic chemist*

The son of a mill owner in Kirkintilloch, Scotland, Couper was educated at Glasgow and Edinburgh universities, reading humanities, classics, and philosophy. He traveled extensively in Europe and about 1854 began to study chemistry, working with Charles WURTZ in Paris (1854–56).

In 1858 he produced an important paper, *On a New Chemical Theory*, in which he anticipated August KEKULÉ's theory of the structure of carbon compounds. The publication of Couper's paper, which he had entrusted to Wurtz, was delayed and Kekulé thus had priority. Couper returned to Edinburgh in 1858 as assistant to Lyon PLAYFAIR but suffered a nervous breakdown soon after.

Couper did no more work and he was largely forgotten until Richard Anschütz, who was Kekulé's successor at Bonn, discovered some work on salicylic acid in which Couper had used an early form of graphic formulae based on dotted lines for the valence bonds. The paper on chemical theory was also rediscovered and Couper's work achieved full recognition.

### **Cournand, André Frederic** (1895–1988) *French–American physician*

Cournand (**kuur**-nand or **koor**-nahn), the son of a Paris physician, was educated at the Sorbonne and, after serving in World War I, at the University of Paris where he finally obtained his MD in 1930. He then went to America for postgraduate work, at Bellevue Hospital, New York, and began working in collaboration with Dickinson RICHARDS. Cournand remained in America, became naturalized in 1941, and continued at Bellevue where he served as professor of medicine from 1951 until his retirement in 1964.

In 1941 Cournand, in collaboration with H. Ranges, continued the earlier work of Werner FORSSMANN and developed cardiac catheterization as a tool of physiological research. He found, contrary to expectation, that the technique did not lead to blood clotting and involved virtually no discomfort.

Cournand spent much time in attempting to determine the pressure drop across the pulmonary system. He investigated the effect of shock on cardiac function and assessed the consequences of various congenital heart defects. He also looked at the action of drugs, notably the digitalin type, on the heart.

In 1945 Cournand introduced an improved catheter with two branches through which simultaneous pressures in two adjacent heart chambers could be recorded. This led to greatly improved diagnoses of anatomical abnormalities, which consequently provided a better guide to treatment.

For his "discoveries concerning heart catheterization" Cournand shared the 1956 Nobel Prize for physiology or medicine with Forssmann and Richards.

### **Courtois, Bernard** (1777–1838) *French chemist*

Courtois (**koor**-twah) was the son of a saltpeter manufacturer from Dijon in France and as a small boy he worked in the plant showing an alert interest. He was later apprenticed to a pharmacist and subsequently studied at the Ecole Polytechnique under Antoine FOURCROY. During his military service as a pharmacist he became the first to isolate morphine in its pure form from opium.

Meanwhile his father's saltpeter business had been running into difficulties because the product could be manufactured more cheaply in India, and Courtois returned to help his father. Saltpeter was obtained from the seaweed washed ashore in Normandy; the ashes (known as "varec") were leached for sodium and potassium salts. Courtois noticed that the copper vats in which the lye was stored were becoming corroded by some unknown substance. By chance, in 1811, during the process of extracting the salts, he added excess concentrated sul-

furic acid to the lye (the solution obtained by leaching) and was astonished to see “a vapor of a superb violet color” that condensed on cold surfaces to form brilliant crystalline plates. Courtois suspected that this was a new element but lacked the confidence and the laboratory equipment to establish this and asked Charles Bernard DÉSORMES and Nicolas Clément to continue his researches. His discovery was announced in 1813, and Joseph GAY-LUSSAC and Humphry DAVY soon verified that it was an element, Gay-Lussac naming it “iodine” (from the Greek for “violet”).

**Cousteau, Jacques Yves (1910–1997)**  
*French oceanographer*

No children ever opened a Christmas present with more excitement than we did when we unpacked the first “aqualung.” If it worked, diving could be revolutionized.... With this equipment harnessed to the back, a watertight glass mask over the eyes and nose, and rubber foot fins, we intended to make unencumbered flights in the depths of the sea.

—*The Silent World* (1956)

Cousteau (koo-**stoh**), who was born at Saint André-de-Cubzac in France, studied at the Ecole Navale in Brest and on graduation entered the French navy. During World War II he served in the French resistance and was awarded the Légion d'Honneur and the Croix de Guerre. During the war he also made his first two underwater films and, despite German occupation of France, designed and tested an aqualung. For this he adapted a valve (hitherto used by Emile Gagnan to enable car engines to work with cooking gas) into an underwater breathing apparatus. Using compressed air, the *Cousteau-Gagnan aqualung* allows long periods of underwater investigation at depths of more than 200 feet (61 m) and frees the diver of the need for a heavy suit and lifeline.

In 1946 Cousteau became head of the French navy's Underwater Research Group and the following year set a world record of 300 feet (91 m) for free-diving. In 1951–52 he traveled to the Red Sea in a converted British minesweeper, the *Calypso*, and made the first underwater color film to be taken at a depth of 150 feet (46 m). Later he helped Auguste PICCARD in the development of the first bathyscaphes. Cousteau also designed and worked on a floating island off the French coast that enabled long-term study of marine life. He was the designer of an underwater diving “saucer” capable of descents to more than 600 feet (183 m) and able to stay submerged for 20 hours. More significantly, he worked on the future exploitation of the sea bed as a living environment for man, conducting various experiments on short-term undersea living.

Cousteau may be said to have made more significant contributions to undersea explo-

ration and study than any other individual. His work was brought to a wide audience by means of movies and television, and a number of his films, for example, *The Silent World* (1956), won Academy Awards. His many books, such as *The Living Sea* (1963), and his television documentaries in the series *The Undersea World of Jacques Cousteau* captured the imagination of millions.

**Crafts, James Mason (1839–1917)**  
*American chemist*

Crafts, who was born in Boston, Massachusetts, initially studied engineering and mining at Lawrence Scientific School, graduating in 1858. He then went to Europe, where he studied chemistry at Freiburg and worked with Robert BUNSEN and Charles Adolphe WURTZ before returning to America in 1866. He became professor of chemistry at Cornell (1868) and held the same post at the Massachusetts Institute of Technology (1871). He returned to Europe in 1874 for health reasons and worked with Charles FRIEDEL at the mining school in Paris. Here in 1877 they discovered the *Friedel-Crafts reaction*, a versatile synthetic method involving the alkylation or acylation of aromatic hydrocarbons with aluminum chloride as a catalyst. Crafts returned to MIT in 1891, becoming president (1898–1900) before retiring through ill health. His other work included research on silicon derivatives, catalysis, and thermometry.

**Craig, Lyman Creighton (1906–1974)**  
*American biochemist*

Born in Palmyra, Iowa, Craig was educated at Iowa State University where he obtained his PhD in 1931. After two years at Johns Hopkins University he moved to Rockefeller University, New York, in 1933 where he was appointed professor of chemistry in 1949.

Craig concentrated on devising and improving techniques for separating the constituents of mixtures. His development of a fractional extraction method named countercurrent distribution (CCD) proved to be particularly good for preparing pure forms of several antibiotics and hormones. The method also established that the molecular weight of insulin is half the weight previously suggested. Craig also used CCD to separate the two protein chains of hemoglobin.

During work on ergot alkaloids Craig, with W. A. Jacobs, isolated an unknown amino acid, which they named lysergic acid. Other workers managed to prepare the dimethyl amide of this acid and found the compound, LSD, to have considerable physiological effects.

**Cram, Donald James (1919–2001)**  
*American chemist*

Born in Chester, Vermont, Cram was educated

at the University of Nebraska and at Harvard, where he completed his PhD in 1947. He moved immediately to the University of California, Los Angeles, where he served as professor of chemistry from 1956 until 1995.

In 1963 Charles PEDERSEN announced his discovery of the first of the crown ethers. Cram, it was reported, spent the next 48 hours in his laboratory fiddling with model kits and making a variety of new structures. He soon came to see that crown ethers could be modified in such a way as to distinguish between different forms of chiral molecules, i.e., molecules and their mirror images. By 1973 he had succeeded in devising crown ethers that could identify optically active amino acids. Cram introduced the name "host-guest" chemistry to describe such reactions.

For his work in this new field Cram shared the 1987 Nobel Prize for chemistry with Pedersen and J-M. LEHN.

### Crick, Francis Harry Compton (1916–2004) *British molecular biologist*

I also suspect that many workers in this field [i.e. molecular biology] and related fields have been strongly motivated by the desire, rarely actually expressed, to refute vitalism.

—*British Medical Bulletin* (1965)

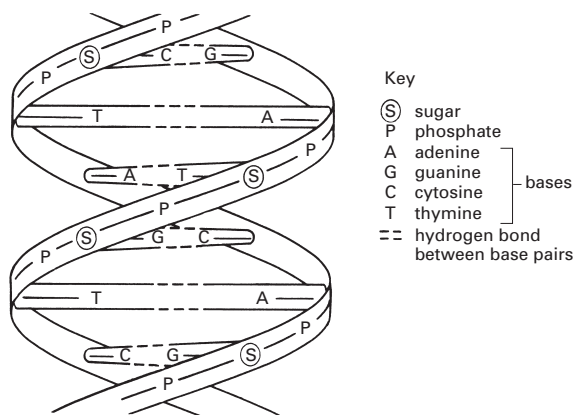

The son of a shoe manufacturer from Northampton in England, Crick was educated at University College, London. After graduating in physics in 1938 he began his research career under E. N. ANDRADE, working on the measurement of the viscosity of water. With the outbreak of war he was posted to the Admiralty to work on the design of acoustic and magnetic mines. Crick found himself at the end of the war at a loss what to do. He was drawn towards pure science and after reading SCHRÖDINGER's book *What Is Life?* (1944), Crick decided that he wanted to work on a "major mystery – the mys-

tery of life and the mystery of consciousness." With backing from the Medical Research Council (MRC) Crick began his odyssey in 1947 at the Strangeways Laboratory, Cambridge, working on tissue culture. Two years later he moved to the newly formed MRC unit at the Cavendish Laboratory, studying the structure of proteins by x-ray diffraction analysis.

In 1951 a young American student, James WATSON, arrived at the unit. Watson suggested to Crick that it was necessary to find the molecular structure of the hereditary material, DNA, before its function could be properly understood. Much was already known about the chemical and physical nature of DNA from the studies of such scientists as Phoebus LEVENE, Erwin CHARGAFF, Alexander TODD, and Linus PAULING. Using this knowledge and the x-ray diffraction data of Maurice WILKINS and Rosalind FRANKLIN, Crick and Watson had built, by 1953, a molecular model incorporating all the known features of DNA. Fundamental to the model was their conception of DNA as a double helix. Despite the significance of Crick's work on DNA he remained officially a graduate student. Consequently he returned to his work on protein structure and completed his PhD in 1953 at the age of 37.

Ten years' intensive research in many laboratories around the world all tended to confirm Crick and Watson's model. For their work, which has been called the most significant discovery of the 20th century, they were awarded, with Wilkins, the 1962 Nobel Prize for physiology or medicine.

Crick, in collaboration with Sydney BRENNER, made important contributions to the understanding of the genetic code and introduced the term "codon" to describe a set of three adjacent bases that together code for one amino acid. He also formulated the adaptor hypothesis in which he suggested that, in protein syn-

DNA The double-helix structure of DNA according to Crick and Watson.

thesis, small adaptor molecules act as intermediaries between the messenger RNA template and the amino acids. Such adaptors, or transfer RNAs, were identified independently by Robert HOLLEY and Paul BERG in 1956. Crick is also known for his formulation of the *Central Dogma* of molecular genetics, which assumes that the passage of genetic information is from DNA to RNA to protein. David BALTIMORE was later to show that in certain cases, information can actually go from RNA to DNA.

In 1977 Crick moved to the Salk Institute, San Diego, California. While at Salk he worked on the second of the great mysteries that had inspired him in 1947, namely, the nature of consciousness. At an early stage he rejected computer models of the mind and the “neural Darwinism” of G. EDELMAN. He went on to publish his mature views on the nature of mind in his *The Astonishing Hypothesis* (1994), in which he argued that “your joys and your sorrows, your memories and ambitions, your sense of personal identity and free will, are in fact no more than the behavior of a vast assembly of nerve cells and their associated miracles.” He had previously published in 1983, with Graeme Mitchinson, a novel account of dreams. “We dream in order to forget,” he claims. Dreams allow the brain to eliminate the unwanted information collected during the day which would otherwise clog up the system. Crick also published his intellectual biography, *What Mad Pursuit* (New York, 1988).

### **Croll, James** (1821–1890) *British geologist*

Croll, the son of a stonemason and crofter from Cargill in Scotland, started work as a millwright. He became caretaker at Anderson's College, Glasgow, in 1859, and was later made resident geologist in the Edinburgh office of the Geological Survey, where he remained until his retirement in 1880.

In 1864 he studied the work of A. J. ADHEMAR and began research into the idea of an astronomical causation of ice ages. He developed the theory that the answer lay in the orbital history of the Earth. Using work done by Urbain LE VERRIER in 1843, he found that the degree of eccentricity had been subjected to substantial change – 100,000 years ago it was highly eccentric while 10,000 years ago its eccentricity was quite small. He concluded that if winter occurred when the Earth was furthest away from the Sun in its precessional cycle and if the orbit of the Earth was at its most eccentric, then the two factors would produce an ice age. He followed Adhemar in seeing this as alternating between the two hemispheres and having a period of about 26,000 years.

This view was generally accepted by other geologists, notably by James Geikie in his pioneering work *The Great Ice Age* (1874–84), but

tests made on the theory were too rudimentary to be conclusive.

Croll's work was published in his *Climate and Time* (1875) and *Climate and Cosmology* (1885).

### **Cronin, James Watson** (1931– ) *American physicist*

Cronin, who was born in Chicago, Illinois, was educated at the Southern Methodist University and at Chicago, where he obtained his PhD in 1955. After a period at the Brookhaven National Laboratory he moved to Princeton in 1958 and later served as professor of physics from 1965 until 1971 when he was appointed to a comparable chair at the University of Chicago.

In 1956 Tsung Dao LEE and Chen Ning YANG made the startling claim that parity (P) was not conserved in weak interactions. To the surprise of physicists their bold conjecture was confirmed in a matter of months. It was however widely assumed that in a reaction the combination of parity and a property called charge conjugation (C) was conserved. Cronin and Val FITCH, together with James Christenson and René Turlay, tested this CP conservation in 1964 by investigating the decay of neutral kaons. It was known that one type of kaon could decay into two pions; the other could not without violating CP conservation. Cronin and his colleagues discovered a small number of decays of the second type into two pions, clearly demonstrating that CP is violated.

The result is of fundamental interest for it is known that the combined properties of charge conjugation (C), parity (P), and time (T) are conserved – so that if CP is violated then the decay of the kaons is not symmetrical with respect to time reversal.

Cronin and Fitch shared the 1980 Nobel Prize for physics for this work.

### **Cronstedt, Axel Frederic** (1722–1765) *Swedish chemist and mineralogist*

Born in Södermanland in Sweden, Cronstedt (**kroon**-stet) studied chemistry at the University of Uppsala and the School of Mines until 1748, becoming a member of the Swedish Academy of Sciences soon after; he held no academic post. Cronstedt used the blowpipe extensively for studying minerals and classified minerals according to chemical principles rather than the physical characteristics that had been used previously. This work was published (at first anonymously) in *An Essay toward a System of Mineralogy* (1758). In 1751 he discovered nickel by reducing a mineral known as devil's copper, or *kupfernicker*, and observed its magnetic properties.

**Crookes, Sir William** (1832–1919) *British chemist and physicist*

We have actually touched the border land where matter and force seem to merge into one another...I venture to think that the greatest scientific problems of the future will find their solution in this border land ... .  
—*Chemical News* No. 40 (1879)

Crookes studied at the Royal College of Chemistry in his native city of London, under August von Hofmann (1848). After working at the Radcliffe Observatory, Oxford, and the Chester College of Science, he returned to London in 1856, where, having inherited a large fortune, he edited *Chemical News* and spent his time on research.

Following the invention of the spectroscope by Robert BUNSEN and Gustav KIRCHHOFF, Crookes discovered the element thallium (1861) by means of its spectrum. In investigating the properties and molecular weight of thallium, he noticed unusual effects in the vacuum balance that he was using. This led him to investigate effects at low pressure and eventually to invent the instrument known as the *Crookes radiometer* (1875). This device is a small evacuated glass bulb containing an arrangement of four light metal vanes. Alternate sides of the vanes are polished and blackened. When radiant heat falls on the instrument, the vanes rotate. The effect depends on the low pressure of gas in the bulb; molecules leaving the dark (hotter) surfaces have greater momentum than those leaving the bright (cooler) surfaces. Although the instrument had little practical use, it was important evidence for the kinetic theory of gases.

Crookes went on to investigate electrical discharges in gases at low pressure, producing an improved vacuum tube (the *Crookes tube*). He also investigated cathode rays and radioactivity. *Crookes glass* is a type of glass invented to protect the eyes of industrial workers from intense radiation.

From about 1870, Crookes became interested in spiritualism and became one of the leading investigators of psychic phenomena.

**Cross, Charles Frederick** (1855–1935) *British industrial chemist*

Cross, who was born in Brentford, Middlesex, in England, studied chemistry at King's College, London, in Zurich, and at Owens College, Manchester. There he met Edward BEVAN, whose partner he became and with whom he developed the viscose process of rayon manufacture. Cross was subsequently involved in the industrial development of this process. He wrote several books on cellulose and papermaking.

**Crum Brown, Alexander** (1838–1922) *British organic chemist*

The son of a Presbyterian minister in the Scottish capital Edinburgh, Crum Brown studied arts and then medicine and chemistry there, gaining an MA degree in 1858 and his MD in 1861. He was also awarded a doctorate from London University (1862) and worked with Robert BUNSEN at Heidelberg and Hermann KOLBE at Marburg before returning to Edinburgh as a lecturer in 1863, becoming professor of chemistry in 1869.

Crum Brown was essentially a theoretician of organic chemistry and his structural formulae, introduced in his MD thesis *On the Theory of Chemical Combination* (1861) and taken up by Edward FRANKLAND in 1866, are essentially the symbols used today. In 1867–68, with T. R. Fraser, he carried out pioneering work in what is now called structure/activity relationships in pharmacology. In 1892 (with J. Gibson) he proposed a rule (*Crum Brown's rule*) concerning the effect of substitution of an organic group into a benzene ring that already contains a group. The rule can be used to predict the position into which the existing group will direct the second group. Other research interests were physiology (the function of the semicircular canals in the ear), phonetics, mathematics, and crystallography.

**Crutzen, Paul** (1933– ) *Dutch chemist and meteorologist*

Crutzen (**kruut**-sen) first worked in Sweden, at Stockholm University, moving in 1974 to the National Oceanic and Atmospheric Administration and the National Center for Atmospheric Research in Boulder, Colorado. In 1980 he moved to Germany, where he served as director of the Department of Atmospheric Chemistry at the Max Planck Institute for Chemistry, Mainz, until 2000. Crutzen has also held part-time professorships at Chicago (1987–91), California (1992–2000), and Utrecht (1997–2000).

It began to be suspected in the 1950s that the concentration of ozone in the stratosphere was lower than expected. In 1970 Crutzen argued that nitrous oxide, arising from the use of nitrogen-rich fertilizers and the combustion of fossil fuels, could be responsible. As it was relatively unreactive, nitrous oxide could rise unchanged into the stratosphere, where, under the influence of ultraviolet radiation, it could initiate a series of reactions that would lead to the conversion of ozone into molecular oxygen.

Little notice was taken of Crutzen's argument – if only because it was felt that the amount of nitrous oxide produced was too insignificant to cause any noticeable depletion of the ozone layer. The debate, however, was revived by the growing fear in the early 1970s that a proposed armada of supersonic transport aircraft (SSTs) would emit large quantities of nitrous oxide from their exhausts. Conse-

quently the anti-SST lobby seized upon Crutzen's work.

In fact, the SSTs were never constructed. Soon after, Crutzen's warnings were overshadowed by the greater threat from the chlorofluorocarbons (CFCs), first identified in 1974 by F. Sherwood ROWLAND and Mario MOLINA, with whom Crutzen shared the 1995 Nobel Prize for chemistry. Crutzen was also one of the first scientists to warn of the dangers of a "nuclear winter." In 1982, two years before Carl SAGAN and his colleagues published their famous paper on the subject, Crutzen argued that fires lit by large nuclear explosions would be extensive enough to generate massive amounts of smoke, which, added to the dust produced by the bomb, would profoundly restrict the amount of sunlight reaching the ground.

**Cugnot, Nicolas-Joseph** (1725–1804)  
*French engineer*

Cugnot (koo-nyoh), who was born in Poid, France, served as a military engineer in the Austro-Hungarian army during the Seven Years' War (1756–63). Following this he built what was probably the first fuel-driven vehicle. Independently of James WATT and Thomas NEWCOMEN he designed, in 1770, a two-piston steam boiler, demonstrating that steam traction was feasible. It was intended for pulling heavy artillery and was the first engine to use high-pressure steam, although its application was limited by problems with the water supply.

**Culpeper, Nicholas** (1616–1654) *English medical writer and astrologer*

Culpeper, a Londoner, studied briefly at Cambridge University, where he learned Latin and Greek, before being apprenticed to an apothecary. In 1640 he established himself as an astrologer and physician in Spitalfields, London. Culpeper invoked the indignation of the College of Physicians by publishing, in 1649, an unauthorized translation of their *Pharmacopeia*, which listed the preparation and uses of all major drugs. In 1652, he published, with Peter Cole, *The English Physician*, in which he attacked the medical establishment. The enlarged version, published the following year, listed many herbal medicines and became very popular, running into several editions and being dubbed "Culpeper's Herbal." His prolific output included works dealing with astrology, medicine, and politics. He was a fervent supporter of the Parliamentary side in the English Civil War and was apparently wounded in battle. This may have contributed to his early death.

**Cunitz, Marie** (?1604–1664) *Polish astronomer*

Born in Silesia, the daughter of a physician, Cunitz defied the social conventions of her time

to become arguably the first woman scientist of the modern era. Yet much remains unknown about her life and career. She was educated chiefly by her father, and became known for her skills in languages, painting, poetry and music. However, her main interest was astronomy, one shared by her husband, the physician Elias von Löwen, whom she married in 1630. Cunitz is best remembered for her sole publication, *Urania propitia* (1650). This contained new simplified planetary tables based on a recalculation of the Rudolphine tables compiled by the astronomer Johannes KEPLER. Cunitz corrected some of the errors of Kepler, but also introduced new ones of her own. The work was privately published, and few copies remain in existence. She corresponded with other eminent scientists of her day, but many of her letters and other papers were lost in a fire in 1656. Nevertheless, Cunitz is credited as being one of the first astronomers to comprehend fully the significance of Kepler's work on the laws of planetary motion.

**Curie, Marie Skłodowska** (1867–1934)  
*Polish-French chemist*

In this shed with an asphalt floor, whose glass roof offered us only incomplete protection against the rain, which was like a greenhouse in summer and which an iron stove barely heated in winter, we passed the best and happiest years of our existence, consecrating our entire days to the work...I remember the delight we experienced when we happened to enter our domain at night and saw on all sides the palely luminescent silhouettes of the products of our work.

—In the Preface to Pierre Curie's *Collected Works*

Marie Curie (koo-ree) was born Skłodowska; her father was a physics teacher and her mother the principal of a girls' school in the Polish capital Warsaw. She acquired from her father a positivism and an interest in science although to aid the family finances she was forced, in 1885, to become a governess. She seems to have been on the fringe of nationalist revolutionary politics at a time when Polish language and culture were very much under Russian domination, but her main interest at this time appears to have been science. There was no way in which a girl could receive any form of higher scientific education in Poland in the 1880s, and so in 1891 she followed her elder sister to Paris. Living in poverty and working hard she graduated in physics from the Sorbonne in 1893, taking first place. She received a scholarship from Poland, which enabled her to spend a year studying mathematics; this time she graduated in second place.

In 1894 she met Pierre Curie and they married the following year. He was a physicist of some distinction, having already made several important discoveries, and was working as chief

of the laboratory of the school of Industrial Physics and Chemistry. Marie was at this time looking for a topic for research for a higher degree. Her husband was in full sympathy with her desire to continue with research, by no means a common attitude in late 19th-century France. She was also fortunate in her timing and choice of topic – the study of radioactivity. In 1896 Henri BECQUEREL had discovered radioactivity in uranium. Marie Curie had reason to believe that there might be a new element in the samples of uranium ore (pitchblende) that Becquerel had handled, but first she needed a place to work and a supply of the ore. It was agreed that she could work in her husband's laboratory. Her first task was to see if substances other than uranium were radioactive. Her method was to place the substance on one of the plates of Pierre's sensitive electrometer to see if it produced an electric current between the plates. In a short time she found that thorium is also radioactive.

Her next discovery was in many ways the most fundamental. She tried to see whether different compounds of uranium or thorium would have differing amounts of radioactivity. Her conclusion was that it made no difference what she mixed the uranium with, whether it was wet or dry, in powder form or solution; the only factor that counted was the amount of uranium present. This meant that radioactivity must be a property of the uranium itself and not of its interaction with something else. Radioactivity had to be an atomic property; it would soon be recognized as an effect of the nucleus.

One further advance was made by Marie Curie in 1898; she found that two uranium minerals, pitchblende and chalcocite, were more active than uranium itself. She drew the correct conclusion from this, namely that they must contain new radioactive elements. She immediately began the search for them. By the end of the year she had demonstrated the existence of two new elements, radium and polonium, both of which were highly radioactive. No precautions were taken at this time against the levels of radiation, as their harmful effects were not recognized. (Indeed, her notebooks of this period are still too dangerous to handle.)

Her next aim was to produce some pure radium. The difficulty here was that radium is present in pitchblende in such small quantities that vast amounts of the ore were needed. The Curies managed to acquire, quite cheaply, several tons of pitchblende from the Bohemian mines thanks to the intercession of the Austrian government. As there was too much material for her small laboratory she was offered the use of an old dissecting room in the yard of the school. It was freezing in winter and unbearably hot in summer – Wilhelm OSTWALD later described it as a cross between a stable and a potato cellar. The work was heavy and

monotonous. The limitations of her equipment meant that she could only deal with batches of 20 kilograms at a time, which had to be carefully dissolved, filtered, and crystallized. This procedure went on month after month, in all kinds of weather. By early 1902 she had obtained one tenth of a gram of radium chloride. She took it to Eugene DEMARÇAY who had first identified the new elements spectroscopically. He now had enough to determine its atomic weight, which he calculated as 225.93.

The crucial question arising from the discovery of these new elements was, what was the nature of the radiation emitted? It was thought that there were at least two different kinds of rays. One kind could be deflected by a magnetic field while the other was unaffected and would only travel a few centimeters before disappearing. (These were identified as the alpha and beta rays by Ernest RUTHERFORD.) A further question was the nature of the source of the energy. Pierre Curie showed that one gram of radium gave out about a hundred calories per hour. One further mystery at this time was the discovery of induced radioactivity – they had found that metal plates that had been close to, but not in contact with, samples of radium became radioactive themselves and remained so for some time.

The mysteries of radioactivity were explained not by the Curies but by Rutherford and his pupils. Although Marie Curie was no great theorist, she was an industrious experimentalist who with great strength and single-mindedness would pursue important but basically tedious experimental procedures for years. Her thesis was presented in 1903 and she became the first woman to be awarded an advanced scientific research degree in France. In the same year she was awarded the Nobel Prize for physics jointly with her husband and Becquerel for their work on radioactivity.

In 1904, when her husband was given a chair at the Sorbonne, Marie was offered a part-time post as a physics teacher at a girls' Normal School at Sèvres. In the same year her second daughter Eve was born. It is also about this time that she first appears to have suffered from radiation sickness. Given all these distractions it is not surprising that for a few years after the completion of her thesis she had little time for research. In 1906 Pierre Curie died in a tragic accident. The Sorbonne elected her to her husband's chair and the rest of her life was largely spent in organizing the research of others and attempting to raise funds. She made two long trips to America in 1921 and 1929. On her first trip she had been asked what she would most like to have. A gram of radium of her own was her reply, and she returned from America with a gram, valued at \$100,000. She also received \$50,000 from the Carnegie Institution. In 1912 the Sorbonne founded the Curie laboratory for the study of radioactivity. It was

opened in 1914 but its real work could only begin after the war, during which Marie Curie spent most of her time training radiologists. Later her laboratory, with its gram of radium, was to become one of the great research centers of the world.

Her position in France was somewhat odd. As a foreigner and a woman France was never quite sure how to treat her. She was clearly very distinguished for in 1911 she was awarded her second Nobel Prize, this time in chemistry for her discovery of radium and polonium. Her eminence was recognized by the creation of the Curie laboratory, yet at almost the same time she found herself rejected by the Académie des Sciences. She allowed her name to go forward in 1910 as the first serious female contender but was defeated. There is no doubt that this offended her. She refused to allow her name to be submitted for election again and for ten years refused to allow her work to be published in the proceedings of the Académie.

The following year, 1911, worse was to happen and she became the center of a major scandal. The physicist and former pupil of her husband, Paul LANGEVIN was accused of having an affair with her. Langevin had left his wife and four children, but although he was close to Madame Curie it is by no means clear that there were grounds for the accusations. Some of her letters to Langevin were stolen and published in the popular press and doubts were raised about Pierre Curie's death. Most of the attacks seem to have emanated from Gustave Téry, editor of *L'Oeuvre* (The Work) and a former classmate of Langevin. Langevin retaliated by challenging Téry to a duel. Langevin faced Téry late in 1911 at 25 yards with a loaded pistol in his hand. Both refused to fire and shortly afterward the scandal died down.

Her major published work was the massive two-volume *Treatise on Radioactivity* (1910). The Curies' daughter Irène and her husband Frédéric JOLIOT-CURIE continued the pioneering work on radioactivity and themselves received the Nobel Prize for physics.

### Curie, Pierre (1859–1906) *French physicist*

We might still consider that in criminal hands radium might become very dangerous; and here we must ask ourselves if mankind can benefit by knowing the secrets of nature, if man is mature enough to take advantage of them, or if this knowledge will not be harmful to the world.

—Nobel Prize address, 1903

Pierre Curie was the son of a Paris physician. He was educated at the Sorbonne where he became an assistant in 1878. In 1882 he was made laboratory chief at the School of Industrial Physics and Chemistry where he remained until he was appointed professor of physics at

the Sorbonne in 1904. In 1895 he married Marie Skłodowska, with whom he conducted research into the radioactivity of radium and with whom he shared the Nobel Prize for physics in 1903.

His scientific career falls naturally into two periods, the time before the discovery of radioactivity by Henri BECQUEREL, when he worked on magnetism and crystallography, and the time after when he collaborated with his wife Marie Curie on this new phenomenon.

In 1880 with his brother Jacques he had discovered piezoelectricity. "Piezo" comes from the Greek for "to press" and refers to the fact that certain crystals when mechanically deformed will develop opposite charges on opposite faces. The converse will also happen; i.e., an electric charge applied to a crystal will produce a deformation. The brothers used the effect to construct an electrometer to measure small electric currents. Marie Curie later used the instrument to investigate whether radiation from substances other than uranium would cause conductivity in air. Pierre Curie's second major discovery was in the effect of temperature on the magnetic properties of substances, which he was studying for his doctorate. In 1895 he showed that at a certain temperature specific to a substance it will lose its ferromagnetic properties; this critical temperature is now known as the *Curie point*.

Shortly after this discovery he began to work intensively with his wife on the new phenomenon of radioactivity. Two new elements, radium and polonium, were discovered in 1898. The rays these elements produced were investigated and enormous efforts were made to produce a sample of pure radium.

He received little recognition in his own country. He was initially passed over for the chairs of physical chemistry and mineralogy in the Sorbonne and was defeated when he applied for membership of the Académie in 1902. He was however later admitted in 1905. The only reason he seems eventually to have been given a chair (in 1904) was that he had been offered a post in Geneva and was seriously thinking of leaving France. Partly this may have been because his political sympathies were very much to the left and because he was unwilling to participate in the science policies of the Third Republic.

Pierre Curie was possibly one of the first to suffer from radiation sickness. No attempts were made in the early days to restrict the levels of radiation received. He died accidentally in 1906 in rather strange circumstances – he slipped while crossing a Paris street, fell under a passing horse cab, and was kicked to death. The unit of activity of a radioactive substance, the *curie*, was named for him in 1910.

The Curies' daughter Irène JOLIOT-CURIE carried on research in radioactivity and also re-

ceived the Nobel Prize for work done with her husband Frédéric.

**Curl, Robert Floyd Jr.** (1933– ) *American chemist*

Curl was educated at Rice University, Texas, and the University of California, Berkeley, where he gained his PhD in 1957. After working at Harvard he returned to Rice in 1967 as professor of chemistry.

Curl's initial work was on small clusters of atoms of semiconductors, such as germanium and silicon. In 1984, under the influence of Harold KROTO, he became interested in the possibility of producing long-chain carbon molecules, and persuaded his colleague Richard SMALLEY to deploy the resources of his laboratory towards this end. Although they expected on theoretical grounds to discover linear chain clusters with up to 33 carbon atoms, they in fact came across an unexpected molecule with 60 carbon atoms and with a cage-like structure. The discovery of this new allotrope of carbon, later named buckminsterfullerene, opened up a new branch of materials science.

Curl shared the 1996 Nobel Prize for chemistry with Smalley and Kroto.

**Curtis, Heber Doust** (1872–1942) *American astronomer*

Born in Muskegon, Michigan, Curtis obtained his BA (1892) and MA (1893) from the University of Michigan, where he studied classics. He moved to California in 1894 where he became professor of Latin and Greek at Napa College. There his interest in astronomy was aroused and from 1897 to 1900 he was professor of mathematics and astronomy after the college merged with the University (now the College) of the Pacific. After obtaining his PhD from the University of Virginia in 1902 he joined the staff of the Lick Observatory where he remained until 1920 when he became director of the Allegheny Observatory of the University of Pittsburgh. Finally, in 1930 he was appointed director of the University of Michigan's observatory.

Curtis's early work was concerned with the measurement of the radial velocities of the brighter stars. From 1910 however he was involved in research on the nature of "spiral nebulae" and became convinced that these were isolated independent star systems. In 1917 he argued that the observed brightness of novae found by him and by George RITCHEY on photographs of the nebulae indicated that the nebulae lay well beyond our Galaxy. He also maintained that extremely bright novae (later identified as supernovae) could not be included with the novae as distance indicators. He estimated the Andromeda nebula to be 500,000 light-years away.

Curtis's view was opposed by many, including Harlow SHAPLEY who proposed that our Galaxy was 300,000 light-years in diameter, far larger than previously assumed, and that the spiral nebulae were associated with the Galaxy. In 1920, at a meeting of the National Academy of Sciences, Curtis engaged in a famous debate with Shapley over the size of the Galaxy and the distance of the spiral nebulae. Owing to incomplete and incorrect evidence the matter was not settled until 1924 when Edwin HUBBLE re-determined the distance of the Andromeda nebula and demonstrated that it lay well beyond the Galaxy.

**Curtius, Theodor** (1857–1928) *German organic chemist*

Born at Duisburg, in Germany, Curtius (**kuurtsee-uus**) gained his doctorate under Adolph KOLBE at Leipzig and later became professor at Kiel (1889), Bonn (1897), and Heidelberg (1898). Two reactions are named for Curtius; the first, discovered in 1894, is a method for the conversion of an acid into an amine via the azide and urethane, and the second, discovered in 1913, is a method of converting an azide into an isocyanate. Curtius also discovered diazoacetic ester, which was the first known aliphatic diazo compound (1883), hydrazine (1887), and hydrazoic acid (1890).

**Cushing, Harvey Williams** (1869–1939) *American surgeon*

Born in Cleveland, Ohio, Cushing received his MD from Harvard Medical School in 1895. He then joined Massachusetts General Hospital, Boston, before moving to Johns Hopkins Hospital, where he progressed to associate professor of surgery. In 1912 he was appointed professor of surgery at Harvard. Cushing's specialty was brain surgery and he pioneered several important techniques in this field, especially in the control of blood pressure and bleeding during surgery. From his many case histories, he distinguished several classes of brain tumors and made great improvements in their treatment. Cushing also demonstrated the vital role of the pituitary gland in regulating many bodily functions. He was the first to associate adenoma (tumor) of the basophilic cells of the anterior pituitary with the chronic wasting disease now known as *Cushing's syndrome*. The characteristic symptoms include thin arms and legs, atrophied skin with red lines, obesity of the trunk and face, and high blood pressure. This syndrome is now known to be caused by any of several disorders that result in the increased secretion of corticosteroid hormones by the adrenal glands.

Cushing had a lifelong interest in the history of medicine and wrote the *Life of Sir William Osler* (1925), which won him a Pulitzer Prize.

He donated his large collection of books and papers to the Yale Medical Library.

**Cuvier, Baron Georges (1769–1832)**  
*French anatomist and taxonomist*

Cuvier (**kyoo-vee-ay** or **koo-vyay**) was born in Montbéliard (now in France) and as a child was greatly influenced by Georges BUFFON's books. In 1795 he became assistant to the professor of comparative anatomy at the Museum of Natural History in Paris – then the world's largest scientific research establishment. During his lifetime he greatly enlarged the comparative anatomy section from a few hundred skeletons to 13,000 specimens. Cuvier extended LINNAEUS's classification, creating another level, the phylum, into which he grouped related classes. He recognized four phyla in the animal kingdom and his work on one of these, the

fishes, is recognized as the foundation for modern ichthyology. Together with Achille Valenciennes, Cuvier compiled the lengthy *Histoire des poissons* (History of Fish), nine volumes of which had appeared by his death. The fish families delimited in this work remain as orders or suborders in today's classification. Cuvier was the first to classify fossils and named the pterodactyl. His results from investigations of the Tertiary formations near Paris are published in four volumes as *Recherches sur les ossements fossiles des quadrupèdes* (1812; Researches on the Fossil Bones of Quadrupeds).

In 1799 Cuvier became professor of natural history at the Collège de France and in 1802 was also made professor at the Jardin des Plantes. In his later life he became increasingly involved in educational administration and played a large part in organizing the new Sorbonne.

## **d'Abano, Pietro** (c. 1250–1316) *Italian physician and philosopher*

D'Abano (**dah**-bah-noh) was born at Abano near Padua in Italy and studied in Greece and Constantinople before learning medicine in Paris. He became professor of medicine at Padua University in 1306 and soon became a celebrated teacher and physician.

His knowledge of Greek enabled him to study the texts of the ancient scholars and physicians and to attempt to reconcile medicine and philosophy in his most famous book known as the *Conciliator*. This rationalist stance together with his interest in astrology brought d'Abano into conflict with the Catholic Church. In 1315 he was accused of being a heretic and was twice brought before the Inquisition. Acquitted the first time, he died before a second trial was completed and his body was hidden by friends. He was nevertheless found guilty and the Inquisition ordered that his effigy be burned instead.

## **Daguerre, Louis-Jacques-Mandé** (1789–1851) *French physicist, inventor, and painter*

Daguerre (**da-gair**), the inventor of the daguerreotype (the first practical photograph), first became interested in the effect of light on films from the artistic point of view. Born in Corneilles near Paris, France, he worked first as a tax officer, later becoming a painter of opera scenery.

Working with Charles-Marie Bouton he invented the diorama – a display of paintings on semitransparent linen that transmitted and reflected light – and opened a diorama in Paris (1822).

From 1826 Daguerre turned his attention to heliography (photographing the sun) and he was partnered in this by Joseph-Nicéphore NIEPCE until Niepce's death in 1833. Daguerre continued his work and in 1839 presented to the French Academy of Sciences the daguerreotype, which needed only about 25-minutes exposure time to produce an image, compared with over eight hours for Niepce's previous attempts. In the daguerreotype a photographic image was obtained on a copper plate coated with a light-sensitive layer of silver iodide and bromide.

## **d'Ailly, Pierre** (1350–1420) *French geographer, cosmologist, and theologian*

D'Ailly (**da-ye**), who was born in Compiègne, France, studied at the University of Paris, serving as its chancellor from 1389 until 1395. He then became a bishop, first of Le Puy and subsequently of Cambrai. He became a cardinal in 1411.

Primarily concerned with church affairs, in which he advocated reform, d'Ailly was also interested in science and was the leading geographical theorist of his time. He was the author of the influential work *Imago mundi* (Image of the World), which was completed by 1410 and printed in about 1483. This was a summary of the classical and Arabian geographers, typical of the medieval period, and was influenced by Roger BACON. D'Ailly's underestimate of the Earth's circumference and exaggeration of the size of Asia may well have influenced Columbus, whose copy of d'Ailly's work, with his marginal annotations, still survives. D'Ailly's work had been written without the benefit of PTOLEMY's *Geography*, which only became available in a Latin version shortly afterward. He produced, in 1413, the *Compendium cosmographiae* (Compendium of Cosmography). This was basically a summary of Ptolemy, reviving uncritically the full fabric of Ptolemaic geography, which was already being dismantled by such travelers as Marco Polo.

## **Daimler, Gottlieb Wilhelm** (1834–1900) *German engineer and inventor*

Daimler (**dīm**-ler or daym-ler), who was born in Schorndorf, Germany, became a gunsmith's apprentice in 1848. He studied at Stuttgart technical school, worked for a period at an engineering plant, and completed his education at Stuttgart Polytechnic. After traveling in England and France, he worked from 1863 in German engineering companies, beginning work on an internal-combustion engine in 1872.

In 1885 Daimler set up a company with Wilhelm Maybach and in 1883 and 1885 designs for an internal-combustion engine suitable for light vehicles were patented. In 1890 he founded the Daimler-Motoren-Gesellschaft company, which, in 1899, built the first Mercedes car.

**Dainton, Frederick Sydney** (1914–1997)  
*British physical chemist and scientific administrator*

Perhaps science will only regain its lost primacy as peoples and governments begin to recognize that sound scientific work is the only secure basis for the construction of policies to ensure the survival of mankind without irreversible damage to Planet Earth.  
—*New Scientist*, 3 March 1990

Born in the English industrial city of Sheffield, Dainton was educated at the universities of Oxford and Cambridge. After World War II he remained in Cambridge until 1950, when he moved to the University of Leeds as professor of physical chemistry. In 1965 Dainton was appointed vice-chancellor of the University of Nottingham. He returned to chemistry in 1970, when he was elected professor of chemistry at Oxford. Soon after, in 1973, he was made chairman of the University Grants Committee, a post he held until his retirement in 1978.

Dainton's early work in physical chemistry was on the kinetics and thermodynamics of polymerization reactions. From about 1945 he turned his attention to studies of radiolysis – i.e., chemical changes produced by high-energy radiation (alpha, beta, or gamma rays). In particular, he studied the properties and reactions of hydrated electrons in liquids.

From 1965 he was a member of the Council for Scientific Policy and was its chairman from 1969 to 1973. While holding this office he was influential in decisions made about the way British academic research is financed. He was raised to the British peerage, as Baron Dainton of Hallam Moors, in 1986.

**Dale, Sir Henry Hallett** (1875–1968)  
*British physiologist*

Educated at Cambridge University and St. Bartholomew's Hospital in his native city of London, Dale became, in 1904, director of the Wellcome Physiological Research Laboratories. His work there over the next ten years included the isolation (with Arthur Ewins) from ergot fungi of a pharmacologically active extract – acetylcholine – which he found had similar effects to the parasympathetic nervous system on various organs. It was later shown by Otto LOEWI that a substance released by electrical stimulation of the vagus nerve was responsible for effecting changes in heartbeat. Following up this work, Dale showed that the substance is in fact acetylcholine, thus establishing that chemical as well as electrical stimuli are involved in nerve action. For this research Dale and Loewi shared the 1936 Nobel Prize for physiology or medicine. Dale also worked on the properties of histamine and related substances, including their actions in allergic and anaphylactic conditions. He was the chairman of an international committee responsible for

the standardization of biological preparations, and from 1928 to 1942 was director of the National Institute for Medical Research.

**d'Alembert, Jean Le Rond** (1717–1783)  
*French mathematician, encyclopedist, and philosopher*

Push on, and faith will catch up with you.  
—Advice to people unable to accept the methods of the calculus

D'Alembert (da-lahm-bair) was the illegitimate son of a Parisian society hostess, Mme de Tenzin, and was abandoned on the steps of a Paris church, from which he was named. He was brought up by a glazier and his wife, and his father, the chevalier Destouches, made sufficient money available to ensure that d'Alembert received a good education although he never acknowledged that d'Alembert was his son. He graduated from Mazarin College in 1735 and was admitted to the Academy of Sciences in 1741.

D'Alembert's mathematical work was chiefly in various fields of applied mathematics, in particular dynamics. In 1743 he published his *Traité de dynamique* (Treatise on Dynamics), in which the famous *d'Alembert principle* is enunciated. This principle is a generalization of NEWTON's third law of motion, and it states that Newton's law holds not only for fixed bodies but also for those that are free to move. D'Alembert wrote numerous other mathematical works on such subjects as fluid dynamics, the theory of winds, and the properties of vibrating strings. His most significant purely mathematical innovation was his invention and development of the theory of partial differential equations. Between 1761 and 1780 he published eight volumes of mathematical studies.

Apart from his mathematical work he is perhaps more widely known for his work on Denis Diderot's *Encyclopédie* (Encyclopedia) as editor of the mathematical and scientific articles, and his association with the philosophes. D'Alembert was a friend of VOLTAIRE's and he had a lively interest in theater and music, which led him to conduct experiments on the properties of sound and to write a number of theoretical treatises on such matters as harmony. He was elected to the French Academy in 1754 and became its permanent secretary in 1772 but he refused the presidency of the Berlin Academy.

**Dalén, Nils Gustaf** (1869–1937) *Swedish engineer*

Born in Stenstorp, Sweden, Dalén (da-layn) graduated in mechanical engineering in 1896 from the Chalmers Institute at Göteborg and then spent a year at the Swiss Federal Institute of Technology at Zurich. For several years he researched and improved hot-air turbines, com-

pressors, and air pumps and from 1900 to 1905 worked with an engineering firm, Dalén and Alsing. He then became plant manager for the Swedish Carbide and Acetylene Company, which in 1909 became the Swedish Gas Accumulator Company with Dalén as managing director.

Dalén is remembered principally for his inventions relating to acetylene lighting for light-houses and other navigational aids, and in particular an automatic light-controlled valve, for which he received the 1912 Nobel Prize for physics. The valve, known as "Solventil," used the difference in heat-absorbing properties between a dull black surface and a highly polished one to produce differential expansion of gases, and thus to regulate the main gas valve of an acetylene-burning lamp. The lamp could thus be automatically dimmed or extinguished in daylight, and this allowed buoys and light-houses to be left unattended and less gas to be used. The system soon came into widespread use and is still in use today.

Another invention of Dalén's was a porous filler for acetylene tanks, "Agamassan," that prevented explosions. It was ironic that in 1912 he was himself blinded by an explosion during the course of an experiment. This did not, however, deter him from continuing his experimental work up to his death.

### **Dalton, John** (1766–1844) *British chemist and physicist*

An enquiry into the relative weights of the ultimate particles of bodies is a subject, as far as I know, entirely new; I have lately been prosecuting this enquiry with remarkable success.

—*On the Absorption of Gases by Water* (1802)

The son of a hand-loom weaver from Eaglesfield in the northwest of England, Dalton was born into the nonconformist tradition of the region and remained a Quaker all his life. He was educated at the village school until the age of 11, and received tuition from Elihu Robinson, a wealthy Quaker, meteorologist, and instrument maker, who first encouraged Dalton's interest in meteorology. At the age of only 12, Dalton himself was teaching in the village. He then worked on the land for two years before moving to Kendal with his brother to teach (1781). In 1793 he moved to Manchester where he first taught at the Manchester New College, a Presbyterian institute. In 1794 he was elected to the Manchester Literary and Philosophical Society at which most of his papers were read.

From 1787 until his death Dalton maintained a diary of meteorological observations of the Lake District where he lived. His first published work, *Meteorological Observations and Essays* (1793), contained the first of his laws concerning the behavior of compound atmospheres: that the same weight of water vapor is

taken up by a given space in air and in a vacuum. Both Dalton and his brother were color blind and he was the first to describe the condition, sometimes known as daltonism, in his work *Extraordinary Facts Relating to the Vision of Colours* (1794).

In 1801 Dalton read four important papers to the Manchester Philosophical Society. *On the Constitution of Mixed Gases* contains what is now known as the law of partial pressures and asserts that air is a mixture, not a compound, in which the various gases exert pressure on the walls of a vessel independently of each other. *On the Force of Steam* includes the first explanation of the dew point and hence the founding of exact hygrometry. It also demonstrates that water vapor behaves like any other gas. The third paper, *On Evaporation*, shows that the quantity of water evaporated is proportional to the vapor pressure. *On the Expansion of Gases by Heat* contains the important conclusion that all gases expand equally by heat. This law had been discovered by Jacques CHARLES in 1787 but Dalton was the first to publish. During this time, Dalton was developing his atomic theory, for which he is best known. A physical clue to the theory was provided by the solubility of gases in water. Dalton expected to find that all gases had the same solubility in water but the fact that they did not helped to confirm his idea that the atoms of different gases had different weights. The first table of atomic weights was appended to the paper *On the Absorption of Gases by Water*, read in 1802 but not printed until 1805. In another paper read in 1802 and printed in 1805 he showed that when nitric oxide is used to absorb oxygen in a eudiometer they combine in two definite ratios depending on the method of mixing. This was the beginning of the law of multiple proportions and led Dalton to much work on the oxides of nitrogen and the hydrocarbons methane and ethylene to confirm the law.

The atomic theory was first explicitly stated by Dalton at a Royal Institution lecture in December 1803 and first appeared in print in Thomas Thomson's *System of Chemistry* (1807). Dalton's own full exposition appeared in *A New System of Chemical Philosophy* (1808), with further volumes in 1810 and 1827. The basic postulates of the theory are that matter consists of atoms; that atoms can neither be created nor destroyed; that all atoms of the same element are identical, and different elements have different types of atoms; that chemical reactions take place by a rearrangement of atoms; and that compounds consist of "compound atoms" formed from atoms of the constituent elements.

Using this theory, Dalton was able to rationalize the various laws of chemical combination (conservation of mass, definite proportions, multiple proportions) and show how they followed from the theory. He did, however, make

 Hydrogen	 Sulphur	 Strontian	 Lead
 Azote	 Magnesia	 Barytes	 Silver
 Carbon	 Lime	 Iron	 Gold
 Oxygen	 Soda	 Zinc	 Platina
 Phosphorus	 Potash	 Copper	 Mercury

CHEMICAL ELEMENTS The symbols for the chemical elements used by John Dalton.

the mistake of assuming “greatest simplicity”: i.e., that the simplest compound of two elements must be binary (e.g., water was HO). His system of atomic weights was not very accurate (e.g., he gave oxygen an atomic weight of seven rather than eight). Dalton’s theory remained open to dispute until 1858 when Stanislao CANNIZZARO’s rediscovery of Amedeo AVOGADRO’s work removed the last objections to the theory. Dalton’s symbols for atoms and molecules were spherical and he used wooden molecular models similar to the modern version.

### Dam, Carl Peter Henrik (1895–1976) Danish biochemist

Dam was born in Copenhagen and educated at the polytechnic and the university there, obtaining his doctorate in 1934. He taught at the university from 1923 until 1941, when – although stranded in America because of the war – he was appointed professor of biochemistry at the Copenhagen Polytechnic. From 1956 until 1963 Dam served as director of the Biochemical Division of the Danish Fat Research Institute.

From 1928 to 1930 Dam worked on the problem of cholesterol metabolism in chickens. Cholesterol, first analyzed by Heinrich WIELAND, is a sterol with an important role in mammalian physiology. It was known that many mammals could readily synthesize it, but it was assumed that chickens lacked this ability. To test this assumption Dam began to rear chickens on a cholesterol-free diet enriched with vitamins A and D.

As it turned out he found that chickens could synthesize cholesterol but, more importantly, he also found that if kept on such a diet for two to three weeks the chickens developed hemorrhages under the skin, and blood removed for examination showed delayed coagulation. Supplementing the diet with fat, vitamin C, and cholesterol made no appreciable difference, so Dam concluded that the condition was due to lack of a hitherto unrecognized factor in the diet.

The missing factor, found to be present in

green leaves and pig liver, was designated vitamin K by Dam in 1935 (K being the initial letter of “koagulation,” the Scandinavian and German form of the word). Using ether, Dam went on to extract the fat-soluble vitamin K from such sources as alfalfa, and in 1939 succeeded, with Paul KARRER, in isolating it. It was for this work that Dam shared the 1943 Nobel Prize for physiology or medicine with Edward DOISY.

### Dana, James Dwight (1813–1895) American geologist, mineralogist, and zoologist

We should give a high place in our estimate to all investigation tending to evaluate the variation of permanence of species, their mutability or immutability.  
—*Thoughts on Species* (1856)

Dana was born at Utica in New York State and educated at Yale (1830–33) where he became interested in geology. He worked initially as assistant to Benjamin SILLIMAN and published, in 1837, *A System of Mineralogy*, one of the major textbooks on the subject.

He sailed as geologist and naturalist on the Wilkes expedition (1838–42) visiting the Antarctic and Pacific. On his return, Dana published a series of research reports on the voyage during the period 1844–54, which established his reputation as an important scientist. These included *Zoophytes* (1846), *Geology* (1849), and *Crustacea* (1852).

In 1847 Dana formulated his geosynclinal theory of the origin of mountains. He introduced the term geosyncline to refer to troughs or dips in the Earth’s surface that became filled with sediment. These huge deposits of sediment could then, Dana proposed, be compressed and folded into mountain chains.

He was appointed to the chair of natural history at Yale in 1856 and in 1864 to the chair of geology and mineralogy where he remained until his retirement in 1890. He published several important books while at Yale, including his most notable textbook, *Manual of Geology* (1863), and the synthesis of his work on coral reefs in *Coral and Coral Islands* (1872). In agreement with Charles DARWIN’s ideas, pub-

lished in 1842, Dana argued that coral islands are the result of subsidence of the island together with the upward growth of corals.

**Daniell, John Frederic** (1790–1845) *British chemist and meteorologist*

His extensive intercourse with men in general added to his natural perspicacity, gave him a clear insight into character, and conferred on him advantages which men of science in general do not possess.

—Obituary notice of Daniell (1845)

Daniell was the son of a London lawyer. He started work in the sugar-refining factory of a relative and, on the basis of early researches, he was elected to the Royal Society at the age of 23. He was appointed as first professor of chemistry at the newly opened King's College, London, in 1831.

Daniell invented a number of scientific instruments, including a hygrometer (1820) to measure humidity in the atmosphere. His theories on the atmosphere and wind movements were published in *Meteorological Essays and Observations* (1823). He also stressed the importance of moisture in hothouse management.

Daniell is best remembered for his introduction in 1836 of a new type of electric cell. The voltaic cell, introduced by Alessandro VOLTA in 1797, lost power once the current was drawn. This was due to bubbles of hydrogen collecting on the copper plate and producing resistance to the free flow of the circuit (polarization). With the growth of telegraphy there was a real need for a cell that could deliver a constant current over a long period of time. In the *Daniell cell* a zinc rod is immersed in a dilute solution of sulfuric acid contained in a porous pot, which stands in a solution of copper sulfate surrounded by copper. Hydrogen reacts with the copper sulfate. The porous pot prevents the two electrolytes from mixing, and at the positive (copper) electrode, copper is deposited from the copper sulfate. Thus no hydrogen bubbles can form on this electrode.

**Daniels, Farrington** (1889–1972) *American chemist*

Born in Minneapolis in Minnesota, Daniels was educated at the University of Minnesota and at Harvard, where he obtained his PhD in 1914. He moved to the University of Wisconsin in 1920, spending his whole career there and serving as professor of chemistry from 1928 until his retirement in 1959.

Daniels worked on a wide variety of chemical problems. In addition to a textbook, *Outlines of Physical Chemistry* (1931), he wrote on photochemistry, nitrogen fixation, and thermoluminescence.

He was also interested in the utilization of solar energy, publishing a book on the subject, *Direct Use of the Sun's Energy* (1964), and or-

ganizing a symposium on it in 1954, many years before the discussion of solar energy had become fashionable.

**Dansgaard, Willi** (1922– ) *Danish meteorologist*

Dansgaard (**dans**-gord) was born in the Danish capital of Copenhagen and educated at the university there, obtaining his PhD in 1961. He is currently emeritus professor of geophysics.

Dansgaard has studied the applications of environmental isotopes to meteorological, hydrological, and glaciological problems, and in particular to the climate of the last 100,000 years. Oxygen is present in two stable isotopes – the normal oxygen-16 and a much smaller proportion of oxygen-18 with two extra neutrons in its nucleus. In 1947 Harold UREY demonstrated that the variation of the two isotopes in sea water depended on temperature, i.e., the colder the temperature the smaller the oxygen-18 content of the seas. He had further established that a slight change of temperature would produce a measurable alteration in oxygen-18 levels.

In the early 1960s the U.S. army drilled down into the Greenland icecap, producing an ice core 4,600 feet (1,400 m) long and with a 100,000-year history. Dansgaard realized that by making careful measurement of the core's varying oxygen-18 level he should be able to reconstruct the climatic history of the last 100,000 years. The most recent ice age, ending 10,000 years ago, was clearly marked, as was evidence of a weather cycle during the last 1,000 years.

**Darby, Abraham** (c. 1678–1717) *British metallurgist*

Darby, who was born in Dudley, England, developed the first successful method of smelting iron ore with coke, and in doing so made possible the large-scale production of good quality iron castings. Previously only wood charcoal had been used but supplies of this were depleted and there were insufficient fuel supplies to provide the growing volume of iron. Attempts to use coal were unsuccessful because the sulfur impurities it contained spoiled the iron. By coking the coal the sulfur could be removed. Darby, who had experience in smelting copper with coke, founded a factory at Coalbrookdale to smelt iron using coke, achieving success in 1709. Abundant coal supplies and Darby's process meant that brass could be replaced by iron from large furnaces. Thomas NEWCOMEN's new steam engine (1712) needed hard-wearing metal parts for cylinders, etc. The iron castings introduced by Darby soon became an integral part of the industrial developments of the day.

Darby's grandson, also named Abraham,

built the world's first iron bridge at Coalbrookdale (1779).

**Darlington, Cyril Dean** (1903–1981)  
*British geneticist*

Mankind ... will not willingly admit that its destiny can be revealed by the breeding of flies or the counting of chiasmata.

—Royal Society Tercentenary Lecture, 1960

Born at Chorley in Lancashire, England, Darlington graduated in agriculture from Wye College, London, in 1923 and joined the John Innes Horticultural Institution, which was then under the directorship of William BATESON. He studied nuclear division, comparing mitosis (normal cell division) with meiosis (the reduction division that halves the chromosome number prior to gamete formation). He demonstrated that the chromosomes have already replicated by the first stage of mitosis whereas the chromosomes are still single in the earliest stage of meiosis, a discovery basic to nuclear cytology.

Darlington was also extremely interested in the crossing over of chromosomes that occurs at meiosis. He saw it as a mechanism that not only allows for recombination of genes between chromosomes; it is also able to account for the complete succession of meiotic events.

Darlington became director of the John Innes Institute in 1939 and presided over the move of the Institute from Merton to Bayfordbury in 1949. He became professor of botany at Oxford in 1953 and became emeritus professor in 1971. Darlington wrote a number of books on genetics, including *Evolution of Genetic Systems* (1939). With Ronald FISHER, he founded the journal *Heredity* in 1947.

**Dart, Raymond Arthur** (1893–1988)  
*Australian anatomist*

The loathsome cruelty of mankind to man forms one of his inescapable, characteristic, and differentiative features; it is explicable only in terms of his cannibalistic origins.

—Quoted by Richard Leakey in *The Making of Mankind* (1981)

Born in Toowong, Australia, Dart was educated at the universities of Queensland and Sydney where he qualified as a physician in 1917. After a short period (1919–22) at University College, London, Dart moved to South Africa to serve as professor of anatomy at the University of the Witwatersrand, Johannesburg, a post he held until his retirement in 1958.

In 1924 Dart was privileged to make one of the great paleontological discoveries of the century, the Taung skull. For this he was indebted to his student Josephine Salmons who brought him in the summer of 1924 a fossil collected from a mine at Taung, Bechuanaland. Dart named it *Australopithecus africanus*, meaning southern African ape, and declared it to be in-

termediate between anthropoids and man. Such a claim was far from acceptable to many scholars at the time who, like Arthur Keith, dismissed the skull as that of a young anthropoid. Other and older australopithecine remains were later discovered by Robert BROOM in South Africa, East Africa, and Asia, making it clear that they were in fact hominid. It is still however a matter of controversy whether *Australopithecus* lies in the direct line of descent to *Homo sapiens* or whether it represents a quite separate and unsuccessful evolutionary sideline.

**Darwin, Charles Robert** (1809–1882)  
*British naturalist*

We must, however, acknowledge, as it seems to me, that man with all his noble qualities ... still bears in his bodily frame the indelible stamp of his lowly origin.

—*The Descent of Man* (1871)

The preservation of favourable variations and the rejection of injurious variations, I call Natural Selection, or Survival of the Fittest.

—*On the Origin of Species* (1859)

Darwin, who was born in Shrewsbury in England, began his university education by studying medicine at Edinburgh (1825), but finding he had no taste for the subject he entered Cambridge University to prepare for the Church. At Cambridge his interest in natural history, first stimulated by the geologist Adam SEDGWICK, was encouraged by the professor of botany John Henslow. Their friendship led to Henslow's recommending Darwin to the admiralty for the position of naturalist on HMS *Beagle*, which was preparing to survey the coast of South America and the Pacific.

The *Beagle* sailed in 1831 and Darwin, armed with a copy of Charles LYELL's *Principles of Geology*, initially concerned himself more with the geological aspects of his work. However, his observations of animal species – particularly the way in which they gradually change from region to region – also led him to speculate on the development of life. He was particularly struck by the variation found in the finches of the Galápagos Islands, where he recorded some 14 different species, each thriving in a particular region of the islands. Darwin reasoned that it was highly unlikely that each species was individually created; more probably they had evolved from a parent species of finch on mainland Ecuador. Further considerations, back in England, as to the mechanism that brought this about resulted in probably the most important book in the history of biology.

On returning to England in 1836, Darwin first concerned himself with recording his travels in *A Naturalist's Voyage on the Beagle* (1839), which received the acclaim of Alexander von HUMBOLDT. His interest in geology was reflected in *Structure and Distribution of Coral*

*Reefs* (1842) and *Geological Observations on Volcanic Islands* (1844). These early works, which established his name in the scientific community and won the respect of Lyell, were fundamental to the development of his theories on evolution.

Early on Darwin had perceived that many questions in animal geography, comparative anatomy, and paleontology could only be answered by disregarding the theory of the immutability of the species (an idea widely held at the time) and accepting that one species evolved from another. The idea was not original but Darwin's contribution was to propose a means by which evolution could have occurred and to present his case clearly, backed up by a wealth of evidence. In 1838 he read Thomas MALTHUS's *An Essay on the Principle of Population* and quickly saw that Malthus's argument could be extended from man to all other forms of life. Thus environmental pressures, particularly the availability of food, act to select better adapted individuals, which survive to pass on their traits to subsequent generations. Valuable characteristics that arise through natural variability are therefore preserved while others with no survival value die out. If environmental conditions change, the population itself will gradually change as it adapts to the new conditions, and with time this will lead to the formation of new species. Darwin spent over 20 years amassing evidence in support of this theory of evolution by natural selection, so as to provide a buffer against the inevitable uproar that would greet his work on publication. In this period the nature of his studies was divulged only to close friends, such as Joseph HOOKER, T. H. HUXLEY, and Charles Lyell.

The stimulus to publish came in June 1858 when Darwin received, quite unexpectedly, a communication from Alfred Russel WALLACE that was effectively a synopsis of his own ideas. The question of priority was resolved through the action of Lyell and Hooker, who arranged for a joint paper to be read to the Linnean Society in July 1858. This consisted of Wallace's essay and a letter, dated 1857, from Darwin to the American botanist Asa GRAY outlining Darwin's theories. Darwin later prepared an "abstract" of his work, published in November 1859 as *On the Origin of Species by Means of Natural Selection*.

As expected the work made him many enemies among orthodox scientists and churchmen since beliefs in the Creation and divine guidance were threatened by Darwin's revelations. Darwin, a retiring man, chose not to defend his views publicly – a task left to (and seemingly immensely enjoyed by) Huxley, "Darwin's bulldog," notably at the famous Oxford debate in 1860. Darwin continued quietly with his work, publishing books that extended and amplified his theories. One of these was *The*

*Descent of Man* (1871), in which he applied his theory to the evolution of man from subhuman creatures. Many of his books are seen as pioneering works in various fields of biology, such as ecology and ethology.

Darwin was, however, troubled by one flaw in his theory – if inheritance were blending, i.e., if offspring received an average of the features of their parents (the then-held view of heredity), then how could the variation, so essential for natural selection to act on, come about? This problem was put in a nutshell by Fleeming Jenkin, professor of engineering at University College, London, who wrote a review of the *Origin* in 1867. In this Jenkin pointed out that any individual with a useful trait, assuming it mated with a normal partner, would pass on only 50% of the character to its children, 25% to its grandchildren, 12½% to its great-grandchildren, and so on until the useful feature disappeared. The logic of this drove Darwin to resort to Lamarckian ideas of inheritance (of acquired characteristics) as elaborated in his theory of pangenesis in the sixth edition of the *Origin*. The question was not resolved until the rediscovery, nearly 20 years after Darwin's death, of Gregor MENDEL's work, which demonstrated the particulate nature of inheritance, i.e., that hereditary characteristics are transmitted from parents to offspring by discrete entities later known as genes.

Darwin was troubled through most of his life by continuous illness, which most probably was due to infection by the trypanosome parasite causing Chagas's disease, contracted during his travels on the *Beagle*. On his death he was buried, despite his agnosticism, in Westminster Abbey.

### Darwin, Erasmus (1731–1802) *British physician*

Soon shall thy arm, unconquer'd steam, afar  
 Drag the slow barge, or drive the rapid car;  
 Or on wide-waving wings expanded bear  
 The flying chariot through the field of air.  
 —Predicting the uses of steam power.  
*The Botanic Garden* (1791)

Darwin was born at Elston in England. He studied medicine at the universities of Cambridge and Edinburgh, obtaining his MB from Cambridge in 1755. Darwin set up practice in Lichfield, where he soon established a reputation such that George III asked him to move to London to become his personal physician – an offer Darwin declined. He remained in Lichfield and founded, with friends, the Lunar Society of Birmingham – so called because of the monthly meetings held at members' houses. It included such eminent men as Joseph PRIESTLEY, Josiah Wedgwood, James WATT, and Matthew BOULTON.

Darwin was something of an inventor, but is best remembered for his scientific writings,

which often appeared in verse form. These were generally well received until the politician George Canning produced a very damaging parody of his work. This was part of a general campaign by the government against the Lunar Society for its support of the French and American revolutions and its denouncement of slavery.

In his work *Zoonomia* (1794–96), Darwin advanced an evolutionary theory stating that changes in an organism are caused by the direct influence of the environment, a proposal similar to that put forward by Jean Baptiste LAMARCK some 15 years later.

Darwin was the grandfather, by his first wife, of Charles Robert Darwin and, by his second wife, of Francis GALTON.

**Darwin, Sir George Howard** (1845–1912) *British astronomer and geophysicist*

I appeal ... for mercy to the applied mathematician ... If our methods are often wanting in elegance and do but little to satisfy that aesthetic sense of which I spoke before, yet they constitute honest attempts to unravel the secrets of the universe in which we live.  
—Speech to the Fifth International Congress of Mathematicians, 1912

Darwin, the second son of the famous biologist Charles Darwin, was born at Down in England. He was educated at Clapham Grammar School, where the astronomer Charles PRITCHARD was headmaster, and Cambridge University. He became a fellow in 1868 and, in 1883, Plumian Professor of Astronomy, a post he held until his death. He was knighted in 1905.

His most significant work was on the evolution of the Earth–Moon system. His basic premise was that the effect of the tides has been to slow the Earth's rotation thus lengthening the day and to cause the Moon to recede from the Earth. He gave a mathematical analysis of the consequences of this, extrapolating into both the future and the past. He argued that some 4.5 billion years ago the Moon and the Earth would have been very close, with a day being less than five hours. Before this time the two bodies would actually have been one, with the Moon residing in what is now the Pacific Ocean. The Moon would have been torn away from the Earth by powerful solar tides that would have deformed the Earth every 2.5 hours.

Darwin's theory, worked out in collaboration with Osmond Fisher in 1879, explains both the low density of the Moon as being a part of the Earth's mantle, and also the absence of a granite layer on the Pacific floor. However, the theory is not widely accepted by astronomers. It runs against the Roche limit, which claims that no satellite can come closer than 2.44 times the planet's radius without breaking up; there are also problems with angular momentum. Astronomers today favor the view that

the Moon has formed by processes of condensation and accretion. Whatever its faults, Darwin's theory is important as being the first real attempt to work out a cosmology on the principles of mathematical physics.

**Daubrée, Gabriel Auguste** (1814–1896) *French geologist*

Daubrée (doh-bray), who was born at Metz in France, was educated at the University of Strasbourg. After investigating the tin mines of England he was employed, in 1838, as an engineer for Bas-Rhin and prepared a geological map of the area (1840–48). He was then appointed professor of geology at the University of Strasbourg, becoming professor of geology at the Museum of Natural History, Paris, in 1861. Finally, in 1862 he became director of the Imperial School of Mines.

Daubrée was a pioneer of experimental geology, publishing his research in his most significant work, *Etudes synthétiques de géologie expérimentale* (1879; *Synthesis Studies on Experimental Geology*), in which he tried to show that an understanding of geochemical processes can be attained by reproducing them in the laboratory. In particular he worked on the effect that heating water at great depths in the Earth would have on the production of metamorphic rocks.

Daubrée also built up an extensive collection of meteorites and published his findings in *Météorites et la constitution géologique du globe* (1886; *Meteorites and the Geological Constitution of the World*). He concluded from his study of the composition of meteorites that the Earth has an iron core.

**Dausset, Jean** (1916– ) *French physician and immunologist*

Dausset (doh-say), the son of a doctor from Toulouse in southern France, gained his MD from the University of Paris in 1945 following wartime service in the blood transfusion unit. He was professor of hematology at the University of Paris from 1958 and professor of immunohematology from 1968. He was professor of experimental medicine at the Collège de France from 1977 to 1987 and is currently professor of medical genetics at the University of Paris.

Dausset's war experience stimulated his interest in transfusion reactions, and in 1951 he showed that the blood of certain universal donors (those of blood group O), which had been assumed safe to use in all transfusions, could nonetheless be dangerous. This was because of the presence of strong immune antibodies in their plasma, which develop following antidiptheria and antitetanus injections. Donor blood is now systematically tested for such antibodies.

In the 1950s Dausset noticed a peculiar feature in the histories of patients who had received a number of blood transfusions: they developed a low white blood cell (leukocyte) count. He suspected that the blood transfused could well have contained antigens that stimulated the production of antibodies against the leukocytes. With insight and considerable courage Dausset went on to claim that the antigen on the blood cells, soon to be known as the HLA or human lymphocyte antigen, was the equivalent of the mouse H-2 system, described by George SNELL.

The significance of Dausset's work was enormous. It meant that tissues could be typed quickly and cheaply by simple blood agglutination tests as opposed to the complicated and lengthy procedure of seeing if skin grafts would take. Such work made the technically feasible operation of kidney transplantation a practical medical option, for at last the danger of rejection could be minimized by rapid, simple, and accurate tissue typing. Further confirmation of Dausset's work was obtained when the specific regions of the HLA gene complex were later identified by J. van Rood and R. Ceppellini as a single locus on human chromosome 6.

Dausset later shared the 1980 Nobel Prize for physiology or medicine with Snell and Baruj BENACERRAF.

### **Davaine, Casimir Joseph** (1812–1882) *French physician*

I congratulate myself on having often carried on your clever researches.

—Louis Pasteur, letter to Davaine (1879)

Born in St. Amand-les-Eaux, France, Davaine (da-ven) studied medicine and worked for most of his life in general practice in Paris. Around 1850 he began studying anthrax in cattle and became, arguably, the first scientist to recognize the role of a specific bacteria as the causal agent of an identifiable disease.

The rodlike organisms of anthrax were first described by Franz Pollender in 1849. Pollender found these organisms in the blood of cattle killed by anthrax but was unsure whether they were the cause or consequence of the disease. In 1863 Davaine took the crucial step of demonstrating that the disease could be transmitted to other cattle by inoculating them with the blood of diseased animals. However, if the blood was heated the disease could no longer be transmitted. Further, Davaine found, if the blood was mixed with water and the mixture allowed to stand then fluid taken from the top of the vessel proved harmless but anthrax could still be transmitted with a sample from the bottom. Such was the evidence assembled by Davaine to support the existence of disease transmitting "bactéries."

His theory, however, did not explain the well-established fact that anthrax could break out in

apparently uncontaminated areas. It was only when Robert KOCH was able to show in 1876 that the bacillus formed spores, which could exist unchanged in the soil, that the full force of Davaine's work became clear.

### **Davenport, Charles Benedict** (1866–1944) *American zoologist and geneticist*

Davenport, who was born in Stamford, Connecticut, obtained a zoology doctorate at Harvard in 1892, where he taught until 1899. From 1901 until 1904 he was curator of the Zoological Museum at the University of Chicago, and from 1904 until 1934 was director of the Carnegie Institution's Department of Genetics at Cold Spring Harbor. In 1910 Davenport founded the Eugenics Record Office, directing it until 1934.

Davenport's early studies of animal genetics, using chickens and canaries, were carried out at the turn of the century, and he was among the first to accept Gregor MENDEL's rediscovered theory of heredity. He later turned his attention to man, and in *Heredity in Relation to Eugenics* (1912) offered evidence for the inheritance of particular human traits, suggesting that the application of genetic principles to human breeding might improve the race (eugenics). From 1898 Davenport was assistant editor of the *Journal of Experimental Zoology*; he was also editor of both *Genetics* and the *Journal of Physical Anthropology*.

### **Davis, Raymond** (1914–2006) *American chemist*

Born in Washington, DC, Davis was educated at the universities of Maryland and Yale where he obtained his PhD in 1942. After serving four years in the U.S.A.A.F., Davis took the post of senior chemist at the Brookhaven National Lab, New York, and remained there until his retirement in 1984. He continued to work, however, as a research professor in the astronomy department of the University of Pennsylvania, Philadelphia.

For many years Davis, an experimentalist, worked on the detection of neutrinos emitted by the Sun. In working out the reactions that power the Sun, theorists, such as John BAHCALL, predict that a certain number of neutrinos should be produced, and that a measurable number should be detectable on Earth.

The problem is that neutrinos have a very low probability of interaction with matter. Millions of them pass unimpeded through the Earth every second. The average time lapse for an interaction of a neutrino with an atom is  $10^{36}$  seconds. To increase the probability of detecting a neutrino it was necessary to use a detector containing a large number of atoms. The result was a 100,000-gallon tank of cleaning fluid (tetrachloroethene), containing about  $10^{30}$

atoms. To exclude confusing interactions with cosmic rays Davis deposited his tank in 1969 at the bottom of the one-mile-deep Homestake Mine at Lead, South Dakota.

Davis was looking for a specific reaction. Neutrinos can react with the isotope chlorine-37 (about a quarter of chlorine atoms) converting it into the radioactive argon-37. The argon atoms could be removed at regular intervals and counted. Theory predicted that Davis should observe  $7.9 \pm 2.6$  solar neutrinos per second, otherwise known as solar neutrino units (SNU). Actually Davis began by observing about 2 SNUs, and after twenty years of continuous observation he observed no more than 2 SNUs.

Davis sought to eliminate the possibility that the anomalous results were the products of a faulty experimental design. After twenty years spent refining his work, he remained convinced that any errors were unlikely to be traced to the experiment. Further, other workers have produced very similar results. This discrepancy between theory and experiment constitutes the *solar neutrino problem*.

**Davis, William Morris (1850–1934)** *American physical geographer*

No one now regards a river and its valley as ready-made features of the earth's surface. All are convinced that rivers have come to be what they are by slow processes of natural development ...

—*National Geographic Magazine* (1889)

Davis, who was born in Philadelphia, Pennsylvania, was educated at Harvard. He returned to teach there in 1877 after a period as a meteorologist in Argentina and as an assistant with the North Pacific Survey. He became professor of physical geography in 1890 and of geology in 1898.

Davis is acknowledged as the founder of the science of geomorphology, the study of landforms. In his *The Rivers and Valleys of Pennsylvania* (1889) he first introduced what later became known as the *Davisian systems* of landscape analysis. His aim was to provide an explanatory description of how landforms change in an ideal situation and his most important contribution to this was his introduction of the "cycle of erosion" into geographical thought.

He proposed a complete cycle of youth, maturity, and old age to describe the evolution of a landscape. In youth rivers occupy steep V-shaped valleys while in old age the valleys are broad. The end product would be a flat featureless plain he called a "peneplain." This was an ideal cycle but in practice the cycle would invariably be interrupted by Earth movements. It was, nevertheless, strongly attacked by German geographers, who objected to it on the grounds that it neglected such vital factors as weathering and climate in transforming the

landscape. They also believed him to be undermining their argument that landforms could only be discovered by local fieldwork and the production of regional monographs.

Davis also produced an influential work, *Elementary Meteorology* (1894), which was used as a textbook for over 30 years, and, in 1928, published *The Coral Reef Problem*.

**Davisson, Clinton Joseph (1881–1958)** *American physicist*

Davisson, who was born in Bloomington, Illinois, was educated at the University of Chicago and at Princeton, where he obtained his PhD in 1911. After working for a short period at the Carnegie Institute of Technology, Pittsburgh, Davisson joined the Bell Telephone Laboratory (then Western Electric) in 1917 and remained there until his retirement in 1946.

Davisson began his work by investigating the emission of electrons from a platinum oxide surface under bombardment by positive ions. He moved from this to studying the effect of electron bombardment on surfaces, and observed (1925) the angle of reflection could depend on crystal orientation. Following Louis de BROGLIE's theory of the wave nature of particles, he realized that his results could be due to diffraction of electrons by the pattern of atoms on the crystal surface.

In 1927 he performed a classic experiment with Lester GERMER in which a beam of electrons of known momentum ( $p$ ) was directed at an angle onto a nickel surface. The angles of reflected (diffracted) electrons were measured and the results were in agreement with de Broglie's equation for the electron wavelength ( $\lambda = h/p$ ). In 1937 he shared the Nobel Prize for physics with George THOMSON for "their experimental discovery of the diffraction of electrons by crystals."

**Davy, Sir Humphry (1778–1829)** *British chemist*

Sir Humphrey Davy  
Abominated gravy.

He lived in the odium

Of having discovered sodium.

—Edmund Clerihew Bentley, *Biography for Beginners* (1905)

The progression of physical science is much more connected with your prosperity than is usually imagined. You owe to experimental philosophy some of the most important and peculiar of your advantages. It is not by foreign conquests chiefly that you are become great, but by a conquest of nature in your own country.

—Lecture at the Royal Institution (1809)

The son of a small landowner and wood-carver, Davy went to school in his native town of Penzance and in Truro. At the age of 17 he was apprenticed to an apothecary and surgeon with a

view to qualifying in medicine. He was self-reliant and inquisitive from an early age and taught himself chemistry from textbooks. In 1798 he was appointed to Thomas BEDDOES's Pneumatic Institute at Clifton, Bristol, to investigate the medicinal properties of gases. Davy's first papers were published by Beddoes in 1799. In one he concluded, independently of Count RUMFORD, that heat was a form of motion; the other contained some fanciful speculations on oxygen, which he called phosoxygen. Davy soon discovered the inebriating effect of nitrous oxide and his paper *Researches, Chemical and Philosophical; chiefly concerning Nitrous Oxide* (1800), and the subsequent fashion for taking the "airs," made him famous. At Clifton he met many eminent people, including the poets William Wordsworth, Samuel Taylor Coleridge, and Robert Southey (Davy was himself a Romantic poet), and his flirtation with fashionable society began.

In 1801 Davy moved to London, to the Royal Institution, where his lectures were spectacularly successful. At Clifton he had begun to experiment in electrochemistry, following William NICHOLSON's electrolysis of water, and this was to prove his most fruitful field. In the early years at the Royal Institution, however, he did much work of an applied nature, for example on tanning and on agricultural chemistry. In his 1806 Bakerian Lecture to the Royal Society he predicted that electricity would be capable of resolving compounds into their elements and in the following year he was able to announce the isolation of potassium and sodium from potash and soda. This result cast doubts on Antoine LAVOISIER's oxygen theory of acidity. Davy was essentially a speculative and manipulative chemist, not a theorist, and he reasoned incorrectly that ammonia (because of its alkaline properties), and hence nitrogen, might contain oxygen. He remained skeptical about the elementary nature of bodies for many years and tried to show that sulfur and phosphorus contained hydrogen.

Davy's work in the years immediately following the discovery of sodium was hindered by his social success and competition for priority with the French chemists Joseph GAY-LUSSAC and Louis Thenard. He prepared boron, calcium, barium, and strontium by electrolysis but his priority was disputed. In 1810 he published a paper on chlorine, which established that it contained no oxygen – another blow against the oxygen theory of acidity – and was in fact an element. The name "chlorine" was proposed by Davy.

In 1812 Davy was knighted, married a wealthy widow, and published his book *Elements of Chemical Philosophy*. In 1813 he appointed Michael FARADAY as his assistant and the Davys and Faraday visited France. Working in Michel CHEVREUL's laboratory, he established that iodine, discovered two years before by

Bernard COURTOIS, was an element similar in many properties to but heavier than chlorine. On his return to England, Davy was commissioned to investigate the problem of firedamp (methane) explosions in mines. In 1816, only six months after beginning the investigation, he produced the famous safety lamp, the *Davy lamp*, in which the flame was surrounded by a wire gauze. Davy became president of the Royal Society in 1820 and the rest of his life was much taken up by traveling on the Continent. Despite his successes there is something incomplete about his life. He never accepted the atomic theory of DALTON, his great contemporary. He had in fact more in common with his Romantic poet friends than he did with Dalton. Jöns BERZELIUS said of him that his work consisted of "brilliant fragments."

### **Dawes, William Rutter** (1799–1868) *British astronomer*

Dawes's father was an astronomer, often on colonial service, and later taught mathematics in a London school. Dawes, who was born in London, was originally intended for the Church but finding the views of the established church uncongenial, studied medicine at St. Bartholomew's Hospital, London, instead. He practiced for some time in Berkshire and in 1826 went to Liverpool where he was persuaded to exchange medicine for the post of a Dissenting minister in Ormskirk, Lancashire.

It was in Ormskirk that Dawes took up the serious study of astronomy in 1829. He built his own observatory and equipped it with a Dollond refractor. In 1839 Dawes moved to London to take charge of George Bishop's observatory in Regent's Park. Bishop had made a fortune in the wine trade and hoped to gain recognition by sponsoring some important discovery in his observatory. A second marriage to a wealthy widow in 1842 allowed Dawes to leave the somewhat disagreeable service of Bishop in 1844 and, despite persistent ill health, to devote himself to his own private astronomical researches first in Kent at Cranbrook and Maidstone and after 1857 at Haddenham in Buckinghamshire.

Dawes, the keenest of observers, worked for many years on double stars. During his Ormskirk period he published details on over 200 of them. Basic data on a further 250 were published in 1852 in Bishop's *Astronomical Observations at South Villa*. In November 1850 he narrowly missed an important discovery when he reported that while observing Saturn's rings he noted in the ansa, that part visible at the side of the planet and sticking out like a handle, "a light ... at both ends." Dawes had in fact observed the faint inner "crepe ring" of Saturn, Ring C, but had been narrowly anticipated in this by the American astronomer William C. BOND.

**Dawkins, Richard** (1941– ) *British ethologist*

We are survival machines – robot vehicles blindly programmed to preserve the selfish molecules known as genes. This is a truth which still fills me with astonishment.  
—*The Selfish Gene* (1976)

Dawkins was educated at Oxford University where he worked for his doctorate under Nicolaas TINBERGEN. He initially taught at the University of California, Berkeley, before returning to Oxford in 1970 as lecturer in animal behavior. He was appointed reader in zoology in 1989. In 1995 he was awarded the Charles Simonyi Chair for the Public Understanding of Science.

In *The Selfish Gene* (1976) Dawkins did much to introduce the work of such scholars as William Hamilton, Robert L. Trivers, and John MAYNARD SMITH to a wider public. He tried to show that such apparently altruistic behavior as birds risking their lives to warn the flock of an approaching predator can be seen as the “selfish” gene ensuring its own survival (by ensuring the survival of the descendants and relatives of the “heroic” bird) – indeed that such behavior is as relentlessly under the control of the selfish gene as the compulsive rutting of the dominant stag. The work was immensely successful, being translated into eleven languages and selling 150,000 copies in English alone. *The Extended Phenotype* (1982) is a further work on evolutionary theory.

In 1986 Dawkins published another successful work, *The Blind Watchmaker*. The title refers to the image used by William Paley in his *Natural Theology* (1802). If anyone were to find a watch he would be able to infer from its mechanism that it had a maker; equally with nature, where the mechanisms of hand, eye, heart, and brain demand the existence of a designer just as strongly. Dawkins accepted the argument but insisted that the watchmaker was merely the operation of natural selection. In case after case he argued that the same effects could be produced by natural selection a good deal more plausibly than by a divine watchmaker.

One of the most original features of Dawkins’s work was his demonstration that with few simple recursive rules, and some very simple starting points, various complex life forms or biomorphs were produced on his computer screen. And, he emphasized, the biomorphs were produced not by Dawkins as designer (he was as surprised as anyone else by the outcome) but by the application of simple rules to a large number of apparently random initial positions.

In 1993 in an essay *Viruses of the Mind* he introduced the idea of a “mental virus” analogous to biological and computer viruses. He argues that religious belief is a mental virus.

Dawkins has continued to write on evolutionary theory in *River out of Eden* (1995) and

most notably in his *Climbing Mount Improbable* (1996), where he shows how such unlikely candidates as a spider’s web and the vertebrate eye can have evolved under the guiding power of natural selection.

Dawkins is a noted atheist and campaigner against religious extremism in television programs, radio programs, lectures, and through his website. In 2006 he published *The God Delusion* openly attacking religion. In 2006 he also founded The Richard Dawkins Foundation for Reason and Science.

**Day, David Talbot** (1859–1925) *American chemist*

Day was born in East Rockport, Ohio, and educated at Johns Hopkins University, gaining his PhD in 1884. He started his career as a demonstrator in chemistry at the University of Maryland but left to become head of the Mineral Resources Division of the U.S. Geological Survey in 1886.

Day investigated the reasons for the differences found in the composition of various petroleum deposits and concluded that percolation through mineral deposits affected the nature of the underlying petroleum. His experiments, in which he ran crude petroleum through fuller’s earth, anticipated the later development of adsorption chromatography by Mikhail TSVET.

Day did much to stimulate the growth of the petroleum industry and in 1922 produced one of its basic texts, *Handbook of the Petroleum Industry*. From 1914 to 1920 he was a consultant chemist with the Bureau of Mines.

**Deacon, Henry** (1822–1876) *British industrial chemist*

Deacon, a Londoner, started his career as an apprentice with an engineering firm at the age of 14. He later joined the firm of NASMYTH and GASKELL, near Manchester, before joining Pilkington’s glassworks at St. Helens. There he introduced, in 1844, a new method for grinding and smoothing glass. Leaving the glassworks in 1851, Deacon went into partnership with the younger William Pilkington in 1853 to manufacture alkali at Widnes.

Deacon made a significant improvement in the LEBLANC process for producing alkali, using one of its by-products, hydrochloric acid, to produce chlorine. William GOSSAGE had introduced his tower to condense and collect the toxic hydrochloric acid fumes in 1836. In 1870 Deacon patented his method where the hydrochloric acid was passed over clay balls soaked in copper chloride, which, in air, oxidized the acid, yielding chlorine. The chlorine was used in making bleaching powder for the textiles industry. The process was supplanted by an alternative method of converting the hydrochloric

acid into chlorine introduced by Walter WELDON (1866–69).

**de Bary, Heinrich Anton** (1831–1888)  
*German botanist*

De Bary (de bah-ree), who was born in Frankfurt am Main in Germany, gained his medical degree from Berlin in 1853 and practiced briefly in Frankfurt before devoting all his time to botany. He became *Privatdozent* (nonstipendiary lecturer) in botany at Tübingen and then professor of botany, first at Freiburg im Breisgau (1855), then Halle (1867), and finally Strassburg (1872), where he remained until his death.

When de Bary began working on fungi some people still believed in the spontaneous generation of fungi, and the general ignorance of fungal life cycles severely impeded the development of intelligent control measures against fungal epidemics of crops. De Bary's first mycological publication, *Researches on Fungal Blights* (1853), dealt with the rust and smut diseases of plants and maintained that fungi are the cause, and not the effect, of these diseases. In 1865 he demonstrated that the fungus that causes stem rust of wheat, *Puccinia graminis*, needs two hosts – wheat and barberry – to complete its life cycle. De Bary showed in 1866 that individual lichens consist of a fungus and an alga in intimate association and in 1879 he introduced the term “symbiosis” to describe mutually advantageous partnerships between dissimilar organisms.

De Bary's work was instrumental in encouraging a more developmental approach to mycology and his research on host–parasite interactions greatly helped in the fight against plant diseases.

**De Beer, Sir Gavin Rylands** (1899–1972)  
*British zoologist*

Born in London, De Beer graduated from Oxford University, where he was a fellow from 1923 to 1938. He served in both World Wars; during World War II he landed in Normandy in 1944, where he was in charge of psychological warfare. He was professor of embryology at University College, London, 1945–50, and then director of the British Museum (Natural History) in London (1950–60).

In an early publication, *Introduction to Experimental Biology* (1926), de Beer finally disproved the germ-layer theory. Embryological investigations had indicated that vertebrate structures such as cartilage and certain bone cells were formed from the ectoderm, or outer layer of the embryo, and not, as was previously thought, from the mesoderm. As this goes against the germ-layer theory, orthodox embryologists argued that the experimental manipulations involved in such work altered the

normal course of development. De Beer's contribution was to find a system that does not involve such manipulations so establishing the validity of earlier work.

De Beer also did work to show that adult animals retain some of the juvenile characters of their evolutionary ancestors (*pedomorphosis*), thus refuting Ernst HAECKEL's theory of recapitulation. He suggested that gaps in the evolutionary development of animals may be accounted for by the impermanence of the soft tissues of young ancestors. Studies of *Archeopteryx*, the earliest known bird, led him to propose piecemeal evolutionary changes in such animals, thus explaining the combination of reptilian and avian characters (e.g., teeth and feathers). De Beer also carried out research into the functions of the pituitary gland. In the field of ancient history, de Beer applied scientific methods to various problems, for example, the origin of the Etruscans and Hannibal's journey across the Alps. His other books include *Embryology and Evolution of Chordate Animals* (1962, with Julian Huxley), *The Elements of Experimental Embryology* (1962), and a biography of Charles DARWIN (1961). He was knighted in 1954.

**Debierne, André Louis** (1874–1949)  
*French chemist*

Born in Paris, France, Debierne (de-byairn) was educated at the Ecole de Physique et Chemie. After graduation he worked at the Sorbonne and as an assistant to Pierre and Marie CURIE, finally succeeding the latter as director of the Radium Institute. On his retirement in 1949 he in turn was succeeded by Marie Curie's daughter, Irène JOLIOT-CURIE.

Debierne was principally a radiochemist; his first triumph came in 1900 with the discovery of a new radioactive element, actinium, which he isolated while working with pitchblende. In 1905 he went on to show that actinium, like radium, formed helium. This was of some significance in helping Ernest RUTHERFORD to appreciate that some radioactive elements decay by emitting an alpha particle (or, as it turned out to be, the nucleus of a helium atom). In 1910, in collaboration with Marie Curie, he isolated pure metallic radium.

**de Broglie, Prince Louis Victor Pierre Raymond** (1892–1987) *French physicist*

De Broglie (de broh-glee) was descended from a French family ennobled by Louis XIV. He was born in Dieppe, France, and educated at the Sorbonne. Originally a historian, he became interested in science in World War I when he was posted to the Eiffel Tower as a member of a signals unit. He pursued this interest after the war and finally obtained his doctorate in physics from the Sorbonne in 1924. He taught

there from 1926, serving as professor of theoretical physics at the newly founded Henri Poincaré Institute (1928–62).

De Broglie is famous for his theory that particles (matter) can have wavelike properties. At the start of the 20th century physicists explained phenomena in terms of particles (such as the electron or proton) and electromagnetic radiation (light, ultraviolet radiation, etc.). Particles were “matter” – conceived as discrete entities forming atoms and molecules; electromagnetic radiation was a wave motion involving changing electric and magnetic fields.

In 1905 two papers by Albert EINSTEIN began a change in this conventional view of the physical world. His work on the special theory of relativity led to the idea that matter is itself a form of energy. More specifically he explained the photoelectric effect by the concept that electromagnetic radiation (a wave) can also behave as particles (photons). Later, in 1923, Arthur COMPTON produced further evidence for this view in explaining the scattering of x-rays by electrons.

In 1924 de Broglie, influenced by Einstein’s work, put forward the converse idea – that just as waves can behave as particles, particles can also behave as waves. He proposed that an electron, for instance, can behave as if it were a wave motion (a *de Broglie wave*) with wavelength  $h/p$ , where  $p$  is the momentum of the electron and  $h$  is PLANCK’s constant. This revolutionary theory was put forward in de Broglie’s doctoral thesis. Experimental support for it was obtained independently by George THOMSON and by Clinton J. DAVISSON and the wavelike behavior of particles was used by Erwin SCHRÖDINGER in his formulation of wave mechanics.

The fact that particles can behave as waves, and vice versa, is known as wave–particle duality and has caused intense debate as to the “real” nature of particles and electromagnetic radiation. De Broglie took the view that there is a true deterministic physical process underlying quantum mechanics – i.e., that the current indeterminate approach in terms of probability can be replaced by a more fundamental theory. He based his ideas on the concept of particles that are concentrations of energy guided through space by a real wave and exchanging energy with a “subquantum medium.”

De Broglie received the 1929 Nobel Prize for physics for his “discovery of the wave nature of the electron.”

**Debye, Peter Joseph William** (1884–1966) *Dutch–American physicist and physical chemist*

Only experiments can decide ...

—*Notes on Magnetization at Low Temperatures* (1926)

Born at Maastricht in the Netherlands, Debye (de-**bi**) studied electrical engineering at Aachen and gained his PhD at Munich in 1910. He held chairs of physics at Zurich (1911–12 and 1919–27), Utrecht (1912–14), Göttingen (1914–19), and Leipzig. He was director of the Kaiser Wilhelm Institute for Theoretical Physics (1935–40) before emigrating to America where he was professor of chemistry at Cornell (1940–50).

Debye was essentially a theoretician and most of his work, although varied, had a common theme: the application of physical methods to problems of molecular structure. An early work was the derivation of a relation governing the change of the specific heat capacity of solids with temperature. In 1915 he gave a theoretical treatment of electron diffraction by gases, not realized in practice until 1930. At Göttingen, Debye and P. Scherrer discovered a method of producing x-ray diffraction patterns from powders. This was later extended to the production of diffraction patterns from simple molecules such as  $\text{CCl}_4$  (1928).

A major part of Debye’s work was devoted to dipole moments, beginning in 1912. He used these to determine the degree of polarity of covalent bonds and to determine bond angles. Together with his x-ray work and results from rotational spectra, this enabled the precise spatial configuration of small molecules to be deduced. For example, the planarity of the benzene molecule was confirmed by dipole moment measurements. Debye is probably better known, however, for the *Debye–Hückel theory* of electrolytes (1923). This was a theory that could be applied to concentrated solutions of ionic compounds, and was a great advance on the theories of the time, which applied only to very dilute solutions. The Debye–Hückel theory takes account of the fact that an ion in solution tends to attract other ions of opposite charge.

**Dedekind, (Julius Wilhelm) Richard** (1831–1916) *German mathematician*

For what I have accomplished and what I have become, I have to thank my ... indefatigable working rather than any outstanding talent.

—Quoted by Hans Zincke in *Richard Dedekind Recalled* (1916)

The son of an academic lawyer from Braunschweig, Germany, Dedekind (**day**-de-kint) was educated at the Caroline College there and at Göttingen, where he gained his doctorate in 1852. After four years spent teaching at Göttingen, he was appointed professor of mathematics at the Zurich Polytechnic. In 1862 he returned to Braunschweig to the Technical High School where he remained until his retirement in 1912.

In 1872 Dedekind published his most important work *Stetigkeit und Irrationale Zahlen* (Continuity and Irrational Numbers) in which

he provided a rigorous definition of the irrational numbers. He began by “cutting” or dividing the rational numbers into two nonempty disjoint sets  $A$  and  $B$  such that if  $x$  belongs to  $A$  and  $y$  to  $B$ , then  $x < y$ . If  $A$  has a greatest member  $A'$  then  $A'$  is a rational number; if  $B$  has a smallest number  $B'$  then  $B'$  will also be a rational number. But if  $A$  has no greatest number and  $B$  no smallest, then the cut defines an irrational number.

In the same work Dedekind gave the first precise definition of an infinite set. A set is infinite, he argued, when it is “similar to a proper part of itself.” Thus the set  $N$  of natural numbers can be shown to be “similar,” that is, matched or put into a one-to-one correspondence with a proper part, in this case  $2N$ :

$N$	1	2	3	4	5	6	7	8	9	...
	↓	↓	↓	↓	↓	↓	↓	↓	↓	
$2N$	2	4	6	8	10	12	14	16	18	...

Whereas the only thing a finite set can be matched with is the set itself.

In a later work, *Was sind und was sollen die Zahlen?* (What Numbers Are and Should Be, 1888) Dedekind demonstrated how arithmetic could be derived from a set of axioms. A simpler but equivalent version, formulated by PEANO in 1889, is much better known.

### de Duve, Christian René (1917– ) *Belgian biochemist*

De Duve (de **doo**-ve) was born at Thames Ditton in southern England and educated at the Catholic University of Louvain, where he obtained his MD in 1941. After holding brief appointments at the Nobel Institute in Stockholm and at Washington University, he returned to Louvain in 1947 and was appointed professor of biochemistry in 1951. From 1962 to 1988 he held a similar appointment at Rockefeller University in New York.

In 1949 de Duve was working on the metabolism of carbohydrates in the liver of the rat. By using centrifugal fractionation techniques to separate the contents of the cell, he was able to show that the enzyme glucose-6-phosphatase is associated with the microsomes – organelles whose role was only speculative until de Duve began this work. He also noted that the process of homogenization led to the release of the enzyme acid phosphatase, the amount of which seemed to vary with the degree of damage inflicted on the cells. This suggested to de Duve that the enzyme in the cell was normally enclosed by some kind of membrane. If true, the supposition would remove a problem that had long troubled cytologists – namely how it was that such powerful enzymes did not attack the normal molecules of the cell. This question could now be answered by proposing a self-contained organelle, which neatly isolated the digestive enzymes. Confirmation

for this view came in 1955 with the identification of such a body with the aid of the electron microscope. As its role is digestive or lytic, de Duve proposed the name *lysosome*. The peroxisomes (organelles containing hydrogen peroxide in which oxidation reactions take place) were also discovered in de Duve’s laboratory.

For such discoveries de Duve shared the 1974 Nobel Prize for physiology or medicine with Albert Claude and George PALADE.

### De Forest, Lee (1873–1961) *American physicist and inventor*

The radio was conceived as a potent instrumentality for culture, fine music, the uplifting of America’s mass intelligence. You have debased this child, you have sent him out in the street in rags of ragtime, tatters of jive and boogie-woogie, to collect money from all and sundry.

—Complaining to radio executives about the quality of broadcasting

De Forest, who was born in Council Bluffs, Iowa, was interested in science from the age of 13. His father, a congregational minister, wanted him to study for the Church, but De Forest refused, going instead, in 1893, to the Sheffield Scientific School at Yale University. His PhD thesis, *Hertzian Waves from the Ends of Parallel Wires* (1899), was probably the first PhD thesis on radio in America, and drew on the work of Heinrich HERTZ and Guglielmo MARCONI. While working for the Western Electric Company in Chicago, he developed an electrolytic detector and an alternating-current transmitter.

In 1907 De Forest patented the Audion tube, a thermionic grid-triode vacuum tube that was a very sensitive receiver of electrical signals. This invention was crucial to the development of telecommunications equipment. In 1912 he had the idea of “cascading” these to amplify high-frequency radio signals, making possible the powerful signals needed for long-distance telephones and for radio broadcasting. His invention formed the basis of radio, radar, telephones, and computers until the advent of solid-state electronics.

Throughout his career De Forest pushed for the acceptance of radio broadcasting. He was not a very good business manager, however, and had to sell many of his patents. Later he worked on a sound film system that was similar to the one eventually adopted. In the 1930s he designed Audion diathermy machines for medical use and during World War II he worked on military research at the Bell Telephone Laboratories.

### De Geer, Charles (1720–1778) *Swedish entomologist*

De Geer (de yayr) was born in Finspang, Sweden, and educated in the classics at the Uni-

versity of Utrecht; he then studied under LINNAEUS at Uppsala. His extensive *Mémoires pour servir à l'histoire des insectes* (7 vols., 1752–78; Contributory Notes on the History of Insects) include excellent drawings and probably the earliest published accounts of the maternal instinct in such nonsocial insects as the earwig *Forficula auriculara* and the shield bug *Elasmucha griseus*. He also initiated a system of insect classification based on the wings and mouthparts.

**Dehmelt, Hans Georg** (1922– ) *American physicist*

Born at Gorlitz in Germany, Dehmelt (**day-melt**) left the Berlin Gymnasium in 1940 to join the German army. He was allowed for a time to study physics at Breslau University but, in 1945, he was taken prisoner by the Americans at Bastogne, Belgium. After the war he continued his education at Göttingen, gaining his PhD there in 1950. He went to America in 1952 as a postdoctoral student at Duke University, North Carolina, and remained there until 1955. He then moved to the University of Washington, Seattle, where he was appointed professor of physics in 1961, the same year he became a naturalized American citizen. He retired in 2002.

Dehmelt has worked for many years on the seemingly impossible task of imprisoning a single electron for an extended period in a suitable container. In this manner Dehmelt hoped to measure more accurately the magnetic moment ( $g$ ) of the electron. Earlier experiments by H. R. Crane at the University of Michigan had involved passing a beam of electrons through a magnetic field. But the evidence gathered in this manner necessarily involves the interactions of other electrons.

In 1955 Dehmelt began work on what later became known as a *Penning trap*. In 1973 he succeeded in isolating a single electron and went on to show (1975) how accuracy could be further improved by “cooling” the electron (i.e., decreasing its kinetic energy). In this way it proved possible to measure  $g$  with an accuracy of 4 parts in a trillion.

The Penning trap operates with a combination of electrical and magnetic fields. An electron in a uniform magnetic field cannot move across the field lines, but is able to escape by moving parallel to the field. To avoid this, an electric field is imposed upon the magnetic field. This field is produced by three electrodes – two negatively charged end traps and a positively charged encircling nickel ring.

For his work in this area Dehmelt shared the 1989 Nobel Prize for physics with Wolfgang Paul and Norman RAMSEY.

**Deisenhofer, Johann** (1943– ) *German chemist*

Deisenhofer (**dee-zen-hof-er**), who was born in Zusamaltheim, Germany, obtained his PhD from the Max Planck Institute for Biochemistry, at Martinsried near Munich, in 1974. He remained at the Institute until 1987 when he moved to America to work at the Howard Hughes Medical Institute, Dallas, Texas. He is professor of biochemistry and also professor of biomolecular science at the University of Texas.

In 1982 Hartmut MICHEL had succeeded in crystallizing the membrane proteins of the photosynthetic reaction center. Clearly, to understand how photosynthesis worked at the molecular level it would be necessary to determine the structure of these proteins, and Michel invited his colleague Deisenhofer to tackle the problem. By 1985, using the well-established techniques of x-ray crystallography, Deisenhofer's group had managed to locate the position of more than 10,000 atoms.

Deisenhofer's analysis revealed complex protein structures holding a molecular cluster containing four chlorophyll molecules, two pheophytins (molecules resembling chlorophyll), two quinones (dehydrogenizing agents), and a single iron atom. It has been possible to show how this center can transform energy from incident photons. On absorbing a photon, one of the chlorophyll molecules releases an electron. This is transferred by the pheophytins and quinones to the membrane's outer surface. At the same time, an adjoining cytochrome molecule donates an electron to one of the chlorophyll molecules and thus gains a positive charge. In this way the photon energy has been stored in the charge separation of the negative electron and the positive cytochrome. And so begins the molecular process of photosynthesis.

For this work Deisenhofer shared the 1988 Nobel Prize for chemistry with his Institute colleagues Hartmut Michel and Robert HUBER.

**De la Beche, Sir Henry Thomas** (1796–1855) *British geologist*

De la Beche (de la besh) entered the army but at the end of the Napoleonic Wars he chose to devote himself to geology instead. After traveling extensively in Europe and Jamaica on his own research work, he became, in 1835, director of the Geological Survey of Great Britain, which had been recently formed largely on his initiative. He was also instrumental in setting up the Royal School of Mines in 1851, of which he was the first principal.

He wrote extensively on the geology of southwest England and Jamaica, publishing the first account of the geology of Jamaica in 1827 and his report on the geology of Devon during the period 1832–35.

In 1834, while working in Devon, he made his most significant discovery. He observed that some rock strata contained fossil plants similar to those of the Carboniferous system, discov-

ered by William CONYBEARE in 1822, but did not contain any of the fossils of the preceding Silurian system, recently discovered by Roderick MURCHISON. The Silurian was believed to merge directly into the Carboniferous and De la Beche assumed the strata he had discovered came before the Silurian. However, William Lonsdale, librarian of the Geological Society, convincingly argued for a system, later named the Devonian, which overlay the Silurian and underlay the Carboniferous.

De la Beche wrote extensively on geology; his *A Geological Manual* (1831), *How to Observe* (1835), and *Geological Observer* (1851) were in part aimed at satisfying the growing popular interest in geology.

**Delambre, Jean Baptiste Joseph** (1749–1822) *French astronomer and mathematician*

Born in Amiens in northern France, Delambre (de-lahm-bre) was most unusual for a mathematician and astronomer in that he did not begin the serious study of his subject until he was well over 30 years old. As a student he had been interested in the classics and only turned to the exact sciences when he was 36. He published tables of Jupiter and Saturn in 1789 and of Uranus in 1792. He also measured an arc of the meridian between Dunkirk and Barcelona to establish a basis for the new metric system. He succeeded Joseph de LALANDE as professor of astronomy at the Collège de France in 1795. In his later years he devoted himself to a monumental six-volume *Histoire de l'astronomie* (1817–27; History of Astronomy).

**De la Rue, Warren** (1815–1889) *British astronomer*

Born in Guernsey, in the Channel Islands, De la Rue was the son of a printer and worked most of his life in his father's business. He was educated in Paris and studied science privately. He was initially interested in chemistry, being a friend of and working with August Hofmann, but later, at the suggestion of James NASMYTH, he took up astronomy, building a small observatory for himself.

De la Rue devoted himself to problems of photographic astronomy. He was the first to apply the collodion process (invented by Frederick Archer in 1851) to photographing the Moon. In 1852 he took some photographs that were sharper than any previously produced and that could be enlarged without blurring. Ten years later he was producing photographs that could show as much as could be seen through any telescope. In 1854 he designed the photoheliograph, a device for taking telescopic photographs of the Sun. In 1860 he used it to take dramatic photographs of prominences during the total eclipse in Spain, proving that they

were solar (and not, as had been thought, lunar) in origin. De la Rue gave up active astronomical investigation in 1873, donating his telescope to the observatory at Oxford and devoting the rest of his life to his business and to his chemical researches.

**Delbrück, Max** (1906–1981) *German-born American physicist and molecular biologist*

While the artist's communication is linked forever with its original form, that of the scientist is modified, amplified, fused with the ideas and results of others.

—*The Eighth Day of Creation*

The son of a history professor, Delbrück (del-bruuk) trained as a physicist first in his native city of Berlin, and then at Tübingen, Bonn, and Göttingen, where he completed his doctorate in 1930. After spending the period from 1931 to 1933 in Copenhagen, Delbrück was appointed to the Kaiser Wilhelm Institute for Chemistry, Berlin. He left Germany for America in 1937, working first at the California Institute of Technology and from 1940 until 1947 at Vanderbilt University, Nashville. Delbrück returned to Cal Tech in 1947 and remained there as professor of biology until his retirement in 1976. He became a naturalized American citizen in 1945.

While at Copenhagen, under the influence of Niels BOHR, Delbrück's interest was diverted from atomic physics to questions about the nature of life. In the late 1930s he began to work with bacteriophages, the viruses discovered by D'Hérelle that infect and destroy bacteria. They were relatively simple, reproduced quickly, and were easy to handle; an ideal organism, Delbrück argued, in which to study the mechanisms of replication and development.

In 1939, with E. Ellis, he first demonstrated the phenomenon of "one-step growth." Working with the phage T4 he found that "a virus particle enters a bacterial cell and after a certain period (between 13 and 40 minutes, depending on the virus, on the dot for any particular type), the bacterial cell is lysed and 100 particles are liberated." How can one particle, Delbrück asked, become 100 in a mere 20 minutes?

Soon after he began to collaborate with Salvador LURIA. In 1943 they published a paper, *Mutations of Bacteria from Virus Sensitivity to Virus Resistance*. How, they asked, do bacteria acquire resistance to lethal phage? Is it induced by contact, or does it arise from a fortunate mutation? Luria and Delbrück realized that the dynamics of bacterial growth would differ in each case. The number of resistant strains found in bacterial colonies exposed to phage should fluctuate more than if the resistance was induced. Delbrück worked out the statistics and Luria performed the experiment; the results clearly revealed that bacteria underwent mutations.

Delbrück went on to show in 1945, in collab-

oration with W. Bailey, that phage can reproduce sexually. They were working with the two viruses T2 and T4r, both of which could be bred in bacterium B. They found that:

T2 formed small colonies and attacked bacterium A.

T4r formed large colonies and attacked bacterium C.

When both T2 and T4r were bred together in B, the parent types produced two new strains:

Strain 1: formed small colonies and attacked bacterium C.

Strain 2: formed large colonies and attacked bacterium A.

Obviously, Delbrück concluded, “the parents had got together and exchanged something.”

By this time Delbrück had begun to be recognized as the leader of what became known as “the phage group.” From 1945 onwards he ran an annual summer phage course at Cold Spring Harbor Laboratory, New York, which was attended over the years by most of the leading molecular biologists of the following decade. For Delbrück himself, however, the mid-1950s seemed to be a good time to move on. He turned to the study of sensory mechanisms in the fungus *Phycomyces*. It grew towards the light, against gravity, and into the wind. How did it sense these stimuli? What range of light did it respond to? These and other questions were tackled by Delbrück and his coworkers in what was soon called “the *Phycomyces* group.” His last published paper in 1981 was in this field and proposed that the chemical photoreceptor of *Phycomyces* was a flavin and not, as had been supposed, a carotene.

For his earlier work with the phage group Delbrück shared the 1969 Nobel Prize for physiology or medicine with Salvador Luria and Alfred HERSHEY

### **D’Elhuyar, Don Fausto (1755–1833)** *Spanish chemist and mineralogist*

No city on the New Continent, not even in the United States, offers scientific establishments so vast and so solid as does the capital of Mexico. It is enough to cite here the School of Mines, of which the scholar D’Elhuyar is director.

—Alexander von Humboldt, *Political Essay on the Kingdom of New Spain* (1826)

Born in Logroño, Spain, D’Elhuyar (**del-yoo-ar**) studied mineralogy with his brother, Juan José, at the Freiberg Mining Academy under Abraham WERNER. He then studied chemistry in Paris (1772–77). He returned to Spain shortly after and was sent to Mexico in 1788 to supervise mining operations. On his return to Spain in 1821 he was made director general of mines.

The D’Elhuyar brothers working together in 1783 discovered the element tungsten (formerly also known as wolfram). Two very dense min-

erals were known to chemists in the 18th century: “tungsten” (Swedish meaning “heavy stone”) and wolframite. In 1781 Karl SCHEELÉ had discovered that “tungsten” (now known as scheelite) contained tungstic acid. The brothers proved that the same acid is present in wolframite, from which mineral they succeeded in isolating the element tungsten.

### **DeLisi, Charles (1941– )** *American biophysicist*

DeLisi (**de-lee-see**) was educated at City College, in his native New York, and at New York University, where he completed his PhD in 1969. After periods at Yale and Los Alamos, he moved, in 1975, to the National Institutes of Health, Bethesda, Maryland, as head of mathematical biology. In 1985, he moved to Washington to head the Office of Health and Environmental Research (O.H.E.R.), a part of the U.S. Department of Energy. DeLisi returned to academic life in 1988 and since 1990 he has been professor of biomedical engineering at Boston University.

While at O.H.E.R. DeLisi was concerned with the health effects of radiation. Some people, he realized, were genetically disposed to develop cancer when exposed to low levels of radiation. But, before one could spot such tendencies in any individual, it would first be necessary to know more about the human genome. As a physicist DeLisi was used to thinking in terms of large expensive projects and consequently began to consider the possibility of mapping the entire human genome. He soon heard that similar ideas had been canvassed by Robert Sinsheimer, a molecular biologist at the University of California, at a small conference in 1985 at Santa Cruz.

### **Del Rio, Andrés Manuel (1764–1849)** *Spanish mineralogist*

Del Rio (**del-ree-oh**) was born in the Spanish capital Madrid and graduated in Spain in 1781 before going on to study in France, England, and Germany, where he was a pupil of Abraham WERNER at the Freiberg Mining Academy. He had been chosen by Charles III to develop and modernize the mining industry in the Spanish empire. Consequently he was sent to Mexico City to become, in 1794, professor of mineralogy at the School of Mines set up by Fausto D’Elhuyar. While in Mexico he published the *Elementos de oritognosia* (1795; Principles of the Science of Mining), possibly the first mineralogical textbook published in the Americas. He was forced into exile in the period 1829–34 after Mexico’s war of independence but on his return he tried to reestablish the scientific tradition he had first introduced.

As a scientist he is best remembered for his independent discovery of the element vana-

dium in 1801. He had found what he took to be a new metal in some lead ore from the Mexican mines and named it “erythronium” (from the Greek *erythros*, red) as its salts turned red when ignited. However, he failed to press his claim, being persuaded by other scientists that it was probably a compound of lead and chromium. Nils Gabriel SEFSTRÖM rediscovered the metal in 1830 and named it vanadium. Its identity with Del Rio’s erythronium was demonstrated by Friedrich WÖHLER in 1831.

**De Luc, Jean André (1727–1817)** *Swiss geologist and meteorologist*

[De Luc] was probably one of the most accurate observers of nature that ever existed. —John Frederic Daniell, *Meteorological Essays and Observations* (1823)

De Luc (de look) came from an Italian family, which had moved to Switzerland from Tuscany in the 15th century; he was born in the Swiss lakeside city of Geneva. He initially concentrated on commercial activities with science as a side line but, in 1773, after the collapse of his business, he moved to England where he devoted himself to science. He was appointed as reader to Queen Charlotte, retaining that post until his death.

In a series of letters *Sur l’histoire de la terre* (On the History of the Earth) addressed to Queen Charlotte in 1779, James HUTTON in 1790, and Johann BLUMENBACH in 1798, De Luc, following in the tradition of Thomas BURNET, tried to write a history of the Earth that took account of the advances in geology yet was still compatible with the Creation as described in Genesis.

De Luc proposed that the Earth itself was old though the flood was recent. The flood was caused by a collapse of the existing lands causing their inundation by the oceans and the emergence of the present continents. As these had been the prediluvial ocean floor it was only reasonable to suppose that they should contain marine fossils. De Luc thus explained one of the puzzles facing early geologists – the presence of marine fossils in the center of continents.

De Luc opposed Hutton’s fluvial theory that such major terrestrial features as valleys are the result of the still continuing action of the rivers. He pointed out that many valleys contain no rivers, that rivers far from eroding actually deposit material, and that there seems to be no relation between the size of the river and the valley it is supposed to have created. His main objection was over downstream lakes, for in this case, when the enormous amount of material eroded from the valley is considered, De Luc argued that the lake should have been filled in long before. Hutton’s unsatisfactory answer was that such infilling does take place but that the lakes are much younger than the rivers. This issue was not finally resolved until

the crucial role of glaciation was established by Louis AGASSIZ some fifty years later.

De Luc was also a major figure in meteorological research. His two works, *Recherches sur la modification de l’atmosphère* (1772; Studies on Atmospheric Change) and *Idées sur la météorologie* (1786–87; Thoughts on Meteorology), made important suggestions for advances in instrumental design. His most important achievement was his formula, in 1791, for converting barometric readings into height, which provided the first accurate measurements of mountain heights.

**Demarçay, Eugene Anatole (1852–1904)** *French chemist*

Born in Paris, France, Demarçay (de-mar-say) was a research chemist who also maintained his own private laboratory in the city. In 1901, while working with a sample of the newly discovered element samarium (discovered by Paul Lecoq de Boisbaudran in 1879) he found traces of an additional element, europium. More dramatic, however, was his earlier work with the Curies in 1898. They had discovered one new radioactive element, polonium, early in the year. But they found further radioactivity in their sample of pitchblende after the removal of polonium. They took the small sample they had extracted to Demarçay, an expert spectroscopist, who was able to find a new line in the spectrum. This enabled the Curies to announce the existence of a much more strongly radioactive element, radium.

**Demerec, Milislav (1895–1966)** *Croatian–American geneticist*

Demerec (**dem-er-ek**) was born in Kostajnica in Croatia and graduated from the College of Agriculture in Krizevci in 1916. After a few years’ work at the Krizevci Experimental Station, he moved to America. He gained his PhD in genetics from Cornell University in 1923 and then worked at the Carnegie Institution, Cold Spring Harbor, where he remained for most of his career, becoming director in 1943.

Demerec was concerned with gene structure and function, especially the effect of mutations. He found that certain unstable genes are more likely to mutate than others and that the rate of mutation is affected by various biological factors, such as the stage in the life cycle. He also demonstrated that chromosome segments that break away and rejoin in the wrong place may cause suppression of genes near the new region of attachment. This lent additional support to the idea of the “position effect,” first demonstrated by Alfred STURTEVANT.

Demerec’s work with the bacterium *Salmonella* revealed that genes controlling related functions are grouped together on the chromosome rather than being randomly distributed

through the chromosome complement. Such units were later termed “operons.” His radiation treatment of the fungus *Penicillium* yielded a mutant strain producing much larger quantities of penicillin – a discovery of great use in World War II. He showed that antibiotics should be administered initially in large doses, so that resistant mutations do not develop, and should be given in combinations, because any bacterium resistant to one is most unlikely to have resistance to both.

Demerec greatly increased the reputation of Cold Spring Harbor while director there and also served on many important committees. He founded the journal *Advances in Genetics* and wrote some 200 scientific articles.

**Democritus of Abdera** (c. 460 BC–c. 370 BC) *Greek philosopher*

Everything existing in the Universe is the fruit of chance and necessity.

—Quoted by Diogenes Laertius (3rd century)

Democritus (de-**mok**-ri-tus) was reputedly a prolific author but only fragments of his work still exist and little is known about his life. He is believed to have been born a wealthy citizen of Abdera and to have traveled in Egypt and Persia. He wrote on many subjects, and was reputedly the most learned man of his time.

Democritus is best known for his atomic theory. Despite the fact that LEUCIPPUS is generally regarded as the originator of the atomic theory, and the difficulty in separating Democritus’s contribution from that of the later EPICURUS and LUCRETIUS, Democritus was acknowledged by ARISTOTLE (the principle source for Democritus’s ideas) to be the leading exponent of the theory. In the “classical” atomic theory, coming into being and dissolution were explained by the linking and flying apart of small hard indestructible particles. Conservation of matter was recognized (“nothing is created out of nothing”) and the important doctrine of primary and secondary qualities (later taken up by GALILEO and John Locke) was enunciated by Democritus in the memorable aphorism: “Ostensibly there are sweet and bitter, hot and cold, and color; in reality only atoms and the void.” The primary qualities were size, shape, and position. Whether or not Democritus attributed weight to atoms is controversial. The theory was deterministic in that the atomic interactions were thought to be ordered by “necessity.” Atomism was ignored from the time of Aristotle until the mid-17th century when it was reintroduced by Pierre GASSENDI and Galileo.

**De Moivre, Abraham** (1667–1754) *French mathematician*

The manner of his [De Moivre’s] death has a certain interest for psychologists. Shortly before it he declared that it was necessary for

him to sleep some ten minutes or quarter of an hour longer each day than the preceding one. The day after he had thus reached a total of something over twenty-three hours he slept up to the limit of twenty-four hours, and then died in his sleep.

—W. W. Rouse Ball, *A Short Account of the History of Mathematics*

Although born at Vitry in France, as a Huguenot De Moivre (de **mwah**-vre) was forced to flee to England to escape the religious persecution that flared up in 1685 after the revocation of the Edict of Nantes. In England he came to know both Isaac NEWTON and Edmond HALLEY, eventually becoming a fellow of the Royal Society of London himself in 1697.

De Moivre made important contributions to mathematics in the fields of probability and trigonometry. His interest in probability was no doubt stimulated by the fact that despite his abilities he was unable to find a permanent post as a mathematician and so was forced to earn his living by, among other things, gambling. De Moivre was the first to define the concept of statistical independence and to introduce analytical techniques into probability. His work on this was published in *The Doctrine of Chances* (1718), later followed by *Miscellanea analytica* (1730; Analytical Miscellany). De Moivre also introduced the use of complex numbers into trigonometry. *De Moivre’s theorem* is the relationship  $(\cos A + i \sin A)^n = \cos nA + i \sin nA$ .

**Dempster, Arthur Jeffrey** (1886–1950) *Canadian-American physicist*

Dempster was born in Toronto, Ontario, in Canada and educated at the university there. He emigrated to America in 1914, attended the University of Chicago, obtained his PhD in 1916, and began teaching in 1919. In 1927, he was made professor of physics.

He is noted for his early developments of and work with the mass spectrograph (invented by Francis W. Aston). In 1935, he was able to show that uranium did not consist solely of the isotope uranium–238, for seven out of every thousand uranium atoms were in fact uranium–235. It was this isotope,  $^{235}\text{U}$ , that was later predicted by Niels BOHR to be capable of sustaining a chain reaction that could release large amounts of atomic fission energy.

**Derham, William** (1657–1735) *British physicist*

Let us ransack all the globe, let us with the greatest accuracy inspect every part thereof, search out the innermost secrets of any of the creatures; let us examine them with all our gauges ... pry into them with all our microscopes and most exquisite instruments, till we find them to bear testimony to their infinite workman.

—*Physico-theology* (1713)

Born at Stoughton in Worcestershire, England, and educated at Trinity College, Oxford, Derham was ordained in 1682. He was appointed to the living of Upminster where he remained for the rest of his life.

Derham is best known for his attempt to measure the speed of sound. Marin MERSENNE in 1640 had claimed a value of 1,038 feet per second while NEWTON, in the first edition of *Principia* (1687), had calculated it to be 968 feet per second. In 1705 Derham observed from the tower of his Upminster church the flash of cannons being fired 12 miles away across the Thames at Blackheath. By timing the interval between the flash and roar of the cannon he was able to calculate the speed of sound to be 1,142 feet per second, a result in good agreement with the 1,130 feet per second at 20°C given in modern textbooks. In the second edition of his *Principia* (1713), Newton revised his calculation in the light of Derham's published results.

Derham was also the author of two immensely popular works: *Physico-theology* (1713) and *Astro-theology* (1715). Based on his BOYLE lectures, they set out to show that the basic facts of Newtonian mechanics and cosmology were convincing evidence for the "being and attributes of God."

Also known as an editor, Derham published a number of posthumous works of John RAY as well as *The Philosophical Experiments* (1726) of Robert HOOKE.

### Desaguliers, John Theophilus (1683–1744) *French–English physicist*

Desaguliers (day-sa-goo-lyay) was born into a Huguenot family in La Rochelle, France. The family was forced by religious persecution to flee to England; John began giving popular lectures on science and its applications in Oxford in 1710. In 1713 he moved to London where he continued to lecture and became experimental assistant to Isaac NEWTON until Newton's death in 1727. He is important in spreading Newtonian theory both in England and on the Continent. He was also an experimenter – particularly on the flow of electricity, being the first to use the terms "conductor" and "insulator" – and an inventor, improving the design of Thomas SAVERY's steam engine by adding a safety valve and an internal water jet.

### Desargues, Girard (1591–1661) *French mathematician and engineer*

Little is known of the early life of Desargues (day-zarg) except that he was born in Lyons in France. He did serve as an engineer at the siege of La Rochelle (1628) and later became a technical adviser to Cardinal de Richelieu and the French government. He is said to have known René DESCARTES.

Around 1630 Desargues joined a group of mathematicians in Paris and concentrated on geometry. In his most famous work, *Brouillon projet d'une atteinte aux événements des rencontres d'une cône avec un plan* (1639; Proposed Draft of an Attempt to Deal with the Events of the Meeting of a Cone with a Plane), he applied projective geometry to conic sections. *Desargues's theorem* states that if the corresponding points of two triangles in nonparallel planes in space are joined by three lines that intersect at a single point, then the pairs of lines that are the extensions of corresponding sides will each intersect on the same line. Blaise PASCAL was greatly influenced by Desargues, whose contribution to projective geometry was not recognized until a handwritten copy of his work was found in 1845. This oversight probably arose because he used obscure botanical symbols instead of the better-known Cartesian symbolism.

### Descartes, René du Perron (1596–1650) *French mathematician, philosopher, and scientist*

*Cogito, ergo sum.* (I think, therefore I am.)

—*Discours de la méthode* (1637; Discourse on Method)

It is contrary to reason to say that there is a vacuum or space in which there is absolutely nothing.

—*Principia philosophiae* (1644; Principles of Philosophy)

Descartes (day-kart) was the son of a counselor of the Brittany *parlement*; his mother, who died shortly after his birth, left him sufficient funds to make him financially independent. Born at La Haye in France, he was educated by the Jesuits of La Flèche (1604–12) and at the University of Poitiers, where he graduated in law in 1616. For the next decade Descartes spent much of his time in travel throughout Europe and in military service, first with the army of the Prince of Orange, Maurice of Nassau, and later with the Duke of Bavaria, Maximilian, with whom he was present at the battle of the White Mountain outside Prague in 1620. In the years 1628–49 Descartes settled in the freer atmosphere of Holland. There, living quietly, he worked on the exposition and development of his system. Somewhat unwisely, he allowed himself to be enticed into the personal service of Queen Christina of Sweden in Stockholm in 1649. Forced to indulge the Queen's passion for philosophy by holding tutorials with her at 5 a.m. on icy Swedish mornings Descartes, who normally loved to lie thinking in a warm bed, died within a year from pneumonia and the copious bleeding inflicted by the enthusiastic Swedish doctors.

Descartes is in many ways, in mathematics, philosophy, and science, the first of the moderns. The moment of modernity can be dated

precisely to 10 November 1619, when, as later described in his *Discours de la méthode* (1637; Discourse on Method), he spent the whole day in seclusion in a *poêle* (an overheated room). He began systematically to doubt all supposed knowledge and resolved to accept only “what was presented to my mind so clearly and distinctly as to exclude all ground of doubt.”

Descartes thus managed to pose in a single night the problem whose solution would obsess philosophers for the next 300 years. The same night also provided him with one of the basic insights of modern mathematics – that the position of a point can be uniquely defined by coordinates locating its distance from a fixed point in the direction of two or more straight lines. This was revealed in his *La Géométrie* (1637; Geometry), published as an appendix to his *Discourse*, and describing the invention of analytic or coordinate geometry, by which the geometric properties of curves and figures could be written as and investigated by algebraic equations. The system is known as a *Cartesian coordinate system*.

His theories on physics were published in his *Principia philosophiae* (1644; Principles of Philosophy). “Give me matter and motion and I will construct the universe,” Descartes had proclaimed. The difficulty for him arose from his account of matter which, on metaphysical grounds, he argued, “does not at all consist in hardness, or gravity or color or that which is sensible in another manner, but alone in length, width, and depth,” or, in other words, extension. From this initial handicap Descartes was forced to deny the existence of the void and face such apparently intractable problems as how bodies of the same extension could possess different weights. With such restrictions he was led to describe the universe as a system of vortices. Matter came in three forms – ordinary matter opaque to light, the ether of the heavens transmitting light, and the subtle particles of light itself. With considerable ingenuity and precious little concern for reality Descartes used such a framework within which he was able to deal with the basic phenomena of light, heat, and motion. Despite its initial difficulties it was developed by a generation of Cartesian disciples to pose as a viable alternative to the mechanics worked out later in the century by NEWTON. Unlike many less radical thinkers Descartes did not shrink from applying his mechanical principles to physiology, seeing the human body purely in terms of a physicommechanical system with the mind as a separate entity interacting with the body via the pineal gland – the supposed seat of the soul. The fundamental impact of Descartes’s work was basically one of demystification. Apart from the residual enigma of the precise relationship between mind and body, the main areas of physics and physiology had been swept

clear of such talk as that of occult powers and hidden forms.

### **Desch, Cyril Henry** (1874–1958) *British metallurgist*

Desch, the son of a London surveyor, was educated at King’s College, London. He taught in Glasgow from 1909 until 1920, when he took up an appointment at the University of Sheffield where he served as professor of metallurgy from 1920 to 1931. Desch then moved to the National Physical Laboratory at Teddington, Middlesex, where he was in charge of the metallurgy department until his retirement in 1939.

Desch is mainly known for his publication in 1910 of his *Textbook of Metallography*, a work that served as the standard account of the subject for the first half of the century.

### **de Sitter, Willem** (1872–1934) *Dutch astronomer and mathematician*

De Sitter (de *sit*-er), the son of a judge from Leiden in the Netherlands, studied mathematics and physics at the University of Groningen, his interest in astronomy being aroused by Jacobus KAPTEYN. After serving at the Cape Town Observatory from 1897 to 1899 and, back at Groningen, as assistant to Kapteyn from 1899 to 1908, he was appointed to the chair of astronomy at the University of Leiden. He also served as director of Leiden Observatory from 1919 to 1934.

De Sitter is remembered for his proposal in 1917 of what came to be called the “de Sitter universe” in contrast to the “Einstein universe.” EINSTEIN had solved the cosmological equations of his general relativity theory by the introduction of the cosmological constant, which yielded a static universe. But de Sitter, in 1917, showed that there was another solution to the equations that produced a static universe if no matter was present. The contrast was summarized in the statement that Einstein’s universe contained matter but no motion while de Sitter’s involved motion without matter.

The Russian mathematician Aleksandr FRIEDMANN in 1922 and the Belgian Georges LEMAITRE independently in 1927 introduced the idea of an expanding universe that contained moving matter. It was then shown in 1928 that the de Sitter universe could be transformed mathematically into an expanding universe. This model, the “Einstein–de Sitter universe,” comprised normal Euclidean space and was a simpler version of the Friedmann–Lemaître models in which space was curved.

De Sitter also spent much time trying to calculate the mass of Jupiter’s satellites from the small perturbations in their orbits. The results were published in 1925 in his *New Mathematical Theory of Jupiter’s Satellites*.

**Desmarest, Nicolas** (1725–1815) *French geologist*

Desmarest (day-ma-**ray**) was the son of a school teacher from Soullaines-Dhuys in France. He first came to notice when he won a prize essay set by the Amiens Academy in 1751 on whether England and France had ever been joined together. Working for a while in Paris as an editor of scholarly works, he eventually started work for the department of commerce in 1757 investigating and reporting on various trades and industries. He served as inspector-general of manufactures (1788–91).

In 1763, following the work of Jean GUETTARD, he noticed large basalt deposits and traced these back to ancient volcanic activity in the Auvergne region. He mapped the area and worked out the geology of the volcanoes and their eruptions in great detail, publishing his work in the *Encyclopédie* (Encyclopedia) of 1768. This work disproved the theory that all rocks were sedimentary by revealing basalt's igneous origins. He later produced an influential work, *Géographie physique* (1794; Physical Geography).

**Désormes, Charles Bernard** (1777–1862) *French chemist*

Désormes (day-**zorm**), who was born at Dijon in France, studied at the Ecole Polytechnique and was an assistant to Guyton de Morveau until 1804. With Jacques and Joseph MONTGOLFIER and his son-in-law, Nicolas Clément, he was coowner of a chemical factory at Verberie.

Clément and Désormes discovered carbon monoxide (1801), investigated the catalytic effect of nitric oxide in the lead-chamber process of sulfuric acid manufacture, and were involved in the early work on iodine, which was discovered by Bernard COURTOIS in 1811. Their most important work, however, was in physical chemistry on the specific heats of gases. In 1819 they published an important paper on the determination of the ratio of the principal specific heats (i.e., the ratio of the specific heat of a gas at constant pressure to that at constant volume).

**Deville, Henri Etienne Sainte-Claire** (1818–1881) *French chemist*

The son of a wealthy shipowner from the West Indies island of St. Thomas, Deville (de-**veel**) studied medicine in Paris but became interested in chemistry by attending Louis Thenard's lectures. He isolated toluene and methyl benzoate from tolu balsam and investigated other natural products before turning to inorganic chemistry, following his appointment as professor of chemistry at Besançon (1845).

Deville's first major discovery was that of nitrogen pentoxide (1849). Following this success he became professor of chemistry at the Ecole

Normale Supérieure (1851) and also lectured at the Sorbonne from 1853. Deville is best known for his work on the large-scale production of aluminum. This had been obtained by Kaspar Wöhler in 1827 but had been produced only in small quantities. Deville developed a commercially successful process involving reduction of aluminum chloride by sodium; the first ingot was produced in 1855. Deville was an expert on the purification of metals and produced (among others) crystalline silicon (1854) and boron (1856), pure magnesium (1857), and pure titanium (1857; with Wöhler). He did much work on the purification of platinum and in 1872 was commissioned to produce the standard kilogram.

After his work on aluminum, Deville's most important researches were those on dissociation. Working with L. J. Troost, he discovered that many molecules were dissociated at high temperature, giving rise to anomalous vapor-density results. Deville's work explained these results and helped to confirm Amedeo AVOGADRO's hypothesis. His other work included the production of artificial gemstones and improved furnaces.

**de Vries, Hugo** (1848–1935) *Dutch plant physiologist and geneticist*

Born the son of a politician at Haarlem in the Netherlands, de Vries (de vrees) studied botany at Leiden and Heidelberg. He became an expert on the Netherlands flora and later turned his attention from classification to physiology and evolution. He entered Julius von SACHS's laboratory at Würzburg University, where he conducted important experiments on the water of plant cells. He demonstrated that the pressure (turgor) of the cell fluid is responsible for about 10% of extension growth, and introduced the term *plasmolysis* to describe the condition in nonturgid cells in which the cell contents contract away from the cell wall. His work in this field led to Jacobus VAN'T HOFF's theory of osmosis.

During the 1880s, de Vries became interested in heredity. In 1889 he published *Intracellular Pangenesis*, in which he critically reviewed previous research on inheritance and advanced the theory that elements in the nucleus, "pangenes," determine hereditary traits. To investigate his theories, he began breeding plants in 1892 and by 1896 had obtained clear evidence for the segregation of characters in the offspring of crosses in 3:1 ratios. He delayed publishing these results, proposing to include them in a larger book, but in 1900 he came across the work of Gregor MENDEL, published 34 years earlier, and announced his own findings. This stimulated both Karl CORRENS and Erich von Tschermak-Seysenegg to publish their essentially similar observations.

De Vries's work on the evening primrose,

*Oenothera lamarckiana*, began in 1886 when he noticed distinctly differing types within a colony of the plants. He considered these to be mutants and formulated the idea of evolution proceeding by distinct changes such as those he observed, believing also that new species could arise through a single drastic mutation. He published his observations in *The Mutation Theory* (1901–03). It was later shown that his *Oenothera* “mutants” were in fact triploids or tetraploids (i.e., they had extra sets of chromosomes) and thus gave a misleading impression of the apparent rate and magnitude of mutations. However, the theory is still important for demonstrating how variation, essential for evolution, can occur in a species.

De Vries was professor of botany at Amsterdam from 1878 to 1918 and was elected a fellow of the Royal Society in 1905.

**Dewar, Sir James** (1842–1923) *British chemist and physicist*

Dewar, the son of a wine merchant, was born at Kincardine-on-Forth in Scotland. He was educated at Edinburgh University where he was a pupil of Lyon PLAYFAIR. In 1869 he was appointed lecturer in chemistry at the Royal Veterinary College, Edinburgh, and from 1873 also held the post of assistant chemist to the Highland and Agricultural Society of Scotland. In 1875 Dewar became Jacksonian Professor of Experimental Philosophy at Cambridge University, England, and from 1877 he was also Fullerian Professor of Chemistry at the Royal Institution, London. He did most of his work in London where the facilities for experimental work were much better.

Dewar conducted his most important work in the field of low temperatures and the liquefaction of gases. In 1878 he demonstrated Louis CAILLETET's apparatus for the liquefaction of oxygen and by 1891 he was able to produce liquid oxygen in quantity. In about 1872 he devised a double-walled flask with a vacuum between its highly reflective walls, the *Dewar flask*, and used this to store liquefied oxygen at extremely low temperatures. This vessel (the thermos flask) has come into everyday use for keeping substances either hot or cold.

Hydrogen had so far resisted liquefaction and Dewar now turned his attention to this. Using the Joule–Thomson effect together with Karl von LINDE's improvements of this, he produced a machine with which he obtained temperatures as low as 14 K and he produced liquid hydrogen in 1898 and solid hydrogen in 1899. Only helium now resisted liquefaction; this was achieved by Heike KAMERLINGH-ONNES in 1908. From about 1891 Dewar also studied explosives and with Frederick ABEL he developed the smokeless powder, cordite. He was knighted in 1904.

**Dewar, Michael James Stuart** (1918–1997) *British–American chemist*

Born at Ahmednagar in India, Dewar was educated at Oxford University, where he obtained his DPhil in 1942. After research at Oxford he worked in industry as a physical chemist for the Courtauld company from 1945 until his appointment in 1951 as professor of chemistry at Queen Mary College, London. In 1959 Dewar moved to America and served successively as professor of chemistry at the University of Chicago and from 1963 at the University of Texas. In 1990 he was appointed graduate research professor at the University of Florida.

Dewar is noted for his contributions to theoretical chemistry. In his *Electronic Theory of Organic Chemistry* (1949) he argued strongly for the molecular-orbital theory introduced by Robert MULLIKEN. He did much to improve molecular-orbital calculations and by the 1960s he was able to claim that he and his colleagues could rapidly and accurately calculate a number of chemical and physical properties of molecules.

**d'Hérelle, Felix** (1873–1949) *French–Canadian bacteriologist*

D'Hérelle (day-rel), the son of a Canadian father and Dutch mother, was born in Montreal, Quebec, and went to school in Paris, later studying medicine at the University of Montreal. He worked as a bacteriologist in Guatemala and Mexico from 1901 until 1909, when he returned to Europe to take up a position at the Pasteur Institute in Paris. D'Hérelle moved to the University of Leiden in 1921 but after only a short stay resigned to become director of the Egyptian Bacteriological Service (1923). Finally, in 1926, d'Hérelle was appointed to the chair of bacteriology at Yale, a position he held until his retirement in 1933.

D'Hérelle is best known for his discovery of the bacteriophage – a type of virus that destroys bacteria. This work began in 1910 in Yucatan, when he was investigating diarrhea in locusts as a means of locust control.

While developing cultures of the causative agent, a coccobacillus, d'Hérelle found that occasionally there would develop on a culture a clear spot, completely free of any bacteria. The cause of these clear spots became clear to him in 1915, while investigating a more orthodox form of dysentery in a cavalry squadron in Paris. He mixed a filtrate from the clear area with a culture of the dysentery bacilli and incubated the resulting broth overnight. The next morning the culture, which had been very turbid, was perfectly clear: all the bacteria had vanished. He concluded that this was the action of “a filterable virus, but a virus parasitic on bacteria.”

A similar discovery of what d'Hérelle termed a “bacteriolytic agent” was announced inde-

pendently by Frederick TWORT in 1915. D'Hérelle published his own account first in 1917, followed by his monograph *The Bacteriophage, Its Role in Immunity* (1921). He spent the rest of his career attempting to develop bacteriophages as therapeutic agents. Thus he tried to cure cholera in India in 1927 and bubonic plague in Egypt in 1926 by administering to the patients the appropriate phage. D'Hérelle himself claimed good results with his treatment, although in the hands of other workers the effect of phage on such diseases as cholera and plague appeared to be minimal. This conclusion d'Hérelle continued to resist until his death, claiming that no proper test using his methods had ever been carried out.

However, the importance of the bacteriophage as a research tool in molecular biology cannot be disputed. It was the so-called phage group, centered on Max DELBRÜCK, that made many of the early advances in this discipline in the 1940s.

### **Dicearchus of Messina** (about 310 BC) *Greek geographer and philosopher*

Dicearchus (dI-see-ar-kus) was a pupil of ARISTOTLE and spent most of his life in Sparta. As none of his works have survived it is difficult to be sure of his contributions to geography. He wrote on a large number of topics including the soul, prophecy, and political theory.

His main work in geography was entitled *Periodos ges* (Tour of the Earth) and he also wrote a history of Greek civilization entitled *Bios Hellenados* (Life of Greece). As Dicearchus was writing so soon after Alexander the Great's campaigns it is assumed that his works would have contained much new information on the geography of Asia. He is variously reported to have been the first to establish lines of latitude on maps, to have included the heights of mountains, and to have made a reasonable attempt at measuring the size of the Earth using methods that ERATOSTHENES was later to perfect.

### **Dicke, Robert Henry** (1916–1997) *American physicist*

Dicke, who was born in St. Louis, Missouri, graduated in 1939 from Princeton University and obtained his PhD in 1941 from the University of Rochester. He spent the war at the radiation laboratory of the Massachusetts Institute of Technology, joining the Princeton faculty in 1946. In 1957 he was appointed professor of physics and served from 1975 to 1984 as Albert Einstein Professor of Science. In 1984 he was appointed Albert Einstein Emeritus Professor of Science.

In 1964, unaware that he was repeating a line of thought pursued earlier by George GAMOW, Ralph ALPHER, and Robert C. Herman

in 1948, Dicke began to think about the consequences of a big-bang origin of the universe. Assuming a cataclysmic explosion some 18 billion years ago with a temperature one minute after of about 10 billion degrees, then intense radiation would have been produced in addition to particles of matter. As the universe expanded this radiation would gradually lose energy. Could there still be any trace left of this "primeval fireball"? It would in fact be detected as black-body radiation, characteristic of the temperature of the black body, which is a perfect emitter of radiation. At Dicke's instigation his colleague P. J. E. Peebles made the necessary calculations and concluded that the remnant radiation should now have a temperature of only about 10 K, later corrected to about 3 K, i.e.,  $-270^{\circ}\text{C}$ . At this temperature a black body should radiate a weak signal at microwave wavelengths from 0.05 millimeter to 50 centimeters with a peak at about 2 millimeters. Further, the signal should be constant throughout the entire universe.

Dicke began to organize a search for such radiation and had actually begun to install an antenna on his laboratory roof when he heard from Arno PENZIAS and Robert WILSON that they had detected background microwave radiation at a wavelength of 7 centimeters. It was this confluence of theory, calculation, and observation that really established the big-bang theory.

Another major area of study for Dicke is gravitation. In the 1960s he carried out a major evaluation of the experiment originally performed by Roland von EÖTVÖS to confirm that the gravitational mass of a body is equal to its inertial mass. Dicke was able to establish the accuracy of the equivalence to one part in  $10^{11}$ . This equivalence is basic to Einstein's theory of general relativity.

In 1961, following a suggestion of Paul DIRAC in 1937, Dicke and Carl BRANS proposed that the gravitational constant was not in fact a constant, but slowly decreases at a rate of one part in  $10^{11}$  per year. The resulting *Brans-Dicke theory* differs somewhat from Einstein's general relativity at a number of points. Thus while Einstein predicts that a ray of light should be deflected by the Sun's gravitational field 1.75 seconds (") of arc, the Brans-Dicke theory leads to a figure of 1.62"; such a difference is within the range of observational error and so is not readily detectable. Again the perihelion of Mercury should advance for Einstein by 43" per century, for Brans-Dicke a mere 39". A value of 43" has in fact been measured but Dicke maintains that part of this value, 4", could be explained by the Sun's nonspherical shape. It has however been claimed that very precise measurements of radio pulses from pulsars appear to favor Einstein. The theory was concurrently and independently developed by Pascual JORDAN, and is thus sometimes known as the

*Brans–Dicke–Jordan theory.* The idea of a changing gravitational constant was put forward by Paul Dirac.

**Diels, Otto Paul Hermann** (1876–1954)  
*German organic chemist*

The son of Hermann Diels (deelz), a famous classical scholar, Diels was born in Hamburg, Germany. He gained his doctorate under Emil FISCHER in Berlin (1899), becoming professor there in 1906. From 1916 until his retirement in 1948 he was professor at Kiel. In 1906 he made an extremely unexpected discovery, that of a new oxide of carbon, carbon suboxide ( $C_3O_2$ ), which he prepared by dehydrating malonic acid with phosphorus pentachloride. Diels's second major discovery was a method of removing hydrogen from steroids by means of selenium. He used this method in research on cholesterol and bile acids, obtaining aromatic hydrocarbons that enabled the structures of the steroids to be deduced.

In 1928 Diels and his assistant Kurt ALDER discovered a synthetic reaction in which a diene (compound containing two double bonds) is added to a compound containing one double bond flanked by carbonyl or carboxyl groups to give a ring structure. The reaction proceeds in the mildest conditions, is of general application, and hence of great utility in synthesis. It has been used in the synthesis of natural products, such as sterols, vitamin K, and cantharides, and of synthetic polymers. For this discovery Diels and Alder were jointly awarded the Nobel Prize for chemistry in 1950.

**Diesel, Rudolph Christian Carl** (1858–1913)  
*German engineer and inventor*

Diesel (**dee**-zel), the designer of the *diesel engine*, was born to German parents in Paris and brought up there until the age of 12. He was academically talented, but his schooling was interrupted in August 1870, when the Franco-Prussian war broke out and the Diesels were deported to London. His cousin, a teacher in Augsburg, Bavaria, invited Diesel to go there to study and he later won a scholarship to the Munich Institute of Technology.

After graduating, Diesel worked as a mechanic for two years in Switzerland and then worked in Paris as a thermal engineer. He was a devout Lutheran and a dedicated pacifist, believing in international religious liberation. In the laboratory that he set up in 1885, an accident with ammonia gas gave him the idea of using chemical firework-type weapons instead of lethal bombs and bullets on the battlefields. In 1893, he demonstrated his first engine and, although the first few attempts failed, within three years he had developed a pressure-ignited heat engine with an efficiency of 75.6%.

(Equivalent steam engines had an efficiency of 10%.)

By 1898 Diesel was a millionaire but his fortune soon disappeared. He toured the world giving lectures and visited America in 1912. His health was bad, he suffered from gout, and was depressed by the buildup to World War I. On the ferry returning from London in 1913, after dining apparently happily with a friend, he disappeared and was assumed to have drowned in the English Channel.

**Diophantus of Alexandria** (about 250)  
*Greek mathematician*

This tomb holds Diophantus. Ah, how great a marvel! The tomb tells scientifically the measure of his life. God granted him to be a boy for the sixth part of his life...five years after his marriage He granted him a son. Alas! late-born wretched child; after attaining the measure of half his father's life, chill Fate took him. After consoling his grief by this science of numbers for four years he ended his life.  
—*The Greek Anthology*

Diophantus (dI-oh-**fan**-tus) was one of the outstanding mathematicians of his era but almost nothing is known of his life and his writings survive only in fragmentary form. His most famous work was in the field of number theory and of the so-called *Diophantine equations* named for him. His major work, the *Arithmetica* (Arithmetic), contained many new methods and results in this field. It originally consisted of 13 books but only 6 survived to be translated by the Arabs. However Diophantus was not solely interested in equations with only integral (whole number) solutions and also considered rational solutions. Diophantus made considerable innovations in the use of symbolism in Greek mathematics – the lack of suitable symbolism had previously hampered work in algebra.

**Dioscorides, Pedanius** (c. 40 AD–c. 90 AD)  
*Greek physician*

If you have not sufficient facility in reading Greek, then you can turn to the herbal of Dioscorides, which describes and draws the herbs of the field with wonderful faithfulness.  
—Cassiodorus (6th century)

Little is known of the life of Dioscorides (dI-os-**kor**-i-deez) except that he was born in Anazarbus (now in Turkey) and became a surgeon to Emperor Nero's armies, having most probably learned his skills at Alexandria and Tarsus. Many writings are attributed to him but the only book for which his authorship is undisputed is *De materia medica* (On Medicine). This pharmacopeia remained the standard medical text until the 17th century, undergoing many revisions and additions and greatly influencing both Western and Islamic cultures. It describes animal derivatives and

minerals used therapeutically but is most important for the description of over 600 plants, including notes on their habitat and the methods of preparation and medicinal use of the drugs they contain. Many of the common and scientific plant names in use today originate from Dioscorides and the yam family, Dioscoreaceae, is named for him.

**Dirac, Paul Adrien Maurice (1902–1984)**  
*British mathematician and physicist*

It seems that if one is working from the point of view of getting beauty in one's equations, and if one has really a sound insight, one is on a sure line of progress.

—*Scientific American*, May 1963

Dirac (di-**rak**), whose father was Swiss, was born in Bristol in the west of England. After graduating in 1921 in electrical engineering at Bristol University, Dirac went on to study mathematics at Cambridge University, where he obtained his PhD in 1926. After several years spent lecturing in America, he was appointed (1932) to the Lucasian Professorship of Mathematics at Cambridge, a post he held until his retirement in 1969. In 1971 he became professor of physics at Florida State University.

Dirac is acknowledged as one of the most creative of the theoreticians of the early 20th century. In 1926, slightly later than Max BORN and Pascual JORDAN in Germany, he developed a general formalism for quantum mechanics. In 1928 he produced his relativistic theory to describe the properties of the electron. The wave equations developed by Erwin SCHRÖDINGER to describe the behavior of electrons were non-relativistic. A significant deficiency in the Schrödinger equation was its failure to account for the electron spin discovered in 1925 by Samuel GOUDSMIT and George UHLENBECK. Dirac's rewriting of the equations to incorporate relativity had considerable value for it not only predicted the correct energy levels of the hydrogen atom but also revealed that some of those levels were no longer single but could be split into two. It is just such a splitting of spectral lines that is characteristic of a spinning electron.

Dirac also predicted from these equations that there must be states of negative energy for the electron. In 1930 he proposed a theory to account for this that was soon to receive dramatic confirmation. He began by taking negative energy states to refer to those energy states below the lowest positive energy state, the ground state. If there were a lower energy state for the electron below the ground state then, the question arises, why do some electrons not fall into it? Dirac's answer was that such states have already been filled with other electrons and he conjured up a picture in which space is not really empty but full of particles of negative energy. If one of these particles were to collide

with a sufficiently energetic photon it would acquire positive energy and be observable as a normal electron, apparently appearing from nowhere. But it would not appear alone for it would leave behind an empty hole, which was really an absence of a negatively charged particle or, in other words, the presence of a positively charged particle. Further, if the electron were to fall back into the empty hole it would once more disappear, appearing to be annihilated together with the positively charged particle, or positron as it was later called.

Out of this theory there emerged three predictions. Firstly, that there was a positively charged electron, secondly, that it could only appear in conjunction with a normal electron, and, finally, that a collision between them resulted in their total common annihilation. Such predictions were soon confirmed following the discovery of the positron by Carl ANDERSON in 1932. Dirac had in fact added a new dimension of matter to the universe, namely antimatter. It was soon appreciated that Dirac's argument was sufficiently general to apply to all particles.

In 1937 Dirac published a paper entitled *The Cosmological Constants* in which he considered "large-number coincidences," i.e., certain relationships that appear to exist between the numerical properties of some natural constants. An example is to compare the force of electrostatic attraction between an electron and a proton with the gravitational attraction due to their masses. The ratio of these is about  $10^{40}:1$ . Similarly, it is also found that the characteristic "radius" of the universe is  $10^{40}$  times as large as the characteristic radius of an electron. Moreover,  $10^{40}$  is approximately the square root of the number of particles in the universe.

These coincidences are remarkable and many physicists have speculated that these apparently unrelated things may be connected in some way. The ratios were first considered in the 1930s by Arthur EDDINGTON, who believed that he could calculate such constants and that they arose from the way in which physics observes and interprets nature. Dirac used the  $10^{40}$  number above in a model of the universe. He argued that there was a connection between the force ratio and the radius ratio. Since the radius of the universe increased with age the gravitational "constant," on which the force ratio depends, may decrease with time. There is modern tentative evidence that this could be the case.

Above all else, however, Dirac was a quantum theorist. In 1930 he published the first edition of his classic work *The Principles of Quantum Mechanics*. In 1933 he shared the Nobel Prize for physics with Schrödinger.

**Dirichlet, (Peter Gustav) Lejeune**  
(1805–1859) *German mathematician*

In mathematics as in other fields, to find

oneself lost in wonder at some manifestation is frequently the half of a new discovery.

—*Works*, Vol. II

Born in Düren (now in Germany), Dirichlet (dee-ri-**klay**) studied mathematics at Göttingen where he was a pupil of Karl GAUSS and Karl JACOBI. He also studied briefly in Paris where he met Joseph FOURIER, who stimulated his interest in trigonometric series. In 1826 he returned to Germany and taught at Breslau and later at the Military Academy in Berlin. He then moved to the University of Berlin, which he only left 27 years later when he returned to Göttingen to fill the chair left vacant by Gauss's death.

Dirichlet's work in number theory was very much inspired by Gauss's great work in that field, and Dirichlet's own book, the *Vorlesungen über Zahlentheorie* (1863; *Lectures on Number Theory*), is of comparable historical importance to Gauss's *Disquisitiones*. He made many very significant discoveries in the field and his work on a problem connected with primes led him to make the fundamentally important innovation of using analytical techniques to obtain results in number theory.

His stay in Paris had stimulated Dirichlet's interest in Fourier series and in 1829 he was able to solve the outstanding problem of stating the conditions sufficient for a Fourier series to converge. (The other problem of giving necessary conditions is still unsolved.) Fourier also gave the young Dirichlet an interest in mathematical physics, which led him to important work on multiple integrals and the boundary-value problem, now known as the *Dirichlet problem*, concerning the formulation and solution of those partial differential equations occurring in the study of heat flow and electrostatics. These are of great importance in many other areas of physics. The growth of a more rigorous understanding of analysis owes to Dirichlet what is essentially the modern definition of the concept of a function.

### **Djerassi, Carl** (1923– ) *American chemist*

Djerassi (jer-as-i) was born in the Austrian capital of Vienna, the son of a Bulgarian physician and an Austrian mother. As both parents were Jewish, Djerassi emigrated to America in 1939. He was educated at Kenyon College, Ohio, and at the University of Wisconsin, where he completed his PhD in 1945, the same year in which he became an American citizen. From 1945 to 1949 he worked for the pharmaceutical company CIBA in Summit, New Jersey, as a research chemist. In 1949 Djerassi decided to join a new pharmaceutical company, Syntex, in Mexico City, to work on the extraction of cortisone from plants. At that time it was being produced from cattle bile at a cost of \$200 a gram.

Despite competition from other leading lab-

oratories, Syntex was the first to extract cortisone ( $C_{21}H_{28}O_5$ ) from a vegetable source, namely diosgenin ( $C_{27}H_{42}O_3$ ), a steroid derived from a variety of wild Mexican yam. Following their initial success Djerassi and his team turned their attention to the steroid hormone progesterone. Known as "nature's contraceptive," the hormone inhibits ovulation. Why, then, could it not be taken as a simple, natural contraceptive? The difficulty was that taken orally it lost most of its activity. Further, as hormones were extracted from such animal sources as human urine, bull's testicles, and sow's ovaries where they occur in small amounts, they tended to be very expensive. The first step was to produce progesterone synthetically. This was achieved at Syntex by Djerassi and others in the early 1950s, the price of progesterone dropped dramatically and it became available in large quantities.

Chemists were inhibited by the belief that steroid hormones were structure-specific; change the structure, the claim went, and the potency is lost. Djerassi was aware, however, that Max Ehrenstein had destroyed this myth a decade earlier and that it was at least conceivable that progesterone could be changed into an oral form without necessarily changing its potency.

Progesterone ( $C_{21}H_{30}O_2$ ) contains four rings of carbon atoms. Following some hints in the literature Djerassi thought that the removal of the methyl group at position 19, thus forming 19-norprogesterone, would increase its potency. His hunch proved to be sound. He was also aware that an acetylene bond introduced into position 17 of the male hormone testosterone increased its oral activity; although known as "ethisterone," it had found no use.

Djerassi's crucial step was to propose that ethisterone's potency could be enhanced, as with progesterone, by removing a methyl group. By October 1951 he had produced testosterone minus a methyl group, but with an added acetylene group. The precise result was 19-nor-17a-ethinyltestosterone, which proved to be a highly active oral progestational hormone. A patent was filed in November 1951. After the appropriate testing it received Federal approval in 1962 under the name Ortho-Novum. Djerassi received one dollar for the patent, a standard payment by a pharmaceutical company to its staff. In 1951 Djerassi left Syntex for Wayne State University, Detroit, where he remained until 1959 when he was appointed professor of chemistry at Stanford. He continued to work for Syntex, as vice-president in charge of research (1957–69) and as president of research (1969–72).

He has also served since 1968 with Zoecon, a company partly owned by Syntex and specializing in pest control by using natural juvenile hormones that prevent insects maturing and breeding. In 1977 Zoecon was taken over by

Occidental Petroleum and was then sold in 1982 to Sandoz, a Swiss pharmaceutical company. Djerrassi has remained as chairman of the board.

Djerrassi's business interests have had little impact on his productivity with over 600 papers to his credit. He has also written four science-fiction novels (*Cantor's Dilemma*, *The Bowbaki Gambit*, *Menachem's Seed*, and *No*) along with a collection of verse, and his autobiography, *The Pill, Pigmy Chimps, and Degas' Horse* (1992). He has also written and collaborated on plays.

### **Döbereiner, Johann Wolfgang** (1780–1849) *German chemist*

I love science more than money.  
—Explaining his failure to patent his invention of the Döbereiner lamp

Born the son of a coachman in Hof an der Saale, Germany, Döbereiner (**du(r)-be-rIn-er**) had little formal education and worked as an assistant to apothecaries in several places from the age of 14. He was largely self-taught in chemistry and was encouraged by Leopold GMELIN whom he met at Strasbourg. After several failures in business, he was appointed assistant professor of chemistry at Jena (1810).

In 1823 he discovered that hydrogen would ignite spontaneously in air over platinum sponge, and subsequently developed the *Döbereiner lamp* to exploit this phenomenon. Döbereiner was interested in catalysis in general and discovered the catalytic action of manganese dioxide in the decomposition of potassium chlorate. His law of triads (1829), based on his observation of regular increments of atomic weight in elements with similar properties, was an important step on the way to Dmitri MENDELEEV's periodic table. Thus in triads such as calcium, strontium, and barium or chlorine, bromine, and iodine, the middle element has an atomic weight that is approximately the average of the other two. It is also intermediate in chemical properties between the other two elements. Döbereiner also worked in organic chemistry.

### **Dobzhansky, Theodosius** (1900–1975) *Russian–American geneticist*

Nothing in biology makes sense except in the light of evolution.  
—Title of article in the *American Biology Teacher* (1973)

Dobzhansky (dob-**zhan**-ski), who was born in Nemirov, in Ukraine, graduated in zoology from Kiev University in 1921; he remained there to teach zoology before moving to Leningrad, where he taught genetics. In 1927 he took up a fellowship at Columbia University, New York, where he worked with T. H. MORGAN. Morgan was impressed by Dobzhansky's ability and, when the fellowship was completed, offered him

a teaching post at the California Institute of Technology. Dobzhansky accepted and became an American citizen in 1937.

Dobzhansky studied the fruit fly (*Drosophila*) and demonstrated that the genetic variability within populations was far greater than had been imagined. The high frequency of potentially deleterious genes had previously been overlooked because their effects are masked by corresponding dominant genes. Dobzhansky found that such debilitating genes actually conferred an advantage to the organism when present with the normal type of gene, and therefore they tended to be maintained at a high level in the population. Populations with a high genetic load – i.e., many concealed lethal genes – proved to be more versatile in changing environments. This work profoundly influenced the theories on the mathematics of evolution and natural selection with regard to Mendelism.

In addition, Dobzhansky wrote many influential books, including *Genetics and the Origin of Species* (1937), a milestone in evolutionary genetics.

### **Doherty, Peter Charles** (1940– ) *Australian immunologist*

Doherty was educated at Queensland and later at Edinburgh, where he gained his PhD in 1970. After serving at the Wistar Institute in Philadelphia, he was appointed in 1982 professor of experimental pathology at the Curtin Institute, Canberra. In 1988 Doherty moved to St. Jude's Children's Research Hospital, Memphis, as chairman of the Immunology Department. From 2002 he became a professor in the Department of Microbiology and Immunology at the University of Melbourne.

In 1974 Doherty, in collaboration with Rolf ZINKERNAGEL, began to consider the response of the mouse immune system to viral meningitis. It was commonly held at this time that the presence of bacterial or viral invaders were sufficient in themselves to initiate an immune response. Consequently, as expected, the infected cells were attacked by the mouse's own T lymphocytes. Yet, to their surprise, when T cells from one mouse strain were deployed against infected cells from another strain, the lymphocytes failed to respond. Clearly an additional factor was required to trigger the immune response.

They were aware, following the work of George SNELL and others, that major histocompatibility (MHC) antigens played a significant role in controlling the immune response to transplants. They consequently began to examine the role of MHC proteins in the immune response. Working with mice from various strains, they found that T cells from one strain could be provoked to attack infected cells only

if the invaders shared at least one MHC antigen.

For his work in this field Doherty shared the 1997 Nobel Prize for physiology or medicine with Rolf Zinkernagel. He is currently working on viral immunity. In 1995 he published an account of science: *The Beginner's Guide to Winning the Nobel Prize*.

**Doisy, Edward Adelbert (1893–1986)**  
*American biochemist*

Doisy was born in Hume, Illinois, and educated at the University of Illinois and at Harvard, where he obtained his PhD in 1920. From 1919 to 1923 he worked at the Washington University School of Medicine. In 1923 he was appointed to the chair of biochemistry at the St. Louis University Medical School, a position he retained until his retirement in 1965.

Doisy worked initially on ovarian biochemistry. In 1929 he succeeded in isolating the hormone estrone ( $C_{18}H_{12}O_2$ ), and soon after the more potent estradiol ( $C_{18}H_{24}O_2$ ). In 1938 he isolated, and in the following year synthesized, vitamin K, recently discovered by Carl DAM. He discovered that the vitamin existed in two forms, the physiologically active form  $K_1$ , extracted from alfalfa, and  $K_2$ , differing in a side chain and derivable from rotten fish. For his discovery of the chemical nature of vitamin K, technically a naphthoquinone, Doisy shared the 1943 Nobel Prize for physiology or medicine with Dam.

**Dokuchaev, Vasily Vasilievich (1846–1903)**  
*Russian soil scientist*

Climate, vegetation, and animal life are distributed on the earth's surface, from north to south, in a strictly determined order.

—*Collected Works*, Vol. VI

Dokuchaev (dok-uu-**cha**-ef) was born in Milyukovo near Smolensk, Russia, the son of the village priest. He too was originally trained for the priesthood but later turned to the study of science at St. Petersburg University where he graduated in 1871. He was immediately appointed to the faculty, initially as curator of the geological collection but he also served as professor of geology until poor health forced him to retire in 1897.

Dokuchaev made the first comprehensive scientific study of the soils of Russia, details of which are to be found in his *Collected Works* (9 vols., 1949–61). He also, in the 1890s, set up at the Kharkov Institute of Agriculture and Forestry, the first department of soil science in Russia.

In the West he is mainly known for his work on the classification of soils, his insistence that soil is a geobiological formation, and his use of soil to define the different geographical zones. It is also owing to Dokuchaev that the Russian

term “chernozem,” used to describe a black soil rich in humus and carbonates, has entered most languages.

**Doll, Sir (William) Richard Shaboe (1912–2005)**  
*British epidemiologist*

Doll was born in Hampton, Greater London, and in 1937 graduated from St. Thomas' Hospital Medical School in London. Following the outbreak of World War II in 1939, Doll served in the Royal Army Medical Corps. In 1946 he started working for the statistical research unit of the Medical Research Council (MRC), becoming its director in 1961. In 1969 he was appointed Regius Professor of Medicine at Oxford University.

Doll was a key figure in the development of modern epidemiology and preventive medicine, most notably through his confirmation of the causal link between smoking and lung cancer. In 1951 he and colleagues at the MRC published strong evidence that smoking is associated with lung cancer: they surveyed 649 such patients and found that only 2 were non-smokers. So convincing were the results that Doll himself gave up smoking while carrying out the study. Doll's team repeated their survey using the much larger sample of all 40,000 doctors in the UK. The results, published in 1954, prompted a sea change in public attitudes to smoking. Doll's statistical epidemiological approach had produced convincing evidence that people who smoked ran a greatly increased risk of contracting lung cancer.

In subsequent work, Doll turned to numerous other public health issues, including the hazards of oral contraceptives, electrical power lines, radiation, and environmental contaminants. He was no stranger to controversy, often seeming to downplay the cancer risks posed by certain chemicals and forms of radiation, and instead arguing that smoking and other lifestyle factors were preeminent as factors. Nonetheless his work earned him many honors and awards, including the United Nations Award for Cancer Research in 1962 and the European Cancer Society's Gold Medal in 2000. He received a knighthood in 1971.

**Dollfus, Audouin Charles (1924– )**  
*French astronomer*

Dollfus (**dol**-foos), the son of an aeronaut, studied at the university in his native city of Paris. In 1946 he joined the staff of the astrophysical division of the Paris Observatory at Meudon and is now head of the Laboratory for Physics of the Solar System.

Dollfus has established a reputation as an authority on the solar system and a leading planetary observer. He began a study of Saturn's rings in 1948 and soon noted the presence of occasional brightness ripples. Work in the

1950s showed that they could not be explained by the effects of the known satellites and Dollfus concluded that other forces seemed to be acting, possibly attributable to an unknown satellite very close to the rings. A favorable viewing time, with the rings appearing edge-on to an Earth-bound observer, came in 1966. Although early visual attempts to detect the satellite failed, Dollfus was more successful when he examined photographic plates taken with the 43-inch (1.1-m) reflecting telescope of the Pic du Midi Observatory in December 1966, virtually the last opportunity for favorable viewing before 1980. On these he found the image of an unknown satellite.

Following independent confirmation, the satellite was named Janus and was widely accepted as Saturn's tenth satellite, its period having been calculated by Dollfus as 18 hours. When no such satellite was found by the Pioneer II and Voyager I spacecraft in 1979 and 1980, Dollfus rechecked his measurements. It now appears that he photographed one of the "twin" satellites that appeared in the spacecraft pictures and that recent calculations have shown to move in nearly identical orbits with periods of about 16.7 hours.

### **Döllinger, Ignaz Christoph von** (1770–1841) *German biologist*

After studying medicine in his native city of Bamberg, then at Würzburg, Vienna, and Pavia (Italy), Döllinger (**du(r)l**-ing-er) gained his doctorate at Bamberg in 1794. In 1796 he was appointed professor of medicine at the University of Bamberg, and in 1803 became professor of physiology and normal and pathological anatomy at Würzburg. From 1823 Döllinger was curator of academic sciences at Munich and then became (1826) professor of anatomy and physiology and director of the anatomical museum of the University of Munich. He was one of the pioneers of the use of the microscope in medical studies and made investigations of blood circulation, the spleen and liver, glandular secretions, and the eye, as well as comparative anatomy studies. His embryological work exercised a considerable influence on Louis AGASSIZ.

### **Dollond, John** (1706–1761) *British optician*

Dollond was born in London, the son of Huguenot refugees. He started life as a silk weaver but later joined his eldest son, Peter, in making optical instruments, and devoted years of experiment to developing an achromatic lens. The problem confronting lens makers at the time was chromatic aberration – the fringe of colors that surrounds and disturbs images formed by a lens. This put a limit on the power of lenses (and of refracting telescopes), for the

stronger the lens, the more chromatically disturbed the images became. Chromatic aberration is caused by the different wavelengths that make up white light being refracted to different extents by the glass, each being focused at a different point.

In 1758 Dollond succeeded in making lenses without this defect by using two different lenses, one of crown glass and one of flint glass (one convex and one concave), so made that the chromatic aberration of one was neutralized by the aberration of the other. In fact he was not the first to make such a lens, since Chester Hall had already done so in 1753, but Dollond managed to patent the idea because he was the first to publicize the possibility.

In 1761 he was appointed optician to George III but died of apoplexy later that year.

### **Domagk, Gerhard** (1895–1964) *German biochemist*

If I could start again, I would perhaps become a psychiatrist and search for a causal therapy of mental disease, which is the most terrifying problem of our times.

—On his scientific career

Domagk (**doh**-mahk), who was born in Lagow, now in Poland, graduated in medicine from the University of Kiel in 1921 and began teaching at the University of Greifswald and later at the University of Münster. At this time he carried out important researches into phagocytes – special cells that attack bacteria in the body. He became interested in chemotherapy and in 1927 he was appointed director of research in experimental pathology and pathological anatomy at the giant chemical factory I. G. Farbenindustrie at Wuppertal-Elberfeld. Pursuing the ideas of Paul EHRLICH, Domagk tested new dyes produced by the Elberfeld chemists for their effect against various infections. In 1935 he reported the effectiveness of an orange-red dye called prontosil in combating streptococcal infections. For the first time a chemical had been found to be active *in vivo* (in a living organism) against a common small bacterium. Earlier dyes used as drugs were active only against infections caused by much larger protozoa.

The work was followed up in research laboratories throughout the world – Alexander FLEMING neglected penicillin to work on prontosil in the early 1930s – but the most significant ramifications were discovered by Daniele BOVET and his coworkers. Prontosil and the sulfa drugs that followed were effective in saving many lives, including those of Franklin D. Roosevelt Jr., Winston Churchill, and Domagk's own daughter. In 1939 Domagk was offered the Nobel Prize for physiology or medicine. The Nazis forced him to withdraw his acceptance because Hitler was annoyed with the Nobel Committee for awarding the 1935 Peace Prize

to a German, Carl von Ossietzky, whom Hitler had imprisoned. In 1947 Domagk was finally able to accept the prize. In his later years he undertook drug research into cancer and tuberculosis.

**Donati, Giovanni Battista** (1826–1873)  
*Italian astronomer*

After graduating from the university in his native city of Pisa, Donati (do-nah-tee) joined the staff of the Florence Observatory in 1852, and was appointed director in 1864. He died from bubonic plague in 1873.

Much of his work was concerned with comets. He discovered six new comets, one of which, first appearing in June 1858 has since been known as *Donati's comet*. He went on in 1864 to make the first observations of a comet's chemical composition. Spectroscopic observation of the 1864 comet produced a line spectrum with three lines named alpha, beta, and gamma by Donati. The three lines were also seen in an 1866 comet by SECCHI. The lines were shown by HUGGINS in 1868 to be due to the presence of carbon.

**Dondi, Giovanni de** (1318–1389) *Italian astronomer and clockmaker*

Dondi (don-dee), born the son of a professor of medicine and clock designer in Chioggia, Italy, taught medicine and astronomy at the universities of Padua and Pavia. He became famous throughout the whole of Europe for his construction of a marvelous astronomical clock that he began in 1348 and that took him 16 years to complete. It was built for the duke of Milan and was put in his library in Pavia. Although the clock has long been destroyed, Dondi wrote a treatise on it, which has survived. It was weight driven, had a verge and foliot escapement, and was made of brass and bronze. It was completely unlike a modern clock being so unconcerned with the time of day that it did not even have hands. It was intended to show the movements of the planets and the time of the movable and fixed ecclesiastical festivals. It involved advanced gear work and showed mechanical skill of a high order. Such was his fame that Dondi was known throughout Europe as "John of the Clock."

**Donnan, Frederick George** (1879–1956)  
*British chemist*

Donnan, the son of a Belfast merchant, was born in Colombo, the capital of Ceylon (now Sri Lanka). He was educated at Queen's College, Belfast, and the universities of Leipzig and Berlin where he obtained his PhD in 1896 and some of the German expertise in physical chemistry. On his return to England he worked at University College, London, with Sir William RAMSAY from 1898 until 1904, when he accepted

the post of professor of physical chemistry at the University of Liverpool. In 1913 Donnan returned to succeed Ramsay at University College, remaining there until his retirement in 1937.

Donnan is mainly remembered for the *Donnan membrane equilibrium* (1911) – a theory describing the equilibrium which arises in the passage of ions through membranes.

**Doodson, Arthur Thomas** (1890–1968)  
*British mathematical physicist*

Doodson, the son of a manager of a cotton mill in Worsley in the north of England, was educated at the University of Liverpool. After working at University College, London, from 1916 to 1918 he joined the Tidal Institute, Liverpool, in 1919 as its secretary. Doodson remained through its re-formation as the Liverpool Observatory and Tidal Institute as assistant director (1929–45) and as director until his retirement in 1960.

Much of Doodson's early work was on the production of mathematical tables and the calculation of trajectories for artillery. Proving himself an ingenious, powerful, and practical mathematician he found an ideal subject for his talents in the complicated behavior of the tides. He made many innovations in their accurate computation and, with H. WARBURG in 1942, produced the *Admiralty Manual of Tides*.

**Doppler, Christian Johann** (1803–1853)  
*Austrian physicist*

Christian Doppler, the son of a stonemason from the Austrian city of Salzburg, studied mathematics at the Vienna Polytechnic. In 1835 he started teaching at a school in Prague and six years later was appointed professor of mathematics at the Technical Academy there.

Doppler's fame comes from his discovery in 1842 of the *Doppler effect* – the fact that the observed frequency of a wave depends on the velocity of the source relative to the observer. The effect can be observed with sound waves. If the source is moving toward the observer, the pitch is higher; if it moves away, the pitch is lower. A common example is the fall in frequency of a train's whistle or a vehicle siren as it passes. Doppler's principle was tested experimentally in 1843 by Christoph BUYS BALLOT, who used a train to pull trumpeters at different speeds past musicians who had perfect pitch.

Doppler also tried to apply his principle to light waves, with limited success. It was Armand FIZEAU in 1848 who suggested that at high relative velocities the apparent color of the source would be changed by the motion: an object moving toward the observer would appear bluer; one moving away would appear redder. The shift in the spectra of celestial objects

(the *Doppler shift*) is used to measure the rate of recession or approach relative to the Earth.

**Dorn, Friedrich Ernst** (1848–1916) *German physicist*

Dorn, who was born in Guttstadt (now Dobre Miasto in Poland), studied at Königsberg and in 1873 was made professor of physics at Breslau. In 1886 he transferred to a professorship at Halle and started working with x-rays. He is noted for his discovery, in 1900, that the radioactive element radium gives off a radioactive gas, which Dorn called “radium emanation.” The gas was isolated in 1908 by William RAMSAY, who named it “niton.” The name radon was adopted in 1923. Dorn’s discovery is the first established demonstration of a transmutation of one element into another.

**Douglas, Donald Wills** (1892–1981) *American aircraft engineer*

Douglas, the son of an assistant bank cashier in New York City, was educated at the U.S. Naval Academy and the Massachusetts Institute of Technology. He gained his first experience of aircraft design working for the Glenn L. Martin Company of California on the development of a heavy bomber.

In 1920 he set up on his own with \$600 and the backing of David Davis, a wealthy sportsman willing to invest \$40,000 to produce a plane capable of flying nonstop across America. Although the *Cloudster*, the result of their venture, only reached Texas it was in fact the first aircraft in history capable of lifting a useful load exceeding its own weight.

By 1928, on the strength of some profitable navy contracts, Douglas was ready to go public with his new Douglas Aircraft Company. The company had many years of success, with such planes as the DC-3, first flown in 1935, contributing substantially to their profits. In 1967 the company was taken over by the McDonnell Aircraft Company and reformed as the McDonnell–Douglas Corporation.

**Douglass, Andrew Ellicott** (1867–1962) *American astronomer and dendrochronologist*

Douglass came from a family of academics in Windsor, Vermont, with both his father and grandfather being college presidents. He graduated from Trinity College, Hartford, Connecticut in 1889 and in the same year was appointed to an assistantship at Harvard College Observatory. In 1894 he went with Percival LOWELL to the new Lowell Observatory in Flagstaff, Arizona, moving to the University of Arizona in 1906 as professor of astronomy and physics.

Douglass’s first interest was the 11-year sunspot cycle. In trying to trace its history he

was led to the examination of tree rings in the hope that he would find some identifiable correlation of sunspot activity with terrestrial climate and vegetation. Soon the tree rings became the center of his studies.

The only previously established method of dating the past, except by inscriptions, was the geological varve-counting technique, which was developed from 1878. But this was of no use if there were no varves (thin seasonally deposited layers of sediment in glacial lakes) to be found. Douglass soon found that he could identify local tree rings with confidence and use them in dating past climatic trends. He thus founded the field of dendrochronology. By the late 1920s he had a sequence of over a thousand tree rings with six thin rings, presumably records of a severe drought, correlated with the end of the 13th century. In 1929 he found some timber that contained the six thin rings and a further 500 in addition. This took him to the eighth century and over the years he managed to get as far as the first century. This was extended still further and by careful analysis scholars have now established a sequence going back almost to 5000 BC.

The dated rings of Arizona and New Mexico were found however not to correlate with sequences from other parts of the world: the tree-ring clock was a purely local one. The search for a more universal clock continued, and the method of radiocarbon dating was developed by Willard LIBBY in 1949.

**Drake, Frank Donald** (1930– ) *American astronomer*

Drake, who was born in Chicago, Illinois, graduated in 1952 from Cornell University and obtained his PhD in 1958 from Harvard. He worked initially at the National Radio Astronomy Observatory (NRAO), West Virginia (1958–63) and at the Jet Propulsion Laboratory, California (1963–64) before returning to Cornell and serving as professor of astronomy from 1964. He was appointed professor of astronomy at the University of California in 1984.

Although Drake has made significant contributions to radio astronomy, including radio studies of the planets, he is perhaps best known for his pioneering search for extraterrestrial intelligence. In April 1959 he managed to gain approval from the director at NRAO, Otto STRUVE, to proceed with his search, which was called “Project Ozma.” The name was taken from the Oz stories of Frank Baum. Drake began in 1960, using the NRAO 26-meter radio telescope to listen for possible signals from planets of the Sunlike stars Tau Ceti and Epsilon Eridani, both about 11 light-years away. He decided to tune to the frequency of 1,420 megahertz at which radio emission from hydrogen occurs. This would have considerable significance for any civilization capable of build-

ing radio transmitters. No signals were received although at one time excitement was generated when signals from a secret military radar establishment were received while the antenna was pointed at Epsilon Eridani. In July 1960 the project was terminated to allow the telescope to fulfill some of its other obligations. Drake revived the project in 1975, in collaboration with Carl SAGAN, when they began using the Arecibo 1,000-foot (305-meter) radio telescope to listen to several nearby galaxies on frequencies of 1,420, 1,653, and 2,380 megahertz. No contact was made nor was it likely, they declared, for "A search of hundreds of thousands of stars in the hope of detecting one message would require remarkable dedication and would probably take several decades." He has published a number of works on this issue including *Is Anyone There? The Search for Extra Terrestrial Intelligence* (1992).

**Draper, Henry** (1837–1882) *American astronomer*

I think we are by no means at the end of what can be done. If I can stand 6 hours' exposure in midwinter another step forward will result.  
—Remark made in the last months of his life, describing his work photographing stars and planets

Draper, the son of the distinguished physician and chemist John W. Draper, was born in Prince Edward County, Virginia. He studied at the City University of New York, completing the course in medicine in 1857 before he was old enough to graduate. He obtained his MD in 1858, spending the preceding months in Europe where his interest in astronomy was aroused by a visit to the observatory of the third earl of ROSSE at Parsonstown, Ireland. On his return to New York he joined the Bellevue Hospital and was later appointed professor of natural science at the City University in 1860. Draper later held chairs of physiology (1866–73) and analytical chemistry (1870–82) and in 1882 succeeded his father briefly as professor of chemistry. He retired in 1882 in order to devote himself to astronomical research but died prematurely soon after.

One of the most important events in Draper's life was his marriage in 1867 to Anna Palmer, daughter and heiress to Courtlandt Palmer who had made a fortune in hardware and New York real estate. His wife's money allowed him to purchase a 28-inch (71-cm) reflecting telescope and to begin a 15-year research partnership.

Draper was interested in the application of the new technique of photography to astronomy. He started by making daguerrotypes of the Sun and Moon but in 1872 succeeded for the first time in obtaining a photograph of a stellar spectrum, that of Vega. In 1879 he found that dry photographic plates had been developed and that these were more sensitive and con-

venient than wet collodion. By 1882 he had obtained photographs of over a hundred stellar spectra plus spectra of the Moon, Mars, Jupiter, and the Orion nebula. He also succeeded in directly photographing the Orion nebula, first with a 50-minute exposure in 1880 and then, using a more accurate clock-driven telescope, with a 140-minute exposure. He thus helped to establish photographic astronomy as an important means of studying the heavens.

At the time of his death his widow hoped to continue his work herself, but with prompting from Edward PICKERING at the Harvard College Observatory, she set up the Henry Draper Memorial Fund. It was with the aid of this fund that the famous *Henry Draper Catalogue*, some nine volumes with details of the spectra of 225,000 stars, was published from 1918 to 1924 through the labors of Pickering and Annie CANNON.

**Draper, John William** (1811–1882) *British-American chemist*

How is it that the Church produced no geometers in her autocratic reign of twelve hundred years?  
—*The Conflict Between Science and Religion* (1890)

Draper, who was born in St. Helens, Lancashire, in northwestern England, was educated at University College, London, before he emigrated to America in 1833. He qualified in medicine at the University of Pennsylvania in 1836. After a short period teaching in Virginia he moved to New York University (1838) where he taught chemistry and in 1841 helped to start the medical school of which he became president in 1850.

Most of his chemical work was done in the field of photochemistry. He was one of the first scientists to use Louis DAGUERRE's new invention (1837) of photography. He took the first photograph of the Moon in 1840 and in the same year took a photograph of his sister, Dorothy, which is the oldest surviving photographic study of the human face. In 1843 he obtained the first photographic plate of the solar spectrum. He was also one of the first to take photographs of specimens under a microscope. On the theoretical level Draper was one of the earliest to grasp that only those rays that are absorbed produce chemical change and that not all rays are equally powerful in their effect. He also, in a series of papers (1841–45), showed that the amount of chemical change is proportional to the intensity of the absorbed radiation multiplied by the time it has to act. Draper's work was continued and largely confirmed by the work of Robert BUNSEN and Henry ROSCOE in 1857. Draper's work also resulted in the development of actinometers (instruments to measure the intensity of light) which he named

“tithonometers.” He also wrote on a wide variety of other topics.

Draper’s son Henry was an astronomer of note after whom the famous Harvard catalog of stellar spectra was named.

**Dreyer, Johann Louis Emil** (1852–1926)  
*Danish astronomer*

Dreyer (**dr**-er), the son of a general of the Danish Army, was born in Copenhagen and studied at the university there, obtaining his MA in 1874 and his PhD in 1882. He began his career in 1874 as an assistant at the observatory of William PARSONS, third earl of ROSSE, in Parsonstown, Ireland, moving in 1878 to another assistantship at the Dunsink Observatory, Dublin. In 1882 Dreyer was appointed director of the Armagh Observatory, in what is now Northern Ireland, a post he occupied until his retirement in 1916 when he settled in Oxford, England.

Dreyer’s major contribution to astronomy was his three catalogs. He began by preparing in 1878 a supplement to John HERSCHEL’s catalog of 5,000 nebulae. The work naturally led to the production of a totally new work, the *New General Catalogue of Nebulae and Clusters of Stars* (1888) containing details of 7,840 celestial objects and known invariably as the NGC. It listed all the nebulae and clusters that had been discovered up to 1888 and included many galaxies that had not yet been identified as such. This in turn was followed by the two *Index Catalogues* (IC), the first in 1895 containing details of a further 1,529 nebulae and clusters (and galaxies) and the second in 1908 adding a further 3,857. The catalogs with over 13,000 nebulae, galaxies, and clusters were reissued in a single volume in 1953. Many of the objects listed are still referred to by their NGC or IC numbers.

Dreyer is also remembered as a historian of astronomy. In 1890 he published a biography of his countryman, *Tycho Brahe*, and followed this with Brahe’s *Omnia opera* (15 vols. 1913–29; Complete Works). He had earlier published his *History of Planetary Systems from Thales to Kepler* (1906), a work, despite its age, still without any competitor in the English language.

**Drickamer, Harry George** (1918–2002)  
*American physicist*

Born in Cleveland, Ohio, Drickamer was educated at the University of Michigan, where he obtained his PhD in 1946. He then joined the staff of the University of Illinois, Urbana, serving first as professor of physical chemistry and then as professor of chemical engineering from 1953 until his retirement in 1990. He specialized in the study of the structure of solids by means of high pressures, producing in the

course of his researches pressures of the order of some 500,000 atmospheres.

**Driesch, Hans Adolf Eduard** (1867–1941)  
*German biologist*

Born in Bad Kreuznach, in southwest Germany, Driesch (dreesh) held professorships at Heidelberg, Cologne, and Leipzig, and was visiting professor to China and America. A student of zoology at Freiburg, Jena, and Munich, he was for some years on the staff of the Naples Zoological Station.

Driesch carried out pioneering work in experimental embryology. He separated the two cells formed by the first division of a sea-urchin embryo and observed that each developed into a complete larva, thus demonstrating the capacity of the cell to form identical copies on division. He was also the first to demonstrate the phenomenon of embryonic induction, whereby the position of and interaction between cells within the embryo determine their subsequent differentiation.

Driesch is perhaps best known for his concept of entelechy – a vitalistic philosophy that postulates the origin of life to lie in some unknown vital force separate from biochemical and physiological influences. This also led him to investigate psychic research and parapsychology.

**Dubois, Eugène** (1858–1940)  
*Dutch physician and paleontologist*

Dubois (doo-**bwah**) was born in Eijsden in the Netherlands and studied medicine at the University of Amsterdam. After briefly working there as a lecturer in anatomy, he served as a military surgeon in the Dutch East Indies, now Indonesia, from 1887 to 1895. On his return to Amsterdam he held the chair of geology, paleontology, and mineralogy from 1899 until his retirement in 1928.

The decision to go to the Indies was no accident. Dubois was determined to find the “missing link” and had reasoned that such a creature would have originated in proximity to the apes of Africa or the orang-utang of the Indies. After several years fruitless search in Sumatra, Dubois moved to Java and in 1890 discovered his first humanoid remains (a jaw fragment) at Kedung Brubus. The following year, at Trinil on the Solo river, he found the skullcap, femur, and two teeth of what he was later to name *Pithecanthropus erectus*, more commonly known as Java man. He published these findings in 1894.

Although Dubois’s estimate of the cranial capacity of *Pithecanthropus* was, at 850 cubic centimeters (later estimates ranged up to 940 cubic centimeters), on the low side for a hominid, the femur it had been found with indicated to Dubois that it must be a form with a very erect

posture. However, many doubted this, stating the usual objections that the remains belonged to different creatures, to apes or (Rudolf VIRCHOW's view) to deformed humans. So irritated did Dubois become by this reception that he withdrew the fossils from view, keeping them locked up for some 30 years.

When they were once more made available to scholars in 1923 and Peking man was discovered in 1926 it at last became widely agreed that *Pithecanthropus* was, as Dubois had earlier claimed, a link connecting apes and man. By this time however Dubois would have no part of such a consensus and began to insist the bones were those of a giant gibbon, a view he maintained until his death.

**Du Bois-Reymond, Emil Heinrich** (1818–1896) *German neurophysiologist*

The more one advances in the knowledge of physiology, the more one will have reason for ceasing to believe that the phenomena of life are essentially different from physical phenomena.

Of Swiss and Huguenot descent, Du Bois-Reymond (doo bwah-ray-mon) was born in Berlin and educated at the university there and in Neuchâtel (Switzerland). He is famous as the first to demonstrate how electrical currents in nerve and muscle fibers are generated. He began his studies under the eminent physiologist Johannes MÜLLER at Berlin with work on fish capable of discharging electric currents as an external shock (e.g., eels). Turning his attention to nerve and muscle activity he then showed (1843) that applying a stimulus to the nerve brings about a drop in the electrical potential at the point of stimulus. This reduction in potential is the impulse, which travels along the nerve as waves of "relative negativity." This variation in negativity is the main cause of muscle contraction. Du Bois-Reymond's pioneering research, for which he devised a specially sensitive galvanometer capable of measuring the small amounts of electricity involved, was published as *Untersuchungen über tierische Elektrizität* (2 vols. 1848–84; *Researches on Animal Electricity*): a landmark in electrophysiology, although subject to later elaboration. Du Bois-Reymond's collaboration with fellow physiologists Hermann von HELMHOLTZ, Carl Ludwig, and Ernst von Brücke was of great significance in linking animal physiology with physical and chemical laws.

Du Bois-Reymond was elected a member of the Berlin Academy of Sciences in 1851 and succeeded Müller as professor of physiology at Berlin in 1858. He was also instrumental in establishing the Berlin Physiological Institute, opened in 1877, then the finest establishment of its kind.

**Dubos, René Jules** (1901–1982) *French–American microbiologist*

Dubos (doo-bos) was born in Saint Brice, France, and graduated in agricultural sciences from the National Agronomy Institute in 1921. After a period with the International Institute of Agriculture in Rome as assistant editor, he emigrated to America in 1924.

Dubos was awarded his PhD in 1927 from Rutgers University for research on soil microorganisms, continuing his work in this field at the Rockefeller Institute for Medical Research. Reports that soil microorganisms produce antibacterial substances particularly interested him and in 1939 he isolated a substance from *Bacillus brevis* that he named tyrothricin. This is effective against many types of bacteria but unfortunately also kills red blood cells and its medical use is therefore limited. However, the discovery stimulated such workers as Selman WAKSMAN and Benjamin DUGGAR to search for useful antibiotics and led to the discovery of the tetracyclines. He won the 1969 Pulitzer Prize for his book *So Human an Animal*.

**Duesberg, Peter** (1936– ) *American molecular biologist*

Born in Germany, Duesberg (dooz-berg) was educated at the University of Frankfurt where he obtained his PhD in chemistry in 1963. He immediately moved to the U.S. to work at the University of California, Berkeley, and was appointed professor of molecular biology in 1974.

Duesberg established his reputation in molecular biology by his discovery of cancer-causing genes (oncogenes) in the retrovirus first described by Peyton ROUS in 1910. In 1970 Duesberg and his Berkeley colleagues identified three genes, gag, pol, and env, which encode the proteins of the viral capsid, the enzyme reverse transcriptase, and the proteins of the viral envelope, respectively.

Consequently when GALLO and MONTAGNIER identified the HIV retrovirus in 1983 as the cause of AIDS, Duesberg was well qualified to comment on their judgment. In 1987 he published in *Cancer Research* a paper entitled *Retroviruses as Carcinogens and Pathogens: Expectation and Reality* in which he surveyed the published literature, citing 278 references in the process. The paper turned Duesberg into an international celebrity, winning praise from a few but savage rejection and complaints of irresponsibility from the majority of his colleagues.

Duesberg attacked what he saw as a complacent orthodoxy by denying there was any evidence for the claim that HIV was responsible for AIDS. Being antibody positive would cause him no worry, he insisted, and he would be even prepared to inject himself with pure HIV to establish his point.

In defence of his claim Duesberg offered six main arguments:

1. Many AIDS cases are HIV negative.
2. T-cells, the site of HIV attack, are regenerated more quickly than they are destroyed.
3. Viruses typically cause disease in the absence of antibodies; HIV stimulates the production of antibodies.
4. HIV should cause AIDS on infection, not years later.
5. In general retroviruses sustain rather than destroy cells.
6. No known virus discriminates between men and women.

Duesberg's views have been vigorously defended in a popular book by Jad Adams, *AIDS: the HIV Myth* (London, 1989). They have also been vigorously rejected by Robert Gallo and other virologists, and dismissed by them as more inept than challenging.

Despite a hostile reaction to his work from lay and professional press alike, Duesberg continues to campaign vigorously for his views. So much so that in 1995 he collected his previously published papers on the issue in his *Infectious AIDS: Have We Been Mised?* and went on to produce in 1996 a new comprehensive survey of the whole field in his *Inventing the AIDS Virus*.

### Du Fay, Charles François de Cisternay (1698–1739) *French chemist*

Du Fay (doo fay), a Parisian by birth, started his career in the French army, rising to the rank of captain. He left to become a chemist in the Académie Française and in 1732 became superintendent of the Jardin du Roi. His great achievement was to discover the two kinds of electricity, positive and negative, which he named "vitreous" and "resinous." This was based on his discovery that a piece of gold leaf charged from an electrified glass rod would attract and not repel a piece of electrified amber. This was the "two-fluid theory" of electricity, which was to be opposed by Benjamin FRANKLIN'S "one-fluid theory" later in the century.

### Duggar, Benjamin Minge (1872–1956) *American plant pathologist*

Duggar was born into the farming community of Gallion, Alabama, and soon developed an interest in agriculture. He graduated with honors from the Mississippi Agricultural and Mechanical College, in 1891. He devoted his career to studying plant diseases, and while professor of plant physiology at Cornell University wrote *Fungus Diseases of Plants* (1909), the first publication to deal purely with plant pathology.

Duggar is known for his work on cotton diseases and mushroom culture, but he made his most important discovery after retiring from

academic life. In 1945 he became consultant to the American Cyanamid Company, and soon isolated the fungus *Streptomyces aureofaciens*. Three years' work with this organism resulted in Duggar extracting and purifying the compound chlortetracycline (marketed as Aureomycin), the first of the tetracycline antibiotics. This drug was on the market by December 1948, and has proved useful in combating many infectious diseases.

Duggar was one of the foremost coordinators of plant science research in America and was editor of many important publications.

### Duhamel du Monceau, Henri-Louis (1700–1782) *French agriculturalist and technologist*

Duhamel (doo-a-mel) first took an interest in science following lectures at the Jardin du Roi in his native city of Paris during the 1720s. His study of the parasitic fungus found to attack saffron bulbs earned him admission to the French Academy of Sciences in 1728. In 1739 Duhamel was appointed inspector-general of the navy, his duties including supervision of the timber used by the French fleet.

During the 1730s he undertook a series of chemical investigations in collaboration with the chemist Jean Grosse. His most important work during this period was *Sur la base du sel marin* (1736; On the Composition of Sea Salt) in which he distinguished between potassium and sodium salts.

His major work was his contribution to agriculture with studies of French and English methods of practice. He published a series of writings entitled *Traité de la culture des terres* (1775; Treatise on Land Cultivation) in which he adapted Jethro TULL'S system to France taking into account his own readings, experiments, and case histories.

### Duhem, Pierre Maurice Marie (1861–1916) *French physicist, philosopher, and historian*

A physical theory ... is a system of mathematical propositions, deduced from a small number of principles, which has the object of representing a set of experimental laws as simply, as completely, and as exactly as possible.

—*The Aim and Structure of Physical Theory* (1906)

The son of a commercial traveler, Duhem (doo-em) was born in Paris and educated at the Ecole Normale. In his doctoral thesis he had managed to annoy BERTHELOT, an influential figure in French science and politics, and consequently found himself permanently exiled to the provinces. After teaching at the universities of Lille and Rennes (1887–94), he settled finally at the University of Bordeaux where he remained until his death from a heart attack in

1916. There had been a move shortly before his death to create a chair in the history of science for Duhem in Paris at the Collège de France. Duhem would have none of it, insisting that he was a physicist and that “he would not enter Paris by a side door.”

As a historian, his reputation is immense. His most important work, *Le système du monde* (vols. 1–5, 1913–17; vols. 6–10, 1954–59; The Global System), was one of the first attempts to argue for a deep continuity in the history of science. He saw and documented an unbroken tradition linking medieval and modern science, and was able to trace the influence of such medieval writers as BURIDAN and Jordanus upon such moderns as Leonardo and GALILEO.

Duhem's contribution to the philosophy of science has also been influential in the form of the *Duhem-Quine thesis*. Scientific theories, he argued, are seldom falsified by experience; more commonly they are modified by such techniques as redefining terms and introducing new hypotheses. His views were presented in his *The Aim and Structure of Physical Theory* (Paris, 1906; New York, 1954).

As a scientist Duhem published books on thermodynamics (1886), hydrodynamics (1891), chemical mechanics (1897–99), electricity (1902), and elasticity (1906). He took the general position that it was impossible to reduce physics and chemistry to mechanics. For, he argued, mechanics had become “a branch of a more general science. This science embraces not only movement which displaces bodies in space but also every change of qualities, properties, physical state, and chemical constitution. This science is contemporary thermodynamics or, according to the word created by RANKINE, Energetics.” Duhem's final attempted synthesis, *Traité d'énergétique* (1911; Treatise on Energetics), shunned atomism and failed to extend the new science to electricity and magnetism.

### Dujardin, Félix (1801–1860) French biologist and cytologist

Largely self-educated, Dujardin (doo-zhar-dan), who was born in Tours, France, studied geology, botany, optics, and crystallography while working variously as a hydraulics engineer, librarian, and teacher of geometry and chemistry at Tours. In 1839 he was elected to the chair of geology and mineralogy at Toulouse, and in the following year was appointed professor of botany and zoology and dean of the Faculty of Sciences at Rennes. As a skilled microscopist, Dujardin carried out extensive studies of the microorganisms (infusoria) occurring in decaying matter. These led him, in 1834, to suggest the separation of a new group of protozoan animals, which he called the rhizopods (i.e., root-foot). He was the first to recognize and appreciate the contractile nature of the proto-

plasm (which he termed the *sarcode*) and also demonstrated the role of the vacuole for evacuating waste matter. Such studies enabled Dujardin to refute the supposition, reintroduced by Christian EHRENBERG, that microorganisms have organs similar to those of the higher animals. Dujardin also investigated the cnidarians (jellyfish, sea anemones, corals, etc.), echinoderms (sea-urchins, starfish, etc.), as well as the platyhelminths, or flatworms, the last mentioned providing the basis for subsequent parasitological investigations.

### Dulbecco, Renato (1914– ) Italian-American physician and molecular biologist

Born in Catanzaro, Italy, Dulbecco (dul-bek-oh) obtained his MD from the University of Turin in 1936 and taught there until 1947 when he moved to America. He taught briefly at Indiana before moving to California in 1949, where he served as professor of biology (1952–63) at the California Institute of Technology. Dulbecco then joined the staff of the Salk Institute where, apart from the period 1971–74 at the Imperial Cancer Research Fund in London, he has remained.

Beginning in 1959 Dulbecco introduced the idea of cell transformation into biology. In this process special cells are mixed *in vitro* (Latin, meaning literally “in glass,” i.e., in a test tube) with such tumor-producing viruses as the polyoma and SV40 virus. With some cells a “productive infection” results, where the virus multiplies unchecked in the cell and finally kills its host. However, in other cells this unlimited multiplication does not occur and the virus instead induces changes similar to those in cancer cells; that is, the virus alters the cell so that it reproduces without restraint and does not respond to the presence of neighboring cells. A normal cell had in fact been transformed into a “cancer cell” *in vitro*.

The significance of this work was to provide an experimental setup where the processes by which a normal cell becomes cancerous can be studied in a relatively simplified form. It was for this work that Dulbecco was awarded the Nobel Prize for physiology or medicine in 1975, sharing it with Howard TEMIN and David BALTIMORE.

In March 1986 Dulbecco published a widely read paper in *Science*, entitled *A Turning Point in Science*, in which he argued that “if we wish to learn more about cancer, we must now concentrate on the cellular genome.” The paper appeared shortly after various groups of scientists had held a meeting at Sante Fe to discuss sequencing the entire human genome. Dulbecco's timely paper publicized the project, gave it some authority, and linked it with a practical purpose. He was still working and publishing in 2007.

**Dulong, Pierre-Louis** (1785–1838)  
*French chemist and physicist*

Born in Rouen, France, Dulong (doo-**long**) studied chemistry at the Ecole Polytechnique (1801–03) and later studied medicine. He was an assistant to Claude-Louis BERTHOLLET before becoming professor of physics at the Ecole Polytechnique (1820), and later its director (1830).

In 1813 Dulong accidentally discovered the highly explosive nitrogen trichloride, losing an eye and nearly a hand in the process. He is best known for the law of atomic heats (1819), discovered in collaboration with Alexis-Thérèse PETIT.

**Dumas, Jean Baptiste André** (1800–1884)  
*French chemist*

I do not claim to have discovered it, for it does no more than reproduce more precisely and in a more generalized form opinions that could be found in the writings of a large number of chemists.

—Concerning his substitution theory of chemistry

Dumas (doo-**mah**) was educated in classics at the college in his native city of Alais and intended to serve in the navy. However, after Napoleon's final defeat he changed his mind and became apprenticed to an apothecary. In 1816 he went to Geneva, again to work for an apothecary. His first research was in physiological chemistry, investigating the use of iodine in goiter (1818). He also studied chemistry in Geneva and was encouraged by Friedrich von HUMBOLDT to go to Paris, where he became assistant lecturer to Louis Thenard at the Ecole Polytechnique (1823). He subsequently worked in many of the Parisian institutes, becoming professor at the Ecole Polytechnique (1835) and at the Sorbonne (1841).

Dumas's early work included a method for measuring vapor density (1826), the synthesis of oxamide (1830), and the discoveries of the terpene cymene (1832), anthracene in coal tar (1832), and urethane (1833). In 1834 Dumas and Eugene PELIGOT discovered methyl alcohol (methanol) and Dumas recognized that it differed from ethyl alcohol by one  $-CH_2$  group. The subsequent discovery that CHEVREUL'S "ethal" was cetyl alcohol (1836) led Dumas to conceive the idea of a series of compounds of the same type (this was formalized into the concept of homologous series by Charles Gerhardt).

Dumas was both a prolific experimentalist and a leading theorist and he took a vigorous part in the many controversies that bedeviled organic chemistry at the time. He was originally an exponent of the "etherin" theory (in which ethyl alcohol (ethanol) and diethyl ether were considered to be compounds of etherin (ethene) with one and two molecules of water, respectively). However, he was converted to the

radical theory (an attempt to formulate organic chemistry along the dualistic lines familiar in inorganic chemistry) by Justus von LIEBIG in 1837. He then introduced his own theory – the substitution theory – which was his greatest work. It had been noticed that candles bleached with chlorine gave off fumes of hydrogen chloride when they burned. Dumas discovered that during bleaching the hydrogen in the hydrocarbon oil of turpentine became replaced by chlorine. This seemed to contradict Jöns BERZELIUS'S electrochemical theory and the latter was bitterly opposed to the substitution theory. Liebig, too, was hostile at first. Dumas then prepared trichloroacetic acid (1838) and showed that its properties were similar to those of the parent acetic acid. This convinced Liebig but not Berzelius. Further work on this series of acids, combined with the substitution theory, led him to a theory of types (1840), essentially similar to the modern concept of functional groups, although the credit for this theory was disputed between Dumas and Auguste LAURENT.

Dumas also carried out important work on atomic weights. He had been an early supporter of Amedeo AVOGADRO but he never properly distinguished between atoms and molecules and the problems this raised caused him to abandon the theory. He also supported William PROUT'S hypothesis that atomic weights were whole-number multiples of that of hydrogen. In 1840, working with Jean STAS, he obtained the figure 12.000 for carbon instead of the figure 12.24 in use at that time.

Following the revolution of 1848 Dumas became involved in administration, becoming minister of agriculture and commerce (1849–51), minister of education, and permanent secretary of the Academy of Sciences (1868).

**Dunning, John Ray** (1907–1975)  
*American physicist*

Born in Shelby, Nebraska, Dunning was educated at the Wesleyan University, Nebraska, and at Columbia University, New York, where he obtained his PhD in 1934. He took up an appointment at Columbia in 1933, being made professor of physics in 1950.

Dunning was one of the key figures in the Manhattan project to build the first atomic bomb. It had been shown by Niels BOHR that the isotope uranium-235 would be more likely to sustain a neutron chain reaction than normal uranium. Only 7 out of every 1,000 uranium atoms occurring naturally are uranium-235, which presents difficulties in extraction. Various techniques were tried and Dunning was placed in charge of the process of separation known as gaseous diffusion. This involved turning the uranium into a volatile compound (uranium hexafluoride,  $UF_6$ ) and

passing the vapor through a diffusion “filter.” As  $^{235}\text{U}$  atoms are slightly less massive than the normal  $^{238}\text{U}$  they pass through the filter a little faster and can thus be concentrated. The difference in mass is so small, however, that simply to produce a gas enriched with  $^{235}\text{U}$  atoms required its passage through thousands of filters.

As early as 1939 Dunning had shown that the process would work but to produce  $^{235}\text{U}$  in the quantities required by the Manhattan project was a daunting prospect and the engineering problems were immense. The gas is extraordinarily corrosive and a single leak in one of the hundreds of thousands of filters would lose the precious  $^{235}\text{U}$ . But as the other projects ran into even more formidable difficulties it was largely through gaseous diffusion that sufficient enriched uranium was made available for the bomb to be built.

**Durand, William Frederick** (1859–1958)  
*American engineer*

Born in Beacon Falls, Connecticut, Durand graduated from the U.S. Naval Academy in 1880 and entered the Engineering Corps of the U.S. Navy (1880–87). He then took a post as professor of mechanical engineering at Michigan State College in 1887. He moved to Cornell in 1891 to the chair of marine engineering and, in 1904, he accepted the professorship of mechanical engineering at Stanford, a position he held until his retirement in 1924.

Durand worked mainly on problems connected with the propeller, both marine and, after 1914, aeronautical. He was general editor of an important standard work, *Aerodynamic Theory*, produced in six volumes (1929–36). He also served on the National Advisory Committee for Civil Aeronautics (NACA) (1915–33) and, in 1941, was recalled to advise the government on the construction of an American jet-propelled airplane.

**Du Toit, Alexander Logie** (1878–1949)  
*South African geologist*

Du Toit (doo toit), who was born at Rondebosch, near Cape Town in South Africa, studied at the South Africa College (now the University of Cape Town), the Royal Technical College, Glasgow, and the Royal College of Science, London.

After a short period teaching at Glasgow University (1901–03) he returned to South Africa and worked with the Geological Commission of the Cape of Good Hope (1903–20), during which he explored the geology of South Africa. For the next seven years he worked for the Irrigation Department and produced six detailed monographs on South African geology. He served as a consulting geologist to De Beers Consolidated Mines during the period 1927–41.

Following a visit to South America in 1923,

du Toit became one of the earliest supporters of Alfred WEGENER's theory of continental drift, publishing his observations in *A Geological Comparison of South America with South Africa* (1927). He noted the similarity between the continents and developed his ideas in *Our Wandering Continents* (1937), in which he argued for the separation of Wegener's Pangaea into the two supercontinents, Laurasia and Gondwanaland.

**Dutrochet, René Joachim Henri** (1776–1847)  
*French physiologist*

Born in Néon, France, Dutrochet (doo-tro-shay) began medical studies while serving in the army in Paris in 1802. After graduating in 1806 he served as an army surgeon in Spain. However, through illness he resigned his post in 1809 and thereafter devoted his time to natural science.

In 1814 he published his investigations into animal development, suggesting a unity of the main features during the early stages. Later research into plant and animal physiology led to his assertion that respiration is similar in both plants and animals. In 1832, Dutrochet showed that gas exchange in plants was via minute openings (stomata) on the surface of leaves and the deep cavities with which they communicate. He further demonstrated that only cells containing chlorophyll can fix carbon and thus transform light energy into chemical energy. Dutrochet studied osmosis and suggested it may be the cause of ascent and descent of sap in plants. Although sometimes lacking in accuracy, the importance of his work lies mainly in his endeavor to demonstrate that the vital phenomena of life can be explained on the basis of physics and chemistry.

**Dutton, Clarence Edward** (1841–1912)  
*American geologist*

Born in Wallingford, Connecticut, Dutton graduated from Yale in 1860 and then entered the Yale Theological Seminary. He joined the army in 1862 during the Civil War and remained in the army although not always on active service. He became interested in geology and joined the Geographical and Geological Survey of the Rocky Mountains and the West in 1875.

The term “isostasy” was introduced into geology by Dutton in 1889. This described a theory propounded by George AIRY in which it is supposed that mountain ranges and continents rest on a much denser base. As mountains are eroded the land rises while the settling sediment will compensate by depressing some other part of the Earth.

After his return to the army in 1890 Dutton turned to the study of earthquakes and volcanoes. His research was published in 1904 in

his *Earthquakes in the Light of the New Seismology*.

**Duve, Christian René de** See **DE DUVE, CHRISTIAN RENÉ**.

**Du Vigneaud, Vincent** (1901–1978)  
*American biochemist*

Born in Chicago, Illinois, Du Vigneaud (doo veen-yoh) graduated from the University of Illinois in 1923; he remained there to take his master's degree before going to the University of Rochester. There he studied the hormone insulin, gaining his PhD in 1927. The research on insulin marked the beginning of his interest in sulfur compounds, particularly the sulfur-containing amino acids – methionine, cystine, and cysteine.

In 1938 Du Vigneaud became head of the biochemistry department of Cornell University Medical College. Two years later he had isolated vitamin H (biotin) and by 1942 had determined its structure. He then went on to examine the hormones secreted by the posterior pituitary gland, especially oxytocin and vasopressin. He found oxytocin to be composed of eight amino acids, worked out the order of these, and in 1954 synthesized artificial oxytocin, which was shown to be as effective as the natural hormone in inducing labor and milk flow. This was the first protein to be synthesized and for this achievement Du Vigneaud received the Nobel Prize for chemistry in 1955. Du Vigneaud's other work included research on penicillin and on methyl groups. He was professor of chemistry at Cornell University from 1967 to 1975 and subsequently professor of biochemistry there.

**Dyson, Sir Frank Watson** (1868–1939)  
*British astronomer*

Dyson, the son of a Baptist minister from Ashby-de-la-Zouche in Leicestershire, England, graduated in mathematics from Cambridge University in 1889; in 1891 he was elected to a fellowship. After first working as chief assistant at the Royal Observatory at Greenwich from 1894 to 1905, he was Astronomer Royal for Scotland from 1905 to 1910 and then returned to Greenwich as Astronomer Royal, serving from 1910 to 1933. He was knighted in 1915.

Dyson's early observational work was done in collaboration with William G. Thackeray: they measured the positions of over 4,000 circumpolar stars that had first been observed by Stephen Groombridge at the beginning of the

19th century. They were thus able to determine the proper motions of the stars. Dyson could then extend the work of Jacobus KAPTEYN on star streaming to fainter stars.

Dyson observed the total solar eclipses of 1900, 1901, and 1905, obtaining spectra of the atmospheric layers of the Sun. He also organized the detailed observations of the total solar eclipse in 1919, sending expeditions to Principe in the Gulf of Guinea and Sobral in Brazil. The measured positions of stars near the Sun's rim during the eclipse provided evidence for the bending of light in a gravitational field, as predicted by EINSTEIN in his theory of general relativity; this was the first experimental support for the theory.

**Dyson, Freeman John** (1923– ) *British–American theoretical physicist*

The son of Sir George Dyson, director of the Royal College of Music, Dyson was born at Crowthorne in England and educated at Cambridge University. During World War II he worked at the headquarters of Bomber Command. In 1947 he went on a Commonwealth Fellowship to Cornell University and in 1953 joined the Institute of Advanced Studies, Princeton, where he served as professor of physics until his retirement in 1994.

Dyson has worked on a number of topics but is best known for his contribution to quantum electrodynamics, i.e., the application of quantum theory to interactions between particles and electromagnetic radiation. The observation in 1946 by Willis LAMB of a small difference between the lowest energy levels of the hydrogen atom was an experimental result against which such theories could be tested. In the period 1946–48 independent formulations of quantum electrodynamics were put forward by Julian SCHWINGER, Sin-Itiro TOMONAGA, and Richard FEYNMAN. Dyson showed that the three methods were all consistent and brought them together into a single general theory.

Dyson later became known to a wider public through his work on the nuclear test ban treaty and for his quite serious considerations of space travel and the "greening of the galaxy." He also reached a wider audience with the publication of his autobiography *Disturbing the Universe* (1980) and his 1985 Gifford Lectures, *Infinite in All Directions* (1988). More recently (2007) he claimed that the global warming problem had been exaggerated. He has long advocated reducing carbon dioxide by planting large areas with trees.

# E

---

**Eastman, George** (1854–1932) *American inventor*

Eastman, who was born in Waterville, New York, began his career in banking and insurance but turned from this to photography. In 1880 he perfected the dry-plate photographic film and began manufacturing this. He produced a transparent roll film in 1884 and in the same year founded the Eastman Dry Plate and Film Company. In 1888 he introduced the simple hand-held box camera that made popular photography possible. The Kodak camera with a roll of transparent film was cheap enough for all pockets and could be used by a child. It was followed by the Brownie camera, which cost just one dollar.

Eastman gave away a considerable part of his fortune to educational institutions, including the Massachusetts Institute of Technology. He committed suicide in 1932.

**Ebashi, Setsuro** (1922–2006) *Japanese biochemist*

Ebashi (e-**bash**-ee), who was born in the Japanese capital of Tokyo, received his MD from the university there in 1944 and his PhD in 1954. He became professor of pharmacology there in 1959 and, from 1963, held the chair of biochemistry.

Ebashi was, for many years, one of the leading workers in the field of muscle contraction. His work threw considerable light on the identity and workings of the so-called “relaxing factor.” As early as 1952, B. Marsh had isolated a substance from muscle that produces relaxation in muscle fibers, and he noted that its effect could be neutralized by the presence of calcium ions.

While the process of muscle contraction appeared to be initiated by the release of calcium ions from the sarcoplasmic reticulum, Ebashi and his colleagues were able to show, in the 1960s, that such ions were not enough. The presence of two globular proteins, troponin and tropomyosin, is also necessary. Neither protein alone is sufficient as only the complex of both sensitizes muscle to calcium ions.

The globular proteins appear to prevent the interaction of myosin and actin as first described by Hugh HUXLEY. However, once a certain level of calcium is reached such inhibition

is prevented and contraction occurs. Later x-ray analysis by many workers seems to have confirmed Ebashi’s model.

**Eccles, Sir John Carew** (1903–1997) *Australian physiologist*

Born in Melbourne, Australia, Eccles was educated at the university there and at Oxford University. In Oxford he worked with Charles SHERRINGTON on muscular reflexes and nervous transmission across the synapses (nerve junctions) from 1927 to 1937. He then worked in Australia at the Institute of Pathology from 1937 to 1943. After a period in New Zealand, as professor of physiology at the University of Otago from 1944 to 1951, Eccles returned to Australia to the Australian National University, Canberra, where he served as professor of physiology from 1951 to 1966. In 1966 Eccles moved to the U.S., working first in Chicago and finally, from 1968 until his retirement in 1975, at the State University of New York, Buffalo.

While at Canberra Eccles carried out work on the chemical changes that take place at synapses, pursuing the findings of Alan HODGKIN and Andrew HUXLEY, with whom he subsequently shared the 1963 Nobel Prize for physiology or medicine. Eccles showed that excitation of different nerve cells causes the synapses to release a substance (probably acetylcholine) that promotes the passage of sodium and potassium ions and effects an alternation in the polarity of the electric charge. It is in this way that nervous impulses are communicated or inhibited by nerve cells. Eccles is the author of *Reflex Activity of the Spinal Cord* (1932) and *The Physiology of Nerve Cells* (1957).

After his retirement Eccles began to publish a number of works on the mind-body problem. Notable among them are *The Self and the Brain* (1977), written in collaboration with Karl POPPER, *The Human Mystery* (1979), and *The Creation of the Self* (1989).

**Eckert, John Presper Jr.** (1919–1995) *American computer scientist*

Born in Philadelphia, Pennsylvania, Eckert was educated at the Moore School of Electrical Engineering at the University of Pennsylvania in his native city. After graduating in 1941 he im-

mediately joined the faculty. Soon after he began his long and profitable career with his colleague, J. W. MAUCHLY. Together they built the historically important computers, ENIAC, EDSAC, and UNIVAC.

In 1946 Eckert resigned from the Moore School to set up the Electronic Control Co. with his colleague, Mauchly. As they failed to raise any money on Wall Street they began with a \$25,000 loan from Eckert's father. Initially things went well but the constraints of a fixed-price contract with the U.S. Census Bureau led them into virtual bankruptcy. Consequently, they were forced to sell out to Remington Rand in 1950. They received \$200,000 plus a guaranteed executive position for eight years in a separate UNIVAC Division.

While some of the initial ideas emerged from Mauchly, Eckert has been described as "the mainspring of the whole operation." Thus it was Eckert who solved the problem of the vacuum tubes. How does one ensure that sufficient numbers of the 17,000 tubes of ENIAC work at any one time to keep the computer running? The answer was stringent testing and, less obviously, to run the tubes well below their rated voltage and so extend their working lives.

It was also Eckert who devised the mercury delay lines, used as memory stores in early computers, and successfully deployed by M. V. WILKES in EDSAC.

### **Eddington, Sir Arthur Stanley (1882–1944)** *British astrophysicist and mathematician*

We used to think that if we knew one, we knew two, because one and one are two. We are finding that we must learn a great deal more about "and".

—Quoted by A. L. Mackay in *The Harvest of a Quiet Eye* (1977)

Born at Kendal in northwestern England, Eddington moved with his mother and sister to the southwestern county of Somerset after the death of his father in 1884. He was a brilliant scholar, graduating from Owens College (now the University of Manchester) in 1902 and from Cambridge University in 1905. From 1906 to 1913 he was chief assistant to the Astronomer Royal at Greenwich after which he returned to Cambridge as Plumian Professor of Astronomy. He was knighted in 1930. Eddington was a Quaker throughout his life.

Eddington was the major British astronomer of the interwar period. His early work on the motions of stars was followed, from 1916 onward, by his work on the interior of stars, which was published in his first major book, *The Internal Constitution of the Stars* (1926). He introduced "a phenomenon ignored in early investigations, which may have considerable effect on the equilibrium of a star, viz. the pres-

sure of radiation." He showed that for equilibrium to be maintained in a star, the inwardly directed force of gravitation must be balanced by the outwardly directed forces of both gas pressure and radiation pressure. He also proposed that heat energy was transported from the center to the outer regions of a star not by convection, as thought hitherto, but by radiation.

It was in this work that Eddington gave a full account of his mass-luminosity relationship, which was discovered in 1924 and shows that the more massive a star the more luminous it will be. The value of the relation is that it allows the mass of a star to be determined if its intrinsic brightness is known. This is of considerable significance since only the masses of binary stars can be directly calculated. Eddington realized that there was a limit to the size of stars: relatively few would have masses exceeding 10 times the mass of the Sun while any exceeding 50 solar masses would be unstable owing to excessive radiation pressure. Eddington wrote a number of books for both scientists and laymen. His more popular books, including *The Expanding Universe* (1933), were widely read, went through many editions, and opened new worlds to many enquiring minds of the interwar years. It was through Eddington that EINSTEIN'S general theory of relativity reached the English-speaking world. He was greatly impressed by the theory and was able to provide experimental evidence for it. He observed the total solar eclipse of 1919 and submitted a report that captured the intellectual imagination of his generation. He reported that a very precise and unexpected prediction made by Einstein in his general theory had been successfully observed; this was the very slight bending of light by the gravitational field of a star – the Sun. Further support came in 1924 when Einstein's prediction of the reddening of starlight by the gravitational field of the star was tested: at Eddington's request Walter ADAMS detected and measured the shift in wavelength of the spectral lines of Sirius B, the dense white-dwarf companion of the star Sirius. Eddington thus did much to establish Einstein's theory on a sound and rigorous foundation and gave a very fine presentation of the subject in his *Mathematical Theory of Relativity* (1923).

Eddington also worked for many years on an obscure but challenging theory, which was only published in his posthumous work, *Fundamental Theory* (1946). Basically, he claimed that the fundamental constants of science, such as the mass of the proton and the mass and charge of the electron, were a "natural and complete specification for constructing a universe" and that their values were not accidental. He then set out to develop a theory from which such values would follow as a consequence, but never completed it.

**Edelman, Gerald Maurice** (1929– )  
*American biochemist*

Born in New York City, Edelman was educated at Ursinus College, the University of Pennsylvania, and Rockefeller University, where he obtained his PhD on human immunoglobulins in 1960. He remained at Rockefeller where he was appointed professor of biochemistry in 1966 and Vincent Astor Distinguished Professor in 1974. Edelman left Rockefeller in 1992 to set up and direct the Neuroscience Institute at the Scripps Research Institute, La Jolla, California.

Edelman was interested in determining the structure of human immunoglobulin. The molecule is very large and it was first necessary to break it into smaller portions, which was achieved by reducing and splitting the disulfide bonds. Following this, Edelman proposed that the molecule contained more than one polypeptide chain and, moreover, that two kinds of chain exist, light and heavy. Such studies helped Rodney PORTER propose a structure for the antibody immunoglobulin G (IgG) in 1962.

Edelman was more interested in attempting to work out the complete amino-acid sequence of IgG. As it contained 1,330 amino acids it was by far the largest protein then attempted. By 1969 he was ready to announce the results of his impressive work, the complete sequence, and was able to show that while much of the molecule was unchanging the tips of the Y-like structure were highly variable in their amino-acid sequence. It thus seemed obvious that such an area would be identical with the active antigen binding region in Porter's structure and that such variability represented the ability of IgG to bind many different antigens. It was for this work that Edelman and Porter shared the 1972 Nobel Prize for physiology or medicine.

Edelman has also speculated on antibody formation and the mechanism behind the spurt in production after contact with an antigen. In the former area he argued in 1966 for a major modification of the clonal theory of Macfarlane BURNET. In the latter case he suggested, in 1970, that the signal to the immune system to increase production is set off by the change in shape of the antibody molecule as it combines with its antigen.

Following his biochemical successes Edelman turned to the neurosciences. In such works as *Neural Darwinism* (1987) and *Bright Air, Brilliant Mind* (1993), he produced a distinctive theory of the development and nature of the mind. We are, he claims, at the beginning of a neuroscientific revolution from which we will learn "how the mind works, what governs our nature, and how we know the world." Edelman was struck by a number of similarities between the immune system and the nervous system. Just as a lymphocyte can recognize and respond to a new antigen, the nervous system can re-

spond similarly to novel stimuli. Neural mechanisms are selected, he argued, in the same manner as antibodies. Although the  $10^9$  cells of the nervous system do not replicate, there is considerable scope for development and variation in the connections that form between the cells. Frequently used connections will be selected, others will decay or be diverted to other uses. There are two kinds of selection: developmental, which takes place before birth, and experiential. There are also innate "values," built in preferences that is, for such features as light and warmth over the dark and the cold. In Edelman's model, higher consciousness, including self-awareness and the ability to create scenes in the mind, have required the emergence during evolution of a new neuronal circuit. To remember a chair or one's grandmother is not to recall a bit of coded data from a specific location; it is rather to create a unity out of scattered mappings, a process called by Edelman a "reentry." Edelman's views have been dismissed by many as obscure; some neurologists, however, consider Edelman to have begun what will eventually turn out to be a major revolution in the neurosciences.

**Edison, Thomas Alva** (1847–1931) *American physicist and inventor*

In 1879 the performance of the Edison telephone was illustrated in the theatre of the Royal Institution.... Perhaps the most striking illustration of the pliant power of the instrument was its capability to reproduce a whistled tune. Mr Edison's whistling at the Circus was heard in Albemarle Street almost as distinctly as if it had been produced upon the spot.

—John Tyndall, *On Sound* (1883)

My personal desire would be to prohibit entirely the use of alternating currents. They are unnecessary as they are dangerous ... I can therefore see no justification for the introduction of a system which has no element of permanency and every element of danger to life and property.

—Quoted by R. L. Weber in *A Random Walk in Science*

Genius is one percent inspiration and ninety-nine percent perspiration.

—Quoted in *Life* (1932)

Edison was born in Milan, Ohio, and was taught at home by his mother – he had been expelled from school as "retarded," perhaps because of his deafness. From the age of seven he lived in Port Huron, Michigan, and when he was twelve years old began to spend much of his time on the railroad between Port Huron and Detroit, selling candy and newspapers to make money. However, he was also fascinated by the telegraph system, designing his own experiments and training himself in telegraphy. He became a casual worker on telegraphy (1862–68), reading and experimenting as he

traveled. At the age of 21 he bought a copy of FARADAY's *Experimental Researches in Electricity* and was inspired to undertake serious systematic experimental work.

While Edison was living in a Wall Street basement (1869) he was called in to carry out an emergency repair on a new telegraphic gold-price indicator in the Gold Exchange. He was so successful that he was taken on as a supervisor. Later he remodeled the equipment and, soon after being commissioned to improve other equipment, his skill became legendary.

For a while Edison had a well-paid job with the Western Union Telegraph Company, but he gave it up to set up a laboratory of his own at Menlo Park, New Jersey. This he furnished with a wide range of scientific equipment, costing \$40,000, and an extensive library. He employed 20 technicians and later a mathematical physicist. The laboratory was the first organized research center outside a university and produced many inventions. In 1877 Edison became known internationally after the phonograph was invented. His original instrument used a cylinder coated with tinfoil to record sounds, and was not commercially practical. In 1878, after seeing an exhibition of glaring electric arc lights, he declared that he would invent a milder cheap alternative that could replace the gas lamp. Because of his past successes, he managed to raise the capital to do this and the Edison Electric Light Company was set up. It took 14 months to find a filament material but by October 1879, Edison was able to demonstrate 30 incandescent electric lamps connected in parallel with separate switches. Three years later a power station was opened in New York and this was the start of modern large-scale electricity generation. Edison later merged his electric-light company with that of Joseph SWAN who developed the carbon-filament light independently. Also in his work on incandescent filaments, Edison discovered that a current flows in one direction only between the filament and a nearby electrode. The use of this *Edison effect* in the thermionic valve was independently achieved by J. A. FLEMING. In 1887 Edison's laboratory moved to larger premises in West Orange, now a national monument. In his lifetime he took out over 1,000 patents covering a variety of applications, including telephone transmission, cinematography, office machinery, cement manufacture, and storage batteries. No other inventor has been so productive.

**Edlén, Bengt** (1906–1993) *Swedish physicist*

Born at Gusum in Sweden, Edlén (ed-lyen) studied at the University of Uppsala, where he gained his PhD in 1934 and also served on the faculty from 1928 until 1944. He was then appointed professor of physics at the University of

Lund, a post he retained until his retirement in 1973.

Edlén is recognized for his research on atomic spectra and its applications to astrophysics. In the early 1940s he carried out important work on the emission lines, first described in 1870, in the Sun's corona, i.e., the outermost layer of the solar atmosphere. The problem with the 20 "well-measured lines" was that none had ever been observed in a laboratory light source. At one time they were thought to indicate the presence of an unknown element, conveniently described as "coronium," but it had become apparent when Edlén began his work that the periodic table no longer contained any suitable gaps.

Edlén succeeded in showing in 1941 that the coronal lines were mainly caused by iron, nickel, calcium, and argon atoms deprived of 10–15 electrons; i.e., by highly charged positive ions. The implications of such extreme ionization were not lost on Edlén, who was quick to point out that it must indicate temperatures of over a quarter of a million degrees in the solar corona.

**Edsall, John Tileston** (1902–2002) *American biochemist*

Edsall was born in Philadelphia, Pennsylvania, and educated at Harvard and at Cambridge University, England. He joined the Harvard faculty in 1928 and from 1951 to 1973 served there as professor of biochemistry.

Edsall was basically a protein chemist. He spent much time establishing basic data on the constitution and properties of numerous proteins – information that has since been reproduced in innumerable textbooks. With Edwin Cohn he was the author of the authoritative work *Proteins, Amino Acids and Peptides* (1943).

In later years Edsall turned his attention to the history of biochemistry, his books in this field including *Blood and Hemoglobin* (1952).

**Egas Moniz, Antonio** (1874–1955) *Portuguese neurologist*

Frontal leukotomy ... one of the most important discoveries ever made in psychiatric therapy...a great number of suffering people and total invalids have recovered and have been socially rehabilitated.

—Herbert Olivecrona, presentation speech at award of the 1949 Nobel Prize

Egas Moniz (eg-ash mon-ish) was born at Avanca in Portugal and educated at the University of Coimbra, where he gained his MD in 1899. After postgraduate work in Paris and Bordeaux he returned to Coimbra, becoming a professor in the medical faculty in 1902. He moved to Lisbon in 1911 to a newly created chair of neurology, a post he retained until his retirement in 1944. At the same time he was

pursuing a successful political career, being elected to the National Assembly in 1900. He served as ambassador to Spain in 1917 and in the following year became foreign minister, leading his country's delegation to the Paris Peace Conference.

Egas Moniz achieved his first major success in the 1920s in the field of angiography (the study of the cardiovascular system using dyes that are opaque to x-rays). In collaboration with Almeida Lima, he injected such radiopaque dyes into the arteries, enabling the blood vessels of the brain to be photographed. In 1927 he was able to show that displacements in the cerebral circulation could be used to infer the presence and location of brain tumors, publishing a detailed account of his technique in 1931.

Egas Moniz is better known for his introduction in 1935 of the operation of prefrontal leukotomy. It was for this work, described by the Nobel authorities as "one of the most important discoveries ever made in psychiatric therapy," that they awarded him the 1949 Nobel Prize for physiology or medicine.

The operation consisted of inserting a sharp knife into the prefrontal lobe of the brain, roughly the area above and between the eyes; it required the minimum of equipment and lasted less than five minutes. The technique was suggested to Egas Moniz on hearing an account (by John Fulton and Carlyle Jacobsen in 1935) of a refractory chimpanzee that became less aggressive after its frontal lobes had been excised. Egas Moniz believed that a similar surgical operation would relieve severe emotional tension in psychiatric patients. He claimed that 14 of the first 20 patients operated upon were either cured or improved. The operation generated much controversy, since the extent of the improvement in the patients' symptoms was not easy to judge and the procedure often produced severe side-effects. Today a more refined version of the operation, in which selective incisions are made in smaller areas of the brain, is still quite widely practiced.

**Ehrenberg, Christian Gottfried (1795–1876)** *German biologist and microscopist*

Until now my favorite pursuit has been neither naked systematizing nor unsystematic observation, and whenever time and circumstances, together with my ability, allow it, I prefer getting down to the grass-roots level.

—Letter to Nees von Esenbeck (1821)

Ehrenberg (**air-en-berg**) was born in Delitzsch, which is now in Germany, and took an MD degree at the University of Berlin in 1818. In the same year he was elected a member of the Leopoldine German Academy of Researchers in Natural Sciences. Two years later he took

part in a scientific expedition to Egypt, Libya, the Sudan, and the Red Sea, sponsored by the Prussian Academy of Sciences and the University of Berlin. During these travels (1820–25) Ehrenberg collected and classified some 75,000 plant and animal specimens, both terrestrial and marine, including microorganisms. On a further expedition in 1829 to Central Asia and Siberia, sponsored by Czar Nicholas I, he was accompanied by Alexander von HUMBOLDT. In 1827 Ehrenberg was appointed assistant professor of zoology at Berlin and was elected a member of the Berlin Academy of Sciences. He became professor of natural science at Berlin in 1839.

Ehrenberg's studies in natural science were primarily concerned with microorganisms, especially the protozoans. His paleontological investigations led him to demonstrate the presence of single-celled fossils in certain rock layers of various geological formations, and he was also able to show that marine phosphorescence (strictly, bioluminescence) was due to the activity of species of animal plankton. He described fungal development from spores, as well as their sexual reproduction, and also carried out detailed studies of corals. His most important thesis lay in the belief that microorganisms were complete in the sense of sharing the same organs as higher animals, and that social behavior provided the basis for a new approach to animal classification. Ehrenberg's theory was demolished, with the help of experimental evidence, by Félix DUJARDIN. Ehrenberg's publications include *Travels in Egypt, Libya, Nubia and Dongola* (1828) and *The Infusoria as Complete Animals* (1838). His descriptions and classification of fossil protozoans were published as *Microgeology* (1854).

**Ehrlich, Paul (1854–1915)** *German physician, bacteriologist, and chemist*

Success in research needs four Gs: *Glück, Geduld, Geschick und Geld* [luck, patience, skill, and money].

—Quoted by M. Peruz in *Nature* (1988)

Born in Strehlen (now Strzelin in Poland), Ehrlich (**air-lik**) studied medicine at the universities of Breslau, Strasbourg, and Freiburg, gaining a physician's degree at Breslau in 1878. For the next nine years he worked at the Charité Hospital, Berlin, on many topics including typhoid fever, tuberculosis, and pernicious anemia. He was awarded the title of professor by the Prussian Ministry of Education in 1884 for his impressive work in these fields. In 1887 he became a teacher at the University of Berlin but was not paid because of the antisemitic feeling at the time – Ehrlich would not renounce his Jewish upbringing. As a result of his laboratory work he contracted tuberculosis and was not restored to health until 1890, when he

set up his own small research laboratory at Steglitz on the outskirts of Berlin.

In 1890 Robert KOCH announced the discovery of tuberculin and suggested its use in preventing and curing tuberculosis. He asked Ehrlich to work on it with him at the Moabit Hospital in Berlin. Ehrlich accepted and for six years studied TB and cholera. In 1896 he accepted the post of director of the new Institute for Serum Research and Serum Investigation at Steglitz and in 1899 moved to the Institute of Experimental Therapy in Frankfurt. Here he investigated African sleeping sickness and syphilis along with his other studies. In 1908 he was awarded the Nobel Prize for physiology or medicine for his work on immunity and serum therapy.

Two years later he announced his most famous discovery, Salvarsan – a synthetic chemical that was effective against syphilis – and until the end of his life he worked on the problems associated with the treatment of patients using this compound of arsenic.

Ehrlich is considered to be the founder of modern chemotherapy because he developed systematic scientific techniques to search for new synthetic chemicals that could specifically attack disease-causing microorganisms. Ehrlich sought for these “magic bullets” by carefully altering the chemical structure of dye molecules that selectively stained the microorganisms observable in his microscope but did not stain cells in the host. He was persevering and optimistic – Salvarsan (compound number 606) was not “rediscovered” until almost 1,000 compounds had been synthesized and tried. He made and tested about 3,000 compounds based on the structure of Salvarsan in an attempt to make a drug that was bacteriocidal to streptococci.

### **Eichler, August Wilhelm** (1839–1887) *German botanist*

Eichler (**Ik**-ler) was born in Neukirchen (which is now in Germany) and studied natural science and mathematics at the University of Marburg, gaining his PhD in 1861. Eichler then became assistant to Karl von Martius at Munich. With Martius he began editing the 15-volume *Flora of Brazil*, continuing this work single-handed after Martius's death in 1868. In 1878 he was appointed professor of systematic and morphologic botany at Berlin and also became director of the university's herbarium. The same year he published the second volume of his two-volume *Diagrams of Flowers*, describing the comparative structure of flowers.

In 1886, the year before his death, Eichler developed a plant classification system in which the plant kingdom is split into four divisions: Thallophyta (algae, fungi), Bryophyta (mosses, liverworts), Pteridophyta (ferns, horsetails), and Spermatophyta (seed plants). He further

subdivided the Spermatophyta into the Gymnospermae (conifers, cycads, ginkgos) and Angiospermae (flowering plants). This system was later adopted by nearly all botanists, but because of his early death from leukemia Eichler did not live to see the general acceptance of his work.

### **Eigen, Manfred** (1927– ) *German physical chemist*

A theory has only the alternative of being right or wrong. A model has a third possibility: it may be right, but irrelevant.

—*The Physicist's Conception of Nature* (1973)

Eigen (**I**-gen), the son of a musician, was born at Bochum in Germany and educated at the University of Göttingen where he obtained his PhD in 1951. He joined the staff of the Max Planck Institute for Physical Chemistry at Göttingen in 1953 and served as its director from 1964 until his retirement in 1995.

In 1954 Eigen introduced the so-called relaxation techniques for the study of extremely fast chemical reactions (those taking less than a millisecond). Eigen's general method was to take a solution in equilibrium for a given temperature and pressure. If a short disturbance was applied to the solution the equilibrium would be very briefly destroyed and a new equilibrium quickly reached. Eigen studied exactly what happened in this very short time by means of absorption spectroscopy. He applied disturbances to the equilibrium by a variety of methods, such as pulses of electric current, sudden changes in temperature or pressure, or changes in electric field.

The first reaction he investigated was the apparently simple formation of a water molecule from the hydrogen ion,  $H^+$ , and the hydroxide ion,  $OH^-$ . Calculations of reaction rates made it clear that they could not be produced by the collision of the simple ions  $H^+$  and  $OH^-$ . Eigen went on to show that the reacting ions are the unexpectedly large  $H_9O_4^+$  and  $H_7O_4^-$ , a proton hydrated with four water molecules and a hydroxyl ion with three water molecules. For this work Eigen shared the 1967 Nobel Prize for chemistry with George PORTER and Ronald NORRISH.

Eigen later applied his relaxation techniques to complex biochemical reactions. He has also become interested in the origin of nucleic acids and proteins; with his colleague R. WINKLER he has proposed a possible mechanism to explain their formation. Much of this and subsequent work was described by Eigen in his *Laws of the Game: How Principles of Nature Govern Chance* (1982).

### **Eijkman, Christiaan** (1858–1930) *Dutch physician*

Eijkman (**Ik**-man) was born at Nijkerk in the

Netherlands and qualified as a physician from the University of Amsterdam in 1883. He served as an army medical officer in the Dutch East Indies from 1883 to 1885, when he was forced to return to the Netherlands to recuperate from a severe attack of malaria. In 1886 he returned to the East Indies as a member of an official government committee to investigate beriberi. After the completion of the committee's work, Eijkman remained in Batavia (now Djakarta) as director of a newly established bacteriological laboratory. In 1896 he took up the post of professor of public health at the University of Utrecht.

Eijkman was responsible for the first real understanding of the nature and possible cure of beriberi. For this work he shared the 1929 Nobel Prize for physiology or medicine with Frederick Gowland HOPKINS. Beriberi is a disorder caused by dietary deficiency, producing fatal lesions in the nervous and cardiovascular systems. Physicians of the late 19th century, however, were not trained to recognize its cause: with the clear success of the germ theory recently demonstrated by Robert KOCH it was difficult to realize that symptoms could be produced by the absence of something rather than by the more obvious presence of a visible pathogen. Eijkman's discovery was prompted by the outbreak of a disease very similar to human beriberi among the laboratory chickens. Despite the most thorough search no causative microorganisms could be identified, and then, for no obvious reason, the disease disappeared.

On investigation, Eijkman discovered that the symptoms of the disease had developed during a period of five months in which the chickens' diet was changed to hulled and polished rice. With a return to their normal diet of commercial chicken feed the symptoms disappeared. Eijkman subsequently found that he could induce the disease with a diet of hulled and polished rice and cure it with one of whole rice. However, he failed to conclude that beriberi was a deficiency disease. He argued that the endosperm of the rice produced a toxin that was neutralized by the outer hull: by eating polished rice the toxin would be released in its unneutralized form. Thus although Eijkman had clearly demonstrated how to cure and prevent beriberi it was left to Hopkins to identify its cause as a vitamin deficiency. It was not until the early 1930s that Robert WILLIAMS identified the vitamin as vitamin B<sub>1</sub> (thiamine).

**Einstein, Albert** (1879–1955) *German–Swiss–American theoretical physicist*

Everything should be made as simple as possible, but not simpler.

—Quoted in *Reader's Digest*, October 1977

Imagination is more important than knowledge.

—*On Science*

Einstein was born at Ulm in Germany where his father was a manufacturer of electrical equipment. Business failure led his father to move the family first to Munich, where Einstein entered the local gymnasium in 1889, and later to Milan. There were no early indications of Einstein's later achievements for he did not begin to talk until the age of three, nor was he fluent at the age of nine, causing his parents to fear that he might even be backward. It appears that in 1894 he was expelled from his Munich gymnasium on the official grounds that his presence was "disruptive." At this point he did something rather remarkable for a fifteen-year-old boy. He had developed such a hatred for things German that he could no longer bear to be a German citizen. He persuaded his father to apply for a revocation of his son's citizenship, a request the authorities granted in 1896. Until 1901, when he obtained Swiss citizenship, he was in fact stateless.

After completing his secondary education at Aarau in Switzerland he passed the entrance examination, at the second attempt, to the Swiss Federal Institute of Technology, Zurich, in 1896. He did not appear to be a particularly exceptional student, finding the process of working for examinations repellent. Disappointed not to be offered an academic post, he survived as a private tutor until 1902, when he obtained the post of technical expert, third class, in the Swiss Patent Office in Bern. Here he continued to think about and work on physical problems. In 1905 he published four papers in the journal *Annalen der Physik* (Annals of Physics) – works that were to direct the progress of physics during the 20th century. The first, and most straightforward, was on Brownian motion – first described by Robert BROWN in 1828. Einstein derived a formula for the average displacement of particles in suspension, based on the idea that the motion is caused by bombardment of the particles by molecules of the liquid. The formula was confirmed by Jean PERRIN in 1908 – it represented the first direct evidence for the existence of atoms and molecules of a definite size. The paper was entitled *Über der von molekularkinetischen Theorie der Wärme geförderte Bewegung von in ruhenden Flüssigkeiten suspendierten Teilchen* (On the Motion of Small Particles Suspended in a Stationary Liquid According to the Molecular Kinetic Theory of Heat).

His second paper of 1905 was *Über einen die Erzeugung und Verwandlung des Lichtes betreffenden heuristischen Gesichtspunkt* (On a Heuristic Point of View about the Creation and Conversion of Light). In this Einstein was concerned with the nature of electromagnetic radiation, which at the time was regarded as a wave propagated throughout space according to

Clerk MAXWELL's equations. Einstein was concerned with the difference between this wave picture and the theoretical picture physicists had of matter. His particular concern in this paper was the difficulty in explaining the photoelectric effect, investigated in 1902 by Philipp LENARD. It was found that ultraviolet radiation of low frequency could eject electrons from a solid surface. The number of electrons depended on the intensity of the radiation and the energy of the electrons depended on the frequency. This dependence on frequency was difficult to explain using classical theory.

Einstein resolved this by suggesting that electromagnetic radiation is a flow of discrete particles – quanta (or photons as they are now known). The intensity of the radiation is the flux of these quanta. The energy per quantum, he proposed, was  $h\nu$ , where  $\nu$  is the frequency of the radiation and  $h$  is the constant introduced in 1900 by Max PLANCK. In this way Einstein was able to account for the observed photoelectric behavior. The work was one of the early results introducing the quantum theory into physics and it won for Einstein the 1921 Nobel Prize for physics.

The third of his 1905 papers is the one that is the most famous: *Zur Elektrodynamik bewegter Körper* (On the Electrodynamics of Moving Bodies). It is this paper that first introduced the special theory of relativity to science. The term “special” denotes that the theory is restricted to certain special circumstances – namely for bodies at rest or moving with uniform relative velocities.

The theory was developed to account for a major problem in physics at the time. Traditionally in mechanics, there was a simple procedure for treating relative velocities. A simple example is of a car moving along a road at 40 mph with a second car moving toward it at 60 mph. A stationary observer would say that the second car was moving at 60 mph relative to him. The driver of the first car would say that, relative to him, the second car was approaching at 100 mph. This common-sense method of dealing with relative motion was well established. The mathematical equations involved are called the Galilean transformations – they are simple equations for changing velocities in one frame of reference to another frame of reference. The problem was that the method did not appear to work for electromagnetic radiation, which was thought of as a wave motion through the ether, described by the equations derived by Maxwell. In these, the speed of light is independent of the motion of the source or the observer. At the time, Albert MICHELSON and Edward MORLEY had performed a series of experiments to attempt to detect the Earth's motion through the ether, with negative results. Hendrik LORENTZ proposed that this result could be explained by a change of size of moving bodies (the Lorentz–Fitzgerald contraction).

Although Einstein was unaware of the Michelson–Morley experiment, he did appreciate the incompatibility of classical mechanics and classical electrodynamics. His solution was a quite radical one. He proposed that the speed of light *is* a constant for all frames of reference that are moving uniformly relative to each other. He also put forward his “relativity principle” that the laws of nature are the same in all frames of reference moving uniformly relative to each other. To reconcile the two principles he abandoned the Galilean transformations – the simple method of adding and subtracting velocities for bodies in relative motion. He arrived at this rejection by arguments about the idea of simultaneity – showing that the time between two events depends on the motions of the bodies involved. In his special theory of relativity, Einstein rejected the ideas of absolute space and absolute time. Later it was developed in terms of events specified by three spatial coordinates and one coordinate of time – a space–time continuum. The theory had a number of unusual consequences. Thus the length of a body along its direction of motion decreases with increasing velocity. The mass increases as the velocity increases, becoming infinitely large in theory at the speed of light. Time slows down for a moving body – a phenomenon known as time dilation. These effects apply to all bodies but only become significant at velocities close to the speed of light – under normal conditions the effects are so small that classical laws appear to be obeyed. However, the predictions of the special theory – unusual as they may seem – have been verified experimentally. Thus increase in mass is observed for particles accelerated in a synchrocyclotron. Similarly, the lifetimes of unstable particles are increased at high velocities.

In that same year of 1905 Einstein had one more fundamental paper to contribute: *Ist die Trägheit eines Körpers von seinem Energieinhalt abhängig?* (Does the Inertia of a Body Depend on Its Energy Content?). It was in this two-page paper that he concluded that if a body gives off energy  $E$  in the form of radiation, its mass diminishes by  $E/c^2$  (where  $c$  is the speed of light) obtaining the celebrated equation  $E = mc^2$  relating mass and energy.

Within a short time Einstein's work on relativity was widely recognized to be original and profound. In 1908 he obtained an academic post at the University of Bern. Over the next three years he held major posts at Zurich (1909), Prague (1911), and the Zurich Federal Institute of Technology (1912) before taking a post in Berlin in 1914. This was probably due in part to the respect in which he held the Berlin physicists, Max Planck and Walther NERNST.

By 1907 Einstein was ready to remove the restrictions imposed on the special theory showing that, on certain assumptions, accelerated motion could be incorporated into his new, gen-

eral theory of relativity. The theory begins with the fact that the mass of a body can be defined in two ways. The inertial mass depends on the way it resists change in motion, as in NEWTON'S second law. The gravitational mass depends on forces of gravitational attraction between masses. The two concepts – inertia and gravity – seem dissimilar yet the inertial and gravitational masses of a body are always the same. Einstein considered that this was unlikely to be a coincidence and it became the basis of his principle of equivalence.

The principle states that it is impossible to distinguish between an inertial force (that is, an accelerating force) and a gravitational one; the two are, in fact, equivalent. The point can be demonstrated with a thought experiment. Consider an observer in an enclosed box somewhere in space far removed from gravitational forces. Suppose that the box is suddenly accelerated upward, followed by the observer releasing two balls of different weights. Subject to an inertial force they will both fall to the floor at the same rate. But this is exactly how they would behave if the box was in a gravitational field and the observer could conclude that the balls fall under the influence of gravity. It was on the basis of this equivalence that Einstein made his dramatic prediction that rays of light in a gravitational field move in a curved path. For if a ray of light enters the box at one side and exits at the other then, with the upward acceleration of the box, it will appear to exit at a point lower down than its entrance. But if we take the equivalence principle seriously we must expect to find the same effect in a gravitational field. In 1911 he predicted that starlight just grazing the Sun should be deflected by 0.83 seconds of arc, later increased to 1".7, which, though small, should be detectable in a total eclipse by the apparent displacement of the star from its usual position. In 1919 such an eclipse took place; it was observed by Arthur EDDINGTON at Principe in West Africa, who reported a displacement of 1".61, well within the limits of experimental error. It was from this moment that Einstein became known to a wider public, for this dramatic confirmation of an unexpected phenomenon seemed to capture the popular imagination. Even the London *Times* was moved to comment in an editorial, as if to a recalcitrant government, that "the scientific conception of the fabric of the universe must be changed." In 1916 Einstein was ready to publish the final and authoritative form of his general theory: *Die Grundlage der allgemeinen Relativitätstheorie* (The Foundation of the General Theory of Relativity). It is this work that gained for Einstein the reputation for producing theories that were comprehensible to the very few. Eddington on being informed that there were only three people capable of understanding the theory is reported to have replied, "Who's the third?" It is true that Einstein introduced into gravitational

theory a type of mathematics that was then unfamiliar to most physicists, thus presenting an initial impression of incomprehension. In his theory Einstein used the space–time continuum introduced by Hermann MINKOWSKI in 1907, the non-Euclidean geometry developed by Bernhard RIEMANN in 1854, and the tensor calculus published by Gregorio Ricci in 1887. He was assisted in the mathematics by his friend Grossmann. The theory of gravitation produced is one that depends on the geometry of space–time. In simple terms, the idea is that a body "warps" the space around it so that another body moves in a curved path (hence the notion that space is curved). Einstein and Grossmann in 1915 succeeded in deriving a good theoretical value for the small (and hitherto anomalous) advance in the perihelion of Mercury. The theory was put to an early test. Because of perturbations in the orbit of Mercury produced by the gravitational attractions of other planets, its perihelion (point in the orbit closest to the Sun) actually precesses by a small amount (9' 34" per century). When these perturbation effects were calculated on the basis of Newtonian mechanics, they could only account for a precession rate of 8' 51" per century, a figure 43" too small. In 1915 Einstein, while completing his 1916 paper on General Relativity, calculated Mercury's perihelion precession on the basis of his own theory and found that, without making any extra assumptions, the missing 43" were accounted for. The discovery, Einstein later reported, gave him palpitations and "for a few days I was beside myself with joyous excitement."

The theory also predicted (1907) that electromagnetic radiation in a strong gravitation field would be shifted to longer wavelengths – the *Einstein shift*. This was used by Walter ADAMS in 1925 to explain the spectrum of Sirius B. In 1959 Robert Pound and Glen Rebka demonstrated it on Earth using the Mossbauer effect. They found that at a height of 75 feet (23 m) above the ground gamma rays from a radioactive source had a longer wavelength than at ground level. Physicists have been less successful, however, with the prediction in 1916 of the existence of gravitational waves. Despite an intensive search from 1964 onward by Joseph WEBER and others, they have yet to be detected.

Einstein was less successful in applying his theory to the construction of a cosmological model of the universe, which he assumed to be uniform in density, static, and lacking infinite distances. He found himself forced to complicate his equations with a cosmological constant,  $\lambda$ . It was left to Aleksandr FRIEDMANN in 1922 to show that the term could be dropped and a solution found that yielded an expanding universe, a solution that Einstein eventually adopted. He later described the cosmological constant as "my greatest mistake." By the early

1920s Einstein's great work was virtually complete. He wrote in 1921 that: "Discovery in the grand manner is for young people ... and hence for me a thing of the past." From the early 1920s he rejected quantum theory – the theory he had done much to establish himself. His basic objection was to the later formulation that included the probability interpretation. "God does not play dice," he said, and, "He may be subtle, but he is not malicious." He felt, like Louis de BROGLIE, that although the new quantum mechanics was clearly a powerful and successful theory it was an imperfect one, with an underlying undiscovered deterministic basis. For the last 30 years of his life he also pursued a quest for a unified field theory – a single theory to explain both electromagnetic and gravitational fields. He published several attempts at such a theory but all were inadequate. This work was carried out right up to his death.

Also, from about 1925 onward, Einstein engaged in a debate with Niels BOHR on the soundness of quantum theory. He would present Bohr with a series of thought experiments, which seemed undeniable even though they were clearly incompatible with quantum mechanics. The best known of these was presented in a paper written with Boris Podolsky and Nathan Rosen and entitled: *Can Quantum Mechanical Description of Physical Reality Be Considered Complete?* (1935). The *EPR experiment*, as it soon became known, assumed that, after interacting, two particles become widely separated. Quantum theory allows the total momentum of the pair (A, B) to be measured accurately. Thus if the momentum of B is also measured accurately, it is a simple matter, as momentum is conserved, to calculate the momentum of particle A. We can then measure the position of A with as much precision as is practically possible. It would therefore seem to follow that, without violating any laws of physics, both the position and momentum of particle A have been accurately determined. But, according to the uncertainty principle of HEISENBERG, we are prevented from ever knowing accurately a particle's position and momentum simultaneously.

The paper troubled Bohr. He spent six weeks going through the text word by word and analyzing every possibility. Eventually he saw that the measurements of A's position and momentum are separate and distinct. The uncertainty principle insisted that no *single* measurement could determine a particle's precise position and momentum, and this central claim remained unchallenged by the EPR experiment. Einstein's correspondence with Bohr about quantum mechanics is published as the *Bohr-Einstein letters*.

Einstein was also involved in a considerable amount of political activity. When Hitler came to power in 1933 Einstein made his permanent

home in America where he worked at Princeton. In 1939 he was persuaded to write to President Roosevelt warning him about the possibility of an atomic bomb and urging American research. He was, in later years, a convinced campaigning pacifist. He was also a strong supporter of Zionist causes and, on the death of Chaim Weizmann in 1952, was asked to become president of Israel, but declined.

### **Einthoven, Willem** (1860–1927) *Dutch physiologist*

Einthoven (**Int**-hoh-ven), the son of a physician, was born at Semarang on the Indonesian island of Java and educated at the University of Utrecht in the Netherlands, where he gained his MD in 1885. In the following year he moved to Leiden as professor of physiology.

As early as 1887 the English physiologist Augustus Waller had recorded electric currents generated by the heart. He had used the capillary electrometer invented by Gabriel LIPPMANN in 1873, which – although sensitive to changes of a millivolt – turned out to be too complicated and inaccurate for general use. In 1901 Einthoven first described a recording system using a string galvanometer, which he claimed would overcome the inadequacies of Waller's device.

A string galvanometer consists of a fine wire thread stretched between the poles of a magnet. When carrying a current it is displaced at right angles to the directions of the magnetic lines of force to an extent proportional to the strength of the current. By linking this up to an optical system the movement of the wire can be magnified and photographically recorded. As the differences in potential developed in the heart are conducted to different parts of the body it was possible to lead the current from the hands and feet to the recording instrument to obtain a curve that was later called an *electrocardiogram* (ECG).

Having demonstrated the potentiality of such a machine, two further problems needed solution. Einthoven first had to standardize his ECG so that different machines or two recordings of the same machine would produce comparable readings. It was therefore later established that a 1 millivolt potential would deflect a recording stylus 1 centimeter on standardized paper. The second problem was how to interpret such a curve in order to distinguish normal readings from recordings of diseased hearts. By 1913 Einthoven had worked out the interpretation of the normal tracing and, by correlating abnormal readings with specific cardiac defects identified at post mortem, was able to use the ECG as a diagnostic tool.

For his development of the electrocardiogram Einthoven was awarded the 1924 Nobel Prize for physiology or medicine.

**Ekeberg, Anders Gustaf (1767–1813)**  
*Swedish chemist*

Ekeberg (**ay-ke-berg**), who was born in the Swedish capital of Stockholm, graduated from the University of Uppsala in 1788 and, after traveling in Europe, began teaching chemistry at Uppsala in 1794. He was an early convert to the system of Antoine LAVOISIER and introduced this new chemistry to Sweden. He was partially deaf from a childhood illness but the further loss of an eye (1801) caused by an exploding flask did not impede his work.

Ekeberg is remembered chiefly for his discovery of the element tantalum. In 1802, while analyzing minerals from Ytterby quarry, Sweden, he isolated the new metal. The name supposedly comes from its failure to dissolve in acid, looking like Tantalus in the waters of Hell. It was a long time before it was recognized as a separate element as it was difficult to distinguish from niobium, isolated by Charles HATCHETT in 1801. WOLLASTON failed to distinguish between them and it was as late as 1865 that Jean MARGINAC conclusively demonstrated the distinctness of the two new metals.

**Ekman, Vagn Walfrid (1874–1954)**  
*Swedish oceanographer*

Ekman (**ayk-man**), the son of an oceanographer, was born in the Swedish capital of Stockholm and educated at the University of Uppsala, graduating in 1902. He worked at the International Laboratory for Oceanographic Research in Oslo (1902–08) before he moved to Lund, Sweden, as a lecturer in mathematical physics, being made a professor in 1910.

In 1905 Ekman published a fundamental paper, *On the Influence of the Earth's Rotation on Ocean Currents*. This work originated from an observation made by the explorer Fridtjof NANSEN that in the Arctic drift ice did not follow wind direction but deviated to the right. He showed that the motion, since known as the *Ekman spiral*, is produced as a complex interaction between the force of the wind on the water surface, the deflecting force due to the Earth's rotation (Coriolis force), and the frictional forces within the water layers.

Ekman also studied the phenomenon of dead water, a thin layer of fresh water from melting ice spreading over the sea, which could halt slow-moving ships. This, he established, resulted from the waves formed between water layers of different densities. The *Ekman current meter*, invented by him, is still in use.

**Elhuyar, Don Fausto D' See D'ELHUYAR, DON FAUSTO.**

**Elion, Gertrude Belle (1918–1999)**  
*American biochemist*

It was watching her beloved grandfather die

slowly and painfully from stomach cancer that prompted the young Gertrude Elion, in 1933, to decide on a career in biochemistry. Thus began a vocation that would result in the discovery of many new drugs to combat cancer, AIDS, and other diseases, and bring Elion a Nobel Prize. She was born in New York and attended Hunter College, graduating BA in chemistry in 1937. She began graduate studies at New York University while working as a high-school teacher, and gained her MS degree in 1941. However, prejudice against women in scientific research meant that she had to take a series of humdrum jobs, and opportunity came only with the entry of the United States into World War II. Now, women were in demand to fill jobs vacated by servicemen, and in 1944 Elion joined the Wellcome Research Laboratories, Tuckahoe, NY, where she began a long and fruitful collaboration with George HITCHINGS. Guided by Hitchings, Elion worked on identifying compounds that would interfere with the synthesis of DNA by cancer cells. By 1951 she had synthesized a purine analogue, 6-mercaptopurine (6MP), that halted DNA synthesis in leukemia cells and subsequently proved to be an effective treatment for certain types of human cancer. The drug was also shown to suppress the immune system in dogs, which motivated Elion and Hitchings to search for other immunosuppressive drugs. This led to the discovery of the 6MP derivative, azathioprine, which is still used to prevent rejection of human kidney transplants by the immune system. Several other notable discoveries were made by Elion and Hitchings during the 1950s and 1960s, including allopurinol (used to treat gout), pyrimethamine (an antimalaria drug), and trimethoprim (an antibacterial drug). Another breakthrough, this time against viral disease, came in 1969, when one of Elion's compounds yielded the forerunner of acyclovir, a drug that combats herpesviruses responsible for shingles, chickenpox, and other infections. The first anti-HIV drug, azidothymidine (AZT), was developed in Elion's lab shortly before her retirement in 1983. Elion received many honours and awards, including the 1988 Nobel Prize, shared with her long-time colleague, George Hitchings, and with James BLACK.

**Ellet, Charles (1810–1862)**  
*American civil engineer*

Born at Penns Manor in Pennsylvania, Ellet began work as a surveyor and assistant engineer, and then traveled to Europe to study engineering, returning to America in 1832. He concentrated on designing suspension bridges and built his first in 1842 over the Schuylkill River in Pennsylvania, with a span of 358 feet (109 m). He went on to build the world's first long-span wire-cable suspension bridge, with a central span of 1,010 feet (308 m), over the

Ohio River (1846–49). The bridge failed in 1854 because of aerodynamic instability.

Ellet also devised a steam-powered ram that helped to win the Mississippi River for the Union in the Battle of Memphis on 6 June 1862. Ellet was mortally wounded in this battle.

**Elliott, Thomas Renton** (1877–1961)  
*British physician*

Elliott was the son of a retailer from the north-eastern English city of Durham. He was educated at Cambridge University and University College Hospital, London, where he later served as professor of clinical medicine from the end of World War I until his retirement in 1939.

It was as a research student under John LANGLEY at Cambridge that Elliott made his greatest discovery. In 1901 Langley had injected animals with a crude extract from the adrenal gland and noted that the extract stimulated the action of the sympathetic nerves. Adrenaline (epinephrine) had earlier (1898) been isolated by John ABEL at Johns Hopkins University. Elliott therefore decided to inject adrenaline into animals to see if he got the same response as Langley had with the adrenal gland extract. He did indeed achieve increases in heart beat, blood pressure, etc., characteristic of stimulation of the sympathetic nervous system. Elliott is remembered for his subsequent suggestion that adrenaline may be released from sympathetic nerve endings – the first hint of neurotransmitters. Langley discouraged such speculation but later work by Henry DALE and Otto LOEWI on acetylcholine supported Elliott's early work.

**Elsasser, Walter Maurice** (1904–1991)  
*German–American geophysicist*

Elsasser was born in the German city of Mannheim and educated at the University of Göttingen, where he obtained his doctorate in 1927. He worked at the University of Frankfurt before leaving Germany in 1933 following Hitler's rise to power. He taught at the Sorbonne, Paris, before emigrating to America (1936) where he joined the staff of the California Institute of Technology. He became professor of physics at the University of Pennsylvania (1947–50) and at the University of Utah (1950–58). In 1962 he became professor of geophysics at Princeton and he was appointed research professor at the University of Maryland from 1968 until his retirement in 1974.

Elsasser made fundamental proposals on the question of the origin of the Earth's magnetic field. It had been known for some time that this could not be due to the Earth's iron core for its temperature is too high for it to serve as a simple magnet. Instead he proposed that the molten liquid core contains eddies set up by the Earth's rotation. These eddies produce an

electric current that causes the familiar terrestrial magnetic field. Elsasser also made predictions of electron diffraction (1925) and neutron diffraction (1936). His works include *The Physical Foundation of Biology* (1958) and *Atom and Organism* (1966).

**Elton, Charles Sutherland** (1900–1991)  
*British ecologist*

Born in the English city of Liverpool, Elton graduated in zoology from Oxford University in 1922. He was assistant to Julian HUXLEY on the Oxford University expedition to Spitzbergen (1921), where Elton carried out ecological studies of the region's animal life. Further Arctic expeditions were made in 1923, 1924, and 1930. Such experience prompted his appointment as biological consultant to the Hudson's Bay Company, for which he carried out investigations into variations in the numbers of fur-bearing animals, using trapper's records dating back to 1736. In 1932 Elton helped establish the Bureau of Animal Population at Oxford – an institution that subsequently became an international center for information on and research into animal numbers and their ecology. In the same year he became editor of the new *Journal of Animal Ecology*, launched by the British Ecological Society, and in 1936 was appointed reader in animal ecology as well as a senior research fellow by Oxford University.

Elton was one of the first biologists to study animals in relation to their environment and other animals and plants. His demonstration of the nature of food chains and cycles, as well as such topics as the reasons for differences in animal numbers, were discussed in *Animal Ecology* (1927). In 1930 *Animal Ecology and Evolution* was published in which he advanced the notion that animals were not invariably at the mercy of their environment but commonly, perhaps through migration, practiced environmental selection by changing their habitats. Work on the rodent population of Britain, and how it is affected by a changing environment, was turned to eminently practical account at the outbreak of World War II when Elton conducted intensive research into methods of controlling rats and mice and thus conserving food for the war effort. *Voles, Mice and Lemmings: Problems in Population Dynamics* was published in 1942, and *The Control of Rats and Mice* in 1954, the latter becoming accepted as the standard work on the subject.

**Elvehjem, Conrad Arnold** (1901–1962)  
*American biochemist*

Elvehjem (el-ve-yem), the son of a farmer from McFarland, Wisconsin, graduated from and spent his whole career at the University of Wisconsin. He obtained his PhD in 1927, and served as professor of biochemistry from 1936

until 1958, when he became president of the university, a position held until his retirement in 1962.

In 1937, following discoveries by Casimir FUNK and Joseph GOLDBERGER, Elvehjem succeeded in producing a new treatment for pellagra. In the 1920s Goldberger had postulated that this disease was caused by a deficiency of "P-P" (pellagra preventive) factor present in milk. In 1913 Funk, while searching for a cure for beriberi, came across nicotinic acid in rice husks. Although it was of little use against beriberi, Elvehjem found that even in minute doses it would dramatically remove the symptoms of blacktongue, the canine equivalent of pellagra. Tests on humans revealed the same remarkable effects on pellagra.

Elvehjem, a prolific author with over 800 papers to his credit, also worked on the role of trace elements in nutrition, showing the essential role played by such minerals as copper, zinc, and cobalt.

**Embden, Gustav George (1874–1933)**  
*German physiologist*

Embden, the son of a lawyer from Hamburg in Germany, was educated at the universities of Freiburg, Munich, Berlin, and Strasbourg. From 1904 he was director of the chemical laboratory in the medical clinic of the Frankfurt hospital, becoming in 1907 director of the Physiological Institute (which evolved from the medical clinic) and in 1914 director of the Institute for Vegetative Physiology (which in its turn evolved from the Physiological Institute).

In 1918 Otto MEYERHOF threw considerable light on the process of cellular metabolism by showing that it involved the breakdown of glucose to lactic acid. Embden spent much time in working out the precise steps involved in such a breakdown, as did many other chemists and physiologists. By the time of his death the details of the metabolic sequence from glycogen to lactic acid, later known as the *Embden-Meyerhof pathway*, had been worked out. Embden's earlier work concentrated on the metabolic processes carried out by the liver. In his experiments he used a new perfusion technique to maintain the condition of the dissected livers. In this way he discovered the breakdown of amino acids by oxidative deamination, realized that abnormal sugar metabolism can lead to the formation of acetone and acetoacetic acid, and showed that sugar is synthesized from lactic acid.

**Emeleus, Harry Julius (1903–1993)**  
*British inorganic chemist*

Emeleus was educated at Imperial College, in his native city of London, and at Karlsruhe and Princeton. He returned to Imperial College in 1931 and taught there until 1945 when he

moved to Cambridge University, where he served as professor of inorganic chemistry until his retirement in 1970.

In 1938, in collaboration with John Anderson, he published the well-known work, *Modern Aspects of Inorganic Chemistry*. He also worked on fluorine, publishing a monograph on the subject in 1969: *The Chemistry of Fluorine and its Compounds*.

**Emiliani, Cesare (1922–1995)** *Italian–American geologist*

Emiliani (e-meel-yah-ni) was born in the Italian city of Bologna and educated at the university there. He moved to America in 1948, obtaining his PhD from the University of Chicago in 1950. After teaching at Chicago (1950–56) he moved to the University of Miami, where he served as professor of geology at the Institute of Marine Science from 1963 until his retirement in 1993.

Emiliani specialized in using oxygen isotopic analysis of pelagic microfossils from ocean sediments. Albrecht PENCK and Eduard Brückner had, in 1909, established the long-held orthodox view that four ice ages had occurred during the Pleistocene. In his fundamental paper *Pleistocene Temperatures* (1955), Emiliani produced evidence that there had been more. Using the principle established by Harold UREY that the climate of past ages can be estimated by the ratio of oxygen-16 to oxygen-18 present in water (i.e., the less oxygen-18 present the colder the climate must have been), he examined the oxygen-18 content of fossils brought up from the mud of the Caribbean. By choosing fossils that he knew had lived near the surface he could reconstruct the climatic history, and consequently identified seven complete glacial cycles.

**Empedocles of Acragas (c. 490 BC–c. 430 BC)** *Greek philosopher*

Empedocles (em-ped-oh-kleez) was a poet and a physician as well as a philosopher. Born at Acragas in Greece, he was probably a pupil of PARMENIDES. Much legend surrounds what is known of his life. Styling himself as a god, he reputedly brought about his own death in an attempt to persuade his followers of his divinity by throwing himself into the volcanic crater of Mount Etna. Fragments of two poems by Empedocles survive: *On Nature* and *Purifications*. There is some difficulty in reconciling the two because the first is purely physical while the second deals with the progress of the soul from fall to redemption.

**Encke, Johann Franz (1791–1865)** *German astronomer*

The son of a Lutheran pastor from Hamburg in Germany, Encke (eng-ke) was educated at Göt-

tingen where he impressed Karl GAUSS. In 1816 he was appointed to the staff of the Seeberg Observatory, Gotha, where he remained until 1825 when he moved to the Berlin Observatory as its director.

A faint comet had first been observed by P. Mechain in 1786. Over the years other reports were made in 1795, 1805, and 1818 of a series of faint comets. Although several astronomers suspected there was only one comet involved, it was Encke who provided in 1819 the necessary computations. He showed that *Encke's comet*, as it became known, had a period of 3.3 years and predicted that it would be at perihelion again on 24 May 1822. His prediction was accurate to within a few hours and Encke thus became, after HALLEY, only the second man to predict the return of a periodic comet successfully.

### **Enders, John Franklin (1897–1985)** *American microbiologist*

Enders, the son of a wealthy banker from West Hartford in Connecticut, was educated at Yale and Harvard where he obtained his PhD in 1930. His career was somewhat delayed by the war, in which he served as a flying instructor, and also by his initial intention to study Germanic and Celtic languages. This was upset by the influence of the bacteriologist Hans Zinsser who "seduced" Enders into science in the late 1920s.

In 1946 Enders set up an Infectious Diseases Laboratory at the Boston Children's Hospital; it was here that he did the work to be later described as opening up a "new epoch in the history of virus research." This referred to his success, in collaboration with Thomas WELLER and Frederick ROBBINS, in 1949 in cultivating polio virus in test tube cultures of human tissue for the first time. They further demonstrated that the virus could be grown on a wide variety of tissue and not just nerve cells.

This at last allowed the polio virus to be studied, typed, and produced in quantity. Without such an advance the triumphs of Albert SABIN and Jonas SALK in developing a vaccine against polio in the 1950s would have been impossible. In 1954 Enders, Weller, and Robbins were awarded the Nobel Prize for physiology or medicine.

By this time Enders had already begun to work on the cultivation of the measles virus. This time, working with T. Peebles, they followed up their success in cultivating the virus with, in 1957, the production of the first measles vaccine.

### **Engelbart, Douglas C. (1925– )** *American computer scientist*

Engelbart was born in Oregon and educated at Oregon State University, where he studied electrical engineering. His university education

was disrupted by World War II. Having joined the navy he spent two years in the Philippines as a radar technician. Here he read a visionary and influential article by Vannevar Bush entitled *As We May Think*, in which Bush envisaged the possibility of a machine that could augment human memory by letting the user of the machine store and retrieve documents that are linked by associations.

After the war Engelbart returned to university and obtained his degree in 1948. After graduating he worked for the NACA Ames Laboratory, the predecessor of NASA. Engelbart then became a graduate student in electrical engineering at the University of California at Berkeley, obtaining his PhD in 1955. He remained at Berkeley for a short time as an assistant professor before obtaining a research position at the Stanford Research Institute (SRI).

In 1962 he wrote the definitive exposition of his views in a paper entitled *Augmenting Human Intellect: A Conceptual Framework*, in which he discussed how technology could be used to help to find solutions to problems. Engelbart set up his own research laboratory, which he called the Augmentation Research Center, in 1963. In the 1960s and 1970s this laboratory developed a system called oNLine System (NLS), which made the creation of digital libraries and the storing and retrieving of documents easier. This was done using *hypertext*, the first time the idea had been successfully implemented. The NLS also improved the computer interaction with Engelbart's invention of the mouse, although the device was not commonly used until the 1980s. The NLS produced some other technological innovations such as on-screen video teleconferencing.

Engelbart was a central figure in the ARPANET project, which pioneered computer networking. He founded the Bootstrap Institute in 1989 with the purpose of encouraging collaboration in the development of technology. Engelbart's work has been widely recognized. In 2000 he was awarded the US National Medal of Technology and in 2001 he was awarded the British Computer Society's Lovelace Medal. In 2005 he received a grant to fund his Hyperscope Project.

### **Engelmann, George (1809–1884)** *American botanist*

Born the son of a schoolmaster at Frankfurt in Germany, Engelmann was educated at the universities of Heidelberg, Berlin, and Würzburg where he obtained his MD in 1831. In the following year he visited America to invest in some land for a wealthy uncle and decided in 1835 to settle and practice medicine in St. Louis.

Engelmann was not only a plant collector of some importance; he also did much to initiate

and organize major collecting expeditions of the flora of the West. It was thus through Engelmann that many of the newly collected specimens passed on their way to eastern scholars as Asa GRAY at Harvard. Engelmann's role became more official with the setting up of the Missouri Botanical Garden in 1859 with the backing of the St. Louis businessman Henry Shaw.

He is also remembered for his demonstration that some stocks of American vine were resistant to the pest *Phylloxera*, which had begun to devastate the vineyards of Europe from 1863 onward.

**Engelmann, Theodor Wilhelm** (1843–1909) *German physiologist*

Engelmann, the son of a publisher, was educated at Jena, Heidelberg, and Göttingen, before obtaining his PhD from the university in his native city of Leipzig in 1867. He immediately joined the faculty of the University of Utrecht, serving there as professor of physiology from 1888 until 1897 when he returned to Germany to a similar chair at the University of Berlin, where he remained until his retirement in 1908.

Between 1873 and 1895 Engelmann published a number of papers on muscle contraction. By this time, following the work of such physiologists as William BOWMAN, the main anatomical details of striated muscle had been established. However an explanation was needed as to why the anisotropic or A bands refract polarized light quite differently to the isotropic or I bands. Engelmann had noted that in contraction the A bands increased in volume while the I bands decreased. He consequently proposed his "imbibition" theory in which the contraction of striped muscle is attributed to a flow of fluid from the I to the A bands.

Engelmann also worked on the nature and mechanism of the heartbeat and in 1875 devised an experiment that proved the heartbeat is myogenic; that is, the contraction originates in the heart muscle and not from an external nerve stimulus. In 1881 he discovered the chemotactic response of certain bacteria to oxygen, and he also demonstrated that red and blue light are far more effective in stimulating plant chloroplasts during photosynthesis than other parts of the spectrum.

**Engler, Heinrich Gustav Adolf** (1844–1930) *German botanist*

Engler was born in Sagan (which is now in Poland) and studied botany at Breslau University, gaining his PhD in 1866 for his thesis on the genus *Saxifraga*. After teaching natural history he became custodian of the Munich botanical collection and then professor of botany at Kiel University; in 1884 he returned

to Breslau to succeed his former teacher in the chair of botany. At Breslau Engler replanned the botanic garden, ordering the plants according to their geographical distribution. In 1887 he took up the important chair of botany at Berlin and successfully reestablished the garden in Dahlem.

Between 1878 and his retirement from Berlin in 1921, Engler contributed greatly to the development of plant taxonomy with his classifications, presented in such books as *The Natural Plant Families* (1887–1911) and *The Plant Kingdom* (1900–37). Much of his work was drawn from first-hand observation gained during travels through Africa, Europe, India, China, Japan, and America.

**Eötvös, Baron Roland von** (1848–1919) *Hungarian physicist*

Born in Budapest, Eötvös (**u(r)t-vu(r)sh**) studied at the University of Königsberg and at Heidelberg where he obtained his PhD in 1870 for a thesis concerning a method of detecting motion through the ether by measuring light intensity. At Königsberg in 1886 he introduced the *Eötvös law* – an equation approximately relating surface tension, temperature, density, and relative molecular mass of a liquid.

He then started teaching at Budapest University, where he was appointed professor in 1872. His work from then on centered on gravitation. In 1888 he developed the *Eötvös torsion balance*, consisting of a bar with two attached weights, the bar being suspended by a torsion fiber. He argued that if the two weights were made from different materials, and if the inertial and gravitational forces were not equivalent, there would be a discernible twisting force, which would cause a slight rotation of the bar about a vertical axis. Observations were made with copper, aluminum, asbestos, platinum, and other materials. No torque was found and Eötvös concluded that the masses of different materials were equivalent to a few parts per billion. His experiments were repeated in the 1960s by DICKE and in 1970 by Braginsky, with results affirming the equivalence to 1 part per 100 billion and 1 part per trillion respectively. The experiment became one of the foundation stones of general relativity since, by failing to distinguish between inertial and gravitational mass experimentally, it supported EINSTEIN'S principle of equivalence.

Eötvös spent much of his time trying to improve the Hungarian education system and for a short time was minister of instruction. He was also an excellent mountain climber and a peak in the Dolomites is named for him.

**Epicurus** (c. 341 BC–270 BC) *Greek philosopher*

The atoms come together in different order

and position, like the letters, which, though they are few, yet, by being placed together in different ways, produce innumerable words.

—Quoted by Max Muller in *Science of Language* (1871)

Epicurus, who was born on the Greek island of Samos, traveled to Athens when he was about 18 years old, and received military training. He then taught at Mytilene and Lampsacus before returning to Athens (305 BC) where he founded a school of philosophy and attracted a substantial following.

Epicurus revived Democritean atomism and was little influenced by his predecessors, PLATO and ARISTOTLE. His work is known through substantial fragments in the writings of Diogenes Laërtius and especially through the long poem, *De rerum natura* (On the Nature of Things), by his Roman disciple LUCRETIUS. The Epicurean philosophy aimed at the attainment of a happy, though simple, life and used the atomic theory to sanction the banishment of the old fears and superstitions. Epicurus also made important additions to the atomic theory, asserting the primacy of sense-perception where DEMOCRITUS had distrusted the senses, and he introduced the concept of random atomic “swerve” to preserve free will in an otherwise deterministic system.

### **Epstein, Sir Michael Anthony** (1921– ) *British virologist*

Epstein, a Londoner, was educated at Cambridge University and at the Middlesex Hospital Medical School in his native city. After serving in the Royal Army Medical Corps (1945–47), he returned to the Middlesex Hospital as an assistant pathologist. He left the Middlesex in 1965 and in 1968 he was appointed professor of pathology at Bristol University, a position he held until his retirement in 1985. He has continued to work in the Department of Clinical Medicine at Oxford.

In 1961 Epstein heard Denis BURKITT describe the distribution of a particularly savage lymphoma throughout Africa. Epstein saw that “anything which has geographical factors such as climate affecting distribution must have some kind of biological cause.” That biological cause, Epstein suspected, for no very good reason, was a virus. Although Epstein received tumor samples from Burkitt, he found them impossible to culture and saw no trace of any virus. After struggling unsuccessfully for two years, Epstein and his assistant Yvonne Barr developed a new approach. Instead of working with small tumor lumps they divided the pieces into single cells. The technique proved successful and for the first time ever human lymphocytes were being grown in a continuous culture. Yet Epstein initially found no virus until he examined some cells under an electron microscope. The virus was named the *Epstein-Barr*

*virus* and proved to be a member of the herpes family. The virus turned out to have a worldwide distribution and was identified as the cause of mononeucleosis. Clearly, its presence alone is insufficient to cause lymphoma. For if most of us have the virus, why is lymphoma not distributed more widely? Epstein and Burkitt argued that only in cases in which malaria or some other chronic condition has suppressed a child’s immature immune system could the virus provoke lymphoid cells into malignant growth.

### **Erasistratus of Chios** (c. 304 BC–c. 250 BC) *Greek anatomist and physician*

Erasistratus (er-a-sis-stra-tus), who was born on the Greek island of Chios, came from a distinctly medical background and studied in Athens, Cos, and Alexandria. Following HEROPHILUS he became the leading figure in the Alexandrian School of Anatomy.

It is possible with Erasistratus, unlike his contemporaries, to make out at least the outline of his physiological system. Every organ and part of the body was served by a “threefold network” of vein, artery, and nerve. Indeed, he believed the body tissues were a plaiting of such vessels, which at their extremities became so fine as to be invisible. The veins carried blood and the nerves and arteries transported nervous and animal spirits respectively.

As an atomist he rejected all attractive and occult forces seeking instead to explain everything in terms of atoms and the void. He thus accounted for the bleeding of severed arteries by assuming the escaped pneuma left a vacuum that was filled by blood from adjoining veins.

One of the most interesting aspects of his thought was his unusual rejection of the humoral theory of disease which, formulated by the Hippocratics and authorized by GALEN, became the sterile orthodoxy of Western medicine for 2,000 years. Instead he seems to have argued for a more mechanical concept of disease, attributing it to a “plethora” of blood, vital spirit, or food, which produces a blocking and inflammation of the various vessels.

His objection to the humoral theory found little support and with the passing of Erasistratus the great innovative period of Alexandrian medicine came to an end.

### **Eratosthenes of Cyrene** (c. 276 BC–c. 194 BC) *Greek astronomer*

Eratosthenes (er-a-tos-the-nee-z) was born in Cyrene, now in Libya, and educated at Athens. He then taught in Alexandria where he became tutor to the son of Ptolemy III and librarian. He was prominent in history, poetry, mathematics, and astronomy and was known by the nick-

name “beta” because, some say, he was the second PLATO.

In number theory he introduced the procedure named for him to collect the prime numbers by filtering out all the composites. The method, called the *sieve of Eratosthenes*, was to write down a list of ordered numbers and to strike out every second number after 2, every third number after 3, every fourth number after 4, and so on. The numbers remaining are primes.

Eratosthenes achieved his greatest fame by using a most ingenious and simple method to measure the circumference of the Earth. He was aware that on a certain day the Sun at Syene (now Aswan) was exactly at its zenith (it was known to shine directly down a deep well on that day). He found that on the same day at Alexandria it was south of its zenith by an angle corresponding to  $1/50$  of a circle ( $7^\circ 12'$ ). He also knew that the distance between Syene and Alexandria was 5,000 stadia – a distance that he estimated from the time it took a camel train to make the journey. Therefore, 5,000 stadia must be  $1/50$  of the circumference of the Earth; that is, 250,000 stadia. (Since the exact length of a stade is not known it is impossible to work out exactly how accurate his measurement was but it has been thought to be within 50 miles of the presently accepted value.) Eratosthenes also established an improved figure for the obliquity of the ecliptic (the tilt of the Earth’s axis) of  $23^\circ 51' 20''$ . Finally, he produced the first map of the world, as he knew it, based on meridians of longitude and parallels of latitude.

**Ercker, Lazarus** (c. 1530–1594) *Bohemian metallurgist*

Ercker was born in Annaberg, now in Germany, and studied at the University of Wittenberg (1547–48). In 1554 he was made assayer in Dresden, Saxony, and later he became control tester of coins in a town near Prague.

Ercker’s main contribution to metallurgy was to write the first systematic account of analytical and metallurgical chemistry. This manual, *Beschreibung allerfürnemisten mineralischen Erztz und Berckwerchsarten* (1574; Description of Leading Ore Processing and Mining Methods), described the testing of alloys, minerals, and compounds containing silver, gold, copper, antimony, mercury, bismuth, and lead.

**Erdős, Paul** (1913–1996) *Hungarian mathematician*

Paul Erdős has the theory that God has a book containing all the theorems of mathematics with their absolutely most beautiful proofs, and when he wants to express particular appreciation of a proof he exclaims, “This is one from the book!”

—Ross Honsberger, *Mathematical Morsels*

The son of two mathematics teachers from the Hungarian capital of Budapest, Erdős (er-du(r)sh) devoted his life to mathematics to an unequalled degree. He was educated at the University of Budapest where he obtained his PhD in 1934. Sensing difficult political times ahead, Erdős moved to Manchester, England, on a four-year fellowship. Shortly before the outbreak of war he left for America. At the height of the McCarthy era he was denied a reentry permit after attending a conference in Amsterdam. Erdős then settled in Israel for several years until, in the 1960s, he was allowed a U.S. visa once more.

With no official job and no family, Erdős lived out of a suitcase and traveled from one mathematical center to another. His life was spent working up to 20 hours a day on mathematical problems, usually with colleagues. In the process he produced over 1,000 papers. He lived on lecture fees, prizes, grants and the hospitality of his wide circle of collaborators. He wrote up to 1,500 letters a year and had more than 250 published collaborators.

**Erlanger, Joseph** (1874–1965) *American neurophysiologist*

Erlanger, the son of a German immigrant drawn to California in the gold rush, was born in San Francisco. He was educated at the University of California and at Johns Hopkins University in Baltimore, where in 1899 he obtained his MD. After working on the staff for a few years Erlanger moved to the University of Wisconsin (1906) to accept the chair of physiology. In 1910 he moved to Washington University, St. Louis, where he held the chair of physiology in the Medical School until his retirement in 1944.

Between 1921 and 1931 Erlanger carried out some fundamental research on the functions of nerve fibers with his former pupil and colleague, Herbert GASSER. They investigated the transmission of a nerve impulse along a frog nerve kept in a moist chamber at constant temperature. Their innovation was to study the transmission with the cathode-ray oscillograph, invented by Ferdinand BRAUN in 1897, which enabled them to picture the changes the impulse underwent as it traveled along the nerve.

Erlanger and Gasser found that on stimulating a nerve, the resulting electrical activity indicating the passage of an impulse was composed of three waves, as observed on the oscillograph. They explained this by proposing that the one stimulus activated three different groups of nerve fibers, each of which had its own conduction rate. They went on to measure these rates, concluding that the fastest fibers (the A-fibers) conduct with a speed of up to 100 meters per second (mps) while the slowest (the C-fibers) could manage speeds of no more than 2 mps. The intermediate B-fibers conducted in the range 2–14 mps. Erlanger and Gasser were

able to relate this variation to the thickness of the different nerve fibers, A-fibers being the largest.

It was a short step from this to the theory of differentiated function, in which it was proposed that the slender C-fibers carry pain impulses whereas the thicker A-fibers transmit motor impulses. But it was soon demonstrated that while such propositions may be broadly true the detailed picture is more complex.

Erlanger and Gasser produced an account of their collaboration in *Electrical Signs of Nervous Activity* (1937); they were awarded the 1944 Nobel Prize for physiology or medicine for their work.

### **Erlenmeyer, Richard August Carl Emil** (1825–1909) *German chemist*

Born near Wiesbaden in Germany, Erlenmeyer (er-len-mI-er) studied at Giessen and practiced at first as a pharmacist. In 1855 he became a private pupil of August KEKULÉ at Heidelberg and later was appointed professor at the Munich Polytechnic (1868–83). He synthesized guanidine and was the first to give its correct formula (1868). He also synthesized tyrosine and formulated the *Erlenmeyer rule*, which states the impossibility of two hydroxy groups occurring on the same carbon atom or of a hydroxy group occurring adjacent to a carbon-carbon double bond (chloral hydrate is an exception to this rule). His son F. G. C. E. Erlenmeyer introduced the Erlenmeyer synthesis of amino acids and synthesized cystine, serine, and phenylalanine.

### **Ernst, Richard Robert** (1933– ) *Swiss chemist*

Born at Winterthur in Switzerland, Ernst (ernst) was educated at the Federal Institute of Technology, Zurich, where he obtained his PhD in 1962. He spent the period from 1963 until 1968 working as a research chemist for Varian Associates, Palo Alto, California, before returning to the Federal Institute where he was appointed professor of physical chemistry in 1976. He became emeritus professor in 1988.

The technique of nuclear magnetic resonance (NMR) described by I. I. RABI in 1944, and developed by Felix BLOCH and Edward PURCELL in the late 1940s, quickly became a recognized tool for the exploration of atomic nuclei. As nuclei possess a magnetic moment they will tend to align themselves with any strong magnetic field. If, however, nuclei are subjected to radiowaves of the appropriate frequency, they will be raised to a higher energy level, and align themselves in a different direction with respect to the field. With the removal of the radio signal, the nuclei will revert to their original energy state by emitting radiation of a characteristic frequency. The frequency of the

radiation emitted allows nuclei to be identified, and the structure of certain molecules determined. But, the process was time-consuming because, in order to find which radiofrequency a sample responded to, it was necessary to sweep the applied frequency through a range of frequencies. Ernst developed a technique in which the sample was subjected to a single high-energy radio pulse. In this way numerous nuclei would respond and emit an apparently jumbled signal. But Ernst showed that, with the aid of FOURIER analysis and a computer, the signal could be unraveled into its separate components. Ernst's procedure considerably increased the sensitivity of NMR.

In 1970 Ernst made a further advance. He found that if he subjected his samples to a sequence of high-energy pulses instead of to a single pulse, it enabled him to use NMR techniques to study much larger molecules. Ernst's "two-dimensional analysis," as it became known, opened the way to investigate complex biological molecules such as proteins. His work also laid the foundation for the development by Peter MANSFIELD and others of MRI (magnetic resonance imaging).

For his work on NMR Ernst was awarded the 1991 Nobel Prize for chemistry.

### **Ertl, Gerhard** (1936– ) *German chemist and physicist*

Gerhard Ertl was born in Bad Cannstadt in Germany. He studied at the Technical University of Stuttgart where he received a Diploma in physics in 1961. In 1965 he received his PhD from the Technical University of Munich. Subsequently, Ertl held positions at the Technical University of Munich (1965–1968), the Technical University of Hannover (1968–1973), and the Ludwig Maximilians University of Munich (1973–1986). Since 1986 he has been at the Fritz Haber Institut der Max Planck Gesellschaft in Germany, being the Director of the Institut from 1986 until his retirement in 2004.

Ertl's most significant research has been his experimental work on the molecular process involved in heterogeneous catalysis. Ertl has used a number of experimental techniques in surface studies, including low-energy electron diffraction (LEED), ultraviolet photoelectron spectroscopy (UPS), ultraviolet photoelectron microscopy (UPM), and scanning electron microscopy (SEM). In particular, he investigated the catalytic synthesis of ammonia (the Haber process) and the catalytic oxidation of carbon monoxide in great detail and was able to elucidate the mechanisms involved. This work on heterogeneous reactions has many industrial applications. The importance of Ertl's work has been recognized by the award of many prizes, culminating in the Nobel Prize for chemistry in 2007.

**Esaki, Leo** (1925– ) *Japanese physicist*

Born in the Japanese city of Osaka, Esaki (**e-sah**-ki) graduated in physics at the University of Tokyo in 1947, gaining his doctorate there in 1959. His doctoral work was on the physics of semiconductors, and in 1958 he reported an effect known as “tunneling,” which he had observed in narrow p–n junctions of germanium that were heavily doped with impurities. The phenomenon of tunneling is a quantum-mechanical effect in which an electron can penetrate a potential barrier through a narrow region of solid, where classical theory predicts it could not pass.

Esaki was quick to see the possibility of applying the tunnel effect, and in 1960 reported the construction of a device with diodelike properties – the tunnel (or *Esaki*) diode. With negative bias potential, the diode acts as a short circuit, while under certain conditions of forward bias it can have effectively negative resistance (the current decreasing with increasing voltage). Important characteristics of the tunnel diode are its very fast speed of operation, its small physical size, and its low power consumption. It has found application in many fields of electronics, principally in computers, microwave devices, and where low electronic noise is required. Esaki shared the Nobel Prize for physics in 1973 with Brian JOSEPHSON and Ivar GJAEVER.

Esaki worked for the computer firm International Business Machines at the Thomas J. Watson Research Center, Yorktown Heights, New York, until 1992, when he returned to Japan to become president of Tsukuba University, Ibaraki. He is also president of the Yokohama College of Pharmacy.

**Eschenmoser, Albert** (1925– ) *Swiss chemist*

Born at Erstfeld in Switzerland, Eschenmoser (**esh**-en-moh-ser) was educated at the Federal Institute of Technology, Zurich, where he has taught since 1956 and where, in 1960, he was appointed professor of organic chemistry.

He is best known for his work in synthesizing a number of complex organic compounds. His first success came with colchicine – an alkaloid found in the autumn crocus – which has important applications in genetical research. He also collaborated with Robert WOODWARD on the synthesis of vitamin B<sub>12</sub> (cyanocobalamin), which had first been isolated and crystallized by Karl FOLKERS in 1948. Its empirical formula was soon established and in 1956 Dorothy HODGKIN established its structure. It took many years with samples passing between Zurich and Harvard before Eschenmoser and Woodward were finally able to announce its synthesis in 1965.

**Eskola, Pentti Elias** (1883–1964) *Finnish geologist*

The son of a farmer from Lellainen in Finland, Eskola (**es**-ko-la) was educated at the universities of Helsinki and Freiburg, Germany, where he obtained his PhD in 1915. He joined the faculty of Helsinki University in 1916, and became professor of geology in 1924, a position he held until his retirement in 1953.

Early in his career Eskola introduced the important notion of metamorphic facies. He pointed out (1915) that in any rock of metamorphic formation that has arrived at chemical equilibrium under conditions of constant temperature and pressure, the mineral composition is controlled only by its chemical composition. Initially he recognized five types of facies, namely, sanidine, hornfels, greenschist, amphibolite, and eclogite. By 1939 he had raised the number to eight while later workers have continued to add further types.

**Espy, James Pollard** (1785–1860) *American meteorologist*

Espy was born in Washington County, Pennsylvania, and graduated from Transylvania University in Lexington, Kentucky, in 1808. He became principal of the Academy in Cumberland, Maryland (1812–17), and, after teaching mathematics and physics in Philadelphia, he became a full-time meteorologist in 1835. He was made state meteorologist in 1839 and from 1842 took up a national appointment, being attached at various times to the War Department, the Navy, and, after 1852, the Smithsonian, which eventually took over his network of observers and out of which the Weather Bureau was later to grow.

In addition to collecting and issuing basic data, Espy also wrote on questions of theoretical meteorology. He was the first to argue for the convective theory of precipitation in which the ascent and cooling of moist air with the release of latent heat leads to condensation and the formation of clouds. Much of the evidence for this came from his “nepheloscope,” a device whereby he could simulate cloud behavior and measure cooling rates. Espy published, in 1841, his *Philosophy of Storms* and then became involved in a prolonged and bitter controversy with William REDFIELD on the cause and nature of storms. Here he argued that storms consisted of radially convergent winds with the air escaping up the middle. Although his views on storms were influential in Europe, Redfield and Elias LOOMIS were able to produce convincing contrary evidence.

**Euclid** (c. 330 BC–c. 260 BC) *Greek mathematician*

A line is length without breadth.  
—*Elements*

Euclid (**yoo**-kloid) is one of the best known and most influential of classical Greek mathematicians but almost nothing is known about his life. He was a founder and member of the academy in Alexandria, and may have been a pupil of PLATO in Athens. Despite his great fame Euclid was not one of the greatest of Greek mathematicians and not of the same caliber as ARCHIMEDES.

Euclid's most celebrated work is the *Elements*, which is primarily a treatise on geometry contained in 13 books. The influence of this work not only on the future development of geometry, mathematics, and science, but on the whole of Western thought is hard to exaggerate. Some idea of the importance that has been attached to the *Elements* is gained from the fact that there have probably been more commentaries written on it than on the Bible. The *Elements* systematized and organized the work of many previous Greek geometers, such as Theaetetus and EUDOXUS, as well as containing many new discoveries that Euclid had made himself. Although mainly concerned with geometry it also deals with such topics as number theory and the theory of irrational quantities. One of the most celebrated number theoretic results is Euclid's proof that there are an infinite number of primes. The *Elements* is in many ways a synthesis and culmination of Greek mathematics. Euclid and APOLLONIUS of Perga were the last Greek mathematicians of any distinction, and after their time Greek civilization as a whole soon became decadent and sterile.

Euclid's *Elements* owed its enormously high status to a number of reasons. The most influential single feature was Euclid's use of the axiomatic method whereby all the theorems were laid out as deductions from certain self-evident basic propositions or axioms in such a way that in each successive proof only propositions already proved or axioms were used. This became accepted as the paradigmatically rigorous way of setting out any body of knowledge, and attempts were made to apply it not just to mathematics, but to natural science, theology, and even philosophy and ethics.

However, despite being revered as an almost perfect example of rigorous thinking for almost 2,000 years there are considerable defects in Euclid's reasoning. A number of his proofs were found to contain mistakes, the status of the initial axioms themselves was increasingly considered to be problematic, and the definitions of such basic terms as "line" and "point" were found to be unsatisfactory. The most celebrated case is that of the parallel axiom, which states that there is only one straight line passing through a given point and parallel to a given straight line. The status of this axiom was long recognized as problematic, and many unsuccessful attempts were made to deduce it from the remaining axioms. The question was only settled in the 19th century when Janos BOLYAI

and Nicolai Lobachevski showed that it was perfectly possible to construct a consistent geometry in which Euclid's other axioms were true but in which the parallel axiom was false. This epoch-making discovery displaced Euclidean geometry from the privileged position it had occupied. The question of the relation of Euclid's geometry to the properties of physical space had to wait until the early 20th century for a full answer. Until then it was believed that Euclid's geometry gave a fully accurate description of physical space. No less a thinker than Immanuel KANT had thought that it was logically impossible for space to obey any other geometry. However when Albert EINSTEIN developed his theory of relativity he found that the appropriate geometry for space was not Euclid's but that developed by Bernhard RIEMANN. It was subsequently experimentally verified that the geometry of space is indeed non-Euclidean.

In mathematical terms too, the discovery of non-Euclidean geometries was of great importance, since it led to a broadening of the conception of geometry and the development by such mathematicians as Felix KLEIN of many new geometries very different from Euclid's. It also made mathematicians scrutinize the logical structure of Euclid's geometry far more closely and in 1899 David HILBERT at last gave a definitively rigorous axiomatic treatment of geometry and made an exhaustive investigation of the relations of dependence and independence between the axioms, and of the consistency of the various possible geometries so produced. Euclid wrote a number of other works besides the *Elements*, although many of them are now lost and known only through references to them by other classical authors. Those that do survive include *Data*, containing 94 propositions, *On Divisions*, and the *Optics*. One of his sayings has come down to us. When asked by Ptolemy I Soter, the reigning king of Egypt, if there was any quicker way to master geometry than by studying the *Elements* Euclid replied, "There is no royal road to geometry."

### **Eudoxus of Cnidus** (c. 400 BC–c. 350 BC) *Greek astronomer and mathematician*

Born in Cnidus, which is now in Turkey, Eudoxus (**yoo**-**dok**-sus) is reported as having studied mathematics under Archytas, a Pythagorean. He also studied under PLATO and in Egypt. Although none of his works have survived they are quoted extensively by HIPPARCHUS. Eudoxus was the first astronomer who had a complete understanding of the celestial sphere. It is only this understanding that reveals the irregularities of the movements of the planets that must be taken into account in giving an accurate description of the heavens. For Eudoxus the Earth was at rest and around this center 27 concentric spheres rotated. The

outermost sphere carried the fixed stars, each of the planets required four spheres, and the Sun and the Moon three each. All these spheres were necessary to account for the daily and annual relative motions of the heavenly bodies. He also described the constellations and the changes in the rising and setting of the fixed stars in the course of a year.

In mathematics, Eudoxus is thought to have contributed the theory of proportion to be found in Book V of EUCLID – the importance of this being its applicability to irrational as well as rational numbers. The method of exhaustion in Book XII is also attributed to Eudoxus. This tackled in a mathematical way for the first time the difficult problem of calculating an area bounded by a curve.

### **Euler, Leonhard (1707–1783) *Swiss mathematician***

Mathematicians have tried in vain to this day to discover some order in the sequence of prime numbers, and we have reason to believe that it is a mystery into which the human mind will never penetrate.

—Quoted by G. Simmons in *Calculus Gems*

Euler (**oi-ler**) was one of the outstanding figures of 18th-century mathematics, and also the most prolific. He was born at Basel in Switzerland and studied at the university there, where he came to the notice of the BERNOULLI family; he became, in particular, a friend of Daniel Bernoulli. Having completed his studies Euler applied unsuccessfully for a post at Basel University. He was encouraged by his friend Bernoulli to join him at the St. Petersburg Academy of Science. Bernoulli obtained for Euler a post in the medical section of the academy and in 1727 Euler left for Russia to find on arriving that the empress had just died and that the future of the academy was doubtful. Fortunately it survived intact and he managed to find his way into the mathematical section. In 1733 Bernoulli left Russia to return to Switzerland and Euler was appointed to replace him as head of the mathematical section of the academy. Euler was not particularly happy in the highly repressive political climate and devoted himself almost exclusively to his mathematics. In 1740 he eventually left Russia to join Frederick the Great's Berlin Academy. He returned to Russia in 1766 at the invitation of Catherine the Great, remaining there for the rest of his life. He had lost the sight of his right eye through observing the Sun during his first stay in Russia and shortly after returning there his blindness became total. However, such was his facility for mental calculation and the power of his memory that this did not affect his mathematical creativity.

Euler contributed to almost all areas of mathematics, and did equally important work in both pure and applied mathematics. One of

his most significant contributions was to the development of analysis. Although he was working before the development of modern standards of rigor by such mathematicians as Karl Friedrich GAUSS and Augustin CAUCHY and thus lacked a rigorous treatment of such key topics as convergence, nonetheless his work in analysis constitutes a major advance over previous work in the area. He wrote three treatises on different aspects of analysis, which together collect, systematize, and develop what the mathematicians of the 17th century had achieved. These treatises became important and influential textbooks. It is worth noting that unlike some great mathematicians, such as Gauss, Euler was a highly successful and effective teacher. It is a measure of his intuitive insight into mathematics that even though he did lack truly rigorous analytical techniques he was still able to arrive at so many novel and important results. His phenomenal ability for calculation came to his aid here, for he frequently arrived at results, for example about infinite series, by induction from a great many calculations and gave only a highly dubious proof, leaving future mathematicians to give properly rigorous proofs of results that were indeed quite correct.

Outside analysis Euler made extremely important contributions both to the calculus of variations and mechanics. Mechanics was transformed by his treatment of it in his treatise of 1736. In essence he transformed the subject into one to which the full resources of analytical techniques could be applied. In doing so he paved the way for the work of mathematicians such as Joseph LAGRANGE.

Euler put his expertise in mechanics to practical use in his work on the three-body problem. He was interested in this problem because he wished to investigate the motion of the Moon. He published his first lunar-motion theory in 1753 and then a second theory in 1772. Euler was able to invent methods of approximating solutions that were accurate enough to be of practical use in navigation. Here his prodigious ability as a sheer calculator came into its own.

In addition to these pieces of work Euler made notable contributions to number theory and geometry. Numerous theorems and methods are named for him.

### **Euler, Ulf Svante von *See VON EULER, ULF SVANTE.***

### **Euler-Chelpin, Hans Karl August Simon von (1873–1964) *German–Swedish biochemist***

Euler-Chelpin (**oi-ler-kel-pin**) was born at Augsburg in Germany and educated at the universities of Berlin, Strasbourg, and Göttingen and at the Pasteur Institute. In 1898 he moved to Sweden, being appointed to the staff of the Uni-

versity of Stockholm, where in 1906 he became professor of general and inorganic chemistry. In 1929 he also became director of the Institute of Biochemistry where he remained until his retirement in 1941. Although he became a Swedish citizen in 1902 he served Germany in both world wars.

In 1904 important work by Arthur HARDEN had shown that enzymes contain an easily removable nonprotein part, a coenzyme. In 1923 Euler-Chelpin worked out the structure of the yeast coenzyme. He showed that the molecule is made up from a nucleotide similar to that found in nucleic acid. It was named diphosphopyridine nucleotide (now known as NAD). Euler-Chelpin shared the 1929 Nobel Prize for chemistry with Harden for this work. His son, Ulf VON EULER, was also a Nobel prizewinner.

### **Eustachio, Bartolommeo** (c. 1524–1574) *Italian anatomist*

The son of a physician from San Severino in Italy, Eustachio (ay-oo-**stah**-kyoh) received a sound humanist education acquiring a good knowledge of Latin, Greek, and Arabic. In the early 1540s he was appointed physician to the duke of Urbino and, from 1547, served the duke's brother, Cardinal Rovere, with whom he moved to Rome in 1549. While there he also served from 1562 as professor of anatomy at the Sapienza or Papal College.

In 1564 he collected some of his earlier work in his *Opuscula anatomica* (Anatomical Works). It contains his *De auditus organis* (On the Auditory Organs), which describes the eustachian tubes connecting the middle ear to the pharynx and named in his honor (although these were first described by Alcmaeon). It also contained the *De renum structura* (On the Structure of the Kidney), in which he published the first description of the adrenal glands.

Eustachio was not in fact as influential an anatomist as he might have been for his anatomical plates, prepared for a text never completed, were lost and only rediscovered in the early 18th century. They were finally published as the *Tabulae anatomica* in 1714 and republished with full notes by Bernhard ALBINUS in 1744. It has been claimed that the plates manifest an originality equaled only by Andreas VESALIUS and Leonardo da Vinci and that Eustachio's plates of the sympathetic nervous system are the best yet produced.

### **Evans, Martin J.** (1941– ) *British developmental biologist*

Evans graduated from Cambridge University in 1963 with a BA in biochemistry, and began postgraduate research at University College, London, in the department of anatomy and embryology, gaining his PhD in 1969. He stayed on as a lecturer until returning to Cambridge in

1978 to join the department of genetics. In 1999 he was appointed professor of mammalian genetics at Cardiff University, and director of the school of biosciences.

From his early postgraduate work at University College, Evans' prime interest was the genetic control of vertebrate development, and he sought a means of studying this using cultured cells that could be genetically manipulated. A promising avenue involved undifferentiated cells derived from a mouse testicular tumor, termed a teratocarcinoma, that were capable of differentiating into a range of tissue cells, in ways that mimicked embryonic development. Evans devised a method of maintaining these embryonal carcinoma (EC) cells in culture, whereby their ability to differentiate was retained indefinitely. So, for example, such cells could give rise to skin, nerve, and even beating heart muscle.

Evans and a collaborator, Richard Gardner, saw the potential for creating mice containing cells derived from genetically modified EC cells. They injected EC cells into early mouse embryos (blastocysts) and reimplanted the embryos in surrogate mothers to complete development. The resulting offspring were genetic chimeras, comprising a mix of normal cells from the natural parents, and EC cells, but they developed multiple tumors and failed to establish breeding lines of mice. Another way had to be found to achieve this.

In 1981 Evans and colleague Matt Kaufmann reported their discovery in normal mouse embryos of cells that had properties similar to the EC cells. Laboriously, they devised ways of isolating such cells from mouse embryos, and maintaining them in culture. Evans' team subsequently showed that when these embryonic stem (ES) cells were transfected with foreign DNA and injected into blastocysts, the embryos completed their development to form chimeric mice incorporating cells containing the foreign DNA. Moreover, unlike the EC cells, the foreign DNA could be transmitted through the germline to descendants of the chimeric adults. In 1987 Evans and coworkers confirmed the strength of this approach by inserting into ES cells several copies of a mutant gene for the enzyme hypoxanthine phosphoribosyltransferase (HPRT), and producing mouse chimeras that contained the mutation in their cells. The mutation was inherited through the germline, and affected progeny could be identified by virtue of the defective HPRT enzyme.

In the meantime, other researchers, notably Mario Capecchi and Oliver SMITHIES, had independently developed a method of introducing targeted genetic modifications to a genome using the phenomenon of homologous recombination. Applying this process to the ES cells discovered by Evans represented a breakthrough that heralded a new era in developmental biology and experimental medicine.

Within a few years, numerous mouse lines had been bred to contain specific stably inherited genetic alterations; these were often 'knockout' mice, with a particular gene disabled, or mice containing other, more subtle, genetic changes.

Evans remained at the forefront of this emerging field, using the new technique to engineer mouse models that mimicked human diseases, such as cystic fibrosis and breast cancer. Besides providing insights into the genetic mechanisms underlying such disease, such models also suggest novel approaches to treatment, including gene therapy.

In 2001 Evans was awarded the Albert Lasker Award for basic medical research, jointly with Capecchi and Smithies. The trio were honoured again in 2007, by receiving the Nobel Prize for physiology or medicine, for discovering principles for introducing specific gene modifications in mice by the use of embryonic stem cells.

**Evans, Robley Dunglison (1907–1996)**  
*American physicist*

Born in University Place, Nebraska, Evans was educated at the California Institute of Technology, where he obtained his PhD in 1932. He went to the Massachusetts Institute of Technology in 1934 and was appointed professor of physics there in 1945.

In 1940 Evans suggested that radioactive potassium-40 could be of use in geologic dating. It is widespread in the Earth's crust and has an exceptionally long half-life of over a thousand million years. It decays to the stable isotope argon-40, and determination of the ratio of  $^{40}\text{K}$  to  $^{40}\text{Ar}$  allows estimations of the age of potassium-bearing rocks ranging from 100,000 to about 10 million years. The technique proved to be particularly valuable as it permitted accurate dating beyond the limits of Willard LIBBY's carbon-14 technique.

**Everett III, Hugh (1930–1982)** *American physicist*

Everett was a doctoral pupil of John WHEELER in the 1950s at Princeton. In 1957 he published a famous paper on the foundations of quantum mechanics describing what has become known as the "many worlds" interpretation. The paper was entitled *Relative State Formulation of Quantum Mechanics*.

The traditional Copenhagen interpretation of quantum mechanics applied only to the sub-microscopic world. Everett broke away from this tradition and attempted to apply quantum mechanics to the universe. He established a universal wave function that could be applied to both microscopic entities and macroscopic observers. As a consequence, there is no collapse of the wave function and quantum paradoxes, such as Schrödinger's cat, are avoided.

This approach, however, is not without paradoxical conclusions of its own. In Everett's formulation, the result of a measurement is to split the universe into as many ways as to allow all possible outcomes of the measurement. Thus if an observer were to check the outcome of a die throw, the universe would split into six copies with each one containing one of the six possible outcomes of the throw. Everett proposed that each outcome is realized in a number of parallel universes between which there is no communication.

While Everett's work has inevitably been taken up by many science fiction writers, it has also been taken seriously by other scientists. GELL-MANN, for example, has tried to develop a version of quantum theory that eliminates the role of the observer, in the manner of Everett, but reduces the idea of "many worlds" to one of possible histories of the universe to which a probability value can be assigned.

**Ewing, Sir James Alfred (1855–1935)**  
*British physicist*

The son of a minister of the Free Church of Scotland, Ewing was educated at the University of Edinburgh where he studied engineering. He served as professor of engineering at the Imperial University, Tokyo, from 1878 until 1883 when he returned to Scotland to a similar post at the University of Dundee. In 1890 he was appointed professor of applied mechanics at Cambridge University, but in 1903 moved into higher levels of administration, first as director of naval education and from 1916 until his retirement in 1929 as principal and vice-chancellor of Edinburgh University.

In Japan he worked on problems in seismology and in 1883 published *Treatise on Earthquake Measurement*. However, his most notable achievement as a physicist was his work on hysteresis, first described by him in 1881. Hysteresis is an effect in which there are two properties, M and N, such that cyclic changes of N cause cyclic variations of M. If the changes of M lag behind those of N, there is hysteresis in the relation of M to N. Ewing came across the phenomena when working on the effects of stress on the thermoelectric properties of a wire. Hysteresis effects were later shown to apply to many aspects of the behavior of materials, in particular in magnetization.

Ewing was put in charge of the cryptologists at the Admiralty from 1914 to 1916. He described his work there in his book *The Man in Room 40* (1939).

**Ewing, William Maurice (1906–1974)**  
*American oceanographer*

Ewing was born at Lockney in Texas and educated at the Rice Institute, Houston, obtaining his PhD in 1931. He taught at Lehigh Univer-

sity, Pennsylvania from 1934 until moving in 1944 to Columbia University, New York, where he organized the new Lamont Geological Observatory into one of the most important research institutions in the world.

Ewing pioneered seismic techniques to obtain basic data on the ocean floors. He was able to establish that the Earth's crust below the oceans is only about 3–5 miles (5–8 km) thick while the corresponding continental crust averages 25 miles (40 km).

Although the Mid-Atlantic Ridge had been discovered when cables were laid across the Atlantic, its dimensions were unsuspected. In 1956 Ewing and his colleagues were able to show that the ridge constituted a mountain range extending throughout the oceans of the world and was some 40,000 miles (64,000 km) long. In 1957, working with Marie Tharp and Bruce HEEZEN, he revealed that the ridge was divided by a central rift, which was in places twice as deep and wide as the Grand Canyon.

His group found that the oceanic sediment, expected to be about 10,000 feet (3,000 m) thick, was nonexistent on or within about 30 miles (50 km) of the ridge. Beyond this it had a thickness of about 130 feet (40 m) – much less than the depth of the corresponding continental sediment. All this seemed to be consistent with the new sea-floor spreading hypothesis of Harry H. HESS. Ewing was however reluctant to support it until Frederick VINE and Drummond H. MATTHEWS showed how the magnetic reversals discovered by B. Brunhes in 1909 could be used to test the theory.

Ewing also proposed, with William Donn, a mechanism to explain the periodic ice ages. If the Arctic waters were icefree and open to warm currents this source of water vapor would produce greater accumulations of snowfall. This would increase the Earth's reflectivity and reduce the amount of solar radiation absorbed. Temperatures would fall and glaciers move south, but with the freezing of the Arctic seas the supply of water vapor would be cut off and the ice sheets would retreat. This would cause an increase in solar radiation absorbed and the cycle would begin again. No hard evidence has yet been found in support of the theory.

### **Ewins, Arthur James** (1882–1957) *British pharmaceutical chemist*

Ewins was born in Norwood on the outskirts of London and went straight from school to the brilliant team of researchers at the Wellcome Physiological Research Laboratories at Beckenham in Kent. Here he worked on alkaloids with George BARGER and in 1914, with Henry DALE, isolated the important neurotransmitter acetylcholine from ergot. Following wartime experience in manufacturing arsenicals with the Medical Research Council, he became head of research with the pharmaceutical manufac-

turers May and Baker, where he remained until his retirement in 1952. Under Ewins in 1939, the team produced sulfapyridine, one of the most important of the new sulfonamide drugs. An important later discovery was the antiprotozoal drug pentamidine (1948).

### **Eyde, Samuel** (1866–1940) *Norwegian engineer and industrialist*

Born in Arendal in Norway, Eyde (Id) trained as a civil engineer in Berlin. Up until 1900 he worked in Germany and also on harbor and railroad-station projects in Scandinavia. Here he became interested in industrial electrochemical processes – a subject of some potential in Scandinavia because of the availability of cheap hydroelectric power.

In 1901 Eyde met Kristian BIRKELAND with whom he developed a process (1903) for reacting atmospheric nitrogen with oxygen in an electric arc. Processes in which nitrogen in the atmosphere is “fixed” in nitrogen compounds are of immense importance in the production of nitrogenous fertilizers for agriculture. The main method is the catalytic reaction with hydrogen developed by Fritz HABER. The *Birkeland–Eyde process*, which gives nitrogen oxides, needed plentiful and cheap supplies of electricity, leading to a significant growth in the production of hydroelectric power. In 1900 Norway had an output of little more than 100,000 kilowatts; by 1905 production had jumped to 850,000 kilowatts. In the same year Birkeland started the company Norsk Hydro-Elektrisk.

Kvaelstof, with the help of French capital, began to produce fertilizers by the Birkeland–Eyde process. As a result of this, Norway's export of chemicals was to treble before the start of World War I. Eyde retired from the firm in 1917. As well as his industrial interests, he was also a member of the Norwegian parliament.

### **Eyring, Henry** (1901–1981) *Mexican–American physical and theoretical chemist*

Eyring, a grandson of American missionaries who had become Mexican citizens, was born at Colonia Juarez in Mexico. He thus first came to America in 1912 as a Mexican citizen and did not take American citizenship until 1935. He was educated at the University of Arizona and the University of California, where he obtained his PhD in 1927. He then held a number of junior appointments before joining the Princeton faculty in 1931, becoming professor of chemistry there in 1938. Eyring moved to a similar chair at the University of Utah, holding the post until his retirement in 1966.

Eyring, the author of 9 books and over 600 papers, was as creative a chemist as he was productive. His main work was probably in the field of chemical kinetics with his transition-state theory. Since the time of Svante ARRHEN-

NIUS it had been appreciated that the rate constant of a chemical reaction depended on temperature according to an equation of the form:

$$k = Ae^{-E/RT}$$

The constant  $A$  is the frequency factor of the reaction;  $E_A$  is the activation energy. The values of  $A$  and  $E_A$  can be found experimentally for given reactions. Eyring's contribution to the field was to develop a theory capable of predicting reaction rates.

In a reaction, the atoms move – i.e., molecules break and new molecules form. If the potential energy of a set of atoms is plotted against the distances between atoms for chosen arrangements, the result is a surface. Positions of low energy on the surface correspond to molecules; a reaction can be thought of as a change from a low-energy point, over a higher energy barrier, to another low-energy position.

A. Marcelin, in 1915, had shown that reactions could be represented in this way, and in 1928 Fritz London pointed out that it was possible to calculate potential surfaces using quantum mechanics. Eyring, with Michael Polyani,

first calculated such a surface (1929–30) for three hydrogen atoms and Eyring later went on to calculate the potential surfaces for a number of reactions. The activation energy of the reaction is the energy barrier that the system must surmount.

Eyring later (1935) showed how to calculate the frequency factor ( $A$ ). He assumed that the configuration of atoms at the top of the energy barrier – the “activated complex” – could be treated as a normal molecule except for a vibrational motion in the direction of the reaction path. Assuming that the activated complex was in equilibrium with the reactants and applying statistical mechanics, Eyring derived a general expression for reaction rate. Eyring's theory, called absolute-rate theory, is described in his book (with Samuel Glasstone and Keith J. Laidler) *The Theory of Rate Processes* (1941). It can also be applied to other processes, such as viscosity and diffusion.

Eyring also worked on the theory of the liquid state and made contributions in molecular biology.

## **Fabre, Jean Henri** (1823–1915) *French entomologist*

History ... records the names of royal bastards, but cannot tell us the origin of wheat.

—*Souvenirs entomologiques* (1879–1907; Entomological Recollections)

If there is one vegetable which is God-given, it is the haricot bean.

—As above

Although world famous for his detailed studies of insect habits and life histories, Fabre (**fah-bre**) did not attain stature as a field entomologist until late in his life, his earlier years being spent under great difficulty and comparative poverty. Described by DARWIN, with whom he corresponded, as “an inimitable observer,” Fabre’s best-known entomological observations were largely made in his native Provence and the Rhône valley. His enthusiasm for his subject had been stimulated by reading an essay on the habits of the *Cerceris* wasp, which prompted Fabre to make his own detailed observations of these and other parasitic wasps, as well as many other insect groups. His descriptions of their development and behavior, written in a clear simple style, still stand as models of accurate observation. Fabre’s earliest entomological observations appeared in *Annales des sciences naturelles* (Annals of the Natural Sciences), but his major publication is the classic *Souvenirs entomologiques* (10 vols. 1879–1907; Entomological Recollections).

## **Fabricius, David** (1564–1617) *German astronomer*

Fabricius (**fah-bree-tsee-uus**), who was born in Essen, now in Germany, was a clergyman and amateur astronomer. He engaged in a prolonged correspondence with Johannes KEPLER but remained unconvinced by Kepler’s Copernican arguments. In 1596 he noticed the variability of the star Omicron Ceti and called it “Mira” (the marvelous). Fabricius was murdered by one of his parishioners. His son Johannes Fabricius was also an astronomer and was one of the discoverers of sunspots.

## **Fabricius ab Aquapendente, Hieronymus** (1537–1619) *Italian anatomist and embryologist*

Fabricius (**fa-brish-ee-us**) was born at Aquapendente in Italy and educated at the University of Padua where he studied under Gabriel FALLOPIUS, succeeding him, in 1565, as professor of anatomy.

As an anatomist his most significant work was his *De venarum ostioliis* (1603; On the Valves of the Veins), which contains a clear and detailed description of the venous system and which exercised a considerable influence on his most famous pupil, William HARVEY. Fabricius himself entertained no such idea as the circulation of the blood, explaining the role of the valves as retarding the blood flow, thus allowing the tissues to absorb necessary nutriment.

He spent much time observing the development of the chick embryo and published two works *De formato foetu* (1600; On the Formation of the Fetus) and *De formatione ovi et pulli* (1612; On the Development of the Egg and the Chick). These were hailed as elevating embryology into an independent science but they still contain many incorrect assumptions.

Thus for Fabricius semen did not enter the egg but rather initiated the process of generation from a distance in some mysterious way. He also made a now totally unfamiliar distinction between what nourishes and what produces the embryo. Thus he believed both the yolk and albumen merely nourished the embryo. Having eliminated the sperm, yolk, and albumen, Fabricius claimed that the chalaza – the spiral threads holding the yolk in position – produces the chick.

It was while engaged upon this work that he discovered and described the bursa of Fabricius. This is a small pouch in the oviduct of the hen, which Fabricius thought to be a store for semen. In the 1950s however the young research student B. Glick showed that this obscure organ plays a key role in the immune system of chickens, and by implication of humans who must possess a comparable system.

## **Fahrenheit, (Gabriel) Daniel** (1686–1736) *German physicist*

Possibly owing to a business failure, Fahrenheit (**fah-ren-hIt**) emigrated to Amsterdam from his native Danzig (now Gdańsk in Poland) to become a glass blower and instrument maker. He specialized in the making of meteorological in-

struments, and proceeded to develop a reliable and accurate thermometer. GALILEO had invented the thermometer in about 1600, using changes in air volume as an indicator. Since the volume of air also varied considerably with changes in atmospheric pressure liquids of various kinds were quickly substituted. Fahrenheit was the first to use mercury in 1714. He fixed his zero point by using the freezing point of a mixture of ice and salt as this gave him the lowest temperature he could reach. His other fixed point was taken from the temperature of the human body, which he put at 96°. Given these two fixed points the freezing and boiling points of water then work out at the familiar 32° and 212°. One advantage of the system is that, for most ordinary purposes, negative degrees are rarely needed.

Using his thermometer, Fahrenheit measured the boiling point of various liquids and found that each had a characteristic boiling point, which changed with changes in atmospheric pressure.

**Fairbank, William** (1917–1989) *American physicist*

Fairbank was born at Minneapolis in Minnesota and educated at Whitman College, Walla Walla, Washington, and at the University of Washington. He gained his PhD at Yale in 1948. He spent the war years at the Radiation Laboratory of the Massachusetts Institute of Technology. After working at Amherst, Maryland (1947–52) and Duke University, North Carolina (1952–59), Fairbank was appointed professor of physics at Stanford, a post he held until his death from a heart attack in 1989.

In 1977, Fairbank, in collaboration with George Larue, claimed to have experimental evidence for the existence of a quark. The concept of quarks, with an electric charge  $-1/3$  or  $+2/3$  the electron charge, had been proposed by Murray GELL-MANN in 1963 to explain the behavior of hadrons. It was known that it would be unlikely that quarks could be produced at the energies available in particle accelerators. However, it was possible that some might be created in the atmosphere as a result of high-energy cosmic rays. A number of physicists set up ingenious sensitive experiments to “hunt the quark.”

Fairbank’s technique was a much more sensitive and sophisticated version of Robert MILLIKAN’s oil-drop experiment for measuring the charge of the electron. A small sphere (0.25 millimeter diameter) of niobium was suspended between metal plates at a temperature close to absolute zero. The charge on the sphere could be measured by the electric field between the plates.

When Fairbank examined his results he found that in the case of one ball there was “a nonzero residual change of magnitude  $-0.37 \pm$

0.03.” At first, Fairbank warned, the results did not necessarily imply the presence of a quark as there could well be spurious charge forces present. Consequently, Fairbank spent a good deal of time eliminating these and numerous other possible distortions from his experimental setup.

Theorists were suspicious of Fairbank’s work because free quarks are thought to be impossible to produce – the doctrine of “quark confinement.” Despite this, Fairbank announced in 1979 that, using modified apparatus, he had detected a second particle with a fractional charge.

While no one has managed to reproduce Fairbank’s experiments, he was sufficiently respected as a careful and skillful experimentalist for his work to be taken seriously. Consequently, for some particle physicists at least, the issue of quark confinement remains an open question.

**Fajans, Kasimir** (1887–1975) *Polish–American physical chemist*

Fajans (**fah**-yahns) was born in the Polish capital of Warsaw and gained his doctorate at Heidelberg (1909). He was professor of physical chemistry at Munich (1925–35) before emigrating to America in 1936. He was a member of the Faculty of the University of Michigan (1936–57) and emeritus professor from 1957.

He is best known for *Fajan’s laws* (1913), which state that elements emitting alpha particles decrease in atomic number by two while those undergoing beta emission gain in atomic number by one. These were independently discovered by Frederick SODDY. In 1917 Fajans discovered, with Otto Gohring, uranium  $X_2$  – a form of the element protactinium  $^{234}\text{P}$ .

**Fallopium, Gabriel** (1523–1562) *Italian anatomist*

Fallopium (**fa-loh**-pee-us) was born in Modena, Italy. He originally intended to enter the Church and served as a canon in his native city for some time before turning to the study of medicine at Ferrara and Padua where he was a pupil of the great Andreas VESALIUS. He held the chair of anatomy at the University of Pisa from 1548 until 1551 when he moved to a similar post at the University of Padua, remaining there until his early death at the age of 39.

On the strength of his masterpiece *Observationes anatomicae* (1561; Anatomical Observations) he has been described as a better and more accurate anatomist than his teacher, Vesalius. His main innovations were in the anatomy of the skull and the generative system. In the former area he introduced the terms cochlea and labyrinth, going on to give a clear account of the auditory system.

In his account of the reproductive system he described the clitoris and introduced the term

“vagina” into anatomy. He is mainly remembered today, however, for his description of the eponymous fallopian tubes. The tubes, connecting the uterus and the ovaries, were described by him as resembling at their extremity a “brass trumpet” (tuba). This somehow became mistranslated into English as tube. It was many years before their function was understood.

**Faraday, Michael** (1791–1867) *British physicist and chemist*

Mr. Faraday is not only a man of profound chemical and physical science (which all Europe knows), but a very respectable lecturer. He speaks with ease and freedom, but not with a gossiping, unequal tone, alternately inaudible and bawling, as some very learned professors do; he delivers himself with clearness, precision, and ability.

—Friedrich Ludwig Georg von Raumer in  
*Cyclopaedia of Literary and Scientific Anecdote*  
(19th century)

Faraday’s father was a blacksmith who suffered from poor health and could only work irregularly. Faraday, who was born in Newington, England, knew real poverty as a child and his education was limited for he left school at the age of 13. He began work for a bookseller and binder in 1804 and was apprenticed the following year. His interest in science seems to have been aroused by his reading the 127-page entry on electricity in an *Encyclopaedia Britannica* he was binding and this stimulated him to buy the ingredients to make a Leyden jar and to perform some simple experiments. He joined the City Philosophical Society, which he attended regularly, broadening his intellectual background still further. The turning point in his life came when he attended some lectures by Humphry DAVY at the Royal Institution in 1812. He took very full notes of these lectures, which he bound himself.

By now he was no longer satisfied with his amateur experiments and evening lectures and wanted desperately to have a full-time career in science. He wrote to the President of the Royal Society, Joseph BANKS, asking for his help in obtaining any post but received no reply. Faraday now had a little luck. Davy had had an accident and needed some temporary assistance. Faraday’s name was mentioned and proved acceptable. While working with Davy he showed him the lecture notes he had taken and bound. When a little later, in 1813, a vacancy for a laboratory assistant arose, Davy remembered the serious young man and hired him at a salary of a guinea a week (less than Faraday had been earning as a bookbinder).

Faraday was to spend the rest of his working life at the Royal Institution, from which he finally resigned in 1861. In 1815 he was promoted to the post of assistant and superintendent of the apparatus of the laboratory and

meteorological collection. In 1825 he was made director of the laboratory and, in 1833, he was elected to the newly endowed Fullerian Professorship of Chemistry at the Royal Institution. He had earlier turned down the offer of the chair of chemistry at University College, London, in 1827.

The paucity of the salary paid him was made up by Faraday with consultancy fees and a part-time lectureship he held at the Royal Military Academy, Woolwich. These extra sources took up his time and in 1831, when he was working as hard as he could on his electrical experiments, he gave up all his consultancies. This left him in some financial difficulties and moves were made to arrange for a government pension. He called on the prime minister of the day, Lord Melbourne, who made some sneering remark about such pensions being, in his view, a “gross humbug.” This was enough to make Faraday refuse the pension. In fact, Faraday was one of nature’s great refusers. Apart from the pension and the chair at University College, he also refused a knighthood and, what must surely be a record, the presidency of the Royal Society, not once, but twice. Faraday also had strong views on awards – “I have always felt that there is something degrading in offering rewards for intellectual exertion, and that societies or academies, or even kings and emperors, should mingle in the matter does not remove the degradation.” He had become a fellow of the Royal Society in 1824 but not without some friction between himself and the president, Davy. He was asked to withdraw his application by Davy. Just why Davy behaved in this way is not clear. Some have seen it as jealousy by Davy of someone whose talents so clearly surpassed his own. There is no evidence of this but it is reasonably clear that when Faraday insisted on going ahead with his application Davy voted against him.

Faraday’s financial problems were solved when, in 1835, Melbourne apologized, enabling him to accept the pension. After his labors of the 1830s he suffered some kind of breakdown in 1841 and went into the country to rest. Just what was wrong is not known; he wrote in 1842 that he could see no visitors because of “ill health connected with my head.” For two years he did no work at all until in 1844 he seemed to be able to resume his experiments. Faraday continued to work but by the 1850s his creativity was in decline. He gave his last children’s lectures at the Royal Institution in 1860 and resigned from it the following year, taking up residence in a house at Hampton Court made available to him by Prince Albert in 1858.

Faraday’s first real successes were made in chemistry. In 1823 he unwittingly liquefied chlorine. He was simply heating a chlorine compound in a sealed tube and noticed the formation of some droplets at the cold end. He realized that this was the result of both tem-

perature and pressure and on and off over the years applied the method to other gases. In 1825 he discovered benzene ( $C_6H_6$ ) when asked to examine the residue collecting in cylinders of illuminating gas; he called the new compound "bicarburet of hydrogen" because he took its formula to be  $C_2H$ . As a working chemist Faraday was one of the best analysts of his day. All his working life he was working and publishing as a chemist but in 1820 he also turned to a new field that was to dominate his life.

Faraday had begun by accepting the view that electricity is composed of two fluids. It was common in the 18th century to see such phenomena as light, heat, magnetism, and electricity to be the result of weightless fluids. In 1820 Hans Christian OERSTED made a most surprising discovery: he had found that a wire carrying a current is capable of deflecting a compass needle; the direction in which the needle turned depended on whether the wire was under or over the needle and the direction in which the current was flowing. André Marie AMPÈRE found that two parallel wires attract each other if the current in each is traveling in the same direction but repel each other if the currents are moving in opposite directions. Finally François ARAGO discovered that a copper disk rotating freely on its own axis would produce rotation in a compass needle suspended over it.

These phenomena were difficult to fit into fluid theories of electricity and magnetism. They enabled Faraday to make his first important discovery in 1821, that of electromagnetic rotation. A magnet was placed upright in a tube of mercury and secured firmly at the bottom with the pole of the magnet above the surface. A wire dipping into the mercury but free to rotate was suspended over the pole. When a current was passed through the mercury and through the wire, the wire rotated around the magnet. If the wire was secured and the magnet allowed to move, then the current caused the magnet to rotate. The first electric motor had been constructed.

When Faraday published his results they were to cause him much distress. William WOLLASTON had spoken of the possibility of such rotation and many concluded that Faraday had stolen his ideas. Faraday was only too aware of the stories about him but found there was little he could do about them. It may well have been this that Davy thought disqualified him from membership of the Royal Society.

In any case it was not really electromagnetic rotation that interested Faraday. All the new results involved the production of a magnetic force by an electric current and Faraday, with many others, was sure that it should also be possible to induce an electric current by magnetic action. He tried intermittently for ten years without success until in 1832 he hit upon an apparatus in which an iron ring was wound

with two quite separate coils of wire. One was connected to a voltaic cell; the other to a simple galvanometer. He showed that on making and breaking the current in the cell circuit, the galvanometer momentarily registered the presence of a current in its circuit. The following few months were some of the most active of his life. He showed that the same results can be obtained without a battery: a magnet moved in and out of a coil of wire produced a current. A steady current could be produced by rotating a copper disk between the poles of a powerful magnet. His results were published in his *Experimental Researches in Electricity, first series* (1831).

Faraday found this deeply satisfying for it reinforced one of his strongest convictions about nature "that the various forms under which the forces of matter are made manifest have one common origin." That electricity and magnetism could interact made this view more plausible. At the time it was by no means clear that the various types of electricity – static, voltaic, animal, magnetic, and thermoelectric – were the same and FARADAY spent the period 1833–34 on this problem, publishing his results in the third series of his *Experimental Researches*.

Faraday had also continued the work of Davy on electrolysis – i.e., on the chemical reaction produced by passing an electric current through a liquid. He applied his ideas on the quantity of electricity to this chemical effect and produced what are now known as *Faraday's laws of electrolysis*. By careful analysis he showed that the chemical action of a current is constant for a constant quantity of electricity. This was his first law, that equal amounts of electricity produce equal amounts of decomposition. In the second law he found that the quantities of different substances deposited on the electrode by the passage of the same quantity of electricity were proportional to their equivalent weights.

In his explanations of magnetic and electrical phenomena Faraday did not use the fluid theories of the time. Instead he introduced the concept of lines of force (or tension) through a body or through space. (A similar earlier idea had been put forward by R. J. Boscovich with his picture of point atoms surrounded by shells of force.) Thus Faraday saw the connection between electrical and magnetic effects as vibrations of electrical lines communicated to magnetic lines. His experiments on induction were described in terms of the cutting of magnetic lines of force, which induces the electrical current. He explained electrical induction in dielectrics by the strain in "tubes of induction" – and electrolysis was complete breakdown under such strain.

Faraday was no mathematician, relying instead on his wonderful experimental skill and his imagination. His lines of force were taken

up by others more skillful mathematically. In the latter half of the century Clerk MAXWELL developed Faraday's ideas into a rigorous and powerful theory, creating an orthodoxy in physics that lasted until the time of EINSTEIN. Faraday's greatness rests in his courage and insight in rejecting the traditional physics and creating an entirely new one. Few can compete with Faraday at the level of originality.

One further effect discovered by Faraday lay in optics. His discovery of *Faraday rotation* in 1845 was one that gave him pleasure for it seemed to be further evidence for the unity of nature by showing that "magnetic force and light were proved to have a relation to each other." Here, he showed that if polarized light is passed through a transparent medium in a magnetic field its plane of polarization will be rotated. Not the least of Faraday's achievements was as a lecturer and popularizer of science. In 1826 he started the famous Christmas lectures to children at the Royal Institution in London and gave 19 of these lecture courses. For most only the notes exist but a couple of lectures were taken down in shorthand and later published: *The Chemical History of a Candle* and *Lectures on Various Forces of Matter*. The children's Christmas lectures still continue to be given every year by eminent scientists.

**Farman, Joe** (1930– ) *British atmospheric chemist*

Farman has been engaged in the study of the Antarctic atmosphere since 1957, working in recent years for the British Antarctic Survey based in Cambridge, England. The Survey operates five Antarctic stations.

One of the tasks of Farman's team has been to measure Antarctic ozone levels. This is normally done with a spectrophotometer recording the amount of ultraviolet radiation (UV) reaching the Earth's surface. As ozone absorbs UV, the less ozone in the atmosphere, the greater the amount of UV reaching the Earth. The ozone level was measured in Dobson units (DU) and normally had a value of about 400 DUs (after the designer of the spectrophotometer, G. M. Dobson). In 1982 Farman first noted a very low reading of 130 DUs. Initially he merely assumed that his instruments were breaking down. Further, ozone levels were known to fluctuate widely and shortlived, unusual levels, both high and low, had been known before. And as nothing unusual had been detected by the Nimbus satellite, Farman suspected his readings were, in some unknown way, unreliable. Nonetheless new equipment was installed and when similar low levels were recorded in the following season Farman began to take the matter seriously. An examination of past records revealed that there had been a decline in ozone levels since 1977. He further checked

the readings by organizing measurements at another research station 1,000 miles away.

By the end of the 1984 season Farman was convinced that he had detected a persistent seasonal fall in Antarctic ozone levels of about 40%. Soon after the southern winter's end in October, the polar vortex collapses and ozone levels rise as air is drawn in from elsewhere. A check on the Nimbus satellite revealed that it was programmed to ignore readings that varied from the average by more than a third.

Farman was aware of the work of ROWLAND and began to suspect that ozone depletion was connected with atmospheric CFCs. He published his results in *Nature* in May 1985. All subsequent work, whether by Farman or others, has confirmed his initial measurements of 1982.

**Fechner, Gustav Theodor** (1801–1887) *German physicist and psychologist*

Fechner (**fek-ner**), who was born at Gross-Särchen in Germany, studied medicine at the University of Leipzig; after graduating, however, his interest turned toward physics. He did some research on the galvanic battery and, on the strength of this, was appointed professor of physics at Leipzig in 1834. However, partial blindness, caused by overlong study of the Sun, and mental illness forced him to resign five years later.

It was after his recovery that he started trying to put psychology on a scientific basis. He studied the relationship between the intensities of external stimulæ and subjective sensations, and elaborated Ernst WEBER's work to develop the *Weber-Fechner law* governing this connection. This work, published in 1860, founded the science of psychophysics.

Fechner also became interested in spiritualism, like many scientists of his day, and wrote much on mystical and philosophical subjects. He also wrote satirical poems under the pseudonym of Dr. Mises.

**Fehling, Hermann Christian von** (1812–1885) *German organic chemist*

Fehling (**fay-ling**), who was born in Lübeck, now in Germany, gained his doctorate at Heidelberg in 1837 and studied with Justus von LIEBIG at Giessen. He was professor of chemistry at the polytechnic school at Stuttgart from 1839 to 1882.

Fehling did much work in organic chemistry, including the preparation and hydrolysis of benzonitrile and the discovery of succinosuccinic ester. However, he is best known for his invention of *Fehling's solution*, used as a test for aldehydes and reducing sugars (e.g., glucose, fructose, lactose). It consists of a solution of copper(II) sulfate (Fehling's I) and an alkaline solution of a tartaric acid salt (Fehling's II).

The solutions are boiled with the test material and a positive result is a brick-red precipitate (insoluble copper(I) oxide), formed by the reduction of copper(II) sulfate.

**Feigenbaum, Edward Albert** (1936– )  
*American computer scientist*

Born at Weehawken, New Jersey, Feigenbaum (**fl**-gen-bowm) first studied electrical engineering at Carnegie Institute of Technology, Pittsburgh; there, under the influence of Herbert SIMON, his interests were diverted into the newly emerging field of artificial intelligence (AI). Consequently after completing his PhD in 1960 at Carnegie in cognitive psychology, Feigenbaum spent the period from 1960 to 1964 at the University of California, Berkeley, before being appointed professor of computer science at Stanford University in 1965.

Feigenbaum was an early pioneer in the expert-systems approach to AI. Workers like Allan NEWELL had tried to provide computers with a general understanding that would enable them to tackle a wide variety of problems. Their ambitions, however, remained unfulfilled. Feigenbaum opted for a more specialized alternative. "We found," he commented, "it was better to be knowledgeable than smart"; to build computers, that is, capable of playing high-level chess, but unable to understand the rules of tick-tack-toe.

Against this background Feigenbaum set out to program a computer to be able, on the basis of data from mass spectrometers and elsewhere, to identify organic compounds. By 1971 he had developed DENDRAL which was capable of formulating hypotheses about molecular structure, and then testing the hypothesis against further data. It finally offered a list of compounds ranked in terms of decreasing likelihood. DENDRAL has proved to be remarkably successful and, allowing for later improvements and refinements, is recognized to be almost as proficient as a human chemist.

**Fenn, John B.** (1917– ) *American chemist*

Fenn was born in New York City and educated at Berea College, where he obtained a BA in chemistry in 1937, and at Yale University, where he obtained a PhD in 1940. He then worked for about a dozen years at Monsanto and Sharples Chemical in Michigan and subsequently for seven years at Richmond, working for a small company. Between 1959 and 1967 he was the director of Project SQUID, a program of research in jet propulsion run by Princeton University. Between 1967 and 1980 he was a professor of applied science and chemistry at Yale University, and between 1980 and 1987 he was a professor of chemical engineering at Yale. He remained at Yale as an emeritus professor until 1994, when he moved to Vir-

ginia Commonwealth University. He celebrated his 90th birthday in 2007.

In 1988 Fenn published papers on a method of mass spectrometry known as electrospray ionization (ESI). In this method charged droplets of protein solution are produced. As the water evaporates, the droplets shrink, thus increasing their charge density, and after some time protein ions remain. The masses of these protein ions are determined by getting them to move over some fixed distance and measuring their time of flight. The technique was an important advance in extending the use of mass spectrometry to large molecules that could not be vaporized. Fenn shared the 2002 Nobel Prize for chemistry with Koichi TANAKA and Kurt WÜTHRICH for this work.

**Fermat, Pierre de** (1601–1665) *French mathematician and physicist*

It cannot be denied that he [Fermat] has had many exceptional ideas, and that he is a highly intelligent man. For my part, however, I have always been taught to take a broad overview of things, in order to be able to deduce from them general rules, which might be applicable elsewhere.

—René Descartes

Fermat (**fer-mah**) was one of the leading mathematicians of the early 17th century although not a professional mathematician. Born at Beaumont-de-Lomagne in France, he studied law and spent his working life as a magistrate in the small provincial town of Castres. Although mathematics was only a spare-time activity, Fermat was an extremely creative and original mathematician who opened up whole new fields of enquiry.

Fermat's work in algebra built on and greatly developed the then new theory of equations, which had been largely founded by François VIÈTE. With PASCAL, Fermat stands as one of the founders of the mathematical theory of probability. In his work on methods of finding tangents to curves and their maxima and minima he anticipated some of the central concepts of Isaac NEWTON's and Gottfried LEIBNIZ's differential calculus. Another area of mathematics that Fermat played a major role in founding, independently of René Descartes, was analytical geometry. This work led to violent controversies over questions of priority with Descartes. Nor were Fermat's disagreements with Descartes limited to mathematics. Descartes had produced a major treatise on optics – the *Dioptrics* – which Fermat greatly disliked. He particularly objected to Descartes's attempt to reach conclusions about the physical sciences by purely *a priori* rationalistic reasoning without due regard for empirical observation. By contrast Fermat's view of science was grounded in a thoroughly empirical and observational approach, and to demonstrate the errors of

Descartes's ways he set about experimental work in optics himself. Among the important contributions that Fermat made to optics are his discovery that light travels more slowly in a denser medium, and his formulation of the principle that light always takes the quickest path.

Fermat is probably best known for his work in number theory, and he made numerous important discoveries in this field. But he also left one of the famous problems of mathematics – *Fermat's last theorem*. This theorem states that the algebraic analog of PYTHAGORAS's theorem has no whole number solution for a power greater than 2, i.e., the equation:

$$a^n + b^n = c^n$$

has no solutions for  $n$  greater than 2, if  $a$ ,  $b$ , and  $c$  are all integers. In the margin of a copy of a book *Arithmetica of Diophantos*, an early treatise on equations, he wrote: "To resolve a cube into the sum of two cubes, a fourth power into two fourth powers, or in general any power higher than the second into two of the same kind, is impossible; of which I have found a remarkable proof. The margin is too small to contain it." Fermat never wrote down his "remarkable proof" and the equation was the subject of much investigation for over 350 years. In June 1993 the British-born mathematician Andrew WILES presented a proof to a conference at Cambridge in a lecture entitled "Modular forms, elliptic curves, and GALOIS representations." His proof ran to 1,000 pages – rather more space than Fermat's margin – and it is generally believed that Fermat, given the mathematical techniques available at the time, must have been mistaken in believing that he had a proof of the conjecture.

### Fermi, Enrico (1901–1954) *Italian–American physicist*

Whatever Nature has in store for mankind, unpleasant as it may be, men must accept, for ignorance is never better than knowledge.

—Quoted by Laura Fermi in *Atoms in the Family*

Fermi (**fer-mee**) was without doubt the greatest Italian scientist since GALILEO and in the period 1925–50 was one of the most creative physicists in the world. Unusually in an age of ever-growing specialization he excelled as both an experimentalist and a theoretician.

He was born in Rome and brought up in the prosperous home of his father who, beginning as a railroad official, progressed to a senior position in government service. Fermi's intelligence and quickness of mind were apparent from an early age and he had little difficulty in gaining admission in 1918 to the Scuola Normale in Pisa, a school for the intellectual élite of Italy. He later completed his education at the University of Pisa where he gained his PhD

in 1924. After spending some time abroad in Göttingen and Leiden, Fermi returned to Italy where, after some initial setbacks, he was appointed to a professorship of physics at the University of Rome. This in itself was a considerable achievement for one so young, considering the traditional and bureaucratic nature of Italian universities. It was no doubt due to the reputation he had already established with the publication of some 30 substantial papers, and the support of O. M. Corbino, the most distinguished Italian physicist at the time and also a senator. Corbino was determined to modernize Italian physics and had the good sense to see that Fermi, despite his youth, was the ideal man to advance his cause.

Fermi began by publishing the first Italian text on modern physics, *Introduzione alla Fisica Atomica* (1928; Introduction to Nuclear Physics). Soon his reputation attracted around him the brightest of the younger Italian physicists. But the growth of fascism in Italy led to the dispersal of its scientific talent. By 1938 Fermi, with a Jewish wife, was sufficiently alarmed by the growing anti-Semitism of the government to join the general exodus and move to America.

However, before his departure, his period in Rome turned out to be remarkably productive, with major advances being made in both the theoretical and the experimental field. His experimental work arose out of attempts to advance the efforts of Irène and Frédéric JOLIOT-CURIE who had announced in 1934 the production of artificial radioactive isotopes by the bombardment of boron and aluminum with helium nuclei (alpha particles). Fermi realized that the neutron, discovered by James CHADWICK in 1932, was perhaps an even better tool for creating new isotopes. Although less massive than an alpha particle, the neutron's charge neutrality allowed it to overcome the positive charge of a target nucleus without dissipating its energy.

Fermi reported that in 1934 he had impulsively and for no apparent reason interposed paraffin between the neutron source and the target. "It was with no advance warning, no conscious prior reasoning ... I took some odd piece of paraffin" and placed it in front of the incident neutrons. The effect was to increase the activation intensity by a factor that ranged from a few tens to a few hundreds. Fermi had stumbled on the phenomenon of slow neutrons. What was happening was that the neutrons were slowing down as the result of collisions with the light hydrocarbon molecules. This in turn meant that they remained in the vicinity of the target nucleus sufficiently long to increase their chance of absorption.

The production of slow neutrons was later to have a profound impact in the field of nuclear energy, both civil and military. However, Fermi's immediate task was to use them to irradiate as

many of the elements as possible and to produce and investigate the properties of a large number of newly created radioactive isotopes. It was for this work, for “the discovery of new radioactive substances ... and for the discovery of the selective power of slow neutrons” that Fermi was awarded the 1938 Nobel Prize for physics.

He did however miss one significant phenomenon. In the course of their systematic irradiation of the elements Fermi and his colleagues naturally bombarded uranium with slow neutrons. This would inevitably lead to nuclear fission, but Fermi thought that transuranic elements were being produced and in his Nobel address actually referred to his production of elements 93 and 94, which he named “ausonium” and “hesperium.” In 1938 Otto FRISCH and Lise MEITNER first realized that nuclear fission was taking place in such reactions.

On the theoretical level Fermi’s major achievement while at Rome was his theory of beta decay. This is the process in unstable nuclei whereby a neutron is converted into a proton with the emission of an electron and an antineutrino ( $n \rightarrow p + e^- + \bar{\nu}$ ). Fermi gave a detailed analysis which introduced a new force into science, the so-called “weak” force. An account was published in Italian in 1933 as an original English version was rejected by the journal *Nature* as being too speculative.

In America Fermi soon found himself caught up in the attempt to create a controlled nuclear chain reaction. In 1942 he succeeded in building the first atomic pile in the stadium of the University of Chicago at Stagg Field. Using pure graphite as a moderator to slow the neutrons, and enriched uranium as the fissile material, Fermi and his colleagues began the construction of the pile. It consisted of some 40,000 graphite blocks, specially produced to exclude impurities, in which some 22,000 holes were drilled to permit the insertion of several tons of uranium. At 2:20 p.m. on 2 December 1942, the atomic age began as Fermi’s pile went critical, supporting a self-supporting chain reaction for 28 minutes. In a historic telephone call afterwards Arthur COMPTON informed the managing committee that “the Italian navigator has just landed in the new world,” and that the natives were friendly.

Fermi continued to work on the project and was in fact present in July 1945 when the first test bomb was exploded in the New Mexico desert. He is reported to have dropped scraps of paper as the blast reached him and, from their displacement, to have calculated the force as corresponding to 10,000 tons of TNT.

After the war Fermi accepted an appointment as professor of physics at the University of Chicago where he remained until his untimely death from cancer. His name has been commemorated in physics in various ways. El-

ement 100, *fermium*, and the unit of length of  $10^{-13}$  centimeter, the *fermi*, were named for him, as was the National Accelerator Laboratory, Fermilab, at Batavia, near Chicago.

### **Fernel, Jean François** (1497–1558) *French physician*

From his [Fernel’s] school there went forth skilled physicians more numerous than soldiers from the Trojan horse, and spread over all regions and quarters of Europe.

—Guillaume Plancy, *Life of Fernel* (1577)

Fernel (fer-**nel**), the son of an innkeeper from Clermont in France, was educated at the Collège de Sainte Barbe in Paris where he graduated in 1519. After some years devoted to such subjects as philosophy and cosmology, Fernel took up the study of medicine, qualifying in 1530 and being appointed professor of medicine in 1534 at the University of Paris. He was also appointed as physician to Henri II after successfully treating Henri’s mistress Diane de Poitiers, although his failure to cure Henri’s father, Francis I, of syphilis appears not to have been held against him.

In 1554 Fernel published his *Medicina*, which went through some 30 editions and was one of the standard texts of the late 16th century. It is here that he introduced the terms “physiology” and “pathology” into medicine. The work was however mainly traditional, describing the physiology of GALEN with but a few modifications. Fernel also wrote an interesting account of the status of medicine in his *On the Hidden Causes of Things* (1548) in which he began to question long accepted magical and astrological accounts of diseases. He fell back on the standard medical objection to therapies offered by competitors, namely that any relief obtained would be only superficial and temporary.

Before turning to medicine Fernel had published his *Cosmotheoria* (1528), a work that contained one of the earliest measurements of a meridian, measured with an odometer between Paris and Amiens.

### **Ferrel, William** (1817–1891) *American meteorologist*

[Ferrel gave] to the science of meteorology a foundation in mechanics as solid as that which Newton laid for astronomy.

—Cleveland Abbe, *Biographical Memoirs* (1895)

Born in Fulton County, Pennsylvania, Ferrel moved with his family to farm in West Virginia in 1829. Since he received only the most rudimentary education, his early scientific knowledge was entirely self acquired. Despite this he developed an interest in mathematical physics and, after graduating from Bethany College in West Virginia in 1844, began to study the *Principia* of Isaac Newton and the *Mé-*

*canique céleste* (Celestial Mechanics) of Pierre Simon de LAPLACE. He earned his living as a school teacher from 1844 until 1857 when, having established his scientific reputation, he was appointed to the staff of the American Ephemeris and Nautical Almanac. He worked there until 1867 when he joined the U.S. Coast and Geodetic Survey.

In 1856 he published his most significant work, *Essay on the Winds and Currents of the Oceans*. He showed that all atmospheric motion, as well as ocean currents, are deflected by the Earth's rotation. He went on in 1858 to formulate his law, which states that if a mass of air is moving in any direction there is a force arising from the Earth's rotation that always deflects it to the right in the northern hemisphere and to the left in the southern hemisphere. The air tends to move in a circle whose radius depends on its velocity and distance from the equator. Ferrel went on to show how this law could be used to explain storms and the pattern of winds and currents. He was in some ways anticipated by Gustave-Gaspard CORIOLIS whose name is much better known.

Ferrel also did fundamental work on the solar system. He was able to correct Laplace and show that the tidal action of the Sun and Moon on the Earth is slowly retarding the Earth's rotation. In 1864 he provided the first mathematical treatment of tidal friction. His other works included his three-volume *Meteorological Researches* (1877–82). In 1880 he invented a machine to predict tidal maxima and minima.

**Ferrier, Sir David** (1843–1928) *British neurologist*

Born in Aberdeen, Scotland, Ferrier graduated in philosophy from the university there in 1863 and then spent some time at Heidelberg studying psychology. He returned to Scotland to study medicine at Edinburgh University and graduated in 1868. Initially he worked in private practice until his appointment as professor of forensic medicine at King's College Hospital, London (1872–89). The chair of neuropathology was created for him in 1889, a post he retained until his retirement in 1908.

Following the fundamental paper of Gustav FRITSCH and Eduard HRTZIG on cerebral localization, Ferrier began, in 1873, a series of experiments that both confirmed and extended their work. Whereas they had worked only with dogs, Ferrier used a wide variety of mammals, including primates. He was thus able to identify many more different areas in the cerebral hemispheres capable of eliciting movement. This work was soon shown to have practical implications. The surgeon William MACEWEN saw that the technique could be reversed and that disturbances of movement in a patient

could be used to indicate the site of a possible brain tumor.

Ferrier was an important figure in the newly emerging discipline of neurophysiology. He was one of the first editors of the influential journal *Brain* (founded 1878) and was also a founder member of the Physiological Society.

**Fert, Albert** (1938– ) *French physicist*

Albert Fert was born in Carcassonne, France. He graduated in physics in 1962 from the Ecole Normale Supérieure in Paris. Fert obtained his masters degree in 1963 at the University of Paris and was awarded his PhD from the Université de Paris-Sud in 1970, where he has been a professor since 1976.

In 1988 he discovered the phenomenon of giant magnetoresistance in layers of iron and chromium. Ordinary magnetoresistance is the small change (about 5%) in the electrical resistance of a metal when it is placed in a magnetic field. In certain materials, such as thin films in which there are alternating layers of ferromagnetic metals and nonferromagnetic metals, there is a large change in the electrical resistance of the non-magnetic layer in the presence of a magnetic field. This phenomenon, known as giant magnetoresistance, is a subtle quantum mechanical effect involving the spins of the electrons in the metals. There are many important applications of the effect. This is because it is ideally suited for reading data from hard disks and has led to vastly increased storage capacities. The technology resulting from giant magnetoresistance is regarded as the first example of spintronics, i.e., electronic devices that exploit the spins of electrons.

Giant magnetoresistance was also discovered independently by Peter GRÜNBERG in 1988. Fert and Grünberg shared several major prizes for their discovery, notably the Wolf Prize in 2006 and the Nobel Prize for physics in 2007.

**Fessenden, Reginald Aubrey** (1866–1932) *Canadian electrical engineer*

Fessenden was born at Milton in Quebec, Canada. After an education in Canada, he worked for EDISON as an engineer and later as head chemist (1886–90) and as an engineer (1890–91) for WESTINGHOUSE, Edison's great rival. He was professor of electrical engineering at Purdue University, Indiana (1882–83), and the Western University of Pennsylvania (now the University of Pittsburgh) from 1893 to 1900. He was then appointed special agent for the U.S. Weather Bureau, adapting the technique of radio telegraphy, newly developed by Guglielmo MARCONI, to weather forecasting and storm warning. In 1902 he became general manager of the National Electric Signaling Company, a company formed by two Pittsburgh financiers to exploit his ideas. From 1910 he

was consultant engineer at the Submarine Signal Company.

Fessenden's inventions were prolific and varied: at the time of his death he held over 500 patents. In 1900 he developed an electrolytic detector that was sufficiently sensitive to make radio telephony feasible. His most significant invention was the technique of amplitude modulation. This involved the use of "carrier waves" to transmit audio signals; he varied the amplitude of a steady high-frequency radio signal so that it corresponded to variations in the sound waves and thus "carried" the audio information. Using this principle he transmitted, on Christmas Eve 1906, what was probably the first program of music and speech broadcast in America. The program was heard by ships' radio operators up to a distance of several hundred miles.

Fessenden had a choleric temperament and a fear of being outwitted by businessmen. He was involved in various lawsuits, one of which was against his financial backers in the National Electric Signaling Company: Fessenden won a judgment of \$406,000 and sent the company into bankruptcy.

**Feyerabend, Paul Karl (1924–1994)** *Austrian philosopher of science*

Unanimity of opinion may be fitting for a church, for the frightened or greedy victims of some (ancient or modern) myth, or for the weak and willing followers of some tyrant. Variety of opinion is necessary for objective knowledge.

—*Against Method* (1975)

Feyerabend (**fī**-er-ah-bent), who was born in the Austrian capital of Vienna, enlisted in the German army immediately after leaving school in 1942. He was seriously wounded on the Russian front in 1945 and was subsequently awarded the Iron Cross. His education after the war was varied and unusual. He was a student of the Vienna Music Academy, but he also studied history, physics, and astronomy at the University of Vienna. In 1952 he moved to London and attended the seminars given by Karl POPPER at the London School of Economics. Though he had never studied philosophy formally, he was appointed in 1955 to a philosophy lectureship at Bristol University. In 1959 Feyerabend moved to the U.S. and in 1962 was appointed professor of philosophy at the University of California, Berkeley, a position he held, along with a similar appointment from 1979 at the Zurich Federal Institute of Technology, until his retirement in 1990.

Feyerabend had arrived at Berkeley at an exciting time. Political radicalism, the free speech movement, and increasing racial toleration were to be found in Berkeley in an exceptionally intense form. Here he began to reexamine the claims of western science to offer

the only valid account of nature. Why, he asked, should modern science be preferred to Hopi cosmology or Aristotelian metaphysics? On examination, he argued, the superiority of western science was no more than an assumption. It assumed the achievements of science were gained through the exercise of a distinctive scientific method. Yet, an examination of the works of COPERNICUS, GALILEO, and others revealed that they had succeeded by adopting extrascientific assumptions. Further, early pre-scientific societies had made such major advances as metalworking and agriculture without recourse to science. Nor, he pointed out, did science give its rivals a fair hearing. Astrology was dismissed out of hand; its principles were untested, and astrologers were denied access to scientific periodicals.

Science had thus, for Feyerabend, flourished by dubious rhetorical devices and by imposing a general consensus by totalitarian methods. As an alternative, in his *Against Method* (London, 1975), a work translated into 16 languages, he argued for an "anarchistic theory of knowledge," guided only by the principle "Anything goes." In *Science and a Free Society* (1978) Feyerabend argued that the democratic process itself is threatened by the authoritarian nature of modern science. His views have been vigorously contested and he has been described in the pages of *Nature* as "currently the worst enemy of science." Shortly before he died Feyerabend completed his autobiography *Killing Time* (1995), in which he revealed that in 1993 he had been diagnosed as having an inoperable brain tumor.

**Feynman, Richard Phillips (1918–1988)** *American theoretical physicist*

For a successful technology, reality must take precedence over public relations, for Nature cannot be fooled.

—Final report of the inquiry into the *Challenger* space shuttle disaster of 1986

The father of Feynman (**fīn**-man) had been brought with his immigrant parents from Minsk, Byelorussia, in 1895. Feynman himself was born in New York and educated at the Massachusetts Institute of Technology and at Princeton, where he completed his PhD in 1942 under the supervision of John WHEELER. In 1943 Feynman moved to Los Alamos to work on the Manhattan Project in the theoretical division under Hans BETHE. He was soon recognized to be, in the words of Robert OPPENHEIMER, "the most brilliant young physicist here." Feynman's own writings about the period deal less with the bomb than with his wife, Arline, who was dying of TB. He had married her in 1942 against much family opposition. She moved into a sanatorium in nearby Albuquerque and died in June 1945, a month before the first atomic bomb was tested.

**FEYNMAN DIAGRAM** Diagrams for (a) electromagnetic scattering of an electron by a proton; (b) scattering of a neutrino by a neutron.

In 1945 Feynman moved to Cornell as professor of physics, a post he held until 1950, when he was appointed to a similar position at the California Institute of Technology, where he remained for the rest of his career. While at Cornell he began to consider anew some of the outstanding problems in quantum electrodynamics (QED) – an area of physics dealing with the interactions between electrons and photons. The electron was seen as a point charge. As the strength of a charged body diminishes with distance in accordance with the inverse square law, it will vary as  $1/r^2$ . But what about the strength of the charge at the electron itself where  $r = 0$ ? At this point the charge (and for a point, density) of the electron must be infinite. To handle this and other similar absurdities physicists developed a number of artificial mathematical techniques which would allow them to “renormalize” their equations so as to remove the infinite terms. Yet the charge on the electron is finite and can be measured accurately. Theoretical calculations, it was felt, should reach the same value without requiring artificial manipulation.

Freeman DYSON has described Feynman at this time as claiming that “he couldn’t understand the official version of quantum mechanics,” and that he had to “reinvent quantum mechanics” in a form he could understand. Feynman first presented his new approach in a paper, turned down by the *Physical Review*, entitled *Space-Time Approach to Non-Relativistic Quantum Mechanics* (1948), in which he introduced the notion of path integrals, also referred to as “sum over histories.”

In Feynman’s approach, the probability of an event that can happen in a number of different ways, such as finding an electron at a certain place, was the sum of the probabilities of all the possible ways the event could happen. When all the probabilities were added, Feynman noted, the result was SCHRÖDINGER’S wave function.

In a 1949 paper, *Space-Time Approach to Quantum Electrodynamics*, Feynman showed how to calculate these path integrals using sim-

ple sketches, which have since become widely known as *Feynman diagrams*. It was for work in this field that Feynman shared the 1965 Nobel Prize for physics with Julian SCHWINGER and Sin-Itiro TOMONAGA. His first reaction had been to decline what he termed “Alfred Nobel’s other mistake” on the grounds that he would thereafter become a celebrity and not just someone who wanted to talk about physics. Warned that a refusal would mark him in the media as an even bigger celebrity, Feynman agreed to accept the award.

Feynman also worked on problems connected with superconductivity and with particle physics. In 1955 he proposed a new model to represent the structure of liquid helium. In 1958 he published a paper with Murray GELL-MANN on the theory of weak interactions, which extended FERMI’S earlier theory to take parity violations into account. During a visit to Stanford in 1968 Feynman began to work on the strong nuclear interaction. He attributed to the proton a set of constituents he named “partons,” which were pointlike and did not interact with each other. Their value lay in their ability to explain the inelastic scattering results emerging from the Stanford Linear Accelerator (SLAC).

With the publication in 1963 of the *Feynman Lectures in Physics*, Feynman began to be known outside the small community of theoretical physicists. However, he gained international celebrity in the 1980s following a number of TV programs and the publication of *Surely You’re Joking Mr. Feynman* (1985). The picture of a man of rare seriousness and honesty, with little time for honors, institutions, and formality, yet who clearly enjoyed the life of the flesh as well as the mind, had rarely been presented with such clarity. Despite his reluctance to accept the Nobel award, Feynman seems to have enjoyed his fame, and even to accentuate his unconventional character.

When he was asked to serve in 1986 on the presidential commission to investigate the explosion of the *Challenger* space shuttle, he assumed that he was being asked to contribute to

a genuine scientific investigation. Pointed in the right direction by sympathetic colleagues, Feynman soon realized that the immediate cause of the explosion had been the O-ring seals used in the booster rocket. On the morning of the shuttle's launch the temperature was below freezing and the seals failed to retain their elasticity at low temperatures. Feynman also found out that the NASA officials had been warned about this potential failure. Feynman demonstrated the point, unannounced, at a televised meeting of the commission. He placed the O-rings in a glass of iced water for a few minutes and showed that, for several seconds after their removal, the seals had lost their resilience.

Feynman wrote up his findings as a separate appendix. He was aware that, while the commission would not actually suppress any evidence, much that was critical of NASA could be scattered throughout the report and consequently picked up by only the most careful of readers. Before the commission agreed to publish his report in a form acceptable to Feynman, he first found it necessary to threaten to resign and issue the report elsewhere. FEYNMAN found his Washington experiences genuinely distressing. Much of his life had been spent trying to understand various natural phenomena. The work had been hard, demanding many hours of intense intellectual concentration. He went to Washington intending to put the same effort into the service of the commission. Yet he found himself working with people who, though not crooks, liars, or lazy, were only marginally interested in the truth. It was more important for them to find a story acceptable to a community consisting of the Washington establishment, NASA, and "the American people," than to set out to establish what happened.

By this time, however, Feynman was a seriously ill man. In 1978 a malignant growth had been removed from his abdomen. A second cancer, involving bone marrow, was diagnosed in 1986. The abdominal cancer returned in late 1987 and soon after Feynman died from kidney failure. His influential lectures on gravitation and computation were published after his death.

### **Fibiger, Johannes Andreas Grib** (1867–1928) *Danish physician*

Fibiger (**fee**-bi-ger), born the son of a physician at Silkeborg in Denmark, was educated at the University of Copenhagen, completing his medical studies in 1890. After some hospital work and further study in Berlin under Robert KOCH and Emil von BEHRING, Fibiger joined the Institute of Pathological Anatomy at the University of Copenhagen in 1897, serving there as its director from 1900.

It was realized that cancers could be chemically induced by factors in the environment but all attempts to induce such cancers artificially

had failed. Fibiger thought he could change this when, in 1907, he observed extensive papillomatous tumors virtually filling the stomachs of three wild rats. Microscopic examination showed the presence in the stomachs of formations similar to nematode worms, and Fibiger naturally concluded that these parasites were the cause of the tumors. A search of a further 1,200 wild rats, however, produced no additional cases of cancer. This suggested to him that the nematodes were transmitted by an intermediate host, and a report published in 1878 confirmed that such nematodes had been found as parasites of a common kind of cockroach. Before long Fibiger found rats from a sugar refinery that fed regularly on the cockroaches there: examination of 61 of these rats showed that 40 had nematodes in their stomachs and 7 of these 40 had the earlier identified tumor. By 1913 Fibiger was able to claim that he could induce such malignancies in rats by feeding them with cockroaches infested with nematode larvae, noting a proportional relationship between the number of parasites and the degree of anatomic change in the stomach. It was for this work, described somewhat extravagantly by the Nobel Committee as the "greatest contribution to experimental medicine in our generation," that Fibiger was awarded the 1926 Nobel Prize for physiology or medicine.

Although no one disputed that Fibiger had induced cancer it was never completely accepted that such growths were caused by the nematodes. In any case Fibiger's work had little impact on experimental cancer research: simpler methods of carcinogenesis were almost universally preferred.

### **Fibonacci, Leonardo** (c. 1170– c. 1250) *Italian mathematician*

Fibonacci (**fee**-boh-**nah**-chee) lived in Pisa and is often referred to as Leonardo of Pisa. Although he was probably the most outstanding mathematician of the Middle Ages virtually nothing is known of his life. The modern system of numerals, which originated in India and had first been introduced to the West by al-Khwarizmi, first became widely used in Europe owing to Fibonacci's popularization of it. His father served as a consul in North Africa and it is known that Fibonacci studied with an Arabian mathematician in his youth, from whom he probably learned the decimal system of notation.

Fibonacci's main work was his *Liber abaci* (1202; Book of the Abacus) in which he expounded the virtues of the new system of numerals and showed how they could be used to simplify highly complex calculations. Fibonacci also worked extensively on the theory of proportion and on techniques for determining the roots of equations, and included a treatment of

these subjects in the *Liber abaci*. In addition it contains contributions to geometry and Fibonacci later published his *Practica geometriae* (1220; Practice of Geometry), a shorter work that was devoted entirely to the subject.

Fibonacci was fortunate in being able to gain the patronage of the Holy Roman Emperor, Frederick II, and a later work, the *Liber quadratorum* (1225; Book of Square Numbers) was dedicated to his patron. This book, which is generally considered Fibonacci's greatest achievement, deals with second order Diophantine equations. It contains the most advanced contributions to number theory since the work of DIOPHANTUS, which were not to be equaled until the work of FERMAT. He discovered the "Fibonacci sequence" of integers in which each number is equal to the sum of the preceding two (1, 1, 2, 3, 5, 8, ...).

### **Finch, George Ingle** (1888–1970) *Australian physical chemist*

Finch was born at Orange in Australia and educated at Wolaroi College in his native country and the Ecole de Médecine in Paris. Finding the study of medicine unappealing, Finch moved to Switzerland where he studied physics and chemistry, first at the Federal Institute of Technology in Zurich and afterward at the University of Geneva. On moving to Britain in 1912 he worked briefly as a research chemist at the Royal Arsenal, Woolwich, joining the staff of Imperial College, London, in 1913. Finch remained there until his retirement in 1952, having been appointed professor of applied physical chemistry in 1936. After his retirement Finch spent the period 1952–57 in India as director of the National Chemical Laboratory.

Finch worked mainly on the properties of solid surfaces. In the 1930s he developed the technique of low-energy electron diffraction, using the wavelike properties of electrons, demonstrated by George THOMSON and Clinton J. DAVISSON in 1927, to investigate the structure of surfaces. X-rays are neutral and too penetrating to provide much information about surfaces or thin films; electrons, however, are charged and are deflected after penetrating no more than a few atoms below the surface. With this new and powerful tool Finch began the study of lubricants and the BEILBY layer – a thin surface layer produced by polishing, and differing in its properties from the underlying material. Finch had earlier worked on the mechanism of combustion in gases as initiated by an electric discharge.

Finch was also widely known as a mountaineer. As one of the leading climbers of his generation he was a member of the 1922 Everest expedition, climbing to the then unequaled height of 27,300 feet (8,321 m).

### **Finlay, Carlos Juan** (1833–1915) *Cuban physician*

Finlay's father was a Scottish physician who had fought with Simon Bolivar. Carlos, who was born at Puerto Principe, now Camagüey, in Cuba, was educated in Paris and at the Jefferson Medical College, Philadelphia, where he graduated in 1855. He then returned to Cuba where he spent his life in general practice.

In 1881 Finlay published a prophetic paper *The Mosquito Hypothetically Considered as the Agent of the Transmission of Yellow Fever*, naming the species *Culex fasciatus* (now *Aedes aegypti*) as the vector. He had been struck by the presence of *Aedes* in houses during epidemics and noted that the yellow fever and mosquito seasons seemed to coincide. Although he campaigned vigorously for his theory he only succeeded in turning himself into a figure of mild ridicule.

There were a number of complicating factors that undermined Finlay's work. Firstly yellow fever is caused by a virus, a microorganism only discovered in 1898 and far too small to be detected by the microscopic techniques of the late 19th century. Further, with the newly established germ theory of Robert KOCH, scientists were demanding visual evidence for the existence of the supposed pathogen. As Finlay could not isolate the causative organism he attempted to demonstrate its existence by such clinical techniques as transmitting the disease from a sick patient via *Aedes* to a healthy individual. But here too, although he repeated such experiments many times, he failed to produce any coherent results. As it turned out, it was only the female mosquito, and then only one who had bitten a victim in the first three days of infection who could, two weeks later, transmit the disease. Consequently many of Finlay's failures could be explained by using the wrong type of mosquito or the right type at the wrong time. But to discover such facts required more ambitious resources than Finlay commanded.

He did however live to see such resources come to Cuba with the arrival of the 4th U.S. Yellow Fever Commission in 1900 under the command of Walter REED. Finlay interested Reed in his views, and Reed, in a classic series of trials, completely vindicated them.

### **Finsen, Niels Ryberg** (1860–1904) *Danish physician*

Finsen (**fin**-sen), the son of a leading civil servant, was born at Thorshavn on the Faeroe Islands, which are part of Denmark; he was educated in Reykjavik and at the University of Copenhagen, where he qualified as a physician in 1890. After teaching anatomy for some time Finsen founded (1895) the Institute of Phototherapy, which he directed until his early death at the age of 43.

In the 1890s, following up some earlier work

suggesting that light had the ability to kill bacteria, Finsen began a systematic appraisal of its therapeutic effects. Arguing that it was light, acting slowly and weakly, rather than heat that was effective, he devised various filters and lenses to separate and concentrate the different components of sunlight. He found that it was the short ultraviolet rays, either natural or artificial, that turned out to have the greatest bactericidal power.

Finsen found phototherapy to be of most use against lupus vulgaris, a skin infection produced by the tubercle bacillus. He claimed that on exposure to ultraviolet rays the skin regained its normal color and the ulcerations began to heal. For this Finsen received the third Nobel Prize for physiology or medicine in 1903.

It was, however, an avenue that few physicians were willing to explore. The use of ultraviolet radiation was mainly restricted to the treatment of lupus vulgaris and even this was superseded by x-rays and, more importantly, by such drugs as cortisone when they became available in the 1950s.

**Fire, Andrew Zachary** (1959– ) *American molecular geneticist*

Born in Palo Alto, California, Fire was awarded a BA in mathematics by the University of California, Berkeley, when still just 19. He then joined the Massachusetts Institute of Technology to study biology, receiving a PhD in 1983. After a three-year spell as a postdoctoral fellow in Cambridge, UK, Fire joined the staff of the Carnegie Institution's Department of Embryology in Baltimore. In 1989 he became adjunct professor of biology at Johns Hopkins University, and in 2003 he joined Stanford University School of Medicine as professor of pathology and genetics.

Fire is lauded for his discovery, in collaboration with Craig MELLO and others, of the phenomenon known as RNA interference (RNAi). In 1998 Fire and Mello published a paper in *Nature* that broke new ground in our understanding of how cells control the flow of genetic information. It was already established that information is encoded by the DNA (deoxyribonucleic acid) in the genes within a cell's chromosomes (located in the nucleus of the cell). Also, when a gene is "switched on," the sequence of chemical bases in the DNA, which contains the genetic code, is copied over (transcribed) into specific messenger molecules, consisting of another type of nucleic acid termed messenger ribonucleic acid (mRNA). The mRNA molecules are exported from the nucleus to the surrounding cytoplasm, where they relay the genetic information to the cell's protein-manufacturing machinery, in a process called translation. Here the machinery "reads" the instructions contained in each mRNA molecule, and assembles each protein accordingly. Hence,

different mRNAs give rise to all the diverse proteins required by the cell, including enzymes, cell receptors, and cell scaffolding.

It was known that RNA could in certain circumstances inhibit the activity of genes. This latter phenomenon was caused by RNA molecules whose base sequence matched that of the gene in question, but it was poorly understood. Then came Fire and Mello. Their experiments were conducted on a tiny nematode worm called *Caenorhabditis elegans*, and focused on a particular gene that affected muscle action. Into the worm they injected RNA whose base sequence matched that of the target gene. When "silencing" of the target gene occurred, it caused a muscle defect in the worm and consequent twitching movements.

The researchers found that their target gene was effectively silenced only by double-stranded RNA molecules (dsRNAs). These comprise two parallel strands of linked bases, one strand (the "antisense" strand) with a base sequence complementary to that of the target gene's mRNA, and hence capable of binding to it by base pairing; the other strand (the "sense strand") with a sequence exactly matching the target mRNA, but unable to bind to it.

Fire and Mello confirmed that the silencing was specific, affecting only the target gene mRNAs, and that it involved fully formed, or "mature" mRNAs, and hence probably took place in the cytoplasm. Also, it could be achieved using only a few molecules of dsRNA, indicating that the dsRNA acted not as a reagent but most likely as some form of catalyst. Moreover, the target mRNA disappeared from the cell, meaning that it was degraded. These findings explained hitherto puzzling aspects of RNA-induced gene inhibition, and pointed to a possible new mechanism for control of gene expression in living cells.

In subsequent studies, Fire and Mello discovered more details about RNAi in living cells. For example, they established that the dsRNA molecules are cut into short double-stranded segments, and that the antisense strand then binds to its complementary sequence on the mRNA molecule, which triggers degradation of the mRNA. Later, the identities of other key components of the RNAi molecular machinery were determined, notably the large protein complex called RISC (RNA-induced silencing complex), which links the antisense RNA and the mRNA, and the endonuclease called Dicer, which cuts the dsRNA into short fragments.

RNAi is now known to be significant in several ways. Firstly, it helps to protect cells against attack by certain viruses, by targeting viral RNA for destruction. Second, it is believed to silence potentially mobile segments of the genome called transposons. These are short segments of DNA derived from viral nucleic acid that have become integrated within the organism's DNA over evolutionary time, and

replicate by making RNA copies of their DNA sequence. Without RNAi to keep them in check, transposons might replicate excessively and overwhelm the genome. Thirdly, RNAi-type cellular machinery in a wide variety of organisms is now known to produce a class of small RNAs called micro-RNAs (miRNAs). These regulate gene expression by binding to mRNAs, causing them to be degraded, or suppressing translation into protein. This form of gene regulation is widespread; for example, in mammals about 30% of all genes are controlled by this mechanism.

Another aspect of RNAi is its enormous importance as an experimental tool, and potential as a therapeutic strategy to treat genetic diseases. As Fire and Mello showed with their worm, dsRNA can be tailor-made to target specific genes. This enables extremely precise and efficient “knockout” of genes to investigate their impact on the organism. It could also lead to new forms of targeted gene therapy, by preventing the expression of faulty genes and so restoring normal cell function.

For his work on RNAi, Fire was awarded the 2006 Nobel Prize in physiology or medicine, jointly with Craig Mello.

### **Fischer, Debra** *American astronomer*

Fischer studied physics, gaining a BS from the University of Iowa in 1975. In 1986 she embarked on graduate studies in the department of physics and astronomy at San Francisco State University (SFSU), becoming a lecturer (1990–92) and gaining an MS in physics (1992). In 1994 she joined the University of California, Santa Cruz, as research assistant, obtaining her PhD in 1998. After a spell in the astronomy department at the University of California, Berkeley (1999–2003), she returned to CFSU as assistant professor.

While a graduate student at SFSU, Fischer joined Geoff Marcy as a member of the newly founded SFU Planet Search project, working at the Lick Observatory, near San Jose. Thus began her career, which has focused on finding planets in other solar systems. Fischer discovered her first planet in orbit around the star HD 217107, using the DOPPLER technique, which detects fluctuations in a star’s velocity resulting from small gravitational forces exerted by orbiting planets. Then in 1998 she analyzed data from the star Upsilon Andromeda, and found that they were best explained by three orbiting planets, dubbed Dinky, Twopiter (twice the mass of Jupiter) and Fourpiter. This was the first discovery of multiple extrasolar planets around a star. Subsequently, the SFU project, now the California and Carnegie Planet Search Project, has discovered many of the over 200 extrasolar planets so far identified. Fischer selects stars with a high abundance of metallic elements as candidates for finding planets. Some of these planets are massive “hot Jupiters” that

orbit close to their host stars; a wealth of information can be gleaned as such planets transit in front of a bright host star. In 2002 Fischer received the Carl Sagan Award of the American Astronomical Society.

### **Fischer, Edmond H.** (1920– ) *American biochemist*

Born in Shanghai, China, Fischer was educated at the University of Geneva, where, after graduation, he worked as assistant in the organic chemistry laboratories (1946–47). After spending two years as a research fellow with the Swiss National Foundation (1948–50) he moved to the University of Washington, Seattle, as a Rockefeller Foundation research fellow (1950–53). After a brief spell at the California Institute of Technology in 1953, he was appointed assistant professor of biochemistry at the University of Washington, subsequently becoming associate professor (1956–61) and professor (1961–90).

Fischer’s most acclaimed work was done at Seattle in the 1950s and 1960s in collaboration with the biochemist Edwin KREBS. In 1955–56 the pair discovered how the enzyme (glycogen phosphorylase) that catalyzes the release of glucose from glycogen in the body is “switched on.” The enzyme receives a phosphate group from ATP (adenosine triphosphate – the body’s major energy carrier) in a transfer reaction catalyzed by a second enzyme, which Fischer and Krebs termed a “protein kinase.” They went on to show that glycogen phosphorylase is then switched off by removal of the phosphate group by a further enzyme (called a protein phosphatase). The addition and removal of the phosphate group reversibly changes the shape of the enzyme molecule, thereby switching it between the inactive and active forms.

These findings opened the way to a major new field of research suggesting how enzymes might function in various physiological processes, such as hormone regulatory mechanisms, gene expression, and fertilization of the egg. Their work also had implications for the understanding of certain diseases; for instance, abnormally phosphorylated proteins have been identified in muscular dystrophy and diabetes, while protein kinases may play a significant role in certain cancers and in airway constriction in asthma.

In recognition of his contributions to our understanding of enzymes Fischer was awarded the 1992 Nobel Prize for physiology or medicine, which he shared with his long-time coworker, Krebs.

### **Fischer, Emil Hermann** (1852–1919) *German organic chemist and biochemist*

The son of a successful businessman from Euskirchen, now in Germany, Fischer joined his

father's firm on leaving school (1869) but left in 1871 to study chemistry with August KÉKULÉ at Bonn. He was not happy with the chemistry instruction there and came close to abandoning chemistry for physics. In 1872, however, he moved to Strasbourg to study with Adolf von BAEYER. Here, he gained his doctorate in 1874 for work on phthaleins. The same year he made the vital discovery of phenylhydrazine, a compound that was later to prove the vital key for unlocking the structures of the sugars.

Fischer became Baeyer's assistant and together they moved to Munich (1875). At Munich, working with his cousin, Otto Fischer, he proved that the natural rosaniline dyes are derivatives of triphenylmethane. In 1879 Fischer became assistant professor of analytical chemistry and soon after became financially independent. He was then professor at Erlangen (1882), Würzburg (1885), and Berlin (1892). Fischer has some claim to be called the father of biochemistry. He carried out extremely comprehensive work in three main fields: purines, sugars, and peptides, the last two effectively founding biochemistry on a firm basis of organic chemistry. The work on purines, begun in 1882, resulted in the synthesis of many important compounds, including the alkaloids caffeine and theobromine, and purine itself (1898). Fischer's early structures were incorrect but from 1897 the correct structures were used.

In 1884 Fischer discovered that phenylhydrazine produces well-defined crystalline compounds with sugars, thus affording a reliable means of identification. In 1887 he synthesized first fructose (from acrolein dibromide) and later mannose and glucose. By 1891 he was able to deduce the configurations of the 16 possible aldohexoses, which he represented in the form of the famous *Fischer projection formulae*.

In 1899 Fischer turned to amino acids and peptides and devised a peptide synthesis that eventually produced a polypeptide containing 18 amino acids (1907). Fischer's other work included the first synthesis of a nucleotide (1914), the "lock-and-key" hypothesis of enzyme action,

work on tannins, and attempts to prepare very high-molecular-weight compounds. He was awarded the 1902 Nobel Prize for chemistry for his work on purines and sugars.

**Fischer, Ernst Otto (1918–1994)** *German inorganic chemist*

Fischer, the son of a physics professor, was educated in his native city at the Munich Institute of Technology, where he obtained his PhD in 1952. He taught at the University of Munich, serving as professor of inorganic chemistry from 1957 to 1964, when he became the director of the Institute for Inorganic Chemistry at the Institute of Technology.

Fischer is noted for his work on inorganic complexes. In 1951 two chemists, T. Kealy and P. Pauson, were attempting to join two five-carbon (cyclopentadiene) rings together and discovered a compound,  $C_5H_5FeC_5H_5$ , which they proposed had an iron atom joined to a carbon atom on each ring.

Fischer, on reflection, considered such a structure inadequate for he failed to see how it could provide sufficient stability with its carbon-iron-carbon bonds. The British chemist Geoffrey WILKINSON suggested a more novel structure in which the iron atom was sandwiched between two parallel rings and thus formed bonds with the electrons in the rings, rather than with individual carbon atoms. Compounds of this type are called "sandwich compounds." By careful x-ray analysis Fischer confirmed the proposed structure of ferrocene, as the compound was called, and for this work shared the Nobel Prize for chemistry with Wilkinson in 1973. Fischer went on to do further work on transition-metal complexes with organic compounds and was one of the leading workers in the field of organometallic chemistry.

**Fischer, Hans (1881–1945)** *German organic chemist*

Fischer, the son of a chemicals industrialist

**FERROCENE** Originally the structure was thought to be that on the left. E. O. Fischer showed it to be a sandwich compound with the iron atom positioned between the two rings.

from Höchst-am-Main in Germany, gained his doctorate in chemistry at the University of Marburg in 1904. He also studied medicine at the University of Munich, gaining his MD in 1908. He was assistant to Emil Fischer before occupying chairs of medical chemistry at Innsbruck (1916) and Vienna (1918). In 1921 he succeeded Heinrich WIELAND as professor at the Technical Institute in Munich.

Fischer's life work was the study of the immensely important biological molecules hemoglobin, chlorophyll, and the bile pigments, especially bilirubin. He showed that hemin – the nonprotein, iron-containing portion of the hemoglobin molecule – consists of a system of four pyrrole rings, linked by bridges, with iron in the center. He synthesized hemin in 1929 and extensively investigated similar molecules – the porphyrins. He was awarded the Nobel Prize for chemistry for this work in 1930. He then turned to the chlorophylls and showed that they are substituted porphyrins with magnesium rather than iron in the center. The bile acids were shown by Fischer to be degraded porphyrins, and he synthesized bilirubin in 1944. Fischer took his own life at the end of World War II, after his laboratories had been destroyed in the bombing of Munich.

**Fischer, Otto Philipp** (1852–1932) *German organic chemist*

Otto Fischer was the cousin of Emil Fischer, with whom he collaborated in some of his work. He was born at Euskirchen, now in Germany, gained his doctorate at Strasbourg (1874), and was professor of chemistry at Erlangen from 1885 to 1925. His most notable work was with dyestuffs: he discovered malachite green, a triphenylmethane dye (1877), and determined the structures of pararosaniline (1880; with Emil) and mauveine (1890).

**Fisher, Sir Ronald Aylmer** (1890–1962) *British statistician and geneticist*

Natural selection is a mechanism for generating an exceedingly high degree of improbability.

—Quoted by A. L. Mackay in *The Harvest of a Quiet Eye* (1977)

Fisher, a Londoner by birth, studied mathematics and physics at Cambridge University, graduating in 1912. In the years before joining Rothamsted Experimental Station in 1919 he undertook a variety of jobs, including farm work in Canada, employment with an investment company, and teaching in various private schools. In this period he also produced two important papers marking his interest in both statistics and genetics. The first, published in 1915, described a solution for the exact distribution of the correlation coefficient, a problem that had been perplexing other statisticians.

The second paper was *The Correlation between Relatives on the Supposition of Mendelian Inheritance* (1918). This demonstrated that the inheritance of continuous variation, which had been thought of as non-Mendelian, is in fact governed by many additive genes, each of small effect and each inherited in a Mendelian manner. Thus continuous variation may be analyzed following Mendelian rules. This work later led to the development of the science of biometric genetics. At Rothamsted, Fisher was appointed to sort out the accumulation of over 60 years' data on field trials. He modified the significance test, enabling more confident conclusions to be drawn from small samples of data, and developed the analysis of variance technique. He emphasized the need for random rather than systematic experimental design so that error due to environmental variation could be analyzed quantitatively. His book *Statistical Methods for Research Workers* (1925) is one of the most influential works in statistics.

Fisher's major researches in genetics at Rothamsted were brought together in *The Genetical Theory of Natural Selection* (1930). In this book he argued that Mendelism, far from contradicting Darwinism as some people believed, actually provides the missing link in the theory of evolution by natural selection by showing that inheritance is by means of particulate entities (genes) rather than by physical blending of parental characteristics. (In 1936 Fisher published a paper arguing that probabilistically MENDEL's famous results were "too good to be true.") The book also summarizes his views on eugenics and on genes controlling dominant characteristics. He believed that dominance develops gradually by selection, showing selection rather than mutation to be the driving force in evolution. *The Genetical Theory of Natural Selection* led to Fisher's appointment as Galton Professor of Genetics at University College, London, in 1933. Here he did important work clarifying the genetics of the Rhesus blood groups. He accepted the chair of genetics at Cambridge University in 1943, remaining there until 1959 although he retired officially in 1957. He spent the last three years of his life working for the Commonwealth Scientific and Industrial Research Organization (CSIRO) in Adelaide. Fisher was knighted in 1952.

**Fitch, Val Logsdon** (1923– ) *American physicist*

Born in Merriman, Nebraska, Fitch was educated at McGill and Columbia universities and obtained his PhD from Columbia in 1954. He then joined the Princeton staff, being appointed professor of physics there in 1960.

Working with Leo James RAINWATER, Fitch was the first to observe radiation from muonic

atoms, i.e., from species in which a muon is orbiting a nucleus rather than an electron. This work indicated that the sizes of atomic nuclei were smaller than had been supposed. He went on to study kaons and in 1964 collaborated with James CRONIN, James Christenson, and René Turley in an experiment that disproved charge–parity conservation. In 1980 Fitch and Cronin shared the Nobel Prize for physics for this fundamental work.

**Fittig, Rudolph** (1835–1910) *German organic chemist*

Fittig (*fit-ik*) was born in Hamburg, now in Germany, and gained his doctorate at Göttingen in 1858, becoming a professor at Tübingen (1870) and at Strasbourg (1876–1902). He was a prolific experimentalist with many discoveries and syntheses to his credit, including pinacol, diphenyl, mesitylene, cymene, coumarone, and phenanthrene in coal tar. He also did extensive work on lactones and unsaturated acids. His name is remembered in the *Wurtz–Fittig reaction*, a variation of the WURTZ reaction for synthesizing alkylaryl hydrocarbons. An example is the reaction to form methylbenzene (toluene):

**Fitzgerald, George Francis** (1851–1901) *Irish physicist*

I am not in the very least sensitive to having made mistakes. I rush out with all sorts of crude notions in hope that they may set others thinking and lead to some advance.

—Letter to Oliver Heaviside, 4 February 1889

Fitzgerald graduated from Trinity College in his native Dublin in 1871 and then joined the staff there, rising to the position of professor in 1881. His work was mainly concerned with the development of electromagnetism from James Clerk MAXWELL's equations, in which he became interested after Heinrich HERTZ had demonstrated the existence of the radio waves predicted by theory. Like Hendrik LORENTZ, he constructed an electromagnetic theory of the reflection and refraction of light.

His name is best known for the *Lorentz–Fitzgerald contraction* – an effect suggested to explain the negative result of the Michelson–Morley experiment. The suggestion was that a body moving relative to an observer contracted slightly in the dimension parallel to the direction of motion, the amount of the contraction being dependent on the velocity. Thus, light emitted by a moving body would have a different speed, but would travel over a different path length. The contraction in size was supposed to result from the effect of the ether on the electromagnetic forces holding the atoms together. The Lorentz–Fitzgerald contraction re-

ceived an alternative explanation in EINSTEIN's theory of relativity.

**Fitzroy, Robert** (1805–1865) *British hydrographer and meteorologist*

Fitzroy, who was born near Bury St. Edmunds in the eastern English county of Suffolk, was educated at the Royal Naval College, Portsmouth, and in 1828 took command of the *Beagle*, on a survey of the South American coast. In 1831 he made a second voyage in the *Beagle* to complete his survey, taking with him as naturalist the then unknown Charles DARWIN. After his return in 1836 he devoted himself to the publication, in 1839, of his *Narrative*, a three-volume account of the voyage. The third volume, known as *The Voyage of the Beagle*, was the work of Darwin.

Fitzroy served as a member of Parliament (1841–43) and was then appointed governor of New Zealand until his dismissal in 1845. He retired from active duty in 1850 but later (1854) took up the newly created post of meteorological statist and remained there until his death. He organized a number of observation stations, designed the barometer named for him, and began the publication of storm warnings that evolved into daily weather forecasts. One of the earliest textbooks on meteorology, *The Weather Book* (1863), was published by him.

He had a reputation for having a quick temper and, while suffering from depression, committed suicide.

**Fizeau, Armand Hippolyte Louis** (1819–1896) *French physicist*

Fizeau (*fee-zoh*), a Parisian by birth, started by studying medicine but his interest turned to optics before he finished the course. In collaboration with Léon FOUCAULT he first tried to improve the newly developed process of photography and, in 1845, they took the first clear pictures of the Sun.

In 1849 he obtained a value for the speed of light in air, using an ingenious toothed-wheel apparatus. Light was directed through a gap between two teeth and reflected back between the teeth from a distant mirror. The wheel was rotated, the rate of rotation being changed until the reflected flashes were blocked by the tooth of the wheel. The speed of light could then be calculated from the rate of rotation of the wheel. Fizeau's experiment was performed using a path of 8 kilometers (5 mi) between Suresnes and Montmartre.

The next year both he and Foucault simultaneously proved that light traveled faster in air than in water, thus giving experimental support to the wave theory of light. Fizeau is also known for analyzing the DOPPLER effect for light waves. The change in wavelength with

relative speed is sometimes called the *Doppler-Fizeau shift*.

Fizeau was elected a member of the Paris Academy in 1860 and was awarded the Royal Society's Rumford medal in 1875.

### **Flammarion, Nicolas Camille** (1842–1925) *French astronomer*

Owing to his family's poverty, Flammarion (fla-ma-ryon), who was born at Montigny-le-Roi, France, was forced to leave school and abandon his intention of going into the priesthood. Instead he got a post in the Paris Observatory in 1858 but eventually was dismissed by Urbain LE VERRIER who accused him of being a poet rather than a scientist. Flammarion made serious contributions to astronomy, including founding the French Astronomical Society in 1887, and built himself a private observatory at Juvisy. However, he is best known as a popularizer of astronomy. His general attitude to astronomy was made clear when he published at the age of 19 *Plurality of Inhabited Worlds* (1862). This was translated into 12 languages, including Chinese and Arabic, and became a best seller in France, making Flammarion famous. His *Popular Astronomy* (1879) was one of the most popular books of the late 19th century. Giovanni SCHIAPARELLI's discovery of "canals" on Mars in 1877 received enthusiastic support from Flammarion. He went even further, claiming that he could discern changes in the lunar craters that could be cultivated fields.

### **Flamsteed, John** (1646–1719) *English astronomer*

In carrying out views of practical utility, with a scrupulous attention to accuracy in the most minute details, in fortitude of resolution under adverse circumstances, and persevering adherence to continuity and regularity of observation throughout a long career, he had few rivals in any age or country.

—Robert Grant, *History of Physical Astronomy* (1852)

Flamsteed was born in Denby, England. Because of ill health, which was to dog his career, he was forced to leave school early and was therefore largely self-educated. He started his scientific career under the patronage of William BRONCKER, the first president of the Royal Society, having impressed him by computing an almanac of celestial events for 1670.

A major problem of the time – one tackled at some time by all major astronomers of the 17th century – was the determination of longitude at sea. A suggestion had been made that the motion of the Moon against the stellar background could be used to determine standard time. Flamsteed, asked by Broncker to comment on this proposal, pointed out that the scheme was impractical because of the inaccuracy of contemporary tables. Charles II subsequently com-

manded that accurate tables should be constructed, appointing Flamsteed as first Astronomer Royal with this responsibility in 1675, and building the Royal Greenwich Observatory for him, which was opened in 1676. The limited nature of the royal patronage is indicated by the fact that Flamsteed was paid a salary of £100 a year but was expected to provide his own instruments and staff. He eventually managed to put together two small telescopes and then began his decades of observation, made more difficult by his lack of staff and the crippling headaches from which he suffered. In order to make ends meet he was forced to become a clergyman at Burstow in Surrey from 1684 until his death.

The results of his labors were eventually published posthumously in 1725 as the *Historia coelestis Britannica* (British Celestial Record). It contains the position of over 3,000 stars calculated to an accuracy of ten seconds of arc. It was the first great modern comprehensive telescopic catalog and established Greenwich as one of the leading observatories of the world. The publication of the work was not without its difficulties. It involved Flamsteed in a long and bitter dispute with NEWTON. Flamsteed was reluctant to rush into print with his catalog, claiming, it seemed to Newton, far too much time for the checking of his numerous observations. The dispute lasted from Newton's assumption of the presidency of the Royal Society in 1703 until Flamsteed's death. It involved the virtual seizure of Flamsteed's papers by Newton, the editing and partial publication by Edmond HALLEY, and their total rejection by Flamsteed who even went so far as to acquire 300 of the 400 printed copies of his own work and burn them. He managed, however, to revise the first volume to his satisfaction before his death in 1719.

### **Fleischmann, Martin** (1927– ) *British chemist*

A cold fusion kit has been marketed by a subsidiary of Japan's *Nippon Telegraph and Telephone* for \$565,000.

—*Wall St. Journal*, 27 November 1992

Born in Karlsbad, Czechoslovakia, Fleischmann (fIish-man) and his family fled to Britain in 1939. He was educated at Imperial College, London, where he gained his PhD in 1951. He taught chemistry at the University of Durham (1952–57) and at Newcastle University (1957–67). In 1967 he was appointed professor of electrochemistry at the University of Southampton.

By 1988 Fleischmann had an international reputation as a productive and innovative electrochemist. Between 1985 and 1988 he coauthored 29 papers with his former student, Stanley PONS. Quite unexpectedly, in March 1989, they announced that they had achieved

nuclear fusion by an electrolytic method under laboratory conditions at room temperature.

Nuclear fusion, the fusion of two light atomic nuclei to produce a heavier nucleus, is a process accompanied by large amounts of released energy. For fusion to occur the nuclei have to be brought close together, and this involves overcoming a high energy barrier caused by the mutual repulsion of the nuclei.

In practical cases this is achieved by high temperatures, as in the Sun or in thermonuclear weapons. Experimental thermonuclear reactors such as the tokamak also use high temperatures (about 300 million degrees) to initiate fusion. There is, however, considerable interest in methods of initiating fusion at low temperatures – so-called “cold fusion.” One approach to this has been *inertial confinement*, in which a sample of material is compressed by intense laser beams or particle beams.

Fleischmann and Pons also thought that pressure might be a way of initiating cold fusion. Palladium metal has a high affinity for hydrogen and, under the right conditions, can absorb large quantities of it. They electrolyzed water containing the deuterium isotope using a palladium cathode and reasoned that the palladium might absorb so much deuterium that the effective deuterium pressure within the electrode would be high enough to cause nuclear fusion. If this occurred, there would be a large increase in temperature, over and above that produced by the heating effect of the current. Fleischmann and Pons reported just such an effect.

Fleischmann was reluctant to reveal too many details of their work lest it prejudice their patent application. He did, however, collaborate with Harwell, the British Atomic Energy Research Establishment, who were best suited to replicate cold fusion. They found no evidence of fusion, no excess heat. Whereas positive results had been obtained by several leading institutions, they were subsequently withdrawn when errors were detected. Despite such setbacks Fleischmann has remained convinced of the essential soundness of his work with Pons.

Since 1990 Fleischmann’s work was mainly supported by Minora Toyoda, a Japanese businessman. He worked at Sophia Antipolis, a research center established by Toyoda outside Nice, France, concerned with the development of future technology. In 1995 he moved to Southampton, where he stayed until 1999. In 2006 he joined the San Francisco company D2 Fusion.

### **Fleming, Sir Alexander (1881–1955)** *British bacteriologist*

“Pain in the mind” was not the spur that drove him to do research ... but rather an urge to do a job better than the next man. Competition was the breath of life to him.

—Leonard Colebrook in *Biographical Memoirs of Fellows of the Royal Society*

Fleming was born at Lochfield in Scotland. After his early education at Kilmarnock Academy and the London Polytechnic Institute, he began his career at the age of 16 as a shipping clerk in a London office. With encouragement from his brother, who was a doctor, he became a medical student at St. Mary’s Hospital Medical School in 1902 and graduated from the University of London in 1908. He worked at St. Mary’s all his life apart from 1914–18, when he served in the Royal Army Medical Corps. During this time he became interested in the control of wound infections and was a vigorous supporter of the physiological treatment of wounds rather than treatment using harsh chemicals, such as carbolic acid. In the 1920s he studied various body secretions and their effects on bacteria. Thus he discovered lysozyme, a bacteriolytic enzyme that is present in serum, saliva, and tears, publishing his findings in 1922.

In 1928 Fleming was appointed professor of bacteriology and in the same year he made his most important discovery. After accidentally leaving a dish of staphylococcus bacteria uncovered, Fleming noticed certain clear areas in the culture. He found these areas were due to contamination by a mold he identified as *Penicillium notatum*, which produced a substance that killed the bacteria. Fleming named this substance “penicillin” and tested the bactericidal effect of the mold on various different bacteria, observing that it killed some but not others. He appreciated the potential of his discovery but was unable to isolate and identify the compound. It was not until World War II, with the urgent need for new antibacterial drugs, that penicillin – the first antibiotic – was finally isolated by Howard FLOREY and Ernst CHAIN.

Fleming was awarded the 1945 Nobel Prize for physiology or medicine jointly with Florey and Chain for his discovery, which initiated a whole new range of lifesaving antibiotics. He received a knighthood in 1944 and many other honors.

### **Fleming, Sir John Ambrose (1849–1945)** *British physicist and electrical engineer*

This war [World War I] is a war quite as much of chemists and engineers as of soldiers and sailors.

—*Nature*

Fleming, who was born at Lancaster in north-western England, studied for a short time at University College, London, but left before graduating. However, he continued his work for a science degree in his leisure hours while employed first in a shipwright’s drawing office and later as a stockbroker’s clerk. Between 1871 and 1880 he had alternate periods of

school science teaching and further study, including working under James Clerk MAXWELL from 1877 at the new Cavendish Laboratory in Cambridge. In 1881 he was appointed professor of mathematics and physics at University College, Nottingham. From 1882 to 1885 he worked as consultant to the Edison Electric Light Company in London. He was then appointed professor of electrical technology at University College, London, a post he held for 41 years.

At University College Fleming gave special courses and experimented on wireless telegraphy, cooperating a great deal with Guglielmo MARCONI. One of Fleming's outstandingly important inventions was the thermionic vacuum tube, a rectifying device based on an effect discovered by Thomas Edison. Fleming's diode consisted of a glass bulb containing two electrodes. One, a metal filament, was heated to incandescence by an electric current, so that it emitted electrons by thermionic emission. The second electrode (the anode) could collect electrons if held at a positive potential with respect to the filament (the cathode) and a current would flow. Current could not flow in the opposite direction – hence the name “valve” for such devices. Lee DE FOREST developed the device into the triode for amplifying current.

Other scientific contributions by Fleming included investigations into the property of materials, transformer design, electrical measurements, and photometry. He was an outstanding teacher and highly successful as a popular lecturer. *Fleming's left-hand rule* and *right-hand rule* are mnemonics for relating the direction of motion, magnetic field, and electric current in electric motors and generators respectively.

### **Fleming, Williamina** (1857–1911) *Scottish-American astronomer*

Sparkling and friendly though she was, her reputation as a strict disciplinarian lived after her, and as late as the 1930s elderly ladies who had worked with her in their youth still regarded her with awe.

—Dorrit Hofleit, *Notable American Women* (1971)

Williamina Paton, as she was born, came from Dundee in Scotland and worked for several years as a schoolteacher. In 1877 she married James Fleming and emigrated with him to Boston, Massachusetts, in 1878. Her marriage broke up and, forced to support her young son, she worked for Edward PICKERING, director of the Harvard College Observatory, as a maid. As it was his policy to employ young women at the observatory as computers, Pickering, who quickly recognized her intelligence, offered her temporary employment as a copyist and computer in 1879. She was given a permanent post in 1881. She remained at the observatory for

the rest of her life, serving as curator of astronomical photographs from 1899 until her death.

She worked with Pickering on the basic classification of stars into spectral types and was thus involved in the introduction of the original 17 classes arranged alphabetically from A to Q in terms of the intensity of the hydrogen spectral lines. This system was later modified and improved by her colleagues Annie CANNON and Antonia MAURY.

Fleming was largely responsible for the classification of over 10,000 stars, published in 1890 in the *Draper Catalogue of Stellar Spectra*. In the course of her work she discovered 10 novae and over 200 variable stars, and estimated that by 1910 she had examined nearly 200,000 photographic plates.

### **Flemming, Walther** (1843–1905) *German cytologist*

Flemming (*flem-ing*) was born at Sachsenberg in Germany, and graduated in medicine from the University of Rostock in 1868. However, after a short period working in a hospital, he turned to physiology and became assistant to Willy Kuhne at the Institute of Physiology in Amsterdam. After serving as a physician in the Franco-Prussian War he held professional posts at Prague (1873) and Kiel (1876).

By making use of the newly synthesized aniline dyes Flemming was able to discern the threadlike structures in the cell nucleus, which Heinrich Waldeyer was later to term chromosomes. The new staining techniques made it possible for Flemming to follow in far greater detail the process of cell division, which he named “mitosis” from the Greek for thread. Most importantly, Flemming detailed the fundamental process of mitosis, that is, the splitting of the chromosomes along their lengths into two identical halves. These results were published in the seminal book *Zell-substanz, Kern und Zelltheilung* (1882; *Cytoplasm, Nucleus and Cell Division*). It was another 20 years before the significance of Flemming's work was truly realized with the rediscovery of Gregor MENDEL's rules of heredity.

### **Flerov, Georgii Nikolaevich** (1913–1974) *Russian nuclear physicist*

Born at Rostov-on-Don, now in Russia, and educated at the Leningrad Industrial Institute of Science, Flerov (*flyair-of*) started his career at the Leningrad Institute of Physics and Technology in 1938. He later became chief of the laboratory of multicharged ions at the Kurchatov Institute of Atomic Energy, Moscow.

Throughout his life, Flerov was involved in the search for new elements and isotopes through synthesis and discovery. In many ways his work paralleled that of Glenn Theodore SEABORG and his research team in America.

Flerov and his coworkers synthesized and analyzed isotopes of elements 102, 103, 104, 105, 106, and 107 (members of the actinide group and transactinides) by bombarding nuclei of heavy elements with heavy ions in a cyclotron. In particular, they have a claim to the first discovery or identification of transactinide elements 104 (1964) and 107 (1968). The correct attribution of these discoveries is still in dispute. Besides his work on the transuranic elements, Flerov was also involved in the search, both by synthesis and discovery in nature (possibly in cosmic rays), of the postulated super-heavy elements. Many theorists believe that although elements beyond the actinides in the periodic table would be highly unstable, there may be "islands of stability" at higher atomic numbers, if they can only be reached.

In 1960 Flerov became director of the nuclear radiation laboratories of the Joint Institute for Nuclear Research, Dubna, near Moscow.

**Florey, Howard Walter** (1898–1968) *Australian experimental pathologist*

If the Professor suggests an experiment always do it, for it is sure to work.

—Colleague of Florey, quoted in obituary notice, *The Times*, 23 February 1968

Florey was born and educated in Adelaide and graduated in medicine from the university there in 1921. Early in 1922 he arrived in Oxford, England, on a Rhodes scholarship and studied physiology for two years under Charles SHERRINGTON. He then moved to Cambridge University where he studied the various roles and behavior of cells and their constituents for his PhD degree.

In 1931 he was appointed professor of pathology at Sheffield University and for four years studied mucus secretions and the role of the cell in inflammation. He was especially interested in the chemical action of lysozyme (an enzyme discovered in 1921 by Alexander Fleming), which is an antibacterial agent that catalyzes the destruction of the cell walls of certain bacteria. In 1935 Florey became head of the Sir William Dunn School of Pathology at Oxford. Here, along with the biochemist Ernst CHAIN, he took up FLEMING's neglected studies on *Penicillium* mold and in 1939 they succeeded in extracting an impure form of the highly reactive compound penicillin. Florey's work on penicillin was a natural extension of his earlier antibacterial work, inspired by the necessity for efficient antibiotics in wartime. Work continued over the next few years on the purification of the drug. The main problem was that vast quantities of mold needed to be grown for just a few milligrams of penicillin. In wartime Britain the necessary financial backing for these innovative biochemical engineering developments could not be obtained, and permis-

sion was given to use companies in the U.S. for the manufacture of the drug. The considerable problems of large-scale production were overcome and from 1943 onward sufficient penicillin was available to treat war casualties as well as cases of pneumonia, meningitis, syphilis, and diphtheria.

Florey is important as a scientist who took Fleming's discovery and made it into a workable treatment for disease – 15 years after the original discovery. He shared the Nobel Prize for physiology or medicine with Chain and Fleming in 1945. He had been knighted in 1944, and in 1965 he was raised to the British peerage.

**Flory, Paul John** (1910–1985) *American polymer chemist*

Flory was born at Sterling, Illinois, and educated at Ohio State University, where he obtained his PhD in 1934. His career was divided between industry and university. He worked with Du Pont from 1934 until 1938 on synthetic polymers and then spent the next two years at the University of Cincinnati. After working for Standard Oil from 1940 until 1943, Flory served as Director of Fundamental Research for the Goodyear Tire Company in Akron, Ohio, until 1948. He was then appointed to the chair of chemistry at Cornell. He left Cornell in 1957 to become director of research of the Mellon Institute in Pittsburgh and, finally, in 1961, accepted the chair of chemistry at Stanford University, California.

Flory was one of the people who, in the 1930s, began working on the properties of polymers. A particular problem at the time was that polymer molecules do not have a definite size and structure; a given polymeric material consists of a large number of macromolecules with different chain lengths. Flory approached this problem using statistical methods, obtaining expressions for the distribution of chain lengths.

In further work he developed a theory of non-linear polymers, which involve cross linkages between molecular chains. He showed how such extended structures can form from a solution of linear polymers. A particular innovation was the concept of *Flory temperature* – a temperature for a given solution at which meaningful measurements can be made of the properties of the polymer.

In later work Flory considered the elasticity of rubbers and similar polymeric materials. He published two authoritative books: *Principles of Polymer Chemistry* (1953) and *Statistical Mechanics of Chain Molecules* (1969). For his major contribution in the field Flory was awarded the Nobel Prize for chemistry in 1974.

**Flourens, Jean Pierre Marie** (1794–1867) *French physician and anatomist*

Flourens (floo-**rahn**), who was born at Mau-reilhan in France, studied medicine at the University of Montpellier, graduating in 1813. Moving to Paris he was fortunate enough to be taken in hand by the powerful Georges CUVIER, serving as his deputy at the Collège de France from 1828. After Cuvier's death in 1832, Flourens succeeded him as professor of anatomy and secretary of the Académie des Sciences.

In 1824 Flourens published his highly influential *Recherches expérimentales sur les propriétés et les fonctions du système nerveux dans les animaux vertébrés* (Experimental Researches on the Properties and Functions of the Nervous System in Vertebrates) in which he demonstrated the main roles of different parts of the central nervous system. Extending the work of the Italian anatomist Luigi Rolando on the nervous system, Flourens removed various parts of the brain and carefully observed the resulting changes. Thus he found that removal of the cerebral hemispheres of a pigeon destroyed the sense of perception. Removal of the cerebellum destroyed coordination and equilibrium and excision of the medulla oblongata caused respiration to cease. He also exposed the spinal cord of a dog from head to tail and found that while stimulation lower down would produce movement there came a point higher up where no muscular reaction could be elicited. Flourens is also known for important work on the semicircular canals in the ear, demonstrating their function in balance.

Although Flourens assigned different roles to different anatomical parts of the brain he was not prepared to go further and localize different roles and powers within each part. It was not until 1870 that Gustav FRITZSCH and Eduard HITZIG were able to break this unitary picture and establish cerebral localization experimentally.

Flourens is also remembered for his attack on DARWIN in his *Examen du livre de M. Darwin* (1864; Examination of Mr. Darwin's Book) in which he poured scorn on Darwin's "childish and out of date personifications."

### **Floyer, Sir John** (1649–1734) *English physician*

Born at Hintes in England, Floyer graduated MD from Oxford University in 1680, after which he spent most of his life in Lichfield in general practice. In *The Physician's Pulse Watch* (2 vols., 1707–10) he described measuring the pulse with a special pulse watch made to run for exactly one minute. The instrument was a considerable improvement over the "string pendulum" of SANCTORIUS.

He also published a number of works on the therapeutic powers of cold baths, a topic on which he became somewhat obsessive. His work on asthma was important in recognizing the

lung condition emphysema in connection with one of the forms of asthma.

### **Fock, Vladimir Alexandrovich** (1898–1974) *Soviet theoretical physicist*

Fock (fok) was educated at the University of Petrograd (now St. Petersburg) where he graduated in 1922. He later worked at the Leningrad Institute of Physics (1924–36) and in 1939 joined the Academy's Institute of Physics. He was also appointed professor of physics at Leningrad University in 1961.

Although Erwin SCHRÖDINGER had published a solution of the wave equation for the hydrogen atom in 1926 it was by no means clear how it could be applied to atoms with more than one electron. The problem was solved between 1927 and 1932 by Fock and, independently, R. Hartree, who developed the method known as the *Hartree–Fock approximation*.

Fock also worked extensively on problems in general relativity.

### **Folkers, Karl August** (1906–1997) *American organic chemist*

Folkers was born in Decatur, Illinois, graduated in chemistry from the University of Illinois in 1928, and gained his PhD from the University of Wisconsin in 1931. After postdoctoral work at Yale he joined the pharmaceutical manufacturers Merck and Company in 1934, becoming director of organic and biochemical research in 1945. He was president of the Stanford Research Institute from 1963 to 1968, and then director of the Institute for Biomedical Research at the University of Texas.

In 1948 Folkers's team isolated the antiper-nicious anemia factor, vitamin B<sub>12</sub> (cyanocobalamin) and they played a major role in the lengthy process of determining the structure of this molecule. Folkers has been involved in many investigations of biologically active compounds, especially antibiotics, and the structure of streptomycin was largely determined by his group in 1948.

### **Forbes, Edward** (1815–1854) *British naturalist*

Forbes was born in Douglas on the Isle of Man. Although his education was primarily in medicine at Edinburgh University, his interests included natural history, and in 1833 he visited Norway, collecting mollusks and plants. In 1841–42 he went as naturalist on the HMS *Beacon* to investigate the botany and geology of the Mediterranean and Asia Minor. After lecturing for the Geological Society, Forbes became its curator, and in 1843 was elected to the chair of botany at King's College, London. From 1844 he was paleontologist to the Geological Survey, and subsequently became pro-

fessor of natural history both at the Royal School of Mines and Edinburgh University.

Forbes traveled widely over Europe, North Africa, and the Middle East, collecting plants and animals (especially mollusks) and studying their relationships. His observations of the littoral zones produced evidence of oceanic sedimentation, while he also investigated molluskan migration, and speculated on the origin and distribution of animal and vegetable life – stimulating later research along these lines. Some of Forbes's most important work was concerned with the starfishes, the British species of which he was the first to classify systematically (*History of British Starfishes*; 1842). His dredging up of a starfish from a depth of a quarter of a mile in the Mediterranean confounded previously held views that life was largely confined to the upper layers of the sea. Forbes also wrote *A History of British Mollusca* (1848–52) and *Naked-eyed Medusae* (1848). His geological investigations of the Purbeck Beds (1849) proved them to be of the Oolitic series.

**Ford, Edmund Brisco** (1901–1988)  
*British geneticist*

One of the most far-reaching results of recent work on ecological genetics is the discovery that unexpectedly great selective forces are normally operating to maintain or to adjust the adaptations of organisms in natural conditions.

—*Ecological Genetics* (1964)

Ford, who was born at Papcastle in England, studied at Oxford University and began research there, in collaboration with Julian HUXLEY, on the genetic control of growth. Together they demonstrated that one type of gene action is to affect the rate rather than nature of chemical reactions. During the same period (1923–26) Ford was also working with Ronald FISHER and was stimulated by Fisher's work on genetic dominance to expand his own work on adaptation and evolution in natural populations.

Having gained his MA in 1927, Ford developed techniques to identify the conditions that promote rapid adaptation and evolution, and then subjected such conditions to ecological investigation. He termed these methods "ecological genetics" and the application of his methods was later to show that selection for beneficial characters is some 30 to 40 times greater than had been believed – an important consideration in evolutionary studies.

Most of Ford's work was conducted on moths and butterflies. He showed that in a given moth population the amount of genetic diversity corresponds to the population size, proportionally greater variation occurring when numbers are higher. He studied the existence of distinct forms in populations of the butterfly *Maniola jartina* and formulated a definition of such ge-

netic polymorphisms. He speculated that the different human blood groups, which are an example of polymorphism, are maintained by the association of certain blood groups with specific diseases, a theory that was proved correct in 1953.

Ford became professor of ecological genetics at Oxford in 1963 and emeritus professor in 1969. His publications include *Ecological Genetics* (1964) – the culmination of over 30 years' research – and *Genetic Polymorphism* (1965).

**Forest, Lee de See** **DE FOREST, LEE.**

**Forrester, Jay** (1918– ) *American computer engineer*

Forrester, born on a cattle ranch in Nebraska, attended a small country school before studying electrical engineering at the University of Nebraska. He went on to do graduate work at MIT on servomechanisms.

This led him, in 1945, to begin work on the design of a flight simulator for the U.S. Navy. He soon discovered that, without high-speed servomechanisms, realistic systems could not be developed. At this point he was directed, in 1946, toward the possibility that digital computers could be used. Forrester set up a laboratory to tackle what became known as the "Whirlwind Project." The Whirlwind, the largest computer of the time, became operational in the early 1950s. Problems, however, soon emerged. With several thousand vacuum tubes, each with a life of about 500 hours, regular breakdowns occurred.

Forrester's first advance was to increase the life of the tubes using new materials and a checking system. However, the main problem was with the machine's memory, which consisted of electrostatic storage tubes. These were expensive and unreliable, with each tube lasting no more than 1 month and costing \$1,000 to replace. Consequently, Forrester began to think about magnetic systems of data storage. He used magnetic ferrite rings on a grid of wires in a three-dimensional array. Each ring could be magnetized in one of two directions to represent the binary digits 1 or 0. The method was first used in 1953, and gave an access time twice as fast as that using storage tubes.

The improvements were opportune. Following the political crises of the early cold-war years, the SAGE (Semi Automatic Ground Environment) project was initiated by the U.S. Navy under the supervision of Forrester. Very reliable and very fast computers were needed to analyze air traffic, identify any likely threat, and guide interceptors to hostile planes or missiles. SAGE proved remarkably effective, coming into full operation in 1958 and remaining active until 1984. Forrester left the project in 1956, moving to the MIT Sloan Management School as professor of management with the

aim of developing computer systems capable of simulating economic and social systems. He has explained his approach in a number of works, including *Industrial Dynamics* (1961), *Principles of Systems* (1968), and *World Dynamics* (1971). More recently he has worked on a model of the U.S. economy.

**Forssmann, Werner Theodor Otto** (1904–1979) *German surgeon and urologist*

Forssmann (**fors-mahn**) was educated at the university in his native city of Berlin where he qualified as a physician in 1929. He then worked in the 1930s as a surgeon in various German hospitals. After the war he practiced as a urologist at Bad Kreuznach from 1950 until 1958 when he moved to Düsseldorf as head of surgery at the Evangelical Hospital.

In 1929 Forssmann introduced the procedure of cardiac catheterization into medicine. He was struck by the danger inherent in the direct injection of drugs into the heart frequently demanded in an emergency. The alternative that he proposed sounded no less alarming – introducing a catheter through the venous system from a vein in the elbow directly into the right atrium of the heart. Drugs could then be introduced through this.

After practice on cadavers and an unsuccessful attempt on himself made with the aid of a nervous colleague, Forssmann decided to do the whole thing himself. He consequently introduced a 65-centimeter (25.6-in) catheter for its entire length, walked up several flights of stairs to the x-ray department and calmly confirmed that the tip of the catheter had in fact reached his heart. There had been no pain or discomfort.

Unfortunately further development was inhibited by criticism from the medical profession, which assumed the method must be dangerous. Consequently it was left to André COURNAND and Dickinson RICHARDS to develop the technique into a routine clinical tool in the 1940s; for this work they shared the Nobel Prize for physiology or medicine with Forssmann in 1956.

**Foster, Sir Michael** (1836–1907) *British physiologist*

Foster, the son of a surgeon from Huntingdon in eastern England, was educated at University College, London, where he obtained his MD in 1859; after several years in private practice with his father, he returned in 1867 as a lecturer in physiology. He moved to Cambridge University in 1870 where he later served as the first professor of physiology from 1883 until his retirement in 1903.

Foster's greatest achievement was undoubtedly the Cambridge school of physiology. Just as the late 19th century saw the emergence in

Cambridge of a major physics laboratory, the Cavendish, so too did it witness the creation of a major center for physiological research. Foster did much to establish physiology as a major scientific discipline in Cambridge and, indeed, in Britain. He pressed for the construction of new laboratories, produced the *Textbook of Physiology* (1877), and founded the Physiological Society (1875) and the *Journal of Physiology* (1878). From Foster's laboratory there emerged, as clear proof of his success, such scholars as Charles SHERRINGTON, Henry DALE, John LANGLEY, and Walter GASKELL.

Much of Foster's work as a research physiologist was devoted to the problem of the genesis of the heartbeat, namely whether it was under nervous control. The role of the vagus nerve in inhibiting the heartbeat had been known since the 1840s, as had the presence of nervous ganglia in the heart itself. Against such impressive evidence Foster pointed out, in 1859, that in the snail's heart neither the inhibitory nerve nor ganglia could be found, yet small pieces taken from it would continue to contract rhythmically for some time. He concluded from this that the cause of the heartbeat was a "peculiar property of general cardiac tissue." Several years later this work was extended and confirmed by Gaskell.

After 1880 Foster did little original work, being more concerned with the demands of his growing organization. When he began there were 20 students studying physiology at Cambridge; when he retired there were over 300.

**Foucault, Jean Bernard Léon** (1819–1868) *French physicist*

Foucault (**foo-koh**), the son of a Parisian bookseller, originally intended to study medicine, but transferred his interest to physical science. In 1855 he became a physicist at the Paris Observatory.

His main work was on measurements of the speed of light. He helped Armand FIZEAU in his toothed-wheel experiment and, in 1850, took over D. F. J. ARAGO's experiments on comparing the speed of light in air with that in water. The experiment was important for distinguishing between the wave and particle theories of light: the wave theory predicted that light should travel faster in air than in water; the particle theory predicted the opposite. In 1850, Foucault showed that the wave-theory prediction was correct. In 1862 he obtained the first accurate value for the speed of light using a rotating-mirror apparatus.

Foucault also worked on other topics. Thus he noted (1849) that a bright yellow line in the spectrum of sodium corresponded to a dark line in the FRAUNHOFER spectrum, although he failed to follow this up.

His most famous experiments began in 1850 and involved pendulums. While trying to con-

struct an accurate timing device for his work on light, he noticed that a pendulum remained swinging in the same plane when he rotated the apparatus. He then used a pendulum to demonstrate the rotation of the Earth. Over a long period of time the plane in which a pendulum is swinging will appear to rotate. In fact the pendulum swings in a fixed plane relative to the fixed stars, and the Earth rotates “underneath” it.

At the Earth’s poles, the plane of the pendulum will make one full rotation every 24 hours; this period increases as the equator is approached. Foucault derived an equation relating the time of rotation to the latitude. He also gave public exhibitions of the effect, including one in which he suspended an iron ball of 28 kilograms (62 lbs) by steel wire 67 meters (222 ft) long from the dome of the Panthéon in Paris. Foucault also invented the gyroscope.

### **Fourcroy, Antoine François de** (1755–1809) *French chemist*

Fourcroy (foor-**krwah**) was born and grew up in poverty in Paris and began to study medicine in 1773. Graduating in 1780, he became professor of chemistry at the Jardin du Roi in 1784. He was an excellent lecturer, a prolific writer, and played a leading role in the scientific life of France. He helped to found the Ecole de Santé (1795) and the Ecole Polytechnique (1795) and was minister of public instruction under Napoleon (1802–08). With VAUQUELIN he carried out many researches, especially on natural products, and they were the first to prepare a relatively pure form of urea and to name this compound. Fourcroy was an important advocate of the system of Antoine LAVOISIER, which he taught from 1786. Among his many writings was the massive *Système de connaissance chimique* (1801–02; System of Chemical Knowledge).

### **Fourier, Baron (Jean Baptiste) Joseph** (1768–1830) *French mathematician*

There cannot be a language more universal and more simple, more free from errors and obscurities ... more worthy to express the invariable relations of natural things [than mathematics].

—*Théorie analytique de la chaleur* (1822; The Analytical Theory of Heat)

Fourier (foor-ee-ay), the son of a tailor from Auxerre in France, was educated at the local military school and later at the Ecole Normale in Paris. He held posts at both the Ecole Normale and the Ecole Polytechnique where he was a very effective and influential teacher. In 1798 he accompanied Napoleon on the invasion of Egypt and later contributed to and oversaw the publication of the *Description de l’Egypte* (1808–25; Description of Egypt), a mas-

sive compilation of the cultural and scientific materials brought back from the expedition.

Fourier’s most important mathematical work is contained in his *Théorie analytique de la chaleur* (1822; The Analytical Theory of Heat), a pioneering analysis of the conduction of heat in solid bodies in terms of infinite trigonometric series, now known as *Fourier series*. Fourier was led to consider these series when attempting to solve certain boundary-value problems in physics and his interest was always in the physical applications of mathematics rather than in its development for its own sake. His work continues to be extremely important in many areas of mathematical physics, but it has also been developed and generalized to yield a whole new branch of mathematical analysis, namely, the theory of harmonic analysis.

### **Fourneau, Ernest François Auguste** (1872–1949) *French medicinal chemist and pharmacologist*

Fourneau (foor-**noh**) was born in Biarritz, France. After graduating from the Lyceum of Bayonne, he worked in a Paris hospital pharmacy (1892–96) before becoming director of the research laboratories at the pharmaceutical manufacturers Poulenc Frères (1900–1912). From 1912 to 1942 he was head of the therapeutic chemistry laboratories at the Pasteur Institute. In 1924 he synthesized suramin, an effective drug against African sleeping sickness, which had first been discovered by the German BAYER company in 1920 but had not been published by them. This was followed by acetarsol (1926), an amebicide, and plasmocid (1930), an antimalarial agent. In 1935, working with the newly discovered antibacterial dye, Prontosil, he showed that its metabolite, now known as sulfanilamide, was the active part of the molecule.

### **Fourneyron, Benoît** (1802–1837) *French engineer and inventor*

Fourneyron (foor-nay-**ron**), who was born the son of a mathematician in Saint-Etienne, France, studied at the then newly opened engineering school there until 1816. His professor, Claude Burdin, had written a paper describing a new kind of waterwheel called a “turbine.” This design principle is now basic to electricity generators and many propulsion engines, but Burdin’s paper was rejected by the French Academy of Sciences and by the Society for the Encouragement of Industry. Fourneyron, while he was working in an ironworks at Le Creuset, studied the idea and, in 1827, actually built a six-horsepower unit, in which the force of water flowing outward from a central source onto angled blades turned a rotor.

Ten years later, Fourneyron built a turbine with a wheel one foot (30 cm) in diameter,

which could turn at 2,300 revolutions per minute and had an efficiency of 80%. Weighing only 40 pounds (18 kg), it was very much smaller than an equivalent waterwheel and could be mounted horizontally with a vertical shaft. Fourneyron thought of building steam turbines but was unable to do so because, at that time, no suitable materials and manufacturing techniques were available.

**Fowler, Alfred** (1868–1940) *British astrophysicist*

Although born into a poor family in the industrial city of Bradford, England, Fowler gained a scholarship and in 1882 went to the Normal School of Science (later to become the Royal College of Science and now part of Imperial College, London). After graduating with a diploma in mechanics, he became assistant to Norman LOCKYER at the Solar Physics Observatory in South Kensington, London. He remained there after Lockyer's retirement in 1901, being made professor of astrophysics in 1915. Finally, from 1923 to 1934 he served as Yarrow Research Professor of the Royal Society. Fowler was one of the leading figures behind the founding of the International Astronomical Union in 1919, serving as its first general secretary until 1925.

Not surprisingly Fowler worked very much in the Lockyer tradition of solar and stellar spectroscopy. He became particularly skilled in identifying difficult spectra, using his experience in producing different spectra in the laboratory. He thus detected magnesium hydride in sunspots and carbon monoxide in the tails of comets, and showed that the band spectra of cool M-type stars were due to titanium oxide. In addition, following the announcement in 1913 of the BOHR theory of the atom, Fowler was outstanding in analyzing the structure of atoms from their special characteristics.

**Fowler, William Alfred** (1911–1995) *American physicist*

Fowler was born in Pittsburgh, Pennsylvania, graduated in 1933 from Ohio State University, and obtained his PhD in 1936 from the California Institute of Technology. He was immediately appointed to the staff, serving as professor of physics there from 1946 to 1970; he was Institute Professor from 1970 and professor emeritus from 1982.

Fowler worked mainly in nuclear physics, especially on the nuclear reactions that occur in stars and by which energy is produced and the elements synthesized, on nuclear forces, and on nuclear spectroscopy. In 1957 Margaret and Geoffrey BURBIDGE, Fred HOYLE, and Fowler published a key paper dealing with the problem of the creation of the chemical elements in the interiors of stars. They were aware that the hot

big bang proposed by George GAMOW could produce nothing heavier than helium. Clearly the elements were produced later. They therefore had to identify nuclear reactions that could occur at the immense temperatures of stellar cores; the type of process changed, and hence changed the elements being produced, as the temperature increased and conditions altered inside the stars. A later and fuller version was published by Fowler and Hoyle in their *Nucleosynthesis in Massive Stars and Supernovae* (1965).

Fowler subsequently worked on such fundamental questions as the amount of helium and deuterium in the universe, the answers to such questions having profound implications for knowledge of the age and future development of the universe.

For his work on nuclear astrophysics, Fowler shared the 1983 Nobel Prize for physics with Subrahmanyan CHANDRASEKHAR.

**Fox, Harold Munro** (1889–1967) *British zoologist*

Fox (originally Fuchs), the son of an officer in the Prussian army, was born in London and educated at Cambridge University; after war service, he served as a fellow from 1920 to 1928. He then moved to Birmingham as professor of zoology, a post he held until 1941 when he accepted a similar chair at Bedford College, London, where he remained until his retirement in 1954.

Fox, a zoologist of wide interests, is best known for his work on invertebrate blood pigments. In 1871 Ray LANKESTER had noted that the red blood of the water flea *Daphnia*, a crustacean, was due to the presence of the pigment hemoglobin. Other crustaceans, such as lobsters, were blue-blooded with the pigment hemocyanin in their blood.

It had been observed that the transparent *Daphnia* could become redder or paler by synthesizing or breaking down blood hemoglobin. This was done at a rate far in excess of that noted in any other creature. Fox showed by laboratory experiments in the 1940s that the response was controlled by the level of dissolved oxygen in the water. If this were low, hemoglobin, with its affinity for oxygen, was synthesized; if high, *Daphnia* lose their hemoglobin and become colorless.

Earlier, in 1923, Fox had repeated the controversial experiments of Paul KAMMERER on the supposed elongations produced in the siphons of the sea squirt *Ciona intestinalis*. He reported that in none of the operated animals was there any further growth of the siphons once the original length had been attained, and went on to suggest that Kammerer's results could have been produced by keeping the animals in a highly nutritious solution, an explanation Kammerer was quick to dismiss.

**Fox, Sidney Walter** (1912–1998) *American biochemist*

Born in Los Angeles, Fox was educated at the University of California in his native city and at the California Institute of Technology, where he obtained his PhD in 1940. He taught briefly at Berkeley and the University of Michigan before moving to Iowa State University in 1943, serving as professor of biochemistry from 1947 until 1954. Fox then moved to Florida State University as professor of chemistry, joining the University of Miami in 1964 to take up an appointment as director of the Institute of Molecular and Cellular Evolution. He retired in 1989.

Biochemists dealing with the origin of life at some time or other have to face the problem of which came first, proteins or nucleic acids? In this classic dispute Fox placed himself firmly in favor of the protein-first hypothesis.

He demonstrated in 1958 the existence of what he termed "proteinoids," polymers of amino acids produced by the application of heat alone. Furthermore he found that on cooling, the proteinoids produce microspheres – tiny spheres, a micrometer or two in diameter, apparently resembling bacteria and supposed by Fox to be protocells. Since they appeared to develop some kind of membrane, produced buds, and sometimes divided, the comparison was far from outrageous. One further significant consideration is that the proteinoids are not just a random grouping of amino acids; a selection principle of some kind operates to give preference to some amino acids over others. There is, however, a major difficulty implicit in Fox's work. To construct the proteinoids he was forced to use an above-average concentration of the amino acids lysine, glutamic acid, and aspartic acid, and it is unlikely that the early terrestrial environment consisted of such a specialized distribution of amino acids.

**Fracastoro, Girolamo** (1478–1553) *Italian physician*

Fracastoro (frah-kah-stor-oh) was born in Verona, Italy, and educated at the University of Padua where he graduated in 1502. He taught logic there until 1508, when he returned to the family estates at Incaffi, near Verona. He thereafter seems to have divided his time between practicing medicine in Verona and attending to the family estates.

Fracastoro was the author of two important medical works. The first, written as the poem *Syphilis sive morbus Gallicus* (1530; Syphilis or the French Disease), introduced the term "syphilis" into most European languages.

Syphilis seems to have appeared first in Europe at the end of the 15th century with the siege of Naples by the French army of Charles VIII. Called the "Mal de Naples" by the French and the "Mal Francese" by the Neapolitans, the

disease spread rapidly throughout Europe. It was because of this rapidity that Fracastoro rejected the even then popular view attributing the infection to the New World. His descriptions of the symptoms suggest syphilis was then more virulent than it is now.

The second work of Fracastoro, *De contagione et contagiosis morbis* (1546; On Contagion and Contagious Diseases), is claimed to be a precursor of the germ theory of disease. He distinguished three types of infection: by direct contact, by indirect contact through an intermediary, and those, like some fevers, that appear to operate at a distance. He spoke of "seeds of contagion," imperceptible and passing from person to person, which he believed could generate more identical germs. Having made such a theoretical advance in introducing his "seminaria contagium" it was difficult to see what further steps could be taken at that time. Consequently his work remained an isolated curiosity rather than a part of the main tradition of medicine.

Fracastoro also, in 1538, published an astronomical work, *Homocentrica sive de stellis liber* (Homocentricity or the Book of Stars), which attempted to eliminate the epicycles and eccentrics from the geocentric system of PTOLEMY and replace them with the original concentric spheres of EUDOXUS. This work influenced COPERNICUS, a contemporary of Fracastoro at Padua.

**Fraenkel-Conrat, Heinz L.** (1910–1999) *German-American biochemist*

Fraenkel-Conrat (fren-~~kel-kon~~-rat), son of the noted gynecologist Ludwig Fraenkel, was born in Breslau (which was then in Germany and is now Wrocław in Poland). He left Germany for Britain after graduating MD from the University of Breslau in 1934. Having gained his PhD for work on ergot alkaloids and thiamine from the University of Edinburgh in 1936, he moved on to America, where he settled and became an American citizen in 1941. He joined the faculty of the University of California at Berkeley in 1951, becoming professor of virology in 1955 and professor emeritus in 1981.

Fraenkel-Conrat, working with the tobacco mosaic virus (TMV), an RNA virus, provided evidence that RNA, like DNA, can act as the genetic material. This he did by separating the RNA and protein portions of the virus, and then reassembling them to make a fully infective virus. Moreover Fraenkel-Conrat demonstrated that, while the isolated protein was quite dead, the isolated RNA showed slight signs of infectivity. This work was reported in a paper by Fraenkel-Conrat and Robley C. WILLIAMS entitled *Reconstitution of Tobacco Mosaic Virus from Its Inactive Protein and Nucleic Acid Components* (1955). In later work with Wendell Stanley the complete amino-acid sequence, con-

sisting of 158 amino acids, of the TMV protein was established.

Fraenkel-Conrat, in collaboration with R. R. Wagner, edited one of the basic texts of modern virology, *Comprehensive Virology* (19 vols.; 1974–84).

**Francis, Thomas Jr.** (1900–1969) *American virologist*

Francis, the son of a methodist clergyman from Gas City, Indiana, was educated at Allegheny College and Yale where he obtained his MD in 1925. He worked with the Rockefeller Institute from 1925 to 1938 and, after serving as professor and chairman of bacteriology at the New York University College of Medicine, moved to the University of Michigan in 1941 as professor of epidemiology, a post he retained until his death.

Francis became known to a wide public when, in 1954, he reported on the SALK polio vaccine trial. Before this however he had worked for over 20 years on the epidemiology of the influenza virus. The first such virus, the A-type, had been detected by Christopher Andrewes and his colleagues in 1933. In the following year Francis found a further strain of the A-type, the PR 8, present in the Puerto Rican epidemic of 1934. In 1940 he went on to detect a completely distinct type, B, with no immunological relationship to the A-type.

The U.S. Army, fearful of a repeat of the 1918 flu epidemic, set up in 1941 a commission to develop a vaccine and asked Francis to be its chairman. By 1942 he was ready to vaccinate 8,000 soldiers with his vaccine but, perversely, flu was scarce that year. It was not until 1943 that he was able to report that those vaccinated were 70% less likely to be hospitalized compared with the control group. This encouraged the army to vaccinate some 1,250,000 troops in 1947 but this time it disconcertingly seemed to offer no protection at all.

It soon became clear to Francis why the vaccine had failed – the arrival of a new strain of A-type virus, known as A<sup>1</sup>. Francis was thus able to present the dilemma facing flu epidemiologists, namely that while it was certainly possible to develop a vaccine against flu it was more than likely that it would end up as a vaccine against yesterday's flu.

**Franck, James** (1882–1964) *German-American physicist*

Franck, the son of a banker from Hamburg in Germany, was educated at Heidelberg and Berlin where he obtained his doctorate in 1906. After distinguished war service, in which he won two iron crosses, he was appointed to the chair of experimental physics at Göttingen. Although exempt from the 1933 Nazi law that excluded Jews from public office because of his

military service, he insisted on publicly resigning. After spending a year in Copenhagen, he emigrated to America in 1935 where he served as professor of physical chemistry at the University of Chicago from 1938 to 1949.

In collaboration with Gustav HERTZ he produced experimental evidence of the quantized nature of energy transfer, work that won them the 1925 Nobel Prize for physics. Their experiment, conducted in 1914, consisted of bombarding mercury atoms with electrons. Most of the electrons simply bounced off, losing no energy in the process. When the velocity of electrons was increased it was found that on collision with mercury atoms they lost precisely 4.9 electronvolts (eV) of energy. If an electron possessed less energy than 4.9 eV it lost none at all on collision; if it had more than 4.9 eV it made no difference – only 4.9 eV was absorbed by the mercury atoms. Franck and Hertz had thus succeeded in showing that energy can only be absorbed in quite definite and precise amounts. For mercury the minimum amount was 4.9 eV. Their results were quickly confirmed and shown to hold for other atoms.

In America Franck worked mainly on the physical chemistry involved in photosynthesis although he is better known as the author of the *Franck Report* published in 1946. This report, actually produced by a number of distinguished scientists of whom Leo SZILARD was probably the most important, was sent to the Secretary of State for War in June 1945. It argued that it was not necessary to drop the recently produced atomic bomb on Japan as its explosion on a barren island would be sufficient to force the Japanese into submission.

**Frank, Ilya Mikhailovich** (1908–1990) *Russian physicist*

Frank was born at St. Petersburg in Russia and educated at Moscow University. After working at the State Optical Institute from 1930 to 1934, he was made an associate of the Physics Institute of the Soviet Academy of Sciences. He was professor of physics at Moscow University from 1944 to 1990.

Frank and Igor TAMM first gave an explanation of the radiation discovered in 1934 by Pavel CHERENKOV. This occurs when a charged particle is traveling through a medium faster than the speed of light in that medium. The particle displaces electrons in the atoms of the medium and an electromagnetic wave is produced. The effect is similar to the sonic boom produced when a body moves faster than sound in air.

Frank, Cherenkov, and Tamm shared the Nobel Prize for physics in 1958.

**Frankland, Sir Edward** (1825–1899) *British organic chemist*

Born at Churchtown, near Lancaster in north-

western England, Frankland was first apprenticed to a pharmacist in Lancaster; he was later encouraged to go to London to study chemistry under Lyon PLAYFAIR at the Royal College of Engineers (1845). He became Playfair's assistant in 1847 and studied extensively in Europe with Robert BUNSEN and Justus von LIEBIG. He succeeded Playfair as professor of chemistry in 1850, holding the same position at Owens College, Manchester (1851–57), and in London at St. Bartholomew's Hospital (1857), the Royal Institution (1863), and the Royal School of Mines (1865), later the Royal College of Science.

Frankland's first important work was on methylalkyls (1849). He prepared zinc methyl and zinc ethyl but, being at that time an adherent of the radical theory, was led into the error of believing that "methyl hydride" and "ethyl hydride" (actually both ethane) were different compounds.

Frankland is generally credited as the originator of the theory of valence – this being the number of chemical bonds that a given atom or group can make with other atoms or groups in forming a compound. In 1852 he noticed that coordination with an alkyl group could change the combining power of a metal. He showed that the concept of valence could reconcile the radical and type theories and in 1866 he elaborated the concept of a maximum valence for each element. In 1864, working with B. F. Duppa, Frankland pointed out that the carboxyl group (–COOH, which he called "oxatyl") is a constant feature of the series of organic acids. He was also interested in applied chemistry: he investigated the luminosity of flames and his later work was in the field of coal-gas supply and water purification. He was knighted in 1897.

**Franklin, Benjamin** (1706–1790) *American scientist, statesman, diplomat, printer, and inventor*

He snatched lightning from the heavens and  
sceptres from kings.

—Turgot, epitaph on Franklin

Franklin's father left England in 1682 and the following year settled in Boston, Massachusetts, where he worked as a candle maker and soap boiler. Although originally intended for the clergy, Franklin, who was born in Boston, was forced to leave school at the age of ten for financial reasons; after helping his father for some time he was apprenticed to his brother, a printer, in 1718.

He continued his trade as a printer in London (1724–26), and thereafter in Philadelphia where he published, from 1729, the *Pennsylvania Gazette* and, from 1733, the hugely successful *Poor Richard's Almanac*. Shortly afterward Franklin began his life in public affairs serving as clerk of the State Assembly (1736–

51) and as deputy postmaster representing the colonies (1753–74), during which he saw further service in London (1757–62; 1764–75). On his return to America Franklin played an active role in the revolution and was one of the five who drafted the Declaration of Independence in 1776. He was sent to France in 1776 to seek military and financial aid for the colonies and largely through his own popularity succeeded in achieving an alliance in 1778. Returning to America in 1785, he performed his last public duty as a member of the Constitution Convention in 1787 before retiring from public life in 1788.

Despite such an active political and public life Franklin also made important contributions to 18th-century physical theory in the period 1743–52. By conversation with scholars in London, reading, and correspondence with friends, his interest in the newly discovered phenomena of electricity had been aroused.

Franklin would have known of the work of Stephen GRAY and Charles Dufay and the basic distinction established between electrics (such as glass and amber), which could be electrified by rubbing, and nonelectrics (such as metals), which resisted such treatment. Electrics were further divided into vitreous substances, such as glass, and resinous substances, such as amber. Dufay had concluded that there were two distinct electric fluids – the vitreous and the resinous – in his two-fluid theory.

Franklin agreed with Dufay that electricity was a fluid. More significant properties of electricity emerged out of Franklin's experiments from 1747 onward. From these experiments, including those on the Leyden jar, Franklin devised his one-fluid theory of electricity. He also introduced the terminology of "positive" and "negative" into the science.

Practical gains emerged from Franklin's discovery that lightning is an electric charge. He knew that the electric fluid was attracted by points but wondered if lightning would also be attracted. In 1752 he performed his famous, yet hazardous, experiment with a kite during a thunderstorm and established the identity of lightning with electricity. Following this he suggested the use of lightning rods on tall buildings to conduct electricity away from the building and direct to ground.

Franklin also published works on the problems of light, heat, and dynamics. Outside of physics Franklin's most important scientific work was in oceanography with his study of the Gulf Stream. He measured its temperature at different places and depths, estimated the current's velocity, and analyzed its effects on the weather. From reports supplied to him by Nantucket sea captains he also constructed the first printed chart of the Gulf Stream. Franklin is also remembered for his large number of inventions that included (in addition to his light-

ning rod) bifocal spectacles, the rocking chair, and an efficient stove.

**Franklin, Rosalind (1920–1958)** *British x-ray crystallographer*

Franklin was a Londoner by birth. After graduating from Cambridge University, she joined the staff of the British Coal Utilisation Research Association in 1942, moving in 1947 to the Laboratoire Centrale des Services Chimique de L'Etat in Paris. She returned to England in 1950 and held research appointments at London University, initially at King's College from 1951 to 1953 and thereafter at Birkbeck College until her untimely death from cancer at the age of 37.

Franklin played a major part in the discovery of the structure of DNA by James WATSON and Francis CRICK. With the unflattering and distorted picture presented by Watson in his *The Double Helix* (1968) her role in this has become somewhat controversial. At King's, she had been recruited to work on biological molecules and her director, John RANDALL, had specifically instructed her to work on the structure of DNA. When she later learned that Maurice WILKINS, a colleague at King's, also intended to work on DNA, she felt unable to cooperate with him. Nor did she feel much respect for the early attempts of Watson and Crick in Cambridge to establish the structure.

The causes of friction were various, ranging from simple personality clashes to, it has been said, male hostility to the invasion of their private club by a woman. Despite this unsatisfactory background Franklin did obtain results without which the structure established by Watson and Crick would have been at the least delayed. The most important of these was her x-ray photograph of hydrated DNA, the so-called B form, the most revealing such photograph then available. Watson first saw it in 1952 at a seminar given by Franklin, and recognized that it clearly indicated a helix. Franklin also appreciated, unlike Watson and Crick, that in the DNA molecule the phosphate groups lie on the outside rather than inside the helix. Despite such insights it was Watson and Crick who first realized that DNA has a double helix. By March 1953 Franklin had overcome her earlier opposition to helical structures and was in fact producing a draft paper on 17 March 1953, in which she proposed a double-chain helical structure for DNA. It did not, however, contain the crucial idea of base pairing, nor did she realize that the two chains must run in opposite directions. She first heard of the Watson-Crick model on the following day.

**Frasch, Herman (1851–1914)** *German-American industrial chemist*

The son of a wealthy apothecary from Gaildorf,

in Germany, Frasn (frash) was educated in Halle and was apprenticed to an apothecary before emigrating to America in 1868. He worked in the field of petroleum chemistry and in 1876 he joined the Standard Oil Company in Cleveland.

In 1882 Frasn developed a process for reducing the sulfur content of poor-quality crude oil through the use of metallic oxides, thus making it commercially acceptable, and in 1884 he bought such a field at London, Ontario. When, in 1886, Standard Oil discovered high-sulfur oil in Ohio Frasn rejoined them as a part-time consultant to solve the problem. From sulfur as an impurity he turned to the problems of extracting sulfur as a product in its own right. In 1894 he was the first to raise sulfur from deep underground by means of superheated water. In the *Frasch process* three concentric pipes are sunk down to the sulfur deposit. Superheated water is pumped down the outside pipe to liquefy the sulfur, which is forced up the middle pipe by compressed air passed down the center pipe. The process became a commercial proposition in 1900 thanks largely to the availability of cheap local oil to heat the water. Frasn had a 50% share in the company, Union Sulfur, and the Sicilian sulfur monopoly was broken. Eventually other companies used the process, Frasn lost his patent-infringement actions, and his company faded away.

**Fraunhofer, Josef von (1787–1826)** *German physicist and optician*

Fraunhofer (**frown**-hoh-fer), whose family was in the optical trade, was born in Straubing, Germany; he was apprenticed to an optician in Munich after his parents died. He subsequently moved to the Utzschneider optical institute near Munich.

His great ambition was to perfect the achromatic lens, which John DOLLOND had developed a century earlier, and his scientific discoveries came as by-products of this work. The major difficulty was to measure the refractive indices of the different types of glass used in these lenses. In 1814, while testing prisms in order to determine these constants, he observed that the Sun's spectrum was covered with fine dark lines. He also noticed that these *Fraunhofer lines* occurred in the spectra of bright stars, but that their positions were different. The lines had been observed earlier by William WOLLASTON, but Fraunhofer studied them in detail, measuring the positions of 576 of them and giving the main ones letters A–G. He also found the lines to be present in spectra produced by reflection from a grating (1821–22), thus proving them to be a characteristic of the light, not the glass of the prism.

Fraunhofer had in his grasp the key to finding the composition of the stars, but this step was taken half a century later by Gustav

KIRCHHOFF, who showed that lines in the solar spectrum resulted from characteristic absorption by elements in the atmosphere of the Sun.

**Fredholm, Erik Ivar** (1866–1927) *Swedish mathematician*

Fredholm (**fred-holm**), who was born in the Swedish capital of Stockholm, was a pioneer in the theory of integral equations. He studied at the Stockholm Polytechnic Institute, the University of Stockholm, and the University of Uppsala, from which he received his doctorate in 1898. The same year he was appointed lecturer in mathematical physics at the University of Stockholm, becoming professor there in 1906.

In the field of mathematical physics Fredholm's work on the deformation of anisotropic media (such as crystals) led him to the study of partial differential equations. His most important work was on integral equations, establishing the field in which David HILBERT was to do some of his greatest work. A number of results and concepts are named for him, including the *Fredholm integral equations* and the *Fredholm operator*.

**Frege, Gottlob** (1848–1925) *German philosopher and mathematician*

Born at Wismar in Germany, Frege (**fray-ge**) studied at the universities of Jena and Göttingen, where he obtained his PhD in 1873. He then returned to Jena as a lecturer, where he remained for the rest of his working life, rising to the position of professor in 1896. In a series of seminal works Frege laid the foundations of modern mathematical logic, transforming logic with an understanding of and notation for the problem of multiple generality – propositions containing predicates, quantifiers, and variables – and showing how the basic concepts and operations of mathematics could be formalized. He also revolutionized modern philosophy through his influence on the philosophy of language. However, Frege's work was almost completely ignored, misunderstood, or treated with hostility by his contemporaries – notable exceptions were Bertrand RUSSELL and Giuseppe PEANO.

In his first major work, *Begriffsschrift* (Concept Writing, 1879), he provided a new formalism containing an adequate symbolism and an axiomatic base for the rigorous derivation of both propositional and predicate logic. While a few workers, such as the American C. S. Pierce, had been moving in this direction, their work was completely overshadowed by the comprehensive nature of Frege's work.

In *Die Grundlagen der Arithmetik* (1884; The Foundations of Arithmetic) Frege gave a formal definition of cardinal number and showed how basic properties of numbers could be logically derived from it. In *Grundgesetze der Arithmetik*

(1893 and 1903; Basic Laws of Arithmetic) he went further in attempting to derive arithmetic from formal logic. The *Grundgesetze* is still regarded as a massive achievement, but his main aim was doomed to failure. On the eve of the publication of the second volume Russell wrote to Frege pointing out a contradiction – Russell's paradox – that could be derived from his system. This, as Frege acknowledged, vitiated his whole project.

**Fresnel, Augustin Jean** (1788–1827) *French physicist*

I must confess that I am greatly tempted to attribute the transmission of light and heat to the vibrations of a special fluid...One day the cause of electrical phenomena may well be sought in the disequilibrium of this fluid also.  
—On ether. Letter, 5 July 1814

Fresnel (**fray-nel**) was born in Broglie, France, and grew up in the time of the French Revolution; by the time he was 26, Napoleon had been exiled and Louis XVIII was on the throne. At this time Fresnel was a qualified engineer but, when Napoleon returned from Elba, Fresnel supported the royalists and lost his job as a result.

Fresnel started studying optics in 1814 and was one of the major supporters of the wave theory of light. He worked on interference, at first being unaware of the work of Thomas YOUNG, and produced a number of devices for giving interference effects. *Fresnel's biprism* is a single prism formed of two identical narrow-angled prisms base-to-base. Placed in front of a single source it splits the beam into two parts, which can produce interference fringes. Initially, Fresnel believed that light was a longitudinal wave motion, but he later decided that it must be transverse to account for the phenomenon of polarization.

Another important part of Fresnel's work was his development of optical systems for lighthouses. He invented the *Fresnel lens* – a lens with a stepped surface – to replace the heavy metal mirrors that were in use at the time.

**FRESNEL LENS** The stepped structure of a Fresnel lens.

Fresnel became a member of the French Academy of Sciences in 1823 and four years later, shortly before he died, the Royal Society awarded him the Rumford medal.

**Freud, Sigmund** (1856–1939) *Austrian psychoanalyst*

My life and work has been aimed at one goal only: to infer or guess how the mental apparatus is constructed and what forces interplay and counteract in it.

—Quoted by E. Jones in *Life and Work of Sigmund Freud* (1983)

The son of a wool merchant from Freiberg (now Příbor in the Czech Republic), Freud (froid) graduated from the University of Vienna with an MD in 1881 having also spent much time in the study of physiology. He worked at the Vienna General Hospital until 1885 and, after a further period of study in Paris under the neurologist Jean-Martin CHARCOT, set up in private practice in Vienna in the same year. He took the post of part-time head of the neurological outpatients clinic at the Children's Hospital and also held the position of *Privatdozent* in neuropathology at the University of Vienna.

Before Freud worked out the basic principles of psychoanalysis in the 1890s he had produced a substantial body of research in more orthodox fields. In addition to early work on comparative neuroanatomy, he discovered the euphoric effects of cocaine in 1884 and produced two sizable monographs – one on aphasia (1891) and the other on paralysis in children (1893).

By this time he had developed a more ambitious research program, clearly stated in his unpublished *Project for a Scientific Psychology* (1895). In this unfinished work he aimed to explain “the theory of mental functioning” in terms of quantitative physical concepts that would apply to both normal and abnormal psychology. To this end he went into considerable detail, even supposing the existence of three types of neurones with different physiological properties. Freud however drew back from such a neurological approach. In 1893 he collaborated with Josef Breuer on *The Psychical Mechanism of Hysterical Phenomena*, later expanded into *Studien über Hysterie* (1895; *Studies in Hysteria*, 1955), a work that marked the beginning of psychoanalysis. During the period 1892–95 Freud evolved his psychoanalytical method using the technique of free association. Following this he developed his theory that neuroses were rooted in suppressed sexual desires.

Freud's major work, *Die Traumdeutung* (1899; *The Interpretation of Dreams*, 1953), is regarded as his most original. In this he analyzed dreams in terms of unconscious desires and experiences. His other works included *Zur Psychopathologie des Alltagslebens* (1904; *Psy-*

*chopathology of Everyday Life*, 1960), *Totem und Tabu* (1913; *Totem and Taboo*, 1955), *Jenseits des Lustprinzips* (1920; *Beyond the Pleasure Principle*, 1955), and *Das Ich und das Es* (1923; *The Ego and the Id*, 1961).

In 1902 Freud established a circle of colleagues who met to discuss psychoanalytical matters once a week at his house. The group's original members were Alfred ADLER, Max Kahane, Rudolf Reitler, and Wilhelm Stekel. This grew, and later became the Vienna Psycho-Analytical Society (1908), and finally, the International Psycho-Analytical Association (1910). Freud, now becoming famous in Europe, made a tour of America in 1909 where he was well received. By 1911 the International Psycho-Analytical Association had begun to break up through differences of opinion, Carl JUNG and Alfred Adler being among the most significant to leave. However, by the 1920s Freud had become one of the most famous thinkers of the century.

In 1923 Freud was diagnosed as having cancer of the jaw. During the next 16 years he was to suffer more than 30 operations and be compelled to live with a prosthesis which, by substituting for his excised jaw and palette, allowed him to eat, drink, smoke, and talk.

In 1938 he was forced to leave Vienna by the Nazis for exile in London. He continued to see patients and to work on his last book, *Der Mann Moses und die monotheistische Religion* (1939; *Moses and Monotheism*, 1960), but within a matter of months it was clear to him that he could continue to work no more. It was then that he reminded his doctor: “My dear Schur...you promised you would help me when I could no longer carry on.” Schur honored his pledge with morphine ensuring a peaceful death.

**Freundlich, Herbert Max Finlay** (1880–1941) *German–American physical chemist*

Freundlich (**froit**-lik) was born at Charlottenburg, now a district of Berlin, Germany. He studied physical chemistry at Munich and at Leipzig where he became assistant to Wilhelm OSTWALD. From 1911 to 1917 he was professor at the Institute of Technology in Brunswick. He was professor at the Kaiser Wilhelm Institute, Berlin-Dahlem, from 1917 to 1934 when he left Germany because of the Nazi regime. He traveled first to Britain and worked at University College, London, and from 1938 to his death was professor of colloid chemistry at the University of Minnesota.

Freundlich's life work was in colloid chemistry. He showed how colloid stability was changed by the addition of electrolytes and he is well known for the *Freundlich adsorption isotherm*, a theoretical formula for the amount

of adsorption on a surface at constant temperature.

**Frey-Wyssling, Albert Friedrich** (1900–1988) *Swiss botanist*

Born in Küsnacht, Switzerland, Frey-Wyssling (fr-I-voos-ling) graduated in biology from the Federal Institute of Technology, Zurich, in 1923 and gained his PhD the following year. He then studied optics at the University of Jena, followed by plant physiology at the Sorbonne. From 1928 to 1932 he was plant physiologist at the Rubber Experimental Station in Medan, Sumatra, where he investigated latex flow. On his return to Switzerland he took up a lectureship at the Federal Institute of Technology, becoming professor of botany in 1938, and finally serving as rector from 1957 to 1967.

Frey-Wyssling was concerned about the rift in biology between histologists and biochemists and decided to help unite the two camps by promoting research in the intermediate area of submicroscopic morphology. To this end he reintroduced research with the polarizing microscope, using it to study, indirectly, the structure of macromolecules, which are beyond the resolving power of the light microscope. Many of his results were corroborated by the work of x-ray crystallographers, such as William ASTBURY, and later verified directly when the electron microscope was introduced in 1940. His work on “macromolecular chemistry” helped lay the foundations of ultrastructural research and molecular biology.

Frey-Wyssling published a number of books, including (with K. Mühlethaler) *Ultrastructural Plant Cytology* (1959) and *Plant Cell Walls* (1976).

**Friedel, Charles** (1832–1899) *French chemist*

After studying in his native city of Strasbourg with Louis PASTEUR and at the Sorbonne with Charles Adolphe WURTZ, Friedel (free-del) became curator of the mineral collections at the mining school in Paris (1856). Although his most important work was in organic chemistry, he also did much work on the synthesis of minerals. In 1862 he discovered secondary propyl alcohol, thus verifying Hermann KOLBE's prediction of its existence. His most notable work was that carried out with James CRAFTS on the alkylation and acylation of aromatic hydrocarbons – the *Friedel-Crafts reaction* (1877). This was a method of synthesizing hydrocarbons or ketones from aromatic hydrocarbons using aluminum chloride as a catalyst. Friedel and Crafts also did much work on the synthesis of organosilicon compounds. Friedel was professor of mineralogy at the mining school in Paris (1876–84) and professor of organic chemistry at the Sorbonne (1884–99).

**Friedländer, Paul** (1857–1923) *German organic chemist*

Friedländer (freed-lent-er) was assistant to Adolf von BAEYER at Munich during the latter's great researches on indigo, and much of Friedländer's work was concerned with indigo derivatives. He synthesized many derivatives and showed that the ancient dyestuff Tyrian purple is dibromoindigo (1909). He also developed a useful quinoline synthesis (1882). He was the holder of 235 patents concerned with dyestuffs.

**Friedman, Herbert** (1916–2000) *American physicist and astronomer*

Born in New York City, Friedman graduated from Brooklyn College in 1936 and obtained his PhD in 1940 from Johns Hopkins University, Baltimore. Shortly afterwards he joined the U.S. Naval Research Laboratory in Washington, where he spent his whole career, being appointed in 1958 as superintendent of the atmosphere and astrophysics division, and in 1963 superintendent of the space science division. Also in 1963 he became chief scientist at the E. O. Hulbert Center for Space Research. In addition he served as adjunct professor at the universities of Maryland and Pennsylvania.

Friedman was a pioneer in both rocket astronomy and in the study of the x-ray sky. The two went hand in hand in the early days of x-ray astronomy for without rockets it would have been impossible to detect any significant x-ray activity in space since x-rays are absorbed by the Earth's atmosphere. Solar x-rays were detected as early as 1948 by T. R. Burnright and were systematically investigated from 1949 by Friedman and his colleagues, who observed x-ray activity throughout a full solar cycle of 11 years. Friedman also studied ultraviolet radiation from the Sun, and in 1960 produced the first x-ray and ultraviolet photographs of the Sun.

X-ray astronomy really came of age in 1962 when nonsolar x-ray activity was first discovered by Bruno ROSSI. The x-rays came from a source in Scorpio, since named Sco X-1. A second source was discovered in 1963 in Taurus and named Tau X-1. Friedman made the first attempt to locate accurately an x-ray source two years later: when the Moon passed in front of the Crab nebula, a luminous supernova remnant in Taurus, the x-ray activity of Tau X-1 was found to fade out gradually. Tau X-1 was therefore identified with the Crab nebula and seemed to be a source about a light-year across lying in the center of the nebula.

Since then satellites carrying x-ray equipment have been launched, including Uhuru in 1970 and the Einstein Observatory in 1978. These have enormously extended the scope of x-ray astronomy and shown its value in the search for neutron stars and black holes.

**Friedman, Jerome Isaac** (1930– )  
*American physicist*

Chicago-born Friedman was educated at the university in his native city and gained his PhD there in 1956. After spending three years in California at Stanford, Friedman moved to the Massachusetts Institute of Technology in 1961, and was later appointed to a chair of physics in 1967. He is currently Emeritus Institute Professor of Physics at MIT.

Working with his MIT colleague Henry KENDALL and with Richard TAYLOR from Stanford, Friedman began to study the internal structure of the proton. They worked with the 3-kilometer linear accelerator recently opened at Stanford (SLAC). Electrons were accelerated to an energy of 20,000 million electronvolts and directed against a target of liquid hydrogen. In a manner reminiscent of the 1911 experiments of Ernest RUTHERFORD, they analyzed the angles and energies of the electrons and protons of the hydrogen nuclei as they scattered after collision. Similar experiments had been performed by Robert HOFSTADTER in the 1950s and he had found protons not to be mere points, but fuzzy blobs spread out over an area of about  $10^{-15}$  meter. In 1967, however, higher energies were available to Friedman and his colleagues, which led them to hope that they might see into the proton with a little more precision.

In cases of elastic scattering, where beam and target particles retain their identity, the deflections were minor and occurred as expected. When, however, the scattering was inelastic and the protons were struck with sufficient energy to produce new particles, such as pions, the electrons were deflected through much wider angles than expected.

These latter scattering results proved difficult to explain. A possible answer was proposed by Richard Feynmann in 1968 on a visit to SLAC. Protons, he suggested, could be composed of a number of pointlike particles, which he called "partons." From such charged points, electrons could be scattered through large angles. Further, it followed from the angular distribution of the scattered electrons that the partons must have a spin of one half.

As these were the properties calculated for the hypothetical quarks proposed by Murray GELL-MANN, the SLAC experiment was soon taken to be the first experimental evidence for the existence of quarks. It was for this work that Friedman shared the 1990 Nobel Prize for physics with his collaborators Kendall and Taylor.

**Friedmann, Aleksandr Alexandrovich** (1888–1925) *Russian astronomer*

Born the son of a composer in St. Petersburg, Russia, Friedmann (**freed**-man) was educated at the university there. He began his scientific

career in 1913 at the Pavlovsk Observatory in St. Petersburg and, after war service, was appointed professor of theoretical mechanics at Perm University in 1918. In 1920 he returned to the St. Petersburg Observatory where he became director shortly before his early death from typhoid at the age of 37.

Friedmann established an early reputation for his work on atmospheric and meteorological physics. He is, however, better known for his 1922 paper on the expanding universe. This arose from work of EINSTEIN in 1917 in which he attempted to apply his equations of general relativity to cosmology. Friedmann developed a theoretical model of the universe using Einstein's theory, in which the average mass density is constant and space has a constant curvature. Different cosmological models are possible depending on whether the curvature is zero, negative, or positive. Such models are called *Friedmann universes*.

**Friedmann, Herbert** (1900–1987) *American biologist and ornithologist*

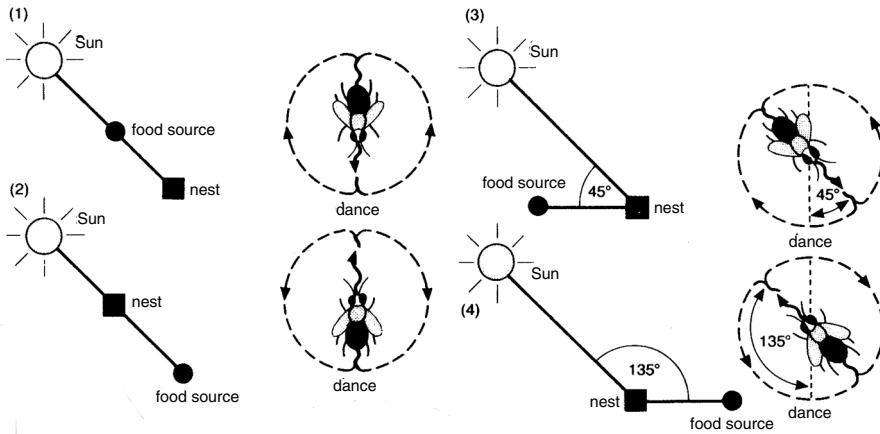

Born in New York City, Friedmann gained a PhD in ornithology from Cornell University in 1923; he then held a fellowship at Harvard for three years during which he spent much time in Argentina and Africa. After a series of academic posts he became, in 1929, curator of birds at the Smithsonian Institution, Washington, and was its head curator of zoology from 1957 to 1961.

Friedmann was especially interested in reproductive parasitism, particularly of birds, studying for example the African cuckoos and parasitic weaverbirds. He also investigated the parasitic honey guides, one species of which was observed to guide people to wild bees' nests. It had been thought that such birds fed on the honey of bee larvae and eggs, but Friedmann demonstrated the birds were actually after the beeswax. This discovery was particularly interesting as it had been assumed wax was indigestible. Friedmann went on to find that a wax-breaking bacterium, *Micrococcus cerolyticus*, was present in the birds' intestine.

Friedmann also investigated the systematics of birds of Africa, North America, and South America. His other work included studies of animal and plant symbolism in European medieval and Renaissance art.

**Fries, Elias Magnus** (1794–1878) *Swedish mycologist*

Fries (frees), who was born in Femsjö, Sweden, grew up in a region particularly abundant in fungi; this – together with botanical instruction he received from his father – resulted in his lifelong interest in mycology (the study of fungi). Fries entered Lund University in 1811, gradu-

**THE TAIL-WAGGING DANCE OF THE BEE** *The relationship between the angle of the straight run of the tail-wagging dance on the vertical surface of the comb and the angle between Sun, nest, and food source.*

ating in 1814 with a dissertation on the flora of Sweden. He continued at Lund until 1835, producing the three-volume *Systema Mycologicum* (1921–32; *A System of Mycology*), which classifies the fungi by their developmental stages and morphological relationships. This work remains the foundation of mycological taxonomy today for all but three groups of fungi.

Fries also produced an important work on the European lichens and issued floras spanning all of Scandinavia. In 1835 he took up the chair of botany at Uppsala University, becoming a member of the Linnean Society in the same year, and in 1875 he was elected a fellow of the Royal Society.

**Frisch, Karl von** (1886–1982) *Austrian zoologist, entomologist, and ethologist*

Frisch (frish) was born in Vienna, Austria, and educated at home and at convent school. He began his academic career by studying medicine at the University of Vienna, but gave this up to study zoology at the Zoological Institute in Munich, an internationally recognized center for research in experimental zoology. He also studied marine biology at the Trieste Biological Institute for Marine Research, taking his PhD for work on the color adaptation and light perception of minnows (1910). Frisch taught at the Munich Zoological Institute and in 1919 became assistant professor of zoology. He then held academic posts at the universities of Rostock and Breslau before returning to Munich in 1925 as director of the Zoological Institute where he continued to work until the end of World War II. In 1946 he assumed the chair of zoology at Graz but returned to Munich where he remained until his retirement in 1958.

Interested in animals from childhood, Frisch devoted 40 years to an intense study of the senses, communication, and social organization of honey (or hive) bees. By means of ingenious experiments he showed that bees can find their way back to the hive, even when the sun is obscured by cloud, by using polarized or ultraviolet light, and that they are able to communicate discovery of a new food source by means of a special “dance.” The bee performs its dance on the vertical surface of the comb. Depending on the distance of the food supply, the bee may perform either the round dance – food within about 80 feet (24 m) – or the tail-wagging dance – food beyond about 325 feet (99 m). At intermediate distances various transitional dance forms between these are seen. In the tail-wagging dance the bee makes a straight run over a short distance, wagging its abdomen rapidly, and then makes a semicircle back to the starting point. This movement is repeated, making a semicircle in the opposite direction. The dance gives information on the direction of the food supply because the angle that the straight run makes with the vertical surface of the comb is the same as the angle between the direction of the food and the Sun at the hive or nest.

Frisch also showed that the bees are unable to distinguish between certain shapes, that they have a limited range of color perception, but can see light of longer wavelength than man. They do not, for example, distinguish red but can see ultraviolet, which is reflected by many flowers. Red poppies are seen as wholly ultraviolet, while many yellow flowers are seen either as yellow or in varying shades of ultraviolet. Frisch’s discoveries have proved of practical benefit to beekeepers in that if hives are painted certain colors – a yellow hive next to a

blue one for example – this aids the bees' homing. His major contribution to ethology was recognized in 1973 when he was awarded the Nobel Prize for physiology or medicine, jointly with Konrad LORENZ and Nicolaas TINBERGEN. His books include *The Dancing Bees* (1927, trans. 1954) and *Animal Architecture* (1974).

**Frisch, Otto Robert** (1904–1979) *Austrian–British physicist*

A really good scientist is one who knows how to draw correct conclusions from incorrect assumptions.

—*What Little I Remember* (1979)

Frisch, the son of a Viennese printer and publisher, was educated at the University of Vienna where he obtained his doctorate in 1926. He was employed in Berlin (1927–30) at the German national physical laboratory, the Physikalisch Technische Reichsanstalt, and moved to the University of Hamburg in 1930. However, with the introduction of Hitler's racial laws, he was fired in 1933 and consequently traveled via Copenhagen to England. After working at the universities of Birmingham and Liverpool (1939–43) he moved to America and spent the period 1943–45 at Los Alamos, working on the development of the atom bomb. With the end of the war Frisch worked briefly at the Atomic Energy Research Establishment at Harwell, England, leaving in 1947 to take up the Jackson Chair of Physics at Cambridge, a post he held until his retirement in 1972.

In 1939 Frisch, with his aunt, Lise MEITNER, was closely involved in the crucial discovery of nuclear fission. He spent Christmas in Sweden visiting Meitner, who reported to him some strange results obtained by her former colleague Otto HAHN. Hahn found that when uranium was bombarded with neutrons, one of its decay products was the much lighter element barium. Frisch said that his first reaction was that Hahn had made a mistake, but Meitner was more inclined to trust Hahn's qualities as a good chemist. After some thought and calculation they concluded that this must in fact be what was later called nuclear fission. Frisch rushed back to Copenhagen to inform Niels BOHR who was able to confirm Hahn's experiments. But in all this excitement the most important point had been missed – the mechanism of the neutron chain reaction. However, the thought did occur independently to many others.

Frisch did further work on fission while at Birmingham, collaborating with Rudolph PEIERLS in confirming Bohr's suggestion that a chain reaction would be more likely to result with uranium-235 rather than with the more common isotope, uranium-238. After much work Frisch came to the basic and frightening conclusion that an "explosive chain reaction" could be produced with a pound or two of ura-

nium-235 rather than the tons of it which he first thought would be necessary. Frisch and Peierls were therefore probably the first two people in the world to be aware not just of the possibility of a nuclear bomb but of its practicality. They immediately wrote a report that was sent to Henry TIZARD, a scientific adviser to the British government, which Frisch claimed was decisive in getting the British Government to take the atomic bomb seriously.

In 1979 Frisch produced his fascinating and witty memoirs, *What Little I Remember*.

**Fritsch, Felix Eugen** (1879–1954) *British algologist*

Fritsch (frich), the son of a London headmaster, was educated at the University of London and at Munich, where he obtained his DPhil in 1899. He taught at University College, London, from 1902 until 1911, when he moved to Queen Mary College, London, where he served as professor of botany from 1924 until his retirement in 1948.

Before Fritsch there was no comprehensive work on algae. He remedied this with his classic work *The Structure and Reproduction of the Algae* (2 vols. 1935–45). He was also instrumental in the foundation of the Freshwater Biological Association in 1929.

**Fritsch, Gustav Theodor** (1838–1927) *German ethnographer, anatomist, and neurologist*

Fritsch, the son of a building inspector from Cottbus, near Berlin in Germany, was educated at the gymnasium in Breslau and the University of Berlin where he obtained his MD in 1862. From 1867 to 1900 Fritsch worked at the Institute of Anatomy in Berlin, also becoming head of the histological section at the Physiological Institute.

Fritsch was a much traveled ethnographer. From 1863 to 1866 he was in South Africa where he made a careful study of the anatomy and culture of the Bushmen. He also made research expeditions to Egypt, Syria, and Persia. He is however best known for his collaboration with Eduard HITZIG in 1870 in which they clearly demonstrated the phenomenon of cerebral localization.

**Frontinus, Sextus Julius** (c. 35 AD–c. 104 AD) *Roman engineer*

Frontinus (fron-tIn-us), praetor in 70 and consul in 74, was governor of Britain from 74 until 78, during which time he subdued the Silures. In 97 he was appointed *curator aquarum* and went on to write an account of the Roman water supply in his *De aquis urbis Romae* (On the Aqueducts of Rome), the main source of information on the water-supply systems of his time.

He devised a method for measuring water

flow based upon a standard pipe called a *quinaria*, made from bronze and about 2 centimeters in diameter and 22 centimeters long. Using figures derived from Frontinus it has been calculated that a Roman citizen used as much water daily as a modern European.

**Fuchs, Klaus Emil Julius (1911–1988)**  
*German physicist*

Born the son of a Lutheran pastor in Russellheim, Germany, Fuchs (fuuks) was educated at the universities of Kiel and Leipzig. Originally a Social Democrat, Fuchs joined the Communist Party in 1932 as an expression of his strong opposition to the Nazis. Following the Reichstag fire in 1932, and the occasional beating up, Fuchs fled to Britain in 1933. He soon found a job as assistant to Nevill MOTT in Bristol where he began to work for his PhD. He remained there until 1937 when he moved to Edinburgh to a research post under Max BORN.

On the outbreak of war Fuchs was interred as an enemy alien, first on the Isle of Man, and soon after in Canada. The detention camp contained one future Nobel laureate, Max PERUTZ, two founders of the Steady State Theory, Thomas GOLD and Hermann BONDI, and, surprisingly, three rabbis. The authorities, under pressure from Born, released Fuchs in late 1941.

In 1940 Otto FRISCH and Rudolph PEIERLS had calculated that only a relatively small amount of uranium-235 would be necessary to produce an atomic bomb. They were asked by the government to continue their work and Peierls invited Fuchs to join him in Birmingham to work on the project. The British intelligence agency, MI5, although familiar with Fuchs's background, raised no objections to his appointment.

Following the German invasion of the Soviet Union in June 1941 Fuchs made his first contact with the Soviet Embassy and began to pass information to them later in the year. Soon after, in 1942, Fuchs became a British citizen. By this time the center of research had moved to America and, in 1943, Fuchs followed it, first to New York, and eventually to Los Alamos where he worked in the Theoretical Physics Division under Hans BETHE on the actual design and construction of the bomb. Once more he made contact with Soviet agents.

By this time Fuchs knew as much about the bomb as almost anyone else on the project. He learned that two bombs were being developed, namely, the original uranium bomb and a plutonium device. He also gathered details about complicated ignition devices needed to explode the bombs. Fuchs further heard of plans to build the "Super," a fusion (hydrogen) bomb. All information that came his way was passed to his connection. He was offered, but refused, \$1,500 for his efforts.

Following the successful explosions of both atomic bombs in 1945, and the end of the war, Fuchs returned to Britain and in the following year was appointed Head of the Theoretical Division at the Atomic Energy Research Establishment, Harwell. It was at Harwell that Britain's own atomic weapons would be made; it was also from Harwell that Fuchs informed his Soviet contact of Britain's plans.

But new forces were at work in Fuchs's life. He was becoming increasingly discontented with his own duplicity. He seems to have felt a genuine personal loyalty to his Harwell colleagues, and he was looking for ways to withdraw from his espionage activities. However, by this time, the security forces had become aware that a high-level scientific spy was passing atom secrets to the Soviet Union. Suspicion fell on Fuchs and after some initial questioning by MI5 he confessed everything. He was arrested, tried, and in 1950 was sentenced to fourteen years' imprisonment and the loss of his British citizenship.

He served eight years and, on his release in 1959, Fuchs headed straight for East Germany. He was granted citizenship and allowed to join the Communist Party. Until his retirement in 1979, the much honored and bemedalled Fuchs served as Deputy Director of the Institute for Nuclear Research, Rossendorf. He died suddenly in 1988. Had he lived a little longer Fuchs would have seen the collapse of the communist system that he had served so faithfully and so long.

**Fuchs, Leonhard (1501–1566)** *German botanist and physician*

Fuchs was born in Wemding, Germany, and was professor of medicine at Tübingen University from 1535 until his death, his main interest being the medicinal properties of plants. He is remembered for his herbal manual *De historia stirpium* (1542; *On the History of Roots*), in which about four hundred native and a hundred foreign plants are arranged alphabetically, with original descriptions of the form, habitat, and best season for collection of each plant. The herbal is notable for its glossary of botanical terms, accurate woodcut illustrations, and detailed descriptions.

A genus of ornamental shrubs, *Fuchsia*, is named for him.

**Fuchs, Sir Vivian Ernest (1908–1999)**  
*British explorer and geologist*

Fuchs, the son of a farmer of German origin, was born at Freshwater in England. He was educated at Cambridge University where he obtained his MA in geology in 1929 and his PhD (1935). From 1929 he traveled on a series of expeditions as geologist, the first being the Cambridge East Greenland Expedition (1929). In

1947 he became a member of the Falkland Islands Dependencies Survey, and from 1951 to 1960 its director. He also served as director of the British Antarctic Survey from 1958 to 1973.

As a result of his involvement with the survey, Fuchs was made leader of an expedition to Graham Land in Antarctica (1948) to reassert the British claim to the territory, which was being challenged by Argentina. He was stranded on Storington Island by bad weather until 1950.

Fuchs is best known for the Commonwealth Trans-Antarctic Expedition he jointly led with Edmund Hillary in the International Geophysical Year (1957–58). Leaving Shackleton Base on the Weddell Sea on 24 November 1957, he reached the South Pole and met Hillary on 19 January 1958, then continued to reach Scott Base, Victoria Land, on 2 March. From the scientific studies made during this it was established that a single continent exists below the polar ice cap.

Fuchs was knighted in 1958.

**Fukui, Kenichi** (1918–1998) *Japanese theoretical and physical chemist*

Born in Nara, Japan, Fukui (foo-koo-ee) was a lecturer in chemistry at Kyoto Imperial University, becoming professor of physical chemistry from 1951 to 1982. He is noted for his theoretical work on the change in molecular orbitals during reactions, especially reactions of methyl radicals. He also investigated the reaction of molecular nitrogen with transition-metal complexes – a topic potentially important for the fixation of nitrogen.

For his work on frontier orbital theory, Fukui shared the 1981 Nobel Prize for chemistry with Roald HOFFMANN.

**Funk, Casimir** (1884–1967) *Polish–American biochemist*

Funk (fuungk), born the son of a dermatologist in the Polish capital of Warsaw, obtained his doctorate from the University of Bern in 1904. He worked at the Pasteur Institute in Paris, the University of Berlin, and the Lister Institute in London, before emigrating to America in 1915. Although he became naturalized in 1920, Funk returned to Poland in 1923 as director of the Warsaw Institute of Hygiene, but finding the political conditions unattractive moved to Paris in 1927, where he acted as a consultant to a drug company and founded a private research institute, the Casa Biochemica. In 1939 Funk returned to America, where he served as consultant to the U.S. Vitamin Corporation and as president of the Funk Foundation for medical research.

It was while working at the Lister Institute in 1912 that Funk first clearly formulated his crucial idea that certain diseases are caused by food deficiencies. He was working on the antiberiberi factor, which he succeeded in extracting from rice husks. He went on to postulate that there were comparable ingredients whose absence from a regular diet would produce scurvy, rickets, and pellagra.

Noting that the antiberiberi factor contained an amine ( $-NH_2$ ) group, Funk proposed to call such ingredients “vital amines,” or “vitamines.” When it became clear that the amine group was not present in all “vitamines” the term “vitamin” came to be preferred.

**Furchgott, Robert F.** (1916– ) *American pharmacologist*

Furchgott was born in Charleston, South Carolina, and graduated with a BS in chemistry from the University of North Carolina in 1937. Three years later he gained his PhD in biochemistry at Northwestern University. From 1956 to 1988 he worked in the department of pharmacology at the State University of New York, and since 1988 has been Distinguished Professor, State University of New York Health Science Center. In 1998 he shared the Nobel Prize for physiology or medicine with Louis IGNARRO and Ferid MURAD for their discovery that molecules of the gas nitrogen monoxide (nitric oxide, NO) can transmit signals in the cardiovascular system.

Nitrogen monoxide, produced by one cell, acts by penetrating membranes and regulating the function of another cell. Nerves and hormones are well known as signal carriers, but this discovery was a totally new signaling principle in a biological system.

Furchgott began by researching the actions of drugs on blood vessels, but often observed contradictory results. Sometimes a drug acted to contract a vessel, but at other times it dilated the vessel. In 1980 he discovered that the neurotransmitter acetylcholine did not act to dilate blood vessels if the endothelium (surface cells) of the receiving vessel were damaged. He deduced that the cells of the endothelium produce another hitherto unknown signal substance that makes the smooth muscle cells of the vascular system relax. He called the substance endothelium-derived relaxing factor (EDRF). By 1986 he had shown that the substance was in fact the simple compound nitric oxide (NO). Furchgott was awarded the 1998 Nobel Prize for physiology or medicine for this discovery. The prize was shared with Louis Ignarro and Ferid Murad.

## **Gabor, Dennis** (1900–1979) *Hungarian–British physicist*

The most important and urgent problems of the technology of today are no longer the satisfactions of the primary needs or of archetypal wishes, but the reparation of the evils and damages wrought by the technology of yesterday.

—*Innovations: Scientific, Technological and Social* (1970)

Short of a compulsory humanistic indoctrination of all scientists and engineers, with a “Hippocratic oath” of never using their brains to kill people, I believe that the best makeshift solution at present is to give the alpha minus alternative outlets for their dangerous brain-power, and this may well be provided by space-research.

—*Inventing the Future* (1964)

Gabor (**gah**-bor or **ga**-bor), the son of a businessman, was born in the Hungarian capital of Budapest; he was educated at the technological university there and in Berlin, where he obtained a doctorate in engineering in 1927. He worked initially as a research engineer for Siemens and Halske from 1927 until 1933 when, with the rise of Hitler, he decided to leave Germany and took a post with the British Thomson–Houston Company, Rugby. In 1948 he joined the staff of Imperial College, London, later serving as professor of applied electron physics from 1958 until his retirement in 1967.

Gabor is credited with the invention of the technique of holography – a method of photographically recording and reproducing three-dimensional images. The modern technique uses lasers to form such images, but the invention came out of work by Gabor on improving the resolution of the electron microscope – work done in 1948, twelve years before the introduction of the laser.

The electron microscope has theoretically much higher resolution than the optical microscope because of the shorter wavelength of electrons (resolution is limited by diffraction effects). One method of improving the resolution of the electron microscope is to improve the electron lenses used to deflect and focus the beam of electrons. Gabor was interested in increasing the resolution to the point at which atoms in a lattice could be “seen.” Rather than work on the electron optics of the system, he had the idea of extracting more information

from the electron micrographs produced by existing instruments, and to do this he proposed forming a diffraction pattern between the incident beam of electrons and a background beam that was coherent with it (i.e., one with the same wavelength and phase). The principle was that the image produced would have information on the phase of the electrons as well as the intensity and that it would be possible to reconstruct a true image from the resulting electron micrograph.

Gabor began experiments with light to investigate the technique (which he named holography from the Greek *holos* meaning whole – the record contained the whole information about the specimen). He used a mercury lamp and pinhole to form the first, imperfect, holograms. Subsequently, in 1961, E. Leith and J. Upatnieks produced holograms using laser light. The technique is to illuminate a specimen with light from a laser and form an interference pattern between light reflected from the specimen and direct light from the source, the pattern being recorded on a photographic plate. If the photographic record is then illuminated with the laser light, a three-dimensional image of the specimen is generated.

Gabor received the Nobel Prize for physics for his work in 1971.

## **Gabriel, Sigmund** (1851–1924) *German chemist*

Gabriel (**gab**-ri-**el**) studied under August von Hofmann in his native Berlin and under Robert BUNSEN in Heidelberg. He returned to Berlin in 1874, being appointed to the chair of chemistry there in 1886.

In 1880 Zdenko SKRAUP had succeeded in synthesizing the heterocyclic compound quinine. Gabriel helped work out the chemistry of such structures by synthesizing isoquinoline in 1885. Isoquinoline is the parent substance of several opium alkaloids. In 1887, he also worked out methods for the synthesis of primary amines from haloalkanes and potassium phthalimide with subsequent hydrolysis.

## **Gadolin, Johan** (1760–1852) *Finnish chemist*

Gadolin (**gad**-o-**lin**) was born the son of an as-

tronomer and physicist in Åbo, now Turku in Finland. He studied under Torbern BERGMAN at Uppsala and taught at Åbo from 1785, becoming professor of chemistry from 1797 until 1822.

In 1794 Gadolin examined a black mineral from Ytterby, a quarry in Sweden. The rocks from this quarry were found to contain a dozen or so new elements. Gadolin isolated the first lanthanoid element from it in the form of its oxide and named it yttria. The element was named gadolinium after him in 1886 by Lecoq de Boisbaudran. Gadolin also worked on specific heat and published a set of standard tables.

### **Gaffky, Georg Theodor August** (1850–1918) *German bacteriologist*

Gaffky (**gahf**-kee) was born in Hannover, Germany, and educated at the University of Berlin where, after service in the Franco–Prussian War, he obtained his MD in 1873. He served as Robert KOCH's assistant from 1880 to 1885 and, after holding the chair of hygiene at the University of Giessen (1888–1904), succeeded Koch in Berlin as director of the Institute for Infectious Diseases, renamed the Koch Institute in 1912.

In 1880 Carl Eberth had first described the microorganism responsible for typhoid fever. As it was easily confused with several other intestinal organisms, it was only when Gaffky succeeded in obtaining a pure culture in 1884 that Eberth's work could be confirmed.

Gaffky also served on a number of important field investigations. He was with Koch on his trips to Egypt and India in 1883–84, during which the vibrio responsible for cholera was discovered, and wrote the official report of the investigation. Gaffky made a further trip to Egypt in 1897 to work on the bubonic plague.

### **Gahn, Johan Gottlieb** (1745–1818) *Swedish chemist and mineralogist*

A number of entirely new minerals were discovered ... and analysed at the time in Gahn's excellently equipped laboratory.  
—Jöns Jacob Berzelius, *Autobiographical Notes* (1816)

Born at Voxna in Sweden, Gahn (gahn) graduated from the University of Uppsala in 1770 and then taught at the College of Mines. Working with Karl SCHEELE, he showed that phosphorus is present in bones (1770). He also first isolated the element manganese, suspected by Scheele to be present in pyrolusite – an oxide known to the ancients and used chiefly to color glass. Gahn's extraction involved igniting a paste of pyrolusite (manganese(IV) oxide) and charcoal. Gahn also contributed to the discovery of selenium by Jöns Berzelius in 1818.

He became superintendent of mines in 1782

and later became a mine owner himself. The mineral ghanite (zinc spinel) is named for him.

### **Gajdusek, Daniel Carleton** (1923– ) *American virologist*

Gajdusek (**gI**-duu-shek) was born at Yonkers in New York and educated at the University of Rochester and at Harvard, where he obtained his MD in 1946. He specialized in pediatrics, working at Harvard, the Pasteur Institute in Teheran, and the Walter and Eliza Hall Institute for Medical Research in Melbourne, before joining the National Institutes of Health in Bethesda, Maryland, in 1958. Since 1970 he has been with the National Institute of Neurological Diseases.

In 1963 he made an intriguing discovery that could well have profound consequences for the control of a number of serious but little-understood diseases. In the 1950s he began studying the Fore people of New Guinea, a supposedly cannibalistic tribe who suffered from a very localized neurological complaint they called "kuru." With the aid of the district medical officer, who first drew his attention to the disease, Gajdusek spent much of the next ten years among the Fore looking for the cause of kuru. He suspected the disease was transmitted by the Fore custom of ritually eating parts of the brain of their deceased relatives, so he collected samples from the brains of several kuru victims.

Failing to detect any obvious signs of an organism in the brain tissue, he injected filtered extracts into the brains of chimpanzees and waited. After about 12 months the disease at last appeared. This was the first of the so-called "slow virus infections" to be observed in humans. By 1968 Gajdusek and his colleagues had shown that kuru was not unique and that the rare neurological complaint Creutzfeldt-Jakob disease, a presenile dementia, is transmitted after a comparable delay. This immediately opened the still unresolved question as to whether such complaints as Parkinson's disease and multiple sclerosis are also due to slow viruses.

For his work on kuru Gajdusek shared the 1976 Nobel Prize for physiology or medicine with Baruch BLUMBERG. The prize itself he used to set up a trust for the education of the Fore people.

In his work in New Guinea Gajdusek had brought back more than 50 children to America, where he cared for them and paid for their education. In 1996 he was accused of molesting one teenager whom he had brought back some years before. Gajdusek pleaded guilty and spent a year in prison.

### **Galen** (c. 130–c. 200) *Greek physician*

That physician will hardly be thought very

careful of the health of others who neglects his own.

—*Of Protecting the Health*, Bk. V

Galen (**gay**-len) was educated as a doctor supposedly because his father had a dream in which Asklepios, the god of medicine, appeared to him. After an initial period of training in his native city of Pergamum (now Bergama in Turkey), Galen spent the years 148–57 traveling and studying at Corinth, Smyrna, and Alexandria. He then returned home and took the post of surgeon to the Pergamum gladiators. Eventually Galen left for Rome where he made a considerable reputation for himself serving the emperors Marcus Aurelius and Commodus.

In addition to his imperial duties Galen wrote extensively and more than 130 of his texts have survived. Even though some are undoubtedly spurious, there still remains an impressive opus on virtually every aspect of the medicine of his times.

It is this opus that acquired an unprecedented authority, which persisted, unopposed, for another 1,500 years. It was not until William HARVEY proposed his new theory of the circulation of the blood (1628) that anatomists were presented with a viable alternative to the traditional system of Galen.

Galen made few advances in pathology, believing as he did in HIPPOCRATES's humoral theory – that disease is caused by an imbalance of the four body humors; phlegm, black bile, yellow bile, and blood. It was as an anatomist that Galen's true originality lay. He stressed the importance of dissecting personally and frequently, and combined his anatomical studies with a number of neat and conclusive experiments. Thus he clearly demonstrated the falsity of ERASISTRATUS's view that the arteries carry air not blood by placing ligatures both above and below the point of incision and noting the absence of any air escaping before the discharge of blood. Also, by similar experiments he was able to show that urine passes from the kidneys to the bladder irreversibly down the ureters.

Galen however was less successful in describing the complete system and operation of the body. He thought that blood was made in the liver from the food brought by the portal vein from the stomach. This was then transported by the venous system to nourish all parts of the body. Some of the blood however passed along the vena cava to the right side of the heart where it passed to the left side by some supposed perforations in the dividing wall or septum. Belief in such perforations persisted well into the 16th century. In the left ventricle the blood was mixed with air brought from the lungs and distributed round the body via the arterial system carrying the vital spirit or innate heat. Some of this blood was carried by the arteries to the head where in the *rete mirabile* (a vascular network not actually found in man) it was mixed with animal spirit and distrib-

uted to the senses and muscles by the supposedly hollow nerves. It was this spirit or pneuma that produced consciousness.

Thus instead of a single basic circulation Galen has a tripartite system in which the liver, heart, and brain each inject into the body three different spirits – natural, vital, and animal, which travel through the body via the venous, arterial, and nervous channels respectively. Although such a scheme is now recognized as totally misguided it possessed sufficient plausibility and experimental support to persist into the 17th century.

### Galileo (1564–1642) *Italian astronomer and physicist*

In questions of science the authority of a thousand is not worth the humble reasoning of a single individual.

—Quoted in *Smithsonian Report* (1874)

I wish, my dear Kepler, that we could have a good laugh together at the extraordinary stupidity of the mob. What do you think of the foremost philosophers of this University? In spite of my oft-repeated efforts and invitations, they have refused, with the obstinacy of a glutted adder, to look at the planets or the moon or my glass [telescope].

—*Works*

Galileo (gal-i-**lay**-oh or gal-i-**lee**-oh), whose full name was Galileo Galilei (gal-i-**lay**-ee), made major contributions to most branches of physics (especially mechanics), invented and so deployed the telescope to change our view of the nature of the universe completely, and became engaged in a highly dramatic confrontation with the Church.

Born in Pisa, Italy, Galileo was the son of a scholar and musician of some distinction. He entered the University of Pisa in 1581 to study medicine – a subject in which he showed little interest – and failed to complete the course, developing instead a passion for mathematics. He is thought to have made his first important observation in 1583, two years before he left the university. While in Pisa cathedral he noticed that the lamps swinging in the wind took the same time for their swing whatever its amplitude. He timed the swing against his pulse. In 1586 he invented a hydrostatic balance for the determination of relative densities. In 1589 he was appointed to the chair of mathematics at Pisa and later moved to the chair in Padua, in 1592.

It was while in Padua in 1610 that he designed and constructed a simple refracting telescope. He may not have been the first to do so, and there are many other claimants, but he was certainly the first to use the instrument constructively. His initial reaction was sheer amazement at the number of stars in the sky, “So numerous as to be almost beyond belief,” he asserted. Merely looking at the Moon immediately revealed that it is not the smooth un-

changeable object of Aristotelian theory. He also discovered sunspots. His most exciting moment came in January 1610, when he observed Jupiter for the first time telescopically. To his astonishment he found that the planet has four satellites. Contrary to received opinion as to what was possible, these were new bodies, unmentioned in ARISTOTLE, and certainly not circling the Earth. He published his observations immediately, in 1610, in *Sidereus nuncius* (Starry Messenger), dedicating them to his patron and former pupil Cosimo II of Tuscany, in whose honor he named the satellites *Sidera Medicea* (Medici Stars). Within weeks he had received an invitation to a well-paid research chair in Pisa and returned there at the end of 1610.

In a series of works he was also tackling the problem of motion. His mature views were expressed in his *Discorsi...a due nuove scienze ...* (1638; Discourse on Two New Sciences). In a series of brilliant experiments rolling balls down inclined planes (and not, as is commonly thought, by dropping weights from the leaning tower of Pisa) he showed that the speed with which bodies fall is independent of their weight and correctly formulated the law  $s = 1/2at^2$  (where  $s$  is speed,  $a$  acceleration, and  $t$  time). He lacked the concept of inertia and could only accept circular motion as being natural since, for Galileo, a body without any force acting on it would move in perfect circular motion. This was one aspect of his medieval heritage from which he was unable to break away.

After his return to Pisa, Galileo was beginning to meet opposition. Some of this was merely personal; in his criticism of others he wrote with a wit and savagery that many found wounding and impossible to forgive. He also found himself in dispute with many over his numerous discoveries. In these he was never inclined to take a charitable view over the claims of others, and there were many waiting for a chance to humiliate him on his return from the safety of Padua (then part of the independent Venetian republic). Their chance was his open support for the Copernican system. That the Earth moves round the Sun was so contrary to Scripture for many churchmen that those who enthusiastically campaigned for such a view were seen as heretics if not atheists. Galileo made no secret of his views in his writings, talk, and lectures. He openly ridiculed the Aristotelian scholars and supporters of the Ptolemaic (geocentric) system, many of whom were, or were to become, high officers of the Church. To stop the squabbling, Pope Paul V, on the advice of Cardinal Bellarmine, placed COPERNICUS on the Index (a list of books banned by the Catholic Church) in 1616, summoned Galileo to Rome, and informed him that he could no longer support Copernicus publicly. At this point Galileo had no choice; continued support for Copernicus would be to call the authority of

the pope into question and to send him to the stake as it had sent Giordano BRUNO in 1600.

In 1623 an old friend of Galileo's, Cardinal Barberini, was elected pope as Urban VIII. Galileo wasted no time in dedicating his new book *Il sagggiatore* (1623; The Assayer) to him. It was a work that was savagely critical of Aristotle's account of comets. Although Urban was not prepared to go back on the decision of 1616 publicly, Galileo seems to have thought that he would be safe unless he supported Copernicus specifically. One thing that should have made him more prudent was the death of his patron, Cosimo, and the succession of a powerless minor to the duchy of Tuscany.

Galileo thought he could avoid the problem by writing a dialogue between a (Ptolemaic-) Aristotelian and a Copernican without ostensibly committing himself to either side, and the Church gave him permission to do so. Thus he wrote the *Dialogue Concerning the Two Chief World Systems* (1632). However, the form of the dialogue fooled no one. The Aristotelian, Simplicius, is no match for the brilliance of the Copernican, Salviati. It was even suggested to the pope that the bumbling Simplicius was a portrait of Urban himself. Galileo was once more summoned to Rome, threatened with torture, and forced to renounce Copernicus in the most abject terms. There is a tradition that after his renunciation he whispered, "Eppur si muove" ("Yet it moves"), but this is unlikely. Galileo was truly frightened, and it must be remembered that he was nearly 70 years old and facing a powerful body, which might have tortured and burned him at the stake. In the end he was treated reasonably well. He was allowed to return to his villa at Arcetri in isolation. Later, after he became blind and after the death of his daughter, his disciples Vincenzo VIVIANI and Evangelista Toricelli were allowed to stay with him.

### **Gall, Franz Joseph** (1758–1828) *German physician and anatomist*

The author of the true anatomy of the brain.

—Jean Pierre Marie Flourens, *On Phrenology and Genuine Studies of the Brain* (1863)

Born in Tiefenbronn, Germany, Gall (gahl) studied medicine at Strasbourg and then Vienna, where he obtained his MD in 1785 and set up practice. In 1805, seeking a less restrictive scientific community, he left Vienna, where his lectures had been forbidden by the chancellor and after a European tour settled in Paris in 1807.

Although Gall is largely remembered as the founder of phrenology, now a totally discredited system, his crucial place in the development of cerebral localization is little known. Gall began as a conventional anatomist and established that the white matter of the brain consists of nerve fibers. However, he was dis-

tracted from such work by a couple of chance observations.

He noted that the two acquaintances of his with the best memory both had prominent staring eyes. This impressed him to search for cases of distinct traits or skills being linked with a distinctive physiognomy. This path led to him linking specific parts of the brain with specific behavior, a theory that could have been a major advance in anatomy, if properly handled. Unfortunately Gall went too far, recognizing 27 faculties. His collaborator Johann Spurzheim, who worked closely with him for several years and actually coined the term phrenology, added a further eight faculties. The evidence for these was largely anecdotal and uncritically accepted. Thus paintings of the great depicting the appropriate bump would confirm the theory; if, however, the bump was missing this would merely show the painter was working according to standards of beauty not truth.

Operations to test the theory were later performed by Pierre Flourens and tended not to support Gall. It was not in fact until 1861 that Paul BROCA obtained any hard surgical evidence for the localization of cerebral faculties while the full proof of the hypothesis had to wait for the work of Gustav FRITSCH and Edward HITZIG in 1870.

### **Galle, Johann Gottfried (1812–1910)** *German astronomer*

Returning with the chart to the telescope I discovered a star of the eighth magnitude – not at first glance, to tell the truth, but after several comparisons. Its absence from the chart was so obvious that we had to try to observe it.

—On the discovery of Neptune. *Astronomical News* (1877)

Born at Pabsthaus, in Germany, Galle (**gahl**-e) was chief assistant to Johann ENCKE at the Berlin Observatory at a crucial moment in the history of planetary astronomy. Urbain LE VERRIER had worked out what he considered to be the position of an as yet undiscovered planet. Having had some contact with Galle, Le Verrier wrote to him on 18 September 1846, asking him to try to check his prediction. Galle started observing on 23 September. He was favored by having an unpublished copy of a new star chart covering the right part of the sky and, aided by Louis D'Arrest, he found a star that was not on the chart. A wait of 24 hours showed that it had moved against the background of the fixed stars and so was a planet – it was the planet Neptune.

Galle also made an important contribution to determine the mean distance of the Sun from the Earth (the astronomical unit or AU). Conventional means of determining the AU had leaned heavily on the two transits of Venus in each century. In practice it turned out to be dif-

ficult to measure accurately the moment of first contact. Galle proposed instead, in 1872, that measuring the parallax of the planetoids would give a more reliable figure. (Harold SPENCER JONES followed this procedure in 1931 when the planetoid Eros came within 16 million miles of the Earth. He was able to calculate the AU to within 10,000 miles.) In 1851 Galle became director of the Breslau Observatory. He lived long enough to receive the congratulations of the astronomical world on the 50th anniversary of the discovery of Neptune in 1896.

### **Gallo, Robert Charles (1937– )** *American physician*

The son of a metallurgist, Gallo was born at Waterbury in Connecticut and educated at Providence College, Rhode Island, and Jefferson Medical College, Philadelphia, where he received his MD in 1963. He served his internship at the University of Chicago. In 1965, Gallo joined the staff of the National Cancer Institute at the National Institutes of Health, Bethesda, Maryland, and since 1972 he has been head of the Institute's Tumor Cell Biology Laboratory.

Gallo is noted as one of the people who first identified the virus responsible for AIDS. The discovery came out of work in his laboratory on leukemia. The first success by Gallo's team was the identification in 1976 of interleukin-2, a factor that stimulates growth in the lymphocytes known as T-cells. This was followed in 1979 by the crucial discovery of the first human retrovirus, HTLV-1 (human T-cell lymphotropic/leukemia virus). Retroviruses were first described in 1970 by TEMIN and Baltimore and, unlike other viruses, their genetic material is encoded in DNA rather than RNA. HTLV-1 and another virus discovered by Gallo in 1982, HTLV-2, both cause rare forms of leukemia.

In the early 1980s concern was growing about the emergence and spread of AIDS, a disease characterized by suppression of the patient's immune system. Gallo was aware that HTLV viruses acted by attacking the immune system of leukemia patients. He made the bold conjecture that AIDS was caused by yet another retrovirus recently discovered in his laboratory, namely, HTLV-3. Similar conclusions were reached by Luc MONTAGNIER at the Pasteur Institute in Paris, who had succeeded in isolating a retrovirus from an AIDS patient. He named the virus LAV (lymphadenopathy associated virus) and sent Gallo a sample in September 1983.

Gallo began work on finding a test for the AIDS virus. At first the virus proved impossible to grow in sufficient quantities, until Mika Popovich in Gallo's laboratory found a particular strain of T-cell (HUT-78 H9) in which the virus replicated without killing the cell. It was consequently a relatively simple matter, once

large amounts of virus were available, to test for antibodies in AIDS sufferers' blood.

In April 1984, before Gallo had published his results, the U.S. Department of Health announced that he had found the cause of AIDS, HTLV-3, and took out patents on Gallo's blood test for AIDS antibodies. Gallo published his results in May 1984. He pointed out that he had identified the virus in 48 out of 167 cases from a risk group and that no evidence of its presence was found in the blood of "115 healthy heterosexuals."

The award in May 1985 of an exclusive patent for Gallo's test provoked a strong response from the Pasteur Institute. They argued that Gallo's blood test was based upon a virus substantially identical to the LAV strain first isolated by Montagnier. The Institute sued the U.S. Government, and heads of state became involved in the dispute. The issue was finally resolved in 1986 at a meeting in Frankfurt between Gallo and Montagnier. An agreed chronology about the discovery was established and it was also decided that 80% of royalties from the test should go to a new AIDS research foundation. The names of both Gallo and Montagnier would appear on the patent. The issue of the name of the AIDS virus was resolved in 1986 when the International Committee on the Taxonomy of Viruses diplomatically ignored both LAV and HTLV-3 and proposed the name HIV (human immunodeficiency virus).

Gallo's work made him the most cited scientist of the decade with the 418 papers he published between 1981 and 1990 gaining 36,789 citations. He has published a full and popular account of his work in *Virus Hunting: AIDS, Cancer and the Human Retrovirus* (1991).

### **Galois, Evariste** (1811–1832) *French mathematician*

A mind that had the power to perceive at once the totality of mathematical truths – not just those known to us, but all the truths possible – would be able to deduce them regularly and, as it were, mechanically ... but it does not happen like that.

—*Writings and Mathematical Memoirs of Evariste Galois*

Science progresses by a series of combinations in which chance does not play the smallest role; its life is unreasoning and planless and resembles that of minerals that grow by juxtaposition.

—As above

Galois (ga-**lwah**) was born at Bourg-la-Reine, near Paris, France, during the rule of Napoleon. He entered the Collège Royale de Louis-le-Grand in Paris in 1823 and it was here that his precocious mathematical genius first emerged. He published several papers while still a student and at the age of about 16 embarked upon his noted work on algebraic equations. But his career was marred by lack of advancement, as-

sociated with political bitterness. Twice, in 1827 and 1829, he was rejected by the Paris Ecole Polytechnique, and three papers submitted to the Academy of Sciences were rejected or lost. In 1830 he entered the Ecole Normale Supérieure to train as a teacher. That year revolution in Paris caused the abdication of Charles X, who was succeeded by Louis Philippe. Galois – fiercely republican – was expelled for writing an antiroyalist newspaper letter. In 1831 he was arrested twice: once for a speech against the king and the second time for wearing an illegal uniform and carrying arms – for this he received six-months' imprisonment. In the spring of 1832 he died in a duel; the details are uncertain but it may have been provoked by political opponents.

Galois seems to have anticipated that he was to die, for the night before was spent desperately recording his mathematical ideas in a letter to his former schoolmaster, Auguste Chevalier. Here he outlined his work on elliptic integrals and set out a theory of the roots (solutions) of equations, in which he considered the properties of permutations of the roots. Admissible permutations – ones in which the roots obey the same relations after permutation – form what is now known as a *Galois group*, having properties that throw light on the solvability of the equations. The manuscripts were published in 1846 and his work recognized. With the equally tragic Norwegian, Niels Henrik ABEL, he is regarded as the founder of modern group theory.

### **Galton, Sir Francis** (1822–1911) *British anthropologist and explorer*

I always think of you in the same way as converts from barbarism think of the teacher who first relieved them from the intolerable burden of their superstitions.... Consequently the appearance of your *Origin of Species* formed a real crisis in my life; your book drove away the constraint of my old superstition as if it had been a nightmare, and was the first to give me freedom of thought.

—Letter to Charles Darwin, 24 December 1869

Even though Galton's exceptional intelligence was apparent at an early age, his higher education was unremarkable. Born in the English Midlands city of Birmingham, he studied mathematics at Cambridge University and studied medicine in London but abandoned his studies on inheriting his father's fortune, which enabled him to indulge his passion for travel. Following consultations with the Royal Geographical Society, Galton set out to cover various uncharted regions of Africa, and became known as an intrepid explorer. He collected much valuable information and was elected first a fellow of the Royal Geographical Society and three years later, in 1856, a fellow of the Royal Society.

Galton made important contributions to the

science of meteorology, identifying and naming anticyclones and developing the present techniques of weather mapping. This work was published as *Meteorographica* (1863; Weather Mapping). He was also instrumental in establishing the Meteorological Office and the National Physical Laboratory, but he is remembered chiefly for his researches on human heredity, which were stimulated by the publication of *The Origin of Species* by his cousin, Charles Darwin. This led Galton to speculate that the human race could be improved by controlled breeding and he later gave the name *eugenics* to the study of means by which this might be achieved.

Galton studied the histories of notable families to determine whether intelligence is inherited, and concluded that it is. This aroused much controversy among those who believed environment is all important. Galton was the first to use identical twins to try to assess environmental influences. His work was characterized by its quantitative approach and he was also the first to stress the importance to biology of statistical analysis, introducing regression and correlation into statistics.

At a time when most scientists believed in blending inheritance, Galton deviated from contemporary thought and, in a letter to Darwin, outlined a theory of particulate inheritance, which anticipated Gregor MENDEL's work, then still undiscovered. Galton also discussed a concept similar to the phenotypes and genotypes of Wilhelm JOHANNSEN, under the terms patent and latent characteristics.

Galton was knighted in 1909. In his will he left a large sum of money to endow a chair of eugenics at University College, London, which was first held by Karl PEARSON, an energetic advocate of Galton's ideas on eugenics.

**Galvani, Luigi** (1737–1798) *Italian anatomist and physiologist*

It is easy in experimenting to deceive ourselves, and to imagine we see things we hope to see.

—*De viribus electricitatis in motu musculari commentarius* (1791; Commentary on the Effect of Electricity on Muscular Motion)

Galvani (gal-**vah**-nee) studied medicine at the university in his native city of Bologna, gaining his MD in 1762 for his thesis on the structure and development of bones. He stayed at Bologna to teach anatomy and in the late 1770s began his experiments in electrophysiology. He observed that the muscles of a dissected frog twitched when touched by a spark from an electric machine or condenser, such as a Leyden jar. Similar responses could be obtained when such muscles were laid out on metal during a thunderstorm, or even by simple contact with two different metals, without the deliberate application of an electric current. Galvani con-

cluded that the source of the electricity therefore lay in the living tissue, and did not derive from outside. His finding was later disproved by Alessandro VOLTA. However, Galvani is celebrated for his discovery of Galvanic electricity (the metallic arc), as well as for applications of his principle to the galvanization of iron and steel and the invention of the galvanometer, named in Galvani's honor by André AMPERE. Galvani's animal electricity theory was published as *De viribus electricitatis in motu musculari commentarius* (1791; Commentary on the Effect of Electricity on Muscular Motion).

**Gamble, Josias Christopher** (1776–1848) *British industrial chemist*

Gamble came from a Presbyterian background in Enniskillen, now in Northern Ireland, and was educated at Glasgow University, graduating in 1797. He first became a minister, going to Belfast in that capacity in 1804, but soon entered the bleaching industry. He had picked up enough knowledge of Charles Tennant's St. Rollox process to open a factory in Dublin to manufacture chlorine bleach powder. He also produced sulfuric acid, potash, and alum. In 1829 he returned to England and partnered James MUSPRATT to open the first chemical plant in St. Helens, a LEBLANC soda plant, which became a highly profitable business.

**Gamow, George** (1904–1968) *Ukrainian-American physicist*

Perhaps the last example of amateurism in scientific work on a grand scale.

—Stanislaw Ulam on Gamow's work

Gamow (**gam**-of) was born the son of a teacher at Odessa, now in Ukraine. He was educated at the University of Leningrad where he obtained his doctorate in 1928 and later served as professor of physics (1931–34). Before his move to America in 1934 he spent long periods at Göttingen, Copenhagen, and Cambridge, England, the major centers of the revolution then taking place in physics. In America he spent his career as professor of physics at George Washington University (1934–55) and then at the University of Colorado (1956–68).

Gamow made many contributions to nuclear and atomic physics, but is mainly noted for his work on interesting problems in cosmology and molecular biology.

In cosmology he revised and extended the big-bang theory of the creation of the universe (first formulated by Georges Lemaitre). This postulates that the universe expanded from a single point in space and time. It was first announced in Gamow's famous "alpha beta gamma" paper in 1948, which he wrote in collaboration with Ralph ALPHER and Hans BETHE. A fuller account was later published by Gamow in his *Creation of the Universe* (1952). Gamow

dated the expansion to about 17 billion years ago, probably the result of an earlier contraction. The difficulty with any such theory was in accounting for the formation of the chemical elements. He supposed the primeval atom to consist of "Ylem," an old word used by Gamow to refer to a mixture of protons, electrons, and neutrons. Using the conditions of temperature and density prevailing in the first half hour of the universe's history, he tried to work out ways in which the elements could be formed by nuclear aggregation. There was no difficulty in showing that  $^1\text{H}$ ,  $^2\text{H}$ ,  $^3\text{H}$ ,  $^3\text{He}$ , and  $^4\text{He}$  would be formed but at that point he could see no way to advance the chain further, for there is no stable element with an atomic weight of 5. Add either a proton or a neutron to the nucleus of  $^4\text{He}$  and either  $^5\text{Li}$  or  $^5\text{He}$  will be formed, both of which are unstable and decay in less than  $10^{-20}$  second back to the original  $^4\text{He}$ .

The only solution was to suppose that more than one particle collided with the  $^4\text{He}$  nucleus simultaneously but, as Gamow realized, the universe by this time would be insufficiently dense and hot enough to permit such collisions to occur with the required frequency. He was therefore forced to conclude in 1956 that most of the heavy elements have been formed later in the hot interior of stars. One prediction that did emerge from his work and was to have important consequences for cosmology was his claim that the original explosion would produce a uniform radiation background; the discovery of such radiation in 1964 by Arno PENZIAS and Robert WILSON did more than anything else to stimulate interest once more in Gamow's theory.

Gamow later moved from showing how the universe began to the no less interesting question of how life began. He was quick to see the significance of the DNA model proposed by James WATSON and Francis CRICK in 1953. The problem was to show how the sequences of the four nucleic acid bases that constitute the DNA chain could control the construction of proteins, which may be made from 20 or more amino acids. Gamow had the insight to see that the bases must contain a code for the construction of amino acids. But the question of how this worked still remained. It could not be one base to one amino acid for then there would be only four amino acids. Nor would two bases be sufficient for they could produce only  $4 \times 4 = 16$  amino acids. It would therefore need a sequence of three bases to produce one amino acid, a language with a capacity of  $4 \times 4 \times 4 = 64$  words, which was more than adequate for the construction of all proteins. Gamow also produced convincing arguments to show that the code is not overlapping.

The work on DNA allowed Gamow to indulge his passion for science fantasy. He founded the RNA tie club for which he actually designed a tie. It was restricted to 20 members, one for

each amino acid. Each member took the name of one of the acids – Gamow was "phe" (the usual abbreviation for phenylalanine) while Crick was "tyr" (tyrosine). Meetings were held, information was exchanged, and considerable progress was made.

Gamow was also known as one of the most successful popular science writers of his day. He wrote many books, most of which are still in print, which convey much of the excitement of the revolution in physics that he lived through.

### Garrod, Sir Archibald Edward (1857–1936) *British physician*

Garrod's father was also a physician, a specialist in joint diseases who in 1848 demonstrated the presence of uric acid in the joints of his patients with gout. His son was born in London, graduated in natural science from Oxford University in 1880, and qualified in medicine from St. Bartholomew's Hospital, London. Garrod remained at St. Bartholomew's until 1920 when he returned to Oxford to succeed William OSLER as professor of medicine, a post he retained until his retirement in 1927.

In a lecture he gave to the Royal College of Physicians in 1908, *Inborn Errors of Metabolism*, Garrod introduced to the medical world an entirely new and unsuspected class of disease. An early interest in the pathological aspects of urinary pigments led Garrod to investigate alkaptonuria, a complaint in which the urine turns black on exposure to air. This was known to be due to the presence of large amounts of alkapton or homogentisic acid, a breakdown product of the amino acids tyrosine and phenylalanine. It was at first thought that some intestinal microbe was responsible for the disorder but Garrod's initial researches quickly disposed of this supposition when he found a tendency for siblings to be affected while their parents remained quite normal. He therefore argued that the disease was genetically determined and inherited as a recessive Mendelian trait.

He went on to propose a mechanism whereby in a normal individual the homogentisic acid derived from the breakdown of amino acids was itself further reduced to its harmless ingredients. In some individuals, however, there was a "metabolic block." They lacked the specific enzyme that breaks down homogentisic acid into harmless carbon dioxide and water, so allowing the acid to accumulate and overflow into the urine.

Nor was alkaptonuria the only such metabolic disorder; others identified by Garrod included cystinuria, pentosuria and, the cause of George III's madness, porphyria.

Garrod's daughter Dorothy, a distinguished archaeologist, was appointed to the Disney Professorship at Cambridge University in 1939, thus becoming the first woman to hold a Cam-

bridge chair. Of his three sons, two died in action in World War I and the third died of pneumonia.

**Gaskell, Walter Holbrook** (1847–1914)  
*British physiologist*

Gaskell, a lawyer's son, was born at Naples in Italy and graduated in mathematics from Cambridge University in 1869. He then studied medicine at University College Hospital, London, but returned to Cambridge to serve as lecturer in physiology from 1883 until his death. His first studies investigated whether the heartbeat is under external nervous control or is an inherent property of the cardiac musculature (myogenic). Skillful work with tortoises and crocodiles showed that the heart's rhythm is indeed myogenic.

Gaskell also greatly increased knowledge of the structure of the autonomic (involuntary) nervous system. In 1886 he noted three major "outflows" of nerves from the spinal cord and lower part of the brain: the cervico-cranial, thoracic, and sacral. On leaving the central nervous system each nerve passes through a ganglion, or relay station, sited alongside the spine. Gaskell discovered two key properties of the system. He first noted that the nerves of all three groups are enclosed in a white sheath of myelin before entering their adjacent ganglion; on leaving the ganglion however the nerves of the thoracic outflow have lost their sheath in contrast to the still myelinated nerves of the other two outflows. He had thus succeeded in finding a simple anatomical distinction between the myelinated nerves, sacral and cervico-cranial, of the parasympathetic system, and the unmyelinated nerves, thoracic, of the sympathetic nervous system.

He also noted that most parts of the body receive nerves of both types and that their actions seem to be antagonistic. That is, while the myelinated nerves of the parasympathetic system inhibited the action of involuntary muscle, those of the sympathetic system seemed to increase its activity. Although much of Gaskell's work was done on reptiles he realized it had wider implications and boldly predicted that it would apply also to mammals, a prediction soon confirmed. His work was published posthumously in *The Involuntary Nervous System* (1916).

Much of Gaskell's later life was spent studying mammalian evolution. He tried to show how mammals could have evolved from arthropods rather than echinoderms (the orthodox view). His ideas were published in *The Origin of the Vertebrates* (1908), which contains the results of 20 years' work, but his theories have been largely ignored.

**Gassendi, Pierre** (1592–1655) *French physicist and philosopher*

In his Epicurean philosophy, M. Gassendi strongly refutes everything that stands in opposition to Christianity and in so doing, as you rightly remark, he is taking precautions.  
—Marin Mersenne, letter to Rivet, 8 February 1642

Gassendi (ga-sahn-dee) was born at Champertier in France. After being educated in Aix and Paris, he gained a doctorate in theology from Avignon in 1616, was ordained in 1617, and in the same year was appointed to the chair of philosophy at Aix. In 1624 Gassendi moved to Digne where he served as provost of the cathedral until 1645 when he was elected to the professorship of mathematics at the Collège Royale in Paris, resigning because of illness in 1648.

As a practicing astronomer Gassendi made a large number of observations of comets, eclipses, and such celestial phenomena as the aurora borealis – a term he introduced himself. His most significant observation was of the 1631 transit of Mercury, the first transit to be observed, which he recorded in his *Mercurius in sole visus* (1632; Mercury in the Face of the Sun) as support for the new astronomy of Johannes KEPLER.

In physics Gassendi attempted to measure the speed of sound and obtained the (too high) figure of 1,473 feet per second. He also, in 1640, performed the much contemplated experiment of releasing a ball from the mast of a moving ship; as he expected, it fell to the foot of the mast in a straight line.

Gassendi's importance to science rests with his role as a propagandist and philosopher rather than as an experimentalist. Even though the Paris parliament declared in 1624 that on penalty of death "no person should either hold or teach any doctrine opposed to ARISTOTLE," Gassendi published in the same year his *Excertitationes ... adversus Aristoteleos* (Dissertations ... against Aristotle), the first of his many works attacking both medieval Scholasticism and Aristotelianism. Nor did Gassendi find much attraction in the then emerging system of René DESCARTES. Instead he sought in his influential *Animadversiones in decimum librum Diogenes Laertii* (1649; Observations on the Tenth Book of Diogenes Laertius) to revive the classical atomism of EPICURUS, suitably modified to ensure its compatibility with 17th-century Christianity. Unlike Epicurus he insisted that the atoms were created by God who also bestowed on man an immaterial soul; against Descartes he admitted the existence of the void within which his atoms could interact.

Gassendi's works were well known in England and exercised considerable influence on such leading scientists as Robert BOYLE.

**Gasser, Herbert Spencer** (1888–1963)  
*American physiologist*

Gasser, the son of a country doctor from Platteville, Wisconsin, was educated at the University of Wisconsin and at Johns Hopkins University. Having qualified as a physician in 1915, he moved to Washington University, St. Louis, to take up an appointment as professor of pharmacology. Here he joined his old teacher, Joseph ERLANGER, in a famous collaboration that resulted in their sharing the 1944 Nobel Prize for physiology or medicine for work on the differentiated function of nerve fibers. In 1931 Gasser was appointed to the chair of physiology at Cornell Medical School. Finally, in 1935, he was made director of the Rockefeller Institute in New York, a post he retained until his retirement in 1953.

**Gates, William Henry (Bill)** (1955– ) *American software designer and entrepreneur*

The son of a lawyer, Gates developed an early interest in computers and wrote his first piece of software – a tic-tac-toe program – when only 13. He entered Harvard in 1973 but soon dropped out along with an old school friend, Paul Allen, to write and sell software. Gates later noted that, even at this early time, he feared that if he remained at Harvard to complete his education “the revolution would happen without us.”

Gates and Allen had already worked out a version of BASIC to run on the newly available Intel 8008 chip. In 1975, the Altair 8800 was produced in kit form by MITS (Micro Instrumentation and Telemetry Systems). Gates realized that to broaden the PC's appeal it had to be programed in BASIC rather than in machine code. Gates and Allen moved to Albuquerque, New Mexico, the home of MITS, established Microsoft, and began to write software.

There were copyright disputes with MITS, litigation followed, and in 1978 Gates and Allen moved Microsoft to their home town of Seattle. The key moment in their fortune came in 1980 when IBM came to Seattle shopping for an operating system for their newly planned PC. Gates passed them over to Gary KILDALL, owner of the operating system CP/M. IBM failed to reach an agreement with Kildall and consequently returned to Microsoft with an invitation to develop an operating system.

Gates and Allen realized that they needed an operating system in a hurry. They knew that a local company, Seattle Computer, owned by Rod Brock, had such a system known as 86-DOS. Gates bought the system outright for \$50,000. He had in fact purchased one of the most commercially successful properties of the century. Renamed MS-DOS (Microsoft Disk Operating System), over 100 million copies have been sold.

Subsequently, Microsoft went on to develop a graphical user interface (GUI), in which the

operator uses a mouse and icons. The program was introduced to compete with the successful system used on the Apple Macintosh computer. Microsoft's system, called “Windows,” was first introduced in 1983; Windows 3 followed in 1990, Windows 95 in 1995, with other later versions. Gates's success has made him one of the richest men in the world. In 2006 he cut down his work at Microsoft in order to devote more time to philanthropic work. The Bill and Melinda Gates Foundation has supported charities and humanitarian research in many countries. He has described both his plans and his vision of the future in his book *The Road Ahead* (1995).

**Gattermann, Ludwig** (1860–1920) *German organic chemist*

Gattermann (**gah**-ter-man) was born at Goslar in Germany, and studied chemistry at Göttingen University, where he became Victor MEYER's assistant, moving with Meyer to Heidelberg in 1889. In 1900 Gattermann was appointed professor of chemistry at Freiburg University.

Gatterman is noted for his work on derivatives of benzene and a number of reactions are named for him. The *Gattermann-Koch synthesis* (with J. C. Koch, 1897) is a method of introducing the formyl group (CHO) onto a benzene ring using a mixture of carbon monoxide and hydrogen chloride with a metal-chloride catalyst. The *Gattermann synthesis* (1907) uses liquid hydrogen cyanide in place of carbon monoxide to achieve the same result. The *Gattermann-Sandmeyer reaction* (1890) is a method of promoting the conversion of diazonium compounds into other benzene derivatives using freshly precipitated copper powder.

**Gauss, Karl Friedrich** (1777–1855) *German mathematician*

I have had my results for a long time: but I do not yet know how I am to arrive at them.  
—Quoted by A. Arber in *The Mind and the Eye* (1954)

We must admit with humility that, while number is purely a product of our minds, space has a reality outside our minds, so that we cannot completely prescribe its properties *a priori*.

—Letter to Friedrich Wilhelm Bessel (1830)

Gauss (gows) came of a peasant background in Brunswick, Germany, and his extraordinary talent for mathematics showed itself at a very early age. By the age of three, he had discovered for himself enough arithmetic to be able to correct his father's calculations when he heard him working out the wages for his laborers. Gauss retained a staggering ability for mental calculation and memorizing throughout his life. At the age of ten he astonished his school-teacher by discovering for himself the formula

for the sum of an arithmetical progression. As a result of such precocity the young Gauss obtained the generous patronage of the duke of Brunswick. The duke paid for Gauss to attend the Caroline College in Brunswick and the University of Göttingen, and continued to support him until his death in 1806. Gauss then accepted an offer of the directorship of the observatory at Göttingen. This post probably suited him better than a more usual university appointment since he had little enthusiasm for teaching. Working at the observatory no doubt also stimulated his interest in applied mathematics and astronomy.

Gauss's life was uneventful. He remained director of the observatory for the rest of his life and indeed only rarely left Göttingen. Apart from mathematics he had a very keen interest in languages and at one stage hesitated between a career in mathematics and one in philology. His linguistic ability was evidently very great for he was able to teach himself fluent Russian in under two years. He also had a lively interest in world affairs, although in politics as in literature his views were somewhat conservative.

Gauss's contributions to mathematics were profound and they have affected almost every area of mathematics and mathematical physics. In addition to being a brilliant and original theoretician he was a practical experimentalist and a very accurate observer. His influence was naturally very great, but it would have been very much greater had he published all his discoveries. Many of his major results had to be rediscovered by some of the best mathematicians of the 19th century, although the extent to which this was the case was only revealed after Gauss's death. To give but two of many examples – Janos BOLYAI and Nikolai LOBACHEVSKY are both known as the creators of non-Euclidean geometry, but their work had been anticipated by Gauss 30 years earlier. CAUCHY's great pioneering work in complex analysis is justly famous, yet Gauss had proved but not published the fundamental Cauchy theorem years before Cauchy reached it. The reason for Gauss's extreme reluctance to publish seems to have been the very high standard he set himself and he was unwilling to publish any work in a field unless he could present a complete and finished treatment of it.

Gauss received his doctorate in 1799 from the University of Helmstedt for a proof of the fundamental theorem of algebra, i.e., the theorem that every equation of degree  $n$  with complex coefficients has at least one root that is a complex number. This was the first genuine proof to be given; all the supposed previous proofs had contained errors, and it is this standard of rigor that really marks Gauss's work out from that of his predecessors. (Mathematicians of the 18th century and earlier had often possessed an intuitive ability to conjecture

mathematical theorems that were in fact true, but their ideas of rigorous mathematical proof fell short of modern standards.)

Gauss's first publication is generally accepted as his finest single achievement. This is the *Disquisitiones Arithmeticae* (Examinations of Arithmetic) of 1801. Appropriately it was dedicated to Gauss's patron the duke of Brunswick. The *Disquisitiones* is devoted to the area of mathematics that Gauss always considered to be the most beautiful, namely the theory of numbers or "higher arithmetic." Gauss's prodigious ability for mental calculation enabled him to arrive at many of his theorems by generalizing from large numbers of examples. Among many other striking results Gauss was able to prove in the *Disquisitiones* the impossibility of constructing a regular heptagon with straight edge and compass – a problem that had baffled geometers since antiquity.

Gauss's interest was not confined to pure mathematics and he made contributions to many areas of applied mathematics and mathematical physics. Thus he discovered the *Gaussian error curve* and also the method of least squares, which he used in his work on geodesy. In his work on electromagnetism he collaborated with Wilhelm WEBER on studies that led to the invention of the electric telegraph. The invention of the bifilar magnetometer for his own experimental work was another practical consequence of Gauss's interest in electromagnetism. His interest in mathematical astronomy resulted in many valuable innovations; he obtained a formula for calculating parallax in 1799 and in 1808 he published a work on planetary motion. When in 1801 the asteroid Ceres was first observed and then "lost" by Giuseppe PIAZZI, Gauss was able to predict correctly where it would reappear. He also made improvements in the design of the astronomical instruments in use at his observatory. Gauss's work transformed mathematics and he is generally considered to be, with NEWTON and ARCHIMEDES, one of the greatest mathematicians of all time. The cgs unit of magnetic flux density is named in his honor.

### Gay-Lussac, Joseph-Louis (1778–1850) *French chemist and physicist*

There is a general rule that in every case where the same elements can form compounds of different stability (but capable of existing simultaneously under the same given conditions), the first to be formed is the least stable.  
—*Annals of Chemistry* (1842)

Gay-Lussac (gay-loo-sak) was the son of a judge who was later imprisoned during the French Revolution. Born at St. Léonard in France, he entered the recently founded Ecole Polytechnique in 1797 and graduated in 1800. His career was thereafter one of steady promotion. Originally studying engineering, in 1801 he at-

tracted the attention of the chemist Claude-Louis BERTHOLLET who made him his assistant at Arcueil, near Paris. The science of chemistry was then in its infancy. Few chemists were actively engaged in research, and the equipment used was primitive. Chemical symbols had just been introduced, and no chemical formulae were known with certainty. During his career Gay-Lussac contributed to the advancement of all branches of chemistry by his discoveries, and greatly improved and developed experimental techniques.

In 1802, following the researches of the chemist Jacques CHARLES, Gay-Lussac formulated the law now alternatively attributed to himself and Charles – that gases expand equally with the same change of temperature, provided the pressure remains constant. Using superior experimental techniques, Gay-Lussac largely eliminated the errors of his predecessors in this field, in particular by developing a method of drying the gases. He measured the coefficient of expansion of gases between 0°C and 100°C, thus forming the basis for the idea of the absolute zero of temperature. His law was received with satisfaction as complementary to BOYLE'S law. It was later shown that Gay-Lussac's and Boyle's laws applied exactly only to a hypothetical "ideal gas"; real gases obey the law approximately.

Gay-Lussac made his first daring balloon ascent in 1804 with Jean BIOT, during which they made scientific observations and established that there was no change in either the composition of the air or in the Earth's magnetic force at the heights they reached. Gay-Lussac made a second ascent alone, reaching a height of 23,018 feet.

In 1805, by exploding together given volumes of hydrogen and oxygen, Gay-Lussac discovered that one volume of oxygen combined with two volumes of hydrogen to form water. In 1808, after researches using other gases, he formulated his famous law of combining volumes – that when gases combine their relative volumes bear a simple numerical relation to each other (e.g., 1:1, 2:1) and to the volumes of their gaseous product, provided pressure and temperature remain constant. The English chemist John DALTON was immediately interested in Gay-Lussac's discovery, but when, on investigation, the law appeared to conflict with his own theory of the indivisibility of atoms, Dalton rejected the law and sought to discredit Gay-Lussac's experimental methods. The reason for the apparent conflict was that the difference between an atom and a molecule was not clearly understood, and it was left to the Italian chemist Amedeo AVOGADRO to formulate a theory reconciling the two laws, thus laying the basis of modern molecular theory.

From 1808 Gay-Lussac worked with the chemist Louis Thenard. Following Humphry DAVY'S isolation of minute amounts of sodium

and potassium, the two chemists in 1808 prepared these metals in reasonable quantities. It was during his experiments with potassium as a reagent that Gay-Lussac blew up his laboratory, temporarily blinding himself. In collaboration with Thenard he isolated and named the element boron. Simultaneously with Davy, Gay-Lussac investigated in 1813 a substance first isolated by Bernard COURTOIS and established that it was an element similar to chlorine. He named it iodine from the Greek "iode" meaning "violet." In 1815 he prepared cyanogen and described it as a compound radical. He proved that prussic acid (hydrogen cyanide) was made up of this radical and hydrogen, completing the overthrow of LAVOISIER'S theory that all acids must contain oxygen. His recognition of compound radicals laid the basis of modern organic chemistry.

Gay-Lussac also investigated fermentation, the phenomenon of supercooling, the growth of alum crystals in solution, the compounds of sulfur, and the various stages of oxidation of nitrogen. With the young student Justus von LIEBIG he investigated the fulminates. In his later years he improved on experimental techniques, and laid the basis of modern volumetric analysis.

In 1827 he devised the *Gay-Lussac tower*. Oxides of nitrogen arising from the preparation of sulfuric acid by the lead-chamber process, which formerly escaped into the atmosphere, are absorbed by passing them up a chimney packed with coke, over which concentrated sulfuric acid is trickled. This tower and its modifications are used in many chemically based industries today.

Gay-Lussac was a chemist of brilliance and determination. Although said to be cold and reserved as a man, as a researcher he was bold and energetic. Shortly before his death he expressed regret at the experiments that he would never be able to perform.

### **Geber** (about 14th century) *Spanish alchemist*

The name Geber (jee-ber), the Latinized form of Jabir, was adopted by an anonymous medieval writer, probably because of the reputation of the great Arabian alchemist, Jabir ibn Hayyan, who is also known better as Geber.

Four of Geber's works are known, the longest being the *Summi perfectionis magisterii*, which was translated into English as *The Sum of Perfection* or *The Perfect Magistry*. The other works are *De investigatione perfectionis* (The Investigation of Perfection), *De inventione veritatis* (The Invention of Verity), and *Liber fornacum* (Book of Furnaces). The four manuscripts were translated into English in 1678.

Geber's major contribution was to spread Arabian alchemical theories through Europe where they had considerable influence.

**Geber** (c. 721–c. 815) *Arabian alchemist*

Geber (whose Arabic name was Jabir ibn Hayyan) seems to have spent his life among the political uncertainties of the decline of the Umayyad dynasty. His father was executed for his part in a plot to oust the caliph and Geber, who was born in Tus (now in Iran), was sent to southern Arabia. He became a courtier to Harun al-Rashid (of *Arabian Nights* fame) but fell out of favor in 803 and left Baghdad for Kufah, where he probably remained for the rest of his life. He was a Sufi as well as being connected with the Isma'ili sect.

A large number of works carry his name, which is now usually taken to refer to a corpus as a whole without implying actual authorship by one individual. The most important works are *The 112 Books*, *The 70 Books*, *The 10 Books of Rectification*, and *The Books of the Balances*. Geber believed that everything is composed of a combination of earth, water, fire, and air. These elements combined to form mercury and sulfur from which he believed all metals are formed, a view that continued until Robert BOYLE. He further held that if the right proportions of each were combined they would produce gold. Geber's theory was of considerable influence on alchemy and the early development of chemistry.

Geber is regarded as the father of Arabian chemistry. In the 14th century his name was adopted by an anonymous Spanish alchemist to add authority to his work.

**Geer, Charles de** See [DE GEER, CHARLES](#).**Geer, Gerard Jacob de** (1858–1943) *Swedish geologist*

Geer (yayr) came from a noble Swedish family in Stockholm and both his father and brother served as prime minister of Sweden. He graduated from Uppsala University in 1879 and worked initially with the Geological Survey on the problem of raised beaches before taking up an appointment as professor of geology at Uppsala in 1897. In 1924 he became the first director of the Stockholm Geochronological Institute.

Geer originated the varve-counting method for dating the geological past in years, a system that gave unprecedented accuracy in age determinations. In 1878 he had begun a study of the Quaternary Period in Sweden and soon became aware of the layered deposits, known as varves, laid down in glacial lakes. Seasonal differences in the material deposited enabled individual years to be identified, the summer layer consisting of light-colored coarse-grained material and the winter layer of dark-colored fine material, and Geer noticed the analogy of the varves to tree rings.

He tried to see if the sequence of varves from

one region would correlate in any way with those of other areas and found that this could be done for most parts of Sweden. However, this would only allow him to say that two samples came from the same time without being able to say whether that time was a century or a millenium in the past. He was able eventually to establish a base year at 6839 BC from which point individual years could be counted in either direction.

Geer's work was a major breakthrough although it was soon to be overshadowed by radioactive dating and was limited to certain glaciated areas. In his later years, Geer tried to apply his techniques and to establish correlations with other areas of the world, but with varying success.

**Gegenbaur, Karl** (1826–1903) *German comparative anatomist*

The human organism is not isolated in nature, but is only one member of an endless series within which knowledge of the whole will illuminate that of the individual.

—*Manual of Human Anatomy* (1883)

Educated at the university in his native city of Würzburg, Gegenbaur (**gay**-gen-bowr) was professor of zoology and comparative anatomy at the University of Jena from 1855 to 1873. He then held a similar post at Heidelberg until 1901.

Gegenbaur's work was noteworthy in emphasizing the importance of comparative anatomy to the concept of evolution. One of the leading champions of Darwinism in Europe, he may be said to have laid the foundations of modern comparative anatomy with his embryological investigations, which led to his demonstration (1861) that all vertebrate eggs and sperm are unicellular, thus developing an earlier supposition of Theodor SCHWANN. Like T. H. HUXLEY, Gegenbaur denied that the vertebrate skull derived from expanded vertebrae, basing his opinion on studies of cartilaginous fishes. He also investigated the disappearance of the gill clefts in mammalian development and evolution. In his standard textbook on evolutionary morphology, *Grundriss der vergleichenden Anatomie* (1859; *Elements of Comparative Anatomy*), Gegenbaur expounded his view that the most reliable clues to animal evolutionary relationships lay in homology, e.g., the arm of a man as compared to the foreleg of a horse or the wing of a bird. Gegenbaur was editor of the *Morphologisches Jahrbuch* (*Morphology Yearbook*) from 1875, and published his autobiography in 1901.

**Geiger, Hans Wilhelm** (1882–1945) *German physicist*

Geiger (**gi**-ger) was born at Neustadt in Germany and studied physics at the universities of

Munich and Erlangen, obtaining his doctorate (1906) for work on electrical discharges in gases. He then took up a position at the University of Manchester, England, where he worked with Ernest RUTHERFORD from 1907 to 1912. In 1912 he returned to Germany, from then until his death holding a series of important university positions, including director of the German physical laboratory, the Physikalisch Technische Reichsanstalt, in Berlin (1912), and professor of physics at Kiel University (1925).

Geiger, a pioneer in nuclear physics, developed a variety of instruments and techniques for detecting and counting individual charged particles. In 1908 Rutherford and Geiger, investigating the charge and nature of alpha particles, devised an instrument to detect and count these particles. The instrument consisted of a tube containing gas with a wire at high voltage along the axis. A particle passing through the gas caused ionization, and initiated a brief discharge in the gas, and the resulting pulse of current could be detected on a meter. This was the prototype, which Geiger subsequently improved and made more sensitive; in 1928 he produced, with W. Müller, a design of counter that is now widely used (and known as the *Geiger-Müller counter*). With their primitive counter Rutherford and Geiger established that alpha particles are doubly charged helium atoms.

Other important work of Geiger was his investigation with E. Marsden in 1909, of the scattering of alpha particles by gold leaf; this led Rutherford to propose a nuclear theory for the atom.

### **Geikie, Sir Archibald** (1835–1924) *British geologist*

Geikie (**gee-kee**) was born in Edinburgh, the son of a musician. Although intended to be a banker, he was allowed to pursue his interests in natural history and fossils by attending Edinburgh University. With the help of Hugh MILLER he joined the staff of the Geological Survey of Great Britain in 1855 under Roderick MURCHISON. In 1867 he became director of the Scottish branch of the Geological Survey, a position he continued to hold after becoming professor of geology at Edinburgh in 1871. Geikie moved to London to become head of the Geological Survey in 1882, a post he occupied until his retirement in 1901.

Geikie was especially concerned with erosion processes and believed that rivers were a major factor in soil erosion. His studies were confined chiefly to the Scottish landscape and he was an early supporter of the role of glaciation in its formation.

A prolific writer, Geikie published works on the geology of Edinburgh (1861) and of Fife (1900) for the Geological Survey. His other

works include his *Textbook of Geology* (1882), and a fine historical survey, *Founders of Geology* (1897). Perhaps his most original geological work was contained in his *Ancient Volcanoes of Great Britain* (1897).

From 1908 until 1913 Geikie served as president of the Royal Society. He was knighted in 1907.

### **Gelfand, Israil (or Israel) Moiseevich** (1913– ) *Russian mathematician and biologist*

Born in Krasnye Orny, now in Moldova, Gelfand (**gyel-fand**) showed mathematical ability at an early age. Although he had not completed the usual university education course his mathematical expertise was sufficient for him to be admitted to do postgraduate work at the Moscow State University at the age of 19. He began teaching there in 1932 and was appointed an assistant professor in 1935. From 1939 Gelfand worked at the V. A. Steklov Institute of Mathematics of the Soviet Academy of Sciences, and from 1940 to 1991 he was professor of mathematics at the Moscow State University. In 1989–90 he taught at Harvard and in 1990 he also taught at MIT. The same year he emigrated to the U.S., becoming Distinguished Visiting Professor of Mathematics at Rutgers University, New Jersey.

Gelfand is one of the most fertile and brilliant Russian mathematicians of his generation, and his work has been equally influential in both pure and applied mathematics. His first major original contribution was made in his doctoral dissertation, presented in 1940, in which he made advances of great importance in the theory of commutative normed rings. Other outstanding achievements of Gelfand's include his contributions to group theory, in particular his work on infinite dimensional representations of continuous groups, and on the harmonic analysis of noncompact groups.

Gelfand carried out very important studies on the theory of generalized functions. This work focused on the application of such functions to be found in dealing with differential equations. As a result of this research the whole theory of integral transformations was placed on a geometrical basis, and thus became amenable to a whole new range of techniques. In applied mathematics Gelfand's work has provided key mathematical tools needed in developing a theory of symmetry for elementary particles.

From about 1958 Gelfand became interested in biology and physiology and he made studies of the nervous system and of cell biology. He applied mathematical techniques to these studies, for example, devising mathematical models of neurophysiological systems.

**Geller, Margaret Joan** (1947– ) *American astronomer*

The daughter of a crystallographer from Ithaca, New York, Geller was encouraged as a small child to study science and mathematics. She was educated at the University of California, Berkeley, and at Princeton where she obtained her PhD in 1975. After a period at the Institute of Astronomy, Cambridge, England, Geller moved to Harvard in 1980 and was appointed professor of astronomy in 1988. She is also a staff member of the Smithsonian Astrophysical Observatory.

Since the early 1980s Geller in collaboration with John HUCHRA has been carrying out for the Center for Astrophysics (CfA) a red-shift survey of some 15,000 galaxies. The intention is to map all galaxies above a certain brightness, out to about 650 million light years, in a particular sector of the heavens. They were aware that to some observers the sky lacked the uniformity predicted by the big-bang theory. In 1981, for example, a 100-million-light-year gap had been discovered in the constellation Bootes. Geller considered the possibility that this was a local phenomenon, and that the predicted homogeneity would become more apparent on a much larger scale. Further investigations were expected to show a uniform distribution.

But when they came to plot the distribution of galaxies they saw neither a uniform spread, nor a random scattering of galaxies, but large-scale clusters grouped into enormous structures. The largest of these, dubbed the *Great Wall*, stretches for more than 500 million light

years. It was difficult to see how anything as massive could have been formed within the context of current cosmological theory; when Geller reported the initial results of the CfA survey in 1989 she noted, "Something fundamental is missing in our models." Geller has been active in promoting public education in science, with many lectures and TV and radio interviews.

**Gellibrand, Henry** (1597–1636) *English mathematician and astronomer*

Gellibrand, a Londoner, was educated at Oxford University. He was described by the diarist John Aubrey as "good for little a great while, till at last it happened accidentally, that he heard a Geometrie lecture. He was so taken with it, that immediately he fell to studying it, and quickly made great progress in it." In 1626 he became Gresham Professor of Astronomy at Oxford. He did important work on evidence for the variation of the Earth's magnetic field, publishing, in 1635, his observation of the  $7^\circ$  shift in direction of the compass needle over the previous 50 years.

**Gell-Mann, Murray** (1929– ) *American theoretical physicist*

I employed the sound "quark" for several weeks in 1963 before noticing "quark" in *Finnegans Wake*...The allusion to three quarks seemed perfect....

—Quoted in *A Supplement to the Oxford English Dictionary* (1982)

**UNITARY SYMMETRY** An example of an octet consisting of the proton, neutron, sigma, lambda, and xi particles.

Gell-Mann was born in New York City, the son of Austrian immigrants. Having entered Yale at the age of fifteen, he went on to the Massachusetts Institute of Technology, where he completed his PhD in 1951. After spending a year at the Institute for Advanced Study, Princeton, and four years at the University of Chicago, Gell-Mann was appointed professor of physics in 1955 at the California Institute of Technology. In 1967 he was elected R. A. Millikan Professor of Theoretical Physics, a post he held until his retirement in 1993. He is a Distinguished Fellow at the Santa Fe Institute.

Gell-Mann has been mainly concerned with the study of elementary particles. In the early 1950s physicists were puzzled by the “strange” behavior of some apparently strongly interacting mesons. The kaons, as they were called, should have a lifetime of only  $10^{-23}$  second; they actually survived for some  $10^{-10}$  second. Gell-Mann suspected that some unknown property was conserved and that this explained the rapid decay of the kaons via the strong force. He named the new property “strangeness” ( $S$ ) and assigned the kaons a value  $S = +1$ .  $S$  was later defined as  $2Q - B$ , or twice the charge minus the baryon number. Thus the proton with a charge of  $+1/2$  and a baryon number of  $+1$ , will take the value  $S = 0$ , and this value will be conserved in all strong interactions. Similar ideas were proposed in 1954 by K. Nishijima in Japan.

New problems emerged. Physicists had become particularly worried by the discovery of large numbers of supposedly elementary particles. In the late 1950s it was possible to list and classify some thirty subatomic particles. Within five years another 70 “elementary” particles had been discovered. The theorist’s first priority was to bring some kind of order to this unwelcome abundance. In 1964, using group theory, and a number of conservation principles, Gell-Mann demonstrated that hadrons – i.e., particles such as baryons and mesons that interact strongly – could be classified into multiplets of 1, 8, 10, or 27 members. One such multiplet constructed with the group  $SU(3)$ , or symmetry unity theory of dimension 3, yielded the octet. A similar proposal was made at the same time by the Israeli physicist Y. Ne’eman. The new synthesis was described in *The Eightfold Way* (1964), a work edited by Gell-Mann and Ne’eman. That there was more to their theory than arbitrary classifications was soon shown when the  $\Omega^-$  (omega minus) particle, whose existence was previously unsuspected, was discovered in 1964 at Brookhaven with precisely the properties demanded for it by the  $SU(3)$  theory. The name itself alludes to the Buddhist path to enlightenment and to the eight quantum numbers required by the theory.

Following the discovery of the  $\Omega^-$  Gell-Mann began to consider why the theory should be so successful in explaining hadron behavior. In

his 1964 paper *A Schematic Model of Baryons and Mesons*, he proposed the existence of a more fundamental level of reality, that hadrons were composite, built out of more basic entities he proposed to call “quarks.” The name itself was taken from a phrase in James Joyce’s *Finnegans Wake* – “three quarks for muster mark.” In Gell-Mann’s original formulation he worked with three quarks, up ( $u$ ), down ( $d$ ), and strange ( $s$ ), and three antiquarks ( $\bar{u}$ ,  $\bar{d}$ , and  $\bar{s}$ ). As their most distinctive feature Gell-Mann assigned them fractional units of charge:  $s$  and  $d$  with a charge of  $-1/3$ , and  $u$  with  $+2/3$ . It was a simple matter to show that all baryons could be constructed with three quarks, and all mesons from a quark and an antiquark. Similar views were expressed in 1964 by G. Zweig.

The original model soon required some re-fashioning. A fourth quark property, “charm,” was proposed by Sheldon GLASHOW in 1970 and detected in 1974. This required extending the hadron classification scheme from a  $SU(3)$  group to a  $SU(4)$  group. Two further quarks have been added, the  $t$  and  $b$  quarks, known variously as top and bottom, or “beauty” and “truth.” The fifth  $b$  quark was identified by L. LEDERMAN in 1977. The  $t$  quark was discovered in the last few years of the 20th century. A further complication of quark theory emerged with NAMBU’s proposal in 1965 that they came with three varieties of “color.” In 1972 Gell-Mann and his colleagues put forward quantum chromodynamics, a quantum field theory that describes the strong interactions of quarks with great success.

In the 1980s Gell-Mann turned to the study of complexity. He was a cofounder in 1984 of the Santa Fe Institute, which works on adaptive complex systems. Reportedly fluent in fifteen languages himself, Gell-Mann has also worked in the field of historical linguistics.

For his numerous contributions to the study of elementary particles Gell-Mann was awarded the 1969 Nobel Prize for physics.

### Gennes, Pierre Gilles de (1932– ) *French physicist*

Parisian-born Gennes (zhen) was educated at the Ecole Normale in his native city, completing his PhD there in 1955. He was appointed professor of solid-state physics at the University of Paris in 1961; since 1971 he has served as professor of physics at the Collège de France and from 1976 as director of the College of Physics and Chemistry, Paris. He retired in 2002.

Some areas of science have long been thought to be too unstructured and messy to be conducive to traditional physical analysis. Two such areas, liquid crystals and polymers, were consequently largely ignored by physicists. Gennes, however, saw that they behave in many ways just like other better understood physical processes.

Liquid crystals consist of rodlike molecules in a liquid state. They undergo, like magnets and superconductors, phase changes. Thus in what is known as the smetic A phase, the molecules are oriented with their axes perpendicular to the layers; at lower temperatures they adopt the C phase with a parallel orientation. Using concepts derived from the study of phase changes in other fields Gennes was able to throw light on changes in liquid crystals. The results of his work were described in his *The Physics of Liquid Crystals* (1974). Gennes adopted a similar approach to his study of polymers which he described fully in his *Scaling Concepts of Polymer Physics* (1979).

For his work in these fields Gennes was awarded the 1991 Nobel Prize for physics. His more recent work was on granular materials and also the science of the brain.

**Geoffroy Saint-Hilaire, Etienne (1772–1844) French biologist**

It seems to me that nature ... has formed all living things upon one plan, varying in minor details only.  
—*Magasin encyclopédique*, Vol. VII (1796); Encyclopedic Storehouse)

The youngest of fourteen children in a poor family from Etampes in France, Geoffroy (zhofrwah) was supported by the local clergy, who recognized his precocious intelligence. He took a scholarship to the Collège de Navarre, Paris, and was soon appointed as a demonstrator at the Jardin des Plantes, a precursor of the Muséum National d'Histoire Naturelle, as his predecessor, Bernard Lacépède, fled the Revolution. In 1793 Geoffroy became professor of vertebrate zoology at the museum; the comparable chair of invertebrate zoology was held by LAMARCK.

In 1798 Geoffroy accompanied Napoleon on his conquest of Egypt and contributed to the celebrated 24 volumes of the *Description de l'Égypte* (1809–28; Description of Egypt). He traveled as far down the Nile as Aswan and while in Egypt he examined a number of mummified cats taken from ancient tombs. They were, he noted, identical to the animals of his day. Did this mean that species were fixed? If they were fixed why were there so many similarities between different forms? Why, for example, despite differences in external form, do the skeletons of bats, whales, and dogs resemble each other so closely?

Geoffroy derived his answer from German *Naturphilosophie* (nature philosophy), which claimed to see beneath an apparent diversity of form, mere variations on a single plan. There was a vertebrate type which could be identified in all vertebrates. Thus he demonstrated in 1807 that pectoral fins in fish and the bones of the front limbs of other vertebrates were morphologically and functionally similar.

But CUVIER had identified in the operculum, a bony flap covering gill slits in fishes, an apparently unique structure. It took Geoffroy a decade's investigation before he could explain it away as equivalent to the auditory bones in mammals. He was thus able in his *Philosophie anatomique* (1818; Anatomical Philosophy) to announce the principle of anatomical connection claiming that the same anatomical structural plan could be identified in all vertebrates.

By 1830 Geoffroy had begun to argue that there was a universal "unity of composition," quoting in evidence work claiming to have detected a unity in crustacea, fish, and mollusks. Such views brought a savage onslaught from Cuvier who insisted that there were distinct forms in nature, and that parts were formed to meet functional needs.

But, once having accepted a unity of composition, it becomes possible to see how one species can be transformed into another. If birds and reptiles are built to the same plan, then "an accident that befell one of the reptiles ... could develop in every part of the body the conditions of the ornithological type." Geoffroy was thus moving late in his career to some form of evolutionary theory. A stroke in 1840 which left him blind and paralyzed brought such work to an end.

Geoffroy was succeeded at the museum in 1841 by his son, Isidore (1805–61), also a distinguished biologist and best known for his three-volume work on teratology, *Histoire ... des anomalies de l'organisation chez l'homme et les animaux* (1833–37; Account ... of Irregularities in the Structure of Man and the Animals).

**Gerard, John (1545–1612) British herbalist**

Upon my conscience, I do not think for the knowledge of plants, that he [Gerard] is inferior to any.

—George Baker, surgeon to Queen Elizabeth I (1597)

Gerard was born at Nantwich in Cheshire, England, and educated nearby in Willaston, taking up an apprenticeship as a barber-surgeon in London at the age of 16. Thereafter he traveled, probably as ship's surgeon, aboard a merchant ship trading in Scandinavia, Russia, and the Baltic. He then settled in London and began his study of plants, paying particular attention to those with medicinal properties. By 1577 he had become superintendent of the gardens of Lord Burghley, a post he held for over 20 years. His knowledge and practical experience led to his appointment as curator of the gardens of the College of Physicians between 1586 and 1603 or 1604, and in 1597 his election as warden of the Barber-Surgeon's Company.

Gerard had cultivated his own extensive garden in London and in 1596 issued a catalog

listing over a thousand different plants in his possession. In 1597, he published his most famous work, the *Herball*, a survey of plants then available in western Europe. Although probably an adaptation of an earlier work by Rembertus Dodaens and of questionable accuracy, its descriptive style and over 1800 woodcut illustrations make it the most famous of English herbals.

**Gerhardt, Charles Frédéric (1816–1856)**  
*French chemist*

Never before has science been so much a plaything of the imagination as it is today.

—Quoted by René Taton in *Science in the Nineteenth Century* (1965)

Gerhardt (zhay-**rar**) was the son of an Alsatian chemical manufacturer from Strasbourg. He was educated at the universities of Karlsruhe, Leipzig, and Giessen where he studied under Justus von LIEBIG. From 1838 he worked in Paris as assistant to Jean DUMAS before becoming professor of chemistry at Montpellier (1844). He returned to Paris in 1848 and worked with Auguste LAURENT in their private laboratory until he was appointed to the chair at Strasbourg in 1855. He published two original works: *Précis de chimie organique* (1844–45; Summary of Organic Chemistry) and his *Introduction à l'étude de la chimie par le système unitaire* (1848; Introduction to the Study of Chemistry by Means of the Unified System).

Gerhardt is best known for his attempts to rationalize organic chemistry. Like most chemists he was aware that the dualistic system of Jöns BERZELIUS was unsatisfactory and tried to create an alternative. He adopted what became known as “type theory” in which he saw all organic compounds with reference to four “types” – hydrogen, hydrogen chloride, ammonia, and water. Organic compounds were referred to these types by replacing a hydrogen atom in one of these compounds by a radical (i.e., by a group of atoms).

**Germain, Sophie Marie (1776–1831)**  
*French mathematician*

The daughter of a prosperous Parisian merchant, Germain (zher-**man**) showed an early interest in mathematics and from the age of thirteen read whatever texts she could obtain. Although the main higher education institutions were closed to her, she managed to acquire the lecture notes of the mathematician J. L. LAGRANGE, which he had delivered at the newly founded Ecole Polytechnique.

She also began to correspond with prominent mathematicians using the pseudonym Le Blanc and allowing them to assume that she was a man. She had been working on number theory and had begun to tackle the celebrated

last theorem of FERMAT: that there are no integers  $x, y, z, n$ , where  $n > 2$  such that:

$$x^n + y^n = z^n.$$

Germain made a major contribution to showing that the equation does not hold for the case in which  $n$  is equal to 5. She informed GAUSS of the result but, typically, she failed to reply.

In 1809 Germain began to work on the theory behind the appearance of curious patterns formed by sand placed on vibrating plates. The phenomenon had first been described by E. F. CHLADNI who had demonstrated them to Napoleon in 1808. The emperor had been so intrigued that he had offered a one-kilogram gold medal to the first person to explain what are now known as *Chladni's figures*.

Germain submitted a solution in 1811 based on EULER's theory of elasticity. She was the only entrant but her work contained a number of errors. It did, however, provoke Lagrange to produce a corrected equation to derive the patterns theoretically. The competition was extended, and after two further attempts, Germain was finally awarded the prize in 1815. She published her work privately in 1821 as *Recherches sur la théorie des surfaces élastiques* (Researches on the Theory of Elastic Surfaces).

Sophie Germain developed breast cancer in 1829 and died two years later.

**Germer, Lester Halbert (1896–1971)**  
*American physicist*

Born in Chicago, Illinois, Germer began research at the Western Electric and the Bell Telephone Laboratories. Later he moved to Cornell University, New York. In 1927 he assisted Clinton J. DAVISSON in the celebrated *Davison-Germer experiment*, which first demonstrated the wavelike behavior of electrons. Germer's other interests were in thermionics, the erosion of metals, contact physics, and the plating of molybdenum and tungsten, by thermal decomposition of metal carbonyl compounds.

**Gesner, Conrad (1516–1565)** *Swiss naturalist, encyclopedist, and physician*

Although Gesner (**ges-ner**), who was born in Zurich, Switzerland, graduated in medicine from the University of Basel (1541), his main interest was natural history. In the comprehensive survey *Historiae animalium* (1551–87; Description of the Animals) he attempted, in five volumes, to present the facts rather than the myths then known about the animal kingdom. A comparable work that he planned on plants was never written owing to his untimely death from the plague. He nevertheless collected more than 500 plant species not described in ancient texts, mainly alpine species found while indulging his hobby of mountain climbing. The notes and engravings made in

preparation for his botanical encyclopedia were used by botanists for the following 200 years.

Gesner also wrote a major bibliographical work on Latin, Greek, and Hebrew writers, a work on comparative philology, and a book on fossils, containing the first illustrations of these "stony concretions," as Gesner regarded them.

**Giacconi, Riccardo** (1931– ) *Italian-born American astronomer*

Giacconi (jee-a-koh-ni) was born in Italy and educated at the University of Milan, where he gained a PhD in cosmic-ray physics. He began working on x-ray astronomy when he joined American Science and Engineering, a research corporation based at Cambridge, Massachusetts. In 1973 he joined the Harvard-Smithsonian Center for Astrophysics. Between 1981 and 1993 he was the director of the Space Telescope Science Institute, based at the Johns Hopkins University, Baltimore, Maryland. He was director general of the European Southern Observatory from 1993 to 1999. Since 1999 he has been president of Associated Universities, Inc. based at Washington, DC. Between 1982 and 1997 he also held the position of professor of physics at Johns Hopkins University and since 1998 has held the position of research professor there.

Giacconi is frequently called the father of x-ray astronomy because of his pioneering work on this topic. Since cosmic x-rays are absorbed in the atmosphere of the Earth it is necessary to place instruments to investigate them into space. Giacconi and his colleagues constructed several x-ray telescopes and observatories, work that led to the discovery of numerous x-ray stars. It is thought that in many of these stars the emission of x-rays is due to matter falling into neutron stars and black holes. His pioneering work in the field led to him sharing the 2002 Nobel Prize for physics with Raymond DAVIS and Masatoshi KOSHIBA.

**Giaever, Ivar** (1929– ) *Norwegian-American physicist*

Born in Bergen, Norway, Giaever (yay-ver) studied electrical engineering at the Norwegian Institute of Technology. He did service with the Norwegian Army (1952–53) and worked as a patent examiner in the Norwegian Patent Office (1953–54). In 1954 he emigrated to Canada to take up the post of mechanical engineer with the Canadian General Electric Company, transferring to General Electric's Research and Development Center in Schenectady, New York, in 1956. He gained his doctorate in 1964 from the New York Rensselaer Polytechnical Institute, where he became professor of physics in 1988.

At General Electric, Giaever worked on tunneling effects in superconductors, a phenomenon explored by Leo ESAKI. In 1960 he

performed experiments with metals separated by a thin insulating film through which electrons tunneled, and found that if one of the metals was in the superconducting state, the current-voltage characteristics of such junctions were highly nonlinear and revealed much about the superconducting state. This laid the foundation for Brian JOSEPHSON's important discovery of the Josephson effect.

Giaever, Josephson, and Esaki shared the 1973 Nobel Prize for physics for their various contributions to knowledge of the phenomenon of tunneling and superconductivity. Their work has had important application in microelectronics and in the precise measurement of electromotive force.

Subsequently, Giaever has also published work in the field of visual observation of the antibody-antigen reaction.

**Giauque, William Francis** (1895–1982) *Canadian-American physical chemist*

Born at Niagara Falls in Canada, Giauque (jee-ohk) spent his whole academic life at the University of California. He began as a student, obtaining his PhD in 1922, and was immediately appointed to the staff at Berkeley, becoming professor of chemistry in 1934.

Giauque was one of the pioneer workers in low-temperature phenomena. His early work in the 1920s concerned the experimental measurement of entropies at very low temperature – work that depended on the use of the third law of thermodynamics introduced in 1906 by Walther NERNST (the Nernst heat theorem). At the same time, Giauque used statistics to calculate the absolute entropies using the energy levels of molecules obtained from spectroscopy. This method, developed by Josiah Willard GIBBS and others, is known as statistical mechanics. Giauque's work provided support for the validity of both statistical thermodynamics and the third law.

Moreover, it led him to a method of attaining very low temperatures, close to absolute zero. The lowest temperature achieved at that time was 0.8 K, reached by Heike KAMERLINGH-ONNES in 1910 by pumping away the vapor of liquid helium and causing it to evaporate under reduced pressure. Giauque, and independently Peter DEBYE, proposed in 1925 a completely different method known as adiabatic demagnetization.

The basic idea is to take a paramagnetic substance surrounded by a coil of wire in a gas-filled container. The sample can be cooled by surrounding the container by liquid helium and magnetized by a current through the coil. It is thus possible to produce a magnetized specimen at liquid-helium temperature, and then to isolate it in a vacuum by removing the gas from the container. In the magnetized specimen the "molecular magnets" are all aligned. If the mag-

netic field on the specimen is reduced to zero the sample is demagnetized, and in this process the molecular magnets become random again. The entropy increases and work is done against the decreasing external field, causing a decrease in the temperature of the specimen.

There were considerable problems in putting this theory into practice, not least in measuring the temperatures produced. In 1933 Giauque had a working apparatus that improved on Kamerlingh-Onnes's in achieving a temperature of 0.1 K. Giauque received the 1949 Nobel Prize for chemistry for his work on low-temperature phenomena.

He also worked on isotopes, showing in 1929 (with H. L. Johnson) that oxygen was a mixture of  $^{16}\text{O}$ ,  $^{17}\text{O}$ , and  $^{18}\text{O}$ .

**Gibbs, Josiah Willard (1839–1903)** *American mathematician and theoretical physicist*

Mathematics is a language.

—Remark at a Yale faculty discussion concerning the difference between languages and mathematics

Gibbs came from an academic family in New Haven, Connecticut. He entered Yale in 1854, graduated in 1858, and in 1863 received a PhD for research on the design of gears. The same year he traveled to Europe, returning in 1869 to Yale where he remained until his death. In 1871 he was appointed professor of mathematical physics.

His initial work on the theory of James WATT's steam-engine governor led him into a study of the thermodynamics of chemical systems. In a series of long papers published between 1873 and 1876 he developed, and indeed virtually completed, the theory of chemical thermodynamics. Gibbs's most famous paper, *On the Equilibrium of Heterogeneous Substances* (1876), contains the celebrated *Gibbs phase rule*, describing the equilibrium of heterogeneous systems. His name is also associated with the *Gibbs free energy* – a function that determines the conditions in which a chemical reaction will occur – and with several other equations in thermodynamics.

Gibbs was also active in mathematics and physics. He worked on the theory of William Hamilton's quaternions and introduced the simpler, widely used, vector notation. His book *Vector Analysis* (1901) was very influential in promoting the use of vectors by physicists and engineers. Between 1882 and 1889 he published a series of papers on the electromagnetic theory of light. He also made important contributions to statistical mechanics, introducing the fundamental concept of *Gibbsian ensembles* – collections of large numbers of macroscopic systems with the same thermodynamic properties, used in relating thermodynamic properties to statistical properties.

Gibbs, who never married, lived a quiet retiring life at Yale; he was a poor teacher but a brilliant and productive theorist. His work, carried out far from the European mainstream of science, was largely published in the obscure *Transactions of the Connecticut Academy of Sciences*. However, James Clerk MAXWELL understood the importance of his ideas as early as 1875 and in later life Gibbs was widely recognized. Many regard him as the greatest native-born American scientist.

**Gibbs, William Francis (1886–1967)** *American naval architect and marine engineer*

Born in Philadelphia, Pennsylvania, Gibbs was educated at Harvard (1906–10) and Columbia (1910–13) where he studied law. His interest in ship design was aroused by the rapid sinking of the *Empress of Ireland* following a collision in 1914 with the loss of 1,000 lives. He argued that simple compartmentalization and properly designed bulkheads could have prevented such a tragedy. Gibbs consequently joined the International Mercantile Marine Company with whom he stayed until 1922 when, with his brother, Frederick, he founded the company Gibbs Brothers, later (1929) Gibbs and Cox.

Beginning in 1933, Gibbs did much to modernize the U.S. Navy, and persuaded it to adopt high-pressure and high-temperature steam turbines into the design of its destroyers. It was largely due to plans laid down by Gibbs that large numbers of Liberty ships could be rapidly built when America entered World War II. During the war Gibbs served as controller of shipbuilding.

Gibbs is probably best-known as the designer of the SS *United States*, a passenger ship launched in 1952, which set new speed records across the Atlantic, achieving an average speed of 35.05 knots (40.3 statute miles per hour).

**Gilbert, Walter (1932– )** *American molecular biologist*

Born in Boston, Massachusetts, Gilbert was educated at Harvard and at Cambridge University, England, where he obtained his PhD in physics in 1957. He returned to America to take up an appointment in theoretical physics at Harvard. He changed to molecular biology in 1960 under the influence of James WATSON and in 1968 became professor of molecular biology at Harvard. He was elected chairman of the department of cellular and developmental biology in 1987. He is currently an emeritus professor.

In 1961 Jacques MONOD and François Jacob proposed a theoretical answer to one of the most pressing problems of molecular biology, that of genetic control. If the common bacteria *Escherichia coli* is grown in the presence of

milk sugar (lactose) it will produce an enzyme, beta-galactosidase, to split it into its component sugars. However, if grown in the absence of lactose, the enzyme will not be produced. There must therefore presumably be a mechanism whereby the gene controlling the production of the enzyme can be switched on and off. Monod and Jacob proposed a detailed account of such a mechanism, part of which involves the existence of a repressor molecule, which could bind itself to the gene and switch it off in the absence of lactose. The lac repressor, as it was called, would be inactivated, thus switching the gene on, by an inducer molecule produced by the lactose itself.

Plausible and powerful though the Monod–Jacob model appeared, it was still only a model until the basic confirmation provided by the isolation and identification of the lac repressor was achieved. Gilbert began such a search in 1965. This was a formidable task as the repressor was known to exist in small quantities only; nor was its chemical nature known. Gilbert himself likened the task to isolating the neutrino.

By 1966, in collaboration with Benno Muller-Hill, Gilbert had devised an ingenious experimental procedure, known as equilibrium dialysis. They used a specially active inducer, isopropyl thiogalactoside (IPTG), discovered by Melvin CALVIN. Cells of *E. coli* were ground up and placed in a bag with a cellular membrane, allowing the passage of water and IPTG molecules but excluding such larger molecules as proteins. The bag was then placed in water containing radioactive IPTG.

As IPTG can pass through the bag an equal concentration of the inducer should be achieved. But if IPTG should bind itself to the lac repressor inside the bag then it will be too large to pass freely through the bag membrane. Consequently the concentration of the IPTG bound to the repressor should start to build up inside the bag and, being radioactive, should be readily detectable. Eventually they were able to report a concentration of IPTG 4% greater inside the bag than out. This was enough to encourage Gilbert and Muller-Hill to proceed to the next stage of fractionating, purifying, and isolating the repressor. This proved more difficult than they had expected but in late 1966 they were able to report the existence of a large protein molecule, the lac repressor. The following year their Harvard colleague M. Ptashne obtained a similar result with the lambda phage repressor.

Gilbert has also developed techniques for determining the sequence of bases in DNA, which though similar to Frederick SANGER's method differs in that it can be applied to single as well as double-stranded DNA. It was for this work that he shared the 1980 Nobel Prize for chemistry with Sanger and Paul BERG.

**Gilbert, William** (1544–1603) *English physicist and physician*

Look for knowledge not in books but in things themselves.

—*De magnete, magnetisque corporibus, et de magno magnete tellure* (1600; On the Magnet, Magnetic Bodies, and the Great Magnet Earth)

Gilbert, who was born at Colchester in Essex, England, was educated at Cambridge University, where he took his degree in 1569 and later became a fellow. He moved to London in 1573, became a member of the Royal College of Physicians, and served as physician to Queen Elizabeth I and briefly to James I. In 1600 he published the first great English scientific work *De magnete, magnetisque corporibus, et de magno magnete tellure* (On the Magnet, Magnetic Bodies, and the Great Magnet Earth) in which he presented his investigations into magnetic bodies and electrical attractions. It is a remarkably “modern” work – rigorously experimental, emphasizing observation, and rejecting as unproved many popular beliefs about magnetism, such as the supposed ability of diamond to magnetize iron. He showed that a compass needle was subject to magnetic dip (pointing downward) and, reasoning from experiments with a spherical lodestone, explained this by concluding that the Earth acts as a bar magnet. He also introduced the term “magnetic pole.” The book was widely available on the Continent, there being five editions in Germany and Holland alone before 1628, and was very influential in the creation of the new mechanical view of science.

**Gilchrist, Percy Carlyle** (1851–1935) *British industrial chemist*

Gilchrist, who was born at Lyme Regis in Dorset, England, was educated at the Royal School of Mines in London. In 1875 he was appointed chemist at the Cwm Avon works in South Wales, and here in his spare time he assisted his cousin Sidney Gilchrist THOMAS in trials of a new process of smelting iron ore. In the *Gilchrist–Thomas process* the furnace was lined with a basic material (such as magnesium oxide), which combined with phosphorus impurities in the iron to form a “basic slag” of phosphates. Gilchrist later made other improvements to the process, which was extremely important at the time in allowing exploitation of phosphoric ores.

**Gill, Sir David** (1843–1914) *Scottish astronomer*

By his individual achievements and by his leadership he has exerted an incalculable influence on the progress of all that pertains to precision of observation.

—Sir Arthur Eddington, *Monthly Notices of the Royal Astronomical Society* (1915)

Born in Aberdeen, Scotland, Gill was educated at Marischal College and Aberdeen University. He was in charge of the Earl of Crawford's private observatory at Dunecht before becoming royal astronomer at the Cape of Good Hope, where he remained until 1907. He was knighted in 1900.

Gill spent much time and thought on improving the accuracy of the astronomical unit (AU – the mean distance between the Earth and the Sun, one of the basic measurements of astronomy), then determined from measurements of the distances of Venus and Mars. In 1874 he went to Mauritius to observe the transit of Venus. The difficulty is that Venus, on magnification, presents a disk whose edges are not absolutely sharp, thus making it difficult to estimate the moment of first contact. In 1877 Gill went to Ascension Island to measure the distance of Mars using the distance from Greenwich as a base line. Although he obtained reasonable results he realized (as had Johann Galle) that a more accurate figure could be obtained if the planetoids were used instead for they came closer to the Earth and on magnification presented a starlike appearance. (This idea was taken up with great success later by Harold SPENCER JONES.) In 1897, with the co-operation of astronomers in Leipzig and New Haven, Gill made a very accurate determination of the solar parallax.

His other main research was extending Friedrich ARGELANDER's catalog to the southern skies. This began in 1882 when he photographed a comet and was impressed with the clarity of the stars visible in the background. Consequently he started photographing the southern skies, collaborating with the Dutch astronomer Jacobus KAPTEYN. In 1904 the *Cape Photographic Durchmusterung* was published cataloging over 450,000 stars to within 19° of the southern celestial pole.

**Gilman, Alfred Goodman** (1941– )  
*American pharmacologist*

The son of Alfred Gilman Snr, a noted pharmacologist, Gilman received his PhD from Case Western Reserve University, Cleveland, Ohio, in 1969. After working at the University of Virginia Medical School from 1971 until 1981, Gilman moved to the University of Texas Southwestern Medical Center, Dallas, where he became professor of pharmacology.

Gilman's work has been on the processes by which hormones, neurotransmitters, and other stimuli – the so-called “first messengers” – influence cellular activity. It had been shown by Earl SUTHERLAND in 1971 that hormones do not actually enter cells. They seem to bind to receptor sites on the cell's surface and then produce a “second messenger,” cAMP (cyclic adenosine monophosphate), which initiates the appropriate cellular response.

It was further shown by Martin RODBELL that other factors, namely an amplifier and a transducer, were required in the process. Rodbell identified the enzyme adenylate cyclase (AC) as the amplifier and demonstrated that transducers would only work in the presence of the energy-rich molecule guanine triphosphate (GTP).

Gilman set out to elucidate the process further. He established in the late 1970s that the transducers were in fact proteins. They were initially named “guanine nucleotide binding proteins,” a term quickly shortened to G proteins. Gilman went on to outline the main steps in cellular signalling as:

1. A hormone, neurotransmitter, etc., binds to a cell receptor;
2. The receptor binds to and activates a G protein;
3. The activated G protein binds to GTP;
4. The activated GTP stimulates AC to produce cAMP;
5. cAMP produces an appropriate cellular response.

G proteins have been shown to play a number of important physiological roles. In cholera, for example, a toxin is produced that freezes G proteins into their GTP-bound activated state, producing in the body a massive fluid loss with consequent dehydration. G proteins are also thought to be involved in some aspects of diabetes and some types of cancer.

Gilman shared the 1994 Nobel Prize for physiology or medicine with Martin Rodbell for their work on G proteins.

**Gilman, Henry** (1893–1986) *American chemist*

Gilman was born in Boston, Massachusetts, and educated at Harvard, where he obtained his PhD in 1918. After working briefly at the University of Illinois he moved to the Iowa State College of Agriculture and Mechanical Arts in 1919, spending the rest of his career there and serving as professor of organic chemistry from 1923 until his retirement in 1962. He worked extensively in the field of organometallic chemistry and produced one of the standard texts in the field, *Organic Chemistry, an Advanced Treatise* (1938, 2 vols.; revised and extended 1953, 4 vols.).

**Ginzburg, Vitaly L.** (1916– ) *Russian physicist*

Ginzburg was born in Moscow, where he gained his doctor's degree at the local university. He is former head of the Theory Group at the P. N. Lebedev Physical Institute, Moscow. A renowned 20th-century physicist and member of several National Academies of Sciences, he was in residence at the Department of Physics

and Astronomy at the University of Kentucky, Lexington, USA in early 1997.

Ginzburg was among the first people to study superconductors. In particular, in the 1950s he, Lev LANDAU, and their co-workers explained the functioning of type-I semiconductors, which (unlike type-II superconductors) lose their superconductivity in strong magnetic fields. This became known as the *Ginzburg–Landau* theory. For this seminal work, Ginzburg shared the 2003 Nobel Prize for physics with Alexei ABRIKOSOV and Anthony LEGGETT, which was awarded for pioneering contributions to the theory of superconductors and superfluids. (Lev Landau received the 1962 Nobel Prize for physics for different research on condensed matter.)

**Glaser, Donald Arthur** (1926– ) *American physicist*

Glaser was born in Cleveland, Ohio, and took his degree in physics and mathematics at the Case Institute of Technology there. After graduating in 1946, he went on to gain his doctorate for cosmic-ray research from the California Institute of Technology in 1950. From 1949 to 1959, Glaser worked in the physics department of the University of Michigan, becoming professor in 1957. In 1959 he moved to the University of California at Berkeley as a professor of physics and subsequently (1964) as a professor of physics and biology.

While at the University of Michigan, Glaser became interested in techniques for the visualization and recording of elementary particles. The WILSON cloud chamber, using supersaturated vapor, had been in use since the 1920s, but was unsuited to the detection of the highly energetic particles emerging from the new accelerators of the 1950s.

Glaser considered other unstable systems that could be used, and experimented with superheated liquids, in which ionizing particles would leave a trail of vapor bubbles. In 1952 he produced the first radiation-sensitive bubble chamber, in which he used diethyl ether under pressure and controlled temperature. A sudden brief reduction in pressure was used and trails of bubbles forming along the tracks of particles could be captured by high-speed photography before the bulk of the liquid boiled. For this invention, and its subsequent development into a useful research tool, Glaser received the 1960 Nobel Prize for physics.

The bubble chamber, using liquid hydrogen at low temperature, is now a basic component of almost all high-energy physics experiments, and has been the instrument of detection of many strange new particles and phenomena. Present-day bubble chambers are much bigger (and more expensive) than Glaser's original, which was only three cubic centimeters in volume.

In 1962 he turned to molecular biology and was involved in research on bacterial evolution, regulation of cell growth, and the cause of genetic mutation. He later moved into the field of neurobiology.

**Glashow, Sheldon Lee** (1932– ) *American physicist*

Glashow was born in New York City and graduated from the Bronx High School there in 1950. He went on to Cornell University, where he gained his bachelor's degree in 1954. His MA (1955) and PhD in physics (1959) were gained at Harvard University, and his postdoctoral research took him to the Bohr Institute, the European Organization for Nuclear Research (CERN) in Geneva, and the California Institute of Technology. After a year at Stanford he joined the faculty of the University of California at Berkeley (1961–66). In 1967 he returned to Harvard as a professor of physics and remained there until 2000, when he unexpectedly moved to become Metcalf Professor of Mathematics and Physics at Boston University. Glashow is a notable opponent of string theory, a fact that some say explains why he left Harvard.

The award of the 1979 Nobel Prize, shared with Abdus SALAM and Steven WEINBERG, was for the explanation of the forces that bind together elementary particles of matter. The citation was “for their contribution to the theory of the unified weak and electromagnetic interaction between elementary particles, including *inter alia* the prediction of the weak neutral current.”

The Weinberg–Salam theory was a major step in unifying two of the four fundamental forces of physics: the electromagnetic interaction and the weak interaction. The theory was originally applied only to the class of particles known as leptons (electrons and neutrinos). Glashow extended the theory to other elementary particles (including the baryons and mesons) by introducing a new property that he called “charm.” The quark theory of Murray GELL-MANN could be extended by the introduction of a fourth quark – the “charmed quark” – and combinations of the four types of quark could lead to a group of particles with symmetry SU<sub>4</sub>. The idea of charm can be used to explain the properties of the *J/psi* particle, discovered in 1974 by Burton RICHTER and Samuel TING.

Other extensions of the quark theory have since been made involving “colored quarks” – the theory is known as “quantum chromodynamics.”

**Glauber, Johann Rudolf** (1604–1668) *German chemist*

Glauber (**glow**-ber) was the son of a barber in

Karlstadt, now in Germany. He spent the first half of his life traveling and working in Germany, and later settled in Amsterdam. There he made his living chiefly through selling chemicals and medicinals. He made important contributions to chemistry and his fame is largely based on his discovery of a salt called *sal mirabile* (sodium sulfate). He had found that the action of sulfuric acid on common salt produced a new acid, hydrochloric, and a salt, sodium sulfate. This became known as *Glauber's salt* and was originally sold to treat everything from typhus to constipation. It is still widely used, together with Epsom salt (magnesium sulfate), as a laxative.

Glauber's chief work, *Philosophical Furnaces* (1646–48), has been described as the first comprehensive treatise on industrial chemistry outside metallurgy. He seems to have been something of a consultant developing new products and advising on chemical processes in industry. He also speculated on the nature and rules of chemical affinity. His technical works were published as *Opera omnia chymica* (1658; Complete Works on Chemistry) in seven volumes. His *Prosperity of Germany*, written after the Thirty Years' War, looked forward to a peaceful Europe ruled by a Germany whose power arose from a science-based military technology.

**Glauber, Roy J.** (1925– ) *American physicist*

Glauber was born in New York and educated at Harvard University, where he received his PhD in 1949. Most of his subsequent career has been spent as a professor of physics at Harvard University. He was one of the founders of the subject of *quantum optics* – i.e., an extension of the theory of optics in which the electromagnetic field associated with light is analyzed using quantum field theory rather than the classical electrodynamic theory described by MAXWELL's equations.

Glauber first put forward his fundamental work on quantum optics in 1963. This described a quantum theory of optical coherence. In his work, he emphasized that analyzing experiments that detect photons in terms of quantum electrodynamics in a consistent way necessarily involves the idea that, after a photon has been absorbed, the quantum state of the electromagnetic field itself has been changed. Glauber was able to describe interference effects in optical experiments in terms of his theory. In particular, his formalism could give a clear description of the differences between light from a laser, which is characterized by coherence, and light from a source such as a light bulb, in which there is no coherence. He was also able to describe the circumstances under which it is reasonable to regard the

quantum effects on classical light as small fluctuations.

Glauber's work of 1963 provided the foundations for a vast amount of subsequent theoretical and experimental work on quantum optics. Quantum optics has many practical applications and has also been used to investigate the fundamentals of quantum mechanics. For his work in this area Glauber shared the 2005 Nobel Prize for physics with John HALL and Theodor HÄNSCH.

**Glazebrook, Sir Richard Tetley** (1854–1935) *British physicist*

Glazebrook, a Liverpudlian by birth, graduated from Cambridge University in 1876 and at once joined the Cavendish Laboratory, Cambridge, under the directorship of James Clerk MAXWELL. He became lecturer in physics and mathematics and in 1891 was appointed assistant director of the Cavendish. He left to become first principal of University College, Liverpool (1898–99) and then director of the newly established National Physical Laboratory at Teddington (1900–19). He was knighted in 1917.

Glazebrook conducted a considerable amount of research on electrical standards involving very precise electrical measurements. He also made contributions to the fields of optics and thermometry. From 1909 the National Physical Laboratory undertook research into aeronautics. This work included wind-tunnel experiments for aircraft development and the adoption of scientific apparatus for military and aeronautical engineering purposes.

After his retirement in 1919 Glazebrook took on new teaching and administrative responsibilities, serving for many years as chairman of the Aeronautical Research Committee. He was the author of several books on physics and science in general and also edited the *Dictionary of Applied Physics*.

**Glisson, Francis** (1597–1677) *English physician*

Born at Rampisham in southwest England, Glisson was educated at Cambridge University where he obtained his MD in 1634. He was appointed professor of physics at Cambridge in 1636 and retained the post until his death. However most of his time was spent in private practice in London, so an assistant was employed to fulfill his Cambridge teaching obligations.

Glisson was a member of the group that, beginning in 1645, met regularly in London and out of which the Royal Society was later to emerge. From this "Invisible College," as it was later known, came one of the earliest examples of cooperative research. A committee of nine was set up in 1645 to investigate rickets but, as

Glisson's contribution far exceeded that of any other contributor, it was agreed that he should publish the report *De rachitide* (1650; On Rickets) under his own name. Although the nature of rickets could only begin to be comprehended with the discovery of vitamins by Casimir FUNK in 1912, Glisson must be credited for his clear description of the disease.

He was more original and influential in his account of irritability, first formulated in his work on the liver, *Anatomia hepatis* (1654; Anatomy of the Liver). He argued that muscular irritability, that is, their tendency to respond to stimuli, was independent of any external input, nervous or otherwise. This was a considerable improvement over the orthodox position adopted by the followers of René DESCARTES who believed that muscle could only respond by being pumped up like a tire, with a subtle nervous spirit rather than air. Glisson later reported a simple experiment where he placed his arm in a tube filled with water and noted that when his muscles contracted the level of water actually fell. This showed quite clearly, he claimed, that there had been no flow of anything into the limb.

It was this idea of irritability which, picked up by Albrecht von HALLER in the following century, was to find a permanent place in physiology.

### **Gmelin, Leopold** (1788–1853) *German chemist*

Gmelin (**gmay**-leen), whose father and grandfather were botanists, was born at Göttingen (in Germany) and studied at the universities of Tübingen, Göttingen, and Vienna. In 1817 he was appointed to the first chair of chemistry at Heidelberg, where he remained until 1851. In 1817 he published the first edition of what was to become the major chemical textbook of the first half of the 19th century, *Handbuch der Chemie* (Handbook of Chemistry), in three volumes. By 1843 the book was in its fourth edition and had been expanded to nine volumes. In this edition Gmelin adopted the atomic theory and devoted much more space to the growing discipline of organic chemistry. The terms *ester* and *ketone* were introduced by him. His book was translated into English in 1848.

He also worked on the chemistry of digestion, discovering several of the constituents of bile, and introduced *Gmelin's test* for bile pigments. In 1822 he discovered potassium ferrocyanide.

### **Goddard, Robert Hutchings** (1882–1945) *American physicist*

God pity a one-dream man.

—Quoted by Carl Sagan in *Broca's Brain* (1980)

Goddard was educated in his hometown of Worcester, Massachusetts, gaining his BSc in

1908 from the Polytechnic Institute and his PhD in 1911 from Clark University. He did postgraduate work at Princeton, 1912–13. He returned to Clark in 1914 where he was made professor of physics in 1919 and where he remained until his retirement in 1943.

Goddard is remembered as the designer of the first successful liquid-fuel rocket. He had been interested in space travel as a boy and his early views were first publicly revealed in his famous pamphlet *A Method of Reaching Extreme Altitudes*, published in 1919. He had most of the basic ideas of rocket design and travel clear in his mind in his 1919 paper. He realized that a reaction engine would be necessary and that sufficient thrust could only be developed with liquid fuels. In 1923 he therefore started to design rockets powered by liquid oxygen.

Unlike his Russian contemporary Konstantin TSIOLKOVSKY, he was fortunate to attract almost immediate and generous backing. The Smithsonian Institution supported him until 1929 when, through the influence of Charles Lindbergh, the Guggenheim family backed him with \$15,000 a year up to the mid-1940s. His first successful rocket flight was made in 1926 when a four-foot rocket flew for two seconds and reached an altitude of 40 feet (12 m). This was followed by bigger, faster, and inevitably noisier and smellier rockets. To escape the complaints and threatened litigation he set up a research and testing station at Roswell, New Mexico, in 1929, financed by the Guggenheim Foundation.

He continued to make improvements in his design. In 1931 he introduced the now familiar automatic launch sequential system and in 1932 gyroscopic steering. In 1935 his liquid-fuel rockets flew at supersonic speeds. The greatest altitude reached was 12½ miles (20 km).

Goddard's New Mexico station closed down during the war even though he offered his work to the military. He lived just long enough to inspect the captured German V–2 rockets, which, though much bigger than his, were based on the same principles. He was also prudent enough to take out about 100 patents on rocket design. His widow was later to receive \$1,000,000 for their use from the Department of Defense.

### **Gödel, Kurt** (1906–1978) *Austrian–American mathematician*

It is impossible to demonstrate the noncontradictoriness of a logical mathematic system using only the means offered by the system itself.

—Gödel's statement of his "incompleteness" theorem for arithmetic

Born in Brünn (now Brno in the Czech Republic), Gödel (**gu**(**r**)-del) initially studied physics at the University of Vienna, but his interest soon turned to mathematics and mathematical

logic. He obtained his PhD in 1930 and the same year joined the faculty at Vienna. He became a member of the Institute for Advanced Study, Princeton, in 1938 and in 1940 emigrated to America. He was a professor at the Institute from 1953 to 1976, and received many scientific honors and awards, including the National Medal of Science in 1975. He became a naturalized American citizen in 1948.

In 1930 Gödel published his doctoral dissertation, the proof that first-order logic is complete – that is to say that every sentence of the language of first-order logic is provable or its negation is provable. The completeness of logical systems was then a concept of central importance owing to the various attempts that had been made to reveal a logical axiomatic basis for mathematics. Completeness can be thought of as ensuring that all logically valid statements that a formal (logical) system can produce can be proved from the axioms of the system, and that every invalid statement is disprovable.

In 1931 Gödel presented his famous incompleteness proof for arithmetic. He showed that in any consistent formal system complicated enough to describe simple arithmetic there are propositions or statements that can neither be proved nor disproved on the basis of the axioms of the system – intuitively speaking, there are logical truths that cannot be proved within the system. Moreover, as a corollary Gödel showed (what is known as his second incompleteness theorem) that the *consistency* of any formal system including arithmetic cannot be proved by methods formalizable within that system; consistency can only be proved by using a stronger system – whose own consistency has to be assumed.

Gödel's second great result concerned two important postulates of set theory, whose consistency mathematicians had been trying to prove since the turn of the century. Between 1938 and 1940 he showed that if the axioms of (restricted) set theory are consistent then they remain so upon the addition of the axiom of choice and the continuum hypothesis, and that these postulates cannot, therefore, be disproved by restricted set theory. (In 1963 Paul COHEN showed that they were independent of set theory.)

Gödel also worked on the construction of alternative universes that are models of the general theory of relativity, and produced a rotating-universe model.

Gödel apparently suffered from depression throughout much of his life. In 1936–37 he spent some time in an Austrian sanatorium being treated for the condition. He was also something of a hypochondriac. He retired from the institute in 1976 and when, soon after, his wife underwent major surgery, he seems to have stopped eating. Apparently he was convinced that he was being poisoned. In

late 1977 he was admitted to hospital dehydrated and undernourished. He refused to eat and two weeks later died from “malnutrition and inanition caused by personality disturbance.”

### Godwin, Sir Harry (1901–1985) *British botanist*

Godwin was born at Rotherham in Yorkshire, England, and educated at Cambridge University. He remained at Cambridge for his whole career, serving as demonstrator, lecturer, and reader before becoming director of the subdepartment of Quaternary research in 1948. He held the chair of botany from 1960 until his retirement in 1968.

Godwin's early investigations concerned the development of fen and bog vegetation using the technique of pollen analysis. During these studies he compiled a card index of higher plants with information about their Quaternary history. This led to his *History of the British Flora* (1956), which has become a standard reference for archeological, climatic, geological, and botanical investigations of the Quaternary period in Europe.

### Goeppert-Mayer, Maria (1906–1972) *German-American physicist*

Maria Goeppert (**gu(r)**-pert) was born at Katowitz in Poland and educated at the University of Göttingen where she obtained her PhD in 1930. (She changed her name on marrying the physical chemist, Joseph Mayer.) Emigrating to America in 1931 she was employed at Johns Hopkins University, Baltimore (1931–39), Columbia University, New York (1939–46), and the Argonne National Laboratory (1946–60). Finally, in 1960 she took a post at the University of California, San Diego, at La Jolla.

In 1963 she was awarded the Nobel Prize for physics together with Hans JENSEN and Eugene P. WIGNER for their work on nuclear shell theory. The shell theory of the nucleus is analogous to the shell model of the atom. The theory could help explain why some nuclei were particularly stable and possessed an unusual number of stable isotopes. In particular, in 1948, she argued that the so called “magic numbers” – 2, 8, 20, 50, 82, and 126 – which are the numbers of either protons or neutrons in particularly stable nuclei, can be explained in this way. She supposed that the protons and neutrons are arranged in the nucleus in a series of nucleon shells. The magic numbers thus describe those nuclei in which certain key shells are complete. In this way helium (with 2 protons and 2 neutrons), oxygen (8 of each), calcium (20 of each), and the ten stable isotopes of tin with 50 protons all fit neatly into this pattern. Also significant was the fact that, in general, the more complex a nucleus becomes the less

likely it is to be stable (although there are two complex stable nuclei, lead 208 and bismuth 209, both of which have the magic number of 126 neutrons).

**Goethe, Johann Wolfgang von** (1749–1832) *German poet, novelist, dramatist, and natural philosopher*

As for what I may have done as a poet, I take no pride in it whatever.... But that in my century I am the only person who knows the truth in the difficult science of colors – of that, I say, I am not a little proud, and here I have a consciousness of superiority to many.

—Quoted by Johann Peter Eckermann in *Conversations with Goethe* (1837)

Both the way in which the parts of an animal relate to one another and the particular individual characteristics of those parts are determined by the creature's everyday needs. This explains the distinctive, yet strictly delimited, lifestyles of the various animal species ...

—*First Draft of a General Introduction to Comparative Anatomy* (1795)

Born the son of a lawyer at Frankfurt in Germany, Goethe (**gu(r)-te**) was educated privately until 1765 when, under pressure from his father, he agreed to study law at Leipzig University. In 1776 he joined the court of the Duke of Weimar which remained as his main base for the rest of his life. By this time he had established a European reputation following the publication in 1774 of his semi-autobiographical novel *Die Leiden des Jungen Werthers* (The Sorrows of Young Werther). Goethe was a prolific writer, producing about 133 published works. His greatest work *Faust* (Part I, 1808; Part II, 1832) was completed in the last years of his life.

Throughout his life Goethe was interested in science and philosophy, as well as astrology and the occult. He founded the science that he called *morphology* (a term he introduced around 1817). To Goethe this was a general discipline involving the systematic study of all types of formation and transformation – whether of rocks, clouds, colors, living things, or structures of society. To some extent, this integrated view of natural science is echoed in quite modern ideas, such as those of catastrophe theory, chaos theory, and complexity theory.

In particular, Goethe had ideas about the morphology of plants and animals. These are most clearly enunciated in two didactic poems, *Die Metamorphose der Pflanzen* (1798; The Metamorphosis of Plants) and *Metamorphose der Tiere* (1806; Metamorphosis of Animals). There were, he argued, “Urpflanze” and “Urtier,” ideal archetypes of the plant and animal kingdom. Thus the reason many species resembled each other had nothing to do with their history, evolutionary or otherwise, but was because they were built to the same basic

design. Organisms were not only variations on a single type, but each type was composed of morphologically identical segments. Thus for Goethe, the different parts of a plant – stamens, pistils, etc. – are all variations of the leaf.

In Goethe's animal morphology, the archetype for a vertebrate was the vertebra, with the skull seen as a vertebral variation. As a consequence of his assumptions Goethe was forced to argue that any structure present in one mammal would have to be found in all others. As ruminants have an intermaxillary bone in their upper jaw, he was compelled to find a similar structure in man. Even though it is present only in human embryos (the premaxilla), Goethe claimed in 1784 to have found the bone in adult males.

Goethe's poems on plant and animal morphology approach the central issue from opposite directions: whereas the earlier work celebrates the diversity of plant life, the later poem emphasizes that even the most unusual evolutionary feature emanates from the archetype. Thus the very organization of these literary works as complementary contrasts is indicative of Goethe's holistic thinking.

Goethe's other main area of scientific interest was represented in his *Zur Farbenlehre* (On the Science of Colors, 1810), a work he perhaps valued more than any of his poetry. It was deeply (and naively) critical of NEWTON and sought to replace reliance on such abstract notions as “rays” of light with a more direct appeal to observed phenomena. There was much more to vision, he insisted, than the measurements of lines and angles. Ultimately, however, Goethe's attempt to ascribe affective qualities to particular colors abandons the realm of empirical science. Significantly, the *Farbenlehre* finds later resonance in the Expressionist painter Wassily Kandinsky's highly subjective color theory, rather than in the modern chromatatics of such people as CHEVREUL.

Contemporary chemical theory formed the basis of his novel *Elective Affinities* (Die Wahlverwandschaften, 1809). The 18th-century chemist spoke of a “double affinity” in which two compounds AB and CD join to exchange parts and create two new bodies, AC and BD. (Chemists now call this type of reaction “double decomposition.”) In a similar way, in the novel, a married couple Eduard and Charlotte form a double affinity with their two friends, the Captain and Ottilie.

The mineral form of iron oxide, *goethite*, was named in Goethe's honor by LENZ in 1806.

**Gold, Thomas** (1920–2004) *Austrian–American astronomer*

Things are as they are because they were as they were.

—Quoted by Misner, Thorpe, and Wheeler in *Gravitation*

Born in Vienna, Gold became a refugee from the Austrian Anschluss and gained his BA in 1942 from Cambridge University, England. He lectured there in physics from 1948 to 1952 before he joined the Royal Greenwich Observatory as chief assistant to the Astronomer Royal. He moved to America in 1956, becoming director of the Center for Radiophysics and Space Research at Cornell from 1959 to 1981, and professor of astronomy from 1971 to 1986.

Gold is best known for his contribution to cosmology, the study of the origin, evolution, and large-scale structure of the universe. In the 1940s the prevailing cosmological model was the big-bang theory originally proposed by Georges LEMAITRE. Since this theory postulated a "beginning of time" when the incredibly compact universe exploded into being, it was regarded with suspicion and alarm by many astronomers. In 1948 Gold published, with Hermann BONDI, *The Steady-State Theory of the Expanding Universe*. At the heart of this paper was the adoption of what became known as the "perfect cosmological principle." This was an extension of the cosmological principle, which states that the universe looks basically the same from whichever point one observes it; Gold and Bondi added to this that the time of observation was as irrelevant as the place. Thus the universe, on a large scale, is unchanging in time and space. It had no beginning, will never end, and a constant density of matter throughout space will always be maintained. This needed to be reconciled with the work of Edwin HUBBLE, which Gold and Bondi accepted and which showed that the galaxies are receding and the universe is expanding. To maintain the steady state of their universe, Gold and Bondi had to introduce an original and startling proposition, namely, that there must be continuous creation of new matter from nothing. They calculated the amount needed as about one hydrogen atom per cubic kilometer of space every ten years, an amount too small to be detected. Although this proposition conflicted with such deep physical assumptions as the conservation of matter and the laws of thermodynamics they found that it was compatible with all astronomical data.

The steady-state theory proved attractive to a number of cosmologists and crucial evidence only emerged against it in the 1960s. Then Arno PENZIAS and Robert WILSON discovered the background microwave radiation in 1965, and Maarten SCHMIDT produced a survey of the distribution of quasars that seemed to support the evolving universe of the big-bang theory.

In 1968 news of a new type of star, a "pulsar," was published by Jocelyn BELL-BURNELL and Antony HEWISH. The distinguishing features of the pulsar were its high-frequency radio signals, which had a periodicity of the order of a second or less. Gold quickly proposed a structure capable of producing such an effect: rapidly

rotating neutron stars. The same theory was proposed independently by Franco Pacini. Neutron stars are extraordinarily dense stars that have undergone such extreme gravitational collapse following exhaustion of their nuclear fuel that their constituent protons and electrons have combined to form neutrons. These stars would be small and dense enough to rotate with a period equivalent to that of the radio pulses. It had also been shown that they would radiate energy in a narrow beam. If the Earth happened to be in the direction of the beam, the beam would be picked up as a source of pulses, much as the beam of a lighthouse is observed as a series of flashes. The theory of Gold and Pacini was eventually accepted once pulsars rotating even faster than the original one were detected in the Crab and Vela nebulae.

Gold was able to make a prediction that has since been confirmed. He argued that pulsars should be slowing down by a small but measurable amount, because of the loss of energy. Following careful observation of the pulsar in the Crab nebula it was found to be slowing down and its period increasing by  $3.46 \times 10^{-10}$  seconds per day.

### **Goldberger, Joseph (1874–1929) American physician**

Goldberger, the son of Jewish immigrants, had been born at Giralt in Hungary and was brought to America at the age of six. He was educated at the College of the City of New York and at Bellevue Hospital Medical School. After a brief period in private practice Goldberger joined the U.S. Public Health Service in 1899, remaining there for the rest of his life.

Goldberger worked as a field officer for many years, making contributions to the understanding and control of such diseases as yellow fever, typhus, and dengue. He is, however, mainly remembered for his authoritative investigation of the nature, causation, and treatment of pellagra. This disease, which became widely known in America after the Civil War, is typified by chronic diarrhea, roughening of the skin, a sore tongue, and involvement of the nervous system. Death from secondary infection or general emaciation was not uncommon.

When Goldberger began his work in 1913 it was thought that the disease was caused by an unknown toxin produced by bacterial fermentation during storage of grain. But stimulated by the work of Frederick Gowland HOPKINS and Casimir FUNK, Goldberger directed his attention to deficiency diseases. He began a classic investigation into the connection between pellagra and diet in various asylums and orphanages of the southern states. He was immediately struck by the fact that the staff of such institutions – with a diet containing milk, eggs, cheese, and meat – remained free of the disease while the inmates, subsisting virtually

on cereals alone, frequently suffered from epidemics of pellagra.

It was a relatively simple matter to show that the disease could be eliminated by supplementing the inmates' diet with milk. He was further able to trade the offer of a pardon with 11 inmates of a Mississippi prison for their adoption of a diet of corn, rice, sugar, pork fat, potatoes, and turnips. Within a few months 7 of the 11 were showing early symptoms of pellagra. Attempts to transmit the disease by contact with the clothes, excreta, and vomit of the patients ended in failure. All this led Goldberger to propose the existence of a P-P, or pellagra-preventive, factor. Whatever such a factor might be, he was able to show by 1920 that sufficient of it was contained in a daily dose of 15–30 grams of yeast, and by this means alone Goldberger was able to prevent the 10,000 deaths a year attributable to pellagra in the United States.

The active ingredient involved was shown in 1937 by Conrad ELVEHJEM to be nicotinic acid (niacin), part of the vitamin B complex.

### **Goldhaber, Maurice** (1911– ) *Austrian–American physicist*

Goldhaber (**gohld-hahber**), who was born at Lemberg (now Lvov in Ukraine), was educated at the universities of Berlin and Cambridge, where he obtained his PhD in 1936. He emigrated to America in 1938 where he first taught at the University of Illinois, becoming professor there in 1945. He moved to the Brookhaven National Laboratory in 1950, serving as its director from 1961 until 1973.

In 1934, while at the Cavendish Laboratory of Cambridge University, Goldhaber codiscovered the nuclear photoelectric effect with James CHADWICK. This is the disintegration of a nucleus by high-energy x-rays or gamma rays. From this it was later established that the neutron is slightly heavier than the proton. Following Enrico FERMI's discovery of slow neutrons, Chadwick and Goldhaber also discovered (1934–35) the neutron disintegration reactions for lithium, boron, and nitrogen. The nitrogen reaction is the major source of radioactive carbon-14 on Earth.

At the University of Illinois (1938) Goldhaber and his wife, Gertrude Scharff-Goldhaber, demonstrated that electrons and beta particles are the same. In 1940 he discovered that beryllium is a good moderator, i.e., it slows down fast neutrons so they more readily split uranium atoms.

He has also proposed a cosmological theory in which an initial "universon" broke up into a "cosmon" (matter) and an "anticosmon" (antimatter), with the anticosmon forming a second universe made of antimatter. After his retirement from Brookhaven, Goldhaber worked on the Irvine–Michigan–Brookhaven (IMB) un-

derground detector studying proton decay and neutrino oscillations.

### **Goldschmidt, Johann (Hans) Wilhelm** (1861–1923) *German chemist*

Goldschmidt (**gohlt-shmit**), the son of an Essen industrialist, was born at Berlin in Germany. After studying at Berlin and Heidelberg he joined the family business in 1888.

In 1905 Goldschmidt introduced cheaper methods for the reduction of metallic oxides to metals (the "Thermit process"). It had been common for the reduction process to use highly reactive but expensive metals, such as potassium and sodium. Goldschmidt showed that if a mixture of the metal oxide and aluminum powder is ignited with magnesium in contact with barium peroxide, great heat is generated and the pure metal produced. The technique was important in the production of certain metals used in alloy steels. It was also used for localized welding of steel (using iron oxide and aluminum).

### **Goldschmidt, Victor Moritz** (1888–1947) *Swiss–Norwegian chemist*

This poison is for professors of chemistry only. You, as a professor of mechanics, will have to use the rope.

—Explaining his possession of a cyanide capsule to a university colleague during the Nazi occupation of Norway

Goldschmidt, the son of H. J. Goldschmidt, a physical chemist, was born at Zurich in Switzerland. He attended Christiania (now Oslo) University where he obtained his PhD in 1911, remaining in Norway as director of the Mineralogical Institute until 1929 when he moved to the University of Göttingen in Germany. Being a Jew he returned to Norway in 1935, following the rise of anti-Semitism and the Nazi party. He was later sent to a concentration camp but was released by the Norwegian authorities on the grounds of ill health and escaped to England (1942). His time in England was spent first at the Macaulay Institute for Soil Research near Aberdeen, and later at the Rothamsted Experimental Station, Harpenden. He returned to Oslo after the war.

Goldschmidt is acknowledged as the founder of modern geochemistry. Following the work of Max VON LAUE and W. H. and W. L. BRAGG, he laid the foundation for his work by working out the crystal structure of over 200 compounds. His interest was directed to more practical work when, as a result of the naval blockade in the war, he was called upon to investigate Norway's mineral resources.

By the mid-1920s the atomic radii of elements in various stages of ionization had been established. Using this information, together with his detailed knowledge of crystal structure, Goldschmidt began predicting in which

minerals and rocks various elements could or could not be found. His results were published over the years in his eight-volume *Geochemische Verteilungsgesetze der Elemente* (1923–38; The Geochemical Laws of the Distribution of the Elements). His book *Geochemistry* was published posthumously in 1954.

**Goldstein, Eugen** (1850–1930) *German physicist*

Goldstein (**gohlt**-shtIn), who was born at Gleiwitz (now Gliwice in Poland), studied for a year at the University of Breslau (1869–70) then worked with Hermann von HELMHOLTZ at the University of Berlin. He was appointed physicist at the Berlin Observatory in 1878, took his doctorate in 1881, and later established his own laboratory. In 1927 he became head of the astrophysical section of the Potsdam Observatory.

Goldstein's best-remembered scientific work is his studies of electrical discharges in gases at low pressures. He gave the name "cathode rays" to the invisible emanations coming from the cathode of an evacuated discharge tube, showed that the rays could cast sharp shadows, and demonstrated that they were emitted perpendicular to the cathode surface. He later showed that they could be deflected by magnetic fields. Like most German scientists Goldstein believed that cathode rays were waves like light. J. J. THOMSON later identified cathode rays as a stream of electrons. In 1886 Goldstein announced his discovery of *kanalstrahlen* (canal rays), rays that emerged from channels in the anode in a low-pressure discharge tube. These were identified as positively charged particles by Jean Baptiste PERRIN in 1895, and later exploited in mass spectroscopy.

**Goldstein, Joseph Leonard** (1940– ) *American medical geneticist*

Born at Sumpter in South Carolina, Goldstein attended Washington and Lee University, Virginia, and the University of Texas Southwestern Medical School, where he gained his MD in 1966. For two years he worked at Massachusetts General Hospital, Boston. In 1968 he joined the National Institutes of Health as a clinical associate (1968–70). After a stint of research at the University of Washington, Seattle (1970–72), he joined the University of Texas Southwestern Medical Center in Dallas. In 1977 Goldstein was appointed professor of medicine and chairman of the Department of Molecular Genetics, and in 1985 he was made regental professor.

Goldstein's work has centered on the metabolism of cholesterol, fats, and other lipids in the body; much of it has been done in collaboration with his fellow biochemist and geneticist, Michael BROWN, whom Goldstein met when

both were interns at Massachusetts General Hospital in 1966. Starting in the early 1970s, the pair began by studying how cells obtain their cholesterol from blood. Most of the blood's cholesterol is present in the form of low-density lipoproteins (LDLs) – minute particles comprising proteins, cholesterol, and other lipids. Working with cultures of skin cells, Goldstein and Brown discovered receptors on the cell surface that recognize the LDLs and bind them to the cell membrane. The LDL is subsequently engulfed by the cell membrane and taken into the cell where its contents are metabolized (cholesterol, for instance, is a vital component of cell membranes).

They went on to show that there is a deficiency of LDL membrane receptors in individuals suffering from the inherited disorder known as familial hypercholesterolemia. Such persons have abnormally high levels of cholesterol in their blood and run a much greater risk of developing atherosclerosis – the narrowing of the arteries due to a buildup of fatty plaques on their inner surface. This in turn makes them much more prone to heart attacks and strokes. Goldstein and Brown were able to show that in this disorder the gene encoding the LDL receptors is defective, hence the number of such receptors is small and the sufferer's body cells are unable to remove LDLs from the bloodstream. The consequent high blood-cholesterol levels prompt scavenger white cells to remove the cholesterol, turning them into the plaque-forming cells responsible for atherosclerosis.

The work of the Dallas-based duo has covered many other aspects of cholesterol metabolism, particularly how the cholesterol absorbed from the gut into the bloodstream is processed and repackaged by the liver, with the formation of high-density, very-low-density, and intermediate-density lipoproteins. They have not only revealed fundamental features of cellular metabolism but have shown ways in which people with elevated blood cholesterol may be treated, for instance, by increasing the number of LDL receptors on their cells. This, in turn, may reduce their risk of heart attacks and strokes.

For his work on familial hypercholesterolemia and LDL receptors, Goldstein was awarded the 1985 Nobel Prize for physiology or medicine, which he shared with his long-time colleague, Brown.

**Golgi, Camillo** (1843–1926) *Italian cytologist and histologist*

Born at Corteno near Brescia (now in Italy), Golgi (**gol**-jee) studied medicine at Pavia University and thereafter mainly concerned himself with research on cells and tissues. In 1873, while serving as physician at the home for incurables, Abbiategrasso, he devised a method of staining cells by means of silver salts. This al-

lowed the fine processes of nerve cells to be distinguished in greater detail than before and enabled Golgi to confirm Wilhelm von Waldeyer's view that nerve cells do not touch but are separated by gaps called synapses. Golgi also found a specialized type of nerve cell, later called the Golgi cell, which, by means of fingerlike projections (dendrites), serves to connect many other nerve cells. This discovery led to the formulation (by Waldeyer) and establishment (by Santiago Ramón y Cajal) of the neuron theory – a theory that Golgi was nevertheless strongly opposed to.

Golgi was also the first to draw attention to the Golgi bodies: flattened cavities parallel to the cell's nuclear membrane whose function appears to be packaging and exporting various materials from the cell. Apart from work on the sense organs, muscles, and glands, Golgi studied varying forms of malaria. He found that different species of the protozoan parasite *Plasmodium* are responsible for the two types of intermittent fever – the tertian and quartan. He also established that the onset of fever coincides with the release into the blood of the parasitic spores from the red blood cells.

Golgi served as professor of histology (1876) and then of general pathology (1881) at Pavia University. In 1906 he shared with Ramón y Cajal the Nobel Prize for physiology or medicine for his work on the structure of the human nervous system.

### **Gomberg, Moses (1866–1947)** *Ukrainian–American chemist*

Gifted with a remarkable memory, he presented his lectures with the full use of a wealth of historical material and so vividly that they left an indelible imprint on his students.

—C. S. Schoepfle and W. E. Bachmann, *Journal of the American Chemical Society* (1947)

Gomberg's father, an estate owner in Elizavetgrad (now Kirovograd in Ukraine), fled with his family from Russia in 1884 when accused of plotting against the czar. Gomberg was educated at the University of Michigan where he obtained his doctorate in 1894. After a period abroad at Munich and Heidelberg he returned to Michigan where he spent his whole career serving as professor of organic chemistry from 1904 until his retirement in 1936.

Gomberg is noted for the first preparation of a stable free radical – i.e., a group of atoms with an unpaired electron. In 1900, he was trying to make hexaphenylethane, which is simply an ethane molecule ( $C_2H_6$ ) in which all the hydrogen atoms have been replaced by phenyl groups ( $C_6H_5$ ). Gomberg found to his surprise, and everyone else's disbelief, that he was obtaining the free radical, triphenylmethyl –  $(C_6H_5)_3C$  – which clearly has a carbon atom with only three phenyl groups attached to it;

that is, with a forbidden valence of three. In general free radicals are highly reactive short-lived entities. Gomberg's compound, a colorless crystalline substance, was stabilized by the three benzene rings.

Gomberg later discovered a suitable antifreeze for automobile radiators, ethylene glycol.

### **Good, Robert Alan (1922–2003)** *American pathologist and immunologist*

Good was the son of a high-school principal who died of cancer when Good was five. Born in Crosby, Minnesota, he was educated at the University of Minnesota where he simultaneously obtained an MD and PhD in 1947. After this triumph he joined the Minnesota staff and served as professor of pediatrics from 1954 until 1973, when he moved to New York as director of the Sloan-Kettering Institute for Cancer Research. In 1982 Good moved to the University of Oklahoma as professor of microbiology, a post held until 1985, when he was appointed to a similar position in the University of South Florida, Tampa.

One of the great achievements of modern immunology has been the demonstration that the immunological system is not a simple unity but rather a complex interrelationship of a number of different units. The unraveling of this particular tangle was not the work of any one man or, indeed, any one group; Good's contribution was, however, as great as any other.

In the 1940s he showed a link between plasma cells, cells found in lymphoid tissue, and antibodies. Later he noted a simple tendency to recurrent infection among his patients suffering from myeloma (a tumor of bone-marrow cells) despite an abundance of plasma cells. This suggested to Good that there must be more to the immune system than simply the ability to make antibodies. This was reinforced when examining patients with agammaglobulinemia, who had no plasma cells at all, yet who were immunologically active enough to reject foreign skin grafts.

In the mid 1950s Good realized that there are two parts to the immune system: one dealing with defenses against typical bacterial infections; the other more concerned with clearing up "foreign" or unusual cells. By 1961, independently of Jacques MILLER, Good was beginning to suspect that the thymus gland was deeply implicated in providing the latter type of immunity.

Work on chickens' defense mechanisms against bacterial infection had demonstrated that if the bursa (a gland found in the chicken's alimentary canal) was removed, the creature lost the ability to make antibodies in any real quantity. They were in fact just like Good's agammaglobulinemic patients.

Good therefore postulated that there must be

two types of immunity – one related to the thymus and the other related to the human equivalent of the chicken bursa producing antibodies. The details of the two systems and their evolution and interrelationship called for major, and as yet far from complete, research programs by immunologists.

Good became a leading proponent of the view that cancer is somehow the result of an immunological defect, a failure of the system to recognize and destroy the cancerous cell before it has begun to proliferate.

**Goodall, Jane** (1934– ) *British primatologist*

Just as he is overshadowed by us, so the chimpanzee overshadows all other animals. He has the ability to use and make tools for a variety of purposes, his social structure and methods of communication with his fellows are elaborate, and he shows the beginnings of self-awareness.

—*In the Shadow of Man* (1971)

In 1957 Goodall, a Londoner, approached Louis LEAKEY for a job of some kind as she “wanted to get closer to animals.” Leakey employed her, initially as a secretary, and took her with him to Olduvai. He told her that he had long been searching for someone sufficiently interested in animals to be prepared “to forego the amenities of civilization for long periods of time without difficulty.” More precisely he wanted someone to observe the 160 chimps of the Gombe Stream Reserve on the eastern shores of Lake Tanganyika at close quarters over several years. After some initial training at the Royal Free Hospital and the London Zoo, Goodall was installed at Gombe in 1970. She has remained there ever since; under her direction it has become a world-famous and much-respected research center.

In her first full account of her work, *In the Shadow of Man* (1971), Goodall presented what now seems to be a somewhat idealized picture of chimpanzee society. They were seen as mainly vegetarian, living in a relatively peaceful community and spending the bulk of their lives socializing with each other. They were also shown as toolmakers and users, adept at fashioning blades of grass into probes to be inserted into mounds to extract termites.

Her later work, however, presented in *Through a Window* (1990), revealed a darker side of chimpanzee society. The Gombe Reserve was home for three communities of about 50 chimpanzees each. Males will routinely attack and attempt to kill adult females of another group. In 1974, Goodall witnessed the outbreak of war within a single community. At that time the band split into two groups, which she called the Kahama and the Kasakela. Over a period of four years, Goodall noted that the Kasakela systematically and deliberately killed the entire

Kahama group, males, females, and infants, presumably to take over their territory. It took several years for Goodall to come to terms with this picture. Goodall also rejected her earlier account of vegetarian chimpanzee bands. She found that they hunted monkeys, baboon infants, bushpig, bushbuck, and other small mammals. Hunting is undertaken by males and always in groups. Cannibalism took place on a number of occasions and the meat, as at other times, was shared within the group.

Because of her prolonged observation Goodall has been able to document the social development of the individual in the community as well as the histories of a number of families. Males establish a dominance hierarchy and protect the group, while females remain with their mothers until they reach sexual maturity at about the age of ten. Young males leave a few years earlier to establish their place in the male hierarchy. Sibling and maternal ties, however, remain strong.

In more recent years Goodall has campaigned vigorously for the conservation of chimpanzees in the wild and for a less barbarous confinement of the many held in research institutions and zoos. To this end she has set up the Jane Goodall Institute for Research Education and Conservation with centers in the U.S., Canada, and Britain. She has reported on her life's work at Gombe in a number of popular and often moving books, most recently in *The Chimpanzee* (1992). She has been the subject of a number of documentaries and a film *Jane Goodall's Wild Chimpanzees* (2002).

**Goodman, Henry Nelson** (1906–1998) *American philosopher*

If we lack the means for interpreting counterfactual conditions, we can hardly claim to have any adequate philosophy of science.

—*Fact, Fiction, and Forecast* (1955)

Goodman was born in Somerville, Massachusetts, and educated at Harvard where he obtained his PhD in 1941. Before this he had worked as a Boston art dealer from 1929 until 1941. After serving in the U.S. Army during the war he taught at Tufts University (1945–51), the University of Pennsylvania (1951–64), Brandeis (1964–67), and finally at Harvard from 1968 until his retirement in 1977.

In his *Fact, Fiction, and Forecast* (London, 1955) Goodman posed his “new riddle of induction.” The traditional problem of induction was to justify inferences from the particular to the general; for example, from the observation that “some crows are black” to the conclusion that “all crows are black.” Goodman, however, shifted the question from “Why does a positive instance of a hypothesis confirm the hypothesis?” to “What hypotheses are confirmed by positive instances?”

Thus a green emerald might be thought to

support the hypothesis "All emeralds are green." But define the predicate "grue" to refer to objects which are green before the year 2000 or blue thereafter, and a green emerald offers just as much support for the hypothesis that "All emeralds are grue." Why should we, to use Goodman's term, "project" the property green onto emeralds, but feel reluctant to project greenness? Goodman has a response to the objection that "grue" is not a proper predicate, requiring the terms "blue" and "green" to define it. If one defines "bleen" to refer to objects that are blue before the year 2000 or green thereafter, the color green is definable as being grue before 2000 or bleen thereafter.

Goodman's new riddle has been extensively discussed. His own suggestion is that we prefer hypotheses that are "entrenched," that is, the degree with which predicates have been projected in the past.

**Goodpasture, Ernest William** (1886–1960) *American pathologist*

Goodpasture, the son of a lawyer, was born in Montgomery County, Tennessee. He was educated at Vanderbilt University, Nashville, and at Johns Hopkins University, where he gained his MD in 1912. After working as a pathologist for some years at Johns Hopkins and at Harvard, Goodpasture returned to Vanderbilt in 1924 as professor of pathology, a post he retained until his retirement in 1955.

In 1931 Goodpasture devised a method of virus culture that provided an enormous stimulation to virology. Before this, as viruses will grow only in living tissue, they could be studied experimentally either in a living host or, after the work of Alexis CARREL in 1911, *in vitro* (in a laboratory; the Latin *in vitro* literally means "in glass") in a tissue culture. The first method was expensive and difficult to control while the second, before the advent of antibiotics, was susceptible to contamination by bacteria.

Goodpasture, in collaboration with Alice Woodruff, avoided such difficulties by providing a cheap living environment for viral growth – a fertile egg. Their first success was with fowl pox but within a year they had also grown both cowpox and coldsore viruses. Goodpasture went on in 1933 to show that attenuated cowpox vaccine could be produced in a purer and cheaper form in eggs than by the customary method of production in calf lymph.

Within a few years Goodpasture's technique had made possible the production of vaccines against yellow fever by Max THEILER and influenza by Thomas FRANCIS. Thereafter eggs became as standard a part of the virologist's laboratory as the test tube.

**Goodrich, Edwin Stephen** (1868–1946) *British zoologist*

Goodrich's father, a clergyman from Weston-super-Mare in the west of England, died when his son was only two weeks old. He was brought up in France by his mother and, as he intended to be an artist, attended the Slade School of Art at University College, London. His interest in zoology was aroused by Ray LANKESTER with whom he moved to Oxford as an assistant in 1892. Goodrich remained at Oxford for the rest of his career, serving as professor of comparative anatomy from 1921 to 1945.

Goodrich produced two important works, *Evolution of Living Organisms* (1912) and *Studies on the Structure and Development of Vertebrates* (1930). His main achievement in the latter work was to distinguish clearly, for the first time, between the nephridium and the coelomoduct, or the primitive kidney and primitive reproductive tract.

More generally his labors are comparable to those of such other paleontologists and comparative anatomists as David WATSON and Alfred ROMER who, building on the efforts of previous workers, managed to sort out the muddled story of vertebrate evolution.

**Goodricke, John** (1764–1786) *Dutch-British astronomer*

If it were perhaps not too early to hazard even a conjecture on the cause of its [Algol's] variation, I should imagine it could hardly be accounted for otherwise than ... by the interposition of a large body revolving around Algol.

—*Philosophical Transactions of the Royal Society* (1783)

Born at Groningen in the Netherlands, Goodricke was a deaf mute who, although he died when he was 21, had already done work of such importance as to receive the Copley medal of the Royal Society three years before he died. Variable stars had been discovered by FABRICIUS nearly 200 years before but Goodricke was the first scientist to offer a plausible explanation. Noticing the rapid variation in magnitude of Algol he proposed, in 1782, that it was being regularly eclipsed by a dark companion that passed between it and the Earth. His suggestion was confirmed a century later.

**Gordan, Paul Albert** (1837–1912) *German mathematician*

Gordan studied in his native Breslau, at Königsberg, and at Berlin before becoming professor of mathematics at the University of Erlangen. For most of his mathematical career his research was concentrated on a single field, the study of indeterminates. The central problem in the field, which Gordan eventually solved, was to prove the existence of a finite basis for binary forms of any given degree. His result was subsequently refined and extended by many workers including Gordan himself.

Gordan's proof was long and complicated and the result was re-proved in 1888 by David HILBERT using newer and far simpler methods. In collaboration with Rudolf Clebsch, Gordan also wrote a book on Abelian functions that included the central theorem now known as the *Clebsch–Gordan theorem*. This work was influential in giving a new direction to algebraic geometry.

**Gorer, Peter Alfred (1907–1961)** *British immunologist*

Gorer, the son of a wealthy Londoner who died on the Lusitania, was educated at Guy's Hospital, London, graduating in 1929. After studying genetics under J. B. S. HALDANE at University College, London, from 1933 to 1934 Gorer worked at the Lister Institute until 1940 when he returned to Guy's as a morbid histologist and hematologist. In 1948 he became reader in experimental pathology.

As early as 1936 Gorer tried to see if red cells of mice could be divided into antigenic groups similar to the blood groups of humans. Using his own blood serum he distinguished three kinds of mouse red cell on the basis of their ability to agglutinate his serum. He further found that such a property was inherited by the mice in a Mendelian dominant manner. Such work was supported by comparable results obtained in 1937 with the transplantation of a spontaneously appearing tumor among the various distinguished genetic strains of mice.

Gorer had in fact discovered the histocompatibility antigens and established their control at the genetic level, an outstanding result little appreciated in his lifetime but later to be recognized as of fundamental importance in immunology, genetics, and transplantation surgery. One who did recognize the significance of Gorer's work was George SNELL who worked with him in 1948. For his later work Snell was to receive the 1980 Nobel Prize for physiology or medicine, a prize Gorer would have undoubtedly shared with him if he had not died some 19 years before from lung cancer.

**Gorgas, William Crawford (1854–1920)** *American physician*

Gorgas was the son of an army ordnance officer from Toulminville, Alabama, who later served as a general in the Confederate Army. He was educated at the University of the South and at Bellevue Hospital, New York, where he obtained his MD in 1879. In the following year he joined the Army Medical Corps, serving in a number of frontier posts before being appointed (1898) chief sanitary officer of Havana.

Gorgas was fortunate to be in Cuba at the time when Walter REED and his colleagues identified the mosquito *Aedes aegypti* as the vector of yellow fever. Given this information

Gorgas was able to introduce measures to so control the vector that the disease was virtually eliminated in Cuba. The strategy basically involved reducing mosquito breeding grounds by either draining or covering all standing sources of water, attacking the adult mosquitoes by fumigation, and isolating patients with the disease under netting. Such simple procedures, energetically and conscientiously carried out, worked remarkably quickly.

In 1899 the U.S. Government had obtained the shares of the Panama Railroad Company for \$40 million, and when in 1903 they also obtained permission from the newly established state of Panama to attempt the construction of a canal, they realized the enormous medical problems facing them in such a task. The previous attempt (1881–89) by Ferdinand de Lesseps had failed, largely owing to yellow fever killing over 20,000 of his labor force in eight years. On the strength of his success in Cuba, the government appointed Gorgas chief sanitary officer of the Canal Zone in 1904. Unfortunately the chairman of the Canal Commission, Admiral John WALKER, refused Gorgas's request for screening material and sulfur for fumigation on the grounds of economy; privately he tried to get Gorgas removed, proclaiming that "the whole idea of mosquitoes carrying fever is balderdash." Before long, however, Walker resigned. Under his successor, Gorgas was allowed to introduce the measures he had pioneered in Cuba. The extent of Gorgas's achievement is best seen in the mortality figures: when he arrived the death rate from yellow fever was running at about 10%, but after 1906 no further cases were reported.

Gorgas remained in Panama until 1913. In the following year he was appointed surgeon-general of the U.S. Army and was much in demand to advise on public health programs. It was in fact on his way to West Africa to advise on yellow fever control that Gorgas died, of a stroke, in London.

**Gossage, William (1799–1877)** *British chemist*

Born in Burgh-in-the-Marsh, England, Gossage was apprenticed to his uncle, an apothecary in Chesterfield, and later set himself up in business in Leamington selling the spa salt. He moved to Stoke Prior to manufacture salt and alkali by the LEBLANC process.

In 1836 Gossage introduced a basic improvement into the manufacture of alkali. One of the disadvantages of the Leblanc process was the production of large quantities of hydrochloric acid fumes as a waste product. This was released into the atmosphere and as a result polluted the surrounding area. Gossage constructed towers in which the gas was passed up through layers of coke, and then condensed by cold water flowing down. This fluid was fed

into streams and rivers where it still acted as a pollutant until Henry DEACON discovered a method for producing chlorine from the solution. Gossage's tower made possible the introduction of the Alkali Act in 1865, which made it a legal obligation for manufacturers to absorb 95% of their waste hydrochloric acid.

Gossage also tried to invent a process to recover the sulfur from calcium sulfide, a waste product of the Leblanc process. He introduced a technique in 1837 that recovered some by partial oxidation. The thiosulfate resulting could be sold to paper mills. In 1850 Gossage moved to Widnes to open a soap and alkali factory and in 1854 he patented a process for introducing sodium silicate into soap, which produced a soap with improved detergent powers.

### **Goudsmit, Samuel Abraham** (1902–1978) *Dutch–American physicist*

Born in The Hague in the Netherlands, Goudsmit (**goud**-smit) was educated at the universities of Amsterdam and Leiden, where he obtained his PhD in 1927. He emigrated to America shortly afterward, serving as professor of physics at the University of Michigan (1932–46) and Northwestern University (1946–48). He then moved to the Brookhaven National Laboratory on Long Island, New York, where he remained until his retirement in 1970.

In 1925 Goudsmit, in collaboration with George UHLENBECK, put forward the proposal of electron spin. They suggested that electrons rotate about an axis and, as they are charged, set up a magnetic field. This model was successful in clearing up a number of anomalies that were becoming apparent in the fine structure of atomic spectra. A theory of spin was later given by Paul DIRAC.

During World War II Goudsmit worked on radar and then became head of a top secret mission codenamed *Alsos* in 1944. The mission was for Goudsmit to follow the front-line Allied troops in Europe, and even in some cases to precede them, looking for any evidence of German progress in the manufacture of an atomic bomb. He found that the German scientists had, in fact, made little progress and it was clear that Hitler would not be presented with such a weapon before the end of the war. For this war service Goudsmit was awarded the Medal of Freedom from the U.S. Department of Defense and he published his account of the mission in his book *Alsos* (1947).

### **Gould, Benjamin Apthorp** (1824–1896) *American astronomer*

Gould, the son of a merchant and teacher from Boston, Massachusetts, graduated from Harvard in 1844. Having studied for a year at Berlin, he obtained his PhD from Göttingen

University in 1848 under the great Karl Friedrich GAUSS. On his return to America he served as head of the longitude department of the U.S. Coast Survey from 1852 to 1867, pioneering the use of the telegraph in measuring longitude. At the same time Gould founded the *Astronomical Journal* in 1849 and edited it until 1861 when its publication was halted by the Civil War. He was also connected with the Dudley Observatory, Albany, from 1855 and served as its director briefly in 1858 before being forced to get out of town in the following year. After his traumatic expulsion from Albany he handled his father's business for some time. He set up a private observatory in Cambridge, financed by his wife, and in 1862 produced a star catalog that brought together measurements made at various observatories. He left for Argentina in 1870.

The 15 years spent in Cordoba were by far the most productive of Gould's career. He established the Argentine National Observatory there and began the first major survey of the southern skies. The Observatory's first survey of naked-eye stars, i.e., down to 7th magnitude, was published as the *Uranometria Argentina* (1879; Argentinian Survey of the Heavens). This was followed by the fuller recording, published in 1884, of 73,160 stars from 23°S to 80°S and in 1886 by the publication of the *Catálogo General* (General Catalogue) containing the more accurate recording of 32,448 stellar coordinates. This important work was continued by Gould's successor, Juan Thomé. An extended band of young stars, cloud, and dust that forms a spur off one of the spiral arms of our Galaxy and was revealed by the southern surveys was subsequently named *Gould's Belt*.

In 1885 Gould returned to Massachusetts where he restarted the *Astronomical Journal* in 1886 and worked on the 1,000 photographic plates of star clusters he brought back with him from Cordoba.

### **Gould, Stephen Jay** (1941–2002) *American biologist*

A man does not attain the status of Galileo merely because he is persecuted; he must also be right.

—*Ever Since Darwin* (1977)

The grandson of a Hungarian immigrant and the son of a court stenographer, Gould is reported to have developed his interest in biology as a five-year-old when he first saw *Tyrannosaurus rex* at the American Museum of Natural History. Born in New York City, he was educated at Antioch University, Pennsylvania, and at Columbia, where he completed his PhD in 1967. He immediately moved to Harvard where he served as professor of geology and curator of the Harvard Museum of Comparative Zoology from 1973.

Gould is widely known for the volumes of es-

says on natural history that he began publishing in 1978. The articles are usually about some aspect of evolution and are rooted firmly in history, carry a detailed argument, and are relevant to some contemporary issue. Throughout over 300 essays Gould maintained an exceptionally high standard and dealt with a wide variety of topics. These include the panda's thumb, the flamingo's smile, Adam's navel, male nipples, Mickey Mouse's development, and changes in the average size of chocolate bars.

Gould also published a number of influential monographs. In *Ontogeny and Phylogeny* (1977) he examined the notion of recapitulation – the view that individual development (ontogeny) is a rerun of evolutionary history (phylogeny). *The Mismeasure of Man* (1984) sought to demonstrate that attempts to measure man's intelligence were often designed to serve political rather than scientific ends. In a further monograph, *Wonderful Life* (1990), Gould surveyed the fossils of the Burgess Shale, first described by C. D. WALCOTT. He used the fossils to illustrate a familiar theme of his work that evolution is not “a ladder of predictable progress,” it is rather “a copiously branching bush, continually pruned by the grim reaper of extinction.”

In the fields of paleontology and ecology Gould worked for many years on the West Indian land snail, *Cerion*. As an evolutionary theorist he is best known for proposing in 1972, along with Nils Eldredge, the punctuated equilibrium hypothesis, which views evolution as episodic rather than continuous. Relatively short periods of branching speciation, they argued, are followed by much longer periods of stasis.

In 1981 Gould was very much in the news as one of the biologists called as an expert witness in the so-called Scopes II trial in Arkansas. Fundamentalists had claimed as equal a right to teach creationism in the Arkansas public schools as biology teachers had long claimed for Darwinism. Judge William Overton ruled in 1985 that creationism was a religious doctrine and it would therefore be a violation of the constitution if it were to be taught in public schools.

Shortly before his death Gould published a large book, *The Structure of Evolutionary Theory*, which summarized his life's work on this topic.

### **Graaf, Regnier de** (1641–1673) *Dutch anatomist*

Graaf (grahf), who was born at Schoonhoven in the Netherlands, studied at the University of Leiden and later obtained a degree in medicine at the University of Angers, France (1665). He was the first to collect and study the secretions of the pancreas and gall bladder but is best known for his work on the mammalian

sex organs. In 1668 he described the structure of the testicles and in 1673 described the minute follicles of the ovary, which have been called *Graafian follicles* since HALLER coined the term in the mid-18th century. Graaf died of the plague aged 32.

### **Graaff, Robert Jemison van de** See **VAN DE GRAAFF, ROBERT JEMISON**.

### **Graebe, Karl** (1841–1927) *German chemist*

Born at Frankfurt in Germany, Graebe (**greb-e**) graduated from Heidelberg in 1862. He worked as an assistant to BUNSEN and BAEYER before accepting an appointment as professor of chemistry at Königsberg in 1870. In 1878 he moved to the University of Geneva.

With C. T. Liebermann, Graebe made a major contribution to the chemistry of synthetic dyes. While working as assistant to Baeyer he studied alizarin, the coloring matter taken from the madder plant. Graebe and Liebermann vaporized the pigment and passed it over zinc dust and to their surprise found that anthracene was produced. As they had earlier been working on the structure of anthracene, a coal-tar derivative, they had little difficulty in seeing how to synthesize alizarin. They applied for a patent on 15 June 1869, only a day before Sir William Henry PERKIN, the discoverer of mauveine, applied for a patent for the same product.

### **Graham, Thomas** (1805–1869) *Scottish chemist*

Graham was the son of a prosperous Glaswegian manufacturer. He entered Glasgow University at the age of 14 and attended the classes of the chemist Thomas Thomson. Graham's father was determined that he should enter the ministry and on Graham's persistence with his scientific studies his father withdrew his financial support. To continue in chemistry Graham made his living through teaching and writing. In 1829 he became a lecturer at the Mechanics Institution and in 1830 he was elected to the chair of chemistry at Glasgow University. In 1837 he was appointed professor in the recently founded University College, London. He was the first president of the Chemical Society of London, and of the Cavendish Society, which he founded. In 1854 he was made master of the mint.

In 1829 Graham published a paper on the diffusion of gases. Observations on this subject had been made by Joseph PRIESTLEY and Johann DÖBEREINER, but it was Graham who formulated the law of diffusion. He compared the rates at which various gases diffused through porous pots, and also the rate of effusion through a small aperture, and concluded that

the rate of diffusion (or effusion) of a gas at constant pressure and temperature is inversely proportional to the square root of its density.

In 1860 Graham examined liquids. He noticed that a colored solution of sugar placed at the bottom of a glass of water gradually extends its color upwards. He called this spontaneous process *diffusion*. He also noticed that substances such as glue, gelatin, albumen, and starch diffuse very slowly. He classified substances into two types: colloids (from Greek *kolla*, glue), which diffuse slowly, and crystalloids, which diffuse quickly. He also found that substances of the two types differ markedly in their ability to pass through a membrane, such as parchment, and he developed the method of dialysis to separate them. Graham is regarded as the father of modern colloid science, and many terms that he invented, such as sol, gel, peptization, and syneresis, are still in use.

In 1833 Graham published the results of his research on phosphates. The composition of the compound that was then called phosphoric acid was expressed by the formula  $PO_5$ . Graham proved the existence of three "acid hydrates" to which he gave compositions  $PO_5 \cdot 3HO$ ,  $PO_5 \cdot 2HO$ , and  $PO_5 \cdot HO$ , thus laying the foundations for Justus von LIEBIG's theory of the polybasicity of acids. He carried out similar studies with the arsenic acids and the arsenates. Other work done by Graham includes research into the water of crystallization in hydrated salts and investigations into the absorption of hydrogen by palladium. Graham was an excellent and successful teacher.

**Gram, Hans Christian Joachim** (1853–1938) *Danish bacteriologist*

Gram graduated in medicine from the university in his native city of Copenhagen in 1878 and from 1883 to 1885 traveled in Europe, studying pharmacology and bacteriology. While in Berlin (1884) he discovered the method of staining bacteria with which his name has become associated. He followed the method of Paul EHRLICH, using aniline-water and gentian violet solution. After further treatment with Lugol's solution (iodine in aqueous potassium iodide) and ethanol he found that some bacteria (such as pneumococcus) retained the stain (*Gram positive*) while others did not (*Gram negative*). This discovery is of great use in the identification and classification of bacteria. It is also useful in deciding the treatment of bacterial diseases, since penicillin is active only against Gram-positive bacteria; the cell walls of Gram-negative bacteria will not take up either penicillin or Gram's stain.

In 1891 Gram became professor of pharmacology at the University of Copenhagen, where he showed a keen interest in the clinical education of the students. During this time he had a large medical practice in the city. He was

chairman of the Pharmacopoeia Commission from 1901 to 1921 and director of the medical department of Frederick's Hospital, Copenhagen, until he retired in 1923.

**Granit, Ragnar Arthur** (1900–1991) *Finnish neurophysiologist*

Born in the Finnish capital of Helsinki, Granit (**gran-it**) qualified as a physician from the university there in 1927. He taught at the university from 1927 until 1940, serving as professor of physiology from 1935. In 1940 he moved to the Karolinska Institute, Stockholm, becoming professor of neurophysiology at the newly founded Medical Nobel Institute in 1946.

In a long career Granit was a prolific writer on all aspects of the neurophysiology of vision. He demonstrated that light not only stimulates but can also inhibit impulses along the optic nerve. By attaching microelectrodes to individual cells in the retina he showed that color vision does not simply depend on three different types of receptor (cone) cells sensitive to different parts of the spectrum. Rather, some of the eye's nerve fibers are sensitive to the whole spectrum while others respond to a much narrower band and so are color specific.

Granit described his work in *Sensory Mechanisms of the Retina* (1947) and *The Visual Pathway* (1962); for such research he shared the 1967 Nobel Prize for physiology or medicine with George WALD and Haldan HARTLINE. Granit also did important work on the control of muscle spindles by the gamma fibers.

**Grassi, Giovanni Battista** (1854–1925) *Italian zoologist*

The son of a municipal official from Rovellasca in Italy, Grassi (**grah-see**) was educated at the University of Pavia, where he obtained his MD in 1878. He went on to study zoology at the universities of Heidelberg and Würzburg and on his return to Italy was appointed to the chair of zoology in 1883 at the University of Catania. He later moved to the University of Rome, where he served as professor of comparative anatomy from 1895 until his death.

Although Grassi made a number of contributions to zoology working on bees, termites, eels, and other species, he is mainly remembered for his work on malaria. Unfortunately his own contribution in this field is not precisely known, since not only was much of his work done in collaboration with a large number of colleagues but also virtually all his published results were claimed by Ronald ROSS, as his own.

Despite the accusations by Ross of "brigandage" by Grassi and his colleagues it would seem that they were undisputably involved in three major areas of the complex malaria story. Firstly it was the Italians Angelo Celli and Et-

tore Marchiafava who, together with Grassi, made the important point in 1889–90 that there were a number of protozoa producing malaria. *Plasmodium falciparum* had been discovered in 1889 and *P. vivax* in 1890: this was enough to allow them to suggest that the different varieties of malaria, the so-called quartan and tertian fevers, could be understood as due to infection with different species of *Plasmodium*.

Secondly it was Grassi, in 1898, who solved one of the major problems in implicating mosquitoes in the production of malaria. For centuries the association between marshes, malaria, and mosquitoes had been known but no one could confidently make the obvious connection between mosquitoes and malaria as there were numerous areas in Italy that were free of malaria despite being plagued with mosquitoes. In 1897 Ross had shown that avian malaria was transmitted by the *Proteosoma* mosquito; in the following year, quite independently of this work, the Italians demonstrated that it was only the *Anopheles* mosquito that could transmit the disease to humans. Thus the connection was at last established between *Anopheles* mosquitoes and malaria.

Grassi's final major contribution was to collaborate with Patrick MANSON in 1900 in providing the crucial experimental confirmation of their claim. Mosquitoes of the species *Anopheles maculipennis* that had bitten malaria patients were sent by Grassi to London, where they were allowed to feed on Manson's son; 15 days later the boy developed a clear case of tertian fever.

In 1900 Grassi published an account of his work in *Studi di uno zoologo sulla malaria* (Studies of a Zoologist on Malaria).

### **Gray, Asa** (1810–1888) *American botanist*

Born in Sauquoit, New York, Gray studied at Fairfield Medical School, obtaining his MD in 1831. He spent the next five years developing his interest in botany, supporting himself by teaching and library work. During this period he met, and made a favorable impression on, John TORREY, a prominent American botanist with whom he later collaborated to produce the two-volume *Flora of North America* (1838–43).

In 1838 Gray made the first of many visits to Europe, in order to examine type specimens of American plants in various European herbaria so that the taxonomy of his flora could be based on original species descriptions. For the next four years Gray worked full-time on the flora, but with his appointment as professor of natural history at Harvard in 1842 further progress was slow due to the pressure of other commitments. Nevertheless the work was hailed in its time as being second only to A. P. de CANDOLLE's *Prodromus* and its publication marked the

adoption of natural systematics in American classification.

Gray helped promote specialization in natural history by accepting the professorship at Harvard only on the condition that he might limit his work to botany. He remained at Harvard until 1873, during which time he developed the library and botanical gardens from almost nothing. He donated his own vast collection of books and plants to the university in 1865 on the understanding that they would be housed in their own building.

During another visit to Europe in 1851, Gray met Charles DARWIN. The two men later corresponded on matters of plant geography, and in 1857 Darwin wrote to Gray concerning his ideas on the origin of species. When Darwin's theory was published, Gray became his main advocate in America and wrote many essays reconciling Darwinism with Christian doctrine. These articles were collected together and published as *Darwinia* in 1876.

Gray's most widely used book is his *Manual of the Botany of the Northern United States* (1848) but he established his worldwide reputation with the publication in 1859 of a monograph on the flora of Japan and its relation to floras of other north temperate zones.

Gray was president of the American Association for the Advancement of Science from 1863 to 1873 and in 1900 was commemorated in the newly founded Hall of Fame for Great Americans.

### **Gray, Harry Barkus** (1935– ) *American inorganic chemist*

Gray, who was born at Woodburn in Kentucky, was educated at the University of West Kentucky and at Northwestern University, where he obtained his PhD in 1960. After a year at the University of Copenhagen, he joined the Columbia faculty in 1961 but moved to the California Institute of Technology in 1966 and has since served there as professor of chemistry.

As an inorganic chemist Gray has worked on the electronic structure of metal complexes and on inorganic reaction mechanisms. He has also studied the chemistry of biochemical compounds containing metal ions (e.g., proteins containing iron and copper). Later work on the photochemistry of inorganic compounds led to an interest in using complexes as a method of absorbing and storing solar energy. He was awarded the Wolf Prize in 2004.

### **Gray, Stephen** (c. 1670–1736) *English physicist*

Gray made many studies of electrical phenomena and discovered that electricity could be transmitted from one substance to another. In 1729 he electrified a glass tube (by friction) and found that corks in the end of the tube be-

came electrically charged. Further experiments showed that many other materials could conduct electricity, and that electric charges could be transferred over long distances. The results of Gray's investigations were published in the *Philosophical Transactions* of the Royal Society in the years 1731–32 and 1735–36.

**Green, George (1793–1841)** *British mathematician*

Had his life been prolonged, he might have stood eminently high as a mathematician.

—Obituary notice of Green (1841)

Green's father was a prosperous baker from Nottingham in England. Green worked for his father from the age of nine until his father's death in 1829. His father left him a mill which still stands; it has been restored and was opened to the public in 1979.

Green must have been a largely self-taught mathematician. It is known that he joined the Nottingham Subscription Library in 1823 and that the library had copies of such advanced works as the *Mécanique céleste* (Structure of the Heavens) of LAPLACE. The translator, John Toplis, was head of the local grammar school and may well have influenced Green. In 1828 Green published *An Essay on the Application of Mathematics to Electricity and Magnetism*. It was made available to 51 subscribers and few seem to have been aware of its appearance. The work only became widely known when Lord KELVIN came across a copy in 1845 and was so impressed that he arranged for it to be reissued in *Crelle's Journal*. The *Essay* introduced into science *Green's theorem*, *Green's function*, and the notion of the electric potential.

Following the death of his father, Green felt free to follow his scientific interests. He was encouraged in this by Sir Edward Bromhead, a local landowner, who offered to arrange Green's admission to Cambridge. At first Green was reluctant, doubting that it would be suitable "for a person of my age and Imperfect Classical attainments." Nevertheless he arrived in Cambridge at the age of 40, finished as fourth wrangler, and was elected to a fellowship of his college in 1839. He died two years later after contracting flu, leaving seven illegitimate children.

**Greengard, Paul (1925– )** *American neuroscientist*

Greengard was born in New York. He graduated with a PhD in biophysics from the Johns Hopkins University, Baltimore, in 1953. Post-doctoral studies in England (London University, Cambridge University and the National Institute for Medical Research) were followed by a stint at the National Institutes of Health, Bethesda. From 1959 to 1967 he was director of the department of biochemistry at Geigy Re-

search Laboratories. He also held academic positions at the Albert Einstein College of Medicine, New York (1961–70), and Yale University School of Medicine (1968–83), before being appointed professor and head of the Laboratory of Molecular and Cellular Neuroscience at Rockefeller University, New York, in 1983.

Greengard has made significant advances in our understanding of how the chemicals (neurotransmitters) that relay signals between nerve cells in the central nervous system exert their effects. These relays occur at special junctions (synapses), where one nerve cell ending lies extremely close to the outer membrane (plasma membrane) of another nerve cell. Neurotransmitters such as dopamine, noradrenaline, and serotonin are responsible for what is called slow synaptic transmission, which alters the basal responsiveness of the recipient nerve cell, and is important in determining levels of alertness and mood, for example.

Greengard investigated slow synaptic transmission, and unraveled the chain of molecular events that follow when dopamine stimulates a receptor on a recipient cell membrane. The first step is a rise in levels of a so-called second messenger, cyclic AMP (cAMP), inside the cell. This activates protein kinases, enzymes that add phosphate groups to (phosphorylate) various proteins in the cell, thereby altering the shape and function of the proteins. For example, phosphorylation of proteins that form ion channels through the plasma membrane affects the excitability of the nerve cell, and hence how many nerve impulses it can transmit.

Building on this work, Greengard showed that in certain nerve cells neurotransmitters cause a cascade of phosphorylations and dephosphorylations (addition and removal of phosphate groups), and that certain proteins play a key regulatory role in governing the overall changes in excitability. His work has direct relevance to understanding how certain drugs work in relation to nerve cell function.

For his discoveries relating to signal transduction in the nervous system, Greengard was awarded the 2000 Nobel Prize for physiology or medicine, jointly with Arvid CARLSSON and Eric R. KANDEL.

**Greenstein, Jesse Leonard (1909–2002)** *American astronomer*

Born in New York, Greenstein graduated from Harvard in 1929 and then, as he puts it, "rode out four depression years as an operator in real estate and investments." He returned to Harvard and obtained his PhD in 1937. He worked at the Yerkes Observatory from 1937 until 1948 when he moved to the California Institute of Technology. In 1949 he became professor of astrophysics and a staff member at the Mount Wilson and Palomar observatories, where he remained until his retirement in 1981.

Greenstein worked on the constitution of stars, and on how and why the constitution can vary from one star to another, and also made extensive studies of quasars. In 1963, following Maarten SCHMIDT, he interpreted the spectrum of the quasar 3C 48 and was able to show that its peculiarities resulted from a red shift over twice that obtained by Schmidt for the quasar 3C 273.

**Gregor, William** (1761–1817) *British mineralogist*

Born in Trewarthenick in England, Gregor was educated at Cambridge University. Although elected a fellow of his college he decided instead to pursue a career in the Church and became rector of Creed, Cornwall, in 1793.

In 1791 he found a strange black sand in Manaccan (then spelled Menacchan), Cornwall. This contained iron and manganese plus an additional substance that Gregor could not identify. He called it menacchanine and succeeded in extracting its reddish-brown oxide, which, when dissolved in acid, formed a yellow solution. Martin KLAPROTH isolated the same oxide from a different source in 1795 and demonstrated that it was a new element, naming it titanium.

**Gregory, James** (1638–1675) *Scottish mathematician and astronomer*

My salary was ... kept back from me and scholars of most eminent rank were violently kept from me ... the masters persuading them that their brains were not able to endure mathematics.

—On being persecuted at St. Andrews for his radical scientific ideas (1674)

Gregory was one of the many 17th-century mathematicians who made important contributions to the development of the calculus, although some of his best work remained virtually unknown until long after his death.

Born at Drumoak, Scotland, he studied mathematics at the University of Padua in about 1665 and produced *Vera circuli et hyperbolae quadratura* (1667; The True Areas of Circles and Hyperbolas). He was particularly interested in expressing functions as series,

and he sketched the beginnings of a general theory. It was Gregory who first found series expressions for the trigonometric functions. He introduced the terms “convergent” and “divergent” for series, and was one of the first mathematicians to begin to grasp the difference between the two kinds. Gregory also gave the first proof of the fundamental theorem of calculus.

In addition to his mathematical work Gregory's interests in astronomy led him to do some valuable practical work in optics. He anticipated NEWTON by recommending a reflecting telescope in his *Optica promota* (1663; The Advance of Optics). He realized that refracting telescopes would always be limited by aberrations of various kinds. His solution was to use a concave mirror that reflected (rather than a lens that refracted) to minimize these effects. He solved the problem of the observer by having a hole in the primary mirror through which the light could pass to the observer. However, he was unable to find anyone skilled enough actually to construct the telescope.

Gregory held chairs in mathematics at the University of St. Andrews (1669–74) and the University of Edinburgh (1674–75). He died at the age of 37 shortly after going blind.

**Griess, Johann Peter** (1829–1888) *German chemist*

Griess (grees), who came from a farming family in Kirklosbach near Kassel in Germany, was educated at the universities of Jena and Marburg. In 1858 he became August Wilhelm Hofmann's assistant at the Royal College of Chemistry in London. In 1862 he took up a post in industry with Allsopp's brewery in Burton-on-Trent, where he stayed for the rest of his career.

In 1862 he made an important discovery concerned with a new class of dyes. He discovered that aromatic amines (such as aniline,  $C_6H_5NH_2$ ) react with nitrous acid at low temperature to form diazonium salts (of the type  $C_6H_5N_2^+X^-$ ). These would react with phenols to produce larger, colored molecules – the azo dyestuffs. Griess himself had no interest in these products and, in fact, received no reward

**GREGORIAN TELESCOPE** The path of light rays in Gregory's reflecting telescope.

from them. The first azo dye, Manchester or Bismarck brown, was discovered within a year.

**Griffin, Donald Redfield (1915–2003)**  
*American zoologist*

I always found small mammals enough like ourselves to feel that I could understand what their lives would be like, and yet different enough to make it a sort of adventure and exploration to see what they were doing.  
—*Echoes of Bats and Men* (1959)

Born in Southampton, New York, Griffin was educated at Harvard where he obtained his PhD in 1942. He spent the war applying physiological principles to the design of such military equipment as cold-weather clothing and headphones. After the war he worked initially at Cornell but returned to Harvard in 1953 as professor of biology, a position he held until his retirement in 1986.

Bat navigation had been first studied by Lazzaro SPALLANZANI in 1793 when he noted that blinded bats were as efficient in catching insects on the wing as sighted bats. He also noted that impairment of their hearing produced disorientation. How, Griffin asked in 1938, could ears replace eyes in flight guidance? He was fortunate in that he had a colleague in the physics laboratory, G. W. Pierce, who had an interest in high-frequency sound and was willing to use his specialized equipment on bats. In this way they soon found that bats were issuing sounds, in the case of the horseshoe bat, with frequencies between 60 and 120 kilohertz; the limit of human hearing is between 15 and 20 kilohertz.

That the bats were operating by echolocation was demonstrated when either their mouths or ears were covered. In either case they would collide in a dark room with anything in their path, even the room's walls. But, when operating freely, it was found that the small brown bat, *Myotis lucifugus*, could detect in the dark and fly through a screen with wires no more than 24 centimeters apart. Only when the wires were reduced to a diameter of less than 0.07 millimeter, about the size of a human hair, did their detection system break down. Griffin went on to explore in greater detail the nature of bat sonar systems, describing his work in his *Listening in the Dark* (New Haven, 1958), and the more popular account *Echoes of Bats and Men* (1959).

Griffin also worked extensively on the problem of bird navigation. Early work inevitably consisted of homing experiments. But from these no more can be established than the percentage of birds arriving safely, and the time taken. It was, however, established that the number of returns decreased with distance in a way that suggested that birds navigate by identifying local landmarks. To discover more about the process Griffin taught himself to fly and in the late 1940s spent many hours in a Piper

Cub observing the flight paths of gannets and gulls. His observations tended to support the idea that homing from unfamiliar territory was not accurately directed, but succeeded eventually because of exploratory flights.

While this was perhaps a reasonable account of the behavior of gannets and gulls, later work by others showed that in the case of homing pigeons, shearwaters, and starlings there did exist a highly developed ability to select a particular direction. Griffin described his own work and the work of others in his *Bird Migration* (London, 1965).

**Griffith, Fred (1881–1941)** *British microbiologist*

Griffith, who was born at Hale in southern England, has been described variously as a "virtual recluse" or "quiet and retiring." He worked as a bacteriologist at the Ministry of Health's pathology laboratory in London and was killed working in his laboratory during an air-raid.

Despite the general obscurity of his background Griffith has acquired long after his death an almost legendary role as one of the founding fathers of molecular biology by his discovery in 1928 of bacterial transformation in pneumococci. He had first succeeded in distinguishing two types of pneumococci, the nonvirulent R (rough) of serological type I and the virulent S (smooth) of type III.

He inoculated mice with both live nonvirulent R and heat-killed S pneumococci. Although when either were inoculated separately no infection resulted, together they produced in the mice lethal cases of pneumonia. Further, he recovered from the infected mice living, virulent S pneumococci of type III.

It was this awkward result which later led Oswald AVERY and his colleagues in 1944 to carry out the experiments that succeeded in explaining Griffith's results by suggesting that the power to transform bacteria lay with the nucleic acid of the cell rather than its proteins or sugars.

**Grignard, François Auguste Victor (1871–1935)** *French chemist*

Born at Cherbourg in northern France, Grignard (gree-nyar) first studied mathematics at the University of Lyons before he switched to chemistry. He was a lecturer at the universities of Besançon, Nancy, and Lyons before he was appointed professor of chemistry at Nancy in 1910. In 1919 he moved to the chair of chemistry at Lyons.

In 1901 he discovered an important class of organic reagents now known as *Grignard reagents*. For this work he shared the Nobel Prize for chemistry with Paul SABATIER in 1912. He was searching for a catalyst for a methylation reaction he was trying to induce; chemists

had earlier tried to use zinc in combination with various organic compounds and found it moderately successful. Grignard used magnesium mixed with organic halides in ether solution and obtained compounds of the type  $\text{RMgX}$ , where X is a halogen (Cl, Br, I) and R an organic group. These Grignard reagents are very versatile and permit the synthesis of a large number of different classes of compounds, particularly secondary and tertiary alcohols, hydrocarbons, and carboxylic acids.

In 1935 he began the publication of his *Traité de chimie organique* (Treatise on Organic Chemistry), which was continued after his death and is now a massive multivolume work.

### **Grimaldi, Francesco Maria** (1618–1663) *Italian physicist*

Grimaldi (gri-mahl-dee) was born at Bologna, Italy, and became a Jesuit. In 1648 he became professor of mathematics at his order's college in his native city, where he acted as assistant to Giovanni RICCIOLI. His discovery of the phenomenon that he named the diffraction of light was reported in his posthumous work *Physico-mathesis de lumine, coloribus, et iride* (1665; *Physicomathematical Studies of Light, Colors, and the Rainbow*). He showed that when a beam of light passed through two successive narrow apertures, the pattern of light produced was a little bigger than it should have been if the light had traveled in an absolutely straight line. Grimaldi considered that the beam had bent outward very slightly, indicating that light must have a wave nature. The result presented difficulties to all 17th-century corpuscular theories of light.

### **Grisebach, August Heinrich Rudolph** (1814–1879) *German plant taxonomist and phytogeographer*

Grisebach was born in Hanover. His uncle was a professor of botany at Göttingen, and Grisebach originally studied there, later moving to Berlin.

His first taxonomic work was on the family Gentianaceae and in 1838 he published the substantial work *Genera et Species Gentianearum*. The next year, inspired by the scientific expeditions of Alexander HUMBOLDT, he set out on a trip to the Balkan peninsula, where he studied the vegetation. This was the start of his work on phytogeography, which he continued for several years and which resulted in his major work, *Vegetation de Erde*, published in 1872. Grisebach also worked on the botany of the Caribbean and South America.

### **Gross, David J.** (1941– ) *American theoretical physicist*

Gross was born in Washington, DC. He obtained his PhD in physics from the University of Cal-

ifornia, Berkeley, in 1966, and became a junior fellow at Harvard, where he stayed until 1969, when he moved to Princeton University. In 1997 he moved to the Institute for Theoretical Physics at the University of California, Santa Barbara.

In 1973 Gross together with Frank WILCZEK, and independently David POLITZER, discovered the property known as asymptotic freedom in quantum chromodynamics (QCD). QCD is a theory of the strong nuclear interactions put forward by Murray GELL-MANN and his colleagues in 1973, in which the fractionally charged constituents of hadrons (e.g. protons and neutrons), called quarks, interact with each other via massless spin-1 bosons, called gluons. This is analogous to the way in which electrically charged particles such as electrons interact with each other via photons in quantum electrodynamics (QED). In QED the strength of the electromagnetic interactions between electrically charged particles (e.g. electrons) becomes weaker as the distance between the particles increases. By contrast, Gross, Wilczek, and Politzer discovered that in QCD the strength of the strong nuclear interaction between quarks gets stronger as the distance between the quarks becomes larger, and goes to zero as the distance between them goes to zero. This property is known as asymptotic freedom. The theory explained the results of certain high-energy scattering experiments, which suggested that protons and neutrons have point-like objects moving around inside them. In addition, the discovery of asymptotic freedom led to the development of perturbative QCD, i.e., the description of high-energy processes in QCD using perturbation theory. Gross, Wilczek, and Politzer were awarded the 2004 Nobel Prize for physics for their discovery of asymptotic freedom. Gross has also made other contributions to quantum field theory and has played an important role in the development of superstring theory.

### **Grove, Sir William Robert** (1811–1896) *British physicist*

For my part, I must say that science to me generally ceases to be interesting as it becomes useful.

—Address to the Jubilee meeting of the Chemical Society (1891)

Born at Swansea in South Wales, William Grove was educated at Oxford and, after graduating in 1835, became a barrister. However, ill health turned him away from law to science.

His research concentrated on the newly formed science of electrochemistry and in 1839 he produced an improved version of the voltaic battery, which came to be known as the *Grove cell*. He also constructed the first fuel cell and, in 1845, invented a type of electric bulb, which he hoped would be useful in coal mines.

Grove was elected to the Royal Society in 1840 and, the next year, was appointed professor of physics at the London Institution. However, soon after this he returned to the legal profession and rose to the position of a high court judge. He continued to publish books on science, mainly supporting the idea of energy conservation.

**Grubbs, Robert H.** (1942– ) *American chemist*

Grubbs was born in Calvert City, Kentucky, and educated at Columbia University, New York, receiving his PhD in chemistry in 1968. He subsequently became Victor and Elisabeth Atkins Professor of Chemistry at the California Institute of Technology.

The focus of his research has been metathesis reactions in organic synthesis, particularly in finding convenient catalysts for this type of reaction. After Yves CHAUVIN proposed his mechanism for metathesis reactions in 1971, Grubbs was one of the chemists who demonstrated that this mechanism is correct. In the 1980s Grubbs started to investigate the use of ruthenium compounds as catalysts in organic synthesis. In 1992 Grubbs and his colleagues announced their discovery of a well-defined ruthenium compound that was stable in air and could readily be used. Grubbs has continued to investigate ways of improving ruthenium-based catalysts for metathesis. One of these catalysts is usually referred to as *Grubbs' catalyst*.

The work of Grubbs in finding stable, readily applicable catalysts for metathesis reactions has led to their widespread use in organic synthesis in both academic and industrial research. Grubbs himself has worked on the synthesis of polymers with particular properties. Other examples include the synthesis of natural products that are difficult to produce by any other means. Metathesis reactions using the types of catalyst discovered by Grubbs have shorter routes for their synthesis and have higher yields of product than other synthesis techniques. This means that the chemical production processes are cleaner and "greener," i.e., better for the environment. Drugs and herbicides are among the substances which have been produced in this way.

Grubbs shared the 2005 Nobel Prize for chemistry with Yves Chauvin and Richard SCHROCK for the development of the metathesis method in organic synthesis.

**Grünberg, Peter** (1939– ) *German physicist*

Peter Grünberg was born in Pilsen, now in the Czech Republic. He obtained a Diploma in Physics in 1966 and his PhD in 1969, both from the Darmstadt University of Technology, Ger-

many. Between 1969 and 1972 Grünberg did post-doctoral research in Canada at Carleton University, Ottawa. He subsequently joined the Institute for Solid State Physics at the Jülich Research Centre, where he remained until he retired in 2004.

Independently of Albert FERT, he discovered the phenomenon of giant magnetoresistance in 1988. The phenomenon created much interest as a novel and unexpected phenomenon in solid-state physics, but also because of its many important technological applications, especially in data storage. Fert and Grünberg have shared several prizes for their discovery, notably the Wolf Prize in 2006 and the Nobel Prize in physics in 2007.

**Guericke, Otto von** (1602–1686) *German physicist and engineer*

Guericke (**gay-ri-ke**), who was born in Magdeburg, Germany, trained in law and mathematics before becoming an engineer in the army of Gustavus Adolphus of Sweden. After the Thirty Years' War he returned to Magdeburg as mayor, there carrying out numerous dramatic experiments on vacuums and the power of the atmosphere.

In 1650 Guericke constructed the first air pump, which he used to create a vacuum in various containers. He showed that sound would not travel in a vacuum, and furthermore that a vacuum would not support combustion or animal life. In 1654 Guericke gave an impressive demonstration in front of the emperor Ferdinand III, of the force of atmospheric pressure. Two identical copper hemispheres 12 feet (3.66 m) in diameter were joined together. When the air was pumped out, 16 horses could not pull them apart although when the air reentered the hemispheres they fell apart by themselves. He also showed that 20 men could not hold a piston in a cylinder once the air had been evacuated from one end of it. The results of these and other experiments were published in his *Experimenta nova Magdeburgica de vacuo spatio* (1672; New Magdeburg Experiments Concerning Empty Space). In 1663 he built the first electrical friction machine by rotating a sulfur globe against a cloth.

**Guettard, Jean Etienne** (1715–1786) *French geologist*

Guettard (**ge-tar**) was born at Etampes in France. After a training in medicine and chemistry, he worked under the royal patronage of the duc d'Orléans from 1747 as keeper of his natural-history collection. Following the duc's death (1752) he continued this work under the patronage of his son.

In 1751 he made a crucial observation that upset the neptunism theories of Abraham WERNER and his followers. While traveling

through the Auvergne region he noticed an abundance of hexagonal basalt rocks and, exploring the region, identified the surrounding mountain peaks as the cones of extinct volcanoes (which would explain the presence of basalt). However, Werner's theory stated that all volcanic activity is recent, only occurring after the land has completely emerged from the oceans. Therefore, according to Wernerian theory, no volcanoes as ancient as the Auvergne ones should exist. Guettard published his findings in 1752 in his memoir, *On Certain Mountains in France which once have been Volcanoes*. He later changed his mind, distinguishing basalt from lava as it was not to be found among the recent volcanoes. He also observed the lack of vitrification found in basalt, then taken to be a sure sign of volcanic origin, and explained its formation by crystallization from an aqueous fluid.

Guettard was the first to map France geologically, publishing in 1780 his *Atlas et description minéralogiques de la France* (Mineralogical Atlas and Description of France). In the preparation of this he discovered (1765) a source of kaolin in Alençon, which made possible the production of the celebrated Sèvres porcelain.

### **Guillaume, Charles Edouard** (1861–1938) *Swiss metrologist*

As a child Guillaume (gee-yohm) learned a good deal of science from his father, a clockmaker with a considerable scientific knowledge. Born in Fleurier, Switzerland, in 1878 he entered the Zurich Federal Institute of Technology, gaining his doctorate in 1882. In 1883 Guillaume became an assistant at the newly established International Bureau of Weights and Measures at Sèvres, near Paris. He was appointed director in 1915 and held this post until his retirement in 1936.

Guillaume's early work at the Bureau was concerned with thermometry; his treatise of 1889 on this subject became a standard text for metrologists. He was also involved in developing the international standards for the meter, kilogram, and liter. His research on thermal expansion of possible standards materials led him from 1890 to investigate various alloys. After a methodical study of nickel–steel alloys he devised an alloy that showed a very small expansion with temperature rise. Guillaume's new material ("invar") found immediate practical applications, particularly in clocks, watches, and other precise instruments. He also produced a nickel–chromium–steel alloy, known as "elinvar," with an elasticity that remains nearly constant over a wide range of temperatures. It became widely used, for example, for the hairsprings of watches.

In 1920 Guillaume received the Nobel Prize

for physics for his researches into nickel–steel alloys.

### **Guillemin, Roger** (1924– ) *French–American physiologist*

Guillemin (gee-e-man) was educated at the universities of Dijon (his native city), Lyons, and Montreal, where he gained his PhD in physiology and experimental medicine in 1953. The same year he moved to America to join the staff of the Baylor University Medical School, Houston. In 1970 Guillemin joined the staff of the Salk Institute in La Jolla, California, where he remained until 1989, when he moved to the Whittier Institute for Diabetes and Endocrinology, La Jolla, becoming its director in 1993.

Early in his career Guillemin decided to work on the hypothesis of Geoffrey HARRIS that the pituitary gland is under the control of hormones produced by the hypothalamus. As the anterior pituitary secretes a number of hormones it was far from clear which to begin with. He eventually decided to search for the hypothalamic factor that controls the release of the adrenocorticotrophic hormone (ACTH) from the pituitary – it is known as the corticotrophic releasing factor (CRF). As it turned out, this was an unfortunate choice for after seven years Guillemin had nothing to show for his not inconsiderable efforts. Guillemin then worked for a further six years fruitlessly searching for the thyrotropin releasing factor (TRF), exposing him to skepticism from many other workers in the endocrine field. The main difficulty was that such hormones were present in very small quantities. When Guillemin finally did succeed in 1968 in isolating one milligram of TRF it had come from 5 million sheep's hypothalami. It turned out to be a small, relatively simple tripeptide, easy to synthesize. The development of the radioimmunoassay method for the detection of minute quantities by Rosalyn YALOW was also of considerable help. Other successes quickly followed. Andrew SCHALLY isolated the luteinizing-hormone releasing factor in 1971 and Guillemin in 1972 succeeded with somatostatin, which controls the release of the growth hormone.

In 1977 Guillemin shared the Nobel Prize for physiology or medicine with Schally and Yalow.

### **Guldberg, Cato Maximilian** (1836–1902) *Norwegian chemist*

Guldberg (guul-bairg) was educated at the university in his native city of Christiania (now Oslo) and started his career teaching at the Royal Military School there in 1860. He was appointed to the chair of applied mathematics at the university in 1869.

Guldberg's main work was on chemical ther-

modynamics. In 1863 he formulated the law of mass action in collaboration with his brother-in-law, Peter WAAGE. The law states that the rate of a chemical change depends on the concentrations of the reactants. Thus for a reaction:  $A + B \rightarrow C$  the rate of reaction is proportional to  $[A][B]$ , where  $[A]$  and  $[B]$  are concentrations. Guldberg and Waage also investigated the effects of temperature. They did not gain full credit for their work at the time, partly due to their first publishing the law in Norwegian. However, even when published in French (1867) the law received little attention until it was rediscovered by William Esson and Vernon HARCOURT working at Oxford University.

In 1870 Guldberg investigated the way in which the freezing point and vapor pressure of a pure liquid are lowered by a dissolved component. In 1890 he formulated Guldberg's law. This relates boiling point and critical temperature (the point above which a gas cannot be liquefied by pressure alone) on the absolute scale. The law was discovered independently by Phillippe-Auguste Guye.

**Gullstrand, Allvar** (1862–1930) *Swedish ophthalmologist*

Gullstrand (**gul**-strand), a physician's son from Landskrona, Sweden, was educated at the universities of Uppsala, Vienna, and Stockholm, where he obtained his PhD in 1890. After working briefly at the Karolinska Institute in Stockholm Gullstrand moved to the University of Uppsala, where he served as professor of ophthalmology from 1894 until his retirement in 1927.

In 1911 Gullstrand was awarded the Nobel Prize for physiology or medicine for his work on the dioptrics of the eye. Hermann von HELMHOLTZ had earlier shown that the eye solves the problem of accommodation (how to focus on both near and distant objects) by changing the surface curvature of the lens – the nearer the object, the more convex the lens becomes; the further the object, the more concave the lens. Gullstrand showed that this could in fact account for only two thirds of the accommodation a normal eye could achieve. The remaining third was produced by what Gullstrand termed the “intracapsular mechanism” and depended on the fact that the eye was not a homogeneous medium.

**Gutenberg, Beno** (1889–1960) *German-American geologist*

Gutenberg (**goo**-ten-berg) was educated at the Technical University in his native city of Darmstadt and at the University of Göttingen, where he obtained his PhD in 1911. He then taught at the University of Freiburg becoming professor of geophysics in 1926. He emigrated to America in 1930, taking a post at the California Institute

of Technology, and later served as director of the seismological laboratory (1947–58).

In 1913 Gutenberg suggested a structure of the Earth that would explain the data on earthquake waves. It was known that there were two main types of waves: primary (P) waves, which are longitudinal compression waves, and secondary (S) waves, which are transverse shear waves. On the opposite side of the Earth from an earthquake, in an area known as the shadow zone, no S waves are recorded and the P waves, although they do appear, are of smaller amplitudes and occur later than would be expected. Gutenberg proposed that the Earth's core, first identified by Richard OLDHAM in 1906, is liquid, which would explain the absence of S waves as, being transverse, they cannot be transmitted through liquids. Making detailed calculations he was able to show that the core ends at a depth of about 1,800 miles (2,900 km) below the Earth's surface where it forms a marked discontinuity, now known as the *Gutenberg discontinuity*, with the overlying mantle. Its existence has been confirmed by later work, including precise measurements made after underground nuclear explosions.

In collaboration with Charles RICHTER, Gutenberg produced a major study, *On Seismic Waves* (1934–39), in which, using large quantities of seismic data, they were able to calculate average velocity distributions for the whole of the Earth.

**Guth, Alan Harvey** (1947– ) *American physicist and cosmologist*

They say that there is no such thing as a free lunch – but the universe is the ultimate free lunch!  
—Speaking about the inflationary model of the universe

Born in New Brunswick, New Jersey, Guth was educated at the Massachusetts Institute of Technology, where he obtained his PhD in 1969. After holding postdoctoral appointments at Princeton, Columbia, Cornell, and Stanford, Guth returned to MIT in 1980, becoming professor of physics in 1986.

Initially Guth worked as a theorist in elementary-particle physics, but, stimulated by the work of Steven WEINBERG, he began to consider some of the outstanding problems of cosmology. These included a number of difficulties raised against the standard interpretation of the big-bang account of the origin of the universe. Many had found the apparent isotropy of the universe puzzling, while James PEEBLES and Charles MISNER had discovered the flatness and horizon problems. The big-bang was clearly in need of revision.

Consequently in 1980 Guth first proposed the *inflationary universe model*. Guth's theory agrees with the standard model after the first

$10^{-30}$  second. Within the initial brief period, he proposed that the universe had undergone an extraordinarily rapid inflation. During this period the diameter of the universe would have increased by a factor of about  $10^{50}$ . An increase of this size would expand a centimeter to  $10^{32}$  light years.

Thus as the region from which the present universe emerged was so small, thermal equilibrium could have been achieved before the inflation. An observer today would, therefore, detect an isotropic cosmic-background radiation. He would also detect a flat universe – an observer on a globe that had increased  $10^{50}$  times in diameter would have seen his universe flattened.

Guth has conceded that even if the inflationary model is correct “it will be difficult for anyone to ever discover observable consequences of the conditions existing before the inflationary phase transition.” He has also pointed out that the grand unified theories of physics allow that the observed universe could have evolved from nothing. The inflationary model comes close to this by providing a mechanism by which the observable universe could have evolved from an infinitesimal region.

In the 1990s evidence emerged to support the idea that quantum fluctuations in the early Universe, expanded by inflation, were responsible for the large-scale structure in the Universe, such as galaxies.

### **Guthrie, Samuel** (1782–1848) *American chemist*

Guthrie, who was born at Brimfield, Massachusetts, was a student at the University of Pennsylvania, where he qualified as a doctor. In 1831 he discovered chloroform, which was used as an anesthetic by James SIMPSON in 1847. It was, however, discovered independently by Soubeiran in the same year and by Justus von LIEBIG in 1832. Guthrie also discovered percussion powder, a substance that explodes on impact.

### **Guyot, Arnold Henry** (1807–1884) *Swiss–American geologist and geographer*

Intending to enter the Church, Guyot (**gee-yoh**), who was born at Boudevilliers in Switzer-

land, studied at the universities of Neuchâtel, Strasbourg, and Berlin, where his interests in science began to absorb him. After teaching in Paris (1835–40) he was appointed professor of history and physical geography at Neuchâtel in 1839 where he remained until 1848, when he emigrated to America. He taught first at the Lowell Technological Institute in Boston before he was appointed, in 1854, to the chair of geology and physical geography at Princeton University.

While in Switzerland he had studied the structure and movement of glaciers, spending much time testing the new theories of Louis AGASSIZ. In America, under the auspices of the Smithsonian Institution, he began to develop, organize, and equip a number of East Coast meteorological stations. He also surveyed and constructed topographical maps of the Appalachian and Catskill mountains. In 1849 he published his influential work *The Earth and Man*.

### **Guyton de Morveau, Baron Louis Bernard** (1737–1816) *French chemist*

Born at Dijon in France, Guyton (**gee-ton**) began his career as a lawyer; as a member of the Burgundy parliament (1755–82), however, he met the great Georges BUFFON who encouraged his interest in science. In 1782 he gave up law to devote himself to science and he collaborated with Antoine LAVOISIER. During the revolutionary period he reentered politics. He was a founder of and teacher at the Ecole Polytechnique (1795–1805) and in 1800 became master of the mint until his retirement in 1814.

In the period 1776–77 Guyton published his three-volume *Eléments de chimie théorique et pratique* (Rudiments of Theoretical and Practical Chemistry), which was a major attempt to quantify chemical affinities. Guyton was a passionate Newtonian and tried to apply Newtonian laws to chemistry. He tried to do this by floating disks of various metals on mercury and measuring the force necessary to remove them. Thus he obtained figures such as gold needs a force of 446 grains to remove it, lead 397, zinc 204, iron 115, and cobalt 8. He attempted to correlate his figures with the chemical affinities of the elements.

## **Haber, Fritz** (1868–1934) *German physical chemist*

For more than forty years I have selected my collaborators on the basis of their intelligence and their character and not on the basis of their grandmothers, and I am not willing for the rest of my life to change this method which I have found so good.

—Letter of resignation over the Nazis' demand that he dismiss his Jewish colleagues, 30 April 1933

Haber (**hah-ber**), the son of a merchant, was born at Breslau, now Wrocław in Poland. He was educated at Berlin, Heidelberg, Charlottenburg, and Jena, and in 1894 he became an assistant in physical chemistry at the Technical Institute, Karlsruhe, where he remained until 1911, being promoted to a professorship in 1906. He moved to Berlin in 1911 to become director of the Kaiser Wilhelm Institute of Physical Chemistry. Though an intensely patriotic German he was also a Jew and with the rise of anti-Semitism he resigned his post in 1933 and went into exile in England, where he worked at the Cavendish Laboratory, Cambridge. He died in Basel en route to Italy.

Haber is noted for his discovery of the industrial process for synthesizing ammonia from nitrogen and hydrogen. The need at the time was for nitrogen compounds for use as fertilizers – most plants cannot utilize free nitrogen from the air, and need “fixed” nitrogen. The main source was deposits of nitrate salts in Chile, but these would have a limited life.

Haber, in an attempt to solve this problem, began investigating the reaction:

Under normal conditions the yield is very low. Haber (1907–09) showed that practical yields could be achieved at high temperatures (250°C) and pressures (250 atmospheres) using a catalyst (iron is the catalyst now used). The process was developed industrially by Carl BOSCH around 1913 and is still the main method for the fixation of nitrogen. Haber received the Nobel Prize for chemistry for this work in 1918.

During World War I, Haber turned his efforts to helping Germany's war effort. In particular he directed the use of poisonous gas. After the war he tried, unsuccessfully, to repay

the indemnities imposed on Germany by a process for extracting gold from seawater.

## **Hadamard, Jacques Salomon** (1865–1963) *French mathematician*

Some intervention of intuition issuing from the unconscious is necessary at least to initiate the logical work.

—*The Psychology of Invention in the Mathematical Field*

The son of a Latin teacher, Hadamard (**a-damar**) was born at Versailles in France and educated at the Ecole Normale Supérieure in Paris. He taught first at the University of Bordeaux from 1893 until 1897, before returning to Paris to the Sorbonne. In 1909 he took up the chair of mathematics at the Collège de France where he remained until his retirement in 1937.

In his long life Hadamard worked in many areas of mathematics, but remains best known for his proof in 1896 of the *prime number theorem*.

Mathematicians have long been interested in prime numbers. There is no simple formula for determining primes, but it is possible to say something about the distribution of prime numbers. If  $P_n$  is the  $n$ th prime number,  $\pi(n)$  is used to denote the number of primes between 1 and  $n$ . Both GAUSS and Legendre used the formula

$$\pi(n) = n/\log_e n.$$

This does not work at small values of  $n$  but Gauss and Legendre suspected that the ratio of  $\log_e n$  to  $\pi(n)/n$  would approach 1 as  $n$  approaches infinity. They were, however, unable to prove it. Hadamard and, independently, Charles de la Vallée-Poussin produced proofs in 1896 using the Riemann zeta function.

## **Hadfield, Sir Robert Abbott** (1858–1940) *British metallurgist*

Hadfield's father was a steel manufacturer who had opened a factory for the production of steel castings in Sheffield in 1872. Hadfield was educated locally and started work in the laboratory in his father's works, inheriting the business on his father's death (1880). It had been known for some years that if manganese was added to iron the result was hard but was too brittle to be commercially useful. Hadfield

discovered that if a large quantity of manganese was added (about 12–14%) and the steel was heated and quenched in water, the resulting alloy was extremely hard and strong. He patented his discovery in 1883. He also worked on the development of other steel alloys and in 1899 was able to show that silicon steels have a high electrical resistance. This made them suitable for use in transformers as they could substantially reduce bulk.

Hadfield was also interested in the history of metallurgy, forming a fine collection, and out of this interest came his two books: *Faraday and his Metallurgical Researches* (1931) and *Metallurgy and its Influence on Modern Progress: With a Survey of Education and Research* (1925). He was knighted in 1908 and made a baronet in 1917.

**Hadley, George** (1685–1768) *English meteorologist*

The younger brother of the inventor John Hadley, George Hadley was born in London and educated at Oxford University. Although called to the bar in 1709, he became more interested in physics and was made responsible for producing the Royal Society of London’s meteorological observations.

In 1686 Edmond HALLEY had offered a partial explanation of the trade winds, pointing out that heated equatorial air will rise and thus

cause colder air to move in from the tropics, but could not explain why the winds blew from the northeast in the northern hemisphere and the southeast in the southern.

Hadley put forward the explanation, in his paper *Concerning the Cause of the General Trade Winds* (1735), that the airflow toward the equator was deflected by the Earth’s rotation from west to east. This circulation is now known as the *Hadley cell*.

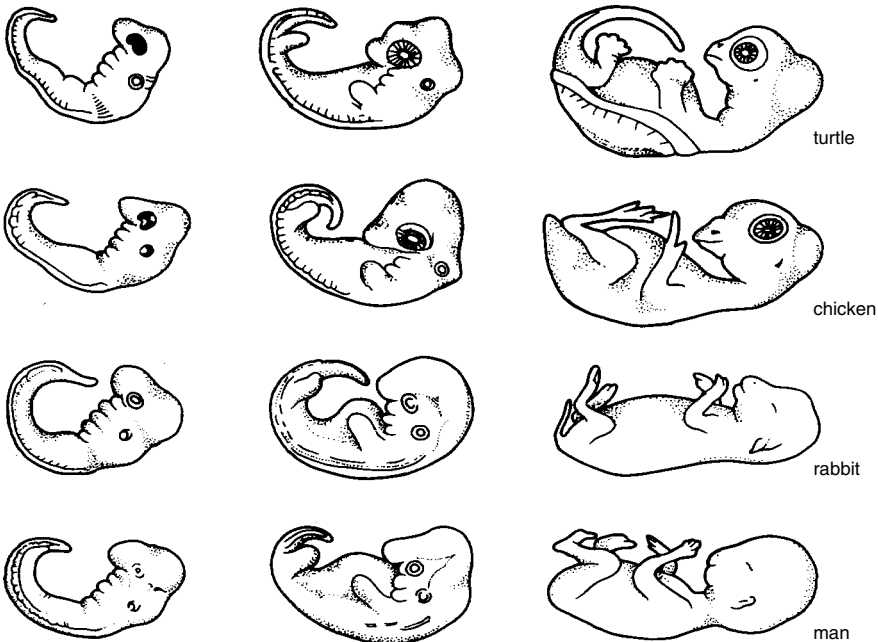

**Hadley, John** (1682–1744) *English mathematician and inventor*

Little is known of Hadley’s life. He is chiefly remembered for developing the reflecting telescope, producing his first in 1721. He was an extremely skilled craftsman and his reflectors were among the first to be useful in astronomy.

Hadley also invented, in 1730, the reflecting quadrant with which a ship’s position at sea could be determined by measurements of the Sun or a star above the horizon. This instrument later developed into the sextant.

**Haeckel, Ernst Heinrich** (1834–1919) *German biologist*

Man is separated from the other animals only by quantitative, not qualitative, differences. —Expounding his idea that man was part of nature

**STAGES OF DEVELOPMENT IN VERTEBRATE EMBRYOS** These show the similarities, particularly in the early stages, that led Haeckel to suggest his theory of recapitulation.

The son of a government lawyer, Haeckel (**hek-el**) was born at Potsdam in Germany and educated at the universities of Warburg, Vienna, and Berlin, where he qualified as a physician in 1858. His main interests lay elsewhere and, after a brief period in practice, he moved to Jena to study zoology. In 1862 he was appointed professor of zoology and comparative anatomy at Jena, a position he held until his retirement in 1909.

Haeckel's contributions to zoological science were a mixture of sound research and speculation often with insufficient evidence. An advocate of monism, which postulated a totally materialistic view of life as a unity, he based his evolutionary ideas on the embryological laws expounded by Karl von BAER. Expanding the idea of his mentor, Johannes MÜLLER, Haeckel argued that the embryological stages of an animal were a recapitulation of its evolutionary history, and indeed that there had once been complete animals resembling the embryonic stages of higher animal forms living today. He formulated a scheme of evolution for the whole animal kingdom, from inorganic matter upward. His studies, with Müller, of marine life, particularly the crystalline radiolarians, encouraged him to compare the symmetry of crystals with the simplest animals, and led him to postulate an inanimate origin for animal life. In 1866 Haeckel anticipated later proof of the fact that the key to inheritance factors lies in the cell nucleus, outlining this theme in his *Die Perigenesis der Plastidule* (1876; *The Generation of Waves in the Small Vital Particles*).

Haeckel also proposed the idea that all multicellular animals derived from a hypothetical two-layered (ectoderm and endoderm) animal, the *Gastraea* – a theory that provoked much discussion. He engaged in much valuable research on marine invertebrates, such as the radiolarians, jellyfish, calcareous sponges, and medusae, and wrote a series of monographs on these groups based largely on specimens brought back by the Challenger Expedition. He was also the first to divide the animal kingdom into unicellular (protozoan) and multicellular (metazoan) animals. An ardent Darwinist, Haeckel made several zoological expeditions and founded the Phyletic Museum at Jena and the Ernst Haeckel Haus, which contains his books, archives, and other effects.

In 1906 the Monist League was formed at Jena with Haeckel as its president. The League held a strong commitment to social Darwinism. Man was seen as part of nature and in no way qualitatively distinct from any other organic form. Human society was as much a creation of natural selection as the bird's wing. To such views Haeckel added a strong anticatholicism, a contempt for politicians, and a forecast of impending doom. After the chaos of World War I, Haeckel's views were taken up by

eugenicists, the Volk movement and, more significantly, the National Socialists.

### Hahn, Otto (1879–1968) *German chemist*

If Hitler gets an atomic bomb, I shall kill myself.

—Quoted in Hahn's obituary notice in *The Times*

Hahn's father, a successful merchant in the German city of Frankfurt, was eager for his son to train as an architect and it was against much family opposition that Hahn was finally allowed to study chemistry at the University of Marburg in 1897. After obtaining his doctorate in 1901 he studied abroad, first with William RAMSAY in London and then at McGill University, Canada, with Ernest RUTHERFORD. Hahn returned to Germany in 1907, where he took up an appointment at the University of Berlin, being made professor of chemistry in 1910. Two years later he joined the Kaiser Wilhelm Institute of Chemistry where he served as director from 1928 to 1945.

Hahn had trained as an organic chemist and had really gone to London to learn English in order to prepare himself for an industrial career. Ramsay had however asked him to separate radium from some radioactive material he had recently acquired from Ceylon. In so doing Hahn found a new material, a highly active form of thorium which he named "radiothorium." So impressed was Ramsay with this work that he wrote to Emil FISCHER in Berlin suggesting that he employ Hahn after he had acquired more experience of radioactivity with Rutherford at McGill.

Hahn was thus diverted into an academic career, most of which was spent in research on radioactivity and much of it in collaboration with Lise MEITNER. With her he discovered a new element, protactinium, in 1917. He went on to define, in 1921, the phenomenon of nuclear isomerism. This arises when nuclei with different radioactive properties turn out to be identical in atomic number and mass.

Hahn's most important work, however, was done in the 1930s when, with Meitner and Fritz STRASSMANN, he made one of the most important discoveries of the century, namely nuclear fission. One of the strange features about Hahn's work was that he was repeating experiments already done and formulating hypotheses already rejected as nonsense or due to some contamination of the materials used. Chemists at this time felt that they understood the process of nuclear transformation. After all it was some twenty years since Rutherford had first detected the transformation of nitrogen into oxygen, and a newer form of the same "alchemy" had been described by Irène and Frédéric JOLIOT-CURIE in 1934. Two basic rules were involved in this understanding. First, that nuclear transmutations always involved the

emission of either an alpha particle (helium nucleus) or a beta particle (electron); and secondly, that the change could take place only between elements separated by no more than two places in the periodic table. If more substantial transformations appeared to occur, as in the transformation of uranium into lead, this was explained as the result of a series of such intermediate steps, each one taking place with the emission of the appropriate particle.

Thus when in 1938 Hahn bombarded uranium with slow neutrons and detected some strange new half-lives, he assumed that the uranium had changed into radium, a close neighbor, with some undetected alpha particles. But when he tried to remove the radium all he could find was barium. This Hahn simply could not understand, for barium was far too low in the periodic table to be produced by the transmutation of uranium; and if the transformation *was* taking place it should be accompanied by the emission of a prodigious number of alpha particles, which Hahn could not have failed to detect. The thought that the heavy uranium nucleus could split into two lighter ones was too outrageous for him to consider seriously. He could not dismiss it entirely for he asserted at the time that “we must really state that we are not dealing with radium but with barium.” But to suppose the barium arose from what he then called nuclear “bursting” he felt would be “in contradiction to all previous experience in nuclear physics.” He did realize that something of importance was going on and quickly sent off for publication a joint paper with Strassmann even though, as he recalled twenty years later, “After the manuscript had been mailed, the whole thing once more seemed so improbable to me that I wished I could get the documents back out of the mail.” Appropriately enough it was his old collaborator Meitner, in exile from the Nazis in Sweden, and her nephew Otto FRISCH, who made the necessary calculations and announced fission to the world early in 1939. Hahn received the Nobel Prize for chemistry in 1944.

**Haken, Wolfgang** (c. 1927– ) *German-born American mathematician*

Haken (**hah**-ken) was born in Berlin, Germany, and educated at the University of Kiel, where he obtained his PhD in 1953. After working for the Siemens Corporation for a number of years, he moved to America in 1961 to take up a visiting professorship at the University of Illinois, Urbana. He spent the period 1963–65 at the Institute for Advanced Study, Princeton, but returned to Urbana in 1966 as professor of mathematics.

Haken’s main work has been in the field of topology. He first established his reputation in 1962 with a proposal for calculating the genus of any knot. The genus is a topological invari-

ant that allows it to be decided whether two given knot diagrams represent the same knot.

He is best known, however, for his solution in 1977, in collaboration with Kenneth APPEL, of the four-color map problem. One unusual feature of the proof was its use of a computer. Some mathematicians objected that unless all parts of a proof can be surveyed by hand and eye, the proof cannot be considered valid. This objection has lost some of its force as mathematicians have offered more and more computer-assisted proofs. Haken has denied that there has been any change in the basic concept of mathematical proof. “What has changed,” he claims, “is not the theory but the practice of mathematics.”

**Haldane, John Burdon Sanderson** (1892–1964) *British geneticist*

My own suspicion is that the universe is not only queerer than we suppose, but queerer than we can suppose.

—*Possible Worlds and Other Essays* (1927)

Religion is still parasitic in the interstices of our knowledge which have not yet been filled. Like bed-bugs in the cracks of walls and furniture, miracles lurk in the lacunae of science. The scientist plasters up these cracks in our knowledge; the more militant Rationalist swats the bugs in the open. Both have their proper sphere and they should realise that they are allies.

—*The Rationalist Annual* (1934)

Physical science is ... no more than a superficial aspect of ultimate philosophical truth.

—*Respiration* (1935)

Haldane, who was born at Oxford in England, became involved in scientific research at an early age through helping in the laboratory of his father, the physiologist John Scott Haldane. His interest in genetics was first stimulated as early as 1901, when he heard a lecture on MENDEL’s work, and he later applied this by studying inheritance in his sister’s (the writer Naomi Mitchison) 300 guinea pigs. On leaving school he studied first mathematics and then the humanities at Oxford University. He served in World War I with the Black Watch Regiment and was wounded at Loos and in Mesopotamia. Some work on gas masks, following the first German gas attacks, marked the beginning of his physiological studies.

In 1919 Haldane took up a fellowship at Oxford, where he continued research on respiration, investigating how the levels of carbon dioxide in the blood affect the muscles regulating breathing. He was next offered a readership in biochemistry at Cambridge, where he conducted some important work on enzymes. These experiments, and later work on conditions in submarines, aroused considerable public interest because he frequently used himself as a guinea pig.

In 1933 Haldane became professor of genetics at University College, London, a position he exchanged in 1937 for the chair of biometry. While at London he prepared a provisional map of the X sex chromosome and showed the genetic linkage between hemophilia and color blindness. He also produced the first estimate of mutation rates in humans from studies of the pedigrees of hemophiliacs, and described the effect of recurring deleterious mutations on a population. With the outbreak of the Spanish Civil War, Haldane joined the Communist Party and advised the republican government on gas precautions. In the 1950s he left the party as a result of Soviet acceptance and promotion of Trofim LYSENKO. In protest at the Anglo-French invasion of Suez, Haldane emigrated to India in 1957, becoming an Indian citizen in 1961. He was director of the laboratory of genetics and biometry at Bhubaneswar from 1962 until his death.

Haldane's books include *Enzymes* (1930), *The Causes of Evolution* (1932), and *The Biochemistry of Genetics* (1954); he also wrote a number of books popularizing science.

**Haldane, John Scott** (1860–1936) *British physiologist*

Haldane, the son of a lawyer, was educated at the university in his native city of Edinburgh, where he obtained his MD in 1884. He worked first at the University of Dundee but moved to Oxford to assist his uncle, John Burdon-Sanderson, the professor of physiology, in 1887. Haldane was made reader in physiology in 1907 but resigned in 1913 to become director of the Mining Research Laboratory, initially sited in Doncaster but transferred to Birmingham in 1921.

From the beginning of his career Haldane sought to apply the results of physiological research to the solution of practical social and industrial problems. He was much concerned with problems of ventilation in mines and in 1896 published an important report, *Causes of Death in Colliery Explosions*. He was struck by the fact that in a serious explosion in 1896 only 4 out of 57 miners died from the blast and its effects, the vast majority succumbing to carbon monoxide poisoning. Haldane recommended the simple and effective safety procedure of taking mice down the pit: with their higher metabolic rate they would show the effects of carbon monoxide poisoning long before it reached levels dangerous to man.

He also worked for the admiralty on the problems faced by their divers at high pressures. It had been known for some time that rapid decompression produced the liberation of nitrogen bubbles into the bloodstream, with crippling and often lethal effects. Haldane showed how such effects could be minimized by pointing out that however long a diver had been

exposed to compressed air it was always safe to halve the pressure; that is, it is just as safe to ascend from six to three atmospheres as from two to one. Using his technique over £5,000,000 of gold was recovered from the wreck of the *Lusitania* between 1917 and 1924.

Haldane also investigated the response of the human body to high temperatures. Haldane's main work as a pure physiologist, however, was on the mechanism of respiration. In 1906 he published his most significant paper, in collaboration with John Priestley, which demonstrated the key role of carbon dioxide in the regulation of breathing. They showed that it was not a deficiency in oxygen that triggers the respiratory reflex but an excess of carbon dioxide in the arterial blood, acting on the respiratory center in the midbrain. Their work was published in full in *Respiration* (1935; 2nd edition).

In much of his work Haldane used for an experimental subject his precocious son J. B. S. Haldane, later to become one of the leading biologists of the 20th century.

**Hale, Alan** (1958– ) *American astronomer*

Alan Hale was raised on the outskirts of Alamogordo, New Mexico. His interest in astronomy developed at school and early in 1970 his father bought him his first telescope – a 4½-inch reflector. After graduating from high school he attended the US Naval Academy, Annapolis, Maryland, where he studied physics. He was then stationed at various naval bases. Throughout this period he continued his astronomical observations, in particular the observation of comets.

In 1983 he left the navy and spent 2½ years working for the Deep Space Network at the Jet Propulsion Laboratory, Pasadena. He then went to New Mexico State University, Las Cruces, where he obtained his PhD in 1992. In 1993 he formed an independent research and education organization, now called the Earthrise Institute.

The organization moved in 1995 to a mountain village of Cloudcroft, New Mexico. It was here on the night of 22–23 July that Alan Hale first observed the comet *Hale-Bopp*. It proved to be perhaps the most prominent comet of the century. The comet was discovered independently by an amateur astronomer, Thomas BOPP.

**Hale, George Ellery** (1868–1938) *American astrophysicist*

Hale may be said to be the father of modern solar observational astronomy.

—Robert Howard

Hale's father, William Hale, was a wealthy manufacturer of elevators in Chicago, Illinois, who stimulated in his son an early interest in

designing and making his own instruments. This interest was directed to astronomy by Sherburne W. Burnham, a neighbor and passionate observer of double stars, and increased during his four years at the Massachusetts Institute of Technology, where he studied physics. He built a solar observatory, financed by his father, at Kenwood, Chicago, and after graduating in 1890 became its director. In 1892 he was appointed assistant professor and later professor of astrophysics at the new University of Chicago and from 1895 to 1905 he was director of the university's Yerkes Observatory. From 1904 to 1923 he was director of the newly established Mount Wilson Observatory in California. The last 15 years of his life were spent organizing the equipping and building of the Palomar Observatory in California and in the pursuit of his solar researches in his private observatory in Pasadena.

Hale was undoubtedly one of the key figures in 20th-century astronomy. He saw very clearly and very early that astronomy could only develop if much more powerful telescopes were constructed. Thus with great vision and enormous persistence and energy he spent 40 years acting as midwife to a series of bigger and bigger telescopes. His insight was clearly justified for it was with his telescopes that Harlow SHAPLEY, Edwin HUBBLE, and many others made their observations.

His first triumph came when he persuaded Charles T. Yerkes, a Chicago trolley-car magnate, to provide \$349,000 to build a 40-inch (1-m) refracting telescope for the University of Chicago. This was and still is the largest refractor ever built. It was first used in 1897. He was soon anxious, however, to build a large reflecting telescope. In 1896 his father acquired a 60-inch (1.5-m) mirror but the University of Chicago was unable to fund its mounting. Hale once more started raising money. This time he interested the Carnegie Institution of Washington in financing the Mount Wilson Observatory. The observatory was founded in 1904 and the 60-inch reflector eventually went into use in 1908. In 1918 this superb instrument was surpassed by the 100-inch (2.5-m) Hooker telescope, largely financed by a Los Angeles business man, John D. Hooker. For 30 years this was the world's largest telescope and it revolutionized astronomy.

Hale had resigned from his directorship of Mount Wilson Observatory in 1923 on the grounds of ill health but lost little time in seeking to interest the Rockefeller Foundation in building a reflecting telescope that would be the ultimate in size, 200 inches (5 m) across, for Earth-based instruments. In 1929 it was finally agreed that \$6 million would be donated for this purpose to an educational institute, the California Institute of Technology, rather than the Carnegie Institution. Hale became chairman of the group directing the planning, con-

struction, and operation of the instrument that was to become his masterpiece.

Thus there began an epic struggle to complete the 200-inch telescope, which was to take nearly 20 years. The first mirror made from fused quartz proved to be a \$600,000 failure. Hale next tried Pyrex and the first experimental 200-inch disk cast proved satisfactory. The actual casting was made in December 1934 when the 65 tons of molten Pyrex began its carefully controlled 10 months' cooling. The mirror managed to survive the flooding of the factory, which necessitated shutting down the temperature control for three days, and its long journey in the spring of 1936 from Corning, New York, to California at a maximum speed of 25 mph. The grinding of the mirror was interrupted by the war and took so long that Hale had been dead for nine years when the instrument was finally commissioned as the Hale telescope in 1948. It was set up at the specially constructed Palomar Observatory, which together with the Mount Wilson Observatory was jointly operated by the California Institute of Technology and the Carnegie Institution. The two observatories were renamed the Hale Observatories in 1969. The Hale telescope was the world's largest telescope until the Soviet 6-meter (236-in) reflector went into operation in 1977 but is still considered by many to be the world's finest.

Hale was not just a highly successful scientific entrepreneur for he made major advances in the field of solar spectroscopy. As early as 1889 he had conceived of his spectroheliograph, an instrument that allowed the Sun to be photographed at a particular wavelength. He also designed an appropriate telescope to which it could be attached. In 1908 Hale made his most significant observation. He found that some of the lines in the spectra of sunspots were double. He realized that this demonstrated the presence of strong magnetic fields in sunspots, being due to the effect discovered by Pieter ZEEMAN in 1896, and was the first indication of an extraterrestrial magnetic field.

### **Hales, Stephen** (1677–1761) *English plant physiologist and chemist*

Since we are assured that the all-wise Creator has observed the most exact proportions, of number, weight and measure, in the make of all things, the most likely way therefore, to get any insight into the nature of those parts of the creation, which come within our observation, must in all reason be to number, weigh and measure.

—*Vegetable Staticks* (1727)

Born at Bekesbourne in Kent, southeast England, Hales entered Cambridge University in 1696 to study theology. He was ordained in 1703 and appointed curate at Teddington, near London, in 1708 (or 1709). During his time at Cambridge, he studied science and was influ-

enced by Isaac NEWTON's ideas, which still dominated scientific thought at the university and probably accounted for Hales's consistent use of the quantitative method in his biological researches.

Hales was elected a fellow of the Royal Society in 1718 but his first work, *Vegetable Statics*, was not published until 1727. In this book, which included his most important observations in plant physiology, Hales demonstrated that plant leaves absorb air and that a portion of air is used in plant nutrition. In addition, he realized that light is necessary for growth and investigated growth rates by marking plants at regular intervals. He measured the rate of water loss (transpiration) in plants, finding that it occurred through the leaves and was responsible for an upward flow of sap in plants. From additional measurements of sap flow he concluded that there was no circular movement of sap in plants analogous to blood circulation in animals.

Hales also made important contributions to the understanding of blood circulation by measuring such properties as blood pressure, output per minute from the heart, rate of flow and resistance to flow in vessels. The results were published in *Haemastatics* (1733; *Blood Statics*).

Other notable discoveries include the development of methods for collecting gases over water, distilling fresh water from sea water, and preserving foodstuffs with sulfur dioxide. He also invented a ventilator for introducing fresh air into prisons, ships, and granaries.

### **Hall, Asaph** (1829–1907) *American astronomer*

The chance of finding a satellite appeared to be very slight, so that I might have abandoned the search had it not been for the encouragement of my wife.

—On discovering the satellites of Mars, August 1877

Born at Goshen in Connecticut, Hall had to leave school at the age of 13 and support his family as a carpenter, following the death of his father. He educated himself, and his interest in astronomy was strong enough for George BOND to employ him as his assistant at Harvard in 1857. In 1863 Hall became professor of mathematics at the Naval Observatory in Washington. He returned to Harvard as professor of astronomy in 1895.

In 1877 Mars was in opposition to the Sun at a distance of about 30 million miles from the Earth. Hall decided to search for Martian satellites using the 26-inch (66-cm) refractor that the Clark firm had provided for the Naval Observatory. On 11 August he discovered a tiny satellite (the smaller moon) but was then compelled to wait a further six nights for the persistent cloud to clear before he could confirm his

sighting and discover a further satellite. Both were very small, having diameters of 17 miles (27 km) and 9 miles (15 km) only. He named the larger "Phobos" and the smaller "Deimos" (Fear and Terror), after the sons of Mars. One curious feature of the two satellites was that Jonathan Swift had spoken of Martian satellites in *Gulliver's Travels* (1726). Not only did Swift get their number correct but also spoke accurately of their size and orbital period.

In 1876, by noticing a white spot on the surface of Saturn, Hall was able to work out correctly the rotation period as 10.75 hours, which compares well with today's figure of 10 hours 14 minutes (for its equatorial region).

### **Hall, Charles Martin** (1863–1914) *American chemist*

Hall was born in Thompson, Ohio, and educated at Oberlin College, graduating in 1885. He became interested in the costly process of manufacturing aluminum – until the late 19th century aluminum was a precious metal costing about \$5.50 an ounce. Napoleon III would have the majority of his guests served from gold plate; he and the chosen few he wished to impress were served from aluminum plates. Hall was stimulated by a remark of his teacher that anyone who could find a cheap way to make aluminum would win great wealth and fame.

Although the ore itself (bauxite, aluminum oxide) was cheap and plentiful, the metal could only be extracted by electrolysis of the molten ore, and aluminum oxide has a very high melting point. Hall tried various added compounds and, in 1886, found that adding 10–15% of cryolite (sodium aluminum fluoride) reduced the melting point to a little over 1,000°C. Hall produced his first sample in the form of buttons, which soon became known as the "aluminum crown jewels." Paul HÉROULT, working in France, discovered the process independently at about the same time. Hall helped to found the Pittsburgh Reduction Company (later the Aluminum Company of America) of which he became vice-president in 1890.

### **Hall, Edwin Herbert** (1855–1938) *American physicist*

Hall was born in Great Falls, Maine, and educated at Johns Hopkins University, Baltimore, where he received his PhD in 1880. After a year in Europe he joined the Harvard faculty and was appointed professor of physics in 1895, a post he held until his retirement in 1921.

While working for his thesis, Hall began to consider a problem first posed by MAXWELL concerning the force on a conductor carrying a current in a magnetic field. Does the force act on the conductor or the current? Hall argued that if the current was affected by the magnetic field then there should be "a state of stress ... the

electricity passing toward one side of the wire.” Hall used a thin gold foil and in 1879 detected for the first time an electric potential acting perpendicularly to both the current and the magnetic field. The effect has since been known as the *Hall effect*. A simple interpretation is that the charge carriers moving along the conductor experience a transverse force and tend to drift to one side. The sign of the Hall voltage gives information on whether the charge carriers are positive or negative.

Other so-called galvanomagnetic effects were later discovered by Walther NERNST and others. Hall spent much of his later life attempting to measure the various effects as exactly as possible.

More than a century after its discovery Klaus von KLITZING was awarded the 1985 Nobel Prize for physics for his work on the *Hall effect*.

### **Hall, James** (1811–1898) *American geologist*

A very great man, not honoured in his family, not well understood in his own community, not always courteously entreated and appreciated by his scientific contemporaries; but on the other hand winning the admiration and acclaim of those great-minded enough to understand his inflexible purpose and the magnitude of his achievement.

—John M. Clarke, *James Hall of Albany* (1921)

Hall, who came from a poor background in Hingham, Massachusetts, was educated at Rensselaer Polytechnic Institute, New York, where he became assistant professor in 1832. In 1837 he started work as a geologist on a survey of New York State, publishing an important report of these studies, *Geology of New York* (1843). In 1843 he became state paleontologist and was later, in 1865, made the curator and, in 1871, director of the New York State Museum in Albany.

Hall's major work was his massive 13-volume *The Palaeontology of New York* (1847–94). This important work became the standard for much of the later geological exploration of America in the 19th century. He was also active in the organization of the geological surveys of the Far and Midwest. He thus became a figure in 1888 as the first president of the Geological Society of the United States.

As a theorist, Hall is remembered for his account of mountain building published in 1859. This theory, known as the geosynclinal theory, was developed in a more comprehensive form by James DANA.

### **Hall, Sir James** (1761–1832) *British geologist*

Born in Dunglass, Scotland, Hall succeeded to his father's baronetcy and fortune in 1776. He studied at Cambridge University (1777–79) but left without taking a degree. He spent two years

traveling in Europe before returning to Edinburgh where he attended the university (1781–83). Following this he once more traveled extensively throughout Europe, meeting most of the scientists and scholars of his day.

Hall performed fundamental experiments to establish the plausibility of his friend James HUTTON's uniformitarian and plutonist theories. The neptunist Abraham WERNER had argued in criticism of James Hutton that great heat cannot have been a major factor in the formation of the Earth. He pointed out that when basalt cools it becomes glassy, not stony, and limestone, when subjected to heat, decomposes. The plutonist theories could therefore not account for the abundance of limestone and stony basalt on the Earth.

In 1798 Hall conducted his first experiment and succeeded in showing that if igneous rocks are allowed to cool slowly they form crystalline rather than glassy rocks. In 1805 he managed to refute Werner's second objection by showing that limestone when heated under pressure does not decompose on cooling but becomes marble.

Although Hall's experiments provided a good deal of support for Hutton's views, Hall himself was only a moderate supporter. In his work *On the Revolutions of the Earth's Surface* (1812) he argued strongly, using his Alpine tours as evidence, for the need to assume the existence of enormous tidal waves and floods in the past to explain the present features of the Earth's surface.

### **Hall, John L.** (1934– ) *American physicist*

John Hall was born in Denver, Colorado, and educated at the Carnegie Institute of Technology, Pittsburgh, where he received his PhD in 1961. He became Senior Scientist at the National Institute of Standards and Technology and Fellow, JILA, University of Colorado, Boulder, Colorado, retiring in 2004.

Hall has been a leading figure in the development of precision spectroscopy using laser sources; in particular, he was a pioneer in a technique known as the *optical frequency comb technique*. His research has involved very accurate experimental determinations of the speed of light, and this led to the definition of the unit of length, the meter, in terms of the distance traveled by light in a defined time period (i.e., a second). A practical difficulty with defining the meter in this way is that the frequency has to be measured very precisely. In the 1980s, Hall and his colleagues were able to attain the desired precision by stabilizing the laser frequency using feed-back mechanisms. Together with the work of Theodor HÄNSCH, this approach has led to the possibility of measuring the frequency of electromagnetic radiation with very high precision; in fact, to one part in 10<sup>18</sup>.

There are many potential technological applications. For example, it could be used practically in satellite navigation systems, such as the Global Positioning System, to improve accuracy. But there are also applications in basic physics. For example, it could be used to determine whether the spectrum of an anti-hydrogen atom (with a positron orbiting an anti-proton) is exactly analogous to the spectrum of normal hydrogen (an electron orbiting a proton). It might also be possible to use the technique to investigate the basic issue of whether fundamental constants, such as the fine-structure constant, can change with time. There is no conclusive evidence for this at present but increased precision might enable this interesting issue to be definitively resolved.

Hall shared the 2005 Nobel Prize for physics with Roy GLAUBER and Theodor Hänsch for his work on laser-based precision spectroscopy.

**Hall, Marshall** (1790–1857) *British physician*

Hall, born the son of a cotton manufacturer at Basford in England, obtained his MD from the University of Edinburgh in 1812. After a period of further study in Europe, Hall returned to England and set up in private practice, first in Nottingham in 1816 and, after 1826, in London where he became one of the most successful and prosperous physicians of his day. His son, also named Marshall, was a famous lawyer who played a leading role in some of the most celebrated cases of his time.

In various publications from 1832 onward Hall described his investigations into reflex actions. He correctly believed that reflexes are controlled by the spinal cord, but this idea only met with ridicule from the Royal Society, who refused to publish his work. His claims were greeted more favorably by European scientists and were later used by such giants as Charles SHERRINGTON to illuminate the workings of the nervous system.

Hall also worked on the function of the blood capillaries, denounced the practice of bloodletting, and introduced a form of artificial respiration for use in accidents involving drowning.

**Haller, Albrecht von** (1708–1777) *Swiss physiologist*

My friend, the artery ceases to beat.

—On death. Quoted by Alan L. Mackay in *The Harvest of a Quiet Eye* (1977)

Born at Bern in Switzerland, Haller (**hahl**-er) studied under Hermann BOERHAAVE at Leiden, gaining his MD in 1727. He was later appointed professor of anatomy, botany, and medicine (1736–53) at the newly established University of Göttingen. He then retired to Bern to spend more time on his research and writing.

Between 1757 and 1766 Haller published in

eight massive volumes his *Elementa Physiologiae Corporis Humani* (Physiological Elements of the Human Body). The work described the advances in physiology made since the time of William HARVEY, enriched with Haller's own experimental researches.

Before Haller, physiology followed the views of René DESCARTES – that bodily systems are essentially mechanical but require some vital principle to overcome their initial inertness. Haller, anticipated somewhat by Francis GLISSON, broke radically with this tradition. When stimulated, muscles contract; such “irritability,” according to Haller, is inherent in the fiber and not caused by external factors.

The implications of this work were not immediately apparent to Haller. It was left to the philosophers of the Enlightenment to hammer home the conclusion that if such an inherent force resided in muscles then there no longer remained a need for the assumption of vital principles to imbue them with activity.

Haller also made important contributions to embryology and was a noted botanist, publishing a major work on the Swiss flora. However, his attempt to construct an alternative classification scheme to that of LINNAEUS, based on fruits rather than sexual organs, received little support despite being a more logical system.

**Halley, Edmond** (1656–1742) *British astronomer and physicist*

Joyfully seize the gifts of the present hour.

—Manuscript in the Bodleian Library, Oxford

Edmond (or Edmund) Halley was the son of a wealthy London merchant. He was educated at St. Paul's School, London, and at Oxford University. He left Oxford without a degree in 1676, but having already published his first scientific paper in the *Philosophical Transactions* of the Royal Society on the theory of planetary orbits. Halley's scientific work and his life covered an enormous range. He started his active scientific career by spending two years on St. Helena mapping the southern skies. In 1679 he published *Catalogus stellarum australium* (Catalog of the Southern Stars), the first catalog of telescopically determined star positions. On his return he traveled extensively in Europe meeting such leading astronomers as Johannes HEVELIUS and Giovanni CASSINI.

Halley now began his enormous contribution to just about all branches of physics and astronomy. He prepared extensive maps showing magnetic variation, winds, and tides. In atmospheric physics he formulated the mathematical law relating height and pressure (1686), making many advances in barometric design. He carried out important studies on evaporation and the salinity of lakes (1687–1694), which allowed him to draw conclusions about the age of the Earth. He used

Newtonian mathematical techniques to improve and augment DESCARTES's work on the optics of the rainbow (1697–1721). He almost incidentally constructed mortality tables, estimated the acreage of England and the size of the atom, improved the design of the diving bell, and published numerous articles on natural history and classical studies.

These were sidelines compared to his work in astronomy and to the help he provided NEWTON. It is owing to Halley that Newton's *Principia* was published in the complete form we know it today. He pressed Newton to publish it, paid for the cost himself, saw it through the press, and even contributed some Latin verses in honor of the author. In 1695 he proposed the secular acceleration of the Moon, in 1718 he discovered the proper motion of the stars, but above all in his *Astronomiae cometicae synopsis* (1705; A Synopsis of the Astronomy of Comets) he laid the foundations of modern cometary study. His grasp of the geometry of cometary orbits allowed him to identify the comet (now known as Halley's comet) of 1531 with those of 1607 and 1682, and confidently to predict its return in 1758 – long after his death.

He held an equally varied and bewildering set of appointments. From 1696 until 1698 he was deputy controller of the mint at Chester. From 1698 to 1700 he actually commanded a Royal Navy man-of-war, the *Paramour*, making prolonged and eventful ocean voyages. In 1702 and in 1703 he made two diplomatic missions to Vienna. In 1703 he was elected to the Savilian Chair of Geometry at Oxford, and in 1720 he succeeded John FLAMSTEED as Astronomer Royal. He held this post until his death, making observations of nearly 1,500 lunar meriodional transits and the full 18-year period of the Moon.

### Halsted, William Stewart (1852–1922) *American surgeon*

Halsted, who was born in New York City, was educated at private schools, Yale, and the College of Physicians and Surgeons, New York. After graduating in 1877 he spent two years as a postgraduate student at the universities of Vienna, Leipzig, and Würzburg. Returning to America he worked as a surgeon in a number of New York hospitals before a growing addiction to cocaine forced him to leave in search of a cure in 1886. He eventually settled in Baltimore, where in 1892 he became professor of surgery at Johns Hopkins University.

The work that led to his addiction was probably his demonstration in 1885 of the localized anesthesia produced by the injection of cocaine into the appropriate nerve. The drug, introduced into medicine by Sigmund FREUD in 1884, quickly became a valuable anesthetic for minor regional surgery.

As a surgeon Halsted pioneered two common

operations. In 1889, independently of Eduardo Bassini in Padua, he devised a permanent surgical cure for inguinal hernia. Previous operative techniques involved such a high relapse rate – 40% in four years – that the operation had fallen into disrepute. He also introduced the operation of radical mastectomy, known in America as *Halsted's operation*. This involved treating breast cancer by the excision not only of the breast but also much of the underlying musculature and surrounding lymphatic tissue. He claimed a recurrence rate of 6%, as opposed to 50% produced by more conventional surgery.

One further important innovation by Halsted was his introduction, in 1889, of thin rubber gloves in operating theaters. This came about when he arranged for the Goodyear Rubber Company to make some gloves for a theater nurse, his future wife Caroline Hampton, whose hands were allergic to the antiseptic used. Over the next few decades rubber gloves gradually came to be used by all theater staff.

### Hamilton, William Donald (1936–2000) *British theoretical biologist*

Hamilton was educated at the universities of Cambridge and London. He served as a lecturer in genetics at Imperial College, London, from 1964 until 1977 when he moved to America to take up an appointment as professor of evolutionary biology at the University of Michigan. He returned to England in 1984 to serve as a Royal Society Research Professor at Oxford.

In the *Origin of Species* (1859) DARWIN raised a “special difficulty,” which he at first considered insurmountable. How could natural selection ever lead to the evolution of neuter or sterile insects? Darwin's answer was that selection may be applied to the family, as well as the individual. In a series of papers, beginning in 1964 with *The Genetical Theory of Social Behaviour*, Hamilton pursued these implications and opened the way for the emergence of sociobiology. The key concept deployed by Hamilton is that of inclusive fitness, which covers not only an individual's fitness to survive but also the effects of that individual's behavior on the fitness of his or her kin.

### Hamilton, Sir William Rowan (1805–1865) *Irish mathematician*

Here, as he walked by on the 16th October, 1843, Sir W. R. Hamilton in a flash of genius discovered the fundamental formula for quaternion algebra [ $i^2 = j^2 = k^2 = ijk = -1$ ] and cut it on a stone of this bridge.

—Inscription on Brougham Bridge, Dublin

Hamilton was a child prodigy, and not just in mathematics; he also managed to learn an extraordinary number of languages, some of them very obscure. In 1823 he entered Trinity College in his native city of Dublin, and four years later

at the age of 22 was appointed professor of astronomy and Astronomer Royal for Ireland; these posts were given to him in order that he could continue to research unhampered by teaching commitments.

In 1827 he produced his first original work, in the theory of optics, expounded in his paper *A Theory of Systems of Rays*. In 1832 he did further theoretical work on rays, and predicted conical refraction under certain conditions in biaxial crystals. This was soon confirmed experimentally. In dynamics he introduced *Hamilton's equations* – a set of equations (similar to equations of Joseph Lagrange) describing the positions and momenta of a collection of particles. The equations involve the *Hamiltonian function*, which is used extensively in quantum mechanics. *Hamilton's principle* is the principle that the integral with respect to time of the kinetic energy minus the potential energy of a system is a minimum.

One of Hamilton's most famous discoveries was that of *quaternions*. These are a generalization of complex numbers with the property that the commutative law does not hold for them (i.e.,  $A \times B$  does not equal  $B \times A$ ). Hamilton's discovery of such an algebraic system was important for the development of abstract algebra; for instance, the introduction of matrices. Hamilton spent the last 20 years of his life trying to apply quaternions to problems in applied mathematics, although the more limited theory of vector analysis of Josiah Willard GIBBS was eventually preferred. Toward the end of his life Hamilton drank increasingly, eventually dying of gout.

### **Hämmerling, Joachim August Wilhelm** (1901–1980) *German biologist*

Born in Berlin, Germany, Hämmerling (**hem-er-ling**) was educated at the universities of Berlin and Marburg. After graduating he worked at the Kaiser Wilhelm Institute of Biology from 1922 until 1948 when he moved to Wilhelmshaven to serve as director of the Max Planck Institute for Marine Biology until his retirement in 1970.

In 1953 Hämmerling carried out a series of classic experiments on the unicellular alga, *Acetabularia*. It is shaped something like a mushroom with the nucleus included in the stem part, thus making its removal a relatively simple and harmless matter. This Hämmerling did. The aim of the experiment was to see if the nucleus itself produced the proteins necessary for the growth and development of an organism, or whether it merely produced the "machinery" with which protein synthesis could take place outside the nucleus. Hämmerling's work seemed to confirm the latter alternative, for the enucleated alga continued to grow and develop, even proving capable in certain circumstances of regenerating a new cap.

On Hämmerling's death a note was found among his papers disclosing that he had suffered from severe depression for much of his life. He estimated that he must have spent a third of his working life in this way.

### **Hammond, George Simms** (1921–2005) *American chemist*

Hammond, the son of a farmer from Auburn, Maine, was educated at Bates College and at Harvard where he obtained his PhD in 1947. He immediately afterward joined the faculty at Iowa State University, serving as professor of chemistry from 1956 until 1958. He then moved to California, being appointed first to the chair of organic chemistry at the California Institute of Technology and in 1972 to the chemistry chair at Santa Cruz. In 1978 he left academic life to become associate director for corporate research with the Allied Chemical Corporation, a post he held until his retirement in 1988.

Coauthor with Donald CRAM of a widely used textbook, *Organic Chemistry* (1959), Hammond worked mainly on the mechanism of photochemical reactions, particularly the behavior of energy-rich molecules.

### **Hänsch, Theodor W.** (1941– ) *German physicist*

Hänsch was born in Heidelberg, Germany, and educated at the University of Heidelberg, where he received his PhD in 1969. He subsequently became the director of the Max-Planck-Institut für Quantenoptik, Garching, and professor of physics at the Ludwig-Maximilians-Universität, Munich, Germany, starting in 1986.

Hänsch's research work has mostly been concerned with laser-based precision spectroscopy. He made crucial contributions to the development of the *optical frequency comb technique*, so-called because it is based on using a range of evenly distributed frequencies, which look like the teeth of a comb when they are plotted on a graph. It is possible to determine an unknown frequency by comparing it with one of the frequencies of the comb. Hänsch made use of lasers in which the whole of the visible part of the electromagnetic spectrum is covered by the frequency comb. This research, some of which involved collaboration with John HALL and his colleagues, was performed in the last decades of the twentieth century and the early years of the twenty-first century. It has led to the development of instruments in which the frequency of an unknown laser can be determined by measuring the beat between the frequency and one of the teeth in the frequency comb.

In the early years of the twenty-first century frequency-comb techniques were extended to very short wavelength ultraviolet radiation. This gives rise to the possibility of even more accurate clocks.

Hänsch shared the 2005 Nobel Prize for physics with Roy GLAUBER and John Hall for his work on laser-based precision spectroscopy.

**Hansen, Gerhard Henrik Armauer**  
(1841–1912) *Norwegian bacteriologist*

Hansen (**hahn**-sen) was born the son of a merchant at Bergen in Norway and graduated in medicine from the University of Christiania (now Oslo) in 1866. He began work in the Bergen leprosy hospital in 1868, an institution under the control of Daniel Danielssen, the leading European authority on leprosy and the future father-in-law of Hansen. Leprosy was thought to be a hereditary affliction, but Hansen concluded from epidemiological studies that it was infectious. He thus took the opportunity in 1870 to travel to Bonn and Vienna to extend his knowledge of bacteriology.

Back in Bergen he observed, in 1873, the rod-shaped bacilli in specimen tissues from leprosy patients, since known variously as Hansen's bacillus or *Mycobacterium leprae*. He later proposed this to be the cause of leprosy but his claim was not appreciated for many years. Hansen however never managed to fulfil the postulates of Robert KOCH and transmit the disease via the bacilli to animals or men, a difficulty also met with by all later workers. He was forced to resign from the leprosy hospital in 1880 for injudiciously injecting live leprosy bacilli into a patient without first obtaining her permission; he did, however, continue to advise the Norwegian government on their policy to leprosy and also carried on with his own research.

He succeeded, by a policy of limited isolation, in reducing the Norwegian incidence of leprosy from 2,833 cases in 1850 to 140 in 1923. Hansen was also an ardent proponent of Darwinism and publicized DARWIN'S work in Norway.

**Hantzsch, Arthur Rudolf** (1857–1935)  
*German chemist*

Hantzsch (**hantsh**) studied at the polytechnic in his native city of Dresden and at the University of Würzburg, where he took his doctorate in 1880. He taught in Leipzig (1880), Zurich (1885), Würzburg (1893), and finally, in 1903, Leipzig. He retired to Dresden in 1927.

Hantzsch's first success came in 1882 when he announced his method for synthesizing substituted pyridines from aldehyde ammonia compounds and keto esters. In 1887 he synthesized thiazole and later prepared imidazole, oxazole, and selenazole. In 1890 he published with his pupil Alfred WERNER an account of the stereochemistry of the organic nitrogen compounds, oximes. Hantzsch later tried to extend this work to the diazo compounds, which were being investigated by Eugen BAMBERGER.

Hantzsch was a prolific writer publishing over 450 papers. He wrote extensively on the theory of acids and bases, the absorption of light by different compounds, and on nitrophenols.

**Harcourt, Sir William Venables Vernon**  
(1789–1871) *British chemist*

Harcourt, whose father was the archbishop of York, was born at Sudbury in England. Before entering Oxford University in 1807, Harcourt received a private education and spent five years in the Royal Navy. On graduation (1811) he moved to Yorkshire as a clergyman and in 1861, on the death of his elder brother, he succeeded to the family estates and retired to Nuneham in Oxfordshire.

Although he set up his own chemical laboratory he was basically an amateur scientist whose importance lies rather with those he stimulated and influenced than in the work he produced himself. He was a friend of John KIDD, William WOLLASTON, and Humphry DAVY, among other early-19th-century chemists. He played a crucial role in the establishment of the British Association for the Advancement of Science in 1830, serving as its first secretary, being responsible for drawing up its laws and constitution, and becoming its president in 1839.

**Harden, Sir Arthur** (1865–1940) *British biochemist*

Harden was born in Manchester and educated at Owens College there (where he subsequently taught) and at the University of Erlangen, Germany. He was professor of biochemistry at the Jenner (later Lister) Institute of Preventive Medicine, where he began research into alcoholic fermentation, continuing the work of Eduard BUCHNER who had discovered that such reactions can take place in the absence of living cells.

Harden demonstrated that the activity of yeast enzymes was lost following dialysis (the separation of large from small molecules by diffusion of the smaller molecules through a semi-permeable membrane). He went on to show that the small molecules are necessary for the successful action of the yeast enzyme and that, whereas the activity of the large molecules was lost on boiling, the activity of the small molecules remained after boiling. This suggested that the large molecules were proteins but the small molecules were probably nonprotein. This was the first evidence for the existence of *coenzymes* – nonprotein molecules that are essential for the activity of enzymes. Harden also discovered that yeast enzymes are not broken down and lost with time, but that the gradual loss of activity with time can be reversed by the addition of phosphates. He found that sugar

phosphates are formed during fermentation as intermediates – phosphates are now known to play a vital part in biochemical reactions. Knighted in 1936, Harden shared the 1929 Nobel Prize for chemistry with Hans von EULER-CHELPIN for his work on alcoholic fermentation and enzymes.

**Hardy, Godfrey Harold** (1877–1947)  
*British mathematician*

There is no scorn more profound, or on the whole more justifiable, than that of the men who make for the men who explain.  
Exposition, criticism, appreciation, is work for second-rate minds.

—*A Mathematician's Apology* (1940)

A science is said to be useful if its development tends to accentuate the existing inequalities in the distribution of wealth, or more directly promotes the destruction of human life.

—As above

Born at Cranleigh in southern England, Hardy had his mathematical education at Cambridge University and remained there as a fellow of Trinity College until 1919, when he became Savilian Professor of Geometry at Oxford. From 1931 to 1942 he was back in Cambridge as Sadleirian Professor of Pure Mathematics.

His central field of interest was in analysis and such related areas as convergence and number theory. *Hardy classes* of complex functions are named for him. For 35 years, starting in 1911, Hardy collaborated with J. E. LITTLEWOOD and together they wrote nearly a hundred papers. The principal areas they covered were Diophantine approximations, the theory of numbers, inequalities, series and definite integrals, and the Riemann zeta-function.

Although primarily a pure mathematician Hardy made one lasting contribution to applied mathematics; the *Hardy–Weinberg law* was discovered independently by Hardy and the physician Wilhelm Weinberg in 1908 and proved to be fundamental to the science of population genetics. It gives a mathematical description of the genetic equilibrium in a large random-mating population and explains the surprising fact that, unless there are outside changing forces, the proportion of dominant to recessive genes tends *not* to vary from generation to generation. The law offered strong confirmation for the Darwinian theory of natural selection.

Hardy was one of the outstanding British mathematicians of his day, an excellent teacher, and one of the first to introduce modern work on the rigorous presentation of analysis into Britain. His *Course of Pure Mathematics* (1908) was influential on the teaching of mathematics in British universities. One of his achievements was his discovery of the young Indian mathematician Srinivasa RAMANUJAN. Partly through Hardy's efforts Trinity College made funds available for Ramanujan to go to Cambridge to

pursue his mathematical researches under Hardy.

Hardy was a passionate devotee of cricket and an equally passionate enemy of the Christian religion. During World War I he was a staunch supporter of Bertrand RUSSELL when Trinity set about depriving Russell of his position on account of his pacifist activities. Hardy wrote a lively autobiographical sketch, *A Mathematician's Apology* (1940).

**Hardy, Sir William Bate** (1864–1934)  
*British biologist and chemist*

You know, this applied science is just as interesting as pure science, and what's more it's a damn sight more difficult.

—Quoted by Sir Henry Tizard in the Haldane Memorial Lecture, 1955

Born at Erdington in England, Hardy was educated at Cambridge University and remained there for the whole of his life, being appointed a lecturer in physiology in 1913 and superintendent of the Low Temperature Research Station in 1922. In addition Hardy served on a number of advisory bodies of which the most significant were his chairmanship of the Advisory Committee on Fisheries Development (1919–31) and his directorship of the Food Investigation Board (1917–34).

He began his research career as a histologist, publishing a number of papers in the 1890s on the morphology and behavior of the leukocytes (white blood cells). He began, however, to have considerable doubts about the value of staining and fixing living tissue suspecting that certain structures seen in cells after fixation may simply be artefacts caused by the fixing reagents themselves. He emphasized the point by the production of reticulated and fibrillar structures in his laboratory by fixing and staining albumin.

This led Hardy to work on colloid chemistry and the properties of proteins in solution. He later studied molecular films and lubrication. He reported on this work in his Croonian lecture *On Globulins* (1905) and his Bakerian lecture of 1925, *Boundary Lubrication*.

**Hare, Robert** (1781–1858) *American chemist*

Born in Philadelphia, Pennsylvania, Hare was the son of the owner of a brewery. He is best known for his invention of the oxyhydrogen blowpipe, which he demonstrated to Joseph PRIESTLEY in 1801. This became of great value in the welding process for it is the ancestor of the later welding torches.

**Hargreaves, James** (d. 1778) *British inventor*

Hargreaves was a poor and uneducated spinner and weaver when, in 1764, he had the idea of a

hand-powered spinning machine that could spin many threads at once. The story is that he saw his daughter, Jenny, knock over a spinning wheel and noticed that it kept turning in an upright position. He built a machine, naming this the "spinning jenny," and started to sell his invention. However, hand weavers who were afraid of unemployment broke into his workshop and destroyed his machines. As a result of this he moved to Nottingham and together with a partner, Thomas James, set up a mill in 1768 in which he used the jennies to spin yarn for making hosiery. His machine was patented in 1770. Thereafter he was moderately successful and worked at his mill until his death.

**Harriot, Thomas (1560–1621)** *English mathematician, astronomer, and physicist*

As to Harriot, he was so learned, saith Dr. Pell, that had he published all he knew in algebra, he would have left little of the chief mysteries of that art unhandled.

—John Collins quoted by J. W. Shirley in *Thomas Harriot: a Biography*

Harriot (or Harriot) is best known as a pioneer figure in the British school of algebra, although his interests and activities were very wide ranging. Born in Oxford, England, he was an associate of Sir Walter Raleigh, whom he accompanied on a voyage to Virginia (1585–86) in the capacity of navigator and cartographer. He later wrote a book about this journey – *A Briefe and True Report of the New Found Land of Virginia* (1588). Among his many innovations in algebra Harriot introduced a number of greatly simplified notations. His central mathematical achievements were in the theory of equations, where he discovered important relationships between the coefficients of equations and their roots. This work was published in his *Artis analyticae praxis ad aequationes algebraicas resoluendas* (1631; *The Analytical Arts Applied to Solving Algebraic Equations*).

Outside mathematics Harriot's achievements as a practical astronomer were noteworthy. He designed and constructed telescopes and made detailed studies of comets and sunspots. Independently of GALILEO he discovered the moons of Jupiter. Harriot also discovered the law governing the refraction of light and was the first to interpret refraction in terms of the scattering of light by atoms. He was granted a pension by the earl of Northumberland and was briefly imprisoned along with the earl during the Gunpowder Plot of 1605. Harriot conducted numerous experiments in a variety of fields including optics, ballistics, and meteorology. However, he published few of his discoveries and it was only after his death that their extent was realized from his voluminous notes and papers.

**Harkins, William Draper (1873–1951)** *American physical chemist*

Harkins, whose father was a pioneer in the Pennsylvania oil fields, was born in Titusville, Pennsylvania, and educated at Stanford University where he obtained his PhD in 1907. After studying abroad under Fritz HABER at Karlsruhe, he taught briefly at the University of Montana before moving to Chicago in 1912, where he spent the rest of his career and was made professor of physical chemistry in 1917.

Harkins was one of the first Americans to establish an international reputation in the field of nuclear studies, although many of his results were independently established by his European counterparts. Thus in 1915 he proposed the "whole number rule" at the same time as Francis ASTON was publishing his theory of isotopes. In 1920 he predicted the existence of the neutron and an isotope of hydrogen, deuterium, which were also predicted by Ernest RUTHERFORD in the same year.

In 1915 he demonstrated that the fusion of four atoms of hydrogen to form helium involved a mass excess that was available for conversion to energy in accordance with the famous formula  $E = mc^2$  of Albert EINSTEIN. He calculated that four grams of hydrogen could form four grams of helium with a release of energy of  $10^{12}$  calories. Such facts of nuclear fusion were taken up by Arthur EDDINGTON in 1920 and proposed as the source of energy in stars.

Harkins also worked on problems of surface tension and, in 1952, published a standard work on the topic, *The Physical Chemistry of Surface Tension*.

**Harris, Geoffrey Wingfield (1913–1971)** *British endocrinologist*

Harris, the son of a physicist, was born in London and educated at Cambridge University and St. Mary's Hospital, London. After qualifying in 1939, he worked at Cambridge as an anatomy lecturer until 1952 when he moved to the Maudsley Hospital, London, to direct the Laboratory of Experimental Neuroendocrinology. In 1962 Harris was appointed Dr. Lee's Professor of Anatomy at Oxford where he remained until his sudden death in 1971.

In the period 1950–52 Harris published several papers that provided evidence for the important theory that the release of pituitary hormones is controlled by the hypothalamus. Such a mechanism had long been suspected but was only really made plausible when Harris showed that while nervous connection between the two glands could be severed without major effect, cutting the connecting blood supply severely restricted the production of pituitary hormones. (Solly ZUCKERMAN announced conflicting results but Harris was able to show that in the experimental animal used, the ferret, the severed vessels tended to regenerate and restore the humoral connection.)

This led to a massive and prolonged search

for the hypothalamic hormones or "releasing factors." As Harris was unwilling to devote himself exclusively to such a demanding and basically tedious exercise, the first hypothalamic hormones were isolated, purified, and synthesized by Roger GUILLEMIN and Andrew SCHALLY in the late 1960s.

**Harrison, John** (1693–1776) *English horologist*

John Harrison was born at Foulby near Pontefract in Yorkshire, the son of a carpenter, a trade he originally took up himself.

In the early 18th century exploration and colonial expansion was an important concern of European governments. A number of naval disasters caused by navigation errors prompted the British Government to set up a Board of Longitude in 1714. The board offered a prize of £20,000 to anyone who discovered a practical method of measuring longitude accurately. The key to determining the position of a ship out of sight of land was accurate timekeeping. The board's conditions effectively meant the construction of a chronometer that kept time to an accuracy of 3 seconds per day.

Harrison became interested in the problem in 1728 and in 1735 completed his first instrument, H1. He improved his design over a period of many years and in 1762 his perfected chronometer, H4, was found to be in error by only 5 seconds (corresponding to 1.25' of longitude) after a voyage to Jamaica.

Harrison's chronometers all met the conditions set up by the Board of Longitude but he had problems obtaining the prize money. In 1763 he was given £5000 and it was not until 1773, after the intervention of King George III, that he received the full amount less expenses. His chronometer was used in 1776 by James COOK on his voyage to Australia and New Zealand.

**Harrison, Ross Granville** (1870–1959) *American biologist and embryologist*

The reference of developmental processes to the cell was the most important step ever taken in embryology.

—*Embryology and its Relations* (1937)

Born in Germantown, Philadelphia, Harrison graduated from Johns Hopkins University in 1889 and continued studying experimental embryology for the next ten years at Bryn Mawr College, Johns Hopkins University, and in Germany at the University of Bonn. He had an excellent ear for languages and spoke German fluently. In 1899 he gained his MD degree from the University of Bonn and returned to America to become associate professor of anatomy at Johns Hopkins. From 1907 to 1938 he worked at Yale, first as professor of anatomy then from 1927 as professor of biology.

Harrison's work in experimental embryology formed a bridge between the morphological studies of the 19th century and the new molecular biology of the 20th century based on cell function and structure. In his most influential work (1910) he demonstrated the outgrowth of nerve fibers from ganglion cells in embryonic tissues by devising techniques so that the event could actually be observed. His early attempts used frog-embryo cells hanging in a nutrient medium from the underside of a special microscope slide. The method was gradually refined to give the important new technique of tissue culture. Although Harrison himself did not pursue tissue culture to any great extent the method has proved immensely useful in testing new drugs and in the production of vaccines.

Harrison founded the influential *Journal of Experimental Zoology* in 1906.

**Hartline, Haldan Keffer** (1903–1983) *American physiologist*

Hartline, who was born in Bloomsburg, Pennsylvania, was educated at Lafayette College, Easton, Pennsylvania, and Johns Hopkins University, Baltimore, where he was professor of biophysics from 1949 to 1953. In 1953 he became professor of physiology at the Rockefeller University, New York City. His work was specially concerned with sense receptors and in particular with the neurophysiology of vision. Using minute electrodes to separate and study individual eye fibers of arthropod and vertebrate eyes, notably horseshoe crabs and frogs, he was able to elucidate the fine working of individual cells in the retina and to show how the eye distinguishes between different shapes. His work in this field led to his sharing the Nobel Prize for physiology or medicine with George WALD and Ragnar GRANIT (1967).

**Hartmann, Johannes Franz** (1865–1936) *German astronomer*

Hartmann was born the son of a merchant in Erfurt, in Germany. He was educated at the universities of Tübingen, Berlin, and Leipzig where he obtained his PhD in 1891. He worked first at the Leipzig and Potsdam observatories before being appointed in 1909 as professor of astronomy and director of the Göttingen University Observatory. He remained there until 1921 when he became director of the La Plata Observatory in Argentina, only returning to Göttingen in 1935 a few months before his death.

Hartmann was responsible for the important observation in 1904 that provided the first clear evidence for the existence of interstellar gas. He noted that in the spectrum of the star Delta Orion, a binary system, the calcium lines failed to exhibit any periodic DOPPLER effect arising

from the orbital motion of the stars: when a star moves in its orbit toward the Earth the wavelength of lines in its spectrum are shifted toward the blue, while as it moves away from the Earth its spectral lines are shifted toward the red. That there were what Hartmann described as “stationary lines” of calcium in the spectrum could only mean that the calcium was not part of the atmosphere of Delta Orion and therefore was not participating in the orbital motion. It must occur somewhere between binary system and observer. The existence of interstellar matter and its significance in the estimation of stellar distances was finally demonstrated by Robert TRUMPLER in 1930.

**Hartwell, Leland H.** (1939– ) *American cell biologist*

Born in Los Angeles, Hartwell was awarded a BS in 1961 by the California Institute of Technology, and a PhD in 1964 by the Massachusetts Institute of Technology. After postdoctoral studies at the Salk Institute (1964–65), he joined the University of Washington, Seattle, in 1968, becoming professor of genetics in 1973. In 1996 he also joined the Fred Hutchinson Cancer Research Center, Seattle, and in 1997 was appointed its president and director.

Since the late 1960s, Hartwell has been one of the foremost investigators of the cell cycle – the sequence of events that mark the growth of a living cell, and prepare it for division into two daughter cells. In particular, he has used baker’s yeast, *Saccharomyces cerevisiae*, as a model to determine the genes responsible for controlling the cell cycle, the so-called cell division cycle (CDC) genes.

During 1970–71 Hartwell isolated yeast mutants with defects in various aspects of the cell cycle, and subsequently identified over 100 CDC genes. Outstanding among these was a particular gene designated *CDC28* by Hartwell. This was found to control the so-called START point in the cell cycle, after which the yeast cell is committed to progress through the growth phase (G1) and embark on the “synthesis” phase (S). The S phase is when the chromosomes are duplicated in readiness for division of the cell’s nucleus prior to cell division.

From his later yeast studies, Hartwell introduced the concept of checkpoints in the cell cycle. These allow a pause in the cell cycle to enable any damage to the cell’s genetic material (DNA) to be repaired. This ensures that errors in the DNA are not transmitted to the daughter cells. Checkpoints also are a means of verifying that all necessary steps have been completed before the cell enters the next phase of the cycle.

Hartwell pointed out the importance of this concept in understanding the behavior of cancer cells. Cancer cells bypass these checkpoints, so transmitting mutations to their progeny

cells, and hence the capability to evolve into malignant cells.

For his discoveries of key regulators of the cell cycle, Hartwell received the 2001 Nobel Prize for physiology or medicine, awarded jointly with R. Timothy HUNT and Paul M. NURSE.

**Harvey, William** (1578–1657) *English physician*

Everything is from an egg.

—*Exercitationes de generatione animalium*  
(1651; Exercises in Animal Reproduction)

Harvey was born in the English coastal town of Folkestone and educated at King’s School, Canterbury, and Cambridge University. In 1599 he made the then customary visit to Italy where he studied medicine at the University of Padua under the anatomist FABRICIUS ab Aquapendente, obtaining his MD in 1602. He was appointed physician at St. Bartholomew’s Hospital, London, in 1609 and in 1618 began working at the court as physician extraordinary to James I. He also served Charles I, accompanying him on his various travels and campaigns throughout the English Civil War. He was rewarded briefly with the office of warden of Merton College, Oxford, in 1645 but with the surrender of Oxford to the Puritans in 1646 Harvey, suffering much from gout, took the opportunity to retire into private life.

In 1628 Harvey published *De motu cordis et sanguinis in animalibus* (On the Motion of the Heart and Blood in Animals). This announced the single most important discovery of the modern period in anatomy and physiology, namely, the circulation of the blood. The orthodox view, going back to GALEN, saw blood originating in the liver and from there being distributed throughout the body. There was no circulation for Galen and he believed that the arteries and veins carried different substances. Harvey made a simple calculation that revealed the prodigious amounts of blood that would have to be produced if there was no circulation. Harvey also could not understand why the valves in the veins were placed so that they allowed free movement of blood to the heart but not away from it. It did however make sense if blood was pumped to the limbs through the arteries and returned through the veins.

Harvey then set about demonstrating his supposition. He examined the action of the heart of such cold-blooded creatures as frogs, snakes, and fishes as their slower heart rate allows clearer observations to be made. This enabled him to establish that blood passes from the right to the left side of the heart not through the wall, or septum, which was solid, but via the lungs. It was also clear that blood is pumped from the heart into the arteries, for he observed that they begin to fill at the moment when the heart contracts. Between con-

tractions, the heart fills with blood from the veins. The heart is thus, Harvey declared, nothing more than a pump. To show that blood passes from the arteries to the veins rather than vice versa, Harvey resorted to a number of simple and compelling experiments with ligatures.

Harvey's 72-page masterpiece received considerable but by no means universal support. There was, as he was well aware, one weak link in his argument, namely the precise connection, or anastomoses, between the arterial and venous system. He thus had to accept, without observation, that the hair-thin capillaries of the two systems did in fact link up. Harvey only had a magnifying glass at his disposal and it was left to Marcello MALPIGHI to observe the implied anastomoses through his microscope in 1661. The importance of Harvey's discovery lay in providing an alternative to the Galenic theory, thus encouraging other scientists to question the authority of ancient texts.

Harvey also worked in embryology. He argued that all life arose from the egg, thus denying spontaneous generation. To describe the process of generation he thought he had observed in chickens and deer, Harvey coined the term *epigenesis*. By this he meant the female egg possessed an independent existence and was capable of completing its development through the activity of its own vital principle. It did not join with the semen, nor was it fertilized by it. Harvey believed the semen acted by initiating the self-contained development of the egg through touch alone. However with the use of the microscope and the earlier identification of anatomical features within the egg by Malpighi in 1673 the alternative preformationist view began to gain ground.

Harvey became a figure of much influence within the College of Physicians. He served as treasurer in 1628 and although offered the presidency in 1654 felt compelled to decline it on grounds of health.

### **Hassell, Odd** (1897–1981) *Norwegian chemist*

Hassell (**has**-el), who was born in the Norwegian capital of Christiania (now Oslo), was educated at the university there and in Berlin where he obtained his doctorate in 1924. He immediately returned to the University of Oslo and served there as professor of chemistry from 1934 until his retirement in 1964.

Early in his career, following studies on how organic dyes photosensitize silver halides, Hassell discovered adsorption indicators. In 1943 he published an important conformational analysis of cyclohexane but, as he refused to use the language of the German conquerors and published it in Norwegian, its influence was considerably reduced. The molecule exists in two main forms, the so-called boat and chair con-

formations; Hassell had little difficulty in showing the chair form to be the most stable. It was for his work on conformation that he shared the 1969 Nobel Prize for chemistry with Derek BARTON.

### **Hatchett, Charles** (1765–1847) *British chemist*

Hatchett was the son of a London coachbuilder. He is noted as the discoverer of the element niobium, which he found in 1801 in a mineral from Connecticut. The following year, Anders EKEBERG found the element tantalum in Sweden and, for some time, it was unclear whether the elements were the same. It was not until 1865 that Jean MARIIGNAC showed that the two were different elements. Hatchett's original name of columbium was replaced by niobium (for Niobe, daughter of Tantalus in mythology). Hatchett later served (1823) with Humphry DAVY on a committee to investigate the corrosion of copper plates on ships. On his father's death he retired from research to take over the family coachbuilding business.

### **Hauksbee, Francis** (c. 1670–c. 1713) *English physicist*

A beautiful Phaenomenon, viz. a fine purple light, and vivid to that degree, that all the included Apparatus was easily and distinctly discernible by the help of it.

—On producing light by friction in a vacuum

Hauksbee, a student of Robert BOYLE, conducted numerous experiments on a wide range of topics. They are fully described in his *Physico-Mechanical Experiments* (1709). He worked as demonstrator at the Royal Society and became a fellow in 1705. Under the supervision of NEWTON he conducted a series of experiments on capillary action (the movement of water through pores, caused by surface tension) using tubes and glass plates. He also made improvements to the air pump and made a thorough investigation of static electricity, showing that friction could produce luminous effects in a vacuum.

### **Hauptman, Herb Aaron** (1917– ) *American mathematical physicist*

Born in New York, Hauptman graduated from Columbia in 1939. After two years spent with the U.S. Census Bureau he was drafted into the U.S. Air Force where he spent much of the war as a radar instructor. In 1947 he joined the staff of the Naval Research Laboratory, Washington, DC. At the same time he pursued his doctorate (awarded 1952) at the University of Maryland. In 1970 Hauptman moved to the Medical Foundation, Buffalo, as its research director, becoming president in 1988.

In collaboration with his Washington colleague Jerome KARLE, Hauptman has made a

significant advance in the use of x-ray crystallography. The classic x-ray photograph of a crystal has a diffraction pattern of dots and it was the task of the crystallographer to find a molecular structure that would give this pattern. A likely structure would be assumed and tested against the x-ray data.

Further progress was made when crystallographers worked out how to apply FOURIER analysis to the scattered x-rays. The difficulty was that, although the amplitudes of the waves could be deduced, their phase could not be determined in this way. In 1953, Hauptman and Karle showed mathematically how the phase problem could be overcome. Their method, known as the *direct method*, was mainly statistical and allowed structures to be determined much more quickly. Whereas previously a 15-atom molecule might require many months' work, the structure of larger molecules, following the work of Hauptman and Karle, could be worked out in a matter of days.

For his work in this area Hauptman shared the 1985 Nobel Prize for chemistry with Karle.

### Haüy, René Just (1743–1822) *French mineralogist*

Haüy (a-oo-ee), whose father was a poor clothworker, was born in St. Just in France. His interest in church music attracted the attention of the prior of the abbey, who soon recognized Haüy's intelligence and arranged for him to receive a sound education. While in Paris, his interest in mineralogy was awakened by the lectures of Louis Daubenton. He became professor of mineralogy at the Natural History Museum in Paris in 1802. His *Traité de minéralogie* (Treatise on Mineralogy) was published in five volumes in 1801 and *Traité de cristallographie* (Treatise on Crystallography) in three volumes in 1822.

Haüy is regarded as the founder of the science of crystallography through his discovery of the geometrical law of crystallization. In 1781 he accidentally dropped some calcite crystals onto the floor, one of which broke, and found, to his surprise, that the broken pieces were rhombohedral in form. Deliberately breaking other and diverse forms of calcite, he found that it always revealed the same form whatever its source. He concluded that all the molecules of calcite have the same form and it is only how they are joined together that produces different gross structures. Following on from this he suggested that other minerals should show different basic forms. He thought that there were, in fact, six different primitive forms from which all crystals could be derived by being linked in different ways. Using his theory he was able to predict in many cases the correct angles of the crystal face. The work aroused much controversy and was attacked by Eilhard MITSCHERLICH in 1819 when he discovered isomorphism

in which two substances of different composition can have the same crystalline form. Haüy rejected Mitscherlich's arguments.

Haüy also conducted work in pyroelectricity. The mineral *haiüyne* was named for him.

### Hawking, Stephen William (1942– ) *British theoretical physicist and cosmologist*

Even as he [Hawking] sits helpless in his wheelchair, his mind seems to soar even more brilliantly across the vastness of space and time to unlock the secrets of the universe.  
—*Time* (1988)

Why does the universe go to all the bother of existing? Is the unified theory so compelling that it brings about its own existence? Or does it need a creator, and, if so, does he have any other effect on the universe? And who created him?

—*A Brief History of Time* (1988)

Hawking, who was born in Oxford, England, graduated from the university there and obtained his PhD from Cambridge University. After holding various Cambridge posts, he became professor of gravitational physics in 1977 and, in 1979, was appointed Lucasian Professor of Mathematics.

Hawking has worked mainly in the field of cosmology, in particular the theory of black holes. In 1965 Roger PENROSE had shown that a star collapsing to form a black hole would ultimately form a singularity – a point at which the density of matter is infinite and at which there is an infinite curvature of space–time. Hawking realized that by reversing the time in Penrose's theory he could show that the big bang originating the Universe must also have come from a singularity. Similarly, if the Universe were to stop expanding and start contracting it would eventually end at a singularity – the so-called “big-crunch.” In a classic paper published in 1970 Penrose and Hawking proved that these results hold in a very complete way. The results of Hawking's work using general relativity were summarized in a book with George Ellis, *The Large Scale Structure of Spacetime* (1973).

In fact, at a singularity, with infinite curvature of space–time, the general theory of relativity breaks down and consequently it cannot be applied to the origin of the Universe. This led Hawking to the application of quantum theory to the gravitational interaction. Of the four fundamental interactions, the strong, weak, electromagnetic, and gravitational interactions, the gravitational interaction is the only one not described by quantum theory. Quantum theory has been successfully applied to the other interactions. Gravitational interactions between masses over long distances are important in cosmology and can be described by the non-quantum theory of relativity. However, at the vanishingly small distances necessarily occurring just after the big bang (or just before a

total collapse), quantum effects would be important. Hawking and others turned their attention to “quantum gravity.”

So far, the general application of quantum mechanics to gravitational interactions has had limited success. One notable discovery has been Hawking’s theory showing that black holes are not in fact “black” – they effectively emit energy as if they were a hot body.

The basis of the mechanism behind “hot” black holes is the HEISENBERG uncertainty principle. According to this, free space cannot be empty because a point in space would then have zero energy at a fixed time and this would contradict the principle. In space, pairs of virtual particles and antiparticles are constantly forming and annihilating. One member of the pair has a positive energy and the other has a negative energy. Under normal conditions a virtual particle does not exist in isolation and is not detected. However, Hawking has shown that in the vicinity of a black hole it is possible for the particles to separate. The negative-energy particle can fall into a black hole and its partner may escape to infinity, appearing as emitted energy.

The theory resolves a problem concerning the thermodynamics of black holes. If matter of high entropy falls into a black hole then there has been a net entropy loss unless the black hole itself gains entropy. One interpretation of the entropy of a black hole is its area, which increases whenever matter falls into the hole. However, if a black hole has an entropy it must also have a temperature. Hawking showed that the emission of energy from a black hole was distributed as if it were radiated from a black body at the appropriate temperature.

A black hole produced by a collapsing star would have a temperature within a few millionths of a degree above absolute zero. Hawking has speculated on the existence of “mini black holes” weighing a billion tons but having a size no bigger than a proton (about  $10^{-15}$  meter). These could be produced during the early stages of the big bang and are consequently known as “primordial black holes.” Because of their small size they would radiate gigawatts of energy in the x-ray and gamma-ray regions of the electromagnetic spectrum. So far there is no experimental evidence for their existence.

Hawking has innovatively applied quantum gravity to the question of the origin of the Universe, making various modifications to the inflationary theory first proposed by Alan GUTH. He has also put forward an original proposal for the origin and evolution of the Universe applying the “sum over histories” formalism of quantum mechanics of Richard Feynmann. Hawking’s model of the Universe is conceptually difficult. It involves a Euclidean space–time in which time is an imaginary quantity (in the mathematical sense). There are no singularities

at which the laws of physics break down; space–time is finite but closed, having no boundaries and no beginning or end.

Hawking is generally regarded as one of the foremost theoretical physicists of the last hundred years despite a severe physical handicap. In the early 1960s he developed motor neuron disease and for many years he has been confined to a wheelchair. Most of his communication is through a computer speech synthesizer. Of this, Hawking has said that he “was fortunate in that I chose theoretical physics, because that is all in the mind.” In 1988 Hawking published a popular account of cosmology, *A Brief History of Time*. The book and its author captured the public imagination and made Hawking an international celebrity, even to noncosmologists. In it he looks forward to a time when a complete theory could be found understandable to everyone. “If we find the answer to that, it would be the ultimate triumph of human reason – for then we would know the mind of God.” Other popular books by Hawking include *Black Holes and Baby Universes and Other Essays* (1993), *The Universe in a Nutshell* (2001), and *A Briefer History of Time* (2005, with Leonard Mlodino).

### Haworth, Sir (Walter) Norman (1883–1950) *British chemist*

Haworth, who was born in Chorley, in northwest England, began work in a linoleum factory managed by his father. This required some knowledge of dyes, which led Haworth to chemistry. Despite his family’s objections he persisted in private study until he was sufficiently qualified to gain admission to Manchester University in 1903, where he studied under and later worked with William PERKIN, Jr. on terpenes. Haworth did his postgraduate studies at Göttingen where, in 1910, he gained his PhD. In 1912 he joined the staff of St. Andrews University and worked with Thomas Purdie and James IRVINE on carbohydrates. He remained there until 1920 when, after five years at the University of Durham, he was appointed Mason Professor of Chemistry at Birmingham, where he remained until his retirement in 1948.

Emil FISCHER had dominated late 19th-century organic chemistry and, beginning in 1887, had synthesized a number of sugars, taking them to be open-chain structures, most of which were built on a framework of six carbon atoms. Haworth however succeeded in showing that the carbon atoms in sugars are linked by oxygen into rings: either there are five carbon atoms and one oxygen atom, giving a pyranose ring, or there are four carbon atoms and one oxygen atom, giving a furannose ring. When the appropriate oxygen and hydrogen atoms are added to these rings the result is a sugar. He went on to represent the carbohydrate ring

by what he called a “perspective formula,” today known as a *Haworth formula*.

With Edmund HIRST he went on to establish the point of closure of the ring using the technique of Irvine and Purdie of converting the sugar into its methyl ester. He later investigated the chain structure of various polysaccharides. In 1929 he published his views in *The Constitution of the Sugars*.

In 1933 Haworth and his colleagues achieved a further triumph. Albert Szent-Györgyi had earlier isolated a substance from the adrenal cortex and from orange juice which he named hexuronic acid. It was in fact vitamin C and Haworth, again in collaboration with Hirst, succeeded in synthesizing it. He called it ascorbic acid.

For this work, the first synthesis of a vitamin, Haworth shared the 1937 Nobel Prize for chemistry with Paul KARRER.

### **Hays, James Douglas** (1933– ) *American geologist*

Hays was born in Johnstown, New York, and educated at Harvard, Ohio State, and Columbia universities, obtaining his PhD from the last in 1964. He joined Columbia's Lamont–Doherty Geological Observatory, New York, in 1967 as director of the deep-sea sediments core laboratory and in 1975 was appointed professor of geology.

In 1971 Hays reported that from his study of 28 deep-sea piston cores from high and low latitudes it was shown that during the last 2.5 million years eight species of radiolaria had become extinct. Prior to extinction these species were widely distributed and their sudden extinction, in six out of eight cases, was in close proximity to a magnetic reversal, a change in the Earth's magnetic polarity. Hays concluded that the magnetic reversals influenced the radiolarians' extinction.

### **Heaviside, Oliver** (1850–1925) *British electronic engineer and physicist*

Should I refuse a good dinner simply because I do not understand the process of digestion?

—On being criticized for using formal mathematical manipulations, without understanding how they worked

Heaviside, a Londoner, was a nephew of Charles WHEATSTONE. Being very deaf, he was hampered in school, and was largely self-taught. He was interested in the transmission of electrical signals and used MAXWELL's equations to develop a practical theory of cable telegraphy, introducing the concepts of self-inductance, impedance, and conductance. However, his early results were not recognized, possibly because the papers were written using his own notation. Heaviside was one of the inventors of vector analysis. He used vector

analysis extensively in his writings on electromagnetic theory.

After radio waves had been transmitted across the Atlantic in 1901, he suggested (1902) the existence of a charged atmospheric layer that reflected the waves. The same year Arthur KENNELLY independently suggested the same explanation. The *Heaviside layer* (sometimes called the Kennelly–Heaviside layer) was detected experimentally in 1924 by Edward APPLETON.

Later in life his fame grew and he was awarded an honorary doctorate at Göttingen and was elected a fellow of the Royal Society in 1891.

### **Hebraea, Maria** (Mary the Jewess; Miriam the Prophetess) (?1st century AD) *Egyptian alchemist*

Little is known about the life of Mary Hebraea, but her alchemical theories and practical inventions have featured in numerous texts, albeit often in fragmented or corrupted form, and been quoted by other famous alchemists. She was a central figure in a flourishing alchemical tradition in Alexandria, then a key city of the Roman Empire. In keeping with the secretive nature of her profession, she was known by various names, including Miriam the Prophetess, Sister of Moses, and was heavily influenced by the religious beliefs of gnosticism. The introduction of several key items of alchemical equipment is attributed to her, including a water bath, or *balneum mariae* (“Maria's bath”), which she used to maintain a constant temperature (hence the modern French name, *bain-marie*). Maria also described a three-armed still, known as a *tribikos*. To investigate the effects of arsenic, mercury, and sulfur vapors on metals, she devised an apparatus called *kerotakis*, which comprised essentially a heating chamber, or retort, with a hemispherical cover. Sulfur, for example, was heated in the chamber over a fire, and the vapor allowed to condense on the underside of the cover and flow onto metal held in a tray beneath the cover. This formed a sulfide deposit known as “Mary's black,” and was believed to be a first step in the transmutation of base metal into gold. Maria is credited with establishing certain principles of laboratory technique that remained little changed until the modern scientific era.

### **Hecataeus of Miletus** (c. 550 BC–c. 476 BC) *Greek geographer*

Hecataeus (hek-a-tee-us), who was born in Miletus (now in Turkey), flourished during the time of the Persian invasion of Ionia, and was one of the ambassadors sent to Persia. One of the earliest geographical works, the *Periegesis* (Tour Round the World), is attributed to him but only fragments of this now exist. It report-

edly contained a map showing the world as Hecataeus believed it to be – a flat disk surrounded by ocean. The work was used by the ancients, notably by the Greek historian Herodotus (who also ridiculed it). Even fewer fragments remain of Hecataeus's other surviving work, *Historiai* (Histories), which gave an account of the traditions and mythology of the Greeks.

**Hecht, Selig** (1892–1947) *American physiologist*

Hecht (hekt) was born in the Austrian town of Glogow and brought to America in 1898. He was educated at the City College, New York, and at Harvard where he obtained his PhD in 1917. After several junior posts and a prolonged traveling fellowship, Hecht was appointed professor of biophysics at Columbia in 1926, a post he retained until his death.

Hecht is best remembered for his photochemical theory of visual adaptation formulated in the mid-1920s. That the eye can readily adapt to changes in brightness is a familiar experience but the exact mechanism behind this response is far from clear. Hecht proposed that in bright light the visual pigment rhodopsin is somewhat bleached while regeneration takes place in the dark. Under steady illumination the amount of rhodopsin bleached would be balanced by that regenerated. Adaptation is thus simply equated with the amount of rhodopsin in the retinal rods.

**Heeger, Alan J.** (1936– ) *American physicist*

Heeger (**hee-ger**) was born in Sioux City, Iowa, and educated at the University of Nebraska, gaining a BS in 1957, and at the University of California, Berkeley, gaining a PhD in 1961. In 1962 he joined the University of Pennsylvania as an assistant professor, becoming an associate professor in 1964 and a full professor in 1967. In 1982 he became a professor of physics at the University of California, Santa Barbara. He retired in 2007.

Heeger was one of the pioneers in the investigation of polymers that conduct electricity. Normally, one thinks of plastics as materials that do not conduct electricity. Indeed, plastic is used for electrical insulation around copper wires in electric cables. However, the work of Heeger, Alan MACDIARMID, and Hideki SHIRAKAWA at the end of the 1970s showed that, when modified in certain ways, some plastics can become electrical conductors.

Plastics are polymers. It is necessary that a polymer has alternate single and double bonds between the carbon atoms of its chain for it to become an electrical conductor. It is also necessary for the polymer to be doped, either by removing electrons by oxidation or introducing

them by reduction. The polymer then conducts because of the motion of the holes or extra electrons along the molecule.

There are many important practical applications of these materials. For example, electrically conducting plastics can be used as shields against electromagnetic radiation for computer screens and for “smart” windows to exclude light from the Sun. Research on such polymers is closely associated with rapid progress being made in the subject of molecular electronics. It may well be the case that, in the future, it will be possible to make transistors and other components that consist of single molecules. This would mean that the size of computers would be dramatically reduced while their speed would be dramatically increased. Heeger and his colleagues at UCSB have investigated semiconducting polymers and their applications in light-emitting diodes, light-emitting electrochemical cells, and lasers.

Heeger has won many awards for his pioneering work in this field, culminating in sharing the 2000 Nobel Prize for chemistry with MacDiarmid and Shirakawa.

**Heezen, Bruce Charles** (1924–1977) *American oceanographer*

Born in Vinton, Iowa, Heezen was educated at Iowa State University, graduating in 1948, and at Columbia, New York, where he received his PhD in 1957. He worked at the Lamont Geological Observatory at Columbia from 1948.

Heezen's work has contributed significantly to knowledge of the ocean floor and the processes that operate within the oceans. In 1952 he produced convincing evidence for the existence of turbidity currents, i.e., currents caused by a mass of water full of suspended sediment. Their existence had been suggested by Reginald Daly in 1936 and proposed as the cause of submarine canyons. Heezen used precise records available from the 1929 Grand Bank earthquake to study these currents. As the area off the Grand Bank was rich with communication cables, exact records of the disturbance caused by the earthquake had been obtained. He was able to reconstruct the movement down the bank of about 25 cubic miles (100 cubic km) of sediment moving with speeds approaching 50 miles per hour (85 km per hour).

In 1957, in collaboration with William EWING and Marie Tharp, the existence of the worldwide ocean rift was demonstrated and its connection with seismic activity postulated. In 1960 Heezen argued for an expanding Earth in which new material is emerging from the rift, increasing the oceans' width and pushing the continents further apart. Such a view, based on the grounds that the gravitational constant decreases slowly with time, had been suggested earlier by Paul DIRAC, but received little support in the early 1960s, particularly when a

more plausible mechanism was suggested by Harry H. HESS in 1962.

**Heidelberger, Michael** (1888–1991)  
*American immunologist*

Heidelberger (**hi**-del-ber-ger) was born in New York City and educated at Columbia where he obtained his PhD in 1911. He first worked at the Rockefeller Institute from 1912 until 1927 when he moved to Columbia, where he served as professor of immunochemistry from 1948 until his retirement in 1956. He then took up the position of adjunct professor of pathology at the New York University Medical School, where he continued to work in his lab when over 100.

Heidelberger in his long career worked on many immunological problems. Between 1928 and 1950 he did much to reveal the chemical structure of antibody and complement, two of the key parts of the immune system.

He also collaborated with a colleague at Rockefeller, Oswald AVERY, and in a famous experiment (1923) demonstrated that the specific antigenic properties of pneumococci are due to certain polysaccharides in their capsules.

**Heisenberg, Werner Karl** (1901–1976)  
*German physicist*

Heisenberg (**hi**-zen-berg), whose father was a professor of Greek at the University of Munich, was born in Würzburg, Germany. He was educated at the universities of Munich and Göttingen, where in 1923 he obtained his doctorate. After spending the period 1924–26 in Copenhagen working with Niels BOHR, he returned to Germany to take up the professorship of theoretical physics at the University of Leipzig. After the war, Heisenberg returned to Göttingen, where he reestablished the Kaiser Wilhelm Institute for Physics. This was renamed the Max Planck Institute and in 1958 it moved to Munich with Heisenberg as its director, a post he occupied until 1970 when he resigned on the grounds of ill health.

In 1925 Heisenberg formulated a version of quantum theory that became known as matrix mechanics. It was for this work, which was later shown to be formally equivalent to the wave mechanics of Erwin SCHRÖDINGER, that Heisenberg was awarded the 1932 Nobel Prize for physics. Heisenberg began in a very radical way, much influenced by Ernst MACH. Considering the various bizarre results emerging in quantum theory, such as the apparent wave-particle duality of the electron, his first answer was that it is simply a mistake to think of the atom in visual terms at all. What we really know of the atom is what we can observe of it, namely, the light it emits, its frequency, and its intensity. The need therefore was to be able to write a set of equations that would permit the correct prediction of such atomic phenomena.

Heisenberg succeeded in establishing a mathematical formalism that permitted accurate predictions to be made. The method was also developed by Max BORN and Pascual JORDAN. As they used the then relatively unfamiliar matrix mathematics to develop this system, it is not surprising that physicists preferred the more usual language of wave equations used in the equivalent system of Schrödinger.

In 1927 Heisenberg went on to explore a deeper level of physical understanding when he formulated his fundamental “uncertainty principle”: that it is impossible to determine exactly both the position and momentum of such particles as the electron. He demonstrated this by simple “thought experiments” of the following type: if we try to locate the exact position of an electron we must use rays with very short wavelengths such as gamma rays. But by so illuminating it the electron’s momentum will be changed by its interaction with the energetic gamma rays. Alternatively a lower-energy wave can be used that will not disturb the momentum of the electron so much but, as lower energy implies longer wavelength, such radiation will lack the precision to provide the exact location of the electron. There seems to be no way out of such an impasse and Heisenberg went on to express the limits of the uncertainty mathematically:

$$\Delta x \cdot \Delta p \geq h/2\pi$$

where  $\Delta x$  is the uncertainty in ascertaining the position in a given direction,  $\Delta p$  is the uncertainty in ascertaining the momentum in that direction, and  $h$  is the Planck constant. What the equation tells us is that the product of the uncertainties must always be about as great as the Planck constant and can never disappear completely. Further, any attempt made to reduce one element of uncertainty to the minimum can only be done at the expense of increasing the other. The consequence of this failure to know the *exact* position and momentum is an inability to predict accurately the future position of an electron. Thus, like Max BORN, Heisenberg had found it necessary to introduce a basic indeterminacy into physics.

After his great achievements in quantum theory in the 1920s Heisenberg later turned his attention to the theory of elementary particles. Thus in 1932, shortly after the discovery of the neutron by James CHADWICK, Heisenberg proposed that the nucleus consists of both neutrons and protons. He went further, arguing that they were in fact two states of the same basic entity – the “nucleon.” As the strong nuclear force does not distinguish between them he proposed that they were “isotopes” with nearly the same mass, distinguished instead by a property he called “isotopic spin.” He later attempted the ambitious task of constructing a unified field theory of elementary particles. Al-

though he published a monograph on the topic in 1966 it generated little support.

Unlike many other German scientists Heisenberg remained in Germany throughout the war and the whole Nazi era. He was certainly no Nazi himself but he thought it essential to remain in Germany to preserve traditional scientific values for the next generation. At one time he came under attack from the Nazis for his refusal to compromise his support for the physics of EINSTEIN in any way. Thus when, in 1935, he wished to move to the University of Munich to succeed Arnold SOMMERFELD he was violently attacked by the party press and, eventually, the post went to the little-known W. MÜLLER.

With the outbreak of war in 1939 Heisenberg was soon called upon to come to Berlin to direct the program to construct an atom bomb. His exact role in the program has become a matter of controversy. He has claimed that he never had any real intention of making such a bomb, let alone giving it to Hitler. As long as he played a key role he was, he later claimed, in a position to sabotage the program if it ever looked like being a success. He even went so far as to convey such thoughts to Niels Bohr in 1941 when he met him in Copenhagen, hinting that the Allies' physicists should pursue a similar policy. Bohr later reported that if such comments had been made to him they were done so too cryptically for him to grasp; he was rather under the impression that Heisenberg was trying to find out the progress made by the Allies.

New information on the role of Heisenberg and other senior German scientists was released in 1992. The Allies had gathered the scientists in a bugged house, Farm Hall, near Cambridge and recorded their conversation for six months. When the possibility of microphones was put to Heisenberg, he casually dismissed the suggestion: "Microphones installed? (Laughing) Oh no, they're not as cute as all that...they're a bit old fashioned in that respect."

Heisenberg learned of the Hiroshima bomb on 6 August 1945. His first reaction was of disbelief. He insisted that the announcement could refer only to high explosives. During further discussion he declared: "I never thought we would make a bomb." He felt that as a bomb could not have been completed before the war's end, he lacked the urgency to argue the case strongly enough before the military and politicians. He was also arrogant enough to believe that the Allies would do no better. The question of having to make a moral choice, of deliberately sabotaging a German nuclear program simply never arose.

**Helmholtz, Hermann Ludwig von** (1821–1894) *German physiologist and physicist*

Whoever, in the pursuit of science, seeks after immediate practical utility may rest assured that he seeks in vain.

—*Academic Discourses* (1862)

The first discovery of a new law ... is of the same quality as the highest performances of artistic perception in the discovery of new types of expression.

—"On Thought in Medicine" in *Popular Lectures on Scientific Subjects* (1884)

Born in Potsdam, Germany, Helmholtz (**helm-**holts) studied medicine at the Friedrich Wilhelm Institute in Berlin and obtained his MD in 1842. He returned to Potsdam to become an army surgeon, but returned to civilian life in 1848 and was appointed assistant at the Anatomical Museum in Berlin. He then held a succession of chairs at Königsberg (1849–55), Bonn (1855–58), Heidelberg (1858–71), and Berlin (1871–77) and later became director of the Physico-Technical Institute at Berlin Charlottenburg.

Helmholtz made major contributions to two areas of science: physiology and physics. In physiology he invented (1851) the ophthalmoscope for inspecting the interior of the eye and the ophthalmometer for measuring the eye's curvature. He investigated accommodation, color vision, and color blindness. His book *Handbuch der physiologische Optik* (Handbook of Physiological Optics) was published in 1867. Helmholtz also worked on hearing, showing how the cochlea in the inner ear resonates for different frequencies and analyzes complex sounds into harmonic components. In 1863 he published *Die Lehre von den Tönemfindungen als physiologische Grundlage für die Theorie der Musik* (The Sensation of Tone as a Physiological Basis for the Theory of Music). Another achievement was his measurement of the speed of nerve impulses (1850).

One of Helmholtz's interests had been muscle action and animal heat and this, inspired by his distaste for vitalism, led him to his best-known discovery – the law of conservation of energy. This was developed independently of the work of James JOULE and Julius von MAYER and published as *Über die Erhaltung der Kraft* (1847; On the Conservation of Force). He showed that the total energy of a collection of interacting particles is constant, and later applied this idea to other systems.

Helmholtz also worked in thermodynamics, where he introduced the concept of free energy (energy available to perform work). In electro-dynamics he attempted to produce a general unified theory. Heinrich HERTZ, who discovered radio waves in 1888, was Helmholtz's pupil.

**Helmolt, Jan Baptista van** (1579–1644) *Flemish chemist and physician*

A citizen being by a Peer openly disgraced and injured; unto whom he might not answer a word without fear of his utmost ruine; in

silence dissembles and bears the reproach: but straightway after, an Asthma arises.

—*Ortus medicinae* (1648; Origin of Medicine)

Van Helmont (**hel**-mont), who came from a noble Brussels family, was educated at the Catholic University of Louvain in medicine, mysticism, and chemistry, but declined a degree from them. Rejecting all offers of employment, he devoted himself to private research at his home. In 1621 he was involved in a controversy with the Church over the belief that it was possible to heal a wound caused by a weapon by treating the weapon rather than the wound. Van Helmont did not reject this common belief but insisted that it was a natural phenomenon containing no supernatural elements. He was arrested, eventually allowed to remain under house arrest, and forbidden to publish without the prior consent of the Church. He wrote extensively and after his death his collected papers were published by his son as the *Ortus medicinae* (1648; Origin of Medicine).

Van Helmont rejected the works of the ancients, although he did believe in the philosopher's stone. He carried out careful observations and measurements, which led him to discover the elementary nature of water. He regarded water as the chief constituent of matter. He pointed out that fish were nourished by water and that substantial bodies could be reduced to water by dissolving them in acid. To demonstrate his theory he performed a famous experiment in which he grew a willow tree over a period of five years in a measured quantity of earth. The tree increased its weight by 164 pounds despite the fact that only water was added to it. The soil had decreased by only a few ounces.

Van Helmont also introduced the term "gas" into the language, deriving it from the Greek for chaos. When a substance is burned it is reduced to its formative agent and its gas and van Helmont believed that when 62 pounds of wood is burned to an ash weighing 1 pound, 61 pounds have escaped as water or gas. Different substances give off different gases when consumed and van Helmont identified four gases, which he named gas carbonum, two kinds of gas sylvester, and gas pingue. These we would now call carbon dioxide, carbon monoxide, nitrous oxide, and methane.

### **Hempel, Carl Gustav** (1905–1997) *American philosopher of science*

Hempel was born in Oranienburg, Germany, and educated at Göttingen, Heidelberg, Vienna, and Berlin, where he completed his doctorate in 1934. Alarmed by political conditions in Germany, he moved to Holland and finally emigrated to America in 1938. He became a naturalized citizen in 1944. Hempel then taught at the University of Chicago, City Col-

lege of New York, and Yale before finally settling at Princeton as professor of philosophy, a position he held until his retirement in 1973.

Hempel established his reputation with a paper, *Studies in the Logic of Confirmation* (1945), which challenged the foundations of inductive logic. He pointed out that if we accept the equivalence condition, namely, that whatever confirms either of two equivalent propositions confirms the other, and the rule that positive instances confirm, then a simple paradox follows. For example, the generalization:

- (1) All ravens are black

is confirmed by finding anything that is a raven and black. But (1) is equivalent to:

- (2) All nonblack things are nonravens.

By the equivalence principle whatever confirms (2) must also confirm (1). But a green pencil, as something that is a nonblack non-raven, confirms (2) and therefore it must also confirm (1). Thus at least according to the rules of inductive logic, it seems that the fact that a pencil is green has confirmed the generalization that all ravens are black. The point can be pushed further to the absurd conclusion that whatever is neither black nor a raven, such as red flags and blue skies, confirms the proposition that all ravens are black.

Hempel went on, in a paper written in collaboration with Paul Oppenheim, *Studies in the Logic of Explanation* (1948), to propose a model of scientific explanation, the Hypothetico-Deductive method (HD), which dominated discussion for a generation. Scientific explanations are seen as deductive consequences from a set of laws and initial conditions. For example, from the initial conditions describing the positions of the Sun, Moon, and Earth together with Newton's laws of motion, the date of a future eclipse can be deduced. The laws and the initial conditions constitute an explanation of the eclipse.

For the reasoning to be valid, Hempel stressed, four conditions must be satisfied, namely, the conclusion must follow logically from the hypotheses, the hypotheses must contain a statement of a law of nature, they must have empirical content, and they must be true. Yet, later critics have argued, even if all conditions are satisfied, the HD method can still lead to error. Further, many explanations in science lie outside the HD framework. Finally, Hempel seems to ignore the crucial question of how the hypotheses are established in the first place. His work is more an account of how scientific discoveries are reported or rationalized; not of how they are arrived at or justified.

### **Hench, Philip Showalter** (1896–1965) *American biochemist*

Born in Pittsburgh, Pennsylvania, Hench was educated at Lafayette College and the Univer-

sity of Pittsburgh, where he obtained his MD in 1920. He spent most of his career working at the Mayo Clinic, becoming head of the section for rheumatic diseases in 1926. Hench was also connected with the Mayo Foundation and the University of Minnesota, where he became professor of medicine in 1947.

For many years Hench had been seeking a method of treating the crippling and painful complaint of rheumatoid arthritis. He suspected that it was not a conventional microbial infection since, among other features, it was relieved by pregnancy and jaundice. Hench therefore felt it was more likely to result from a biochemical disturbance that is transiently corrected by some incidental biological change. The search, he argued, must concentrate on something patients with jaundice had in common with pregnant women. At length he was led to suppose that the antirheumatic substance might be an adrenal hormone, since temporary remissions are often induced by procedures that stimulate the adrenal cortex. Thus in 1948 he was ready to try the newly prepared "compound E," later known as cortisone, of Edward KENDALL on 14 patients. All showed remarkable improvement, which was reversed on withdrawing the drug.

For this development of the first steroid drug Hench shared the 1950 Nobel Prize for physiology or medicine with Kendall and Tadeus REICHSTEIN.

### **Henderson, Thomas** (1798–1844) *British astronomer*

Born in Dundee, Scotland, Henderson started as an attorney's clerk who made a reputation as an amateur astronomer. In 1831 he accepted an appointment as director of a new observatory at the Cape of Good Hope in South Africa. While observing Alpha Centauri he found that it had a considerable proper motion. He realized that this probably meant that the star was comparatively close and a good candidate for the measurement of parallax – the apparent change in position of a (celestial) body when viewed from spatially separate points, or from one point on a moving Earth. All major observational astronomers had tried to detect this small angular measurement and failed. Henderson at last succeeded in 1832 and found that Alpha Centauri had a parallax of just less than one second of arc. The crucial importance of this was that once parallax was known, the distance of the stars could be measured successfully for the first time. Alpha Centauri turned out to be over four light years away. Unfortunately (for Henderson), he delayed publication of his result until it had been thoroughly checked and rechecked. By this time Friedrich BESSEL had already observed and published, in 1839, the parallax of 61 Cygni.

In 1834 Henderson became the first Astronomer Royal of Scotland.

### **Henle, Friedrich Gustav Jacob** (1809–1885) *German physician, anatomist, and pathologist*

A rational system of histology must employ the transformations of the cells as a principle of classification, so that groups of tissue can be formed according to whether, for example, the cells remain discrete or join lengthwise in rows, or expand into star shapes, or split into fibers, and so forth.

—*Allgemeine Anatomie* (1841; General Anatomy)

Henle (**hen-lee**), a merchant's son from Fürth, in Germany, was educated at the universities of Heidelberg and Bonn where he obtained his MD in 1832. He began his career as assistant to Johannes MÜLLER in Berlin and, despite various political troubles (he was tried for treason in Berlin), served as professor of anatomy and physiology at the universities of Zurich (1840–44) and Heidelberg (1844–52) before moving to a similar post at Göttingen where he remained until his death.

By the beginning of the 19th century the humoral theory of disease had been finally expelled from orthodox medicine. It was far from clear, however, what to put in its place. A cogent and comprehensive theory, as developed by Louis PASTEUR and Henle's own pupil, Robert KOCH, would not be available for a further 40 years. Henle however took some preliminary steps, notably his declaration that contagious substances are not only organic but indeed are living organisms. He distinguished between miasmas, which arise from the environment, and contagions, which spread from person to person. Such theorizing had little immediate impact on medicine, largely because of the difficulty in providing experimental support. His work consequently was largely ignored as speculative.

Henle also produced two standard and highly influential textbooks: *Allgemeine Anatomie* (1841; General Anatomy) and *Handbuch der rationelle Pathologie* (2 vols., 1846–53; Handbook of Rational Pathology). In them he first described and emphasized the microscopic structure of the epithelium, the cells that cover the internal and external surface of the human body. He has thus frequently been referred to as the founder of modern histology.

As an anatomist Henle's name has been preserved in the *loop of Henle*, a part of the nephron, or urine-secreting tubules, in the kidney.

### **Henry, Joseph** (1797–1878) *American physicist*

One great object of science is to ameliorate our present condition, by adding to those

advantages we naturally possess ... by a combination of theoretical knowledge with practical skill, machines have been constructed no less useful in their productions than astonishing in their operations.

—*Albany Argus and City Gazette* (1826)

One of the first great American scientists, Henry came from a poor background in Albany, New York, and had to work his way through college. He was educated at the Albany Academy, New York, where he first studied medicine, changing to engineering in 1825. A year later he was appointed a professor of mathematics and physics at Albany. In 1832 he became professor of natural philosophy at Princeton (then the College of New Jersey) where he taught physics, chemistry, mathematics, and geological sciences, and later astronomy and architecture.

Henry is noted for his work on electricity. In 1829 he developed a greatly improved form of the electromagnet by insulating the wire that was to be wrapped around the iron core, thus allowing many more coils, closer together, and greatly increasing the magnet's power. Through this work he discovered, in 1830, the principle of electromagnetic induction. Soon after, and quite independently, Michael FARADAY made the same observation and published first. Faraday is thus credited with the discovery but Henry has the unit of inductance (the *henry*) named for him. However, Henry did publish in 1832 – prior to Faraday and Heinrich LENZ – his discovery of self-induction (in which the magnetic field from a changing electric current induces an electromotive force opposing the current). Earlier (in 1829) he had invented and constructed the first practical electric motor. In 1835 he developed the electric relay in order to overcome the problem of resistance that built up in long wires. This device had an immediate social impact for it was the key step in the invention of the long-distance telegraph, which played a large part in the opening up of the North American continent. In 1846 he became the first secretary of the Smithsonian Institution, which he formed into an extremely efficient body for liaison between scientists and government support of their research. He also did work on solar radiation and on sunspots.

**Henry, William** (1774–1836) *British physician and chemist*

Henry's father, Thomas Henry, was a manufacturing chemist in Manchester, England, and an analytical chemist of some repute. Initially qualifying as a physician from Edinburgh University, Henry practiced for five years in the Manchester Infirmary. Later he took over the running of the chemical works established by his father.

In 1801 he formulated the law now known as *Henry's law*, which states that the solubility of a gas in water at a given temperature is pro-

portional to its pressure. His close friend John DALTON was encouraged by this finding, seeing it as a confirmation of his own theory of mixed gases, and the two men discussed the methods of experimentation in detail.

Henry also researched into the hydrocarbon gases, following Dalton in clearly distinguishing methane from ethylene (ethene). He determined the molecular formula of ammonia by exploding it with oxygen. He also described the preparation, purification, and analysis of coal gas, and developed a method of analyzing gas mixtures by fractional combustion. His textbook, *Elements of Experimental Chemistry* (1799), went through 11 editions in 30 years.

**Hensen, Viktor** (1835–1924) *German physiologist and oceanographer*

Hensen (**hen-zen**) was born in Schleswig, Germany, and studied science and medicine at the universities of Würzburg, Berlin, and Kiel, graduating from the latter in 1858. He remained at Kiel to work in the physiology department and later served as professor of physiology (1871–1911).

Hensen worked on comparative studies of vision and hearing but also discovered, independently of Claude Bernard, the compound glycogen. He is better remembered however for his work on plankton. He introduced the term plankton in 1887 to describe the minute drifting animals and plants in the oceans. Moreover he advanced beyond the descriptive stage and introduced numerical methods into marine biology, notably in constructing the *Hensen net*, a simple loop net designed to filter a square meter of water. This enabled the number of plankton in a known area of water to be counted. Hensen tested his equipment in the North Sea and the Baltic in 1885.

Satisfied with his techniques, he made a more ambitious trip in 1889 covering more than 15,000 miles of the Atlantic. One of his more surprising results was the greater concentration of plankton in temperate than in tropical waters.

**Heracleides of Pontus** (c. 390 BC–c. 322 BC) *Greek astronomer*

Heracleides of Pontus, when he drew the circle of Venus, and also of the Sun, and assigned a single center to both circles, showed that Venus is sometimes above, sometimes below the Sun.

—Calcidius (5th century AD)

Heracleides (**her-a-kil-deez**), who was born in Heraclea, now in Turkey, was an associate and possibly a pupil of PLATO. Although none of his writings have survived, two views that were unusual for the time have been attributed to him. The philosopher Simplicius of Cilicia, a usually reliable source, reports that "Heracleides supposed that the Earth is in the center

and rotates while the heaven is at rest.” If this is accurate he must have been the first to state that the Earth rotates, a view that found as little support in antiquity as it did in the medieval period. The second doctrine attributed to him is that Mercury and Venus move around the Sun, which moves around the Earth – a view adopted later by Tycho BRAHE in the 16th century.

**Heraclitus of Ephesus** (about 500 BC)  
*Greek natural philosopher*

If you do not expect the unexpected, you will not find it; for it is hard to be sought out, and difficult.

—Quoted in C. H. Khan, *The Art and Thought of Heraclitus* (1979)

Virtually nothing is known of the life of Heraclitus (her-a-**klI**-tus), and of his book *On Nature* only a few rather obscure fragments survive. His doctrines contrast with those of his near contemporary PARMENIDES for whom, on purely logical grounds, change of any kind was totally impossible. For Heraclitus, everything is continually in a state of change, hence his characteristic aphorism: “We cannot step twice into the same river,” and his selection of fire as the fundamental form of matter. The mechanism behind such unremitting change was the constant tension or “strife” between contraries or opposites.

**Hérelle, Felix d'** See **D'HÉRELLE, FELIX**.

**Hermite, Charles** (1822–1901) *French mathematician*

Hermite (air-meet) was born in Dieuze, France. His mathematical career was almost thwarted in his student days, since he was incapable of passing exams. Fortunately his talent had already been recognized and his examiners eventually let him scrape through. Hermite obtained a post at the Sorbonne where he was an influential teacher.

Hermite began his mathematical career with pioneering work on the theory of Abelian and transcendental functions, and he later used the theory of elliptic functions to give a solution of the general equations of the fifth degree – the quintic. One long-standing problem solved was proving that the number “e” is transcendental (i.e., not a solution of a polynomial equation). He also introduced the techniques of analysis into number theory. His most famous work is in algebra, in the theory of *Hermite polynomials*. Although Hermite himself had little interest in applied mathematics this work turned out to be of great use in quantum mechanics.

**Hero of Alexandria** (about 62 AD) *Greek mathematician and inventor*

Hero is no scientist, but a practical technician and surveyor.

—J. L. Heiberg, *History of Mathematics and Science in Classical Antiquity* (1925)

Hero (**heer**-oh) produced several written works on geometry, giving formulas for the areas and volumes of polygons and conics. His formula for the area of a triangle was contained in *Metrica* (Measurement), a work that was lost until 1896. This book also describes a method for finding the square root of a number, a method now used in computers, but known to the Babylonians in 2000 BC. In another of Hero's books, *Pneumatica* (Pneumatics), he wrote on siphons, a coin-operated machine, and the aeolipile – a prototype steam-powered engine that he had built. The engine consisted of a globe with two nozzles positioned so that steam jets from the inside made it turn on its axis. Hero also wrote on land-surveying and he designed war engines based on the ideas of Ctesibius. Yet another of his works, *Mechanica* (Mechanics), was quoted by PAPPUS of Alexandria.

**Herophilus of Chalcedon** (about 300 BC)  
*Greek anatomist and physician*

Herophilus (her-off-i-lus), a pupil of PRAXAGORAS of Cos, was one of the founders of the Alexandrian medical school set up at the end of the 4th century BC under the patronage of Ptolemy I Soter. Although none of his works have survived, GALEN lists some eight titles of which the *Anatomica* (Anatomy) was probably the most significant.

Herophilus is widely, even notoriously, remembered as the result of a famous passage in CELSUS reporting that, with ERASISTRATUS, he practiced vivisection on criminals. The passage has been regarded as suspect by many scholars on the grounds that no such reference occurs in any extant, earlier Greek text. It is however certain that from the results attributed to him he must have undertaken both human and animal dissection. For example, he described a passage from the stomach to the intestines as being “12 finger widths” (*dodekadaktylon*) or in its Latin form, the duodenum; he also named the retina and the prostate and did much work on the brain.

It has been claimed that Herophilus was the first to distinguish between sensory and motor nerves. Nerves, or neura, for Herophilus were simply channels that carried the pneuma or vital air to different parts of the body. Thus while he probably identified sensory nerves it is unlikely that he was able to distinguish between motor nerves and tendons.

Herophilus was reported to have advanced Praxagoras's work on the pulse by counting its frequency against a water clock. Also, according to Galen, he made the important observation that the arteries carried blood as well as pneuma.

**Hérout, Paul Louis Toussaint** (1863–1914) *French chemist*

Hérout (ay-roo), who was born at Thury-Harcourt in France, was a student at the St. Barge Institute in Paris and later worked at the Paris School of Mines. In 1886 he discovered a process for extracting aluminum by electrolysis of molten aluminum oxide, with cryolite (sodium aluminum fluoride) added to lower the melting point. Charles HALL developed a similar process independently in America at about the same time.

**Herring, William Conyers** (1914– ) *American physicist*

Herring was born in Scotia, New York, and educated at the University of Kansas where he obtained a BA in astronomy in 1933. He did research in mathematical physics at Princeton and obtained his PhD at Princeton in 1937. During World War II he worked on underwater warfare and then joined the Bell Telephone Laboratories in 1946. Herring remained with Bell as a research physicist until 1978 when he was appointed professor of applied physics at Stanford University, California, a post he held until his retirement in 1981.

Herring has worked on a wide range of theoretical problems in solid-state physics, including electrical conduction, surface tension of solids, anisotropic effects in superconducting materials, and the magnetic properties of solids.

**Herschbach, Dudley Robert** (1932– ) *American chemist*

Herschbach (hersh-bahk), who was born in San José, California, was educated at Stanford University and at Harvard University, where he gained his PhD in 1958. After teaching at the University of California, Berkeley, for four years, he returned to Harvard in 1963 as professor of chemistry.

Herschbach has worked on the details of chemical reactions; for example, a simple reaction in which potassium atoms and iodomethane molecules form potassium iodide and methyl radicals as products, that is:

He decided to use molecular beams to examine the nature of the reaction. The reagent molecules were formed into two collimated beams at a sufficiently low pressure to make collisions within the beams a negligible event. The beams were allowed to collide and the direction and velocity of the product molecules measured.

Herschbach was able to draw some conclusions about the reaction. He demonstrated, for example, that the reagents would only react if the incoming potassium atoms struck the iodomethane molecules at the iodide end.

As techniques were refined and extended Herschbach demonstrated that the study of molecular beams could throw considerable light on reaction dynamics. For his work in this field he shared the 1986 Nobel Prize for chemistry with Yuan LEE and John POLANYI.

**Herschel, Caroline Lucretia** (1750–1848) *German–British astronomer*

Caroline Herschel (her-shel), who was born in Hannover, Germany, was the sister and colleague of William HERSCHEL. Having joined her brother as his housekeeper in Bath in 1772, she rapidly graduated to being his assistant and then to original astronomical research of her own. In 1786 she observed her first comet and before 1797 had detected seven more. She also discovered many new nebulae. Her devotion to her brother and his work must have been completely unconditional judging by the many hundreds of nights spent observing. There is a story that she once slipped and fell on a hook attached to the telescope but made no cry lest she disturb her brother's observations. After his death in 1822 she returned to Hannover where she prepared a catalog of about 2,500 nebulae and star clusters. Although it was never published she received the Gold medal of the Royal Astronomical Society in 1828 for it. Caroline Herschel was awarded money by the government to allow her to continue work. She was the first woman in England to hold a government post.

**Herschel, Sir (Frederick) William** (1738–1822) *German–British astronomer*

I saw, with the greatest pleasure, that most of the nebulae ... yielded to the force of my light and power, and were resolved into stars.

—On the great light-gathering power of his large telescopes

Herschel, who was born in Hannover, Germany, started life in the same occupation as his father — an oboist with the band of the Hannoverian footguards. He moved permanently to England in 1757, where he worked as a freelance itinerant musician until in 1767 he was appointed as organist of a church in Bath. His sister Caroline Herschel joined him in Bath in 1772. He was led by his interest in musical theory to a study of mathematics and ultimately astronomy. Herschel made his own telescopes and his early observations were significant enough to be drawn to the attention of George III in 1782. The king, who had a passionate interest in astronomy and clockwork, was sufficiently impressed with Herschel to employ him as his private astronomer at an initial salary of £200 a year and to finance the construction of very large telescopes. At first Herschel settled at Datchet, near Windsor, but in 1786 he moved to

Slough where he remained for the rest of his life.

Herschel's contributions to astronomy were enormous. He was fortunate to live at a time when prolonged viewing with a large reflector could not but be fruitful and he took full advantage of his fortune. He made his early reputation by his discovery in 1781 of the first new planet since ancient times. He wished to name it after his patron as "Georgium Sidus" (George's Star) but Johann BODE's suggestion of "Uranus" was adopted. Herschel's work is notable for the unbelievable comprehensiveness with which he extended the observations of others. Thus he extended Charles MESSIER's catalog of just over 100 nebulae by a series of publications listing over 2,000 nebulae. He not only began the study of double stars but cataloged 800 of them. He also discovered two satellites of Uranus – Titania and Oberon (1787) – and two of Saturn – Mimas and Enceladus (1789–90). He built a large number of telescopes of various sizes, culminating in his enormous 40-foot (12-m) reflector. This cost George III £4,000 plus £200 a year for its upkeep. The eyepiece was attached to the open end, thus eliminating the loss of light caused by the secondary mirror used in the Newtonian and Gregorian reflectors. The disadvantage was the danger of climbing up to the open end of the 40-foot instrument in the dark. One eminent astronomer, Giuseppe PIAZZI, failing to master this skill, fell and broke his arm. It was finally dismantled in 1839 while William's son John conducted his family in a special requiem he had composed for the occasion.

Herschel produced not only observational work but theoretical contributions on the structure of the universe. He established the motion of the Sun in the direction of Hercules and tried to calculate its speed (1806). But, above all, he was the first to begin to see the structure of our Galaxy. Conducting a large number of star counts, he established that stars are much more numerous in the Milky Way and the plane of the celestial equator, becoming progressively fewer toward the celestial poles. He explained this by supposing that the Galaxy is shaped like a grindstone. If we look through its short axis we see few stars and much dark space; through its long axis we see a stellar multitude. Herschel was supported in his astronomical life by his sister Caroline. His son John also became an astronomer of note.

### **Herschel, Sir John Frederick William** (1792–1871) *British astronomer*

John Herschel, who was born at Slough in the southeast of England, read mathematics at Cambridge University and then began to study law. Although he was the son of the astronomer William HERSCHEL he did not take up astronomy seriously until 1816 when he began, some-

what reluctantly, to assist his father with his observations.

John Herschel went to South Africa in 1834 to make a comprehensive survey of the skies of the southern hemisphere, and succeeded Thomas HENDERSON as director of the Cape of Good Hope Observatory, doing for the southern skies what his father had done for the northern. He discovered and described some 2,000 nebulae and some 2,000 double stars, publishing the results of his surveys in 1847. He seems to have given up astronomical observation on his return from South Africa in 1838, instead becoming interested in photography (introducing the terms "positive" and "negative") and pioneering the use of photographic techniques in astronomy. He also experimented on the spectral lines discovered by Joseph von FRAUNHOFER because he began to see a connection between the absorption and emission lines. He was also a major figure in the regeneration and reorganization of British science in the first half of the 19th century. He was one of the founder members of the Royal Astronomical Society in 1830, and took on many public duties, becoming, like Newton, master of the mint from 1850 to 1855. This, however, proved too taxing for him and he suffered a nervous breakdown, which led to his retirement from public life. His study of scientific method *Discourse on the Study of Natural Philosophy* (1830) influenced the philosopher John Stuart Mill and Charles DARWIN.

### **Hershey, Alfred Day** (1908–1997) *American biologist*

Hershey was born in Owosso, Michigan, and graduated from Michigan State College in 1930, remaining there to do his PhD thesis on the chemistry of *Brucella* bacteria. Having received his doctorate in 1934, he taught at Washington University, St. Louis, until 1950, when he moved to the Genetics Research Unit of the Carnegie Institute, Washington. In 1962 he became director of the unit, a position he retained until his retirement in 1974.

Hershey, along with Salvador LURIA and Max DELBRÜCK, was one of the founders in the early 1940s of the so-called "phage group." In 1945, independently of Luria, he demonstrated that spontaneous mutations must occur in bacterial viruses (phage). In the following year he established, at the same time as Delbrück, that genetic recombination takes place between phages present in the same cell.

Hershey is best known, however, for the experiment conducted with Martha Chase and reported in their 1952 paper, *Independent Functions of Viral Proteins and Nucleic Acid in Growth of Bacteriophage*. At the time it was still uncertain whether genes were composed of protein, nucleic acid, or some complex mixture of the two. They utilized the fact that DNA contains phosphorus but no sulfur, while phage

protein has some sulfur in its structure but no phosphorus. Phage with a protein coat labeled with radioactive sulfur and DNA with radioactive phosphorus was allowed to infect bacteria. After infection the bacteria were spun in a blender. The labeled protein was stripped off the bacteria while the radioactive DNA remained inside the bacterial cell. When allowed to incubate, the bacteria proved capable of producing a new phage crop. The experiment would seem to show that DNA was more involved than protein in the process of replication. Many think that Martha Chase was given insufficient credit for her contribution to this work.

For his fundamental contributions to molecular biology, Hershey received the 1958 Albert Lasker Award and the 1965 Kimber Genetics Award. However, it was not until 1969 that Hershey, together with Delbrück and Luria, was awarded the Nobel Prize for physiology or medicine.

### **Hershko, Avram** (1937– ) *Israeli biochemist*

Hershko was born in Karcag, Hungary, but his family emigrated to Israel in 1950. He studied medicine at the Hebrew University, Jerusalem, gaining his MD in 1965. Following a stint as a physician in the Israel Defense Force (1965–67), he obtained his PhD in 1969. After working as a postdoctoral fellow at the University of California (1969–72), he joined the Israel Institute of Technology (Technion) in Haifa as associate professor (1972–80), then professor. He is currently distinguished professor at the Rappaport Family Institute for Research in Medical Sciences at the Technion.

In the late 1970s and early 1980s Hershko worked closely with his colleague at the Technion, Aaron CIECHANOVER, to investigate mechanisms of energy-dependent protein degradation in cells. The two, along with the American biochemist Irwin ROSE, discovered the crucial role played by the polypeptide ubiquitin, which covalently attaches to proteins as a label, marking out the protein as a target for cutting up by protein complexes called proteasomes. This work has since proved fundamentally important as a control mechanism for many cell activities, and of relevance to the development of cancers and other diseases. In recognition of this, Hershko was awarded the 2004 Nobel Prize for chemistry, jointly with Ciechanover and Rose.

### **Hertz, Gustav** (1887–1975) *German physicist*

A nephew of the distinguished physicist Heinrich HERTZ (hertz), Gustav Hertz was born in Hamburg, Germany, and educated at the universities of Munich and Berlin. He taught in

Berlin and Halle before his appointment in 1928 to the professorship of experimental physics at the Technical University, Berlin. Hertz, as a Jew, was dismissed from his post in 1935. He worked for the Siemens company from 1935 until 1945, somehow managing to survive the war, when he was captured by the Russians. He reemerged in 1955 to become director of the Physics Institute in Leipzig, then in East Germany.

In 1925 Hertz was awarded the Nobel Prize for physics for his work with James FRANCK on the quantized nature of energy transfer.

### **Hertz, Heinrich Rudolf** (1857–1894) *German physicist*

One cannot escape the feeling that these mathematical formulae have an independent existence and an intelligence of their own, that they are wiser than we are, wiser even than their discoverers, that we get more out of them than was originally put into them.

—Quoted by E. T. Bell in *Men of Mathematics*

Hertz came from a prosperous and cultured Hamburg family. In 1875 he went to Frankfurt to gain practical experience in engineering and after a year of military service (1876–77) spent a year at the University of Munich. He had decided on an academic and scientific career rather than one in engineering, and in 1878 chose to continue his studies at the University of Berlin under Hermann von HELMHOLTZ. Hertz obtained his PhD in 1880 and continued as Helmholtz's assistant for a further three years. He then went to work at the University of Kiel. In 1885 he was appointed professor of physics at Karlsruhe Technical College and in 1889 became professor of physics at the University of Bonn. His tragic early death from blood poisoning occurred after several years of poor health and cut short a brilliant career.

Hertz's early work at Berlin was diverse but included several pieces of research into electrical phenomena and equipment. With no laboratory facilities at Kiel he had considered more theoretical aspects of physics and had become more interested in the recent work of James Clerk MAXWELL on electromagnetic theory. Helmholtz had suggested an experimental investigation of the theory to Hertz in 1879 but it was not until 1885 in Karlsruhe that Hertz found the equipment needed for what became his most famous experiments. In 1888 he succeeded in producing electromagnetic waves using an electric circuit; the circuit contained a metal rod that had a small gap at its midpoint, and when sparks crossed this gap violent oscillations of high frequency were set up in the rod. Hertz proved that these waves were transmitted through air by detecting them with another similar circuit some distance away. He also showed that like light waves they were re-

flected and refracted and, most important, that they traveled at the same speed as light but had a much longer wavelength. These waves, originally called *Hertzian waves* but now known as radio waves, conclusively confirmed Maxwell's prediction on the existence of electromagnetic waves, both in the form of light and radio waves.

Once at Bonn Hertz continued his analysis of Maxwell's theory, publishing two papers in 1890. His experimental and theoretical work put the field of electrodynamics on a much firmer footing. It should also be noted that in 1887 he inadvertently discovered the photoelectric effect whereby ultraviolet radiation releases electrons from the surface of a metal. Although realizing its significance, he left others to investigate it.

Hertz's results produced enormous activity among scientists but he died before seeing Guglielmo MARCONI make his discovery of radio waves a practical means of communication. In his honor the unit of frequency is now called the hertz.

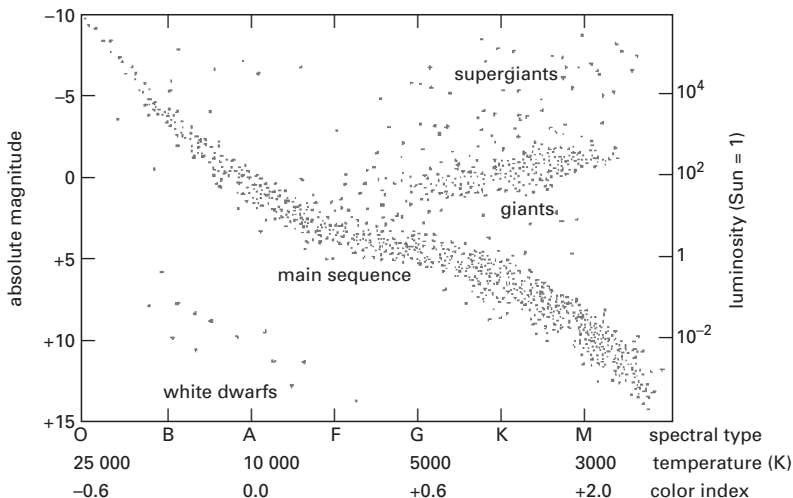

### Hertzsprung, Ejnar (1873–1967) *Danish astronomer*

Hertzsprung (*hairt-sprung*) was born in Frederiksberg, Denmark, the son of a senior civil servant who had a deep interest in mathematics and astronomy but who was anxious to see that his son received a more practical education. Consequently Hertzsprung was trained as a chemical engineer at the Copenhagen Polytechnic, graduating in 1898. He worked as a chemist in St. Petersburg and then studied photochemistry under Wilhelm OSTWALD in Leipzig before returning to Denmark in 1902. His first

professional appointment as an astronomer was in 1909 at the Potsdam Observatory. The bulk of his career, from 1919 to 1944, was spent at the University of Leiden where from 1935 he served as director of the observatory. After his retirement in 1944 he returned to Denmark where he continued his studies for a further 20 years.

Hertzsprung's name is linked with that of Henry RUSSELL as independent innovators of the Hertzsprung–Russell (H–R) diagram. In the late 19th and early 20th centuries, techniques used in photographic spectroscopy were being greatly improved. With his background in photochemistry, Hertzsprung was able to devise methods by which he could determine the intrinsic brightness, i.e., luminosity, of stars. He showed that the luminosity of most of the stars he studied decreased as their color changed from white through yellow to red, i.e., as their temperature decreased. He also found that a few stars were very much brighter than those of the same color. Hertzsprung thus discovered the two main groupings of stars: the highly luminous giant and supergiant stars and the more numerous but fainter dwarf or main-sequence stars. Hertzsprung published his results, although not in diagrammatic form, in 1905 and 1907 in an obscure photographic journal. His work therefore did not become generally known and credit initially went to Russell who published the eponymous diagram in 1913. It would be difficult to exaggerate the importance or usefulness of the H–R diagram, which has been the starting point for discussions of stellar evolution ever since.

Much of Hertzsprung's work concerned open clusters of stars. In 1911 he published the first color-magnitude diagrams of the Pleiades and

**HERTZSPRUNG–RUSSELL DIAGRAM** An example of an H–R diagram for bright stars.

Hyades clusters, showing how the color of member stars varied with observed brightness. He also measured the proper motions of stars, i.e., their angular motions in a direction perpendicular to the observer's line of sight, and used the results to establish membership of clusters.

One other major achievement of Hertzprung was the development of a method for the determination of stellar and galactic distances. In the 19th century Friedrich BESSEL and Friedrich Georg STRUVE had been the first to use measurements of annual parallax to calculate stellar distances but this was only accurate up to distances of about a hundred light-years. In 1913, when Hertzprung announced his results, astronomers had made little progress in measuring distances. The work of Henrietta LEAVITT in 1912 had shown that the period of light variation of a group of stars known as Cepheid variables was related to their observed mean brightness. These Cepheids lay in the Magellanic Clouds. Hertzprung assumed that at the great distance of the Clouds all member stars could be considered to have approximately the same distance. Since observed and intrinsic brightness of a star are directly linked by its distance, the periods of light variation of Cepheids in the Clouds were thus also related to their intrinsic brightness. By extrapolation, Cepheids could thus be an invaluable means of measuring the distance of any group of stars containing a Cepheid by observing the period and apparent brightness of the Cepheid.

The work of establishing the period-luminosity relation on a numerical basis was begun by Hertzprung and continued by Harlow SHAPLEY. Hertzprung determined the distances of several nearby Cepheids from measurements of their proper motions. Using his results and Leavitt's values for the periods and apparent brightness of Cepheids in the Small Magellanic Cloud (SMC) he was then able to calculate the distance to the SMC. Although somewhat smaller than today's value, this was the first measurement of an extragalactic distance.

### **Herzberg, Gerhard** (1904–1999) *Canadian spectroscopist*

Born in Hamburg, Germany, Herzberg (**hertsberg**) was educated at the universities of Göttingen and Berlin. He taught at the Darmstadt Institute of Technology from 1930 until 1935 when, with the rise to power of the Nazis, he emigrated to Canada, where he was research professor of physics at the University of Saskatchewan from 1935 until 1945. He returned to Canada in 1948 after spending three years as professor of spectroscopy at the Yerkes Observatory, Wisconsin. From 1949 until his retirement in 1969 he was director of the division of pure physics for the National Research Council in Ottawa.

Herzberg is noted for his extensive work on the technique and interpretation of the spectra of molecules. He elucidated the properties of many molecules, ions, and radicals and also contributed to the use of spectroscopy in astronomy (e.g., in detecting hydrogen in space). His work included the first measurements of the LAMB shifts (important in quantum electrodynamics) in deuterium, helium, and the positive lithium ion.

Herzberg also produced a number of books, notably the two classic surveys *Atomic Spectra and Atomic Structure* (1937) and *Molecular Spectra and Molecular Structure* (4 vols., 1939–79). He received the Nobel Prize for chemistry in 1971 for his "contributions to the knowledge of electronic structure and geometry of molecules, particularly free radicals."

### **Hess, Germain Henri** (1802–1850) *Swiss–Russian chemist*

Hess, who was born at Geneva in Switzerland, was taken to Russia as a child by his parents. He studied medicine at the University of Dorpat (1822–25) and started his career by practicing medicine in Irkutsk. In 1830 he moved to St. Petersburg, becoming professor of chemistry at the Technological Institute of the university. While there he wrote a chemistry textbook in Russian, which became a standard work.

Hess worked on minerals and on sugars, but his main work was on the theory of heat. By carefully measuring the heat given off in various chemical changes, he was able to conclude in 1840 that in any chemical reaction, regardless of how many stages there are, the amount of heat developed in the overall reaction is constant. *Hess's law*, also called the law of constant heat summation, is in fact a special case of the law of conservation of energy.

### **Hess, Harry Hammond** (1906–1969) *American geologist*

Hess was born in New York City and educated at Yale, graduating in 1927, and Princeton where he gained his PhD in 1932. He worked first as a field geologist in Northern Rhodesia (now Zambia) in the period 1928–29. After a year at Rutgers in 1932 he moved to Princeton in 1934, becoming professor of geology in 1948.

Hess was a key figure in the postwar revolution in the Earth sciences. He was the first to draw up theories using the considerable discoveries on the nature of the ocean floor that were made in the postwar period. Hess himself discovered about 160 flat-topped summits on the ocean bed, which he named guyots for an earlier Princeton geologist, Arnold GUYOT. As they failed to produce atolls he dated them to the Precambrian, 600 million years ago, before the appearance of corals. But in 1956 Cretaceous fossils, from only 100 million years ago,

**SEA-FLOOR SPREADING** Magma rises from the Earth's mantle to the surface along the midoceanic ridge and cools to form the new oceanic crust. H. H. Hess estimated the oceanic crust to be spreading apart along the midoceanic ridge at the rate of about 1 to 2 inches (2.5–5 cm) a year.

were found in Pacific guyots. The whole of the ocean floor was discovered to be surprisingly young, dating only as far back as the Mesozoic, while the continental rocks were much older.

In 1962 Hess published his important paper, *History of Ocean Basins*. The ocean floors were young, he argued, as they were constantly being renewed by magma flowing from the mantle up through the oceanic rifts, discovered by William Morris EWING, and spreading out laterally. This became known as the sea-floor spreading hypothesis and was a development of the convection-currents theory proposed by Arthur HOLMES in 1929. The hypothesis has been modified since its proposal, notably through the work of Drummond Hoyle MATTHEWS and Frederick VINE on magnetic anomalies, but remains largely accepted.

### Hess, Victor Francis (1883–1964) *Austrian-American physicist*

Hess, the son of a forester, was born at Waldstein in Austria and educated at the University of Graz where he obtained his doctorate in 1906. He worked at the Institute for Radium Research, Vienna, from 1910 to 1920 and then took up an appointment at the University of Graz where he became professor in 1925. In 1931 he set up a cosmic-ray observatory near Innsbruck but in 1938 he was dismissed from all his official positions as he was a Roman Catholic. Leaving Nazi Austria, he emigrated to America where he served as professor of physics at Fordham University, New York, from 1938 to 1956.

In 1911–12 Hess made the fundamental discovery of cosmic rays, as they were later called by Robert MILLIKAN in 1925. For this work he shared the Nobel Prize for physics with Carl Andersen in 1936. The work stemmed from an attempt to explain why gases are always slightly ionized; thus a gold-leaf electroscope, however well insulated it might be, will discharge itself over a period of time. Radiation was clearly coming from somewhere and the most likely source was the Earth itself. To test this, attempts were made to see if the rate of

discharge decreased with altitude. But both T. Wulf, who took an electroscope to the top of the Eiffel Tower in 1910, and A. Gockel, who took one up in a balloon in 1912, failed to obtain any clear results.

However when Hess ascended in a balloon to a height of 16,000 feet (4,880 m) he found that although the electroscope's rate of discharge decreased initially up to about 2,000 feet (610 m), thereafter it increased considerably, being four times faster at 16,000 feet than at sea level. He concluded that his results were best explained by the assumption that a radiation of very great penetrating power enters our atmosphere from above.

He was able to eliminate the Sun as the sole cause for he found that the effect was produced both by day and at night. Further, in 1912, he made a balloon ascent during a total eclipse of the Sun and found that during the period when the Sun was completely obscured there was no significant effect on the rate of discharge. Hess however failed to convince everyone that cosmic rays came from outside the Earth's atmosphere as it could still be argued that the source of the radiation was such atmospheric disturbances as thunderstorms. It was left to Millikan in 1925 finally to refute this objection.

### Hess, Walter Rudolf (1881–1973) *Swiss neurophysiologist*

The son of a physics teacher from Frauenfel in Switzerland, Hess was educated at the universities of Lausanne, Bern, Berlin, Kiel, and Zurich where he obtained his MD in 1906. Although he actually began as an ophthalmologist, building up a prosperous practice, he decided in 1912 to abandon it for a career in physiology. After junior posts in Zurich and Bonn he was appointed in 1917 to the directorship of the physiology department at the University of Zurich, where he remained until his retirement in 1951.

In the early 1920s Hess began an important investigation of the interbrain and hypothalamus. To do this he inserted fine electrodes into the brains of cats, and used these to stimulate

specific groups of cells. His most startling discovery was that when electrodes in the posterior interbrain were switched on this would instantaneously turn a friendly cat into an aggressive spitting creature – a transformation instantly reversed by a further press of the switch. Other areas found by Hess would induce flight, sleep, or defecation.

Less dramatic perhaps but no less significant were the two main areas identified by Hess in the hypothalamus. Stimulation of the posterior region prepared the animal for action but stimulation of the anterior region tended to cause relaxation. Hess had discovered the control center for the sympathetic and parasympathetic systems.

Hess's work was enormously influential and led to a detailed mapping of the interbrain and hypothalamus by many different workers in various centers over a number of years. For his discovery of "the functional organization of the interbrain" Hess was awarded the 1949 Nobel Prize for physiology or medicine, sharing it with Antonio EGAS MONIZ.

### **Hevelius, Johannes** (1611–1687) *German astronomer*

I prefer the unaided eye.

Hevelius (hay-**vay**-lee-uus) was the son of a prosperous brewer from Danzig (now Gdańsk in Poland). He followed his father in the family business as well as devoting himself to civic duties. After studying in Leiden, he established his own observatory on the rooftops of several houses overlooking the Vistula, an observatory which soon gained him an international reputation.

He published several major works of observational astronomy. Four years' telescopic study of the Moon, using telescopes of long focal power, led to his *Selenographia* (1647; Pictures of the Moon). Making his own engravings of the Moon's surface he assigned names to the lunar mountains, craters, and plains taken from the Earth, placing, with what the writer Sir Thomas Browne called "witty congruity," "... the Mediterranean Sea, Mauritania, Sicily, and Asia Minor in the Moon." This system of naming, apart from the Alps, did not survive long, Giovanni RICCIOLI's alternative system of scientific eponymy being preferred. His star catalog *Prodromus astronomiae* (Guide to Astronomy) was published posthumously in 1690.

Hevelius is today best remembered for his "aerial" telescopes of enormous focal length and his rejection of telescopic sights for stellar observation and positional measurement. He was widely criticized for the latter eccentricity and in 1679 was paid a famous visit by Edmond HALLEY who had been instructed by Robert HOOKE and John FLAMSTEED to persuade him of the advantages of the new telescopic sights. Hevelius claimed he could do as well with his

quadrant and alidade. Halley tested him thoroughly, finding to his surprise that Hevelius could measure both consistently and accurately. He is therefore the last astronomer to do major observational work without a telescope.

### **Hevesy, George Charles von** (1885–1966) *Hungarian–Swedish chemist*

Hevesy (he-ve-shee) came from a family of wealthy industrialists in Budapest, the Hungarian capital. He was educated in Budapest and at the University of Freiburg where he obtained his doctorate in 1908. He then worked in Zurich, Karlsruhe, Manchester, and Copenhagen, before his appointment to the chair of physical chemistry in 1926 at Freiburg. In 1935 he left Germany for Denmark, fleeing from the Nazis who caught up with him once more in 1942, when he sought refuge in Sweden at the University of Stockholm.

In 1923 Hevesy discovered the new element hafnium in collaboration with Dirk Coster. His most important work, however, began in 1911 in the Manchester laboratory of Ernest RUTHERFORD, where he worked on the separation of "radium D" from a sample of lead. In fact radium D was a radioactive isotope of lead (lead-210) and could not be separated by chemical means. Hevesy was quick to see the significance of this and began exploring the use of radioactive isotopes as tracers. In 1913, with Friedrich Adolph PANETH, he used radioactive salts of lead and bismuth to determine their solubilities. In 1923 Hevesy made the first application of a radioactive tracer – Pb-212 – to a biological system. The Pb-212 was used to label a lead salt that plants took up in solution. At various time intervals plants were burned and the amount of lead taken up could be determined by simple measurements of the amount of radioactivity present. The drawback of this technique was the high toxicity of lead to most biological systems and it was only with the discovery of artificial radioactivity by Irène and Frédéric JOLIOT-CURIE in 1934 that Hevesy's radioactive tracers developed into one of the most widely used and powerful techniques for the investigation of living and of complex systems. For his work in the development of radioactive tracers Hevesy was awarded the 1943 Nobel Prize for chemistry.

### **Hewish, Antony** (1924– ) *British radio astronomer*

Hewish was born at Fowey in Cornwall, England, and studied at Cambridge University. He obtained his BA in 1948 and his PhD in 1952 after wartime work with the Royal Aircraft Establishment, Farnborough. He lectured in physics at Cambridge until in 1969 he was made reader and in 1971 professor of radio astronomy, becoming professor emeritus in 1989.

He continues to work part-time at Cambridge. In 1974 he was awarded the Nobel Prize for physics jointly with Martin RYLE.

One of Hewish's research projects was the study of radio scintillation using the 4.5-acre telescope, which consisted of a regular array of 2,048 dipoles operating at a wavelength of 3.7 meters. Radio scintillation is a phenomenon, similar to the twinkling of visible stars, arising from random deflections of radio waves by ionized gas. The three types of scintillation are caused by ionized gas in the interstellar medium, in the interplanetary medium, and in the Earth's atmosphere. All three types were discovered at Cambridge and Hewish was involved in their investigation. In 1967 a research student, Jocelyn BELL-BURNELL, noticed a rapidly fluctuating but unusually regular radio signal that turned out to have a periodicity of 1.33730113 seconds. She had discovered the first pulsar.

To determine the nature of the signal, Hewish's first job was to eliminate such man-made sources as satellites, radar echoes, and the like. Measurements indicated that it must be well beyond the solar system. It seemed possible that it had been transmitted by an alien intelligence and the LGM (Little Green Men) hypothesis, as it became known, was seriously considered at Cambridge, but with the rapid discovery of three more pulsars it was soon dropped.

Hewish did however manage to establish some of the main properties of the pulsar from a careful analysis of its radio signal. Apart from its striking regularity (it was later shown to be slowing down very slightly) it was extremely small, no more than a few thousand kilometers, and was situated in our Galaxy.

By the end of February 1968 Hewish was ready to publish. His account received wide publicity in the popular press and stimulated much thought among astronomers as to the possible mechanism. The proposal made by Thomas GOLD and others that pulsars were rapidly rotating neutron stars has since won acceptance.

### **Heymans, Corneille Jean François** (1892–1968) *Belgian physiologist and pharmacologist*

Heymans (**hI**-mahns) was educated at the university in his native city of Ghent, where his father was professor of pharmacology, obtaining his MD in 1920. He began as a pharmacology lecturer there in 1923 and in 1930 succeeded his father, holding the chair until his retirement in 1963.

In 1924 Heymans began a series of important cross-circulation experiments. The relationship between respiration and blood pressure had been known for some time – high arterial pressure (hypertension) inhibited res-

piration while low pressure (hypotension) stimulated it – but the mechanism of such a response was far from clear. Heymans's basic experiment consisted of separating the head of a dog from its body in such a way that its only remaining contact with the body was the nervous supply to the heart. The body of the dog could be made to respire artificially while its head could be linked up to the blood supply of a second dog. Even in such circumstances, hypotension produced an increase in the rate of respiration while hypertension inhibited it. This suggested to Heymans that the process was due not to direct action of the blood pressure on the respiratory center but to nervous control.

Heymans went on to show the important role played in the regulation of heart rate and blood pressure by the carotid sinus, an enlargement of the carotid artery in the neck. By severing the sinus from its own blood supply while maintaining its nervous connection and linking it up to the blood supply of another animal he was able to show that changes of pressure initiated nervous reflexes that automatically reversed the process. The sinus was in fact a sensitive pressure receptor. He also demonstrated that a nearby glandlike structure, the glomus caroticum, was a chemoreceptor, responding to changes in the oxygen/carbon dioxide ratio in the blood.

For his work on the regulation of respiration Heymans was awarded the 1938 Nobel Prize for physiology or medicine.

### **Heyrovský, Jaroslav** (1890–1967) *Czech physical chemist*

The reason why I keep some 38 years to ... the dropping mercury electrode is its exquisite property as electrode material.  
—Nobel Prize address, 1959

Heyrovský (**hay**-rawf-skee), the son of an academic lawyer, was educated at Charles University in his native Prague and at University College, London. He joined the staff of Charles University in 1919 where he served as professor of physics from 1919 until 1954. From 1950 he was also head of the Central Polarographic Institute, which, since 1964, has borne his name.

Heyrovský is best known for his discovery and development of polarography, which he described in 1922. This is one of the most versatile of all analytical techniques. It depends on the fact that in electrolysis the ions are discharged at an electrode and, if the electrode is small, the current may be limited by the rate of movement of ions to the electrode surface. In polarography the cathode is a small drop of mercury (constantly forming and dropping to keep the surface clean). The voltage is increased slowly and the current plotted against voltage. The current increases in steps, each corre-

sponding to a particular type of positive ion in the solution. The height of the steps indicates the concentration of the ion. For his work, Heyrovský was awarded the Nobel Prize for chemistry in 1959.

**Higgins, William** (1763–1825) *Irish chemist*

Born at Colooney in Ireland, Higgins worked in London as a young man with his uncle, Bryan Higgins, the chemist. He studied at Oxford University from 1786 and on his return to Ireland became, in 1791, chemist to the Apothecaries Company of Ireland. He moved to Dublin in 1795 to become chemist and librarian to the Royal Dublin Society, this post being made into a professorship in 1800. From 1795 to 1822 he was chemist to the Irish Linen Board.

Higgins is remembered for his contributions to the new atomic theory and for his claim to have anticipated John DALTON. His claim is based on his work *A Comparative View of the Phlogistic and Antiphlogistic Theories with Inductions* (1789), which was written as a reply to Richard KIRWAN's work.

He introduced a clearer symbolism system than that of Dalton but did not follow up his work on atomism until he published a strong attack on Dalton's work in his eight-volume work *Experiments and Observations on the Atomic Theory and Electrical Phenomena* (1814).

Higgins spent the intervening years between these publications trying to introduce new chemical technology into Ireland. In 1799 he published an *Essay on the Theory and Practice of Bleaching*, a work written specifically for the bleachers themselves.

**Higgs, Peter Ware** (1929– ) *British theoretical physicist*

Higgs was born at Bristol in the west of England and educated at Kings College, London, where he completed his PhD in 1955. He worked initially at the University of London but moved to Edinburgh University in 1960 and was elected professor of theoretical physics there in 1980. He is currently emeritus professor. In 2004 he was awarded the Wolf Prize for physics.

Along with many other physicists in the 1960s, Higgs worked on proposals to unify the weak and the electromagnetic forces into a single electroweak theory. At very high temperatures the two forces and their carriers, photons for the electromagnetic force and the W and Z bosons for the weak force, would be indistinguishable. But, at lower temperatures, the symmetry breaks down and massless photons are obviously distinct from the massive W and Z bosons. In 1964 Higgs worked out a mechanism for the breakdown in symmetry, since known as

the *Higgs field*, which would endow the bosons with mass. At the same time, he noted, the mechanism would also produce another massive particle, the *Higgs boson*.

The existence of this particle, it has been claimed, will be the ultimate test of the correctness of the electroweak theory, and of the standard model of particle physics itself. Yet no sign of the particle has so far been detected. The failure is normally explained away by pointing out that the Higgs boson probably has a mass in excess of 1 TeV ( $10^9$  electron volts), well beyond the capacity of any current accelerator. It will therefore be the first task of the Superconducting Proton Synchrotron, with an expected capacity of 20 TeV, if ever completed, to search for the Higgs boson.

**Hilbert, David** (1862–1943) *German mathematician*

Physics is much too hard for physicists.

—Quoted by Constance Reid in *Hilbert* (1970)

One hears a good deal nowadays of the hostility between science and technology. I don't think that is true, gentlemen. I am quite sure that it isn't true, gentlemen. It almost certainly isn't true. It really can't be true. *Sie haben ja gar nichts einander zu tun* [They have nothing whatever to do with one another].

—Quoted by J. R. Oppenheimer in *Physics in the Contemporary World*

Hilbert (**hil-bairt**) studied at the university in his native city of Königsberg (now Kaliningrad in Russia) and at Heidelberg; he also spent brief periods in Paris and Leipzig. He took his PhD in 1885, the next year became *Privatdozent* at Königsberg, and by 1892 had become professor there. In 1895 he moved to Göttingen to take up the chair that he occupied until his official retirement in 1930.

Hilbert's mathematical work was very wide ranging and during his long life there were few fields to which he did not make some contribution and many he completely transformed. His attention was first turned to the newly created theory of invariants and in the period 1885–88 he virtually completed the subject by solving all the central problems. However, his work on invariants was very fruitful as he created entirely new methods for tackling problems in the context of a much wider general theory. The fruit of this work consisted of many new and fundamental theorems in algebra and in particular in the theory of polynomial rings. Much of his work on invariants turned out later to have important application in the new subject of homological algebra.

Hilbert now turned to algebraic number theory where he did what is probably his finest research. Hilbert and MINKOWSKI had been asked to prepare a report surveying the current state of number theory but Minkowski soon dropped out, leaving Hilbert to produce not only

a masterly account but also a substantial body of original and fundamental new discoveries. The work was presented in the *Zahlbericht* (1897; Report on Numbers) with an elegance and lucidity of exposition that has rarely been equaled.

Hilbert then moved to another area of mathematics and wrote the *Grundlagen der Geometrie* (1899; Foundations of Geometry), giving an account of geometry as it had developed through the 19th century. Here his interest lay chiefly in expounding and illuminating the work of others in a systematic way rather than in making new developments of the subject. He devised an abstract axiomatic system that could admit many different geometries – Euclidean and non-Euclidean – as models and by this means go much further than had previously been done in obtaining consistency and independence proofs for various sets of geometrical axioms. Apart from its importance for pure geometry his work led to the development of a number of new algebraic concepts and was particularly important to Hilbert himself because his experience with the axiomatic method and his interest in consistency proofs shaped his approach to mathematical logic and the foundations of mathematics.

In mathematical logic and the philosophy of mathematics Hilbert is a key figure, being one of the major proponents of the formalist view, which he expounded with much greater precision than had his 19th-century precursors. This philosophical view of mathematics had a formative impact on the development of mathematical logic because of the central role it gave to the formalization of mathematics into axiomatic systems and the study of their properties by metamathematical means. Hilbert aimed at formalizing as much of mathematics as possible and finding consistency proofs for the resulting formal systems. It was soon shown by Kurt GÖDEL that *Hilbert's program*, as this proposal is called, could not be carried out, at least in its original form, but it is nonetheless true that Gödel's own revolutionary metamathematical work would have been inconceivable without Hilbert. Hilbert's contribution to mathematical logic was important, especially to the development of proof theory, as further developed by such mathematicians as Gerhard Gentzen.

Hilbert also made notable contributions to analysis, to the calculus of variations, and to mathematical physics. His work on operators and on *Hilbert space* (a type of infinite-dimensional space) was of crucial importance to quantum mechanics. His considerable influence on mathematical physics was also exerted through his colleagues at Göttingen who included Minkowski, Hermann WEYL, Erwin SCHRÖDINGER, and Werner HEISENBERG.

In 1900 Hilbert presented a list of 23 outstanding unsolved mathematical problems to

the International Congress of Mathematicians in Paris. A number of these problems still remain unsolved and the mathematics that has been created in solving the others has fully vindicated his deep insight into his subject. Hilbert was an excellent teacher and during his time at Göttingen continued the tradition begun in the 19th century and built the university into an outstanding center of mathematical research, which it remained until the dispersal of the intellectual community by the Nazis in 1933. Hilbert is generally considered one of the greatest mathematicians of the 20th century and indeed of all time.

### Hildebrand, Joel Henry (1881–1983) *American chemist*

A child of the new generation  
Refused to learn multiplication.  
He said, "Don't conclude  
That I'm stupid or rude;  
I am simply without motivation."

—*Perspectives in Biology and Medicine* (1970)

Hildebrand was born in Camden, New Jersey, and educated at the University of Pennsylvania and at the University of Berlin, where he obtained his PhD in 1906. He returned to Pennsylvania in 1907, but moved to the University of California, Berkeley, in 1913 and served there as professor of chemistry from 1918 until his retirement in 1952.

Hildebrand, the author with R. Powell of a widely read textbook, *Principles of Chemistry* (1964; 7th edition), was engaged in chemical research for virtually the whole of the century. He worked on fluorine chemistry, intermolecular forces, and, above all, on the theory of solubility. Even in his nineties Hildebrand continued with his researches, producing in 1976 a substantial monograph on the subject of viscosity and diffusion.

### Hilditch, Thomas Percy (1886–1965) *British chemist*

A Londoner, Hilditch was educated at the University of London, where he was awarded a DSc in 1911. After further studies in Jena and Geneva he joined the research laboratories of Joseph Crosfield and Sons Ltd., a soap and chemical manufacturer (1911–25). There he began his studies of fat chemistry for which he is best known. He published over 300 papers in this field and produced two standard works, *The Chemical Constitution of Natural Fats* (1940) and *Industrial Chemistry of Fats and Waxes* (1927).

In 1926 Hilditch became the first John Campbell Brown Professor of Industrial Chemistry at Liverpool University, where he remained until his retirement in 1951. He established a large research school of fat chemistry at Liverpool, where with his coworkers he established the fatty acid and glyceride com-

position of a large number of fats and oils – over 1,450 such substances were dealt with in the fourth edition of his 1940 work published in 1964.

**Hill, Archibald Vivian** (1886–1977) *British physiologist and biochemist*

Born at Bristol in the west of England, Hill was professor of physiology at Manchester University (1920–23) and then Jodrell Professor at University College, London, from 1923 to 1925 (and honorary professor from 1926 to 1951). He was Foulerton Research Professor of the Royal Society (1926–51), of which he was also for some years both secretary and foreign secretary. From 1940 until 1946 he was the Independent Conservative member of Parliament for Cambridge University and a member of the War Cabinet Scientific Advisory Committee.

Hill's major research was directed toward accurately recording the minute quantities of heat produced during muscle action. For this he used thermocouples, which recorded the smallest variations in heat generated after the muscle had completed its movement. He was able to show that oxygen was only consumed *after* muscular contraction, and not during it, indicating that molecular oxygen is required only for muscle recovery. In 1922 he shared the Nobel Prize for physiology or medicine (with Otto Meyerhof) for this work on the physiology of muscular contraction.

**Hill, James Peter** (1873–1954) *British embryologist*

Hill, the son of a farmer from Kennoway in Scotland, was educated at the University of Edinburgh and the Royal College of Science, London. He taught in Australia at the University of Sydney from 1892 until 1906 when he returned to England as Jodrell Professor of Zoology at University College, London. In 1921 he became professor of embryology and histology, a post he retained until his retirement in 1938.

Beginning during his time in Australia, Hill spent most of his life working on monotreme and marsupial embryology, a virtually unexplored area. Hill totally dominated the field and in his numerous monographs on the subject revealed the evolutionary relationships between the primitive mammals.

**Hillier, James** (1915–2005) *Canadian-American physicist*

Born in Brantford, Ontario, Hillier was educated at the University of Toronto, where he gained successively his BA (1937), MA (1938), and PhD in physics (1941). He went to live and work in America in 1940 and became a naturalized citizen in 1945. From 1940 to 1953 he worked for the Radio Corporation of America (RCA) Laboratories as a research physicist, pri-

marily on the development of the electron microscope.

Many efforts were being made around the world to develop a commercial electron microscope that could offer higher resolution than optical microscopes. It had been known since the 1920s that a shaped magnetic field could act as a "lens" for electrons, and in the 1930s the first electron micrographs had been taken. Hillier and his colleagues at RCA designed and built the first successful high-resolution electron microscope in America in 1940; they had in fact been anticipated by Ernst RUSKA and Max Knoll who had produced a similar machine for the Siemens and Halske Company in Germany in 1938. The outbreak of war prevented commercial development and exploitation of the German machine.

Hillier made many instrumental advances to the electron microscope. By 1946 he had achieved resolutions (magnifications) approaching close to the theoretical limits. He also involved himself in the development of techniques for the preparation of viral and bacteriological samples for examination.

Hillier's career at RCA continued with only a short break to his position of executive vice-president for research engineering. He was principally concerned with research management and served on various American governmental, research, and engineering committees.

**Hinshelwood, Sir Cyril Norman** (1897–1967) *British chemist*

Hinshelwood, a Londoner, was educated at Oxford University, where he was elected to a fellowship in 1920 and obtained his doctorate in 1924. In 1937 he became Dr. Lee's Professor of Chemistry at Oxford. He retired in 1964 when he moved to Imperial College, London, as a senior research fellow.

Hinshelwood worked mainly in the field of chemical reaction kinetics. He produced a major text on the subject, *The Kinetics of Chemical Change in Gaseous Systems* (1926) and, in 1956, shared the Nobel Prize for chemistry with Nicolay SEMENOV for his work. He later applied his work to a relatively new field in his book, *The Chemical Kinetics of the Bacterial Cell* (1954).

In some papers published earlier, in 1950, Hinshelwood came very close to the true meaning of DNA, established by James WATSON and Francis CRICK three years later. He declared that in the synthesis of protein the nucleic acid guides the order in which the various amino acids are laid down. Little attention was paid to Hinshelwood's proposal at the time although Crick later declared it to be the first serious suggestion of how DNA might work.

Hinshelwood was a linguist and classical scholar as well as a scientist; he had the unique distinction of serving as president of both the

Royal Society (1955–60) and the Classical Association. He was knighted in 1948.

**Hipparchus** (c. 170 BC–c. 120 BC) *Greek astronomer and geographer*

Born at Nicaea, which is now in Turkey, Hipparchus (hi-**par**-kus) worked in Rhodes, where he built an observatory, and in Alexandria. None of his works have survived but many of them were recorded by PTOLEMY. In 134 BC he observed a new star in the constellation of Scorpio. This led him to construct a catalog of about 850 stars. By comparing the position of the stars of his day with those given 150 years earlier he found that Spica, which was then 6° from the autumn equinox, had previously been 8°. He used this observation to deduce not the movement of Spica but the east to west precession (motion) of the equinoctial point. He calculated the rate of the precession as about 45 seconds of arc a year – a value close to the 50.27 seconds now accepted. He also introduced the practice of dividing the stars into different classes of magnitude based on their apparent brightness. The brightest stars he classed as first magnitude and those just visible to the naked eye he classed as sixth magnitude.

As a theorist Hipparchus worked on the orbits of the Sun and Moon. He established more accurate lengths of both the year and the month and was able to produce more accurate eclipse predictions. One of his lasting achievements was the construction of a table of chords, which virtually began the discipline of trigonometry. The concept of a sine had not yet been developed. Instead, Hipparchus calculated the ratio of the chord to the diameter of its own circle, which was divided into 120 parts. Thus if a chord produced by an angle of 60° is half the length of the radius, it would have, for Hipparchus, 60 parts. He much improved the geography of ERATOSTHENES, fixing the parallels astronomically.

**Hippocrates of Cos** (c. 460 BC–c. 370 BC) *Greek physician*

We must turn to nature itself, to the observations of the body in health and disease to learn the truth.

—*Aphorisms*

Science is the father of knowledge, but opinion breeds ignorance.

—*The Canon Law*

Very little is known of the life of Hippocrates (hi-**pok**-ra-teez) except that he was born on the Greek island of Cos. The main source, Soranus, dates from the second century AD and was clearly telling a traditional tale rather than writing a biography. Hippocrates is reported to have studied under his father Heraclides, also a physician, and with the atomist DEMOCRITUS and the sophist Gorgias. He then seems to have

spent most of his life traveling around the Greek world curing the great of obscure diseases and ridding grateful cities of plagues and pestilence.

After the fantasy of his life there is the reality of the *Corpus Hippocraticum* (The Hippocratic Collection). This consists of some 70 works though whether any were actually written by Hippocrates himself will probably always remain a matter of speculation. What is clear, on stylistic and paleographic grounds, is that the corpus was produced by many hands in the second half of the fifth century and the first part of the fourth. Nor do the works represent a single “Hippocratic” point of view but, it has been suggested, probably formed the library of a physician and acquired the name of its first owner or collector.

Of more importance is the character of these remarkable works. They are surprisingly free of any attempt to explain disease in theological, astrological, diabolic, or any other spiritual terms. Diseases in the *Corpus* are natural events, which arise in a normal manner from the food one has eaten or some such factor as the weather. The cause of the disease is for the Hippocratic basically a malfunction of the veins leading to the brain which, though no doubt false, is the same kind of rational, material, and verifiable claim that could be found in any late 20th-century neurological textbook.

Such rationality was not to rule for many years for in the fourth century BC new cults entered Greece and with them the dream, the charm, and other such superstitions entered medicine. More successful in the length of its survival was the actual theory of disease contained in the *Corpus*. This was the view, first formulated by ALICMAEON in the fifth century BC, that health consists of an *isonomia* or equal rule of the bodily elements rather than a *monarchia* or domination by a single element. By the time of Hippocrates it was accepted that there were just four elements, earth, air, fire, and water with their corresponding qualities, coldness, dryness, heat, and wetness. If present in the human body in the right amounts in the right places health resulted, but if equilibrium was destroyed then so too was health.

A new terminology developed to describe such pathological conditions, a terminology still apparent in most western languages. Thus an excess of earth, the cold/dry element, produced an excess of black bile, or in Greek melancholic, in the body; too much water, the cold/moist element, made one phlegmatic.

One striking contrast between Hippocratic and later medicine is the curious yet impressive reluctance of the former to attempt cures for various disorders: the emphasis is rather on prognosis. For example, the *Epidemics* describes the course, but not treatment, of various complaints. At least knowing the expected course and outcome of an illness helped the

practitioner to inform his patient what to expect, information that could be useful and reassuring. Further, if it is known which conditions lead to a disease such conditions could sometimes be avoided.

The works *Regimen in Acute Diseases* and *Regimen in Health*, which deal specifically with therapy, tend to restrict themselves to diet, exercise, bathing, and emetics. Thus the Hippocratic doctor may not have cured many of his patients but he was certainly less likely than his 18th-century counterpart to actually kill them.

### **Hirsch, Sir Peter Bernhard** (1925– ) *British metallurgist*

Hirsch, who was born in Berlin, Germany, gained his doctorate from Cambridge University in 1951. Continuing at Cambridge he lectured in physics from 1959 and took a readership in 1964. In 1966 he moved to the University of Oxford where he was Isaac Wolfson Professor of Metallurgy from 1966 to 1992. His research interests include the development of the Oxford field-emission scanning transmission electron microscope, the weak-beam technique of electron microscopy, and electron microscopy of the chemical behavior of metal oxides. Hirsch is known principally for his pioneering work in applying the electron microscope to the study of imperfections in the crystalline structure of metals, and in relating these defects to mechanical properties. He showed, for instance, that dislocations (faults) play an important part in theories of work-hardening.

### **Hirst, Sir Edmund Langley** (1898–1975) *British chemist*

Hirst, the son of a baptist minister from Preston in the north of England, was educated at St. Andrews University, where he worked with Norman HAWORTH and obtained his PhD in 1921. He continued working with Haworth at the universities of Durham and Birmingham, where Hirst served as reader in natural products from 1934 until 1936 when he was appointed professor of organic chemistry at Bristol University. He moved to Manchester in 1944 but held the chair of organic chemistry there only until 1947 when he accepted a similar post at the University of Edinburgh. Here he remained until his retirement in 1968.

Hirst worked mainly in the field of carbohydrate chemistry, collaborating with Haworth over a long period in working out the structure and synthesis of various sugars. He succeeded in showing that the ring structure of stable methyl glycosides, for example of xylose, rhamnose, arabinose, and glucose, are actually six-membered and not, as previously assumed,

five-membered. That is, they have the pyranose rather than the furanose ring structure.

Hirst is also known for determining the structure of vitamin C and, in collaboration with Haworth, managing to synthesize this compound – the first chemical synthesis of a vitamin.

### **His, Wilhelm** (1831–1904) *Swiss anatomist and physiologist*

His (hiss), a merchant's son from Basel in Switzerland, studied at a number of German and Swiss universities before graduating from the university in his native city in 1854. He served on the staff there as professor of anatomy and physiology from 1857 until 1872 when he moved to a comparable post at the University of Leipzig, which he retained until his death.

His did much to redirect embryological research onto a more fruitful track by arguing powerfully against the so-called biogenetic law as formulated by Ernst HAECKEL. His detailed how, starting from the assumption that the embryonic layers are basically elastic sheets, the principal organs could be constructed by such straightforward processes as cutting, bending, pinching, and folding. He was the first to describe accurately the development of the human embryo. His also worked on the development of the nervous system and was able to show that nerve fibers grow from specialized kinds of cell he termed "neuroblasts."

He had earlier, in 1866, introduced into science that invaluable instrument the microtome. This permitted the cutting of extremely thin slices, a few microns thick, for staining and microscopic examination.

One discovery frequently attributed to His, namely the *bundles of His* – a specialized bundle of fibers connecting the cardiac auricles and ventricles – have nothing to do with him. They were in fact first described by his son, also named Wilhelm, professor of medicine at the University of Berlin.

### **Hisinger, Wilhelm** (1766–1852) *Swedish mineralogist*

Hisinger (**hee**-sing-er) was the son of a wealthy iron foundry owner from Skinnatersberg in Sweden. Following his father's death he ran the family business and also devoted himself to private geological research.

One of his iron mines at Bastnäs produced a mineral with an unexpectedly high density and Hisinger studied this mineral over the years, sending samples to some of the most expert analysts of Europe. Martin KLAPROTH who examined it in 1803 became convinced that it contained a new element. Shortly afterwards both Jöns BERZELIUS and Hisinger isolated a new element from it, which they called cerium,

after the new minor planet Ceres, discovered by Giuseppe PIAZZI in 1801.

Hisinger also made major contributions to the growth of geological knowledge, publishing a geological map of southern and central Sweden (1832) and an account of the fossils of Sweden (1837–41).

**Hitchings, George Herbert** (1905–1998)  
*American pharmacologist*

Hitchings, the son of a naval architect, was born in Hoquiam, Washington, and educated at the University of Washington and at Harvard where he obtained his PhD in 1933 and where he taught until 1939. He then moved briefly to Western Reserve University until in 1942 he joined the Wellcome Research Laboratories, where he spent the rest of his career, serving as vice president in charge of research from 1966 until his retirement in 1975.

Hitchings was one of the most productive of modern chemical pharmacologists. He began in 1942 with the study of purines and pyrimidines on the grounds that, as important ingredients in cell metabolism, their manipulation could lead to the control of important diseases at the cellular level. This insight led to the synthesis in 1951 of the purine analog, 6-mercaptopurine (6MP), which, as it inhibited DNA synthesis and thus cellular proliferation, proved valuable in the treatment of cancer, particularly leukemia.

In 1959 6MP was found to inhibit the ability of rabbits to produce antibodies against foreign proteins. A less toxic form, azathioprine or Imuran, was quickly developed by Hitchings and used in 1960 by the surgeon Roy Calne to control rejection of transplanted kidneys.

One further drug was developed from work on 6MP when it was realized that it was broken down in the body by the enzyme xanthine oxidase, the same enzyme that converts purines into uric acid. As gout is caused by an excess of uric acid Hitchings developed allopurinol, which blocks uric acid production by competing for xanthine oxidase.

Other drugs developed by Hitchings include the malarial prophylactic pyrimethamine, or Daraprim, and the antibacterial, trimethoprim. Hitchings shared the 1998 Nobel Prize for physiology or medicine with his long-time collaborator Gertrude ELION and with James BLACK.

**Hittorf, Johann Wilhelm** (1824–1914)  
*German chemist and physicist*

Born at Bonn in Germany, Hittorf (**hit**-orf) became professor of chemistry and physics at the University of Münster in 1852 and later became director of laboratories there (1879–89).

He carried out fundamental work on electrolytes, publishing, in 1853, his paper *The Migration of Ions during Electrolysis*. Hittorf

showed that changes in concentration around electrodes during electrolysis could be understood if it was assumed that not all ions move with the same speed. He showed how the relative speeds of ions could be calculated from changes in concentration. He also introduced the ideas of complex ions and transport numbers (sometimes called the Hittorf numbers). The transport number of a given ion in an electrolyte is the fraction of total current carried by that ion.

Hittorf was also one of the first to experiment on cathode rays, noting as early as 1868 that obstacles put in their way would cast shadows.

**Hitzig, Eduard** (1838–1907) *German psychiatrist*

I believe that intelligence, or more accurately, the storage of ideas, is to be looked for in all portions of the cerebral cortex, or rather in all parts of the brain.

—*Über die Funktionen der Grosshirnrinde* (1874; On the Function of the Cerebral Cortex)

Incorigible conceit and vanity complicated by Prussianism.

—Anon. on Hitzig

Hitzig (**hit**-sik), the son of a Berlin architect, was educated at the university there and obtained his MD in 1862. He was later appointed, in 1875, director of the Berghölzi asylum and professor of psychiatry at the University of Zurich. In 1885 Hitzig moved to similar posts at the University of Halle, posts he retained until his retirement in 1903.

In 1870, in collaboration with Gustav FRITSCH, Hitzig published a fundamental paper, *On the Excitability of the Cerebrum*, which provided the first experimental evidence for cerebral localization. Following the important work of Pierre FLOURENS in 1824 it was widely accepted that, despite the discoveries of Paul BROCA and John Neethlings Jackson, the cerebral hemispheres constituted a unity, the seat of intelligence, sensation, and volition and not the source of movement.

This was shown to be false when Hitzig and Fritsch electrically stimulated the cerebral cortex of a dog and elicited distinct muscular contractions. They identified five localized centers, which produced various movements on the side of the dog opposite to the side of the brain stimulated. Their work was soon confirmed by David FERRIER and opened up a vast research program, still, a century later, unfinished.

Hitzig himself continued with this work and in 1874 tried to define what soon became known as the motor area of the dog and the monkey. He also tried to identify, though less successfully, the site of intelligence, in the sense of abstract ideas, in the frontal lobes.

**Hjelm, Peter Jacob** (1746–1813) *Swedish chemist and metallurgist*

Hjelm (yelm), who was born at Sunnerbo, Sweden, studied at the University of Uppsala and became assay master of the Royal Mint in Stockholm in 1782. In the same year he discovered the element molybdenum. At the time, the term “molybdaena” (a Latin form of a Greek word for “lead”) was used for a number of substances, including the substances now known as graphite and molybdenite. Karl SCHEEL showed that the mineral molybdenite with nitric acid produced sulfuric acid and an insoluble residue, which he suspected contained a new element. Lacking the appropriate equipment to reduce this, he called on the assistance of Hjelm, who obtained the metallic element molybdenum. This was later obtained in pure form by Jöns BERZELIUS in 1817.

**Hoagland, Mahlon Bush** (1921– ) *American biochemist*

Hoagland was born in Boston, Massachusetts, the son of Hudson Hoagland, a distinguished neurophysiologist. Having obtained his MD from Harvard in 1948, he joined the Huntington Laboratories of the Massachusetts General Hospital. He then served in the Harvard Medical School from 1960 until 1967 when he became professor of biochemistry at Dartmouth. From 1970 to 1985 he was scientific director of the Worcester Institute for Experimental Biology, founded by his father and Gregory PINCUS in 1944.

In early 1955 Francis CRICK published his “adaptor” hypothesis to explain protein synthesis by the cell. Unaware of this work, Hoagland, in collaboration with Paul Zamecnick and Mary Stephenson, provided the experimental confirmation in 1956. It had earlier been shown by George PALADE that protein synthesis occurred outside the nucleus in the ribosomes. Hoagland and Zamecnick discovered that before the amino acids reach the ribosomes to be synthesized into protein, they are first activated by forming a bond with the energy-rich adenosine triphosphate (ATP).

What happened in the ribosome was unveiled by forming a cell-free mixture of ATP, the radioactively labeled amino acid leucine, enzymes, and some of the small soluble RNA molecules found in the cytoplasm. At this point they discovered the crucial step, predicted by Crick, in between the activation of the amino acid and its appearance in the protein; the amino acid became tightly bound to the soluble RNA. Shortly afterward the labeled leucine was no longer bound to the RNA but present in the protein. The discovery of transfer RNA (or tRNA as it soon became known) was also made independently by Paul BERG and Robert HOLLEY.

In his autobiography *Toward the Habit of*

*Truth* (1990), Hoagland described his work as a molecular biologist and sketched the history of the Worcester Institute.

**Hodge, Sir William Vallance Douglas** (1903–1975) *British mathematician*

Hodge studied at the university in his native city of Edinburgh and then at Cambridge. He later taught at Bristol University (from 1926) and in America at Princeton (1931–32). Most of his career was spent in Cambridge, England, where in 1936 he took up the Lowndean Chair in Mathematics.

Hodge’s mathematical work belongs almost entirely to algebraic geometry and although no expert on analysis or physics his work had immense impact in both these fields. Hodge’s principal contribution was to the theory of harmonic forms. One of his central results was a uniqueness theorem showing that there is a unique harmonic form with prescribed periods. In general Hodge helped to initiate the shift of focus in mathematics from a search for purely local results to the more ambitious global approach now so influential.

**Hodgkin, Sir Alan Lloyd** (1914–1998) *British physiologist*

Born at Banbury in England, Hodgkin graduated from Cambridge University and became a fellow in 1936. He spent World War II working on radar for the Air Ministry. He then worked at the physiological laboratory at Cambridge, where he served as Foulerton Research Professor from 1952 to 1969 and as professor of biophysics from 1970 until 1981. He also served from 1978 to 1984 as master of Trinity College, Cambridge; he was knighted in 1972.

In 1951, with Andrew HUXLEY and Bernard KATZ, he worked out the sodium theory to explain the difference in action and resting potentials in nerve fibers. Using the single nerve fiber (giant axon) of a squid, they were able to demonstrate that there is an exchange of sodium and potassium ions between the cell and its surroundings during a nervous impulse, which enables the nerve fiber to carry a further impulse. Hodgkin also showed that the nerve fiber’s potential for electrical conduction was greater during the actual passage of an impulse than when the fiber is resting. For their work on the “sodium pump” mechanism and the chemical basis of nerve transmission, Hodgkin, Huxley, and John ECCLES shared the Nobel Prize for physiology or medicine in 1963. Hodgkin wrote *Conduction of the Nervous Impulse* (1964) and in 1992 he published his autobiography *Chance and Design: Reminiscences of Science in Peace and War*.

**Hodgkin, Dorothy Crowfoot** (1910–1994) *British chemist*

I'm really an experimentalist. I used to say "I think with my hands." I just like manipulation.

—Quoted by L. Wolpert and A. Richards in *A Passion for Science* (1988)

Born Dorothy Crowfoot in Cairo, Egypt, she was educated at Somerville College, Oxford. After a brief period as a postgraduate student at Cambridge University, she returned to Oxford in 1934 and spent her entire academic career there. She served as Wolfson Research Professor of the Royal Society from 1960 until 1977.

Hodgkin had the good fortune to fall under the influence of the inspiring and scientifically imaginative physicist J. D. BERNAL at Cambridge. Bernal was eager to use the technique of x-ray diffraction analysis, introduced by Max VON LAUE in 1912, to investigate important complex organic molecules. He gathered around him a group of enthusiastic scientists to work out the appropriate techniques. Of the Bernal group, Hodgkin was probably the most talented; she also possessed a greater single-mindedness than Bernal himself and, despite the demands of three young children and a busy political life, it was her persistence and talent that produced some of the first great successes of x-ray analysis.

Her first major result came in 1949 when, with Charles Bunn, she published the three-dimensional structure of penicillin. This was followed by the structure of vitamin B<sub>12</sub> (by 1956) and, in 1969, that of insulin. For her work on vitamin B<sub>12</sub> she was awarded the Nobel Prize for chemistry in 1964.

### **Hodgkin, Thomas** (1798–1866) *British pathologist*

Hodgkin, the son of the grammarian John Hodgkin, was born in London and graduated in medicine from Edinburgh in 1823. After further study abroad and practice in London he was appointed in 1825 as pathologist at Guy's Hospital. He resigned in 1837 to devote himself to his practice and, increasingly, to the affairs of the Aborigines' Protection Society, which he helped to found in 1838.

Hodgkin is widely known for his description of lymphadenoma, first described in his paper *On Some Morbid Appearances of the Absorbent Glands and the Spleen* (1832), and named Hodgkin's disease by Samuel Wilks in 1865. Hodgkin reported six cases, in all of whom he found enlargement of the glands in the neck, armpit, and groin together with, in five of the cases, a diseased spleen. However, later studies by Wilks employing the microscope, which Hodgkin did not use, revealed that some of Hodgkin's cases were actually different conditions.

### **Hoff, Marcian Edward** (1937– ) *American computer engineer*

It's like a light bulb. When it's broken, unplug it, throw it away and plug in another.

—When asked how he would repair a chip

Hoff gained his doctorate in 1962 at Stanford, where he worked for a further six years as a research associate. In 1968 he was invited by Robert NOYCE to join his newly formed semiconductor firm, Intel.

Noyce had earlier shown how to assemble a large number of transistors into an integrated circuit (IC). Shortly after joining Intel, Hoff was asked to help some Japanese engineers design a number of IC chips to be used in desktop calculators.

Hoff proposed a calculator that could perform simple hardware instructions but could store complex sequences of these instructions in read-only memory (ROM) on a chip. The result of his idea was the first microprocessor – the Intel 4004 – released in 1971. Despite initial debate about its use and marketability, it became the forerunner of a whole range of advanced microprocessors, leading to a new generation of computers.

Hoff left Intel in 1982 to move to the computer company Atari to investigate new products. When Atari was sold in 1984 Hoff set up as an independent consultant.

### **Hoffleit, (Ellen) Dorrit** (1907–2007) *American astronomer*

The daughter of German immigrants, Hoffleit was born in Florence, Alabama, and raised in Pennsylvania. She attended Radcliffe College and graduated with a BA in mathematics in 1928. Her career began as a research assistant in the astronomy department of Harvard University, and in 1938 she received her PhD. Her chief interest was the spectroscopic analysis of the brightness of stars. During World War II she computed missile trajectories for the Ballistic Research Laboratory. In 1956 she left Harvard to run the star cataloging program at Yale University, and became renowned as the author of *The Bright Star Catalogue*. Now in its fifth edition, this contains basic astronomical data for 9110 stars visible to the naked eye, and has become a standard compendium for astronomers. Hoffleit also became a coauthor of another Yale publication, the *General Catalogue of Trigonometric Stellar Parallaxes*, which contains precise distance measurements of the major stars. Hoffleit was noted for her dedicated and painstaking research, and was director (1957–78) of the Maria Mitchell Observatory, Nantucket, where she spent summers teaching and inspiring a new generation of young women astronomers. She wrote hundreds of research articles, and also an autobiography, *Misfortunes as Blessings in Disguise*. The asteroid Dorrit was named after her in 1987 in recognition of her immense contribution to astronomy.

**Hoffmann, Friedrich** (1660–1742) *German physician*

The son of a physician, Hoffman (**hof**-mahn) was born in Halle, Germany, and studied medicine at the University of Jena where he qualified in 1681. After a period of travel and further study in Holland and England, Hoffmann returned to Germany where he practiced medicine in Minden and Halberstadt. In 1693 Hoffmann was appointed professor of medicine at the University of Halle where he remained for the rest of his life apart from two periods, 1709–12 and 1734, when he served as physician at the Brandenburg court.

Hoffmann belonged to the period of medical history that had come to reject the humoral theory of disease, being one of the new generation of theorists who tried to reconstruct some alternative scheme out of the mechanical philosophy of René DESCARTES. He declared that medicine can only be a science insofar as it uses the four mechanical principles of physics – size, shape, motion, and rest. All natural phenomena and effects may be explained by resort to these principles. However, after this radical start he slipped back, believing the body consisted of an indeterminate number of elements. Various mixtures of these explained temperament, and imbalance accounted for disease.

It is clear that Hoffmann had simply translated ancient medicine into a modern terminology – there had in fact been no radical break with the past.

**Hoffmann, Roald** (1937– ) *Polish-American chemist*

Born in Zloczow, Poland (now Zolochiv in Ukraine), Hoffmann was moved at the age of four with his family to a labor camp. His father was executed for trying to escape, but Hoffmann and his mother were smuggled out in 1943 and spent the rest of the war hiding in the attic of a schoolhouse. Hoffmann has noted that only 80 of the 12,000 Jews of Zloczow survived the war. Following the liberation in mid-1944, Hoffmann's mother returned to Poland and emigrated with her son to America in 1949; he became a naturalized citizen in 1955.

Hoffmann was educated at Columbia and at Harvard, where he obtained his PhD in 1962. He moved to Cornell in 1965 and was appointed professor of chemistry in 1974.

In the mid-1960s Hoffmann began a research collaboration with R. B. WOODWARD on molecular orbital theory. Their work led to the formulation in 1965 of what are now known as the *Woodward-Hoffmann rules*. These laid down general conditions under which certain organic reactions can occur. The rules apply to pericyclic reactions. In reactions of this kind bond breaking and formation occur simultaneously without the presence of intermediates, i.e., they are said to be “concerted.” The reactions also

involve cyclic structures. Woodward and Hoffmann published their work in their *Conservation of Orbital Symmetry* (1969). Hoffmann's collaboration with Woodward won him a share of the 1981 Nobel Prize for chemistry with K. Fukui; Woodward's death in 1979, however, robbed him of his second Nobel Prize.

Hoffmann has also published two volumes of verse, *The Metamict State* and *Gaps and Verges*. He has also written and presented a number of television programs, *The World of Chemistry* and *The Molecular World*, in which he has attempted to introduce chemistry to a wider audience. A similar approach can be seen in his *The Same and Not the Same* (1995), in which he tries to describe for a popular audience how the world behaves at the molecular level.

**Hofmann, August Wilhelm von** (1818–1892) *German chemist*

Hofmann was born at Giessen and initially studied law at Göttingen. He then changed his interest to chemistry and studied with Justus von LIEBIG at the University of Giessen. In 1845 he moved to London to become director of the Royal College of Chemistry, a post he obtained through the influence of Prince Albert. In 1864 he returned to Germany, becoming a professor at the University of Berlin the following year.

August Hofmann is noted for the pioneering work he did in all areas of organic chemistry. In his investigations of coal tar he discovered aniline and this led eventually to his work on amines and organic bases. The standard reactions, the *Hofmann rearrangement* and the *Hofmann elimination*, are named for him. He had a number of important students including Richard ABEGG, Fritz HABER, and William PERKIN. Hofmann was also the originator of the ball-and-stick models used in chemistry and the colors now used (carbon = black, hydrogen = white, oxygen = red, etc.) are the ones he originally chose. It is said that the colors are the result of his use of croquet balls in the original models.

**Hofmann, Johann Wilhelm** (1818–1892) *German chemist*

Born at Giessen, Germany, Hofmann started as a law student but turned his attention to chemistry, becoming assistant to Justus von LIEBIG. In 1842 Liebig had visited England, where his impressive chemical knowledge drew attention to the lack of chemical skills and training in the UK. To overcome this problem a group led by Prince Albert opened the Royal College of Chemistry in London in 1845. Inevitably the college had to rely heavily on foreign staff to begin with, and Liebig recommended Hofmann as its director. He remained there until 1865, when he returned to Germany to take the chair at Berlin. His ap-

pointment in London was a great success; among his staff and pupils were William Henry PERKIN, Edward FRANKLAND, and William ODLING.

It is partly owing to Hofmann that Perkin was able to develop the aniline dyes, since he was working under Hofmann's direction when he made his famous discovery of mauveine, the first synthetic dye, in 1856. Hofmann himself developed a series of violet dyes based on magenta. In theoretical chemistry he worked on type theory, showing that amines are derivatives of ammonia in which a hydrogen atom is replaced by a compound radical.

**Hofmeister, Wilhelm Friedrich Benedict** (1824–1877) *German botanist*

He is represented to us as one of the leading botanists in Germany, a man with the talent of a genius, highest diligence, and excellent powers of exposition ...

—Government report quoted by E. Pfitzer in *Wilhelm Hofmeister* (1903)

The father of Hofmeister (**hof-mI-ster**), a music and book publisher from Leipzig, Germany, was also a keen amateur botanist and encouraged his son's interest in botany. Wilhelm left school at 15 and served a two-year apprenticeship in a music shop before entering his father's business in 1841. He soon began to study botany seriously in his spare time and was greatly influenced by the views of Matthias SCHLEIDEN, who believed that botany could advance rapidly if researchers concentrated on studying cell structure and life histories.

Using procedures recommended by Schleiden, Hofmeister's first work was to disprove Schleiden's theory that the plant embryo develops from the tip of the pollen tube. He believed that a preexisting cell in the embryo sac gave rise to the embryo and his paper *The Genesis of the Embryo in Phanerogams* (1849) gained him an honorary doctorate from Rostock University.

Hofmeister's major discovery, however, was to demonstrate the alternation of generations between sporophyte and gametophyte in the lower plants. The work, published in 1851 as *Vergleichende Untersuchungen* (Comparative Investigations), showed the homologies between the higher seed-bearing plants (phanerogams) and the mosses and ferns (cryptogams) and demonstrated the true position of the gymnosperms between the angiosperms and the cryptogams. In 1863 Hofmeister was appointed professor at Heidelberg University and director of the botanic gardens there, and in 1872 moved to Tübingen University to succeed Hugo von MOHL.

**Hofstadter, Douglas Richard** (1945– ) *American computer scientist*

Hofstadter's Law: it always takes longer than

you expect, even when you take into account Hofstadter's Law.

—*Godel, Escher, Bach* (1979)

Hofstadter (**hof-stat-er**), the son of Nobel laureate Robert Hofstadter, was born in New York and educated at Stanford and at the University of Oregon, where he completed his PhD (1976) in theoretical physics. He worked initially at the University of Indiana, Bloomington, but moved to the University of Michigan in 1984 to take up an appointment as professor of cognitive and computer science. In 1988 he returned to Bloomington as professor of computer science.

In 1979 Hofstadter published a remarkable book, *Godel, Escher, Bach*, described by him as "a metaphorical fugue on minds and machines." In the following year he was invited to succeed the much respected Martin Gardner as monthly columnist with *Scientific American*. For two and a half years Hofstadter contributed a column, *Metamagical Themas* (an anagram of Gardner's *Mathematical Games*).

**Hofstadter, Robert** (1915–1990) *American physicist*

A New Yorker by birth, Hofstadter graduated from the College of the City of New York in 1935 and gained his MA and PhD at Princeton University in 1938. From 1939 he held a fellowship at the University of Pennsylvania, and in 1941 returned to the College of the City of New York as an instructor in physics. From 1943 to 1946 Hofstadter worked at the Norden Laboratory Corporation, and from there took on an assistant professorship in physics at Princeton University. In 1950 he moved to Stanford University as an associate professor and was made full professor in 1954.

His early research was in the fields of infrared spectroscopy, the hydrogen bond, and photoconductivity. One of his first notable achievements, in 1948, was the invention of a scintillation counter using sodium iodide activated with thallium. He is noted for his studies of the atomic nucleus, for which he received the 1961 Nobel Prize for physics (shared with Rudolph Mössbauer).

At Stanford, Hofstadter used the linear accelerator to study the scattering effects of high electrons fired at atomic nuclei. In many ways these experiments were similar in concept to RUTHERFORD's original scattering experiments. He found that the distribution of charge density in the nucleus was constant in the core, and then decreased sharply at a peripheral "skin." The radial distribution of charge was found to vary in a mathematical relationship that depended upon the nuclear mass. Further, Hofstadter was able to show that nucleons (protons and neutrons) were not simply point particles, but had definite size and form. Both appeared to be composed of charged mesonic clouds (or

shells) with the charges adding together in the proton, but canceling each other out in the neutral neutron. This led him to predict the existence of the rho-meson and omega-meson, which were later detected.

Hofstadter served as director of the high-energy physics laboratory at Stanford from 1967 to 1974.

### **Hollerith, Herman** (1860–1929) *American engineer*

The father of Hollerith (**hol**-e-rith) was a German immigrant who settled in Buffalo, New York, and taught classics. Hollerith was educated at the Columbia School of Mines, New York. After graduating in 1879 he assisted his teacher, W. P. Trowbridge, working with him on the 1880 U.S. census. He also helped the head of vital statistics, John Billings, to prepare his final report.

Like many others, Hollerith and his supervisors were dismayed by the thought that, while it took only a few months to carry out the census, it would take the best part of a decade to tabulate and analyze the data collected. They might not even be finished before the 1890 census was taken. Clearly some form of mechanical aid was required. Hollerith spent the 1880s working first as an instructor at the Massachusetts Institute of Technology (1882–84) and for the rest of the decade at the Patent Office in Washington. During much of this time he worked on the census problem. He also developed a set of electrically controlled air brakes for freight trains, which he patented in 1885. His design, however, was not adopted; the Westinghouse system was preferred.

More successful was the tabulating system he invented for the 1890 census. He began with a system of punched tape, run over a metal drum and under some brushes. Whenever the brushes passed over a hole, current flowed and one bit of data was recorded. But, to retrieve an item, operators soon found, the whole tape had to be scanned. The obvious solution of turning the tape into cards was quickly introduced.

Hollerith's punched cards and related equipment operated so well in 1890 that it reduced the number of working days spent tabulating the data by two-thirds. It was quickly adopted by many other countries. By 1896 Hollerith felt sufficiently confident to set up his own company, Tabulating Machine Co., to manufacture and market machinery. The business thrived as it became apparent that Hollerith's tabulating machines could be used to record and analyze data of almost any kind. In 1911, a victim of high blood pressure, Hollerith sold out to the entrepreneur Charles Flint for \$450 a share, a deal which brought Hollerith about \$1.25 million. Hollerith's company thereby became the Computing-Tabulating-Recording Co. and eventually, in 1924, IBM.

### **Holley, Robert William** (1922–1993) *American biochemist*

Holley was born in Urbana, Illinois. After graduating in chemistry from Illinois University in 1942, he joined the team at Cornell Medical School that achieved the first artificial synthesis of penicillin. He remained at Cornell to receive his PhD in organic chemistry in 1947.

Two years (1955–56) spent at the California Institute of Technology marked the beginning of Holley's important research on the nucleic acids. He decided that to work out the structure of a nucleic acid he first needed a very pure specimen of the molecule. Back again at Cornell, his research team spent three years isolating one gram of alanine transfer RNA (alanine tRNA) from some 90 kilograms of yeast. In March 1965 he was able to announce that they had worked out the complete sequence of 77 nucleotides in alanine tRNA. For this work Holley received the 1968 Nobel Prize for physiology or medicine, an award he shared with Marshall NIRENBERG and Har Gobind KHORANA.

### **Holmes, Arthur** (1890–1965) *British geologist*

Holmes came from a farming background in Hebburn-on-Tyne in the northeast of England. He graduated from Imperial College, London, in 1910, and went on to work with Lord RAYLEIGH on radioactivity. After an expedition to Mozambique in 1911 he taught at Imperial College until 1920 when he went to Burma as an oil geologist. In 1925 he returned to England to become professor of geology at Durham University, where he remained until 1943 when he moved to Edinburgh University.

Holmes conducted major work on the use of radioactive techniques to determine the age of rocks, leading to his proposal of the first quantitative geological time scale in 1913 and to his estimate of the age of the Earth being about 1.6 billion years. He continued to revise this estimate throughout his life, producing a figure in 1959 some three times larger.

Holmes also made a major contribution to the theory of continental drift proposed by Alfred WEGENER in 1915. One of the early difficulties the theory faced was that geologists could not envisage a force capable of moving the continents in the way described by Wegener. In 1929 Holmes proposed the existence of convection currents in the Earth's mantle. Rocks in the Earth's interior are, according to Holmes, heated by radioactivity, causing them to rise and spread out and, when cold and dense, to sink back to the interior. It was only after World War II that hard evidence for such a view could be produced.

In 1944 Holmes published his *Principles of Physical Geology*, a major work on the subject.

A substantially revised edition of this book was published in 1965, shortly before Holmes's death.

**Holmes, Oliver Wendell** (1809–1894)  
*American physician*

Science is the topography of ignorance.  
—*Medical Essays*

The truth is, that medicine, professedly founded on observation, is as sensitive to outside influences, political, religious, philosophical, imaginative, as is the barometer to the changes of atmospheric density.  
—As above

Holmes was the son of a congregational minister and the father of the identically named jurist and Supreme Court judge. Born in Cambridge, Massachusetts, he graduated in law from Harvard in 1829 and in medicine in 1836. He was professor of anatomy and physiology at Harvard from 1847 until 1882.

In 1843 Holmes published the classic paper *The Contagiousness of Puerperal Fever* in which he repeated some of the earlier arguments of a number of notable physicians and anticipated some of the work of Ignaz SEMMELWEIS and Joseph LISTER. Puerperal (childbed) fever, a streptococcal infection of maternity wards in the early 19th century, had an average mortality of 5–10%, occasionally rising to as much as 30% in particularly virulent outbreaks. Holmes stated that puerperal fever is frequently carried from patient to patient by physicians and nurses. He advised that no doctor or nurse who had recently participated in a post-mortem should treat a patient in labor, and he also recommended that they should always wash their hands before examining patients. So little attention was paid to Holmes's paper, however, that he felt it necessary to republish it in 1855.

In addition to being a distinguished man of American letters with numerous volumes of essays, verse, and fiction to his credit, Holmes is also remembered for a letter to William MORTON in 1846 concerning the condition induced by Morton's ether inhalation. In this, he wrote, "The state should, I think, be called 'Anaesthesia.' This signifies insensibility." The term had previously been employed in antiquity by PLATO and DIOSCORIDES.

**Honda, Kotaro** (1870–1954) *Japanese metallurgist*

Born in Aichi, Japan, Honda was educated at the Imperial University, Tokyo, graduating in 1897. After studying abroad at the universities of Göttingen and Berlin, he returned to Japan to take up an appointment at the Tohoku Imperial University. In 1922 a research institute for iron and steel was attached to the university and Honda became its director. He finally, in 1931, became president of the university.

Honda is noted for his research on magnetic alloys. In 1917 he found that an alloy of 57% iron, 35% cobalt, 2% chrome, 5% tungsten, and 1% carbon was the most highly magnetic material then known. Its use in such instruments as magnetos and dynamos permitted a marked decrease in their size.

**Honda, Soichiro** (1906–1991) *Japanese motor engineer*

Honda was the eldest son of a poor village blacksmith from Tenryu in the Shizuoka Prefecture, Japan. He showed an early interest in engines, although it was not until he was eight that he actually saw an automobile, an old Model-T. In 1922 he began working as an apprentice in a Tokyo car repair shop and six years later opened his own shop in Hamamatsu.

But Honda had ambitions to do more than repair vehicles; he aimed eventually to design and build them himself. After the war, during which he made piston rings, he set up the Honda Motor Company in 1947. Initially he built small engines to be fitted to bikes. Known in Japan as "bata-bata," they were very successful. Honda went on to build real motorcycles; they proved to be so effective that in 1961 his machines took the first five positions in both the 125 cc and 250 cc classes at the Tourist Trophy races on the Isle of Man.

In 1957 Honda entered the car market and within a few years had overtaken all his competitors other than Toyota and Nissan. Honda had the foresight to develop lightweight engines, which proved to be well suited to the energy crises of the 1970s. The Honda Civic of 1972, for example, was the first Japanese car to meet American pollution standards and allowed Honda to sell more cars in America than any other Japanese manufacturer apart from Toyota. In 1982 Honda established his own production lines in the United States. Honda retired in 1973.

**Hood, Leroy Edward** (1938– ) *American biologist*

Born in Missoula, Montana, Hood was educated at the California Institute of Technology, where he obtained his PhD in biochemistry in 1964, and at Johns Hopkins Medical School, Baltimore, where he qualified as an MD in 1964. He immediately joined the staff of the National Institutes of Health, Bethesda, working in the area of immunology. In 1970 Hood returned to the California Institute of Technology and was appointed professor of biology in 1975.

In May 1985 at a meeting in Santa Cruz, California, plans were laid to map the human genome (the Human Genome Project). As the genome consists of 3 billion base pairs of DNA,

the ability to sequence the genes rapidly would be a crucial factor.

Fortunately an automatic sequencer was almost at hand in 1985, developed by Hood and his colleague Lloyd Smith. The sequencer operates with fluorescent dyes. Each of the four DNA bases – adenine (A), cytosine (C), guanine (G), and thymine (T) – can be tagged with a different dye. Unsequenced dye-tagged DNA fragments are analyzed by gel electrophoresis, in which they migrate at different rates. The dyes are excited by an argon laser and the light emitted is turned into a digital signal by photomultiplier tubes. The digital signals can be analyzed by a computer and identified as A, T, C, or G.

Hood's automatic sequencer enabled work that once took a week or more to be carried out overnight. Later commercial models of the device can read 12,000 base pairs a day, and operate more accurately than any manual sequencing.

In 1992 Bill GATES of Microsoft presented the University of Washington Medical School, Seattle, with \$12 million to establish a department of molecular biotechnology. Hood was persuaded to move to Seattle to head the new department, to work on a faster DNA sequencer, and to analyze the genes controlling the human immune response. That same year Hood, in collaboration with Ronald Cape, a former head of the biotechnology firm Cetus, founded Darwin Molecular in Seattle. Their aim is to develop new drugs utilizing processes comparable to natural selection.

### **Hooke, Robert** (1635–1703) *English physicist*

The truth is, the science of Nature has been already too long made only a work of the brain and the fancy. It is now high time that it should return to the plainness and soundness of observations on material and obvious things.

—*Micrographia* (1665; *Micrography*)

He is certainly the greatest Mechanick this day in the World.

—John Aubrey, *Brief Lives* (17th century)

Hooke, whose father was a clergyman from Freshwater on the Isle of Wight, England, was educated at Oxford University. While at Oxford he acted as assistant to Robert BOYLE, constructing the air pump for him. In 1662 Boyle arranged for Hooke to become first curator of experiments to the Royal Society. There he agreed to “furnish the Society every day they meet with three or four considerable experiments.” Even though the society only met once a week, the pressure on Hooke was still great and may explain why he never fully developed any of his ideas into a comprehensive treatise. He was also something of an invalid.

Hooke made numerous discoveries, perhaps

the best known being his law of elasticity, which states that, within the elastic limit, the strain (fractional change in size) of an elastic material is directly proportional to the stress (force per unit area) producing that strain. He was the first to show that thermal expansion is a general property of matter. He also designed a balance spring for use in watches, built the first Gregorian (reflecting) telescope, and invented a number of scientific instruments, including the compound microscope and the wheel barometer.

In 1665 he published his main work *Micrographia* (*Micrography*), which was an account – fully and beautifully illustrated – of the investigations he had made with his improved version of the microscope. It also contained theories of color, and of light, which he suggested was wavelike. This led to one of the major controversies – over the nature of light and the priority of theories – that he had with Isaac NEWTON. The other conflict was over the discovery of universal gravitation and the inverse square law. It is true that Hooke had revealed, in a letter to Newton in 1680, that he had an intuitive understanding of the form the inverse square law must take. Newton's reply to Hooke's charge of plagiarism was to distinguish between Hooke's general intuition that may have been well founded, and his own careful mathematical treatment of the law and detailed working out of its main consequences.

Hooke was also a capable architect, having written on the theory of the arch and designed parts of London after the great fire of 1666.

### **Hooker, Sir Joseph Dalton** (1817–1911) *British plant taxonomist and explorer*

From my earliest childhood I nourished and cherished the desire to make a creditable journey in a new country and write such a respectable account of its natural features as should give me a niche among the scientific explorers of the globe I inhabit, and hand my name down as a useful contributor of original matter.

—Letter to Charles Darwin (1854)

Hooker was born at Halesworth in Suffolk, England, and studied medicine at Glasgow University, where his father William Hooker was professor of botany. After graduating in 1839, he joined the Antarctic expedition on HMS *Erebus* (1839–43), nominally as assistant surgeon but primarily as naturalist. Between 1844 and 1860, using collections made on the expedition, Hooker produced a six-volume flora of the Antarctic Islands, New Zealand, and Tasmania.

When he returned from the Antarctic expedition Hooker was congratulated on his work by Charles Darwin, who had been following his progress, and in 1844 Darwin confided to Hooker his theory of evolution by natural selection. This communication later proved important in establishing Darwin's precedence

when his theory – together with Alfred Russel WALLACE's essentially identical conclusions – was presented by Hooker and Lyell at the famous Linnaean Society meeting of July 1858.

Following his unsuccessful application in 1845 for the botany chair at Edinburgh University, Hooker was employed to identify fossils for a geological survey, but he took time off between 1847 and 1850 to explore the Indian subcontinent. He visited Sikkim and Assam, Nepal, and Bengal, introducing the brilliant Sikkim rhododendrons into cultivation through the botanical gardens at Kew. Later (1872–97) he produced a seven-volume flora of British India.

In 1855 Hooker was appointed assistant director at Kew Gardens and in 1865 succeeded his father as director. In his 20 years as head of the institute he founded the Jodrell Laboratory and Marianne North Gallery, extended the herbarium, and developed the rock garden. His efforts established Kew as an international center for botanical research and in 1872 he successfully fought a move from the commissioner of works to relegate the gardens to a pleasure park. With George BENTHAM he produced a world flora, *Genera Plantarum* (1862–83; *Genera of Plants*) – a major work describing 7,569 genera and 97,000 species. The Kew herbarium is still arranged according to this classification.

Hooker retired from the directorship of Kew in 1885 owing to ill health but continued working until his death.

### **Hooker, William Jackson** (1785–1865) *British botanist*

The great secret of his success was that he deemed nothing too small for his notice, if it illustrated any fact of science or economy, and nothing too difficult to be attempted.

—William Henry Harvey

The son of a merchant's clerk, Hooker was born in Norwich in the east of England; he attended the grammar school there but had little formal education. An interest in botany led to his first voyage, in 1809, to Iceland, which was followed by an extensive study of the English flora. From 1820 until 1842 Hooker held the botany chair at Glasgow. His main interest was in ferns, mosses, and fungi but his works also include some important regional floras and he was a pioneer of economic botany. Hooker's herbarium was accessible to all scholars, and with his publications (more than 20 major books and numerous articles) and journals he became the leading British botanist of his day.

In 1841 Hooker was appointed the first director of Kew Gardens, a position he held until his death. Under his direction Kew became the world's most important botanical institution and here he founded the Museum of Economic Botany in 1847.

### **Hope, James** (1801–1841) *British cardiologist*

Hope, the son of a wealthy merchant from Stockport near Manchester, England, studied medicine at Edinburgh University and various London hospitals. He became assistant physician at St. George's Hospital in 1834 and in 1839, shortly before his early death from consumption (tuberculosis), was appointed full physician.

In the 1820s use of René Laennec's stethoscope became widespread in Britain. It still remained to link the sounds heard through the stethoscope and actual events in the heart, a task begun by Hope and reported in his influential *A Treatise on the Diseases of the Heart and Great Vessels* (1831), a work that went through three editions in his short life.

Hope made valuable observations on heart murmurs, valvular disease, and aneurism, and thus began the important work of transforming heart complaints from being merely a set of symptoms into identifiable and specific lesions of the heart.

### **Hope, Thomas Charles** (1766–1844) *British chemist*

Hope's father, John Hope, was a professor of botany at Edinburgh University and founder of the new Edinburgh botanic gardens. Thomas, who was born in Edinburgh, studied medicine there and became professor of chemistry at Glasgow in 1787. He returned to Edinburgh in 1795 as joint professor of chemistry with Joseph BLACK, succeeding Black on his death in 1799. He remained as chemistry professor until 1843.

In 1787 Hope isolated the new element strontium and named it after the town of Strontian in Scotland where it was discovered. At first it was thought to be barium carbonate and was only established as a new metal in 1791. Martin KLAPROTH made the same discovery independently but a little later.

Hope was also the first to show the expansion of water on freezing and demonstrated that water attains a maximum density a few degrees above its freezing point (actually 3.98°C). He published his results in his paper *Experiment on the Contraction of Water by Heat* (1805).

### **Hopkins, Sir Frederick Gowland** (1861–1947) *British biochemist*

Life is a dynamic equilibrium in a polyphasic system.

—Joseph Needham, *Order and Life* (1936)

Hopkins was the son of a bookseller and publisher and a distant cousin of the poet Gerard Manley Hopkins. He was born at Eastbourne on the south coast of England and, after attending the City of London School, was apprenticed as a chemist in a commercial laboratory, where

for three years he performed routine analyses. An inheritance in 1881 allowed him to study chemistry at the Royal School of Mines and at University College, London. His work there brought him to the attention of Thomas Stevenson, who offered Hopkins the post of assistant in his laboratory at Guy's Hospital. Feeling the need of more formal qualifications he began to work for a medical degree at Guy's in 1889, finally qualifying in 1894. In 1898 Hopkins moved to Cambridge, where he remained for the rest of his long life and not only served as professor of biochemistry (1914–43) but also established one of the great research institutions of the century.

In 1901 Hopkins made a major contribution to protein chemistry when he discovered a new amino acid, tryptophan. He went on to show its essential role in the diet, since mice fed on the protein zein, lacking tryptophan, died within a fortnight; the same diet with the amino acid added was life-supporting. This work initiated vast research programs in biochemical laboratories.

In 1906–07 Hopkins performed a classic series of experiments by which he became convinced that mice could not survive upon a mixture of basic foodstuffs alone. This ran against the prevailing orthodoxy, which supposed that as long as an animal received sufficient calories it would thrive. He began by feeding fat, starch, casein (or milk protein), and essential salts to mice, noting that they eventually ceased to grow. Addition of a small amount of milk, however, was sufficient to restart growth. It took several years of careful experiments before, in 1912, Hopkins was prepared to announce publicly that there was an unknown constituent of normal diets that was not represented in a synthetic diet of protein, pure carbohydrate, fats, and salts. Hopkins had in fact discovered what were soon to be called vitamins, and for this work he shared the 1929 Nobel Prize for physiology or medicine with Christiaan EIJKMAN.

At the same time Hopkins was working with Walter Fletcher on the chemistry of muscle contraction. In 1907 they provided the first clear proof that muscle contraction and the production of lactic acid are, as had long been suspected, causally connected. This discovery formed the basis for much of the later work done in this field. Hopkins later isolated the tripeptide glutathione, which is important as a hydrogen acceptor in a number of biochemical reactions.

In England Hopkins did more than anyone else to establish biochemistry as it is now practiced. He had to fight on many fronts to establish the discipline, since many claimed that the chemistry of life involved complex substances that defied ordinary chemical analysis. Instead he was able to demonstrate that it was a chem-

istry of simple substances undergoing complex reactions. Hopkins was knighted in 1925.

### **Hopper, Grace** (1906–1992) *American mathematician and computer scientist*

Hopper, born Grace Murray, was educated at Vassar and at Yale, where she gained her PhD in 1934. She taught at Vassar until 1944, when she enlisted in the U.S. Naval Reserve and was immediately assigned to Harvard to work with Howard AIKEN on the Mark I computer, the ASCC (Automatic Sequence Controlled Calculator), for which she wrote the manual. Although she hoped to remain in the Navy after the war, her age prevented this and she had to be satisfied with the Naval reserve as a second choice. Consequently she remained at Harvard working on the Mark II and the Mark III computers.

In 1949 Hopper moved to Philadelphia to work with J. P. Eckert and John MAUCHLY on the development of BINAC and remained with the Eckert-Mauchly Computer Corporation, despite several changes of ownership, until 1967. During this period she made a number of basic contributions to computer programming. In 1952 she devised the first compiler, a program that translated a high-level language into machine code, named A-O. She went on to produce a data-processing compiler known as Flow-matic.

It was apparent by this time to Hopper and other programmers that the business world lacked an agreed and adequate computer language. Hopper lobbied for a combined effort from the large computer companies and consequently a committee was established in 1959 under the guidance of the Defense Department to develop a common business language. Although she did not serve on the committee, the language developed by them, COBOL (Common Business Oriented Language), was derived in many respects from Flow-matic. For this reason Hopper has often been referred to as “the mother of Cobol.”

Although Hopper was forced through age to resign from the U.S. Naval reserve in 1966 she was recalled a year later to work on their payroll program. She remained in the Naval reserve until 1986, having been promoted to the rank of rear admiral in 1985.

### **Hoppe-Seyler, (Ernst) Felix Immanuel** (1825–1895) *German biochemist*

Hoppe-Seyler (hop-e-zI-ler) was born in Freiberg, Germany, and early in his career became assistant to Rudolf VIRCHOW in Berlin. He became professor of physiological chemistry (biochemistry) at Strasbourg, where he established the first exclusively biochemical laboratory, and later founded the first biochemistry journal. In 1871 Hoppe-Seyler discovered the

enzyme invertase, which aids the conversion of sucrose into the simpler sugars glucose and fructose. He was also the first to prepare hemoglobin in crystalline form. He isolated the fatlike compound lecithin, one of the class of compounds called phospholipids. Hoppe-Seyler's classification of the proteins (1875) is still accepted today.

**Horrocks, Jeremiah** (1619–1641) *English astronomer*

Little is known about the early life of Horrocks (or Horrox) other than that he was born into a Puritan family in Toxteth, Liverpool, and was admitted to Cambridge in 1632. Even though he died "in his twenty second year" he had made major contributions to astronomy and several original observations.

Horrocks noted that as the orbits of Venus and Mercury fall between the earth and the Sun, it would seem possible that at certain times the inner planets would appear to an observer on the Earth to cross the face of the Sun. The events, known as transits, are so rare that they are unlikely to be seen by chance. Only five transits of Venus have been observed, those of 1639, 1761, 1769, 1874, 1882, and 2004.

At Cambridge, Horrocks had mastered the new astronomy of KEPLER. From Kepler's recently published *Rudolphine Tables* (1627), he worked out that a transit of Venus was due on 24 November 1639 at 3 p.m. At this time he was probably working as a curate at Hoole near Preston in Lancashire. He prepared for the transit by directing the solar image onto a large sheet of paper in a darkened room. However, a late November afternoon in Lancashire is not the best time to observe the Sun. For Horrocks there was another problem. The predicted day was a Sunday which meant that the puritan curate could well find himself in church at the crucial moment.

Horrocks was successful in observing the transit, however, and left an account of the day in his *Venus in Sole Visa* (Venus in the Face of the Sun), published posthumously in 1662. The day was cloudy but at 3.15, "as if by divine interposition" the clouds dispersed. He noted a spot of unusual magnitude on the solar disc and began to trace its path; but, he added, "she was not visible to me longer than half an hour, on account of the Sun quickly setting."

With the aid of his observations Horrocks could establish the apparent diameter of Venus as 1' 12" compared with the Sun's diameter of 30', a figure much smaller than the 11' assigned by Kepler. Horrocks also attempted to determine the solar parallax, and derived, although with little confidence, a figure of 15", compared with a modern value of 8".8.

Before his death Horrocks was working on an *Astronomia Kepleriana* (Astronomy of Kepler), and essays on comets, tides, and the Moon. Un-

fortunately none of this was published until long after his death. Much of his work had been lost in the chaos of the Civil War. Other material sent to a London bookseller was burned in the Great Fire of 1666. The remainder of his papers were published by John WALLIS as *Opera posthuma* (1678; Posthumous Works).

**Horsfall, James Gordon** (1905–1995) *American plant pathologist*

Born in Mountain Grove, Missouri, Horsfall graduated in soil science from the University of Arkansas and gained his PhD in plant pathology from Cornell in 1929. He remained at Cornell until 1939 when he became chief of the department of plant pathology (1939–48) and director (1948–71) of the Connecticut Agricultural Experimental Station.

A leading plant pathologist, Horsfall coedited, with A. E. Dimond, the three-volume work *Plant Pathology* (1959–60). More recently, with Ellis Cowling, he coedited *Plant Disease: An Advanced Treatise* (5 vols., 1977–80). He had earlier published extensively on fungicides.

**Horvitz, H. Robert** (1947– ) *American cell biologist*

Horvitz (**hor**-vich) initially studied mathematics and economics at the Massachusetts Institute of Technology (MIT), receiving his BA in 1968. He then turned to biology at Harvard University, graduating with an MA in 1972, and gaining his PhD in 1974. After working as a researcher in the UK at the Medical Research Council's Laboratory of Molecular Biology in Cambridge, he returned to MIT in 1978 as assistant professor of biology, subsequently becoming associate professor (1981) and professor (1986). In 1988 he was appointed Investigator at the Howard Hughes Medical Institute, MIT.

Horvitz has devoted much of his career to studying the development and genetics of the nematode (roundworm) *Caenorhabditis elegans*. During his stint at the MRC Laboratory of Molecular Biology in Cambridge in the mid-1970s, he saw at first hand how Sydney BRENNER and his colleagues were developing the potential of this tiny transparent hermaphrodite worm as a model experimental organism. At this time, one of Brenner's team, John E. SULSTON, was mapping the developmental lineage of each of the adult worm's thousand or so cells. Sulston showed how certain cells were destined to die during development by a process called *programmed cell death* (*apoptosis*), and that this was a normal part of organ formation and intrinsic to the patterning of body systems.

By determining the effects of particular mutations on the worm's development, Horvitz was able to pinpoint certain key genes that control apoptosis. For example, in worms with mutations of the *ced-3* or *ced-4* genes, apoptosis

does not occur and all cells survive, whereas a mutation of the *ced-9* gene causes the death of all cells. The *ced-3* gene encodes an enzyme called a *caspase*, which cleaves certain target proteins in the cytoskeleton and nuclear framework, and is instrumental in dismantling the cell during apoptosis. However, the caspase must be activated by CED-4, the protein encoded by the *ced-4* gene. Normally, CED-4 is bound by CED-9 (the protein encoded by *ced-9*). Apoptosis is triggered by the activity of a killer gene, *egl-1*, whose product causes the release of CED-4 from CED-9, and hence the activation of the caspase. Counterparts of these genes and their products occur in humans and other vertebrates, and the apoptosis pathway seems to be highly conserved (i.e., very similar) in all animals.

*C. elegans* has provided Horvitz and his team at MIT with many other valuable insights into the genetic regulation of animal development. In particular, Horvitz has focused on the differentiation and growth of the worm's vulva, which consists of just 22 cells. For example, he has identified a gene, *let-60*, whose protein functions as a switch for vulval induction, and characterized other genes that exert control over vulval development.

Another area illuminated by this simple organism is the relationship between structural features of the nervous system and the animal's behavior. Horvitz's team have discovered that receptors to the neurotransmitter serotonin are important in modulating the worm's rate of locomotion in response to its experience. They have also identified certain genes that control aspects of neurotransmission and muscle contraction.

Through his work, Horvitz has demonstrated that the humble worm *C. elegans* reveals many fundamental aspects of cell biology, and gives us a better understanding of human biology and disease. A complete picture of apoptosis, for instance, will help in developing new treatments for cancer and other diseases in which apoptosis is defective or misregulated.

In 2002, Horvitz was awarded the Nobel Prize in physiology or medicine, jointly with Brenner and Sulston, for their work on the genetic regulation of organ development and on programmed cell death.

### **Hounsfield, Sir Godfrey Newbold** (1919–2004) *British engineer*

Hounsfield was born at Newark in Nottinghamshire, England, and educated in that county before going on to the City and Guilds College, London, and the Faraday House College of Electrical Engineering in London. Having spent the war years in the RAF, he worked for Electrical and Musical Industries (EMI) from 1951 and led the design effort for Britain's first large solid-state computer. Later he

worked on problems of pattern recognition. Although he had no formal university education he was granted an honorary doctorate in medicine by the City University, London (1975).

Hounsfield was awarded the 1979 Nobel Prize for medicine, together with the South-African-born physicist Allan CORMACK, for his pioneering work on the application of computer techniques to x-ray examination of the human body. He was knighted in 1981. Working at the Central Research Laboratories of EMI he developed the first commercially successful machines to use computer-assisted tomography, also known as computerized axial tomography (CAT). In CAT a high-resolution x-ray picture of an imaginary slice through the body (or head) is built up from information taken from detectors rotating around the patient. These "scanners" allow delineation of very small changes in tissue density. Introduced in 1973, early machines were used to overcome obstacles in the diagnosis of diseases of the brain, but the technique has now been extended to the whole body. Although Cormack worked on essentially the same problems of CAT, the two men did not collaborate, or even meet.

### **Houssay, Bernardo Alberto** (1887–1971) *Argentinian physiologist*

Born in the Argentinian capital, Houssay (oo-sI) was the founder and director of the Buenos Aires Institute of Biology and Experimental Medicine. He was also professor of physiology at Buenos Aires from 1910 until 1965, apart from the years 1943–55 when he was relieved of his post by the regime of Juan Perón.

Houssay's work centered upon the role of the pituitary gland in regulating the amount of sugar in the blood, as well as its effects in aggravating or inducing diabetes. Working initially with dogs, he found that diabetic sufferers could have their condition eased by extraction of the pituitary gland, since its hormonal effect is to increase the amount of sugar in the blood and thus counter the influence of insulin. Deliberate injection of pituitary extracts actually increases the severity of diabetes or may induce it when the condition did not previously exist. He was also able to isolate at least one of the pituitary's hormones that had the reverse effect to insulin. Houssay's work on hormones led to his award, in 1947, of the Nobel Prize for physiology or medicine, which he shared with Carl and Gerty CORI. He was the author of *Human Physiology* (1951).

### **Hoyle, Sir Fred** (1915–2001) *British astronomer*

Space isn't remote at all. It's only an hour's drive away if your car could go straight upwards.

—*The Observer*, 9 September 1979

It is the true nature of mankind to learn from mistakes not from example.

—*Into Deepest Space* (1974)

[We must] recognize ourselves for what we are — the priests of a not very popular religion.

—*Physics Today*, April 1968

The son of a textile merchant from Bingley in Yorkshire, England, Hoyle was educated at Cambridge. After graduating in 1936 he remained at Cambridge as a graduate student before being elected to a fellowship at St. John's College in 1939. Hoyle spent the war working on the development of radar at the Admiralty. After the war he returned to Cambridge and was appointed Plumian Professor of Astronomy in 1958.

Hoyle first came to prominence in 1948 with his formulation of the "steady-state theory" of the universe. He was aware that cosmology at the time was inadequate in that it required a smaller age for the universe than geologists had attributed to the Earth. Hoyle's ideas about the steady-state theory were provoked one night in 1946, when he went to see a ghost film with Hermann BONDI and Thomas GOLD. The film was in four parts but linked the sections together to create a circular plot in which the end of the film became its beginning. Hoyle later noted that it showed him that unchanging situations need not be static. The universe could perhaps be both unchanging and dynamic.

Hoyle worked out some of the detailed implications of this view in his 1948 paper *A New Model for the Expanding Universe*. Matter, he argued, was created continually. It arose from a field generated by the matter that already exists — that is, in the manner of the film, "Matter chases its own tail." Created matter is spread throughout the whole of space and, according to the theory, is being produced at a rate of about one atom per year in a volume equal to that of a large building. It is this creation that drives the expansion of the universe. Matter is distributed evenly through space and therefore new clusters of galaxies are forming as other galaxies are receding into the distance.

Although Hoyle's work was initially treated sympathetically, the steady-state theory failed to cope with new evidence emerging in the 1960s from radio astronomy. Counts of radio sources by Martin RYLE in the 1960s and, in particular, the discovery by Robert WILSON and Arno PENZIAS of the cosmic background radiation in 1964, convinced most scientists that the universe had begun with a big bang. Hoyle defended his theory strongly, objecting to the accuracy of the radio counts by arguing that they were so constructed as to allow every error to count against the theory. "Properly analyzed," Hoyle wrote in 1980, "the disproof of the theory claimed in the 1950s and early 1960s fails completely." He also suggested that there could be alternative explanations for the background radiation.

Hoyle subsequently felt that he was not committed to the details of any cosmological orthodoxy, such as either the big-bang or the steady-state theory of 1948. He spent much time exploring the implications of both theories and, in collaboration with Jayant Narlikar, developing a new theory of gravity. In 1964 they proposed, following some early arguments of Ernst MACH, that the inertia of any piece of matter derives from the rest of the matter in the universe. They also predicted that the gravitational constant changes over time.

Hoyle also worked in the 1950s on the formation of the elements. It was widely believed that carbon could be formed, along with many other elements, in the interior of stars. One reaction proposed required three helium nuclei to fuse into a carbon atom as in:

Hoyle realized that the reaction would take place too infrequently to account for the abundance of carbon in the universe. Another possibility was a two-stage reaction:

In this, two helium nuclei first form a beryllium nucleus, which fuses in turn with another helium nucleus to form carbon. As the Be has a longer life-time than the collision time of two  ${}^4\text{He}$  nuclei, the reaction should make the production of carbon more likely. Something more was needed and in 1954 Hoyle predicted that there must be a resonance channel easing the two reaction steps. Hoyle's prediction was confirmed when it was shown experimentally that there was an energy level of 7.65 million electronvolts (MeV) in the  ${}^{12}\text{C}$  nucleus, just above the energy of the Be +  ${}^4\text{He}$  structure of 7.366 MeV.

Further work on the formation of the elements was carried out by Hoyle in collaboration with William FOWLER and Geoffrey and Margaret BURBIDGE. In 1957 their work resulted in a paper, commonly referred to as B<sup>2</sup>FH, that is one of the most authoritative and comprehensive works of modern science. It describes precisely how all the naturally occurring elements other than hydrogen and helium are formed in the interior of stars.

Hoyle spent much of the early 1960s working in the U.S. at the Hale Observatories and at Princeton. In 1967 he was appointed director of the newly formed Institute of Theoretical Astronomy at Cambridge. It was not a happy time. There were bitter disputes with Martin Ryle and the radio astronomers, demands for apologies, and threats of legal action. Hoyle had problems with his requests for funds from the research councils. In 1973 he resigned and subsequently held no permanent post.

He did, however, continue to publish on a wide variety of topics. Much of this later work,

HUBBLE'S CLASSIFICATION OF GALAXIES This is known as his "tuning-fork" diagram.

often in collaboration with Chandra Wickramasingh of Cardiff University, stemmed from his claim that the blind operation of physicochemical laws would have been insufficient to shuffle an assortment of amino acids into an enzyme. The odds against this happening by chance were 1 in  $10^{40,000}$ , as were the chances that an atom with the properties of carbon could be produced by nature. Such considerations led Hoyle to attack the notion of evolution by natural selection.

Hoyle began his campaign with a frontal attack; he asserted that the fossil *Archaeopteryx* was a fake. Probably the most famous of all fossils, *Archaeopteryx* had been bought by the British Museum in 1862 for 700 pounds and supposedly links reptiles with birds. Hoyle published a paper in 1985 claiming that the skeleton was genuine and of a reptile, but that the feathers had been glued on. Hoyle went on to publish a book on the issue, *Archaeopteryx, the Story of a Fake* (1987), in which he identified Richard Owen as the culprit. Tests of the fossil by the British Museum have failed to detect any glue or cement.

But if enzymes, let alone organisms, could not have evolved on Earth, where did they originate? In *Lifecloud* (1978), *Diseases from Space* (1979), and *Space Travellers* (1981), Hoyle argued that life must have come from space. Hoyle was partly led to this view by a long-standing interest in interstellar grains. They had long been thought to be made of ice, but, as they failed to reveal the appropriate infrared absorption bands, this view had to be ruled out. Hoyle pursued the matter and struggled for twenty years to find a particle with the observed spectral properties of the interstellar grains. In 1980 he decided to compare the grains with bacteria and found, to his great surprise, agreement so close that he was forced to conclude that "hitherto unidentified components of dust clouds were in fact bacterial cells."

HOYLE'S new theory allowed him to explain not only the origin of life on Earth but also much about the spread of disease. The abrupt appearance of a new disease, such as syphilis in the 15th century, can be seen as a bacterial

seeding from a passing comet. Other epidemiological problems can also be solved in this way. How, for example, Hoyle asks, did a group of Amerindians in Suriname, isolated from all alien contact until recently, become infected with the polio virus? Because, Hoyle believes, both forest and city dwellers were infected with pathogens rained on them from above.

Hoyle's numerous other publications covered such areas as the history of astronomy in his *Copernicus* (1973), an important textbook, *Astronomy and Cosmology* (1975), archaeoastronomy in *From Stonehenge to Modern Cosmology* (1972), and a first volume of autobiography in his *The Small World of Fred Hoyle* (1986). He also wrote fourteen science-fiction novels, the first being *The Black Cloud* (1957). In 1994 Hoyle published his long-awaited autobiography, *Home Is Where the Wind Blows: Chapters from a Cosmologist's Life*.

### Hubble, Edwin Powell (1889–1953) American astronomer and cosmologist

Equipped with his five senses, man explores the universe around him and calls the adventure Science.

—*Science*

Hubble, who was born in Marshfield, Missouri, was the son of a lawyer. He was educated at the University of Chicago where he was influenced by the astronomer George HALE and, as a good athlete, was once offered the role of "Great White Hope" in a match against the world heavyweight champion, Jack Johnson. Instead he went to England, accepting a Rhodes scholarship to Oxford University where, between 1910 and 1913, he studied jurisprudence, represented Oxford in athletics, and fought the French boxer, Georges Carpentier. On his return to America he practiced law briefly before returning in 1914 to the study of astronomy at the Yerkes Observatory of the University of Chicago. He obtained his PhD in 1917. After being wounded in France in World War I he took up an appointment in 1919 at the Mount Wilson Observatory in California where Hale

was director and where he spent the rest of his career.

Hubble's early work involved studies of faint nebulae, which in the telescopes of the day appeared as fuzzy extended images. He considered that while some were members of our Galaxy and were clouds of luminous gas and dust, others, known as spiral nebulae, probably lay beyond the Galaxy. After the powerful 100-inch (2.5-m) telescope went into operation at Mount Wilson he produced some of the most dramatic and significant astronomy of the 20th century. In 1923 he succeeded in resolving the outer region of the Andromeda nebula into "dense swarms of images which in no way differ from those of ordinary stars." To his delight he found that several of them were Cepheids, which allowed him to use Harlow SHAPLEY's calibration of the period-luminosity curve to determine their distance as the unexpectedly large 900,000 light-years. Although this conflicted sharply with the results of Adriaan van Maanen, Hubble continued with his observations. Between 1925 and 1929 he published three major papers showing that the spiral nebulae were at enormous distances, well outside our own Galaxy, and were in fact isolated systems of stars, now called spiral galaxies. This was in agreement with the work of Heber CURTIS. In 1935 van Maanen reexamined his data and, appreciating their unsatisfactory nature, withdrew the final objection to Hubble's results.

In 1929 Hubble went on to make his most significant discovery and announced what came to be known as *Hubble's law*. Using his own de-

termination of the distance of 18 galaxies and the measurements of radial velocities from galactic red shifts carried out by Vesto SLIPHER and Milton HUMASON, he saw that the recessional velocity of the galaxies increased proportionately with their distance from us, i.e.,  $v = Hd$ , where  $v$  is the velocity,  $d$  the distance, and  $H$  is known as *Hubble's constant*. Further measurements made by Hubble in the 1930s seemed to confirm his earlier insight. It was this work that demonstrated to astronomers that the idea of an expanding universe, proposed earlier in the 1920s by Aleksandr FRIEDMANN and Georges LEMAITRE, was indeed correct. The expansion of the universe is now fundamental to every cosmological model.

Hubble's law was soon seen as containing the key to the size, age, and future of the universe. Hubble's constant can be found from the mean value of  $v/d$ . Hubble himself gave it a value approximately ten times its presently accepted figure. The constant permits a calculation of the observable size of the universe to be made. The limiting value of recession must be the speed of light ( $c$ ). If we divide this by  $H$  we get a "knowable" universe with a radius of about 18 billion light-years. Beyond that no signal transmitted could ever reach us, for to do so it would need to exceed the speed of light.

It is also possible to calculate the time that must have elapsed since the original highly compact state of the universe, i.e., the age of the universe. Hubble's own estimate was 2 billion years but with revisions of his constant, cosmologists now, none too precisely, assign a value of between 12 and 20 billion years.

**HUBBLE DIAGRAM** The variation of red shift with distance for different kinds of galaxies.

Hubble also made a major contribution to the study of galactic evolution by producing the first significant classification of galaxies. William HERSCHEL had simply classified them as bright or faint, large or small, while his son John Herschel introduced five categories in terms of size, brightness, roundness, condensation, and resolvability, each with five subdivisions. Hubble published his scheme in 1926. It involved dividing galaxies into two classes, elliptical and spiral. Ellipticals could be subdivided on the basis of their degree of ellipticity, ranging from the circular form (E0) to the elongated (E7). Spirals could be either barred or normal spirals which were subdivided in terms of their degree of openness. Although anomalous objects were later discovered that failed to fit it, Hubble's scheme is still used as the basis for galactic classification.

**Hubel, David Hunter** (1926– ) *Canadian-American neurophysiologist*

Born in Windsor, Ontario, Hubel was educated at McGill University and then worked at the Montreal Neurological Institute. He moved to America in 1954 and after working at Johns Hopkins joined the Harvard Medical School in 1959 where he was appointed professor of neurobiology from 1968 to 1982.

Beginning in the 1960s, Hubel, in collaboration with Torsten WIESEL, published a number of remarkable papers that explained for the first time the mechanism of visual perception at the cortical level.

Their work was made possible by a number of technical advances. From the early 1950s onward it became possible to use microelectrodes to monitor the activity of a single neuron. Further, the work of Louis SOKOLOFF allowed workers to identify precise areas of neural activity. Using this latter technique it was thus possible to identify the region known as the striate cortex, located at the back of the cortex in the occipital lobes, as one of the key centers of activity during the visual process.

The cells of the striate cortex seemed to be arranged into columns, or "hypercolumns" as they were soon described, that run the length of the cortex (3–4 millimeters) from the outer surface to the underlying white matter. Such hypercolumns were further clearly divided into distinct layers. Hubel and Weisel went on to probe the structure, function, and contents of such columns in great detail.

Above all they succeeded in establishing two crucial points. First that the retinal image was mapped in some way onto the striate cortex. That is, to each point on the retina there corresponded a group of cells in the striate cortex that would respond to a stimulation of that point and of no other.

Furthermore, the response could be evoked only by a relatively precise stimulus. Thus there

were cells that would respond to a spot of light but not to a line. Cells that responded to lines would do so only to those lines with a specific tilt and if the angle of tilt was changed by as little as 10°, in either direction, the cells' ability to react would be diminished or even abolished.

As a result of such work the visual cortex has become the best known of all cortical regions. Hubel and Wiesel shared the 1981 Nobel Prize for physiology or medicine with Roger SPERRY.

**Huber, Robert** (1937– ) *German chemist*

Huber (**hoo**-ber) was educated at the Technical University in his native city of Munich where he obtained his PhD in 1972. He moved to the Max Planck Institute for Biochemistry, Munich, where he later became head of the Institute's crystallography group. In 2006 he moved to Cardiff University to work on the development of structural biology.

In 1982 Hartmut MICHEL had succeeded in crystallizing the membrane proteins of the photosynthetic reaction center. His colleague Johann DEISENHOFER had managed by 1985 to work out the molecular structure of the crystals. For this work they shared the 1988 Nobel Prize for chemistry. The prize also went to Huber as head of the unit in which Michel and Deisenhofer carried out their work.

**Huchra, John Peter** (1948– ) *American astronomer*

Huchra, who was born in Jersey City, New Jersey, was educated at the Massachusetts Institute of Technology and the California Institute of Technology, where he obtained his PhD in 1976. He then moved to Harvard, serving as professor of astronomy and as a staff member at the Smithsonian Astrophysical Observatory.

In the early 1980s Huchra worked on the Tully–Fisher relation, which links the intrinsic luminosity of a spiral galaxy with the rotational velocity of its stars. He found that with regard to galaxies in the Coma cluster there was a departure of up to 20% from the supposed correlation. Huchra went on in 1982 with a number of colleagues to apply the relation to the Local Group of galaxies to see if the peculiar motion tentatively identified by Vera RUBIN could be detected. The peculiar velocities of several hundred galaxies in the region of the Virgo cluster were measured. They found that velocities in the direction of Virgo steadily increased, while decreasing on the other side. The result has been interpreted by some as evidence for the existence of "The Great Attractor," a proposed massive concentration of galaxies lying beyond the Hydra-Centaurus supercluster.

In 1986, in collaboration with Margaret GELLER, Huchra began a galactic survey for the Smithsonian Center for Astrophysics (CfA).

They used a 1.5-meter telescope located on Mount Hopkins, Tucson, Arizona, and sought to measure the red shifts of galaxies below a magnitude of 15.5 and falling within a wedge of sky 6° wide, 120° long, and out to a distance of about 300 million light years. By 1989 they had mapped the positions of 10,000 galaxies.

To their surprise, instead of producing a uniform distribution their maps revealed large voids within which huge clusters of galaxies were distributed. The largest structure they observed, dubbed "The Great Wall," stretched 500 million light years without its edge being found.

**Hückel, Erich Armand Arthur Joseph** (1896–1980) *German chemist*

Born the son of a physician in Berlin, Germany, Hückel (**hoo**-kel) was educated at the University of Göttingen, gaining his PhD in 1921. He worked at a number of institutions, including the Zurich Technische Hochschule and in Copenhagen, Leipzig, and Stuttgart, before taking the chair of theoretical physics at Marburg in 1937.

Initially Hückel worked with DEBYE on electrolyte solutions. From 1930, however, he turned his attention to organic compounds. Since Friedrich KEKULÉ had discovered the structure of benzene (C<sub>6</sub>H<sub>6</sub>) in 1865, it had continued to puzzle chemists. Kekulé had shown that the six carbon atoms of benzene were formed into a ring joined by alternating single and double bonds. Organic chemists call such molecules as benzene "aromatic," thereby indicating, among other things, the molecule's great stability. Yet, double bonds normally make a molecule reactive. How, then, it was asked, can certain molecules like benzene with double bonds be so stable?

In the 1930s Hückel developed an answer to this problem based upon molecular orbital theory. Molecular orbitals are formed from overlapping atomic orbitals. Hückel proposed that the electrons of the pi-orbitals were delocalized and spread diffusely above and below the plane of the carbon ring. As this configuration was energetically more stable than placing electrons in isolated double bonds, benzene's stability followed directly from the model.

Hückel went on to generalize his model to cover other cyclic molecules containing alternating double and single bonds. Aromatic molecules were planar compounds which had precisely  $4n + 2$  pi-electrons, where  $n = 0, 1, 2, 3 \dots$ . This is known as the *Hückel rule*. Benzene represents the case where  $n = 1$ ; and  $n = 2$  and  $n = 3$  represent the 10 and 14 member aromatic rings of naphthalene and anthracene. For  $n = 0$ , the predicted aromaticity of a 3 member ring was confirmed in 1962 with the discovery of the cyclopropenyl cation.

**Huffman, Donald Ray** (1935– ) *American physicist*

Born at Fort Worth in Texas, Huffman was educated at Texas Agricultural and Mechanical College, at Rice University, Houston, and at the University of California, Riverside, where he completed his PhD in 1966. After spending a postdoctoral year at the University of Frankfurt, Huffman moved to the University of Arizona, Tucson, in 1967 and was later appointed professor of physics in 1975. He is currently emeritus professor at Arizona.

In 1985 in the laboratory of Richard SMALLEY a new form of carbon had been discovered: C<sub>60</sub>, known as "buckminsterfullerene." The C<sub>60</sub> was produced by vaporizing a graphite target with a pulsed laser beam. The sooty carbon produced in this manner certainly contained a detectable amount of C<sub>60</sub>, but all efforts to extract the substance from the residue in amounts sufficient to carry out a detailed spectroscopic study failed.

Huffman, in collaboration with Wolfgang Kratschmer of the Max Planck Institute for Physical Chemistry, Heidelberg, was involved in the discovery of the new forms of carbon known as *fullerenes*. For many years they had been interested in the nature of interstellar dust, which they believed to be mainly carbon. The interstellar matter has a characteristic broad absorption spectrum and Huffman and Kratschmer were experimenting with various forms of finely divided carbon produced in electric arcs. During this work, around 1982, they found a form of carbon with a peculiar double hump, which they called "the camel."

When, in 1985, they heard of the discovery of C<sub>60</sub>, buckminsterfullerene, they suspected that this might be the cause of their camel spectrum. Huffman and Kratschmer reproduced their earlier experimental conditions, in which they had formed a carbon powder by striking an arc between graphite electrodes in a low pressure of helium.

They treated the resulting soot with benzene, from which they crystallized a light-yellow solid, which they named "fullerite." It was later found to contain about 75% of C<sub>60</sub> together with 25% of another fullerene, C<sub>70</sub>. The method has allowed the production of fullerenes in large quantities.

**Huggins, Charles Brenton** (1901–1997) *Canadian-American surgeon*

Huggins, who was born at Halifax in Nova Scotia, was educated at Acadia University and at the Harvard Medical School, where he obtained his MD in 1924. After graduate training at the University of Michigan he moved to the University of Chicago in 1927 where he served as professor of surgery from 1936 and director of the May Laboratory of Cancer Research from 1951 until 1969.

In 1939 Huggins made a very simple infer-

ence that led to the development of new forms of cancer therapy. Noting that the prostate gland was under the control of androgens (male sex hormones) he concluded that cancer of the prostate might be treated by preventing the production of androgens. Admittedly his proposed treatment of orchiectomy (castration) might appear somewhat severe but it did lead to remissions in some cases and an alleviation of the condition in others.

Huggins soon appreciated, however, that the same results could probably be achieved by the less drastic procedure of the administration of female sex hormones to neutralize the effect of androgens produced by the testicles. Consequently in 1941 he began to inject his patients with the hormones stilbestrol and hexestrol. He was able to report later that of the first 20 patients so treated 4 were still alive after 12 years. Later workers, inspired by Huggins's work, treated women suffering from cancer of the breast with the male hormone testosterone and claimed improvement in some 20% of the cases.

It was for this work that Huggins shared the 1966 Nobel Prize for physiology or medicine with Peyton ROUS.

### **Huggins, Sir William** (1824–1910) *British astronomer and astrophysicist*

It is remarkable that the elements most widely diffused through the host of stars are some of those most closely connected with the living organisms of our globe, including hydrogen, sodium, magnesium, and iron. May it not be that, at least, the brighter stars are like our Sun, the upholding and energizing centres of systems of worlds, adapted to be the abode of living beings?

—Report on his observations (1863)

Huggins, the son of a London silk merchant, attended school for a short period before being educated privately. After a few years in business he retired to devote himself exclusively to the study of science. His first interest was in microscopy but he became absorbed in the work of Gustav KIRCHHOFF and Robert BUNSEN on spectroscopy and the solar spectrum and decided that he would try to do the same with the stars. He equipped himself with the best of instruments, including a superb 8-inch (20-cm) glass from Alvan CLARK. He spent some time making maps of the terrestrial elements before moving to the stars, collaborating with William MILLER, professor of chemistry at King's College, London. He then began the first major intensive spectral investigation of the stars, which lasted until he was 84 years old, when he found that he could no longer see clearly enough. In later life he was also helped by his wife, Margaret, whom he married in 1875.

Huggins's first observations, published in 1863, showed the stars to be composed of known elements occurring on the Earth and in

the Sun. His next great discovery came when he obtained the spectra of those nebula that earlier astronomers had failed to resolve into stars. His excitement is apparent in his report: "I looked into the spectroscope. No spectrum such as I expected! A single bright line only!...The riddle of the nebula was solved...Not an aggregation of stars, but a luminous gas." He quickly examined the spectra of over 50 nebulae and found that a third were gaseous. In the same year he obtained the spectra of a comet and found that it contained hydrocarbons. In 1866 he showed that a nova was rich in hydrogen. He also discovered previously unidentified bright emission lines in the spectra of certain nebulae and attributed them to a new element "nebulium." The true explanation for these forbidden lines was not provided until the next century, by Ira BOWEN.

In 1868 Huggins successfully employed a use of spectroscopy that has had a more profound impact on cosmology than anything else. It had been shown by Christian DOPPLER and Armand FIZEAU that the light waves of an object leaving an observer would have a lower frequency, and the frequency of an object approaching an observer should increase. In spectral terms this means that the spectra of the former object should be shifted toward the red and the latter toward the blue. In 1868 Huggins examined the spectrum of Sirius and found a noticeable red shift. As the degree of the shift is proportional to the velocity, Huggins was able to calculate that the speed of recession of Sirius was about 25 miles (40 km) per second. He quickly determined the velocity of many other stars. He and Lady Huggins published their spectral work in its entirety as the *Atlas of Representative Stellar Spectra* in 1899. Huggins had tried to photograph Sirius but was only successful in 1876 by which time the gelatine dry plate had been developed.

Huggins was knighted in 1897, and was president of the Royal Society from 1900 to 1905.

### **Hughes, John Russell** (1928– ) *American neurophysiologist*

Born in Du Bois, Pennsylvania, Hughes was educated at Oxford University and at Harvard, where he obtained his PhD in 1954. After some time at the National Institutes of Health and the State University of New York, he moved to Northwestern University where he has served as professor of neurophysiology since 1964.

Among other problems Hughes has worked on the way in which information is transmitted within the central nervous system. In particular he has made a detailed study of the "language" used by the olfactory bulb to inform the brain of the nature of the olfactory medium. His method consisted of implanting electrodes in the olfactory bulb and recording their re-

sponse to gauze soaked with a certain chemical held at a standard distance away. He found that the message transmitted essentially comprises a mixture of various frequency components.

**Huisgen, Rolf** (1920– ) *German chemist*

Huisgen (**hoos**-gen), born the son of a surgeon in Gerolstein, Germany, studied chemistry at the universities of Bonn and Munich where he obtained his PhD in 1943. He initially taught at Tübingen before moving in 1952 to the University of Munich as professor of chemistry and director of the Institute of Physical Chemistry. He retired in 1988.

Huisgen has worked on the mechanisms of organic chemical reactions, and particularly on reactions leading to the formation of ring compounds. Many of his studies have been on reactions to which the principle of orbital symmetry, introduced by Robert Burns WOODWARD and Roald Hoffman, applies.

**Hulse, Russell Alan** (1950– ) *American astrophysicist*

In 1974 Hulse was working as a graduate student at the University of Massachusetts, Amherst, under the supervision of Joseph TAYLOR. It was arranged that he would spend the summer in Puerto Rico using the Arecibo Radio Telescope to search for pulsars, a type of star first observed by Jocelyn BELL-BURNELL in 1967. Among several pulsars detected by Hulse one particular example, named 1913+16 in the constellation Aquila, proved to be of special significance.

Hulse initially found that the pulsar had a short period of 0.059 seconds. More detailed examination, however, revealed that the pulse rate was not constant but varied by some 5 microseconds from day to day. At first Hulse suspected a computer fault. But despite writing a new program, the variability remained. Eventually Hulse spotted that the variation was cyclical, repeating itself every 7.75 hours.

Such phenomena, Hulse argued, would arise naturally if the pulsar was a binary, orbiting an undetected companion star. This would produce a DOPPLER effect. That is, when the pulsar travels in its orbit toward the Earth the pulses would be crowded together, giving a greater than average pulse rate; when, however, it traveled away from the Earth the pulses would be more spread out and yield a lower than average frequency.

In collaboration with Taylor, Hulse went on to establish some of the basic properties of the pulsar. It appeared to have a mass equivalent to 2.8 solar masses, was thought to be a neutron star with a diameter no more than 20–30 kilometers, and to have an approaching velocity of 300 kps (kilometers per second) and a receding

velocity of 75 kps. For his work in this field Hulse shared the 1993 Nobel Prize for physics with Joseph Taylor.

After completing his work on the pulsar 1913+16 in 1977 Hulse moved to Princeton, abandoned astronomy, and began to work at the Plasma Physics Laboratory.

**Hulst, Hendrik Christoffell van de See**  
**VAN DE HULST, HENDRIK CHRISTOFFELL.**

**Humason, Milton La Salle** (1891–1972)  
*American astronomer*

Born in Dodge Center, Minnesota, Humason had no formal university training – in fact he began work as a donkey driver moving supplies to the Mount Wilson Observatory in southern California. Here he quickly developed an interest in astronomy and its techniques, an interest that was stimulated by the staff of the observatory. He was taken on as janitor and by 1919 he was competent enough to be appointed assistant astronomer on the staff of the Mount Wilson Observatory and, after 1948, of the Palomar Observatory, where he spent the rest of his career.

In the 1920s Edwin HUBBLE formulated his law that the distance of the galaxies was proportional to their recessional velocity. This work was based on the careful, painstaking, and difficult measurements of galactic red shifts made by Humason and also by Vesto SLIPHER. Humason developed extraordinary skill in this field. By 1936, using long photographic exposures of a day or more, he was able to measure a recessional velocity of 40,000 kilometers per second, which took him to the limits of the 100-inch (2.5-m) reflecting telescope at Mount Wilson.

With the opening of the Palomar Observatory he was able to use the 200-inch (5-m) Hale reflector and by the late 1950s was obtaining velocities of over 100,000 km per second; this corresponded to a distance, according to Hubble's law, of about six billion light-years.

**Humboldt, Alexander, Baron von**  
(1769–1859) *German explorer and scientist*

An object well worthy of research, and which has long fixed my attention, is the small number of simple substances (earthy and metallic) that enter into the composition of animated beings, and which alone appear fitted to maintain what we may call the chemical movement of vitality.

—*Personal Narrative of Travels to the Equinoctial Regions of America* (1804)

Humboldt (**hum**-bolt or **huum**-bolt) was born in Berlin, Germany. He initially showed little enthusiasm for his studies, but while taking an engineering course in Berlin suddenly became interested in botany, and a year at the University of Göttingen further increased his

interest in the sciences. Geology and mineralogy particularly intrigued him and he went on to join the School of Mines in Freiberg, Saxony, staying there for two years. He then worked for the mining department in Ansbach-Bayreuth, reorganizing and supervising the mines in the region.

In 1796 Humboldt inherited enough money to finance himself as a scientific explorer, and he gave up mining to do two years' intensive preparatory studies in geological measuring methods. Initially his expeditionary plans were thwarted by the Napoleonic Wars but, in 1799, he finally managed to sail with a ship bound for Latin America.

The French botanist, Aimé Bonpland, accompanied him on the five-year journey, during which they navigated the Orinoco River and traveled widely through Peru, Venezuela, Ecuador, and Mexico, collecting scientific specimens and data and covering over 6,000 miles. Humboldt studied the Pacific coastal currents, the *Humboldt current* (now the Peru current) being named for him, and he was the first to propose building a canal through Panama. He investigated American volcanoes, noting their tendency to follow geological faults, and concluded that volcanic action had played a major part in the development of the Earth's crust, thus finally disproving the neptunist theory of Abraham WERNER. He climbed the Chimborazo volcano to what was then a world record height of 19,280 feet (5,876 m), and was the first to attribute mountain sickness to oxygen deficiency. He also measured changes in temperature with altitude and noted its effect on vegetation.

On his return to Europe in 1804, Humboldt settled in Paris and began to publish the data gathered on his travels, a task that took 20 years and filled 30 volumes. He introduced isobars and isotherms on his weather maps, so pioneering the subject of comparative climatology, and also helped initiate ecological studies with his discussions on the relationship between a region's geography and its flora and fauna.

By 1827 Humboldt's finances were severely depleted and he returned to Berlin as tutor to the Prussian crown prince. Two years later he was invited by the Russian finance minister to visit Siberia, and Humboldt made use of the trip to take more geological and meteorological measurements. He also organized a series of meteorological and magnetic observatories through Russia, Asia, and the British Empire, to trace the fluctuations in the Earth's magnetic field.

Humboldt spent the last years of his life writing *Kosmos* (The Cosmos), a synthesis of the knowledge about the universe then known, of which four volumes were published during his lifetime.

### Hume, David (1711–1776) *British philosopher*

If we take in our hand any volume, of divinity or school metaphysics, for instance, let us ask, Does it contain any abstract reasoning concerning quantity or number? No. Does it contain any experimental reasoning concerning matter of fact and existence? No. Commit it then to the flames; for it can contain nothing but sophistry and illusion.  
—*An Enquiry Concerning Human Understanding* (1748)

Hume was the younger son of a laird. Born in Edinburgh, Scotland, and educated at the university there, he intended to study law but found himself stricken with an "insurmountable aversion to everything but the pursuit of philosophy and general learning." He became a tutor, served in a variety of diplomatic posts, and spent the period 1752 to 1763 as librarian of the Edinburgh Faculty of Advocates where he wrote his *History of England* (6 vols., 1754–62). After another period of diplomatic service abroad in Paris, Hume retired to Edinburgh in 1769. In the spring of 1775 Hume contracted cancer. Shortly before his death in the summer of 1776 he was visited by James Boswell, eager to report back to Dr. Johnson that the notorious atheist, Hume, was facing death with apprehension. Instead he found Hume placid and cheerful, denying that death was to be feared and declaring survival to be "an unreasonable fancy." Boswell was most disturbed.

In 1738 Hume published his masterpiece, *A Treatise of Human Nature*, in which his aim was to do for the moral sciences, the science of man, what NEWTON had done for the natural sciences. In pursuing this aim Hume was led into a profound study of causality – the idea of a "necessary connection" between two physical events when one is said to be the cause of the other – work that carried important implications for science. Against Rationalists such as DESCARTES, Hume argued that empirical knowledge can never be deduced a priori, thus aiding the destruction of the Cartesian tradition in science. Hume put forward the basis of modern Empiricism – that all knowledge of matters of fact (and thus scientific knowledge) is based on experience and evidence and is therefore only probable, capable of denial, and can never be logically necessary. Thus in his analysis of causation Hume argued that there is no necessary connection between physical events (e.g., when one is said to be the *cause* of the other); there is no mystical "power" in one event that "brings about" another. We merely observe that one type of event is invariably followed by another, and because of this association of ideas in our minds, when we observe an event of the first type we "predict" an event of the second.

But such a practice will only be sound if the conjunctions we have observed in the past continue to hold in the future. How can, asked

Hume, this latter assumption be justified? Not by pure reason, nor from experience, for we cannot conclude from the fact that nature has behaved uniformly in the past that it will continue to do so without assuming the truth of the very principle we are examining. In this way Hume presented the classical “problem of induction” that has since been puzzled over by generations of philosophers and scientists.

**Hume-Rothery, William** (1899–1968)  
*British metallurgist*

The son of a lawyer, Hume-Rothery was born at Worcester Park in Surrey, England. He originally intended to pursue a military career and consequently entered the Royal Military Academy, Woolwich, on leaving school. An attack of meningitis which left him totally deaf forced him to leave the army and he turned instead to chemistry. Although refused entry to his father's college, Trinity College, Cambridge, because of his deafness, he was more graciously received by Magdalen College, Oxford. After obtaining his PhD from the Royal School of Mines in 1925, Hume-Rothery returned to Oxford where he remained for the rest of his life, being appointed in 1958 to the university's first chair of metallurgy.

With 178 published papers to his credit Hume-Rothery illuminated many areas of metallurgy. His best-known work was concerned with alloys that are solid solutions, in which atoms of the constituent metals share a common lattice. The *Hume-Rothery rules* give the conditions that have to be satisfied for metallic solid solutions to form. The first concerns the atomic size factor and claims that if the atomic diameter of the solvent differs in size from that of the solute by more than 14%, the chances of solubility are small. Secondly, the more electronegative is one component and the more electropositive the other, the more they are likely to form compounds rather than solutions. And, finally, a metal of lower valency is more likely to dissolve one of higher valency than vice versa. Much of his work in this field was published in his book *The Structure of Metals and Alloys* (1936).

**Hund, Friedrich** (1896–1997) *German physicist*

Hund (hunt) was born in Karlsruhe, Germany, and educated at the Universities of Marburg and Göttingen, gaining his PhD from Göttingen under the supervision of Max BORN in 1922. He stayed at Göttingen between 1922 and 1927 before moving to the University of Rostock (1927–29) and the University of Leipzig (1929–46). He was a professor of physics at the University of Jena between 1946 and 1951, the University of Frankfurt-am-Main between

1951 and 1956, and the University of Göttingen between 1956 and his retirement in 1964.

Hund worked on molecular orbital theory and interpreted molecular spectra in terms of this theory in the late 1920s. He is perhaps best known to chemists and physicists for *Hund's rules* – a series of rules for determining the ground state of a many-electron atom. Hund derived these rules using a combination of the old quantum theory of Niels BOHR and Arnold SOMMERFELD and the empirical study of atomic spectra. They were subsequently derived from the quantum theory of many-electron systems. He also wrote a number of books and reviews on atomic and molecular theory and produced a history of quantum theory.

**Hunsaker, Jerome Clarke** (1886–1984)  
*American aeronautical engineer*

Hunsaker was born in Cheston, Iowa, and educated at the U.S. Naval Academy, graduating in 1908. He served in the navy from 1909 until 1926, reaching the rank of commander. Selected for the Construction Corps, he studied naval architecture at the Massachusetts Institute of Technology and aeronautical engineering in Europe. In 1914 he established the first course in aeronautical engineering at MIT. Recalled by the navy (1916) to put aeronautical engineering into practice, he worked on zeppelins, producing the *Shenandoah* (1923), and flying boats. Hunsaker worked in business from 1926, initially at the Bell Telephone Laboratories and then (1928–33) at Goodyear where he built zeppelins. In 1933 Hunsaker was appointed professor of mechanical engineering at MIT, also serving concurrently as head of the department of aeronautical engineering until his retirement in 1951.

He was the author of *Aeronautics at the Mid-century* (1952), a review of the problems facing the industry and the strategies open to it.

**Hunt, Sir Timothy R.** (1943– ) *British cell biologist*

Hunt gained a BA from Cambridge University in 1964, and a PhD in 1968. In 1981 he was appointed university lecturer in biochemistry at Cambridge, and in 1990 joined the Imperial Cancer Research Fund. Hunt was knighted in 2006.

Hunt is noted for his discovery in the early 1980s of the first cyclin molecule. Cyclins are proteins that periodically rise and fall in concentration during the cell cycle, hence their name. Hunt isolated his first cyclin in the sea urchin *Arbacia*, after finding a protein that underwent periodic degradations in step with phases of the cell cycle – a characteristic feature of cyclins. Hunt went on to find cyclins in other species, and showed that they had very similar

molecular structures (i.e. were structurally conserved).

Cyclins are crucial regulators of the cell cycle. They form complexes with another family of proteins, the cyclin-dependent kinases. The cyclin component controls the activity of the complex, determining which proteins the CDK component phosphorylates (adds phosphate groups to) to drive the cycle forward. As the cyclin levels rise and fall, so does the activity of the CDKs. Hence the progress of the cell cycle is controlled.

Hunt's work helps our understanding of cancer. For example, abnormally high or sustained levels of cyclins and CDKs are found in certain human tumors, such as breast cancer and brain tumors, indicating malfunction of the cell-cycle control mechanisms. Inhibitors of these key molecules may have the potential to treat certain cancers.

For his discoveries of key regulators of the cell cycle Hunt was awarded the 2001 Nobel Prize for physiology or medicine, jointly with Leland HARTWELL and Paul NURSE.

### **Hunter, John** (1728–1793) *British surgeon and anatomist*

... A gifted interpreter of the Divine Power and Wisdom at work in the Laws of Organic Life, and ... the founder of Scientific Surgery.  
—Memorial plaque to Hunter in Westminster Abbey (1859)

Hunter, who was born at Long Calderwood in Scotland, joined his elder brother William, the famous obstetrician, in London in 1748. He there assisted his brother and attended surgical classes at Chelsea Hospital. Disputes with William over their research led John to branch out on his own and in 1759 he joined the army to serve as a surgeon in Portugal during the Seven Years' War. On his return to London in 1762 he set up as a private teacher and in 1767 was appointed surgeon at St. George's Hospital, London.

As a surgeon Hunter's major innovation was in the treatment of aneurysm, a bulge appearing at a weak spot in the wall of an artery. Rather than follow the drastic procedure of amputation Hunter instead tied the artery some distance from the diseased part and found that, with the pressure of circulation removed from the aneurysmal sack, the progress of the disease is halted. He also made radical proposals, based on his military experience, for the treatment of gunshot wounds. He wisely argued in his *A Treatise on the Blood, Inflammation and Gunshot Wounds* (1794) that unless the missile in the body was actually endangering life the surgeon should leave it alone and under no circumstances enlarge the wound by opening it.

Hunter also wrote a famous work on venereal disease (1786), inadvertently producing much confusion. In the late 18th century it was

still a matter of dispute whether syphilis with its chancre and gonorrhoea with its purulent discharge were separate complaints. In 1767 Hunter decided to resolve the issue by inoculating himself with gonorrhoea. He developed both gonorrhoea and the typically hard chancre of syphilis, concluding therefore that discharge from a gonorrhoea produces chancres. It seems not to have occurred to Hunter that his "gonorrhoea" was also infected with syphilis.

Hunter's main claim to fame however lay in his superb anatomical collection. He was supposed to have dissected over 500 different species and at his death his collection contained over 13,000 items. Included in his museum in Leicester Square, London, was the skeleton of the Irish giant, C. Byrne, who was so keenly aware of the desire of Hunter for his 7-foot 7-inch frame that he arranged to be secretly buried at sea. Hunter was widely reported to have paid the undertakers the sum of £500 for the corpse.

His collection was purchased by the government after his death and in 1795 was presented to the Royal College of Surgeons in London where, despite some losses from bombing in World War II, it has remained ever since.

### **Hunter, William** (1718–1783) *British obstetrician*

Some physiologists will have it that the stomach is a mill; – others, that it is a fermenting vat; – others again that it is a stew-pan; – but in my view of the matter, it is neither a mill, a fermenting vat, nor a stew-pan – but a stomach, gentlemen, a stomach.  
—In a lecture to medical students

A brother of John Hunter, the famous surgeon, William was born at Long Calderwood in Scotland and studied medicine at Edinburgh University before moving to London in 1740. Hunter went on to specialize in obstetrics and became an eminent practitioner, attending the royal family. He founded the Great Windmill Street School of Anatomy and his most famous work is *The Anatomy of the Human Gravid Uterus* (1774), a collation of 25 years' work, which contains 34 detailed plates produced from engravings of dissections.

Hunter built up a large and valuable collection of coins, medals, pictures, and books, which he bequeathed to Glasgow University. It is now housed in the Hunterian Museum.

### **Huntington, George** (1851–1916) *American physician*

Huntington was born in East Hampton, New York, the son and grandson of physicians. He was initially trained by his father before following a more formal course of medicine at the College of Physicians and Surgeons, Columbia University. He worked for some years with his father in East Hampton before moving to

Palmyra, Ohio. Huntington returned later to Dutchess County, New York.

In 1872 he published a paper, *On Chorea*, in which he described an encounter with two women near East Hampton, a mother and a daughter. They were, he noted, "tall, thin, almost cadaverous, both bowing, twisting, grimacing." The disease was common in the area and he went on to note some of its main features. The condition was invariably fatal and progressed "gradually but surely until the hapless sufferer is but a quivering wreck." He also noted that it was "an heirloom from the past" in that it was confined to a few families – if the parents contracted the chorea then so would one or more of the children. Huntington also reported that it was an adult complaint, unknown in anyone under thirty. Not much more was known about the complaint until a century later when Nancy WEXLER began her search for the responsible gene. The disease, now known as Huntington's chorea, was thought to have been brought to East Hampton by a settler from Suffolk a century earlier.

**Hurter, Ferdinand** (1844–1898) *Swiss chemist*

Born at Schaffhausen in Switzerland, Hurter (**huur-ter**) was educated at the Federal Institute of Technology, Zurich, and at Heidelberg University, where he was a pupil of Robert BUNSEN. In 1867 he moved to England and became the chief chemist at Holbrook GASKELL and Henry DEACON's alkali factory in Widnes. In 1890, when the United Alkali Company was formed, Hurter was appointed its chief chemist and set up one of the first industrial research laboratories. He collaborated with Lunge in producing *The Alkali Maker's Handbook*, a work describing the LEBLANC process in technical detail. Hurter also worked on photography with V. C. Driffield.

**Hutchinson, George Evelyn** (1903–1991) *American biologist*

Hutchinson was born in Cambridge, England, and graduated from the university there in 1924. He was senior lecturer at the University of Witwatersrand (1926–28) before emigrating to America where he served as Sterling Professor of Zoology at Yale from 1945 until 1971. He received American citizenship in 1941.

Hutchinson's most important work was concerned with aquatic ecosystems and the physical, chemical, meteorological, and biological conditions of lakes. He made particular studies of the classification and distribution of aquatic bugs (Hemiptera), and investigated water mixing and movement in stratified lakes, proving the circulation of phosphorus. He also studied lake sediments and investigated certain aspects of evolution. His work took him to many

different regions, including the lakes of western Transvaal, Tibet, and northeastern North America. Hutchinson published much of his life's work in his *A Treatise on Limnology* (3 vols., 1957–75); a fourth volume was completed shortly before his death and published in 1993.

**Hutchinson, John** (1884–1972) *British botanist*

Hutchinson, who was educated at the village school in Wark-on-Tyne, England, where he was born, began work in 1900 under his father, the head gardener on a large estate. In 1904 he was appointed to a junior post at the Royal Botanic Gardens, Kew, where he remained for the rest of his career. Starting as an assistant in the herbarium he was in charge of the Africa section from 1919 until 1936 when he became keeper of the Museum of Economic Botany, a post he occupied until his retirement in 1948.

Hutchinson's most significant work was his *Families of Flowering Plants* (2 vols. 1926–34; 2nd edition 1959), which contains details of 342 dicotyledon and 168 monocotyledon families. Hutchinson drew most of the illustrations for this work himself. In it he concentrated on the different plant families that various workers had considered the most primitive. He concluded that bisexual flowers with free petals, sepals, etc., as seen in the magnolia and butternut families, are more ancient than the generally unisexual catkinlike flowers found in the nettle and beech families, which lack these parts. This conclusion supported the classification of George BENTHAM and Joseph HOOKER and added weight to arguments against the system of Adolf ENGLER. Furthermore Hutchinson stated that families with apparently more simple flowers are in fact more advanced, and have evolved by reduction from more complex structures; that is, the families show retrograde evolution. In this, the now generally accepted view, Hutchinson was developing the earlier ideas of the German botanist, Alexander Braun.

An enormously prolific and industrious worker, Hutchinson also published, with John Dalziel, the standard work, *Flora of West Tropical Africa* (1927–36) and at the time of his death was engaged in a revision of the *Genera Plantarum* (Genera of Plants) of Bentham and Hooker.

**Hutton, James** (1726–1797) *British geologist*

There is presently laying at the bottom of the ocean the foundation of a future land, which is to appear after an indefinite space of time.

—*Concerning the System of the Earth, its Duration, and Stability* (1788)

It is scarcely more difficult to procure the secrets of science from Nature herself, than to dig them from the writings of this philosopher.

—Thomas Thomson (1801)

Hutton was born in Edinburgh, Scotland, the son of a merchant who became the city treasurer. He was educated at Edinburgh University, which he left in 1743 to be apprenticed to a lawyer. This did not retain his interest long for, in 1744, he returned to the university to read medicine. He studied in Paris for two years and finally gained his MD from Leiden in 1749. He next devoted several years to agriculture and industry, farming in Berwickshire and commercially producing sal ammoniac. In 1768 he returned to Edinburgh, financially independent, and devoted himself to scientific studies, especially of geology, for the rest of his life.

Hutton's uniformitarian theories were first published as a paper in 1788 and later extended into a two-volume work, *Theory of the Earth* (1795). This work proved difficult to read and it only reached a wide audience when his friend John PLAYFAIR edited and summarized it as *Illustrations of the Huttonian Theory* (1802). It marked a turning point in geology. The prevailing theory of the day, the neptunism of Abraham WERNER, was that rocks had been laid down as mineral deposits in the oceans. However, Hutton maintained that water could not be the only answer for it was mainly erosive. The water could not account for the non-conformities caused by the foldings and intrusions characteristic of the Earth's strata. Hutton showed that the geological processes that had formed the Earth's features could be observed continuing at the present day. The heat of the Earth was the productive power, according to Hutton, that caused sedimentary rocks to fuse into the granites and flints, which could be produced in no other way. It could also produce the upheaval of strata, their folding and twisting, and the creation of mountains.

A long time scale is essential to Hutton's theory of uniformitarianism as the forces of erosion and combustion work, in general, only slowly, as demonstrated by the presence of visible Roman roads. He concluded that on the face of the Earth "we find no vestige of a beginning – no prospect of an end."

Hutton's work was accepted with little delay by most geologists, including the leading Edinburgh neptunist, Robert Jameson. In the 19th century Charles LYELL expanded the theories of uniformitarianism and these were to influence Charles DARWIN in his theory of evolution.

### **Huxley, Sir Andrew Fielding** (1917– ) *British physiologist*

Huxley, a grandson of T. H. Huxley, was born in London and graduated in 1938 from Cambridge University, receiving his MA there three years later. He is best known for his collaboration with Alan HODGKIN in elucidating the "sodium pump" mechanism by which nerve impulses are transmitted, for which they were awarded,

with John ECCLES, the Nobel Prize for physiology or medicine (1963). He has also done important work on muscular contraction theory and has been involved in the development of the interference microscope and ultramicrotome. Huxley was reader in experimental biophysics at Cambridge (1959–60), and from 1960 to 1969 was Jodrell Professor of Physiology at University College, London. In 1969 he was elected research professor becoming emeritus professor in 1983. In 1980 he succeeded Alexander TODD as president of the Royal Society, a position he held until 1985. He also served as master of Trinity College, Cambridge, from 1984 to 1990 and was knighted in 1974.

### **Huxley, Hugh Esmor** (1924– ) *British molecular biologist*

Huxley (no relation to T. H. Huxley or any of his descendants) was born at Birkenhead in north-west England. He studied physics at Cambridge University where he obtained his PhD in 1952 after wartime research on the development of radar. Like many other physicists after the war Huxley was interested in applying physics to biological problems. After two years in America at the Massachusetts Institute of Technology and the period 1956–61 at the biophysics unit of the University of London, he returned to Cambridge to join the staff of the Medical Research Council's molecular biology laboratory, where he remained until 1987. In 1988 he became director and professor of biology at Brandeis University, Boston. He also served from 1988 to 1994 as director of the Rosentiel Basic Medical Sciences Research Centre at Brandeis. Huxley was awarded the Copley Medal of the Royal Society in 1998.

In 1953, in collaboration with Jean Hanson, Huxley proposed the sliding-filament theory of muscle contraction. This was based on his earlier study of myofibrils, the contractile apparatus of muscle, with the electron microscope. He found that myofibrils are made of two kinds of filament, one type about twice the width of the other. Each filament is aligned with other filaments of the same kind to form a band across the myofibril, and the bands of thick and thin filaments overlap for part of their length. The bands are also linked by an elaborate system of crossbridges. When the muscle changes length the two sets of filaments slide past each other. Further, the two sorts of filaments can be identified with the two chief proteins of muscle, myosin in the thick filament and actin in the thin. This made possible an elegant solution to how muscles contract at the molecular level.

In the areas where both kinds of protein are in contact, Huxley suggested that one, most probably myosin, serves as an enzyme, splitting a phosphate from ATP and so releasing the en-

**MUSCLE CONTRACTION** *The sliding-filament theory proposed by Hugh Huxley and Jean Hanson.*

ergy required for contraction. He concluded that the evidence of the combination of actin and myosin is seen in the bridges between the two kinds of filaments.

The theory has since been much enlarged and taken to deeper levels of molecular understanding. Despite this, the basic insight of Huxley and Hanson has remained intact.

### **Huxley, Sir Julian Sorell (1887–1975)** *British biologist*

Operationally, God is beginning to resemble not a ruler but the last fading smile of a cosmic Cheshire cat.

—*Religion without Revelation* (1927)

A grandson of T. H. Huxley, Julian Huxley was born in London and graduated in zoology from Oxford University in 1909. He did research on sponges (Porifera) at the Naples Zoological Station (1909–10) before taking up the post of lecturer in biology at Oxford (1910–12). From 1912 until 1916 he worked at the Rice Institute, Houston, Texas, where he met the famous American geneticist Hermann MULLER. Before returning to Oxford to take up the post of senior demonstrator in zoology (1919–25) he saw war service in Italy. He was next appointed professor of zoology at King's College, London (1925–27), resigning from this post to devote more time to writing and research.

Huxley was a keen ornithologist and published, in 1914, a classic paper on the courtship of the great crested grebe. In the 1930s he was involved in the production of natural-history films, the most notable of which was the highly praised *Private Life of the Gannet* (1934), which he produced with the help of R. M. Lockley. One of the leading popularizers of science of modern times (especially the years before and just after World War II), Huxley spent much of his life explaining advances in natural science to the layman and in advocating the application of science to the benefit of mankind. To many he is best remembered as a most capable and lucid educationalist, but Huxley was also eminent in many other fields.

In 1946 he was appointed the first director-general of UNESCO, a post he held for two years. As an administrator, he also did much to transform the Zoological Society's collections at Regent's Park (London Zoo). Viewing man as "the sole agent of further evolutionary advance on this planet," he caused considerable controversy by advocating the deliberate physical and mental improvement of the human race through eugenics. Huxley's biological research was also extensive, carrying out work on animal hormones, physiology, ecology, and animal (especially bird) behavior as it relates to evolution. He was president of the Institute of Animal Behaviour and the originator of the term "ethol-

ogy," now in general use to define the science of animal behavior. He also introduced several other scientific terms, such as cline and clade.

Huxley's publications are extensive and include *Evolution: the Modern Synthesis* (1942, 1963). He was knighted in 1958.

### Huxley, Thomas Henry (1825–1895) *British biologist*

The great tragedy of science – the slaying of a beautiful hypothesis by an ugly fact.  
—“Biogenesis and Abiogenesis,” *Collected Essays*, Vol. VIII

Huxley, the seventh child of a school teacher, was born in Ealing in southeast England and received only two years' schooling. From the age of 10 he educated himself, doing sufficiently well to be admitted to Charing Cross Hospital to study medicine. He graduated in 1845 and the following year was employed as surgeon on HMS *Rattlesnake*, which was due to survey the Torres Strait between Australia and Papua. During the voyage Huxley studied the marine life of tropical waters and wrote an important paper on the medusae (jellyfish) and related species, naming a new phylum, the Coelenterata, into which these were placed. Recognizing the value of this work, the Royal Society elected Huxley a member in 1851. In 1854 he became lecturer in natural history at the Royal School of Mines (later the Royal College of Science) and while there gave a lecture on “The Theory of the Vertebrate Skull,” which disproved the idea that the skull originates from the vertebrae.

Huxley is best remembered as the main advocate of Charles DARWIN's theory of evolution, and in 1860 – the year following the publication of *The Origin of Species* – he took part in the famous debate with the bishop of Oxford, Samuel Wilberforce, at the Oxford meeting of the British Association for the Advancement of Science. During the discussion Wilberforce asked whether Huxley traced his ancestry to the apes on his mother's or father's side of the family. Huxley answered witheringly that given the choice of a miserable ape and a man who could make such a remark at a serious scientific gathering, he would select the ape. The meeting resulted in a triumph for science, and after it Huxley continued to gain the better of many other distinguished theologians in long academic wrangles. He introduced the term “agnosticism” to describe his own view that since knowledge rested on scientific evidence and reasoning (and not blind faith) knowledge of the nature and certainty about the very existence of God was impossible.

Huxley worked hard to better educational standards for the working classes and spoke out against the traditional method of learning by rote. He opened Josiah Mason College (later Birmingham University), Owens College Med-

ical School (later part of Manchester University), and Johns Hopkins University, Baltimore. Huxley was the grandfather of the author Aldous Huxley, the Nobel Prize winner Andrew Huxley, and the biologist Sir Julian Huxley.

### Huygens, Christiaan (1629–1695) *Dutch physicist and astronomer*

A man that is of Copernicus's opinion, that this earth of ours is a Planet, carry'd round and enlightn'd by the Sun, like the rest of them, cannot but sometimes have a fancy ... that the rest of the Planets have their Dress and Furniture, nay and their Inhabitants too ...  
—*New Conjectures Concerning the Planetary Worlds, Their Inhabitants, and Productions* (c. 1690)

Huygens (**hi**-genz or **hoi**-gens), whose father was the famous Renaissance poet Constantin Huygens, was born in The Hague and studied at the University of Leiden and the College of Breda. He worked in Paris as one of the founding members of the French Academy of Sciences from 1666 to 1681 when, as a Protestant, he found the growing religious intolerance threatening, and returned to The Hague. His first work was in mathematics, but his greatest achievements were in physical optics and dynamics, and his importance to 17th-century science is second only to that of NEWTON.

Huygens's first great success was the invention of the pendulum clock. GALILEO had noted in 1581 that a pendulum would keep the same time whatever its amplitude. Many, including Galileo himself, had tried unsuccessfully to use this insight to construct a more reliable clock. Huygens showed that a pendulum that moves in the arc of a circle does not move with an exactly equal swing. To produce an isochronous (equal-timed) swing it would need to move in a curve called a cycloid. It should be emphasized that Huygens worked this out largely from first principles. He also showed how the pendulum could be constructed so to move in a cycloidal path and how to make the connection to the escapement. The first clock was made to his design by Salomon COSTER in 1657 and was described in Huygens's book *Horologium* (1658; *The Clock*). The pendulum became one of the basic tools of 17th-century scientific investigation.

Huygens also made major contributions to astronomy as a designer of improved telescopes and as an observer of Saturn. He discovered Titan, Saturn's largest satellite, in 1655 and after prolonged observation was able to describe Saturn's rings correctly.

In 1673 Huygens published *Horologium oscillatorium* (*The Clock Pendulum*), a brilliant mathematical analysis of dynamics, including discussions of the relationship between the length of a pendulum and its period of oscillation, and the laws of centrifugal force. It also included an early formulation of Newton's first

law of motion: that without some external force, such as gravity, a body once set in motion would continue in a straight line. His views on gravity were worked out in *Discours de la cause de la pesanteur* (1690; Discourse on the Cause of Gravity). As a Cartesian (a follower of René Descartes) he could not accept Newtonian action at a distance or, in fact, any talk of forces. Instead he would only accept a mechanical explanation, which meant a return to some kind of vortex theory. That is, bodies can only be heavy not because they are attracted by another body but because they are pushed by other bodies.

Huygens's greatest achievement was his development of the wave theory of light, described fully in his *Traité de la lumière* (1690; Treatise on Light). He assumed that space was pervaded by ether formed of particles, the disturbance of which constituted the radiation of light with the disturbance of one particle being passed on to its neighbor and so on. The disturbances can be considered as waves spreading in a regular spherical form from the point of origin – the particles disturbed in phase constituting a wave front. Each point on a wave front may be regarded as a source of new secondary wavelets and a surface tangent joining such wavelets (i.e., the envelope of the secondary wavelets) can be considered as a new wave front. This method of treating light waves is known as the *Huygens construction*. Using it, Huygens dealt with reflection and refraction and predicted – as Newtonian theory did not – that light should travel more slowly in a denser medium. But as Huygens considered the waves to be longitudinal, the theory could not explain polarization.

Newton's *Opticks* (1704) presented a corpuscular (particle) theory of light, and the wave theory lay dormant until it was taken up by Thomas YOUNG and his contemporaries.

**Hyman, Libbie Henrietta** (1888–1969)  
*American zoologist*

Born in Des Moines, Iowa, and educated at the University of Chicago, Hyman also held a research post there from 1916 until 1931 where, under Charles Manning Child, she worked on the physiology and morphology of the lower invertebrates, particularly the planarians (flatworms). She published a number of works on invertebrate and vertebrate zoology, anatomy, physiology, and embryology, but her major compilation is *The Invertebrates*, a monumental

work, six volumes of which had been published (1940–68) at the time of her death.

**Hypatia** (c. 370–415) *Greek mathematician*

He who influences the thought of his times, influences all the times that follow. He has made his impress on eternity.

—Quoted by Elbert Hubbard in *Little Journeys to the Homes of Great Teachers*

Hypatia (hI-pay-sha), who was born in Alexandria, Egypt, was the daughter of Theon of Alexandria, the author of a well-known commentary on PTOLEMY. In 400 she was reported to be head of the Neoplatonic school in Alexandria. None of her work has survived, although some information about her comes from the letters of her pupil Synesius of Cyrene. To her have been attributed commentaries on Ptolemy's *Almagest*, DIOPHANTUS's *Arithmetic*, and APOLLONIUS's *Conics*. She also designed several scientific instruments including an astrolabe, a hydrometer, and a still.

Learning and science came to a violent conclusion in Alexandria and in the West, as did Hypatia. In conflict with Cyril, bishop of Alexandria, through her friendship with Orestes, the Roman prefect of the city, she was killed by a Christian mob. The circumstances of her death in March 415 have been described by the fifth-century historian Socrates Scholasticus:

All men did both reverence and had her in admiration for the singular modesty of her mind. Wherefore she had great spite and envy owed unto her, and because she conferred oft, and had great familiarity with Orestes, the people charged her that she was the cause why the bishop and Orestes were not become friends. To be short, certain heady and rash cockbrains whose guide and captain was Peter, a reader of that Church, watched this woman coming home from some place or other, they pull her out of her chariot: they hail her into the Church called Caesarium: they strip her stark naked: they raze the skin and rend the flesh of her body with sharp shells, until the breath departed out of her body: they quarter her body: they bring her quarters unto a place called Cinaron and burn them to ashes.

The manner of her death and reports of her intellect and beauty have made her a romantic figure. For many centuries, with the possible exception of the alchemist Maria HEBRAEA, she was regarded as the only woman scientist of the Ancient World.

## **Ignarro, Louis J.** (1941– ) *American pharmacologist*

Ignarro, who was born in Brooklyn, New York, graduated with a BA in pharmacy from Columbia University in 1962 and four years later gained his PhD in pharmacology at the University of Minnesota. From 1979 to 1985 he worked in the department of pharmacology at Tulane University School of Medicine, New Orleans. Since 1985 he has been at the UCLA School of Medicine, Los Angeles, California. In 1998 he shared the Nobel Prize for physiology or medicine with Robert FURCHGOTT and Ferid MURAD for their discovery that molecules of the gas nitrogen monoxide (nitric oxide, NO) can transmit signals in the cardiovascular system. The hitherto unknown substance endothelium-derived relaxing factor (EDRF) had been discovered by Furchgott in 1980. Ignarro made a series of brilliant analyses to determine the chemical nature of EDRF and in 1986 concluded, independently of and together with Furchgott, that the mystery substance was indeed nitrogen monoxide.

## **I-Hsing** (c. 681–c. 727) *Chinese mathematician and astronomer*

I-Hsing (**I-shing**) was a Buddhist monk around whom many legends have grown. Only a small portion of his work has survived so it is difficult to appreciate it in detail. There is, however, no reason to doubt his involvement in two major astronomical achievements. In the period 723–26, in collaboration with the Astronomer Royal, Nankung Yueh, expeditions were organized to measure, astronomically, the length of a meridional line. Over a distance of 1,553 miles (2,500 km) along this line, simultaneous measurements of the Sun's solstitial shadow were made at nine stations. The estimated length of a degree, on the basis of their measurements, was far too large and it must be supposed that some systematic error in the method of observation was taking place. However, when it is appreciated that research expeditions to determine the length of a meridional degree were not organized in Europe until the 17th century, the amazing nature of I-Hsing's work can be appreciated. He also probably anticipated SU SUNG in the use of an escapement in an astronomical clock. It was described in a

13th-century encyclopedia: "Water, flowing into scoops, turned a wheel automatically, rotating it one complete revolution in one day and one night." This turned various rings representing the motion of the celestial bodies. It was soon reported to be corroded, relegated to a museum, and to have fallen into disuse.

## **Imbrie, John** (1925– ) *American geologist*

Imbrie was born at Penn Yan, New York and educated at Princeton and Yale, where he obtained his PhD in 1951. He joined the Columbia faculty in 1952 and, after serving as professor of geology (1961–66), he moved to Brown University where he was professor of geology until 1975. He was then appointed to the chair of oceanography and is currently an emeritus professor.

In his 1956 paper *Biometrical Methods in the Study of Invertebrate Fossils* Imbrie showed how statistical techniques could be applied to the analysis of variation in fossil assemblies. He has also worked on the paleoecology of the Great Bahamas Bank and in his *Ice Ages* (1979) produced a comprehensive and popular survey of the subject.

## **Ingenhousz, Jan** (1730–1799) *Dutch plant physiologist and physician*

Ingenhousz (**ing-en-hows**), who was born at Breda in the Netherlands, studied medicine, chemistry, and physics at the universities of Louvain and Leiden, receiving his MD from Louvain in 1752. In 1765 he visited London and became expert at administering smallpox inoculations using Edward JENNER's method. News of his expertise spread and he was invited to Vienna in 1768 by the Empress Maria Theresa to inoculate her family and to become court physician.

In 1779 Ingenhousz returned to England and published his work on gaseous exchange in plants. His experiments demonstrated that plants absorb carbon dioxide and give off oxygen (in his words, "purify the air") only in the light, and that the reverse process occurs in the dark. The light process later became known as photosynthesis. Ingenhousz also conducted research on soils and on plant nutrition, im-

proved apparatus for generating static electricity, and studied heat conduction in metals.

**Ingold, Sir Christopher Kelk** (1893–1970) *British chemist*

The calculations must have been dreadful ... but one structure like this brings more certainty into organic chemistry than generations of activity by us professionals. —On the structures of hexamethyl benzene and hexachlor benzene as revealed by x-ray crystallography. *Nature*, 1928

Ingold, a Londoner, was educated at the University of Southampton and at Imperial College, London. After serving as professor of organic chemistry at the University of Leeds from 1924 until 1930, he moved to the chair of chemistry at University College, London, where he remained until his retirement in 1961.

With over 400 papers to his credit and as the author of the classic text *Structure and Mechanism in Organic Chemistry* (1953), Ingold was one of the leading figures in British chemistry. The basic aim running through all his work was to understand the mechanism of organic reactions, particularly the kinetics of elimination and substitution reactions. In 1926 he introduced the idea of mesomerism, fully explained in his paper *Principles of an Electronic Theory of Organic Reactions* (1934). This was similar to the concept of resonance proposed by Linus PAULING in the early 1930s. The basic idea was that if a molecule could exist in two electronic structures then its normal state was neither one nor the other but some “hybrid” form. This theory was substantiated by measuring bond lengths in appropriate molecules.

**Ingram, Vernon Martin** (1924–2006) *German–British–American biochemist*

Ingram, born Immerwahr (**im**-er-var) in Breslau (now Wrocław in Poland), was brought to Britain as a child refugee from Nazi Germany. He was educated at Birkbeck College, London, where he obtained his PhD in 1949. After working briefly at Rockefeller and Yale he returned to England and joined the staff of the Medical Research Council’s molecular biology unit at the Cavendish Laboratory, Cambridge, in 1952. In 1958, however, he moved to the Massachusetts Institute of Technology where he served as professor of biochemistry from 1961 and as John and Dorothy Wilson Professor of Biology from 1988.

By the mid-1950s it was clear to Francis CRICK that it should be possible, and was indeed essential, for molecular biology to be able to show that mutant genes produced changes in the amino acid sequences of proteins. Although such a claim was central to the supposed revolution in molecular biology, there was, as Crick realized in 1955, no direct evidence that proteins are in fact coded by genes.

Consequently Crick and Ingram attempted to reveal such a change in the lysozyme of fowl eggs. However, although they succeeded in distinguishing differences between lysozymes from such different birds as duck and pheasant, they failed to find any difference in lysozymes between two hens of the same species. At this point, however, Max PERUTZ gave Ingram some sickle-cell hemoglobin (hemoglobin S) to work with. (Hemoglobin S, possessed by sufferers of a crippling anemia, had been distinguished from normal hemoglobin A by Linus PAULING and his student Harvey Itano in 1949.) Ingram split the hemoglobin into smaller units by using the enzyme trypsin to break the peptide bonds. He then separated these units by electrophoresis and paper chromatography. This allowed him to show that hemoglobin S differs from normal hemoglobin at just one site, where the amino acid valine replaces the glutamic acid of the normal A form. Although it came as a surprise that the alteration of one amino acid in over 500 could produce such major effects, it also dramatically established that molecular biology was not just an abstract and remote branch of structural chemistry.

Ingram went on to show that this and other point mutations of hemoglobin could be used to trace the evolutionary history of vertebrates, work reported in his *The Hemoglobins in Genetics and Evolution* (1963). In later years he focused on the molecular biology of aging and of ALZHEIMER’S disease.

**Ipatieff, Vladimir Nikolayevich** (1867–1952) *Russian–American chemist*

Ipatieff (**i**-pa-tyef), a Muscovite by birth, became an officer in the Imperial Russian Army in 1887 and was educated at the Mikhail Artillery Academy (1889–92) in St. Petersburg. After further study in Germany and France he returned to the academy in 1898 and became professor of chemistry until 1906.

While in Munich (1897) Ipatieff achieved the synthesis of isoprene, the basic unit of the rubber molecule. On his return to Russia he carried out important work on high-pressure catalytic reactions. The first breakthrough in organic catalysis had been due to Paul SABATIER who had demonstrated the use of finely ground nickel to catalyze hydrogenation of unsaturated hydrocarbons (1897). Ipatieff greatly extended this work. He showed how it could be applied to liquids and demonstrated that the process became much more powerful and adaptable at high pressures. To this end he designed the so-called *Ipatieff bomb* – an autoclave that permitted the heating of substances under pressure to above their boiling point. Thus before World War I Ipatieff had synthesized isooctane, and had polymerized ethylene.

During World War I and after the revolutionary years in Russia Ipatieff held a number

of important advisory posts, in addition to continuing with his own research, despite his anti-Communist feelings. In 1930, worried for his own safety, he traveled to America. Despite being 64 when he arrived in America Ipatieff still had much to offer, publishing over 150 papers in this last phase of his career. He was appointed professor of chemistry at Northwestern University, Illinois (1931–35) and also acted as a consultant to the Universal Oil Products Company of Chicago which, in 1938, established at Northwestern University the Ipatieff High Pressure Laboratory, which he directed. With the growth of the petrochemical industry after 1918, Ipatieff's techniques became widely used. Working in America he showed how low-octane gasolines could be converted to high-octane gasoline by "cracking" hydrocarbons at high temperatures.

**Irvine, Sir James Colquhoun** (1877–1952) *British chemist*

Irvine studied chemistry at the Royal Technical College in his native Glasgow and at Leipzig. His father was a manufacturer of light iron castings and appears to have been a capable mathematician. Irvine's whole career was spent at St. Andrews beginning in 1901 as a lecturer, being appointed professor of chemistry in 1909, and finally, in 1921, becoming vice-chancellor of the university. Under Irvine the tradition of carbohydrate studies established by Thomas Purdie was to continue. Irvine's work involved the application of Purdie's methylation technique to carbohydrates. He realized that the constitution of disaccharides and other compound carbohydrates might be found by methylating them and he isolated the first methylated sugars, trimethyl and tetramethyl glucose.

Irvine's fruitful line of research was to be continued at St. Andrews and later at Birmingham by Norman HAWORTH.

**Isaacs, Alick** (1921–1967) *British virologist and biologist*

Isaacs, who was born in Glasgow, Scotland, graduated in medicine from the university there in 1944. After three years' work in the department of bacteriology he moved to Sheffield University for a year and then spent two years in Australia at the Hall Institute for Medical Research, Melbourne. During this time he studied influenza, in particular the genetic variation of the various strains of the virus and also the

response of the body to attack by the virus. He continued with this work from 1950 at the National Institute for Medical Research in London, where he was director of the World Influenza Centre.

In 1957, together with the Swiss virologist Jean Lindenmann, Isaacs reported that a specific low-molecular-weight protein, which interfered with the multiplication of viruses, was produced by animal cells when under viral attack. This was interferon, which he studied closely for the rest of his life, investigating problems associated with its production and isolation, its mechanism of action, and its chemical and physical properties. Isaacs's work formed the basis for all present-day research on this potentially important drug, the full effects of which are still being closely studied.

In the early 1960s his health began to deteriorate but he continued work as head of the Laboratory for Research on Interferon at the National Institute.

**Ivanovsky, Dmitri Iosifovich** (1864–1920) *Russian botanist*

Ivanovsky (i-van-of-skee) was born in Gdov, Russia, and studied natural sciences at St. Petersburg University, graduating in 1888. He obtained his master's degree in botany in 1895 and worked (1896–1901) as an instructor in plant anatomy and physiology at the Technological Institute, St. Petersburg. In 1908 he was appointed professor at the University of Warsaw.

In 1892, following his investigations of tobacco mosaic disease in the Crimea, he demonstrated that a filtrate of the sap from infected tobacco plants had the ability to transmit the disease to healthy plants. Ivanovsky showed that minute crystalline particles were present in the filtrate and asserted that they were somehow linked to the disease. However, he wrongly attributed the cause of the disease to minute bacteria. Ivanovsky's work was confirmed in a publication by the Dutch bacteriologist Martinus Beijerinck in 1898. It was Beijerinck who stated that such infective agents are not bacterial and coined the term "virus." This, together with the work of the French bacteriologist Charles Chamberland on rabies, was one of the earliest pieces of evidence for the existence of viruses although it was not until 1935 that Wendell Stanley confirmed this.

## **Jackson, Charles Thomas** (1805–1880) *American chemist*

No true man of science will ever disgrace himself by asking for a patent; and if he should, might not know what to do with it any more than the man did who drew an elephant at a raffle. He cannot and will not leave his scientific pursuits to turn showman, mechanic, or merchant.

—Address to the American Institute (1851)

Born in Plymouth, Massachusetts, Jackson studied medicine at Harvard and continued his education at the Sorbonne in Paris, working on chemistry and geology. He returned to America and set up a practice in Boston. Jackson's professional career consisted of a series of spectacular claims to the work of others. These started on his homeward voyage and were to persist until he finally became insane in 1873.

While sailing from France to America in 1832 Jackson befriended a fellow American, the portrait painter Samuel MORSE, with whom he discussed the possibilities of electric telegraphy. When Morse exhibited his telegraph to Congress in 1837 he found that he had to establish a right to his own invention against Jackson's claim that Morse had stolen it from him. It took Morse seven years to prove the validity of his claim.

In July 1844 Jackson recommended to William MORTON, a young dentist lodging with him, that he should try treating his patients using ether, which was commonly used by medical students as a joke. Morton took up his suggestion and found it promising. He experimented on himself, gave up his practice to work on dosages and systems of inhalation, and introduced the anesthetic to the medical profession. Nothing was heard from Jackson until it was clear that money and fame were going to be awarded to someone. When Morton went to Congress to ask for compensation for yielding his patent to the U.S. government he found some senators who took him for a thief. When he went to Paris in 1847 to lecture on his discovery he found that Jackson had already lodged a sealed envelope with the Académie claiming a priority going back to 1842. Committees were set up by governments, states, academies, and professional bodies but Jackson managed to so confuse the issue that when

Morton collapsed and died in 1868 he was still fighting his claim and still penniless.

Jackson became obsessive about his "discovery," ignored his other work, took to drink, and spent the last seven years of his life in a lunatic asylum. He even wrote a book on the subject, *A Manual of Etherisation* (1861). Curiously, both Morton and Jackson have monuments in the same cemetery, both proudly proclaiming their triumph in alleviating the misery of mankind.

## **Jackson, John Hughlings** (1835–1911) *British neurologist*

Jackson was born at Green Hammerton in England and educated at York Hospital and St. Bartholomew's Hospital, London. He received his MD from St. Andrews University in 1860. He served on the staff of the London Hospital as assistant physician (1863) and physician (1874–94) and in 1862 began his long association with the National Hospital for the Paralysed and Epileptic, London. Here he specialized in neurology and ultimately exercised a profound influence on the development of clinical neurology. Through his work with epileptics, he described the condition, now called *Jacksonian seizure* or *Jacksonian epilepsy*, in which part of the leg, arm, or face undergoes spasmodic contraction due to local disease of the cerebral cortex in the brain.

Jackson's work supported the findings of Paul BROCA and others – that different bodily functions are controlled by different regions of the cerebral cortex. Jackson also described a local paralysis of the tongue and throat caused by disease of the corresponding cranial nerves. This is now known as *Jackson's syndrome*.

## **Jacob, François** (1920– ) *French biologist*

Myths and science fulfill a similar function: they both provide human beings with a representation of the world and of the forces that are supposed to govern it. They both fix limits of what is considered as possible.

—*The Possible and the Actual* (1981)

Born at Nancy in France, Jacob (zha-kob) served with the Free French forces during World War II. Although badly wounded, he resumed his medical studies in 1945, obtaining his MD from the University of Paris in 1947. In

1950 he became André Lwoff's assistant at the Pasteur Institute, Paris, and, with Elie Wollman, began working on the bacteria, discovered by Lwoff, that carry a nonvirulent virus incorporated in their genetic material. In 1961 they introduced the term "episomes" for genetic elements that become established in bacterial cells. Jacob and Wollman also studied conjugation in bacteria, the process by which genetic material is transferred from one cell to another. They found that the genes of the donor cell enter the recipient cell in a specific order and by interrupting the process, the position of given genes on the chromosome could be determined.

In 1958 Jacob began collaborating with Jacques MONOD and Arthur PARDEE on the control of bacterial enzyme production, research that culminated in a greatly increased understanding of the regulation of gene activity. In 1960 Jacob and Monod proposed the existence of the operon, consisting of an operator gene and structural genes that code for the enzymes needed in a given biosynthetic pathway. When the enzymes are not required another gene outside the operon, the regulator gene, produces a protein that binds with the operator and renders the operon ineffective. Jacob and Monod received the 1965 Nobel Prize for physiology or medicine for this research, sharing the award with Lwoff.

From 1964 until 1991, Jacob occupied the chair of cellular genetics at the Collège de France; the chair was created in his honor. He became a foreign member of the Royal Society in 1973 and a member of the Academy of Sciences, Paris, in 1977. He has also written on some of the wider implications of biology in *The Possible and the Actual* (1981) and has published an autobiography, *The Statue Within* (1987).

**Jacobi, Karl Gustav Jacob** (1804–1851)  
*German mathematician*

Mathematics is the science of things that are self-evident.

—Describing the nature of mathematics

Jacobi (yah-koh-bee) was born at Potsdam, in Germany. After studying in Berlin, he became a lecturer at Königsberg where he managed to attract the favorable attention of Karl Friedrich GAUSS. He was a superb teacher and had an astonishing manipulative skill with formulae. He made a brief but disastrous foray into politics that resulted in his losing a pension he had been granted by the king of Prussia.

Jacobi's most important contributions to mathematics were in the field of elliptic functions. Niels Henrik ABEL had partially anticipated some of Jacobi's work, but the two were equally important in the creation of this subject. Jacobi also worked on Abelian functions and discovered the hyperelliptic functions. He

applied his work in elliptic functions to number theory.

Jacobi worked in many other areas of mathematics as well as the theory of functions. He was a pioneer in the study of determinants and a certain type of determinant arising in connection with partial differential equations is known as the *Jacobian* in his honor. This work was the result of his interest in dynamics, in which field he continued and developed the work of William Hamilton, and produced results that are important in quantum mechanics.

**Jansky, Karl Guthe** (1905–1950) *American radio engineer*

Born in Norman, Oklahoma, Jansky was educated at the University of Wisconsin and started his career with the Bell Telephone Laboratories in 1928. He was given the task of investigating factors that could interfere with radio waves used for long-distance communication. He designed a linear directional antenna, which, mounted on wheels from a Model T Ford, could scan the sky. He identified all the sources of interference, such as thunderstorms, except for one weak emission. This he found to be unconnected with the Sun and in 1931 he discovered that the radio interference came from the stars.

Jansky published his findings in the *Proceedings of the Institute of Radio Engineers* in December 1932, the date that marks precisely the beginnings of radio astronomy. In his paper Jansky made two astute comments: he suggested that the radio emission was somehow connected with the Milky Way and that it originated not from the stars but from interstellar ionized gas. He did not pursue his suggestions and it was left to Grote REBER, the amateur astronomer, to keep the subject alive until it developed into a major research field after 1945.

The unit of radio-wave emission strength was named the *jansky* in his honor.

**Janssen, Pierre Jules César** (1824–1907) *French astronomer*

The 20th century ... will see ... the terrestrial atmosphere navigated by apparatuses that will take possession of it to make a daily and systematic study of it, or to establish among nations communications ... that will take continents, seas, and oceans in their stride.

—On the future role of aviation. Address to the International Aeronautical Congress, Paris (1889)

Janssen (zhahn-sen) studied mathematics and physics at Paris University before becoming professor of general science at the school of architecture. In 1857 he went to Peru to determine the magnetic equator. He observed the transits of Venus of 1874 and 1882 in Japan and Algeria and went on all the major eclipse

expeditions. So eager was he to witness the 1870 eclipse in Algeria that he had to escape from the siege of Paris by balloon. While in India in 1868, observing the solar eclipse spectroscopically, he noticed the hydrogen lines visible in the solar prominences and wondered if they could still be detected after the eclipse. The next day he found them still visible. This meant that while photography and observation would still depend on eclipse work the spectroscope could be used almost anywhere anytime. Janssen made one further important discovery on the same trip; he discovered lines in the solar spectrum that he could not identify. He sent his results to Norman LOCKYER who suggested that they were produced by some element found only on the Sun, which Lockyer called "helium." In 1895 William RAMSAY discovered a substance on Earth that matched exactly with Janssen's spectral lines.

In later life Janssen arranged for an observatory to be built on Mont Blanc in order to avoid as much atmospheric interference as possible. Using data from observations made there, he showed that absorption lines in the solar spectrum are caused by elements in the Earth's atmosphere.

**Janssen, Zacharias** (1580–c. 1638) *Dutch instrument maker*

Zacharias Janssen (**yahn**-sen) was born in Middelburg, now in the Netherlands. Together with his father, Hans, he is believed to have invented the first compound microscope in 1590. He is also credited with having made the first telescope in 1608, although Hans LIPPERSHEY, who also lived in Middelburg, and Jacobus METIUS share claims to this invention.

**Jeans, Sir James Hopwood** (1877–1946) *British mathematician, physicist, and astronomer*

Life exists in the universe only because the carbon atom possesses certain exceptional properties.

—*The Mysterious Universe* (1930)
