2. Tremor (a rhythmic and involuntary movement of any body part): a phenotypic motor feature in dystonia (Defazio et al. 2015)
3. Classifications of dystonia
    1. Classification based on distribution of dystonia
        1. Primary/generalized dystonia
            1. Occurs in childhood
            2. Often begins focally in the legs and progresses to a generalized symptom involving the entire body
        2. Focal dystonia
            1. May occur at any age
            2. Typically starts in adulthood
            3. Affects an isolated body area, such as the hand and arm (writer's cramp), neck (cervical dystonia, previously known as spasmodic torticollis), vocal/laryngeal apparatus (dystonic adductor dysphonia or whispering dysphonia), mouth (oromandibular dystonia, musician's cramp), or eyelids (blepharospasm)
            4. Multifocal dystonia (two or more noncontiguous parts affected)
        3. Segmental dystonia
            1. May occur at any age
            2. Typically starts in adulthood
            3. Involves only the right or left side of the body
            4. Cranial (two or more parts of cranial and neck musculature affected)
            5. Axial (neck and trunk affected)
            6. Brachial (one arm and axial, both arms, with or without neck, with or without trunk)
            7. Crural (one leg and trunk, both legs, with or without trunk)
        4. Hemidystonia: affects the ipsilateral arm and leg
        5. Secondary dystonia
            1. Can be generalized, focal, or segmental
            2. Induced by a disease or ingested substance
            3. Can occur at any time
            4. Treated by identifying the underlying medical disorder or substance

2. Classification based on age of onset of dystonia
    1. Early-onset dystonia
        1. Often starts in a limb
        2. Tends to generalize and frequently has a genetic origin
    2. Adult-onset dystonia
        1. Usually spares the lower extremities
        2. Frequently involves cervical or cranial muscles
        3. A tendency to remain focal
        4. Sporadic in most cases
4. Classification of dystonia based on three axes (Albanese et al. 2006; Bhidayasiri 2006)
    1. By cause (etiology)
        1. Primary (or idiopathic): Dystonia is the only clinical sign, and there is no identifiable exogenous cause or other inherited or degenerative disease (autosomal dominant) (e.g., early-onset limb dystonia (*DYT1*), mixed dystonias (*DYT6*, *DYT3*), and late-onset craniocervical dystonia (*DYT7*))
        2. Secondary dystonia
            1. Dystonia plus: Dystonia is a prominent sign but is associated with another movement disorder. There is no evidence of neurodegeneration. (e.g., dopa-responsive dystonia, rapid-onset dystonia parkinsonism, myoclonus-dystonia (*DYT11*))
            2. Heredo-degenerative: Dystonia is a prominent sign, among other neurological features (autosomal dominant, e.g., Huntington disease, spinocerebellar ataxia, dentatorubral-pallidoluysian atrophy; autosomal recessive, e.g., Wilson disease, GM1 and GM2 gangliosidosis, metachromatic leukodystrophy, homocystinuria; X-linked, e.g., X-linked dystonia parkinsonism/lubag)
            3. Paroxysmal: Dystonia occurs in brief episodes with normalcy in between. These disorders are classified as idiopathic (often familial although sporadic cases also occur) and symptomatic due to a variety of causes. Three main forms are known depending on the triggering factor. In paroxysmal kinesigenic dyskinesia (PKD, *DYT9*), attacks are induced by sudden movement, in paroxysmal exercise-induced dystonia (PED) by exercise such as walking or swimming, and in the nonkinesigenic form (PNKD, *DYT8*) by alcohol, coffee, tea, etc. A complicated familial form with PNKD and spasticity (*DYT10*) has also been described
            4. Acquired causes: Dystonia is a symptom of an identified neurological condition, such as a focal brain lesion and exposure to drugs or chemicals (e.g., drug-induced tardive dystonia, dystonia due to stroke, a brain tumor, AV malformations, or demyelination, intracranial *vs.* peripheral trauma, off-period dystonia in Parkinson's disease)
            5. Unknown etiology: Parkinson's disease, corticobasal degeneration, multiple system atrophy, and progressive supranuclear palsy
    2. By age at onset
        1. Early onset (variably defined as £20–30 years): usually starts in a leg or arm and frequently progresses to involve other limbs and the trunk
        2. Late onset: usually starts in the neck (including the larynx), the cranial muscles, or the one arm. Tends to remain localized with restricted progression to adjacent muscles
    3. By distribution
        1. Focal: single body region (e.g., writer's cramp, blepharospasm)
        2. Segmental: contiguous body regions (e.g., cranial and cervical, cervical and upper limb)
        3. Multifocal: noncontiguous body regions (e.g., upper and lower limb, cranial and upper limb)
        4. Generalized: both legs and at least one other body region (usually one or both arms)

5. Hemidystonia: half of the body (usually secondary to a structural lesion in the contralateral basal ganglia)

5. Clinical characteristic in genetically defined forms of dystonia and dystonia-plus syndromes (Klein et al. 1999; Brűggermann and Klein 2010)
   1. Dystonia type 1 (early-onset generalized primary torsion dystonia)
      1. Early-onset torsion dystonia (onset usually childhood)
      2. May present as focal, usually in the limbs
      3. Often generalizes to other body parts as the disease progresses
   2. Dystonia type 2 (autosomal recessive torsion dystonia)
      1. Early onset
      2. Generalized or segmental torsion dystonia
   3. Dystonia type 3 (X-linked dystonia parkinsonism, "lubag") meaning "twist," a local dialect in the island of Panay in the Philippines)
      1. Only described in individuals from the Philippines
      2. Usually males
      3. Onset usually adulthood
      4. Usually generalized dystonia
      5. Parkinsonism (50% of cases) unresponsive to L-dopa
      6. Progressive neurodegenerative syndrome
   4. Dystonia type 4 (whispering dysphonia)
      1. Described in a single large Australian family
      2. Laryngeal and cervical dystonia
      3. Age of onset: 13–37 years
   5. Dystonia type 5 (dopa-responsive dystonia parkinsonism)
      1. Childhood onset of dystonia
      2. Onset of dystonia in a limb, typically a leg, resulting in gait disturbance
      3. Gradual progression to generalized dystonia (usually more pronounced in the legs)
      4. Dystonia with concurrent or subsequent parkinsonism
      5. Diurnal worsening of symptoms
         1. Aggravation of symptoms toward the evening
         2. Alleviation of symptoms in the morning after sleep
      6. A variety of atypical presentations
         1. Generalized hypotonia
         2. Proximal weakness
         3. Gait disturbance
         4. "Atypical cerebral palsy"
      7. A dramatic response to L-dopa
   6. Dystonia type 6 (adolescent-onset torsion dystonia of mixed type)
      1. Described in two Mennonite families
      2. Adolescent onset
      3. Mostly segmental torsion dystonia
      4. Focal or generalized (rare)
      5. Cranial, cervical, or limb dystonia
   7. Dystonia type 7 (adult-onset focal torsion dystonia)
      1. Described in a single German family
      2. Adult-onset focal dystonia
      3. Torticollis
      4. Writer's cramp
      5. Spasmodic dysphonia
      6. Blepharospasm
   8. Dystonia type 8 (paroxysmal dystonic choreoathetosis)
      1. Variable age of onset (early childhood, adolescence, or early adulthood)
      2. Attacks of dystonia/choreoathetosis
      3. Precipitated by stress, hunger, fatigue, alcohol, caffeine, nicotine, and chocolate
   9. Dystonia type 9 (paroxysmal choreoathetosis with episodic ataxia and spasticity)
      1. Age of onset: 2–15 years
      2. Attacks of dystonia, paresthesias, and double vision
      3. Precipitated by exercise, fatigue, stress, and alcohol
      4. Spastic paraplegia between attacks
   10. Dystonia type 10 (paroxysmal kinesigenic choreoathetosis)
      1. Attacks of dystonia/choreoathetosis
      2. Precipitated by sudden unexpected movements
      3. Respond to anticonvulsant therapy

11. Dystonia type 11 (myoclonus-dystonia)
    1. Onset usually in the first or second decade of life
    2. Rapid, jerk-like movements
    3. Responsive to alcohol
    4. Combined with variable degrees of dystonia
12. Dystonia type 12 (rapid-onset dystonia parkinsonism)
    1. Acute or subacute onset (develop over hours or weeks) of generalized dystonia
    2. In combination with parkinsonism
13. Dystonia type 13 (multifocal/segmental dystonia)
    1. Described in a single Italian family
    2. Juvenile or early adult onset of segmental dystonia
    3. With prominent cranial-cervical and upper limb involvement
    4. Some focal dystonia and some generalized dystonia
14. Dystonia type 15 (myoclonus-dystonia)
    1. Described in a single Canadian family
    2. Characterized by jerky movements of the upper limbs, hands, and axial muscles
    3. Myoclonus dystonia and limb dystonia: alcohol responsive
15. Dystonia type 16 (dystonia Parkinsonism)
    1. Recessively inherited form of early-onset generalized dystonia associated with a homozygous missense mutation in the *PRKRA* gene (Camargos et al. 2008)
    2. Described in three Brazilian families, sharing the same P222L mutation, inherited from a common founder
    3. Clinical features
        1. Prominent bulbar involvement with dysphonia, dysarthria, and even dysphagia
        2. Parkinsonism: a less prominent feature (Klein 2008)
16. Dystonia type 17 (recessive torsion dystonia)
    1. Three sisters from Lebanese family suffering from recessively inherited primary focal torsion dystonia with onset in adolescence
    2. Site of onset: cervical with progression to segmental in two sisters and generalized dystonia in one
    3. Prominent features
        1. Dystonia: not levodopa responsive in this family
        2. Dysarthria
17. Dystonia type 18 (paroxysmal exertion-induced dyskinesia 2)
    1. The attacks: combination of chorea, athetosis, and dystonia in excessively exercised body regions
    2. Legs: most frequently affected
    3. Other features
        1. Epilepsy
        2. Hemolytic anemia
        3. Migraine
    4. A ketogenic diet: an effective therapeutic regimen
    5. Closely resembles DYT type 9 (paroxysmal choreoathetosis with episodic ataxia and spasticity): remains to be seen whether DYT type 18 and DYT type 9 are the same condition
18. Dystonia type 19 (episodic kinesigenic dyskinesia 2): A second form of paroxysmal kinesigenic dyskinesia was designated DYT type 19
19. Dystonia type 20 (paroxysmal nonkinesigenic dyskinesia 2)
    1. A second form of paroxysmal nonkinesigenic dyskinesia was described in a single Canadian family
    2. Clinical features similar to those of DYT8 dystonia/dyskinesia

6. Important clinical "red flags" leading to correct diagnosis of a specific genetic form before molecular testing (Brűggermann and Klein 2010)
    1. Diurnal variation of symptoms and response to levodopa in DRD (DYT5)
    2. Prominent orobulbar and speech involvement (DYT6)
    3. A combination of dystonia with myoclonus, ameliorated by alcohol intake in myoclonus-dystonia (DYT11), and abrupt

onset of severe dystonia and parkinsonism in RDP (DYT12)
4. An inherited dystonia also should be considered in the case of an early onset and when a certain ethnic background and positive family history are present (e.g., a high prevalence of DYT1 dystonia in Ashkenazi Jews and of DYT3 X-linked dystonia parkinsonism [XDP, "lubag"] in Filipinos)
5. Notably, the presence of a heritable condition may be masked by a small number of family members, nonpaternity, or adoption
6. Similarly, reduced penetrance, variable expressivity, and de novo mutations are potential reasons for a "pseudo"-negative family history
7. With the exception of five rare forms (DYT2, DYT3, DYT5b, DYT16, and DYT17), all monogenic dystonias follow an autosomal dominant pattern of transmission with reduced penetrance

Diagnostic Investigations

1. Electromyography shows a simultaneous contraction of both agonist and antagonist muscles
2. MRI of the brain (Cloud and Jinnah 2010)
    1. Warranted for all ages
    2. Can identify a causal structural defect
    3. Can provide clues to some degenerative disorders in adults and specific treatable developmental or metabolic disorders in younger individuals, such as Wilson disease, glutaric aciduria, and biotin-responsive basal ganglia disease
3. Dopa-responsive dystonia
    1. GTPCH1-deficient dopa-responsive dystonia
        1. Decreased concentration of both total biopterin (BP) and neopterin (NP) in cerebrospinal fluid in patients with GTPCH1 deficiencies
        2. Phenylalanine loading test to detect a subclinical defect in phenylalanine metabolism
        3. DNA mutation analysis to detect *GCH1* mutation
    2. TH-deficient dopa-responsive dystonia
        1. Normal BP and NP and reduced-3-methoxy-4-hydroxy-phenylethyle-neglycol in CSF
        2. DNA mutation analysis to detect *TH* mutation
4. Mutational screening has become available on a commercial basis for most of the known dystonia-causing genes
    1. For 10 of the 20 DYT loci (DYT1, DYT3, DYT5a, DYT5b, DYT6, DYT8, DYT11, DYT12, DYT16, and DYT18), genes have been identified (Brűggermann and Klein 2010)
    2. Current guidelines for genetic testing and counseling are based on criteria established by the European Federation of Neurological Societies that were revised in 2009
        1. Molecular testing for the GAG deletion in the *DYT1* gene is recommended in patients with limb-onset generalized dystonia and symptom onset before the age of 26 years, regardless of family history
        2. Comprehensive mutational analysis for GCH1 mutations, including gene dosage studies, is recommended in patients with early-onset generalized dystonia and clear symptom relief following levodopa therapy, irrespective of family history
        3. Mutational screening for *SGCE* mutations is recommended only in cases with the typical combination of dystonia and myoclonus and a suggestive family history
        4. RDP and tyrosine hydroxylase (TH)-associated DRD (DYT5b) are exceedingly rare. XDP (DYT3) is restricted to a specific population. Therefore, no general recommendations have been proposed for these forms (Harbo et al. 2009)
        5. Diagnostic DYT1 testing in conjunction with genetic counseling is recommended for patients with primary torsion dystonia with onset before age 26 years, as this single criterion detected 100% of clinically ascertained carriers (Bressman et al. 2000)

3. Molecular studies of dystonia (Fuchs and Ozelius 2013): A combination of next-generation and traditional Sanger sequencing has expanded the phenotypic spectrum associated with some of the dystonia plus (*ATP1A3*) and paroxysmal (*PRRT2*) loci

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Autosomal recessive inheritance: 25%
        2. Autosomal dominant inheritance: not increased unless one of the parent carries a mutant allele in which case, there is a 50% risk of having an affected sib
        3. X-linked recessive inheritance; 50% of male sib will be affected given the mother is a carrier
        4. Secondary dystonias: risk depending on the etiology
        5. If one of the parents has a GCH1 pathogenic variant, each sib has a 50% chance of inheriting the mutant allele at conception. Because of gender-related incomplete penetrance, a sib who inherits a GCH1 pathogenic variant may be asymptomatic (Furukawa 2015)
        6. If neither parent has a GCH1 pathogenic variant, the risk to the sibs of the proband is usually very low (Furukawa 2015)
    2. Patient's offspring
        1. Autosomal recessive inheritance: not increased (all offspring are carriers) unless the spouse is also a carrier in which case, there is a 50% risk of having an affected offspring
        2. Autosomal dominant inheritance: 50%
        3. X-linked recessive inheritance: None of the sons will be affected; all of the daughters will be carriers
        4. Secondary dystonias: risk depending on the etiology
2. Prenatal diagnosis is possible for some forms of dystonia by DNA analysis of the fetal blood obtained from amniocentesis of CVS provided the disease-causing allele(s) of an affected family member have been identified
3. Management (Goetz and Horn 2001; Klein and Ozelius 2002; Cloud and Jinnah 2010)
    1. Treatment of childhood dystonia (Delnooz and van de Warrenburg 2012; Bertucco and Sanger 2014)
        1. Begins with proper diagnosis and classification
        2. An appropriate search for underlying etiology
        3. An assessment of the associated functional impairment
        4. Must be tailored to the individual needs of the patient
        5. Physical therapy and occupational therapy can be useful in many patients.
        6. Augmented feedback enhances motor learning and is effectively used in rehabilitation
        7. Noninvasive neurostimulation techniques: transcranial direct current stimulation and transcranial magnetic stimulation
        8. Deep brain stimulation
        9. Botulinum neurotoxin: currently the mainstay of treatment for focal and segmental dystonia (cervical dystonia, blepharospasm, oromandibular dystonia, focal hand dystonia, spasmodic dystonia)
        10. Oral drug therapy
            1. Anticholinergic agents: trihexyphenidyl
            2. GABA-mimetic agents: baclofen and clonazepam
            3. Dopamine-altering agents: levodopa
        11. Oral medications and deep brain stimulation: the mainstays of therapy for generalized dystonia
    2. Generalized idiopathic dystonia
        1. Medical therapy
            1. Anticholinergic agents (trihexyphenidyl): first choice (a moderate response in about 40-50% of dystonia patients)
            2. Benzodiazepines (diazepam, clonazepam)

    3. Dopamine depletors (tetrabenazine)
    4. γ-Aminobutyric acidergics (baclofen)
    5. Atypical neuroleptics (clozapine, olanzapine)
  2. Intrathecal baclofen infusion
  3. Ablative therapies, reserved for patients in whom medical therapies fail
    1. Pallidotomy
    2. Thalamotomy
3. Dopa-responsive dystonia
  1. A dramatic response to small dosages of levodopa (100 mg a day) (confirms the diagnosis)
  2. Maintenance with low-dose levodopa for life may improve from severe inability to completely normal function
4. Focal dystonias
  1. Unresponsive to systemic drug treatment in most case
  2. Frequently well controlled by periodic botulinum toxin (BTX) injections into the muscles directly involved in the dystonia (Bhidayasiri 2006)
  3. Try with intrathecal baclofen and surgery if oral medications fail
5. Cervical dystonias resistant to BTX: selective peripheral denervation
6. Disorders with dystonia that have specific disease-modifying therapies (Jinnah and Factor 2015)
  1. Abetalipoproteinemia (Bassen-Kornzweig): vitamin E, reduced-fat diet
  2. Aromatic amino acid decarboxylase deficiency: dopamine agonists and monoamine oxidase inhibitors
  3. Ataxia with vitamin E deficiency: vitamin E
  4. Autoimmune movement disorders: address autoimmune process
  5. Biotinidase deficiency: biotin
  6. Cerebral folate deficiency: folic acid
  7. Cerebrotendinous xanthomatosis: chenodeoxycholic acid
  8. Cobalamin deficiencies (inherited subtypes A–G): cobalamin derivatives and/or protein restriction
  9. Coenzyme Q10 deficiency: coenzyme Q10
  10. Cerebral creatine deficiency type 3: creatine
  11. Dopa-responsive dystonia, classic: levodopa
  12. Dopa-responsive dystonia, complicated: levodopa, 5-hydroxytryptophan, and/or tetrahydrobiopterin
  13. Dystonia with brain manganese accumulation: chelation therapy
  14. Galactosemia: lactose restriction
  15. Glucose transporter 1 deficiency: ketogenic diet
  16. Glutaric aciduria type 1: avoid or treat aggressively any intercurrent illness, lysine restriction
  17. Homocystinuria: methionine restriction
  18. Guanidinoacetate methyltransferase deficiency: arginine restriction, creatine, and ornithine
  19. Maple syrup urine disease: leucine restriction +/− thiamine
  20. Methylmalonic aciduria: avoid or treat aggressively any intercurrent illness, protein restriction
  21. Molybdenum cofactor deficiency (sulfite oxidase): cyclic pyranopterin monophosphate
  22. Niemann-Pick type C: n-butyldeoxynojirimycin (Miglustat)
  23. Paraneoplastic movement disorders: address underlying malignancy
  24. Propionic aciduria: avoid or treat aggressively any intercurrent illness, protein restriction
  25. Pyruvate dehydrogenase deficiency: thiamine, ketogenic diet, and dichloroacetate
  26. Rapid-onset dystonia parkinsonism: avoid or treat aggressively any

intercurrent illness, protein restriction

27. Wilson disease: zinc and tetrathiomolybdate

Fig. 1 A 7-year-old girl with progressive dystonia showing dystonic posturing with gait locking of the knees and swiveling of the hips to propel the legs forward. She developed normally until age 6 when she started to have loss of balance, falling, unable to get the foot off the ground, stiffing of lower and upper extremities, and slurring of speech. Plasma amino acids, urine organic acids, blood chemistry, lactate/pyruvate, ceruloplasmin, copper, arsenic, lead, 5-methyltetrahydrofolate, neurotransmitter metabolites/amines, tetrahydrobiopterin/neopterin, and various lysosomal enzymes were all normal. No mutations were detected on mitochondrial myopathy mtDNA, *DYT1*, and *PANK2*. MRI of the brain showed bilateral hyperdense basal ganglia lesions. The use of levodopa/dopamine agonists has at best been minimally beneficial

Dystrophinopathies

Contents

The dystrophinopathies include a spectrum of muscle disease caused by mutations in the *DMD* gene that encodes the protein dystrophin. They are characterized by a spectrum of muscle disease that ranges from mild to severe. The mild end of the spectrum includes the phenotypes of asymptomatic increase in serum concentration of creatine phosphokinase (CPK) and muscle cramps with myoglobinuria and isolated quadriceps myopathy. The severe end of the spectrum includes progressive muscle diseases that are classified as Duchenne muscular dystrophy (DMD) or Becker muscular dystrophy (BMD) when skeletal muscle is primarily affected and as X-linked dilated cardiomyopathy (XLDCM) when the heart is primarily affected. In this chapter, I will limit my discussion on DMD and BMD.

DMD is one of the most common types of muscular dystrophy in childhood, primarily affecting skeletal and cardiac muscle. It is one of the most common of all clinical genetic disorders. Its incidence is estimated to be approximately 1 in 3,500 live male births. BMD is a milder allelic form of dystrophin deficiency, affecting 1 in 30,000 male births.

Synonyms and Related Disorders

Becker and Duchenne muscular dystrophy

Genetics/Basic Defects

1. DMD (Worton and Thompson 1988):
    1. Inheritance:
        1. X-linked recessive.
        2. Exceptionally high mutation rate of 10^{-4} in both sperm and eggs.
        3. Approximately 1/3 of cases are due to new genetic mutations.
        4. Approximately 2/3 of cases occurring by inheritance of the disease-causing gene from the carrier mother.
        5. Only males affected (as a rule).
    2. *DMD* gene:
        1. Observation of a series of young females affected clinically as Duchenne muscular dystrophy with an X-autosome translocation (Jacobs et al. 1981):

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_76

1. Breakpoint in the X chromosome in the same place (Xp21.1)
2. Different autosomes involved for each affected female
3. Mapping of dystrophin gene to chromosome Xp21

2. The largest human gene, covering 2.5 megabases and including 79 exons.
3. The enormity of the DMD gene along with the spontaneous mutation rate of each base pair allows a high frequency of novel mutations.
4. The most common molecular defect in the DMD gene (Falzarano et al. 2015):
   1. Deletion of one or more exons, occurring in 65% of DMD cases, while the duplication accounts for 6–10% of cases.
   2. The remaining cases (approximately 25%) are due to small mutations (missense, nonsense, and splice site variations) and small rearrangements (insertions/deletions, small inversion).
   3. However, a lower rate of cases (approximately less than 2%) is caused by complex rearrangements and deep intronic changes.

3. Dystrophin, the product (protein) of the human dystrophin gene (*dys*) (Hoffman et al. 1987):
   1. Loss of dystrophin at the muscle membrane clearly related to mutations in the gene encoding dystrophin at band Xp21.
   2. Cloning of the dystrophin gene by positional cloning in the late 1980s constituted the initial proof that deletions in the Xp21 region were associated with the disease.
   3. The dystrophin gene (Muntoni et al. 2003):
      1. The largest gene of the 30,000 genes that encode proteins in the human genome
      2. Consisting of 79 exons spanning more than 2.6 million bp of genomic sequence
      3. Correspond to about 0.1% of the total human genome
      4. Correspond to about 1.5% of the entire X chromosome
   4. Southern blot analysis of affected boys with a complete set of cDNA probes:
      1. Over 60% with detectable deletions
      2. Six percent with duplications (Hu et al. 1990)
      3. A number of point mutations described recently
   5. Consequences of absent dystrophin in skeletal and cardiac muscles in affected patients:
      1. Muscle contraction leading to membrane damage and activation of the inflammatory cascade
      2. Progressing to muscle necrosis, fibrosis, and loss of function
   4. The DMD phenotype most frequently due to mutations that cause a disruption in the reading frame (Wagner 2002)
2. BMD:
   1. Inheritance: X-linked recessive (same as DMD).
   2. Also caused by mutations in the gene for dystrophin at Xp21.1.
   3. The BMD phenotype most often due to mutations that preserve the open reading frame but in which portions of the protein are deleted. Frame deletions of the long rod segment of the gene are particularly forgiving and produce a mild phenotype (Wagner 2002).
3. Molecular basis for Duchenne versus Becker muscular dystrophy: correlation of severity with the type of deletion (Koenig et al. 1989)
4. Mechanism for female DMD and BMD:
   1. Turner syndrome with a *dystrophin* mutation on the remaining X chromosome (Chelly et al. 1986)
   2. Skewed X inactivation either in the female DMD mutation carriers (Yoshioka et al. 1998)
   3. Balanced X-autosome translocation patients (Verellen-Dumoulin et al. 1984)
   4. Uniparental disomy of the entire X chromosome with mutations (Quan et al. 1997)

5. Co-occurrence of mutations in both dystrophin and androgen receptor genes (Katayama et al. 2006)
6. Double dystrophin mutations on both X chromosomes (Fujii et al. 2009)

Clinical Features

1. DMD (Roland 2000):
    1. During early infancy:
        1. Asymptomatic
        2. Normal motor milestones
        3. Rare global developmental delay or delayed achievement of early motor milestones
    2. Four to five years of age: onset of symptoms:
        1. A waddling gait
        2. Difficulty in climbing stairs due to pelvic weakness
        3. Difficulty in running
        4. Toe walking resulting from tight Achilles tendon
        5. Inability to jump
        6. Frequent falling
        7. Neck flexor weakness with marked head lag when pulling to sit from the supine position
    3. Progressive difficulty in rising from the floor secondary to weakness of proximal pelvic girdle and proximal leg muscle, resulting in the Gower's maneuver requiring the use of the hands to "climb up the legs."
    4. Pseudohypertrophy of muscles, especially calf muscles: unusually firm and rubbery consistency on palpation.
    5. Compensatory lumbar lordosis to maintain an upright posture secondary to weakness of hip extensors.
    6. Weakness of the arms (proximal more severely affected than distal) apparent as the disease progresses.
    7. Marked laxity of the shoulder girdle musculature with prominent spontaneous winging of the scapulae.
    8. Inability to walk usually before 13 years of age.
    9. Rapid development of fixed skeletal deformities following loss of ambulation:
        1. Equinovarus deformities of the feet
        2. Scoliosis
        3. Wheelchair confinement by adolescence
    10. Unexplained cardiac arrest and/or myoglobinuria: features of malignant hyperthermia during general anesthesia in rare instances.
    11. Progressive and restrictive respiratory deficit with nocturnal hypoventilation in the latter teens to early 20s secondary to weak intercostal muscles.
    12. Eventual respiratory failure requiring assisted ventilation.
    13. Myocardial disease manifesting predominantly as cardiomyopathy and congestive heart failure: characteristic of Duchenne (and Becker) muscular dystrophies (Cox and Kunkel 1997).
    14. Some degree of mental impairment is usually present. Approximately 25% of patients have IQ below 75, presumably due to the lack of dystrophin in the brain.
    15. Natural history:
        1. Progressive and predictable deterioration of muscle function
        2. Cause of death: cardiopulmonary insufficiency in the late second or third decade
    16. Female carriers:
        1. Usually asymptomatic.
        2. Manifesting female carriers (rare): occasional, slow progressive myopathy of moderate severity with elevated CPK (>1,000) and associated symptoms in about 8% of carriers. The following conditions induce expression of the disease phenotype:
            1. Random X inactivation: the extent of clinical involvement is dependent in part upon the degree of skewed X-chromosome inactivation in somatic cells.

2. Turner syndrome having a single X chromosome.
3. X-autosome translocation that disrupts the dystrophin gene and causes nonrandom inactivation of the normal allele on the other X chromosome.

2. BMD
   1. A more benign and variable presentation with later onset and slower progression.
   2. Onset of symptoms after age 6–12.
   3. Progressive symmetrical muscle weakness and atrophy:
      1. Proximal greater than distal.
      2. Often with calf hypertrophy.
      3. Weakness of quadriceps femoris may be the only sign.
   4. Activity-induced cramping in some patients.
   5. Flexion contractures of the elbows may occur late in the course.
   6. Wheelchair dependency, if present, after 16 years of age.
   7. Preservation of the neck flexor muscle strength in BMD, differentiating it from DMD.
   8. Rare BMD patients not diagnosed until adulthood and never lose ambulation.
   9. A proportion of cases have some degree of mental impairment.
   10. Congestive heart failure from dilated cardiomyopathy (Cox and Kunkel 1997), a common cause of morbidity and the most common cause of death, despite the milder skeletal muscle involvement.
   11. Death usually in the fourth or fifth decade.
   12. Female carriers:
      1. Clinical features similar to DMD female carriers.
      2. About 5–10% of female carriers show some degree of muscle weakness.
      3. Often with calf hypertrophy.
      4. May develop dilated cardiomyopathy.
3. Differential diagnosis with other clinically defined types of muscular dystrophy (Emery 2002; Nair 2014):
   1. Congenital muscular dystrophy
   2. Emery–Dreifuss muscular dystrophy
   3. Distal muscular dystrophy
   4. Facioscapulohumeral muscular dystrophy
   5. Oculopharyngeal muscular dystrophy
   6. Limb–girdle muscular dystrophy
   7. Congenital myopathies (Gilbreath et al. 2014):
      1. Nemaline myopathy
      2. Core myopathy (including minicore)
      3. Fiber-type disproportion
      4. Centronuclear myopathy (including myotubular myopathy)
   8. Disorders of carbohydrate metabolism
   9. Endocrine myopathies
   10. Kennedy disease
   11. Lambert–Eaton myasthenic syndrome
   12. Metabolic myopathies
   13. Neuromuscular and myopathic complications of HIV
   14. Polymyositis
   15. Spinal muscular atrophy

Diagnostic Investigations

1. Determination of serum creatine phosphokinase (CPK):
   1. Fifty-fold elevation (BMD) to 100-fold elevation (DMD) in affected boys, resulting from leakage of the muscle isoform
   2. Serum creatine kinase levels: range of values overlapping with the normal range in carrier females, making the test less than definitive
2. Determination of other enzymes: grossly elevated aldolase, SGOT, lactic dehydrogenase, and pyruvate kinase
3. Electrocardiography and echocardiography to detect cardiac involvement:
   1. Electrocardiography (Perloff et al. 1967):
      1. Abnormalities in the early stage of the disease:
         1. Tall R-wave
         2. Deep Q-wave
      2. Arrhythmias
      3. Progressive cardiomyopathy in the mid-teens:
         1. Myocardial dilatation

    2. Myocardial thickening
  2. Echocardiography:
    1. Left ventricular dilatation and dysfunction
    2. Mitral regurgitation secondary to dilated cardiomyopathy or associated mitral valve prolapse
4. Radiography for scoliosis
5. Muscle MRI (Zheng et al. 2015):
  1. The trefoil with single fruit sign in muscle MRI: highly specific for dystrophinopathies
  2. The three leaflets (trefoil): formed by relative sparing of the sartorius, gracilis, and adductor longus muscles
  3. The single fruit: formed by semitendinosus muscle with relative sparing
6. Pulmonary function testing with negative inspiratory force and forced vital capacity as disease progresses
7. Cytogenetic analysis:
  1. Males affected with DMD and other X-linked disorders such as retinitis pigmentosa, chronic granulomatous disease, McLeod red cell phenotype, glycerol kinase deficiency, and adrenal hypoplasia as part of contiguous gene deletion syndrome:
    1. High-resolution chromosome studies:
      1. To detect visible deletions
      2. To detect chromosome rearrangements involving Xp21.1
    2. FISH analysis with probes covering the *GK* and *NRDB1* genes in addition to exons in the *DMD* gene
  2. Females with classic DMD:
    1. May have X-chromosome rearrangement
    2. May have deletion involving Xp21.1
    3. May have complete absence of an X chromosome (45,X)
    4. May have complete uniparental disomy of the X chromosome
    5. Warrant high-resolution chromosome studies
8. Electromyography (EMG) to distinguish a myopathic process from a neurogenic disorder:
  1. Not diagnostic
  2. Demonstrating characteristic myopathy
  3. Reduction in the duration and amplitude of motor unit action potentials
  4. An enhanced frequency of polyphasic potentials
9. DNA analyses for diagnostic confirmation:
  1. Deletion of the dystrophin gene in 60% of patients: 98% of all deletions which occur in hotspots within the dystrophin gene can be recognized by multiplex PCR (Beggs et al. 1990) which amplifies 18–25 of the gene's 79 exons from genomic DNA obtained from blood samples.
  2. Duplications (6% of cases): the next most common mutation of the dystrophin gene, also detectable by multiplex PCR amplification.
  3. Point mutations (1/3 of patients) difficult to identify due to the large size of the gene.
  4. Enhanced single-strand conformation polymorphism (SSCP) (Mendell et al. 2001) and heteroduplex analysis: highly sensitive and possible to detect approximately 90% of patients with DMD.
  5. RNA-based methods, such as reverse transcriptase PCR (RT-PCR).
  6. Protein truncation test: to rapidly screen the DMD gene for translation-terminating mutations (Roest et al. 1993).
  7. Routinely, the molecular diagnosis is done by a multiplex ligation-dependent probe amplification (MLPA) or array comparative genome hybridization (aCGH), followed, if negative, by Sanger sequencing of all exons (Boulez et al. 2015).
10. Muscle biopsy (needle biopsy (Heckmatt et al. 1984) vs. open biopsy under general anesthesia), frequently performed when a clinically suspected DMD patient does not have a large deletion or duplication by genomic DNA testing:
  1. Histology:
    1. Rounding of muscle fibers
    2. Marked variability in muscle fiber size
    3. Increased central nucleation
    4. Fiber splitting

5. The presence of necrotic and regenerating fibers along with large, round hyaline fibers
6. Virtual replacement of muscle fibers by fatty and fibrous tissue in late stage

2. Dystrophin determination by Western blot analysis or immunostaining (Hoffman et al. 1988; Beggs and Kunkel 1990):
   1. Usually little or no detectable dystrophin in patients with DMD
   2. Dystrophin reduced in amount or abnormal in size (larger or smaller sized) in patients with BMD

11. Carrier testing (Mathews 2003):
    1. Carrier testing of young girls or genetic testing of siblings of patients with DMD should be delayed until they are old enough to participate in the decision-making process.
    2. Appropriate to test the mother who has an affected boy with deletion or duplication identified by standard DNA screening, especially if there are other female relatives of childbearing age who are at risk for being carriers.
    3. Possibility of gonadal mosaicism (up to 15%) exists when the mother does not carry the boy's mutation:
       1. Her sisters could not have inherited the mutation.
       2. Her daughter may have inherited the mutations.
    4. Offer linkage analysis to modify risk of carrier status if no mutation is known or if tissue for DNA analysis is not available:
       1. Knowledge of a childhood CPK level in the at-risk girl is helpful.
       2. Elevated CPK in an at-risk female is presumptive evidence of her being a carrier.
    5. Muscle biopsy:
       1. Not a helpful test in determining carrier status.
       2. Skeletal muscle biopsy for Western blot and immunohistochemistry studies of dystrophin can also be considered in symptomatic at-risk females with a high CPK level and normal molecular genetic testing for DMD (Darras et al. 2014).

Genetic Counseling

1. Recurrence risk (Darras et al. 2014):
   1. Patient's sib given that the mother is a carrier (has a disease-causing mutation) (the carrier mother with one defective gene and one normal gene is usually not affected):
      1. Fifty percent risk to her son to receive the disease gene and express the disease.
      2. Fifty percent risk to her daughter to receive the disease gene and become a carrier.
      3. The mother, regardless of proven carrier status or who does not have a *DMD* mutation detectable in her DNA, has an empiric risk of 15–20% of having an affected male fetus due to the presence of maternal germinal mosaicism.
      4. The mother with concomitant somatic and germline mosaicism: the risk to sibs of inheriting a DMD mutation may be higher than if the mother has germline mosaicism only (van Essen et al. 2003).
   2. Patient's offspring:
      1. Males with DMD: patients usually succumb or are too debilitated to reproduce.
      2. Males with BMD- and *DMD*-associated dilated cardiomyopathy:
         1. May reproduce.
         2. None of the sons will inherit the mutation.
         3. All the daughters are carriers.
   3. Germline mosaicism (van Essen et al. 2003; den Helderman-van Enden et al. 2009):
      1. Causes the presence of multiple affected offspring from apparently noncarrier parents.
      2. In X-linked DMD/BMD, the recurrence risk for noncarrier females due to germline mosaicism has been estimated to be between 14% and 20% (95% confidence interval) (Darras and Francke 1987; Bakker et al. 1987, 1989; van

Essen et al. 1992) if the risk haplotype is transmitted.
3. A recurrence risk of 8.6% (4.8–12.2) if the risk haplotype is transmitted with a remarkable difference between proximal (15.6%) (4.1–27.0) and distal (6.4%) (2.1–10.6) deletions (den Heldermanvan Enden et al. 2009). Overall, most mutations originated in the female. Deletions occur more often on the X chromosome of the maternal grandmother, whereas point mutations occur on the X chromosome of the maternal grandfather. In unhaplotyped de novo DMD/BMD families, the risk of recurrence of the mutation is 4.3%.

2. Prenatal diagnosis (Darras et al. 2014):
   1. In the case of a known and readily detectable gene defect:
      1. Amniocentesis and mutation analysis of amniocytes, usually by multiplex PCR.
      2. Preimplantation diagnosis by single-cell PCR of blastomere or polar body may be an option for some families in which the pathogenic variant has been identified.
      3. Fetal nucleated erythrocytes from maternal blood analyzed by multiplex PCR.
   2. In the case of unknown gene defect:
      1. Fetal sexing, allowing females to proceed to the term.
      2. Linkage analysis.
      3. Fetal muscle biopsy for quantitative dystrophin analysis may serve as a diagnostic option (Nevo et al. 1999).
   3. Comparative genomic hybridization (CGH) (Bovolenta et al. 2010):
      1. Molecular diagnosis of DMD requires a great deal of effort due to enormous size of the gene and to allele heterogeneity.
      2. While multiplex ligation-dependent probe amplification (MLPA) represents the standard molecular technique for detecting exonic DMD gene rearrangements (Kesari et al. 2008), several comparative genomic hybridization (CGH) platforms have recently been reported to rapidly screen the entire DMD gene, as well as neighboring sequences, for deletions and duplications (Hegde et al. 2008; del Gaudio et al. 2008; Bovolenta et al. 2008).

3. Management (Kapsa et al. 2003; Mathews 2003):
   1. Largely supportive:
      1. Physical therapy to eliminate the need for surgical release of contractures:
         1. Night splints with ankle–foot orthoses (AFOs)
         2. Daily stretching
         3. Crucial to maintain ambulation as long as possible because its loss is associated with contractures and scoliosis and, in turn, associated with restrictive lung disease
      2. Regular use of an incentive spirometer at home to prolong pulmonary function
      3. Continuous positive airway pressure (CPAP)
      4. Bilevel positive airway pressure (BiPAP): more physiologic
      5. Careful monitoring of pulmonary function
      6. Psychological support
   2. American College of Chest Physicians statement on the respiratory and management of patients with Duchenne dystrophy undergoing anesthesia (Birnkrant 2009).
   3. Adiponectin proves to be an extremely powerful hormone capable of protecting the skeletal muscle against inflammation and injury, thereby offering novel therapeutic perspectives for dystrophinopathies (Abou-Samra et al. 2015).
   4. Treatment of dystrophic cardiomyopathies (Finsterer and Cripe 2014):
      1. Presymptomatic treatment: steroids, angiotensin-converting enzyme (ACE) inhibitors, β-blockers, and mineralocorticoid receptor antagonists.
      2. Pharmaceutical agents (steroids) have shown great promise in delaying the progression of DMD:
         1. ACE inhibitors, ARBs, or β-blockers, in monotherapy or in combination, in increasing dosages (until a beneficial effect becomes evident or adverse effects occur), and the use of diuretics

2. Glucocorticoid corticosteroids, prednisone (Biggar et al. 2002), and deflazacort (Flanigan 2014)
3. Nonpharmacological cardiac treatments with a direct effect include:
    1. Implantation of a pacemaker
    2. Implantable cardioverter–defibrillator (ICD)
    3. Cardiac resynchronization therapy (CRT) system
    4. Intra-aortic balloon pump
    5. The use of a ventricular assist device (VAD)
    6. Heart transplantation
4. Indirect cardiac therapy includes:
    1. Pharmacotherapy, such as pain relief
    2. Nonpharmacological measures, such as orthopedic surgery (release of joint contractures, spine fusion to minimize painful spinal deformity and secondary pulmonary complications) or nocturnal or whole-day ventilation by noninvasive positive pressure ventilation

5. Multidisciplinary care of Duchenne muscular dystrophy (Bushby et al. 2010):
    1. Physical therapy interventions:
        1. Stretching and positioning
        2. Assistive devices for musculoskeletal management: orthoses
    2. Surgical intervention for lower-limb contractures:
        1. Early ambulatory phase: heel-cord (tendo-Achilles) lengthenings for equinus contractures, hamstring tendon lengthenings for knee-flexion contractures, anterior hip-muscle releases for hip-flexion contractures, and even excision of the iliotibial band for hip-abduction contractures.
        2. Middle ambulatory phase: bilateral multilevel (hip–knee–ankle or knee–ankle) procedures, bilateral single-level (ankle) procedures, and, rarely, unilateral single-level (ankle) procedures for asymmetric involvement.
        3. Late ambulatory phase: generally been ineffectively served to obscure the benefits gained by more timely and earlier interventions.
        4. Early non-ambulatory phase: generally ineffective.
        5. Late non-ambulatory phase: severe equinus foot deformities of more than 30° can be corrected with heel-cord lengthening or tenotomy and varus deformities (if present) with tibialis posterior tendon transfer, lengthening, or tenotomy.
    3. Assistive/adaptive devices for function:
        1. AFOs (ankle–foot orthoses): not indicated for use during ambulation because they typically limit compensatory movements needed for efficient ambulation, add weight that can compromise ambulation, and make it difficult to rise from the floor.
        2. Prescribe a powered wheelchair when dependency becomes inevitable.
    4. Recommendation for exercise
6. Genetic therapies in DMD: the use of viral and plasmid vectors to deliver dystrophin to dystrophin-deficient muscle in vivo (Kapsa et al. 2003; Van Deutekom and Van Ommen 2003):
    1. Truncated dystrophin genes (minidystrophin and microdystrophin transgenes) improve force output and other features of the dystrophic *mdx* phenotype.
    2. Tissue-specific promoters: targeted transgene expression via muscle-specific promoters, a good platform for vector-mediated therapeutic delivery of *dys* to dystrophic muscle.
    3. Plasmid vectors.
    4. Viral vectors:
        1. Adenoviral vectors
        2. Adeno-associated vectors
        3. Retroviral vectors
        4. Lentiviral vectors
        5. Other viral vectors including herpes simplex virus, Epstein–Barr virus, and chimeric adeno-retrovirus
7. Corrective gene therapy (Kapsa et al. 2003; Nelson et al. 2009):

1. Targeted corrective gene conversion therapies:
    1. Introduction of construct of homologous DNA containing a nonhomologous sequence into mammalian cells in vitro induces specific genetic transformations in the host chromosomal DNA.
    2. An attractive therapeutic strategy for DMD if the DNA can be delivered to the muscles efficiently.
2. Small fragment homologous replacement (SFHR) involves the application of PCR amplicons to correct mutant loci in vitro or in vivo.
3. Chimeraplasty with hybrid RNA–DNA molecules (chimeraplasts) that promote gene conversion via intranuclear DNA mismatch repair mechanisms.
4. Gentamicin:
    1. An aminoglycoside antibiotics targeting functional complexes (typically ribosomes)
    2. Causes a relaxation in codon recognition
    3. Enables stop codon readthrough of the *mdx* nonsense mutation (a mutation that produces a stop codon in the transcribed mRNA) in exon 23 of the dystrophin gene in the *mdx* mouse
5. Cell-mediated delivery of *dys*:
    1. Use cell transplantation to deliver normal (non-dystrophic) *dys* to dystrophic muscle.
    2. Use donor myogenic precursor cells to remodel the dystrophic muscle of the recipient.
    3. Systemic applications of stem-cell subpopulations.
    4. Use autologous cells (as an alternative to donor cells) which can be isolated, genetically engineered, and used to deliver functional dystrophin to the dystrophic muscle.
6. Muscle-derived precursor cells:
    1. Delivery of normal dystrophin by the transplantation of non-dystrophic muscle-derived precursor cells
    2. Resulting in some recovery of normal function in dystrophic muscle
    3. Greatly compromised by host immune response
7. Non-muscle stem cells:
    1. Induction of a few systemically injected bone marrow cells to enter muscle after regeneration induced by injury.
    2. These cells with neuronal, osteogenic, myogenic, and hemopoietic expression profiles may provide alternatives for cell-based delivery of non-dystrophic loci to dystrophic muscle.
8. Utrophin:
    1. A 395 kDa ubiquitous protein homologue of dystrophin.
    2. Utrophin expression has a widespread sarcolemmal distribution in human dystrophic muscle.
9. Other alternative approaches that may be useful in the support of functional improvement in dystrophic muscle include:
    1. α7β1 integrin
    2. Myoprotective or myeloproliferative cytokine factors such as leukemia inhibitory factor and insulin-like growth factor-1
    3. Inhibition of myostatin
10. Experimental molecular therapies (replace or correct missing or dysfunctional dystrophin) (Rodino-Klapac et al. 2013; Finsterer and Cripe 2014):
    1. Exon skipping with antisense oligonucleotides.
    2. Gene replacement or gene transfer with adeno-associated viruses.
    3. Mutation suppression with molecules such as aminoglycosides that read through nonsense mutations (premature stop codons).
    4. Other strategies include stem-cell therapy or the introduction of surrogate gene products (such as utrophin)

to compensate for the loss of dystrophin.

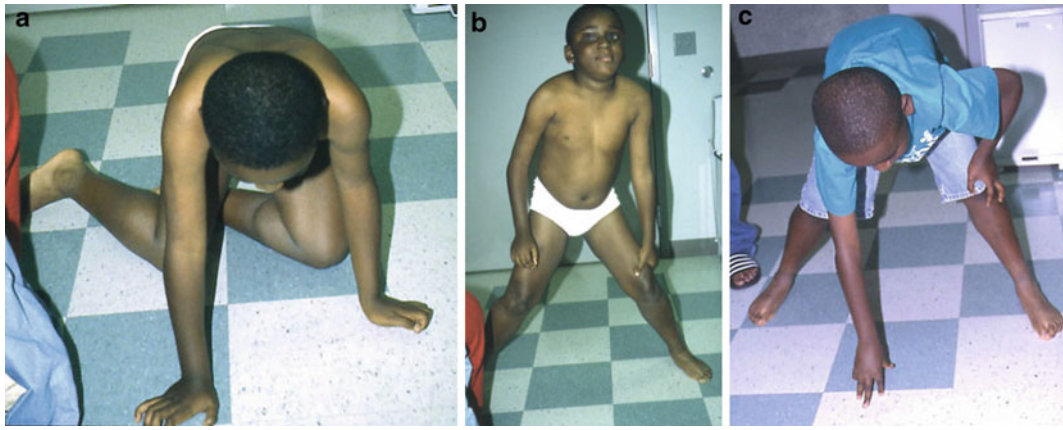

Fig. 1 (**a**–**c**) A 10-year-old boy with DMD showing Gower sign maneuver. He walked before 16 months of age and had trouble getting up. Radiography showed mild cardiomegaly. Muscle biopsy showed the absence of dystrophin. Molecular genetic analysis revealed exons 45–50 deletion of the dystrophin gene

Duchenne muscular dystrophy. *Clinical Genetics, 53*, 102–107.

Zheng, Y., Li, W., Du, J., et al. (2015). The trefoil with single fruit sign in muscle magnetic resonance imaging is highly specific for dystrophinopathies. *European Journal of Radiology, 84*, 1992–1998.

Fig. 2 A 12-year-old boy with DMD showing moderate calf hypertrophy. He began to fall frequently at school, could not get up from sitting position, and had waddling gait, proximal muscle weakness, prominent lordosis, decreased deep tendon reflexes, and mild mental retardation. Muscle biopsy revealed the absence of dystrophin

Fig. 3 A 10-year-old boy with DMD starting to use wheelchair for ambulation. He had tiptoe walking at the age of 6 and markedly elevated CPK at 24,000–26,000. Muscle biopsy of the quadriceps femoris muscle showed marked variation in fiber size, moderate number of necrotic fibers, occasional regeneration fibers and hyalinized fibers, mild increase in internal nuclei, a few split fibers, and moderate increase in perimysial and endomysial connective tissue. Molecular genetic analysis revealed deletion of exon 45 of the dystrophin gene

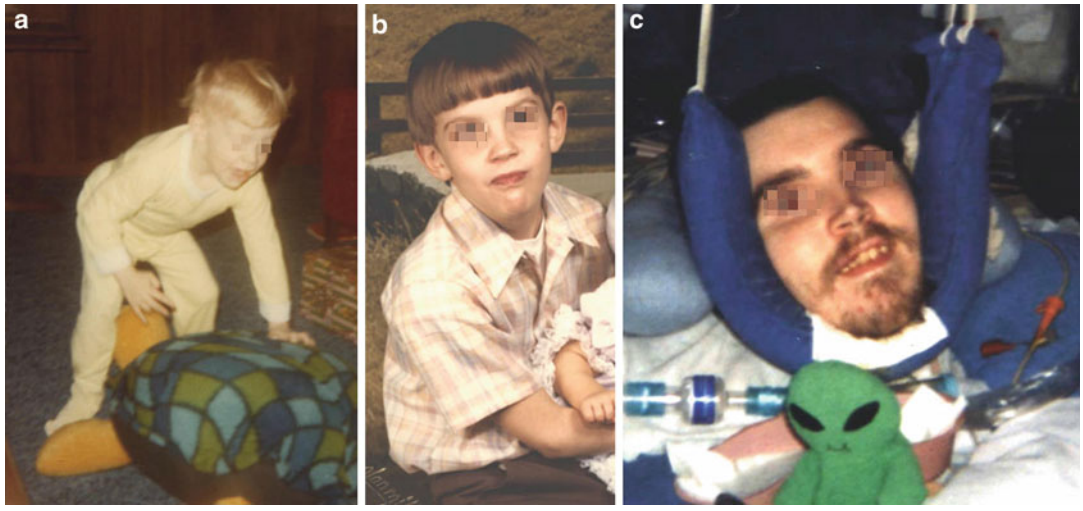

Fig. 4 (**a**–**c**) A male with DMD at 4 (**a**), 10 (**b**), and 29 (**c**) years old showing the progression of the disease. He has deletion of exons 49–54 of the dystrophin gene

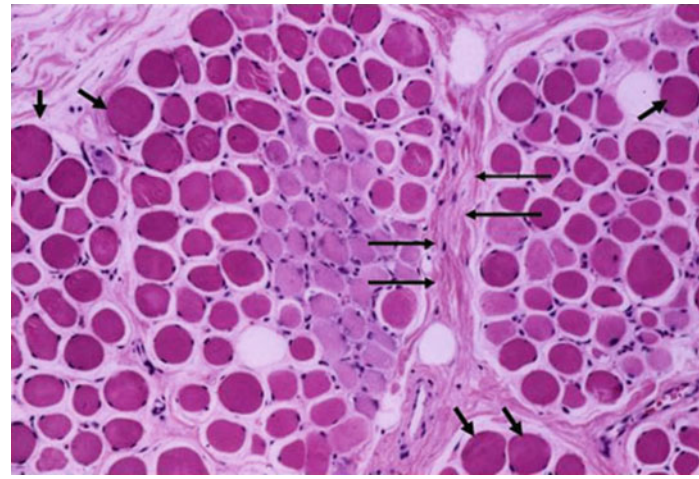

Fig. 5 Biopsy of the left calf muscle of another patient at age 4 showed widening of the perimysium (*large arrows*) and endomysium with fibrosis and variation of fiber size with the presence of large rounded fibers (*small arrows*). Degenerative fibers were often seen (H & E, x400)

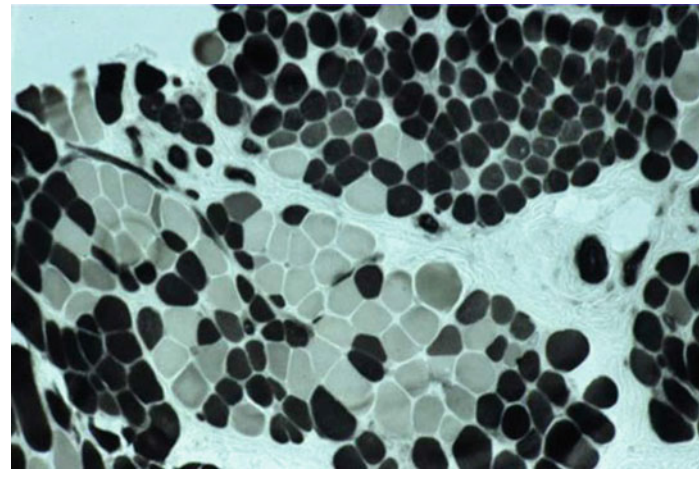

Fig. 6 Enzyme histochemical stain showed both type I (*dark stained*) and type II (*light stained*) fibers are randomly affected and there is a remarkable variation of fiber size even at the early stage (myosin ATPase at 4.6, ×400)

Ectrodactyly-Ectodermal Dysplasia-Clefting (EEC) Syndrome

Contents

EEC syndrome is an ectodermal dysplasia syndrome associated with ectrodactyly and cleft lip/palate.

Genetics/Basic Defects

1. Inheritance (Akahoshi et al. 2003; Barrow et al. 2002; Clements et al. 2010)
   1. Familial cases (50%)
      1. Autosomal dominant inheritance.
      2. Variable clinical expression (Penchaszadeh and de Negrotti 1976; Annerén et al. 1991) and incomplete penetrance (93–98%) (Tse et al. 1990; Roelfsema and Cobben 1996).
      3. A report of a three-generation Brazilian family with three individuals (mother, son and grandfather) affected by EEC syndrome, determined by a novel mutation c.1037C > G (p.Ala346Gly). The disorder in this family exhibits a broad spectrum of phenotypes (Alves et al. 2015).
   2. Sporadic cases (50%): more severe phenotype than the familial cases
2. At least three distinctive EEC loci identified
   1. EEC1 (7q11.2-q21.3) (Qumsiyeh 1992; Scherer et al. 1994)
   2. EEC2 (chromosome 19 pericentromeric region)
   3. EEC3 (3q27)
3. Characterization of the split hand/split foot malformation locus SHFM1 at 7q21.3-q22.1 (Crackower et al. 1996)
4. Molecular basis of EEC
   1. Causative mutations for EEC syndrome have only been identified in *p63* with identification of heterozygous mutations in the DNA-binding domain of the *p63* gene at 3q27.
   2. Heterozygous germline mutations in the p63 gene underlie EEC syndrome (Celli et al. 1999; Wessagowit et al. 2000).
   3. The *p*63 protein:
      1. A member of the *p53* family.
      2. Implicated in apoptosis rather than tumor suppression. Increased susceptibility for cancer development has not been shown in patients with EEC syndrome.
   4. Pathogenic mutations in the *TP63* transcription factor have been identified as the

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_77

molecular basis of EEC syndrome, and to date 34 mutations have been reported (Clements et al. 2010). The majority of mutations involve heterozygous missense mutations in the DNA-binding domain of TP63, a region critical for direct interactions with DNA target sequences.

5. Genotype-phenotype correlation
    1. A genotype-phenotype correlation described for *p63* mutations in EEC syndrome, limb-mammary syndrome, and isolated split hand/split foot malformation: a specific pattern of missense mutations exists in EEC syndrome that are not generally found in split hand/foot malformation or limb-mammary syndrome (Van Bokhoven et al. 2001).
    2. Emerging paradigm for genotype-phenotype correlation (Clements et al. 2010).
    3. EEC syndrome, the prototype of all TP63 ectodermal dysplasia disorders, is the most prevalent syndrome resulting from mutations in the *TP63* gene (Brunner et al. 2002; Bougeard et al. 2003) with more than 200 cases reported in the literature.
6. EEC syndrome as a model of apoptosis disturbance
    1. Split hands and feet are caused by a failure of cell death between fingers and between toes.
    2. Urogenital anomalies are due to abnormal regression of Wolffian or Mullerian duct.
    3. Facial clefts are attributed to the abnormal elimination of excess cells during fusion of the archetypal plate.

Clinical Features

1. Significant phenotypic variation and intra-/interfamilial variability (Rodini and Richieri-costa 1990; Buss et al. 1995; Bigatà et al. 2003)
2. Cardinal signs (triad)
    1. *E*ctrodactyly
    2. *E*ctodermal dysplasia
    3. Orofacial *c*lefts
3. Distal limb malformations: highly variable
    1. Ectrodactyly (84%)
        1. Also called split hand/foot malformation
        2. A central reduction of the hands and feet that is often associated with syndactyly.
    2. Present in all four or any combination of extremities involved or not present at all
4. Ectodermal dysplasia (77%): may exhibit the following signs:
    1. Sparse scalp hair
    2. Sparse eyebrows and eyelashes
    3. Thin and brittle nails
    4. Hypohidrosis
    5. Thin and dry skin with an increased susceptibility to eczema
    6. Dental anomalies
        1. Hypodontia
        2. Coniform-shaped teeth
        3. Enamel dysplasia
5. Characteristic face
    1. Bilateral cleft lip and/or palate (68%)
    2. Maxillary hypoplasia
    3. Short philtrum
    4. Broad nasal tip
    5. Choanal atresia
    6. Anomalies of the lacrimal ducts resulting in blepharitis, keratitis, and dacryocystitis (59%)
6. Common ocular signs and symptoms (Kennedy et al. 2015)
    1. Photophobia
    2. Blepharospasm
    3. Epiphoria
    4. Corneal neovascularization and scarring
7. Urogenital defects (23%) (Rollnick and Hoo 1988)
    1. Hydronephrosis
    2. Hydroureter
    3. Renal agenesis
8. Conductive hearing loss (14%)
9. Developmental delay
10. Occasional CNS malformations
    1. Rare growth hormone deficiency secondary to hypothalamic-pituitary insufficiency

2. Holoprosencephaly associated with hypogonadotropic hypogonadism and central diabetes insipidus (Van Maldergem et al. 1992)
3. Isolated absent septum pellucidum

11. Phenotype overlapping with split hand/foot malformations
12. Diagnostic criteria (Buss et al. 1995)
    1. Major
        1. Ectodermal dysplasia
        2. Ectrodactyly
        3. Cleft lip/palate
        4. Lacrimal duct anomalies
    2. Minor
        1. Renal anomalies
        2. Deafness
        3. Mental retardation
        4. Choanal atresia
13. TP63 (P63) mutation associated disorders (Clements et al. 2010; Sharma et al. 2015): Clinical features overlap with EEC syndrome, although several distinct characteristics may help distinguish them.
    1. Ankyloblepharon-ectodermal dysplasia-clefting (AEC) (Hay-Wells) syndrome (McGrath et al. 2001; Sawardekar and Zaenglein 2011): Typical features include:
        1. Ankyloblepharon filiforme (partial eyelid fusion)
        2. Skin erosions
        3. Ectodermal dysplasia
        4. Orofacial clefts
        5. Sparse eyebrows and eyelashes
    2. Acrodermato-ungual-lacrimal-tooth (ADULT) syndrome (Chan et al. 2004; Avitan-Hersh et al. 2010; Berk et al. 2012): Common features include:
        1. Ectrodactyly
        2. Syndactyly
        3. Mammary gland/nipple hypoplasia
        4. An absence of clefting
        5. Increased skin freckling (excessive skin)
        6. Dry skin
        7. Dysplastic nails
        8. Lacrimal duct atresia
        9. Primary hypodontia
        10. Early loss of permanent teeth
    3. Rapp-Hodgkin syndrome (Bougeard et al. 2003; Chan et al. 2005; Clements et al. 2010): Typical features include:
        1. Cleft lip and palate
        2. Small mouth
        3. Narrow nose
        4. Coarse and wiry hairs progressing to alopecia in adults
        5. Oligodontia or anodontia
        6. Hypoplasia of the nails
        7. Abnormalities of the lacrimal ducts
        8. Deformed ears and ear canals
        9. Hyperplastic mucosa
        10. Cheilitis angularis
        11. Renal dysplasia
        12. Inguinal hernia
        13. Hypospadias in males
        14. Urethral reflux
        15. Perioral ulcer
    4. Limb-mammary syndrome (Van Bokhoven et al. 1999, 2001)
        1. Similar limb defects to those seen in EEC syndrome, including absence or severe hypoplasia of digits and fusion/separation defects such as syndactyly
        2. Additional clinical features
            1. Mammary gland/nipple hypoplasia
            2. Lacrimal duct obstruction
            3. Cleft palate with or without bifid uvula
            4. Dystrophic nails
            5. Hypohydrosis
            6. Teeth defects

Diagnostic Investigations

1. Ophthalmologic evaluation for tear duct obstruction
2. Early audiological assessment
3. Renal ultrasound for associate renal anomalies
4. Radiographic evaluation for ectrodactyly
5. Starch-iodine test (the skin is painted with tincture of iodine, air-dried, and sprayed with starch) after sweat stimulation with intradermal injections of pilocarpine to demonstrate hypohidrosis (Bigatà et al. 2003)

6. Direct molecular analysis is possible for EEC (TP63-related disorders) (www.genetests.org)

Genetic Counseling

1. Counseling according to autosomal dominant inheritance
    1. Patient's sib:
        1. Recurrence risk of 50% if a parent is affected
        2. Recurrence risk not increased if both parents are normal
    2. Patient's offspring: recurrence risk of 50%
    3. Dilemmas in counseling due to highly variable clinical expression (Tse et al. 1990)
    4. Consider the possibility of nonpenetrance due to gonadal mosaicism
2. Prenatal diagnosis
    1. Prenatal ultrasonography (Bronshtein and Gershoni-Baruch 1993; Rios et al. 2012)
        1. The prenatal diagnosis of EEC syndrome can be done early by the 2D US, when the hands and feet malformations (lobster-claw deformity) are associated with a cleft lip and/or palate deformities (Leung et al. 1995).
        2. The 3D US in the rendering mode has been used to better define the malformations; this mode is better to explain the malformations to the parents.
    2. Molecular genetic analysis of p63 gene mutation (South et al. 2002)
        1. On fetal DNA extracted from CVS and amniocytes by direct sequencing and restriction endonucleases digestion (loss of *AciI* site on mutant allele)
        2. Using a preimplantation genetic diagnostic approach
3. Management (Bigatà et al. 2003)
    1. Supportive (multidisciplinary team approach) (Kennedy et al. 2015)
        1. Artificial tear for tear duct blockage.
        2. Anticipate recurrent ophthalmologic infections.
        3. If a non-healing epithelial defect is present with concern for perforation, amniotic membrane transplant by way of surgery or in-office placement of a commercially available ring should be considered.
        4. Corneal perforation can be managed with cyanoacrylate glue and bandage contact lens (Felipe et al. 2012).
        5. Rigid gas-permeable scleral contact lenses (GP-ScCL) have been reported useful in cases of severe ocular surface disease, particularly non-healing epithelial defects (Romero-Rangel et al. 2000; Schornack 2011).
        6. In cases of ocular surface disease related to limbal stem cell deficiency, the benefit is limited to symptomatic improvement of photophobia and pain rather than restoration of a normal ocular surface with corneal epithelium (Van Bokhoven et al. 2001). However, one report does claim that GP-ScCL may provide an environment for damaged but viable epithelial limbal stem cells to recover, restoring a physiologic corneal epithelium (Romero-Rangel et al. 2000).
        7. Periodic odontologic management to prevent dental malocclusion and caries.
        8. Simple emollients for dry skin.
    2. Surgery
        1. Early surgery for tear duct blockage
        2. Surgery for all defects causing functional impairment
            1. Cleft lip/palate
            2. Ectrodactyly
            3. Associated anomalies

Ehlers-Danlos Syndrome

Contents

Ehlers-Danlos syndrome (EDS) is a group of clinically and genetically heterogeneous heritable connective tissue disorders (Yeowell and Pinnell 1993) affecting the skin, ligaments, joints, blood vessels, and internal organs. EDS is characterized by skin extensibility, joint hypermobility (JHM), and tissue fragility. EDS results from mutations in genes involved in extracellular matrix formation and organization, leading to a predisposition for loss of structural integrity in tissues within multiple organ systems (Barabas 1967). The prevalence of EDS is estimated to be about 1 in 5,000 births (Steinmann et al. 1993).

Synonyms and Related Disorders

EDS I (Gravis type); EDS II (mitis type); EDS III (hypermobile type); EDS IV (arterial-ecchymotic type); EDS IX (occipital horn syndrome/X-linked cutis laxa); EDS VI (kyphoscoliotic type); EDS VIIA, VIIB (arthrochalasis type); EDS VIIC (dermatosparaxis type); EDS VIII; EDS X; EDS XI.

Genetics/Basic Defects

1. The Villefranche classification of EDS (Pope and Burrows 1997; Beighton et al. 1998; Mao and Bristow 2001; Byers and Murray 2014)
    1. Classic type (includes EDS type I, gravis type and EDS type II, mitis type)
        1. Autosomal dominant inheritance.
        2. Mutations in the *COL5A1* gene (mapped at 9q34.2-q34.3), *COL5A2* (Michalickova et al. 1998) (mapped at 2q31), and *COL1A1* (mapped at 17q21.31-q22) genes result in EDS I (Nuytinck et al. 2000). Mutations in the *COL1A1* are not a major cause of classic EDS.
        3. Mutations in the *COL5A1* can result in EDS I (Wenstrup et al. 2000) and II (De Paepe et al. 1997), and *COL5A2* genes result in EDS II.
    2. Hypermobile type (EDS type III)
        1. Autosomal dominant inheritance in the classic form of type III EDS.
        2. Mutations in *COL3A1*, typically cause EDS IV, also cause EDS III.
        3. Mutations in the *TNXB* gene that encodes tenascin-X (neither a collagen nor a collagen-modifying protein) result in a variation of the classic form of the Ehlers-Danlos syndrome (Byers 2001;

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_78

Schalkwijk et al. 2001): an autosomal recessive disorder with clinical findings (joint hypermobility, soft hyperextensible skin, and easy bruising without skin scars) compatible with Beighton's description of Ehlers-Danlos syndrome type III or "benign familial hypermobility."

3. Vascular type (EDS type IV, arterial-ecchymotic type) (Byers 1995)
   1. Autosomal dominant inheritance.
   2. *COL3A1 l*ocus: 2q31.
   3. Caused by mutations in the gene that encodes type III procollagen (*COL3A1*), which is the major component of blood vessels, viscera, and the uterus. Consequently, individuals with this type often experience life-threatening vascular and gastrointestinal complications.
   4. Constitutes less than 4% of all EDS cases, usually associated with life-threatening arterial dissections and ruptures in adults (Abayazeed et al. 2014)
4. Kyphoscoliosis type (EDS type VI, ocular-scoliotic type) (Yeowell and Walker 2000)
   1. Autosomal recessive inheritance
   2. *PLOD* gene mapped to 1p36.3-p36.2
   3. Caused by mutations in the *PLOD* gene encoding lysyl hydroxylase
   4. Caused by deficient activity of the enzyme procollagen lysyl hydroxylase
   5. EDS VIA (kyphoscoliosis): reduced activity of lysyl hydroxylase
   6. EDS VIB: normal enzyme level
5. Arthrochalasis type (EDS types VIIA and VIIB, arthrochalasis multiplex congenita) (Byers et al. 1997; Giunta et al. 1999)
   1. Autosomal dominant inheritance
   2. EDS VIIA caused by mutations in the genes for type I collagen (*COL1A1*)
   3. EDS VIIB caused by mutations in the genes for type I collagen (*COL1A2*), mapped at 7q22.1
6. Dermatosparaxis type (EDS type VIIC)
   1. Autosomal recessive inheritance
   2. Caused by homozygous mutations in the *ADAMTS2* gene (5q23) encoding procollagen I N-terminal peptidase resulting in procollagen peptidase deficiency

2. Other types not in the Villefranche Nosology (Pope and Burrows 1997; Byers and Murray 2014; Colombi et al. 2015)
   1. EDS type V
      1. X-linked recessive inheritance (Beighton and Curtis 1985)
      2. Described in only two families with clinical features similar to EDS II
      3. Molecular basis unknown
   2. EDS type VIII (periodontitis)
      1. Autosomal dominant inheritance
      2. Similar to classic type except the presence of periodontal friability
      3. Gingival recessions
      4. Periodontitis
      5. Premature loss of permanent teeth
      6. Alveolar bone resorption by the third decade
      7. Atrophic scars
      8. Joint hypermobility
      9. Umbilical hernia
      10. Arachnodactyly
   3. EDS type IX (occipital horn syndrome (X-linked cutis laxa))
      1. An X-linked recessive condition allelic to Menkes syndrome
      2. Abnormal copper utilization secondary to defective copper transport resulting in decreased activity of lysyl oxidase, an important copper-dependent enzyme required for cross-linking in collagen biosynthesis and elastin fibers
   4. EDS type X (fibronectin-deficient)
      1. Autosomal recessive inheritance
      2. Described only in a single family
      3. Associated platelet aggregation due to a defect in fibronectin
   5. EDS type XI (familial joint hypermobility syndrome)
      1. Autosomal dominant inheritance
      2. Previously removed from the EDS classification

6. Classic vascular-like (*COL1A1*)
    1. Autosomal dominant inheritance
    2. Hyperextensible skin
    3. Atrophic scarring
    4. Easy bruising
    5. Joint hypermobility
    6. Propensity for arterial rupture at adult age
7. Cardiac valvular (*COL1A2*)
    1. Autosomal recessive inheritance
    2. Severe mitral valve regurgitation/insufficiency
    3. Arrhythmia, atrial fibrillation and septal defect, left ventricular enlargement
    4. Joint hypermobility
    5. Skin hyperextensibility
8. EDS due to tenascin-X deficiency (*TNXB*)
    1. Autosomal recessive inheritance
    2. Marked skin hyperextensibility
    3. Normal scarring
    4. Generalized joint hypermobility
    5. Severe easy bruising
9. EDS/OI overlap (*COL1A1*, *COL1A2*) (Malfait and De Paepe 2014) (please see the chapter of "▶ Osteogenesis Imperfecta/Ehlers-Danlos Syndrome Overlap Syndrome")
    1. Autosomal dominant inheritance
    2. Short stature
    3. Blue sclerae
    4. Mild signs of bone fragility
    5. Osteopenia
    6. Infrequent fractures
    7. Generalized JHM
    8. Skin hyperextensibility
    9. Atrophic/hypertrophic scars
    10. Easy bruising
    11. Signs of vascular fragility
    12. Valvular regurgitation
10. Musculocontractural type 1/D4ST1 deficiency (*CHST14*)
    1. Autosomal recessive inheritance
    2. Congenital contractures of thumbs and fingers
    3. Craniofacial dysmorphisms
    4. Blue sclerae
    5. Microcornea
    6. Clubfoot
    7. Arachnodactyly
    8. Severe kyphoscoliosis
    9. Muscle hypotonia
    10. JHM
    11. Hyperextensible skin
    12. Atrophic scars
    13. Easy bruising
    14. Wrinkled palms
11. Musculocontractural type 2 (*DSE*)
    1. Autosomal recessive inheritance
    2. Hyperextensible fragile skin
    3. Atrophic scarring
    4. Easy bruising
    5. Muscle hypoplasia
    6. Gross motor development delay
    7. Facial dysmorphisms
    8. Arachnodactyly
    9. Adducted thumbs
    10. Clubfoot
    11. Inguinal hernia
    12. Generalized mild cerebral atrophy
12. With progressive kyphoscoliosis, myopathy, and hearing loss (*FKBP14*)
    1. Autosomal recessive inheritance
    2. Severe hypotonia and weakness at birth
    3. Hyperextensible skin
    4. Joint hypermobility
    5. Severe progressive scoliosis
    6. Sensorineural hearing impairment
    7. Myopathy
    8. Vascular dissection
13. Brittle cornea syndrome type 1 (*ZNF469*)
    1. Autosomal recessive inheritance
    2. Blue sclerae
    3. Corneal rupture
    4. Keratoconus/keratoglobus
    5. Skin hyperextensibility
    6. Joint hypermobility
14. Brittle cornea syndrome type 2 (*PRDM5*)
    1. Autosomal recessive inheritance
    2. Corneal rupture
    3. Microcornea
    4. Cornea plana
    5. Keratoconus/keratoglobus
    6. Myopia

7. Hyperextensible skin
8. Easy bruising
9. JHM (localized)
10. Pectus excavatum
11. Scoliosis
12. Mitral valve prolapse
13. Hearing loss (conductive and sensorineural deafness)

15. Spondylocheirodysplasia, EDS-like (*SLC39A13*)
    1. Autosomal recessive inheritance
    2. Protuberant eyes
    3. Blue sclerae
    4. Hyperextensible skin
    5. Easy bruising
    6. JHM
    7. Hands with wrinkled palms
    8. Tenar muscle atrophy
    9. Tapering fingers
    10. Spondyloepiphyseal dysplasia
16. Progeroid type 1 (*B4GALT7*)
    1. Autosomal recessive inheritance
    2. Aged appearance
    3. Short stature
    4. Forearm bones and elbow anomalies, radioulnar
    5. Synostoses
    6. Bowing of the extremities
    7. Facial dysmorphisms
    8. Hyperextensible skin
    9. Atrophic/papyraceous scars
    10. Joint hypermobility
    11. Pes planus
    12. Developmental delay
    13. Muscle hypotonia
17. Progeroid type 2/spondyloepimetaphyseal dysplasia with joint laxity type 1 (*B3GALT6*)
    1. Autosomal recessive inheritance
    2. Aged appearance
    3. Developmental delay
    4. Disproportionate short stature
    5. Craniofacial disproportion
    6. Generalized severe osteopenia
    7. Defective wound healing
    8. Hyperextensible skin
    9. Joint hypermobility
    10. Muscle hypotonia
    11. Spondyloepimetaphyseal dysplasia

Clinical Features

1. Classic type (EDS I and II) (McKusick 1972; Beighton 1992; Beighton et al. 1998; Malfait et al. 2011)
    1. Major diagnostic criteria: The presence of scars with joint hypermobility suggests the classical type.
        1. Skin hyperextensibility
        2. Widened atrophic scars (the hallmark "cigarette-paper" scars, a manifestation of tissue fragility)
        3. Joint hypermobility
        4. Positive family history
    2. Minor diagnostic criteria
        1. Smooth, velvety skin
        2. Molluscoid pseudotumors
            1. Fresh lesions associated with scars
            2. Frequently found over pressure points such as elbow and knees
        3. Subcutaneous spheroids
            1. Small subcutaneous spherical hard bodies
            2. Frequently mobile and palpable on the forearms and shins
            3. May be calcified and detectable radiologically
        4. Complications of joint hypermobility
            1. Sprains
            2. Dislocations
            3. Recurrent joint subluxations in the shoulder, patella, and temporomandibular joints (TMJ)
            4. Pes planus
        5. Muscle hypotonia
        6. Delayed gross motor development
        7. Easy bruising
        8. Manifestations of tissue extensibility and fragility
            1. Hiatal hernia
            2. Anal prolapse in childhood
            3. Cervical insufficiency

9. Surgical complications (postoperative hernias)
10. Positive family history

3. Other features
   1. Families with variable severity (mild, moderate, and severe) of the skin manifestations
   2. Dyspareunia and sexual dysfunction: occasional complaints
   3. Fatigue: a frequent complaint

2. Hypermobile type (EDS III) (Levy 2016)
   1. Major diagnostic criteria
      1. Skin involvement (variable hyperextensibility and/or smooth, velvety skin)
      2. Generalized joint hypermobility (dominant clinical feature)
      3. Absence of fragility or other significant skin or soft tissue abnormalities
   2. Minor diagnostic criteria: supportive
      1. Positive family history of EDS, hypermobility type (or family history of joint laxity), without significant skin or soft tissue fragility, in a pattern consistent with autosomal dominant inheritance
      2. Recurrent joint dislocations (particularly shoulder, patella, and temporomandibular joints)
      3. Chronic joint/limb and back pain (early onset, chronic, and possibly debilitating)
      4. Easy bruising
      5. Functional bowel disorders (functional gastritis, irritable bowel syndrome)
      6. Neurally mediated hypotension or postural orthostatic tachycardia
      7. High narrow palate
      8. Dental crowding
   3. Other features
      1. Early-onset, chronic, and possibly debilitating musculoskeletal pain
      2. Aggravation of joint symptoms during pregnancy, but a complete return to the former status is possible
   4. Natural history and manifestations (Castori et al. 2010)
      1. The most difficult form to diagnose
      2. A diagnosis of exclusion for the following disorders:
         1. Underlying bone dysplasia
         2. Neuromuscular disorder (such as Bethlem myopathy)
         3. Various similar connective tissue disorders, including other types of EDS and the fibrillinopathies
      3. Lack of a major clinical trait except for joint hypermobility
      4. Lack of specific diagnostic laboratory tests, although tenascin-X monoallelic or biallelic inactivation can be documented in no more than 10% of the patients (Schalkwijk et al. 2001; Zweers et al. 2003).
      5. Clinical presentations
         1. Recurrent articular dislocations (also after surgical repair)
         2. Chronic/recurrent articular pain in adults or young adults with joint hypermobility and/or a history of infancy/childhood joint hypermobility
         3. Soft/velvety skin and/or easy bruising with joint hypermobility or a history of infancy/childhood joint hypermobility
         4. Chronic asthenia with recurrent articular pain and negative screening for inflammatory arthritis
         5. Acute thoracic pain due to spontaneous rib luxation/subluxation (rare)
         6. Early-onset uterine/vesical/rectal prolapse (19%)
         7. Chronic gastrointestinal discomfort including chronic recurrent dyspepsia/gastritis, gastro-esophageal reflux, irritable bowel disease, recurrent unexplained abdominal pain, and constipation/diarrhea

3. Vascular type (EDS IV) (Beridze and Frishman 2012; Pepin et al. 2015)
   1. Major diagnostic criteria: The presence of any two or more major criteria is highly indicative of the diagnosis of EDS IV;

biochemical testing is strongly recommended to confirm the diagnosis. Arterial/intestinal/uterine fragility or rupture (presenting signs in 70% of adults with vascular type of EDS).

1. Arterial aneurysms, dissection, or rupture: Spontaneous arterial rupture peaks in the third or fourth decade but may occur earlier, most commonly involves midsized arteries, and is the most common cause of sudden death. The sites of arterial rupture are the thorax and abdomen (50%), head and neck (25%), and extremities (25%).
2. Intrapartum uterine rupture and pre-/postpartum arterial rupture result in 15% mortality. Vaginal and perineal tears may complicate pregnancies during delivery.
3. Gastrointestinal ruptures occur in about 25% of patients, most common in the sigmoid colon. Ruptures of the small bowel and stomach are rare. The rupture may present as an acute abdomen.
4. Family history of the vascular type of EDS.

2. Minor diagnostic criteria: The presence of one or more minor criteria contributes to the diagnosis of the vascular type of EDS, but is not sufficient to establish the diagnosis.
    1. Thin translucent skin (especially noticeable on the chest or abdomen)
    2. Characteristic facial appearance in some affected patients due to a decrease in the subcutaneous adipose tissue
        1. Thin vermillion of the lips and philtrum
        2. Micrognathia
        3. Narrow nose
        4. Prominent eyes
    3. Acrogeria (an aged appearance of the extremities, particularly the hands)
    4. Hypermobility of small joints (usually limited to the digits)
    5. Tendon and muscle rupture (knee)
    6. Talipes equinovarus (clubfoot) (12%)
    7. Early-onset varicose veins
    8. Arteriovenous, carotid-cavernous sinus fistula
    9. Pneumothorax/pneumohemothorax (common in childhood)
    10. Mitral valve prolapse
    11. Easy bruising
        1. Lifelong history
        2. Spontaneous or with minimal trauma
    12. Extensive scars and hyperpigmentation over bony prominences and skin
    13. Chronic joint subluxations/dislocations
        1. TMJ
        2. Patella
        3. Ankles
    14. Congenital dislocation of the hips
    15. Talipes equinovarus (clubfoot)
    16. Gingival recession
    17. A positive family history consistent with autosomal dominant inheritance with sudden death in close relatives
3. Other features
    1. An uncommon subtype: Diagnosis often made only after a catastrophic complication or at postmortem examination
    2. Acute abdominal and flank pain (diffuse or localized): a common manifestation of arterial or intestinal rupture
    3. The single vessel most commonly affected: the iliac artery (Abayazeed et al. 2014)
    4. Subcutaneous venous pattern particularly apparent over the chest and abdomen
    5. Hypermobility of large joints and hyperextensibility of the skin: unusual in the vascular type
    6. The teenage boys: at higher risk for arterial rupture possibly due to further weakening of the defective collagen during the prepubertal growth spurt
    7. Patients undergoing surgery: Prone to have arterial rupture in the postoperative period, possibly due to increased

collagenase activity after surgical trauma
8. Aneurysms (if present) resulting from arterial tears with walled-in hematomas or pseudoaneurysms
9. Danger of varicose vein surgery in unrecognized cases since the extreme fragility of all blood vessels can lead to a loss of a limb or even loss of life

4. EDS V
   1. An extremely rare X-linked, recessively inherited disorder
   2. Clinically similar to EDS II
      1. Joint hyperextensibility
      2. Slightly hyperelastic skin
      3. Skin subject to mildly abnormal scarring
   3. Normal life span
   4. Asymptomatic female carriers
5. Kyphoscoliosis type (EDS VI) (Yeowell and Steinmann 2013)
   1. Major diagnostic criteria: Presence of three major criteria is suggestive of diagnosis of EDS, kyphoscoliosis type.
      1. Generalized joint laxity (recurrent joint dislocations common in adults)
      2. Severe muscle hypotonia at birth
      3. Kyphoscoliosis, present at birth or within the first year of life, progressive (adults with severe kyphoscoliosis are at risk for restrictive lung disease and pneumonia)
      4. Scleral fragility and rupture of the ocular globe
   2. Minor diagnostic criteria
      1. Tissue fragility, including atrophic scars
      2. Easy bruising
      3. Marfanoid habitus
      4. Microcornea (most patients)
      5. Radiologically considerable osteopenia (osteoporosis)
      6. Family history (e.g., affected sibs)
   3. Other features
      1. Pronounced muscular hypotonia leading to delayed gross motor development.
      2. Severe phenotype often results in loss of ambulation in the second or third decade.
      3. Scleral fragility leading to rupture of the ocular globe after minor trauma.
      4. Cardiovascular complications.
         1. Vascular rupture: the major life-threatening complication.
         2. Both aortic dilatation/dissection and rupture of medium-sized arteries may occur.
         3. Mitral valve prolapse common.
      5. Differential diagnosis: severe neonatal form of Marfan syndrome.
6. Arthrochalasia type (EDS VIIA and VIIB)
   1. Major diagnostic criteria
      1. Severe generalized joint hypermobility, with recurrent subluxations
      2. Congenital bilateral hip dislocation (present in all biochemically proven individuals, may lead to short stature)
   2. Minor diagnostic criteria
      1. Skin hyperextensibility
      2. Tissue fragility, including atrophic scars
      3. Easy bruising
      4. Muscle hypotonia
      5. Kyphoscoliosis (may lead to short stature)
      6. Radiologically mild osteopenia
   3. Other features
      1. Short stature resulting from complication of severe kyphoscoliosis and/or hip dislocation
      2. Differential diagnosis: Larsen syndrome
7. Dermatosparaxis type (EDS VIIC)
   1. Major diagnostic criteria
      1. Severe skin fragility (wound healing not impaired, scars not atrophic)
      2. Sagging, redundant skin (redundancy of the facial skin resulting in an appearance resembling cutis laxa) analogous to the animal disease dermatosparaxia
   2. Minor diagnostic criteria
      1. Soft, doughy skin texture
      2. Easy bruising (substantial)
      3. Premature rupture of fetal membranes
      4. Large hernias (umbilical, inguinal)

3. Other features
    1. Blue sclerae
    2. Palmar creases
    3. Micrognathia
    4. Joint laxity without subluxations
8. EDS VIII
    1. Chronically inflamed, heavily pigmented, discrete, and pretibial plaques (granulomatous collagen degeneration)
    2. Premature periodontal disease
    3. Premature loss of teeth
    4. Hypermobile joints
    5. Thin, soft, and hyperextensible skin
    6. Easy bruising skin
    7. Skin prone to abnormal scarring
    8. No consistent biochemical or structural changes detectable
9. Occipital horn syndrome (EDS IX)
    1. Also called X-linked cutis laxa
    2. Skeletal dysplasia
        1. Occipital horns
        2. Broad clavicles
        3. Deformed radii, ulnae, and humeri
        4. Narrow rib cage
        5. Undercalcified long bones
        6. Coxa valga
    3. Unusual facial appearance
    4. Hypermobility of finger joints
    5. Limitation of extension of elbows
    6. Chronic diarrhea
    7. Genitourinary abnormalities
        1. Bladder diverticulae
        2. Susceptible to rupture of the bladder
    8. Vascular complications (Mentzel et al. 1999)
        1. Splenic artery aneurysm
        2. Hepatic artery aneurysm
    9. Neuropathologic findings
        1. Neovascularization and extreme reduplication of the cerebral arteries with cystic medial degeneration
        2. Cerebellar hypoplasia
        3. Focal cortical dysplasia
        4. Cerebellar heterotopias
    10. Abnormal copper utilization
        1. Depleted serum copper level
        2. Depleted serum ceruloplasmin level
10. Ehlers-Danlos syndrome with fibronectin deficiency (EDS X)
    1. A mild, recessively inherited variant of Ehlers-Danlos syndrome
    2. Resembling EDS types II and III
    3. Thin, fragile, and easily scarred skin
    4. Joint hypermobility
    5. Excessive bruising
    6. Abnormal platelet aggregation but correctable with normal fibronectin

Diagnostic Investigations

1. Classic type
    1. Ultrastructural studies
        1. Disturbed collagen fibrillogenesis
        2. A characteristic “cauliflower” deformity of collagen fibrils
    2. Abnormal electrophoretic mobility of the proα1(V) and proα2(V) chains of collagen type V in some patients
    3. Demonstration of a mutation in *COL5A1* and/or *COL5A2* genes
    4. Echocardiogram to measure aortic root size (Tiller et al. 1998)
2. Hypermobile type: *TNXB* sequencing or *COL3A1* mutation study
3. Vascular type (Pepin et al. 2015)
    1. Diagnosis of vascular type is established in a proband with any one of the following:
        1. Identification of a heterozygous *COL3A1* pathogenic variant on molecular genetic testing (sequence analysis, gene-targeted deletion/duplication analysis)
        2. Abnormalities in synthesis and mobility of type III collagen chains on biochemical analysis of type III procollagen from cultured fibroblasts when vascular EDS is suspected but molecular genetic testing does not identify a *COL3A1* pathogenic variant or a variant of uncertain significance is identified
    2. Surveillance of aneurysm by MRI or CT scan without contrast material or venous subtraction angiography

4. Kyphoscoliosis type
    1. Demonstration of deficient activity of the enzyme procollagen lysine hydroxylase in affected individuals, diagnosed by biochemical testing of the urine and enzyme assay of cultured fibroblasts
    2. Demonstration of an increased ratio of deoxypyridinoline to pyridinoline crosslinks in the urine measured by HPLC, a highly sensitive and specific test (Malfait et al. 2011)
    3. Demonstration of mutations of the *PLOD* gene that encodes the enzyme procollagen lysyl hydroxylase (Malfait et al. 2011)
    4. Echocardiogram to measure aortic root size (dilatation) (Tiller et al. 1998)
5. Arthrochalasis type
    1. Electrophoretic demonstration of pNα1 (I) or pNα2(I) chains extracted from dermal collagen or harvested from cultured skin fibroblasts
    2. Mutation analysis (complete or partial exon 6 skipping in cDNAs of *COL1A1* or *COL1A2*, respectively)
6. Dermatosparaxis type (Smith et al. 1992): electrophoretic demonstration of pNα1(I) or pNα2 (I) chains from collagen type I extracted from dermis in the presence of protease inhibitors, or obtained from cultured skin fibroblasts

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Autosomal recessive: 25% risk of having an affected sib
        2. Autosomal dominant: risk low (1–5%) unless the parent is affected or having somatic mosaicism or germline mosaicism
        3. X-linked recessive: 50% risk of having an affected brother if the mother is a carrier
    2. Patient's offspring
        1. Autosomal recessive: risk not increased unless the spouse is a carrier.
        2. Autosomal dominant: 50% risk of having an affected offspring.
        3. X-linked recessive: None of the sons will be affected; all daughters will be carriers.
2. Prenatal diagnosis (Yeowell and Steinmann 2013)
    1. Possible by demonstrating the disease-causing mutation in the fetal cells from CVS or amniocentesis or by linkage analysis for families in which linkage has been established
    2. Possible by biochemical assay on cultured fetal cells for demonstrating biochemical defect in the specific type of collagen
3. Preimplantation genetic diagnosis may be an option for some families in which the disease-causing mutations have been identified.
4. Management
    1. General approach: conservative and preventive management of most skin and joint problems
        1. Avoid tension when sutures are applied.
        2. Leave removable sutures in place for twice the usual time.
        3. Physical therapy to strengthen the muscles that need to provide support for the loose ligaments.
    2. Classic type (Malfait et al. 2011)
        1. Medical intervention limited to symptomatic therapy and prophylactic measures.
        2. Wear protection pads or stocking.
        3. Avoid contact sports.
        4. Physiotherapy for children with hypotonia and delayed motor development.
        5. Antimicrobial prophylaxis for patients with mitral valve prolapse.
        6. Ascorbic acid helps avoid easy bruising but does not change the basic clinical picture.
    3. Hypermobile type (Levy 2016)
        1. Physical therapy tailored to the individual.
        2. Assisted devices
            1. Braces to improve joint stability
            2. Wheelchair or scooter to offload stress on lower-extremity joints
            3. Suitable mattress to improve sleep quality
        3. Pain medication tailored to symptoms: Severe pain may need pain specialist's help.

4. Appropriate therapy for gastritis/reflux/delayed gastric emptying/irritable bowel syndrome.
5. Possible beta-blockade or rarely surgical approach for progressive aortic enlargement.
6. Psychological and/or pain-oriented counseling.

4. Kyphoscoliotic type
   1. Orthopedic management of kyphoscoliosis
   2. Physical therapy for older children, adolescents, and adults
   3. Antimicrobial prophylaxis for patients with mitral valve prolapse
   4. Aggressive control of blood pressure
   5. Improve with large doses of ascorbic acid because vitamin C is a cofactor for the enzyme that is deficient (Pyeritz 2000)
      1. Improve urinary excretion of hydroxylysine
      2. Improve muscle strength and wound healing
5. Vascular type (Pyeritz 2000; Pepin et al. 2015)
   1. The most severe form of EDS
   2. Prompt recognition of the major complications
   3. Difficult to repair ruptured arteries because of the pronounced vascular fragility
   4. Rupture of the bowel, a surgical emergency
   5. Avoid pregnancy because the risk of vascular rupture is especially high during pregnancy
   6. Minimize risk of trauma by avoiding contact sport, heavy lifting, and weight training
   7. Treat high blood pressure aggressively with β-adrenergic blockade
   8. Elective surgical management of vascular disorders in EDS patients using open and endovascular procedure (Brooke et al. 2010)
      1. Associated with good outcomes
      2. Can be safely performed and should not be withheld until rupture or acute symptoms arise
   9. Patient education
      1. Possible complications
      2. Need for close monitoring
      3. Attention to sudden unexplained pain

Fig. 1 (**a**, **b**) Hyperextensible joints enable a girl and two sisters with EDS to exhibit difficult hyperextensible joint maneuvers

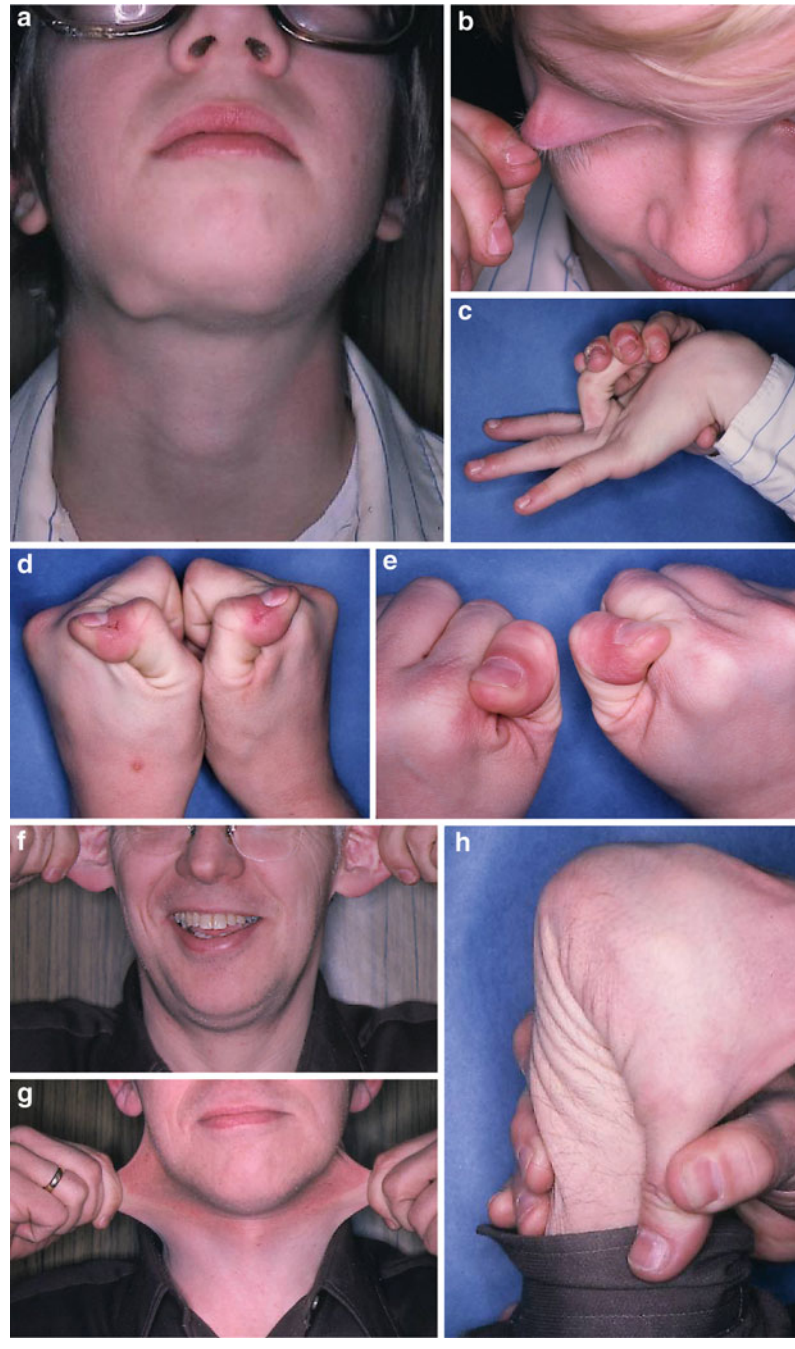

Fig. 2 Familial Ehlers-Danlos syndrome in the son (**a**–**d**), the daughter (**e**), and the father (**f**–**h**) exhibiting hyperextensible joints and hyperelastic skin. The son also has fascia weakness presenting as a hernia on the lower chin

Fig. 3 (**a**–**f**) A male and a female with EDS showing hyperextensible joints and hyperelastic skin

Fig. 4 (**a**–**c**) Three siblings (12-year-old boy, 10-year-old girl, and 7-year-old girl) with Ehlers-Danlos syndrome showing markedly stretchable abdominal walls. Their mother is also affected with a history of hyperextensible joints with subluxations of sternum-collarbone junction, TMJ, hip, and knees

Fig. 5 (**a**, **b**) A 40-year-old female with hypermobile type of Ehlers-Danlos syndrome showing hyperextensible joints and stretch marks of the skin. She suffers from rectal, bladder, and uterine prolapses. She had four placental abruptions and had ventral hernias repaired twice. She had shoulder dislocations three times and patella dislocations more than ten times. She had a history of recurrent articular and abdominal pain and episodic constipations and diarrheas

Fig. 6 Typical EDS showing easy bruises and scars of the skin

Fig. 7 (**a**, **b**) An 8-year-old girl with Ehlers-Danlos syndrome showing marked scarring of the skin

Fig. 8 A 14-year-old girl, a 10-year-old boy, a 4-year-old half-brother, and their mother were evaluated for Ehlers-Danlos syndrome, hypermobile type. The mother had a history of recurrent articular dislocations (pop-out hips and shoulder joints), chronic and recurrent articular pain with joint hypermobility, loose skin, easy bruising, Raynaud phenomenon, and chronic gastrointestinal discomfort, including chronic recurrent dyspepsia, gastro-esophageal reflux, irritable bowel disease, recurrent unexplained abdominal pain, and constipation/diarrhea episodes. Her three children here and two other older brother and sister also have similar signs and symptoms like those of her mother

Ellis-van Creveld Syndrome

Contents

In 1940, Ellis and van Creveld (Ellis and Creveld 1940) described a syndrome, characterized by ectodermal dysplasia, polydactyly, chondrodysplasia, and congenital heart disease. Ellis-van Creveld syndrome, also called chondroectodermal dysplasia, is relatively common in inbred communities, such as the Amish of Lancaster County where it occurs in 1/5,000 births compared to 1/60,000 births in the general population.

Synonyms and Related Disorders

Chondroectodermal dysplasia

Genetics/Basic Defects

1. Inheritance
   1. Autosomal recessive inheritance (Douglas et al. 1959; da Silva et al. 1980; George et al. 2000)
   2. Parental consanguinity (McKusick et al. 1964; Hill 1977; McKusick 2000) in 30% of cases
2. Basic defect (Arya et al. 2001)
   1. Generalized dysplasia of endochondral ossification
      1. Delayed in the primary centers
      2. Premature in the secondary centers
      3. Leads to short stature with progressive distal shortening of the extremities
   2. Caused by mutations in a novel gene, *EVC1*, which is mapped to chromosome 4p16.1 (Polymeropoulos et al. 1996; Ruiz-Perez et al. 2000)
   3. Caused by mutations in a second gene, called *EVC2*, that gives rise to the same phenotype of the syndrome (Galdzicka et al. 2002)
   4. Molecular heterogeneity (Ali et al. 2010) and possibility of involvement of other genes suggested by more mutations in both *EVC1* and *EVC2* in two thirds of the patients (Tompson et al. 2007)
   5. May be allelic to Weyers acrodental dysostosis

Clinical Features

1. A clinical tetrad (Al-Khenaizan et al. 2001; Arya et al. 2001; Chen 2015)
   1. Chondrodystrophy

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_79

1. The most common feature affecting the tubular bones
2. Disproportionate dwarfism
3. Progressive distal limb shortening
    1. Symmetrical
    2. Affects the forearms and lower legs
2. Polydactyly
    1. A constant finding
        1. Bilateral
        2. Postaxial
    2. Polydactyly of the hands observed in most cases
    3. Polydactyly of the feet observed only in 10% of cases
3. Hidrotic ectodermal dysplasia (up to 93%)
    1. Nails
        1. Hypoplastic
        2. Dystrophic
        3. Friable
        4. Completely absent in some cases
    2. Teeth
        1. Neonatal teeth
        2. Partial anodontia
        3. Small teeth
        4. Delayed eruption
        5. Enamel hypoplasia commonly resulting in abnormally shaped teeth with frequent malocclusion
    3. Occasional sparse hair
4. Cardiac anomalies (50–60%) (Husson and Parkman 1961)
    1. A single atrium (Giknis 1963; Sajeev et al. 2002)
    2. AV canal
    3. Ventricular septal defect
    4. Atrial septal defect
    5. Patent ductus arteriosus
    6. The major cause of shortened life expectancy

2. Other clinical findings
    1. Other oral lesions (Hunter and Roberts 1998; Cahuana et al. 2004)
        1. A fusion of the anterior portion of the upper lip to the maxillary gingival margin
            1. Resulting in the absence of mucobuccal fold
            2. Causing the upper lip to present a slight V-notch in the middle
        2. Multiple labiogingival frenula frequent
        3. Lower alveolar ridge often serrated
    2. Orthopedic manifestations (Weiner et al. 2013)
        1. The shoulder, arm, and elbow
            1. Curvature of the humerus and arm
            2. Cubitus valgus
            3. Radial head subluxation-dislocation
        2. The forearm, wrist, and hand
            1. Enlarged distal radius
            2. Stiffness of the PIP joints
            3. Marked loss of ability to make “fist”
        3. The spine and pelvis
            1. Increased lumbar lordosis
            2. Scoliosis
        4. The hip and thigh
            1. Marked external rotation and markedly limited internal rotation
            2. An overall externally rotated thigh and leg
            3. Contracted iliotibial band and lateral quadriceps
        5. The knee and leg
            1. Severe, profound valgus deformity of the knee
            2. Lateral patellar subluxation
            3. Patellar dislocation
            4. Severe contracture iliotibial band, lateral quadriceps, lateral hamstrings, and lateral collateral ligament
            5. Normal knee ligament stability
            6. Proximal medial tibial exostosis
        6. The ankle and feet
            1. Broad foot with pronation
            2. Overriding the 5th toe
            3. The short third toe and longer fourth toe
    3. Genitourinary anomalies (22%)
        1. Hypospadias
        2. Epispadias
        3. Hypoplastic penis
        4. Cryptorchidism
        5. Vulvar atresia
        6. Focal renal tubular dilation in the medullary region
        7. Nephrocalcinosis

8. Renal agenesis
9. Megaureters

4. CNS
   1. Normal intelligence in most patients
   2. Occasional CNS anomalies or mental retardation

Diagnostic Investigations

1. Radiography (Caffey 1952; Arya et al. 2001)
   1. Essential features
      1. Postaxial polydactyly
      2. Progressively distal shortening of segments (acromesomelia with relative shortening of the distal and middle segment of the limbs and phalanges)
      3. Generalized thickness and coarseness of bones
   2. Other features depending on disease severity and age
      1. Curvature of the humerus
      2. Enlargement of distal ends of the radii and ulnae
      3. Hypoplastic distal phalanges
      4. Short, broad middle phalanges
      5. Fusion of metacarpals
      6. Fusion of the hamate and capitate bones of the wrists
      7. Supernumerary carpal bone centers
      8. Clinodactyly
      9. Synostosis
      10. Wedge-shaped tibial epiphyses
      11. Genu valgum with hypoplasia of the upper lateral tibia
      12. Fibula disproportionately smaller than the tibia
      13. Pelvic dysplasia with low iliac wings and spur-like downward projections at the medial and lateral aspects of the acetabula
      14. The narrow thorax with short ribs
2. Echocardiography for cardiac malformations
3. Histopathology: disorganization of chondrocytes in the physeal growth zone of the long bones (Sergi et al. 2001) and vertebrae in the prenatal period (Qureshi et al. 1993) and retardation of physeal growth zones in the childhood
4. Mutation analysis

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: 25%
   2. Patient's offspring: not increased unless the spouse is a carrier
2. Prenatal diagnosis: feasible as early as the first trimester
   1. Fetoscopy (Bui et al. 1984)
   2. Ultrasonography (Horigome et al. 1997; Guschmann et al. 1999; Tongsong and Chanprapaph 2000; Arya et al. 2001; Dugoff et al. 2001; Baujat and Le Merrer 2007)
      1. Increased nuchal translucency thickness
      2. A narrow chest
      3. Postaxial polydactyly
      4. Short limbs, especially middle and distal segments
      5. Cardiac anomalies such as a single atrium
   3. Molecular genetic testing
      1. Using linked microsatellite markers flanking the *EVC* locus (Torrente et al. 1998; Arya et al. 2001)
      2. Mutation analysis of *EVC1* and *EVC2* genes (www.genetests.org)
      3. Sequencing the EVC and EVC2 genes from DNA extracted from fresh fetal tissue identified p.W215X (inherited from the mother) and P.R677X mutation (inherited from the father) (Peraita-Ezcurra et al. 2012)
   4. Array CGH analysis (D'Ambrosio et al. 2015)
      1. Allows genome analysis with a resolution of <1 Mb, while conventional cytogenetic examination allows for a 5–10 Mb resolution.
      2. Currently, considered to be the best method to detect genomic imbalances in particular submicroscopic rearrangements, but it is not designed to

detect point mutations responsible for monogenic disorders.
3. Array CGH (Agilent 60 K)mon non-cultured amniocytes revealed an 800 kb deletion on 4p16.2 (4979855–5747102) (hg19/GRCh37), including complete deletion of EVC2 gene and partial deletion of EVC gene.

3. Management
   1. Dental cares (Hattab et al. 1998; Cahuana et al. 2004)
      1. Childhood.
         1. To prevent caries by dietary counseling, plaque control, and oral hygiene instruction
         2. Crown or composite buildups for microdonts
         3. Partial dentures to maintain space and improve mastication, esthetics, and speech because of congenitally missing teeth
         4. Orthodontic treatment
      2. Adulthood requires implants and prosthetic rehabilitation to replace congenitally missing teeth.
   2. Cardiac surgery to correct cardiac anomalies
   3. Urologic management for genitourinary anomalies
   4. Orthopedic cares
      1. Polydactyly excision
      2. Surgery for genu valgum

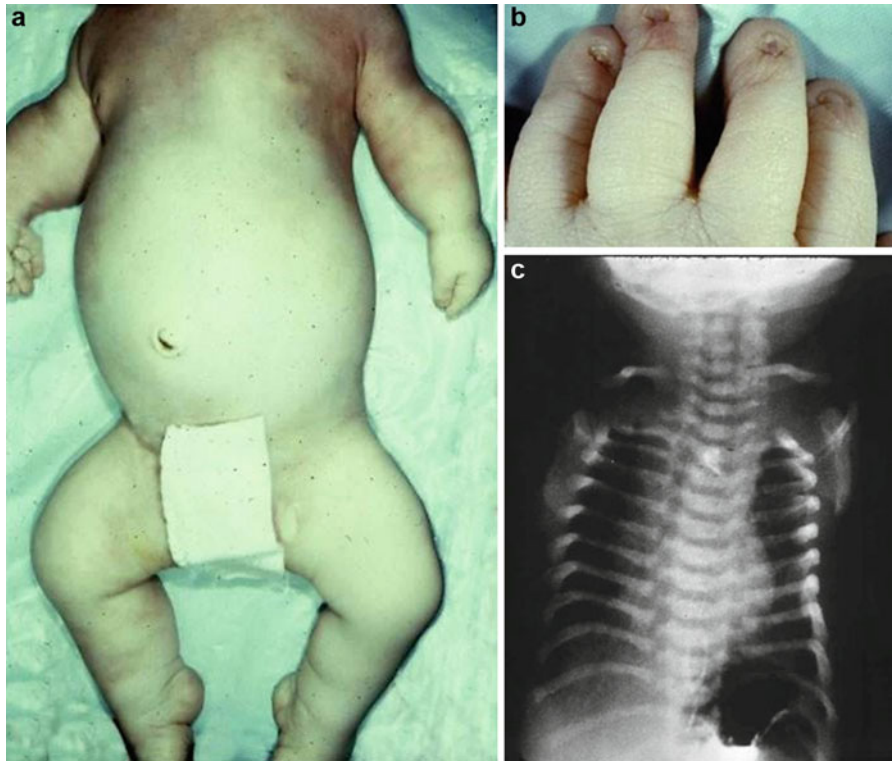

Fig. 1 (**a**–**c**) A neonate with small chest and short extremities. The fingernails are small and deformed. The baby had six fingers on each hand. Radiograph of the chest shows short ribs but the vertebral bodies are normal

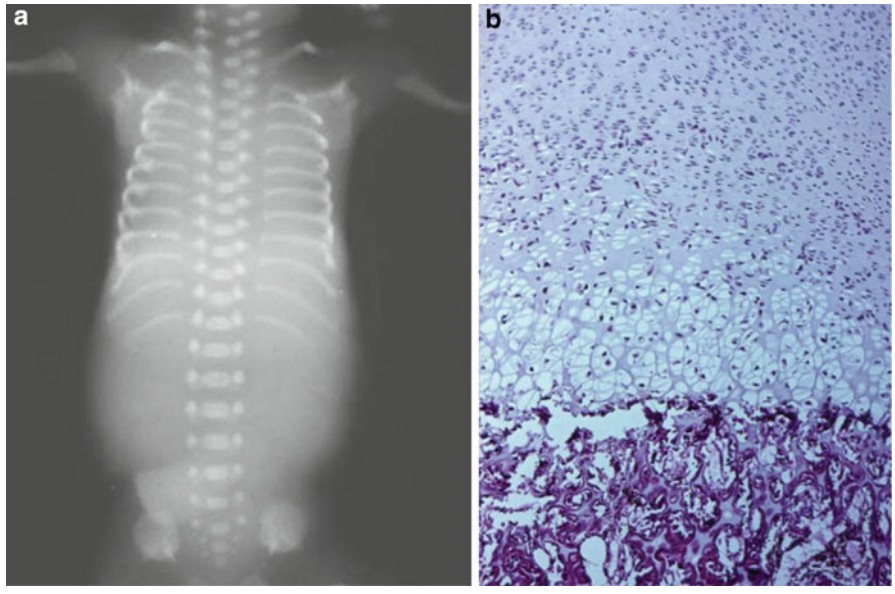

Fig. 2 (**a**, **b**) Radiograph of a fetus with Ellis-van Creveld syndrome showing short ribs and vertically shortened ilia. The vertebral bodies are unremarkable. Photomicrograph of femoral physeal growth zone shows disorganization of chondrocytes. The physeal growth zone of vertebrae showed better columnization

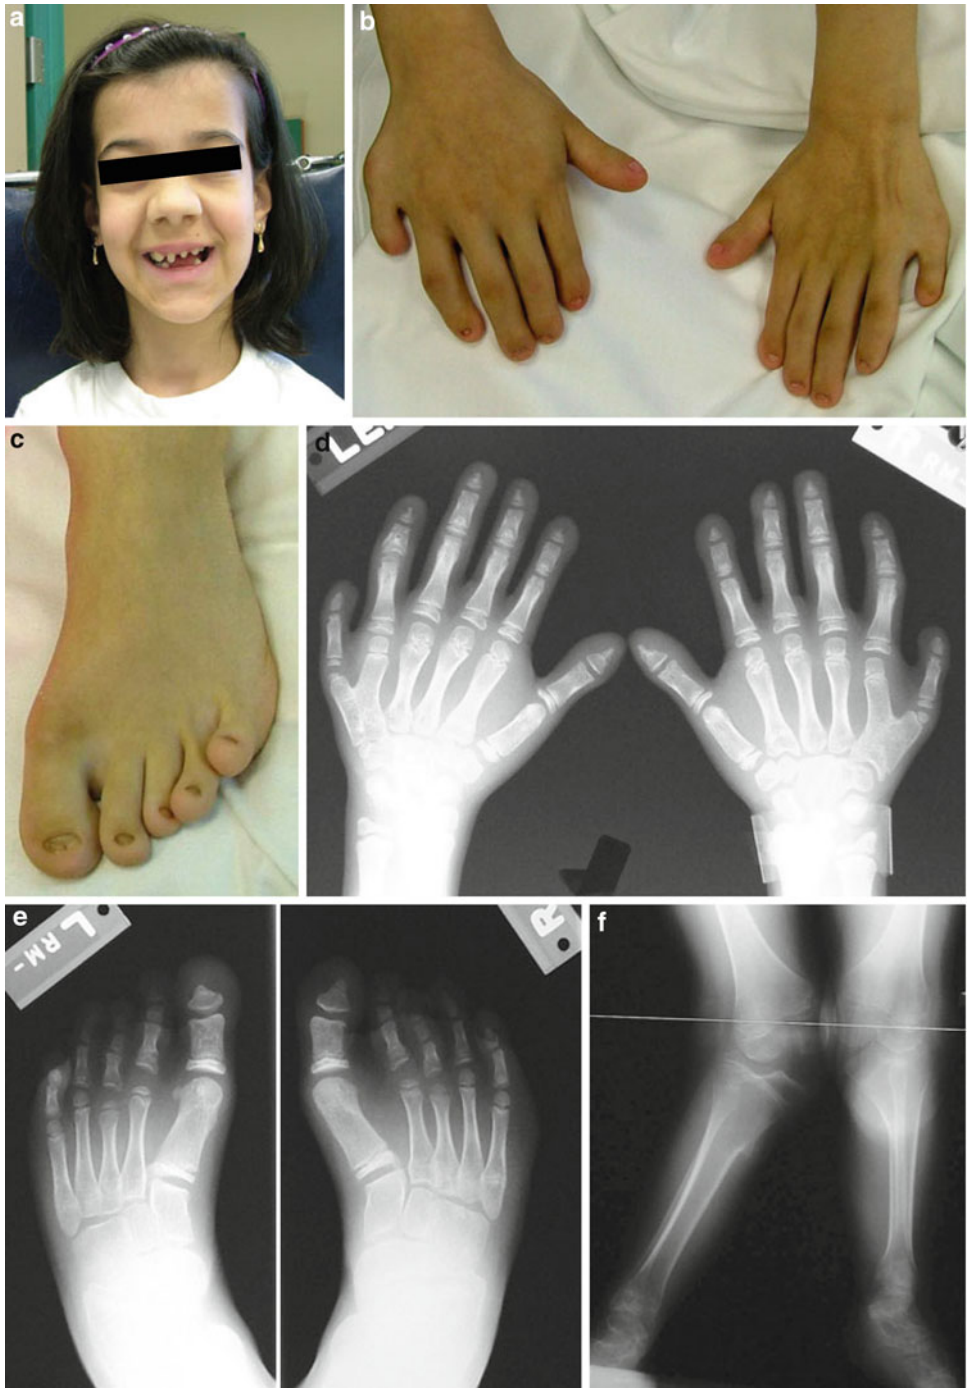

Fig. 3 (**a**–**f**) A 10-year-old Lebanese girl, a product of a consanguineous parents, with Ellis-van Creveld syndrome showing oligodontia and malformed teeth, severe nail hypoplasia of the hands and feet, and broad hands with bilateral postaxial polydactyly. Radiographs show polydactyly, fusion of metacarpals and carpal centers, cone epiphyses of the middle and distal phalanges, and genu valgum

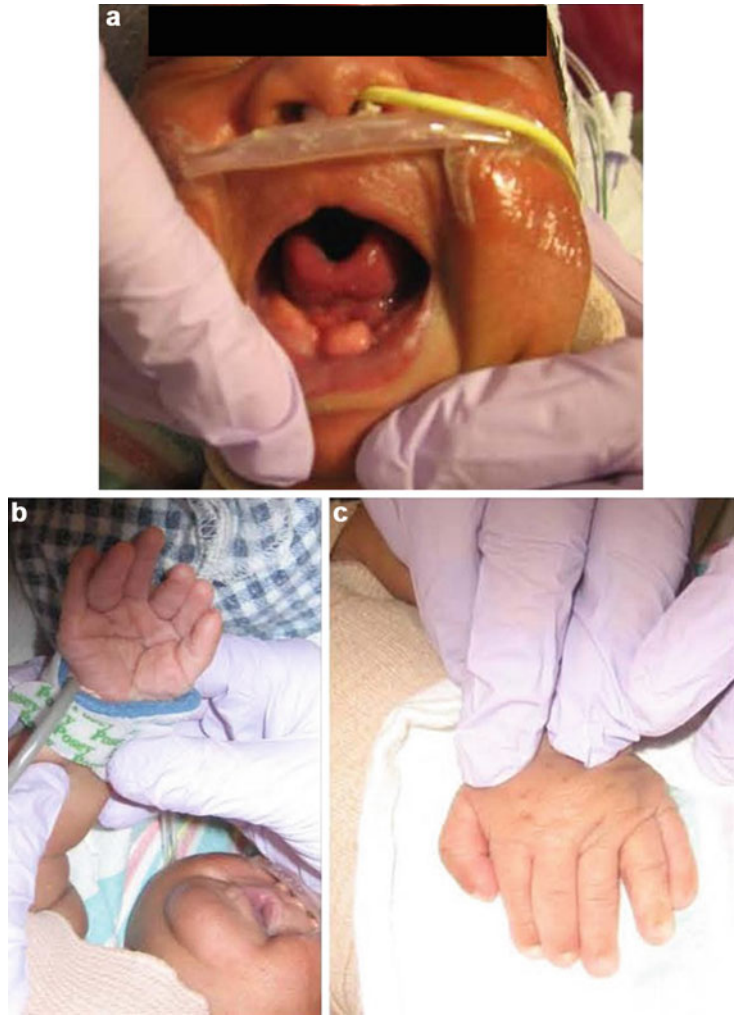

Fig. 4 (**a**–**c**) A 2-day-old male infant with abnormal fetal ultrasound (our OB) showing short limbs and a complex heart defect with a common atrium and AV canal. The infant showed short stature, short extremities, a long narrow chest, some tethering of the internal upper lip to the gingival margin, oral frenula causing clefting of the upper and lower alveolar ridges, and natal teeth on the upper and lower gingiva (**a**). The infant has postaxial polydactyly on both hands, hypoplastic nails on both fingers (**c**) and toes, and distal shortening of the digits of both hands and feet. Cranial and renal ultrasounds were normal. Postnatal echocardiogram showed situs solitus with levocardia, bilateral superior vena cava draining into a common atrium, an AV canal defect, and right ventricular hypertrophy and dilatation. EVC and EVC2 gene analysis showed a homozygous IVS13-9_c.1900del23 in the EVC gene. This 23 nucleotide deletion spans an intron/exon boundary and will result in aberrant mRNA processing. This exact change has been previously reported as a homozygous mutation in a patient with Ellis-van Creveld syndrome (Sund et al. 2009) (Courtesy of Dr. Susonne Ursin)

Fig. 5 (**a**–**c**) The radiologic features included a long narrow thorax with short ribs, acetabulum with spurs medially and laterally and narrow sacrosciatic notches, distal humeri with bony spurs, and small mid- and distal phalanges and absent terminal phalanges of all toes and six digits of the hands

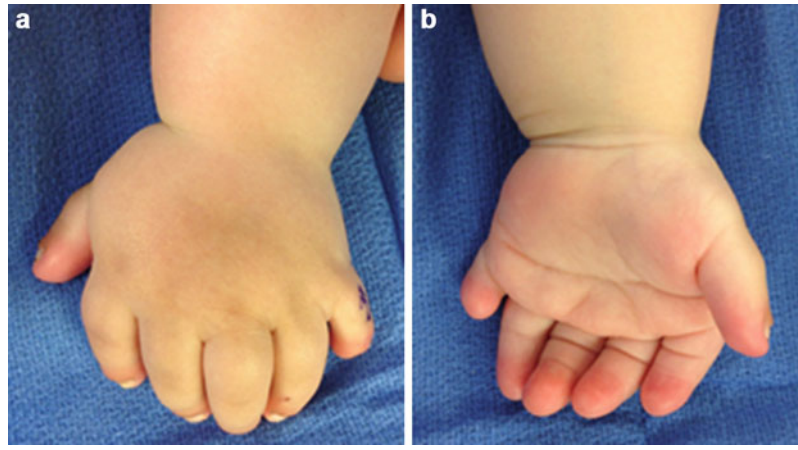

Fig. 6 (**a**, **b**) An 18-month-old boy was evaluated for bilateral postaxial polydactyly of both hands and Ellis-van Creveld syndrome. The boy was born with a birth weight of 3550 g and Apgar scores of 8 and 9 at 1 and 5 min, respectively. He was delivered at 41 weeks via C-section due to breech presentation. He was admitted to NICU for evaluation of atrial septal defect and respiratory distress and pulmonary hypertension. He lives with his parents in the Amish community. Family history revealed that the father's cousin has Ellis-van Creveld syndrome. He was short for his age with a slightly large head and mesomelic shortening of his lower and upper extremities. He had short and plump hands with bilateral postaxial polydactyly, type A (**a**, **b**). The toenails appeared to be hypoplastic (Contributed by Dr. Grace Guo)

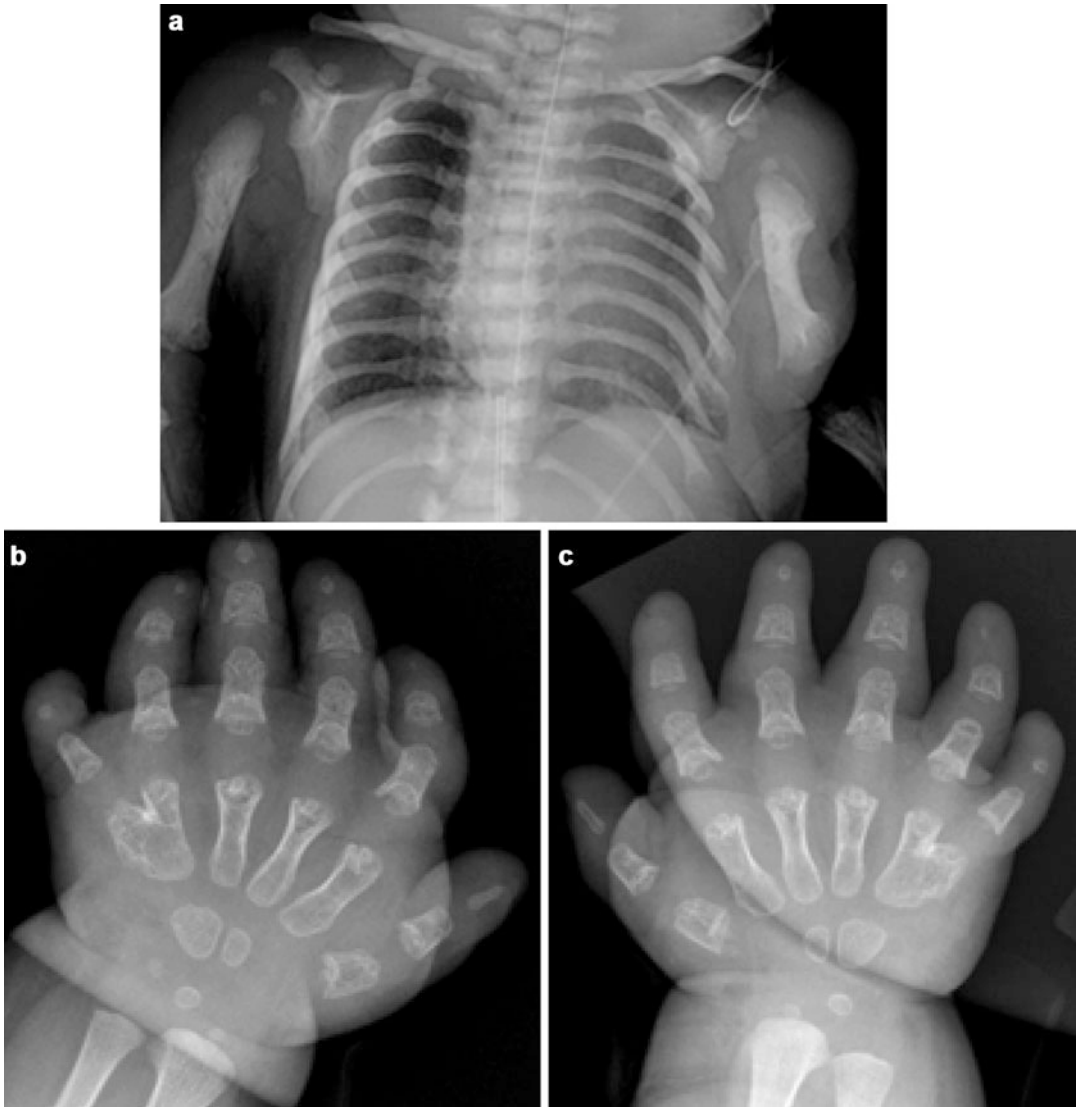

Fig. 7 (**a**–**c**) Chest radiography at 3 weeks age (**a**) showed a small rib cage with short ribs and small scapulae bilaterally. The humeri were hypoplastic and deformed. Radiography of hands showed six rays bilaterally. The phalanges were short and thickened with irregular metaphyses. Distal phalanges were hypoplastic. The fifth and sixth metacarpals of both hands were fused proximally. The patient's clinical and radiographic features were classic for Ellis-van Creveld syndrome (Contributed by Dr. Grace Guo)

Emanuel Syndrome

Contents

Emanuel syndrome (ES) is an unbalanced translocation syndrome that usually arises through a 3:1 meiosis I malsegregation during gametogenesis in a balanced translocation phenotypically normal carrier (Shaikh et al. 1999). ES is a rare inherited chromosomal abnormality syndrome with over 100 cases reported (Fraccaro et al. 1980; Zackai and Emanuel 1980; Lin et al. 1986; Choudhary et al. 2013).

Synonyms and Related Disorders

Derivative 11;22 syndrome; Derivative 22 syndrome; Partial trisomy 11;22; Supernumerary der (22)t(11;22) syndrome

Genetics/Basic Defects

1. Etiology, caused by chromosome imbalance consisting of either of the following (Emanuel et al. 2015):
    1. A derivative chromosome 22 [der(22)] as a supernumerary chromosome with the following karyotype:
        1. 47,XX,+der(22)t(11;22)(q23;q11) in females
        2. 47,XY,+der(22)t(11;22)(q23;q11) in males
    2. Rarely, a balanced (11;22) translocation as well as the supernumerary derivative chromosome
2. The supernumerary der(22) chromosome is easily identified by routine G-band analysis at the 500–550 band level.

Clinical Features

1. Affected children: usually identified in the newborn period as the offspring of a balanced (11;22) translocation carrier
2. A distinctive phenotype (Fraccaro et al. 1980; Zackai and Emanuel 1980; Lin et al. 1986; Hou 2013; Carter et al. 2009; Zaki et al. 2012; Choudhary et al. 2013; Emanuel et al. 2015):
    1. Growth and development
        1. Pre- and postnatal growth retardation
        2. Failure to thrive

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_283

3. Severe intellectual disability
4. Delayed speech and language development (more commonly)

2. Craniofacial features
   1. Microbrachycephaly
   2. Prominent forehead
   3. Downslanting palpebral fissures
   4. Broad and flat nasal bridge
   5. Long pronounced philtrum
   6. Abnormal auricles
   7. Preauricular pits/or tags (76%)
   8. Cleft or high-arched palate (50%)
   9. Micrognathia (60%)
   10. Angular mouth pits
   11. Bifid uvula
   12. Deafness
   13. Otitis media
3. CNS
   1. Microcephaly most commonly present
   2. Seizures
4. Congenital heart defects (60%)
   1. Atrial septal defect
   2. Ventricular septal defect
   3. Tetralogy of Fallot
   4. Patent ductus arteriosus
5. Gastrointestinal
   1. Diaphragmatic hernia
   2. Anal atresia
   3. Inguinal hernias
   4. Biliary atresia
   5. Micropenis (64%)
   6. Cryptorchidism (46%)
6. Renal: kidney abnormalities (36%)
7. Musculoskeletal
   1. Most commonly central hypotonia
   2. Congenital hip dislocation
   3. Arachnodactyly
   4. Club foot and joint
   5. Syndactyly of the toes
   6. Delayed bone age
   7. Hyperextensibility of joints
8. Immunological: congenital immunological deficiency

3. Mortality and survival:
   1. High mortality rate in the first months of life due to life-threatening congenital malformations.
   2. With improved palliative care, survival chances improve and survival into adulthood has been well documented (Emanuel et al. 2015).
4. Differential diagnosis:
   1. Fryns syndrome
   2. Smith-Lemli-Opitz syndrome (please see the chapter of "► Smith–Lemli–Opitz Syndrome")
   3. Pallister-Killian syndrome (please see the chapter of "► Pallister–Killian Syndrome")
   4. Kabuki syndrome (Kapoor 2015) (please see the chapter of "► Kabuki Syndrome")
   5. Wolf-Hirschhorn syndrome (please see the chapter of "► Wolf–Hirschhorn Syndrome")
   6. Other chromosomal abnormalities

Diagnostic Investigations

1. Chromosome analysis: to detect supernumerary der(22)
   1. Supernumerary marker chromosomes (SMCs) are frequent findings in cytogenetic studies, with 13% of SMCs derived from chromosome 22 (Crolla et al. 2005).
   2. This chromosome imbalance consists of either a derivative chromosome 22 [der(22)] as a supernumerary chromosome with the following karyotype: 47,XX,+der(22)t(11;22)(q23;q11) in females or 47,XY,+der(22)t(11;22)(q23;q11) in males rarely (Carter et al. 2009).
2. FISH testing: to detect duplication of 22q11 and 11q23 (Emanuel et al. 2015)
   1. Using probes N25 and TUPLE1 mapping to 22q11.2 and using 11q subtelomeric probe.
   2. In the rare instance in which one of the parents is not a balanced translocation carrier, commercially available FISH probes for the 22q11.2 deletion and for the telomere of 11q can identify the supernumerary chromosome in the karyotype as being derived from chromosomes 11 and 22.
3. Chromosome microarray analysis (array CGH): to detect copy number variations of chromosome 11 and chromosome 22

4. Deletion/duplication analysis: to detect duplication 22q11 (Emanuel et al. 2015)
    1. Testing that identifies exonic or whole-gene deletions/duplications not detectable by sequence analysis of the coding and flanking intronic regions of genomic DNA.
    2. Included in the variety of methods that may be used are quantitative PCR, long-range PCR, multiplex ligation-dependent probe amplification (MLPA), and chromosomal microarray (CMA) that includes this gene/chromosome segment.

Genetic Counseling

1. Recurrence risk (Emanuel et al. 2015)
    1. In more than 99% of cases, one of the parents of a proband with Emanuel syndrome is a balanced carrier of a t(11;22)(q23;q11.2) and is phenotypically normal.
    2. In most cases, a carrier parent has inherited the t(11;22) from one of his or her parents.
    3. When one of the parents of a proband is a carrier of the balanced t(11;22), possible outcomes of future pregnancies of the parents include:
        1. Normal chromosomes
        2. Supernumerary der(22) syndrome
        3. Balanced t(11;22) carrier
        4. Spontaneous abortion as a result of supernumerary der(22) or another meiotic malsegregant
    4. Risks vary depending on whether the mother or father of a proband is the balanced translocation carrier (Fraccaro et al. 1980; Zackai and Emanuel 1980):
        1. The risk of having a live-born infant with supernumerary der(22) is higher if the mother carries a balanced t(11;22) than if the father carries a balanced t(11;22).
        2. The overall risk of having a live-born infant with supernumerary der(22) when a parent carries a balanced t(11;22) is estimated to be between 1.8% and 5.6%.
        3. The overall risk of having a spontaneous abortion with supernumerary der(22) or another meiotic malsegregant when a parent carries a balanced t(11;22) is estimated to be between 23% and 37%.
    5. Patient's offspring: unlike to reproduce due to severe cognitive impairment.
2. Prenatal diagnosis
    1. Tertiary monosomy resulting from the 3:1 segregation is compatible with embryonic survival into the first trimester (Jobanputra et al. 2005).
    2. Prenatal diagnosis for pregnancies at increased risk is possible if the chromosome abnormality has been confirmed in the family (Emanuel et al. 2015).
3. Preimplantation genetic diagnosis: successfully performed on several occasions (Van Assche et al. 1999), may be an option for some families at increased risk
4. Management (Emanuel et al. 2015)
    1. Treatment of manifestations
        1. Gastroesophageal reflux, anal atresia (or stenosis), inguinal hernias, cardiac defects, cleft palate, hip dysplasia, other skeletal complications, hearing loss, cryptorchidism and/or micropenis, refractive errors, and strabismus or other ophthalmologic issues
        2. Physical, occupational, and speech therapies
    2. Prevention of secondary complications: attention to the airway during sedation and/or operative procedures in an institution with pediatric anesthesiologists
    3. Surveillance: regular developmental assessments and periodic reevaluation by a medical geneticist
    4. Female carriers of a balanced t(11;22)
        1. Possible association for premenopausal breast cancer (Lindblom et al. 1994; Jobanputra et al. 2005).
        2. Other studies not confirming such association (Kurahashi et al. 2000; Carter et al. 2009).
        3. Enhanced breast cancer surveillance may be warranted in female carriers of

a balanced t(11;22) only if there is a family history of breast cancer (Wieland et al. 2006; Emanuel et al. 2015).

Fig. 1 (**a**–**c**) This 20-month-old Caucasian female (**a**, **b**) was evaluated for multiple congenital anomalies, consisting of developmental delay, microcephaly, prominent forehead, depressed nasal bridge, large ears, cleft palate, atrial septal defect, mitral valve defect, kyphosis, and left hip subluxation (**c**). Chromosome microarray analysis showed a terminal 18.3 megabase duplication from 11q23.3 to 11q25 and a pericentromeric 3.4 megabase duplication from 22q11.1 to 22q11.21. Metaphase FISH studies using probes within the duplicated interval (RP11-1125D12 and TUPLE1) demonstrated that both of the duplicated regions are present on a supernumerary marker chromosome (performed at Mayo Clinic laboratories). This marker chromosome is likely a derivative chromosome 22 from an 11;22 translocation (47,XX,t(11;22)(q23;q11.2)), which is associated with Emanuel syndrome (reviewed by Emanuel et al. (2015)) (Courtesy of Drs. David Yates, Jennifer Woerner, and Ghali Ghali)

Enchondromatosis

Contents

Enchondromas are benign cartilaginous growth in the intramedullary region of the bones, predominantly affecting the metaphyses of long bones (Silve and Jüppner 2006). When two or more bones are affected with enchondromas, the condition is called multiple enchondromatosis. Maffucci first described the syndrome of multiple enchondromas and subcutaneous hemangiomas in 1881. Eighteen years previously, Ollier (1898) described multiple enchondromatosis. The prevalence of enchondromatosis is estimated to be 1 in 100,000 (Silve and Jüppner 2006). Enchondromatosis encompasses several different subtypes of which Ollier disease and Maffucci syndrome are the most common (Superti-Furga et al. 2012; Cerny et al. 2013).

Synonyms and Related Disorders

Dysspondyloenchondromatosis; Genochondromatosis; Maffucci syndrome (enchondromatosis with soft tissue hemangiomas); Metachondromatosis; Metaphyseal chondromatosis with 2-hydroxyglutaric aciduria; Multiple enchondromatosis; Ollier disease/syndrome (enchondromatosis); Spondyloenchondrodysplasia

Genetics/Basic Defects

1. Inheritance (Superti-Furga et al. 2012; Amyere et al. 2014)
    1. Ollier disease (OD)
        1. Autosomal dominant or sporadic
        2. Caused by somatic or germ line *PTHR1* (3p22p21.1) mutations (Hopyan et al. 2002; Couvineau et al. 2008)
        3. Also caused by somatic mutations in *IDH1* and *IDH2* (Amary et al. 2011; Pansuriya et al. 2011)
    2. Maffucci syndrome (MS)
        1. Sporadic.
        2. Caused by somatic *IDH1 and IDH2* mutations (Amary et al. 2011; Pansuriya et al. 2011).
        3. No *PTHR1* mutations have been detected in MS (Amyere et al. 2014).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_80

3. Metachondromatosis
    1. Autosomal dominant.
    2. Caused by loss of function mutations in the *PTPN11* gene (12q24.1) (Sobreira et al. 2010; Bowen et al. 2011).
    3. The mutations are heterozygous in the germ line but switch to homozygosity within the tumor suppressor gene.
4. Spondyloenchondrodysplasia: caused by recessive mutations in *ACP5* (Lausch et al. 2011; Girschick et al. 2015)
    1. Autosomal recessive
    2. Gene: TRAP (19p13) (Briggs et al. 2011)
5. Enchondromatosis with irregular vertebral lesions: sporadic (Spranger et al. 1978)
6. Generalized enchondromatosis
    1. Sporadic
    2. Gene: dupl PTHLH (12p11p23) (Spranger et al. 1978)
7. Dysspondyloenchondromatosis: a variant of "type 2 collagenopathy"

2. Basic Defect and Pathogenesis
    1. Enchondromas believed to be a part of a generalized mesodermal dysplasia.
    2. Appearance of enchondromas close to the epiphysis can severely affect the progressive development of a bone, resulting in distortion in the shape and length of the bone.
3. Proposed Origin of Enchondroma Formation
    1. Endochondral bone ossification: a highly regulated process, requiring the progression of undifferentiated mesenchymal cells into hypertrophic chondrocytes and the subsequent replacement of a cartilaginous matrix by mineralized bone.
    2. Development of enchondromas in the metaphysis of long tubular bones in close proximity to the growth plate.
    3. Consequently, enchondromas resulted from abnormalities in signaling pathways controlling the proliferation and differentiation of chondrocytes, leading to the development of intraosseous cartilaginous foci.
    4. Osteochondromatosis possibly results from abnormal regulation of proliferation and terminal differentiation of chondrocytes in the adjoining growth plate, since enchondromas are usually present in close proximity to, or in continuity with, growth-plate cartilage (Hopyan et al. 2002).
        1. Parathyroid hormone-related protein (PTHRP) delays the hypertrophic differentiation of proliferating chondrocytes.
        2. Indian hedgehog (IHH) promotes chondrocytes proliferation.
        3. Identification of a mutant PTH/PTHRP type I receptor (PTHR1) in human enchondromatosis that signals abnormally in vitro and causes enchondroma-like lesions in transgenic mice.
            1. The mutant receptor constitutively activates hedgehog signaling.
            2. Excessive hedgehog signaling is sufficient to cause formation of enchondroma-like lesions.
    5. Loss of chromosomes (chromosomes 6 and 3), deletions, amplifications, gains, and genomic copy number neutral structural changes of subtle genes (Hopyan et al. 2002; Rozeman et al. 2006; Kumar et al. 2015).
    6. Hereditary nature of the disorder reported:
        1. Generalized enchondromatosis observed in a son of the father who presented with mild skeletal dysplasia but without evidence of enchondromas.
        2. A heterozygous mutation (R150C) in the PTH/PTHrP receptor (*PTHR1* gene) was inherited from the father in one of these cases (Hopyan et al. 2002).
        3. Heterozygous mutations in PTHR1 that impair receptor function participate in the pathogenesis of Ollier disease in some patients (Couvineau et al. 2008).

Clinical Features

1. Ollier syndrome (Spranger type I)
    1. Nonhereditary cartilage dysplasia of bone
        1. A prototype of enchondromatosis.
        2. Enchondromas appear as radiolucent defects that originate in the metaphyses, grow slowly, and can

attain considerable expansion while remaining centered within the bone of origin (as contrasted to exostoses and metachondromatosis).
3. A form characterized by enchondromas located mainly at the extremities (hand).
4. Consisting of multiple, asymmetrically distributed, intraosseous cartilaginous foci and subperiosteal deposition of cartilage, either exclusively or predominantly involving one side of the body.
5. Can be symmetric lesions (Khoo et al. 2008; Choh and Choh 2009).
6. Multiple enchondromas as described in Maffucci syndrome.
7. Enchondromas in infancy and early childhood:
   1. Quite innocuous
   2. Appearing as small radiolucent defects
8. Characteristic lesions develop as the skeletal growth progresses:
   1. Localized asymmetric impairment of growth
   2. Asymmetric shortening and bowing of extremity parts (especially forearm and/or lower leg)
9. No increase in size of the lesions after the cessation of the normal growth.

2. Taut-elastic skin over hyaline cartilage distensions
3. Marked asymmetry of swellings with local growth deficiency
4. Firm, indolent, rounded distensions continuous with bone on one or more fingers or toes
5. Kyphoscoliosis
6. Joint impairment
7. Spontaneous fractures in affected area (Shapiro 1982)
8. Tumors associated with Ollier disease (Kumar et al. 2015):
   1. Rare malignant (chondrosarcoma) transformation (Liu et al 1987; Schwartz et al. 1987; Bovée et al. 2000)
   2. Osteosarcoma (Liu et al. 1987; Braddock and Hadlow 1966)
   3. Central nervous system tumors:
      1. Chondrosarcoma-like parasellar chondrosarcoma
      2. Glioma, glioblastoma multiforme (Ranger and Szymczak 2009)
      3. Astrocytoma (Schwartz et al. 1987)
      4. High-grade anaplastic astrocytoma (Braddock and Hadlow 1966; Rawlings et al. 1987)
      5. Oligoastrocytoma (Filiz 2006)
      6. Oligodendroglioma (Chang and Prados 1994)
   4. Ovarian tumors
      1. Juvenile granulosa cell tumor (Tamimi and Bolen 1984; Vaz and Turner 1986; Gell et al. 1998; Leyva-Carmona et al. 2009; Rietveld et al. 2009)
      2. Sertoli-Leydig cell tumor (Weyl-Ben Arush and Oslander 1991)
   5. Leukemia
      1. Chronic myeloid leukemia (Au et al. 2004)
      2. Acute myelogenous leukemia (White et al. 2008)
   6. Breast adenoma (Weyl-Ben Arush and Oslander 1991)
   7. Lung tumor: non-small-cell lung cancer (Sendur et al. 2010)
   8. Fibromatosis (deep): extra-abdominal desmoid tumor (Al-Ismail et al. 2002)
9. Major orthopedic manifestations (Fang et al. 2009)
   1. Asymmetrical limb shortening and deformity
   2. Swelling and deformity of the hands or feet
   3. Pathological fracture
10. Prognosis: difficult to assess
    1. In general, cases with early onset have more severe prognosis.
    2. Localized cartilaginous changes, especially in a very young child, may induce major shortening of a

lower extremity leading to limb asymmetry; in contrast, patient with numerous lesions may have a better prognosis.
3. Early development of enchondromas in the phalanges may lead to major finger deformities.
4. Neural compressions: less frequently observed than in hereditary multiple exostosis.
5. Malignant transformation of enchondromas into chondrosarcomas usually occurs in young adults. The estimated incidence of malignant transformation is 5–50% of the cases.
6. Association of Ollier disease with other tumors, such as ovarian juvenile granulosa tumor, has been reported (Tamimi and Bolen 1984; Vaz and Turner 1986).

2. Maffucci syndrome (Spranger type II) (Lewis and Ketcham 1973; Chen and Harrison 1978; Gutman et al. 1978; Kaplan et al. 1993; Superti-Furga et al. 2012)
   1. Age of onset
      1. Bony or soft tissue abnormalities at birth in 27% of cases
      2. Average age of onset: 4 years (ranging from birth to 30 years of age)
   2. Skeletal lesions: multiple enchondromas
      1. Can occur anywhere in the body
      2. Most commonly in the hands, followed by tibia/fibula, foot, femur, humerus, radius/ulna, ribs, pelvis, scapula, and head
      3. Common long bone involvement
      4. Kyphoscoliosis caused by direct involvement of the spine
      5. Progressive skeletal deformities:
         1. Enlarged fingers.
         2. Bowed legs.
         3. Asymmetric limb shortening.
         4. Pathological fractures.
      6. High incidence (23%) of malignancies (Ben-Itzhak et al. 1988), especially chondrosarcomas (15%) which lead to greater tissue destruction.
      7. Vascular malignancies may occur occasionally.
   3. Vascular lesions: cutaneous (Suringa and Ackerman 1970), subcutaneous, and sometimes visceral hemangiomas
      1. Occur anywhere in the body.
      2. Most commonly in the hands, followed by foot, arm, leg, trunk, and head/neck (Lowell and Mathog 1979).
      3. Hemangiomas also reported in the leptomeninges, eyes (Johnson et al 1990) pharynx, tongue, trachea, and intestines.
      4. Appear as blue subcutaneous nodules that sometimes can be emptied by pressure or by elevating the lesions above the level of the heart.
      5. Unilateral or bilateral lesions.
      6. Phlebitis often results from thrombi forming within the hemangiomatous vessels.
      7. Characteristic calcified thrombi.
      8. Histologic types of hemangiomas:
         1. Venous: most often
         2. Capillary
         3. Mixed venous/capillary type
      9. Lymphangiomatosis, a rare aspect of the mesodermal dysplasia in Maffucci syndrome (Loewinger et al. 1977).
      10. Spindle cell hemangiomatosis as a component of Maffucci syndrome (Fernández-Aguilar et al. 2004).
   4. Neoplastic changes
      1. Overall malignancy rate: 37% (Kaplan et al. 1993), 52–57.1% (Herget et al. 2014)
      2. Chondrosarcoma (15%) (Sun et al. 1985; Albregts and Rapini 1995; Abdelmalek and Stanko 2008)
         1. The neoplasm most commonly associated with Maffucci syndrome (Schwartz et al. 1987).
         2. Average age of onset is 40 years (ranging from 13 to 69 years of age).
         3. The most common sites: pelvis, shoulder girdle, distal femur, and proximal tibia (Goto et al. 2003).
      3. Malignant astrocytoma
      4. Ovarian tumors
      5. Pancreatic tumors

6. Hemangiosarcoma
7. Lymphangiosarcoma
8. Other neoplasms

5. Normal intelligence
6. Short stature
7. Minimally affected individuals:
    1. No major functional impairment
    2. Unrestricted employment
    3. Moderate cosmetic deformity only
    4. Reconstructive or corrective surgery, limited to one or two major procedures with acceptable final results
    5. Ablative surgery, restricted to amputation of a finger or a toe
8. Moderately affected individuals:
    1. Significant functional impairment
    2. Self-supporting and able to work most of the time
    3. Ambulatory
    4. Reconstructive surgery or amputation and prosthesis helpful
    5. Ablative surgery restricted to potentially functional (transfemoral or transhumeral) amputation
9. Severely affected individuals:
    1. Severe functional impairment
    2. Inability to work
    3. Chronic invalidism
    4. No surgical rehabilitation possible
    5. Forequarter or hindquarter amputation required

3. Differential diagnosis: other types of enchondromatosis (Spranger et al. 1978; Kozlowski and Masel 2002; Bovée 2008; Ghatan et al. 2010; Pansuriya et al. 2010; Superti-Furga et al. 2012)
    1. Metachondromatosis (Spranger type III)
        1. An autosomal dominant disorder.
        2. Caused by loss of function mutations in the PTPN11 gene (Sobreira et al. 2010; Bowen et al. 2011).
        3. A rare disorder exhibiting synchronous, both multiple osteochondromas and enchondromas in children, with prominent calcification of short tubular bones.
        4. Painless swelling of the hands and feet.
        5. Lesions associated with metachondromatosis may cause a variety of complications due to mass effects; however, they are often asymptomatic, cause cosmetic concern, and, importantly, most regress spontaneously (Fisher et al. 2013).
        6. Normal intelligence.
        7. Short stature.
        8. Radiographic features intermediate between exostosis and enchondromatosis.
    2. Spondyloenchondrodysplasia (Spranger type IV): irregularly distributed discrete enchondromas of long tubular bones, generalized severe platyspondyly, and mild or no involvement of hands and feet (Schorr et al. 1976; Menger et al. 1989; Halal and Azouz 1991)
    3. Enchondromatosis with irregular vertebral lesions (Spranger type V): multiple enchondromas of tubular and flat bones, generalized irregular dysplasia of vertebral bodies, and mild or no involvement of hands or feet
    4. Cheirospondyloenchondromatosis, formerly generalized enchondromatosis (Spranger type VI): characterized by multiple enchondromas, severe hand and foot involvement, mild platyspondyly, and erosions of iliac crests
    5. Dysspondyloenchondromatosis (Springer type VII) (Freisinger et al. 1993; Kozlowski et al. 1994)
        1. Characterized by multiple appendicular enchondromas with hemivertebrae, dwarfism, and limb-length discrepancy
        2. Genetic heterogeneity
            1. Caused by *COL2A1* mutations (Nakane et al. 2011)
            2. Without *COL2A1* mutation (Tran Mau-Them et al. 2014)
    6. Metaphyseal chondromatosis with 2-hydroxyglutaric aciduria (Talkhani et al. 2000; Honey et al. 2003; Bayar et al. 2005; Vissers et al. 2011; Choo et al. 2012)

7. Genochondromatosis I (Le Merrer et al. 1991)
   1. Enchondromatosis with celery type of metaphyseal lesions
   2. Characteristic thickening of the clavicles
   3. Regressive without any complications
8. Genochondromatosis II (Kozlowski and Jarret 1992)
   1. Enchondromatosis with celery type of metaphyseal lesions
   2. Moderately severe hand involvement with long dense streaks and more irregular radiolucent channels
   3. Regress without any complications
9. A new variant of generalized enchondromatosis (Ollier syndrome) (Ghatan et al. 2010)
   1. "Extreme" enchondromatosis appears to be the rarest of all of the variants.
   2. Slow progressive growth of the cartilage tumors.
   3. Develops severe bilateral extremity and spine involvement.
   4. Normal intelligence.
10. Dysplasia epiphysealis hemimelica (tarso-epiphysial aclasis) (Trevor disease) (Oestreich et al. 2002)
    1. A developmental disorder with cartilaginous overgrowth of a portion of one or more epiphyses
    2. Exostosis of epiphyseal growth centers and their equivalents that grow solely by enchondral ossification with no membranous ossification in the lesions
       1. Apophyses
       2. Carpal bones
       3. Tarsal bones
       4. Sesamoids including the patella
    3. Predominantly affects the lower extremity on one side of the body, usually restricted to either the medial (most frequent) or lateral side of the limb (hemimelica)
11. Hereditary multiple exostoses (Pannier and Legeai-Mallet 2008) (see chapter "▶ Hereditary Multiple Exostoses")
    1. An autosomal dominant disorder
    2. A genetically heterogeneous disorder associated with mutations in *EXT1* or *EXT2* genes, which are both tumor suppressor genes
    3. Clinically characterized by the development of benign tumors, multiple osteochondromas (exostoses), growing outward from the metaphyses of long bones
    4. The most important criteria to distinguish enchondromas from osteochondromas seen in hereditary multiple exostoses (radiographic distinction) (Silve and Jüppner 2006):
       1. Osteochondromas are located at the bone surface.
       2. Enchondromas are located in the center of bones.
12. Epiphyseal-metaphyseal enchondromatosis (Gabos and Bowen 1998): the lesions develop extensively within the epiphysis with direct extension across the epiphyseal growth plate into the metaphysis

Diagnostic Investigations

1. Diagnosis of Ollier disease (Silve and Jüppner 2006).
   1. Based on clinical and conventional radiological evaluations
   2. Histological analysis
      1. Limited role
      2. Mainly used if malignancy is suspected
   3. Additional studies such as scintigraphy, ultrasound, and MRI
      1. Not useful for establishing the diagnosis
      2. Indicated for the evaluation and surveillance of lesions that become symptomatic, such as pain and increase in size

2. Radiography (Kaufman 1973).
    1. Enchondromas
        1. Lesions usually arise within the medullary cavity, replacing the normal cancellous bone with the abnormal cartilage.
        2. Lytic lesions initially contain calcifications in a punctate pattern.
        3. Advanced lesions assume a ground glass appearance.
        4. Predilection for the metaphysis or diaphysis.
        5. Bone often expands but with intact cortex.
        6. Often with a scalloped border.
        7. Pathological fractures not uncommon.
        8. Multiple asymmetric enchondromas of long and flat bones (characteristic ovoid or pyramid shaped, linear translucent defects in metaphyses).
    2. Massive metaphyseal enlargement in any bones, particularly metacarpals and fingers
    3. Enchondromatosis with destruction and calcification
    4. Streaks of unossified cartilage in the metaphyses, sometimes extending into the diaphyses
    5. Madelung deformity
    6. Shortening of extremities
    7. Spinal deformity
    8. Occasional malignant degeneration
3. Major radiographic features (Fang et al. 2009).
    1. Oval/elongated radiolucent lesions, often with longitudinal striations
    2. Erosion of the cortices and subsequent calcification of the lesion producing a diffusely speckled appearance typical of enchondromas
    3. Long bones and small bones of hands and feet typically the most commonly affected sites
    4. Enchondromas almost exclusively in the metaphyseal region in long bones, possibly extending to the diaphysis
    5. Epiphysis affected at later age after closure of the growth plate
    6. Affected areas substantially enlarged and shortened cortical thinning associated with pathological fracture
4. Bone scan.
    1. Exhibiting intense and increased uptake
    2. To locate polyostotic lesions
5. CT scan.
    1. To delineate the extent of bone involvement
    2. A good diagnostic tool to demonstrate the high attenuation coefficient (classic in bone affected by fibrous dysplasia)
6. MRI (Herget et al. 2014).
    1. To delineate the extent of bone involvement
    2. Enchondromas, lobulated lesion with (Unger et al. 1988):
        1. Low to intermediate signal intensity on T1-weighted images
        2. High signal intensity on T2-weighted images
        3. High signal intensity on gradient-recalled echo images similar to articular cartilage
    3. Malignant progression of an enchondroma is evident in most cases if one of the following is present:
        1. Cortical destruction
        2. Moth-eaten or permeative osteolysis
        3. Spontaneous pathological fracture
        4. Periosteal reaction
        5. Edema surrounding the tumor
        6. Soft tissue mass
7. F-18 FDG PET-CT imaging may prove to be useful in detecting malignant transformation of enchondromas in Maffucci syndrome (Makis et al. 2010).
8. Bone scintigraphy: recommended for initial staging of chondrosarcomas (Hogendoorn et al. 2010).
9. Histopathology.
    1. Gross view of enchondromas: usually shows multiple oval-shaped or round cartilaginous nodules in osseous portions of the bone
    2. Individual nodules
        1. Limited at their periphery by woven or lamellar bone

2. Separated from each other by intertrabecular marrow spaces
3. Cartilaginous tumor matrix: usually solid with myxoid changes, manifesting as frayings of the matrix
4. Characteristics of enchondromas and chondrosarcomas
   1. Presence of a striking heterogeneity and diversity in the degree of cellularity and chondrocyte phenotype.
   2. Because of the increased cellularity, the distinction between enchondroma and grade *I* chondrosarcoma in the context of enchondromatosis is extremely difficult or even impossible; the diagnosis therefore relies on the combination of radiographic (cortical destruction, soft tissue extension), clinical, and histological criteria.
10. Fine needle aspiration cytology.
    1. Workup of soft tissue tumors
       1. An outpatient procedure
       2. Minimal risk of complications
       3. Can easily be performed from different parts of a large tumor
    2. Workup of bone tumors: comparable to cutting needle biopsy

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: not increased
   2. Patient's offspring: not increased unless in rare familial cases
2. Prenatal diagnosis: bone lesions unlikely to manifest in the prenatal period
3. Management (Flach et al. 2001)
   1. Requires no treatment in the absence of clinical problems.
   2. Relief of symptoms.
   3. Early detection of malignancies.
      1. Suspect malignancy change if skeletal or soft tissue lesions enlarge or become painful without antecedent trauma
      2. Biopsy
4. Surgery indicated in case of complications.
   1. Pathological fractures
   2. Growth defect
   3. Malignant transformation
5. Operative procedures.
   1. Corrective osteotomy
   2. Epiphysiodesis
   3. Hemiepiphysiodesis
   4. Physeal stapling
   5. Lengthening of an arm or leg (Märtson et al. 2005)
   6. Curettage and packing with bone graft material
   7. Sclerotherapy, irradiation, and surgery for the vascular lesions
6. Serial surgery for distortion of knees and unequal leg length.
7. Limb lengthening, either gradual bone grafting or callus distraction: the most common method of correcting deformities in the lower limb.
8. Amputation in suspected malignancy with severe deformity of the limb due to intraosseous cartilaginous foci.
9. Radiotherapy (Le et al. 2003): provides palliative benefit in patients with inoperable chondrosarcoma.
10. Annual surveillance of the enchondromas recommended for children and adults.
11. Periodic surveillance of the brain and abdomen for occult lesions indicated in patients who have enchondromatosis.
12. Long-term consideration to address the potential for malignant changes.
13. Interdisciplinary efforts of health-care professionals from medicine, nursing, physical and occupational therapy, recreational therapy, and social services. Long-term consideration must address the potential for malignant changes.

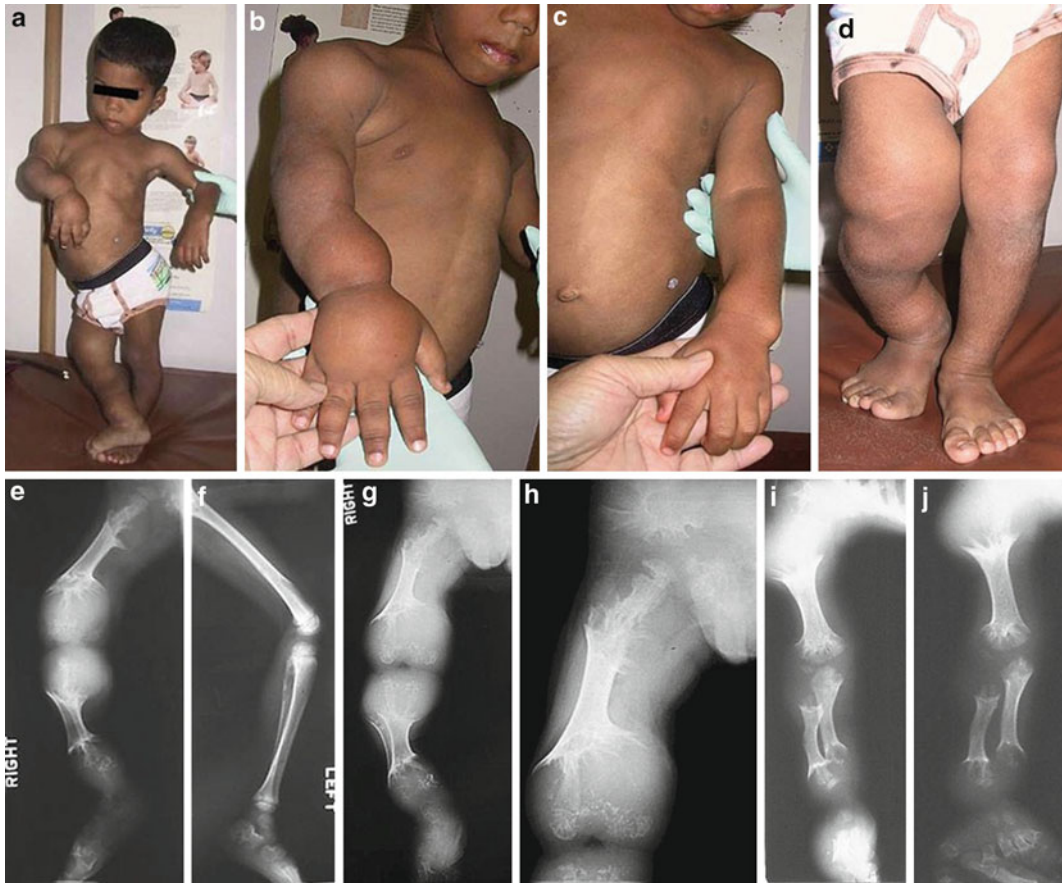

Fig. 1 (**a**–**j**) A 4-year-old boy with Ollier syndrome showing short stature, scoliosis, and severe limb deformities (**a**). The *right* limb (**b**, **d**) was affected by larger lesions with more prominent limb shortening. Marked swellings were evident on the *right* wrist and fingers. The *left* hand (**c**) showed Madelung deformity. The radiographs (**e**–**j**) showed massive metaphyseal enchondromatous lesions in the right upper and lower extremities. Streaks of radiolucency due to the abnormal cartilage extended into the diaphyses. The left femur, tibia, and fibula also showed lytic lesions

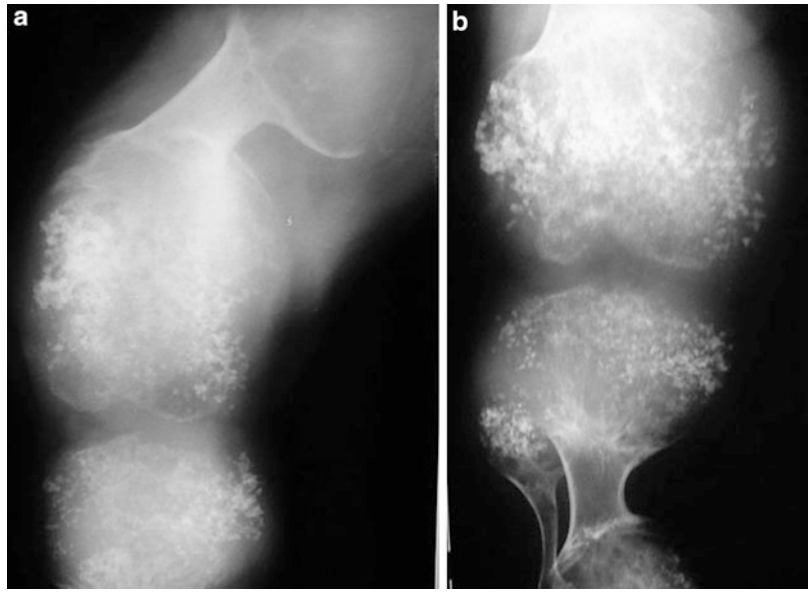

Fig. 2 (**a**, **b**) Radiographs of the right lower leg of the previous boy at 16 years of age showed large deforming enchondromas involved in the proximal and distal parts of the femur, tibia, and fibula (**a**, **b**). This case fits well to the "extreme enchondromatosis" (Ollier syndrome) described by Ghatan et al. 2010

Fig. 3 A 4-year-old boy was seen because of swelling of phalangeal joints of multiple fingers on both hands with occasional joint pain. No vascular malformation was detected. Clinical and radiographic findings are consistent with Ollier disease

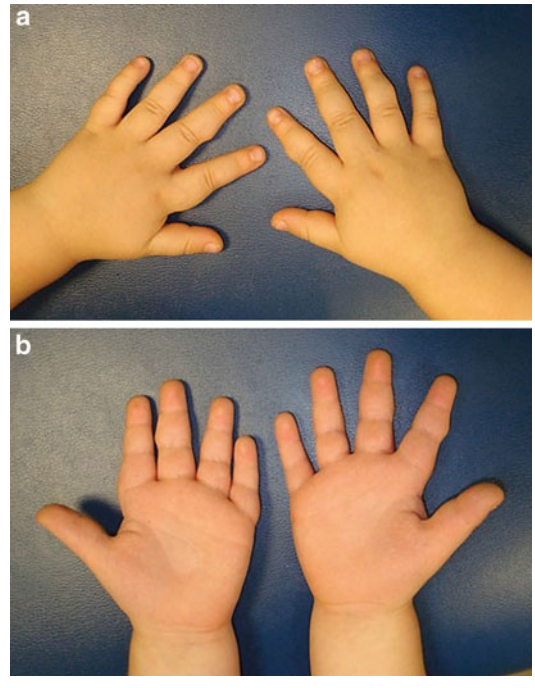

Fig. 4 (**a**, **b**) Close-up view of both hands showing multiple joint swelling on multiple fingers (**a**, **b**)

Fig. 5 (**a**–**d**) Radiographs of both forearms and hands (**a**–**d**) showed multiple enchondromas involving phalanges and metacarpals of both hands and an enchondroma involving the midshaft of the left ulna

Fig. 6 Right hand radiograph showed multiple enchondromas (multiple well-defined osteolytic lesions with endosteal scalloping, cortical thinning, and bony expansion) involving proximal metaphyses of the second to fourth middle and proximal phalanges and the distal metaphyses of the second to third metacarpals

Fig. 7 Left hand radiograph showed multiple enchondromas involving proximal metaphyses of the second to fourth middle phalanges and the second to fifth proximal phalanges

Epidermolysis Bullosa

Epidermolysis bullosa (EB) is a rare group of inherited disorders of skin fragility, characterized by a reduced resistance of the skin and mucous membranes to trauma, manifesting as blistering or erosion of the skin and the epithelial lining of other organs. Epidermolysis bullosa can be classified into three major types, namely, the simplex, the junctional, and the dystrophic types, based on the level of the epidermis or basement membrane zone in which blister is formed.

All types and subtypes of EB are rare. The overall incidence and prevalence of the disease within the USA is approximately 19 per one million live births and 8 per one million population, respectively (Fine 2010).

Synonyms and Related Disorders

Dominant dystrophic EB; Dystrophic EB; EB with congenital localized atrophy of skin (Bart syndrome) Epidermolysis bullosa simplex; Inherited EB; JEB gravis; JEB Herlitz; JEB non-Herlitz; JEB-mitis; JEB-pyloric atresia; Junctional epidermolysis bullosa (JEB); Kindler syndrome; Recessive dystrophic EB, severe generalized

Genetics/Basic Defects

1. Epidermolysis bullosa simplex (EBS) (Eady 2001; Mitsuhashi and Hashimoto 2003; Fine 2010)
    1. Autosomal dominant (AD) simplex type EB (most common type)
        1. Caused by mutations in the cytoskeleton structural proteins, keratin 5 (*KRT5*) and keratin 14 (*KRT14*) genes, leading to disruption of basal cells and the formation of bullae in the basal and parabasal cell zone
        2. Keratins 5 and 14: expressed exclusively in basal cell layer of epidermis keratinocytes and essential for the maintenance of normal structural integrity
        3. Disease severity correlates with the location within the keratin gene mutation
            1. Mutations in highly conserved genetic sequences leading to severe disease
            2. Mutations in less critical keratin gene regions manifesting as milder, more localized symptoms: Koebner variant (generalized blistering but no mucosal or nail changes) and Weber-Cockayne form (blistering is confined primarily to the easily traumatized palms and soles)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_81

2. Autosomal recessive (AR) simplex types (rare type)
    1. Mutation in exon 1a of *PLEC*, leading to disruption of plectin isoform 1a, causes autosomal recessive skin-only epidermolysis bullosa simplex (Gostyńska et al. 2015)
    2. EBS with muscular dystrophy due to abnormal plectin, a protein involved in hemidesmosome formation (currently also classified as a subtype of hemidesmosomal epidermolysis bullosa)
    3. EB without muscular dystrophy in patients homozygous for *KRT14* gene abnormalities
    4. Skin fragility syndrome (a form of ectodermal dysplasia but can also be classified as acantholytic EB simplex variant) with formation of acantholytic vesicles within the epidermis due to plakophilin 1 (*PKP1*) gene mutations
    5. Lethal acantholytic epidermolysis bullosa (McGrath et al. 2010)
        1. The first case report (Jonkman et al. 2005): Recessive mutations in *DSP* leading to truncation of the complete desmoplakin C-terminus (intermediate filament binding); loss of the intermediate filament binding domain of desmoplakin in both isoforms caused loss of keratin insertion of desmosomes which still had an inner and an outer dense plaque
        2. A novel homozygous deletion in *DSP* gene, encoding desmoplakin, in two infants born to same consanguineous parents (Bolling et al. 2010): Novel recessive *DSP* mutation predicted to result in truncation as well
2. Junctional epidermolysis bullosa (JEB) (Dank et al. 1999; Pulkkinen et al. 1994)
    1. Inheritance: autosomal recessive in most cases
    2. Herlitz type (epidermolysis bullosa letalis or JEB gravis)
        1. Caused by mutations in laminin 5 gene
        2. Associated with premature death
    3. Non-Herlitz type (generalized atrophic benign EB or JEB-mitis)
        1. Caused by mutation in laminin 5 and type XVII collagen (*COL17A1*) genes
        2. Generally associated with a good prognosis
    4. Junctional epidermolysis associated with pyloric atresia (Chung and Uitto 2010)
        1. Caused by mutations in a hemidesmosomal component, $\alpha_6\beta_4$ integrin (*ITGA6*, *ITGB4*) (Vidal et al. 1995) and *PLEC1*
        2. Currently also classified as a subtype of hemidesmosomal epidermolysis bullosa
3. Dystrophic epidermolysis bullosa
    1. Inheritance: either autosomal dominant or autosomal recessive
    2. Molecular basis: abnormalities of collagen VII
        1. Caused by mutations in type VII collagen gene. *COL7A1* gene mutations have been identified in most cases in both recessive (Salas et al. 1998) and dominant forms
        2. Type VII collagen is a major component of the anchoring fibrils that tether the basement membrane structure and overlying epidermis to its dermal foundation
        3. Severity of the phenotype dictated by missense mutation that alters a glycine residue in dominant dystrophic epidermolysis bullosa versus a nonsense or frameshift mutations in recessive dystrophic epidermolysis bullosa
4. Kindler syndrome
    1. Inherited in an autosomal recessive manner
    2. Pathogenesis of Kindler syndrome involves loss-of-function mutations in a newly recognized actin cytoskeleton-associated protein, now known as fermitin family homolog 1 and encoded by the gene *FERMT1* (Jobard et al. 2003)
5. Main types and subtypes of hereditary epidermolysis bullosa (Fine et al. 2014; Laimer et al. 2015)
    1. Epidermolysis bullosa simplex, EBS (intradermal [epidermolytic] blisters)

1. Suprabasal EBS (cytolysis of suprabasal keratinocytes)
    1. Acral peeling skin syndrome (AR) (*TGM5*)
    2. Superficial EBS (AD)
    3. Acantholytic EBS (includes variants formerly termed lethal acantholytic EBS and lethal congenital EBS) (AR) (*DSP*, *JUP*)
2. Skin fragility syndromes (very rare variants)
    1. Desmoplakin deficiency (skin fragility/woolly hair syndrome) (AR) (*DSP*)
    2. Plakoglobin deficiency (AR) (*JUP*)
    3. Plakophilin deficiency (skin fragility/ectodermal dysplasia syndrome) (AR) (*PKP1*)
3. Basal EBS (cytolysis of basal keratinocytes)
    1. Localized EBS (formerly type Weber-Cockayne) (AD) (*KRT5*, *KRT14*)
    2. Generalized severe EBS (formerly type Dowling-Meara, herpetiform EBS) (AD) (*KRT5*, *KRT14*)
    3. Generalized intermediate EBS (formerly EBS, generalized other; non-Dowling-Meara; EBS, type Koebner) (AD) (*KRT5*, *KRT14*, *COL17A1*)
    4. EBS with mottled pigmentation (AD) (*KRT5*)
    5. EBS with migratory circinate erythema (AD) (*KRT5*)
    6. Autosomal recessive EBS K14 (AR) (*KRT14*)
    7. Trauma-induced skin blistering (AR) (*EXPH5*)
    8. EBS with muscle dystrophy (AR) (*PLEC1*)
    9. EBS with pyloric atresia (AR) (*PLEC1*, *ITGA6*, *ITGB4*)
    10. EBS type Ogna (AD) (*PLEC1*)
    11. Autosomal recessive EBS, BP230 deficiency (AR) (*DST*)
    12. Autosomal recessive EBS, exophilin-5 deficiency (AR) (*EXPH5*)
2. Junctional epidermolysis bullosa, JEB (junctional [lucidolytic] blisters) within the basement membrane zone
    1. Generalized JEB
        1. Generalized severe JEB (previously type Herlitz) (AR) (*LAMA3*, *LAMB3*, *LAMC2*)
        2. Generalized intermediate JEB (formerly type non-Herlitz; JEB, generalized other; GABEB) (AR) (*LAMA3*, *LAMB3*, *LAMC2*)
        3. JEB with pyloric atresia (AR) (*ITGA6*, *ITGB4*)
        4. JEB, late onset (formerly progressive) (AR) (*COL17A1*)
        5. Localized JEB (AR) (*COL17A1*)
        6. JEB with respiratory and renal involvement (previously EB congenital nephrotic syndrome-interstitial lung disease) (AR) (*ITGA3*)
    2. Localized JEB
        1. Localized JEB (previously localized JEB, non-Herlitz) (AD) (*COL17A1*)
        2. JEB inversa (AR) (*LAMA3*, *LAMB3*, *LAMC2*)
        3. JEB, laryngo-onycho-cutaneous syndromes (AR) (*LAMA3A*)
3. Dystrophic epidermolysis bullosa, DEB (dermolytic blistering below the lamina densa) (Shinkuma 2015)
    1. Dominant DEB
        1. Generalized dominant DEB (formerly type Pasini, Cockayne-Touraine) (AD) (COL7A1)
        2. Acral dominant DEB (AD, AR) (*COL7A1*)
        3. Pretibial dominant DEB (AD, AR) (*COL7A1*)
        4. Dominant DEB pruriginosa (AD, AR) (COL7A1)
        5. Dominant DEB, nails only (AD) (*COL7A1*)
        6. Dominant DEB, bullous dermolysis of the newborn (AD, AR) (*COL7A1*)
    2. Recessive DEB (Soro et al. 2015)
        1. Generalized severe DEB (formerly type Hallopeau-Siemens) (AR) (*COL7A1*)

2. Generalized intermediate DEB (formerly type non-Hallopeau-Siemens; RDEB, generalized other) (AR) (*COL7A1*)
3. Recessive DEB inversa (AR) (*COL7A1*)
4. Localized recessive DEB (formerly acral recessive DEB) (AR) (COL7A1)
5. Pretibial recessive DEB (AD, AR) (COL7A1)
6. Recessive DEB pruriginosa (AR) (*COL7A1*)
7. Recessive DEB (centripetal variant) (AR) (*COL7A1*)
8. Recessive DEB, bullous dermolysis of the newborn (AR) (*COL7A1*)
9. Kindler syndrome (intraepidermal, junctional, or sub-lamina-densa blisters (AR) (*FERMT1* (*KIND1*)))

4. Recently identified autosomal recessive EB variants (McGrath 2015)
   1. Mutations in either *DST-e* (coding for epidermal dystonin, also known as the 230 kDa bullous pemphigoid antigen, BP230)
   2. *EXPH5* (coding for exophilin-5, also known as Slac2-b)
   3. *ITGA3* (coding for the integrin alpha-3 subunit)

Clinical Features

1. Classification of the major EB subtypes was discussed in great detail in the 2008 consensus report on diagnosis and classification (Fine et al. 2008), which was based on the recommendations of an international panel of EB experts, superceding two previously recommended classification schemes (Fine et al. 1991, 2000)
2. Epidermolysis bullosa simplex (Pai and Marinkovich 2002; Pfendner and Bruckner 2011)
   1. General characteristics
      1. The most common heritable blistering process
      2. Intraepidermal blistering at the level of the basal cell
      3. Typical healing of blisters without scarring
      4. Little involvement of other organ systems
      5. Extent and severity of disease improves with age
   2. EBS Koebner type
      1. Commonly involves hands, feet, and extremities
      2. Onset at birth to early infancy
      3. Often present with palmar-plantar hyperkeratosis and erosions
      4. Mildly involves nails, teeth, and oral mucosa
   3. EBS Weber-Cockayne type
      1. Relatively mild variant of EBS
      2. Commonly involves palms and soles only after a clearly identifiable traumatic event
      3. May not present until adulthood
      4. Hyperhidrosis of the palms and soles
      5. Most common complications involve secondary infections of blistering lesions on the feet
   4. EBS Dowling-Meara type (EBS-DM)
      1. A more severe subtype of EBS
      2. Involves a more generalized distribution of blisters occurring at, or shortly after, birth
      3. Pronounced inflammation with milia formation in infancy
      4. Spontaneous blisters occurring in groups on the trunk and proximal extremities
      5. Usually healing without scarring later in life
      6. Hyperkeratosis may develop at age 6 or 7 years
      7. Unlike the previous two subtypes, heat does not appear to exacerbate blistering
   5. EBS with mottled pigmentation
      1. Skin fragility: evident at birth and clinically indistinguishable from EBS-DM
      2. Over time, progressive brown pigmentation interspersed with hypopigmented spots develops on the trunk and

extremities, with the pigmentation disappearing in adult life
3. Focal palmar and plantar hyperkeratoses may occur

6. Lethal acantholytic epidermolysis bullosa (Jonkman et al. 2005; Bolling et al. 2010; McGrath et al. 2010)
1. Striking phenotypic findings
1. Extensive nonbullous epidermal dislodgment
2. Universal alopecia
3. Anonychia
4. Rapid postnatal demise
2. Malformed ears
3. Cardiac enlargement and dysfunction in utero

3. Junctional epidermolysis bullosa (Dank et al. 1999)
1. General characteristics
1. Blistering at the level of the lamina lucida
2. More severe blistering process
3. Presenting spontaneously or at sites of trauma with generalized blistering
2. Herlitz or junctional epidermolysis letalis
1. The commonest form of JEB formerly known as "lethal JEB"
2. Characterized by generalized blistering at birth
3. Extensive dental enamel hypoplasia
4. Tracheolaryngeal involvement leading to a hoarse cry, cough, and/or other respiratory difficulties
5. Gastrointestinal involvement and genitourinary involvement leading to infection and obstructive sequelae
6. Rarely survives beyond 6 months secondary to chronic anemia, failure to thrive, and sepsis
7. Rare survivors: develop exuberant granulation tissue at sites of erosion, especially at the perioral region
3. Non-Herlitz junctional epidermolysis bullosa
1. Early clinical course similar to that found in Herlitz type JEB
2. Often survives infancy
3. May improve clinically with age
4. Rare and mild pulmonary involvement
5. Scalp, nail, and tooth abnormalities common
6. Prominent nonhealing periorificial lesions
7. Erosions in the mucous membranes resulting in strictures
4. Generalized atrophic benign epidermolysis bullosa
1. Generalized cutaneous blistering at birth
2. Blisters heal with a distinctive atrophic appearance
3. Blisters confined to sites of trauma
4. Alopecia
5. Dental anomalies
6. Rare severe nail and mucosal involvement
5. Junctional epidermolysis associated with pyloric stenosis/atresia (Chang et al. 1983; Dank et al. 1999; Pfendner and Lucky 2013)
1. A syndromic association of skin fragility and congenital gastrointestinal atresia, most frequently pyloric, although duodenal atresia with skin fragility has also been reported
2. Often with severe skin blistering and extensive multisystem mucosal blistering
3. Presence of pyloric and/or duodenal atresia: vomiting and abdominal distension resulting from complete obstruction of the gastric outlet
4. Often with urologic abnormalities
1. Hydronephrosis
2. Nephritis
5. Many patients die during infancy

4. Dystrophic epidermolysis bullosa
1. General characteristics
1. Clinical hallmarks (Bruckner-Tuderman 2010)
1. Trauma-induced blisters
2. Healing with scarring
2. Sub-lamina densa blistering
3. Characterized by dermolytic blisters resulting in scarring and milia formations
4. Dystrophic scarring follows cutaneous blistering

5. Congenital localized absence of skin (Bart's syndrome) may be the presenting sign of epidermolysis bullosa (Wojnarowska et al. 1983)

2. Dominantly inherited dystrophic epidermolysis bullosa
   1. Mild phenotype
   2. Present with generalized blistering at birth or during infancy
   3. Blistering at sites of maximal trauma
   4. Healing with scarring and small keratinaceous cysts (milia)
3. Transient bullous dermolysis of the newborn (Hansen et al. 1999)
   1. An uncommon variant
   2. Blistering at sites of trauma that heals after several months without scarring
   3. Variable mucous membrane and nail involvement
4. Recessively inherited dystrophic epidermolysis bullosa: Hallopeau-Siemens type (the most severe form)
   1. Excessive fragile skin leading to blisters with minimal trauma
   2. Extensive scarring leading to contractures and fusion of digital web spaces (pseudosyndactyly, "mitten deformities") that require surgical correction
   3. Extremely itching and painful skin
   4. Regular mucosal blistering leading to eating and swallowing disorders and ocular abnormalities
   5. Tendency to growth retardation and anemia
   6. Devastating complications unique to recessively inherited dystrophic epidermolysis bullosa
      1. Increased propensity for cutaneous malignancy at sites of scarring (>40% of patients develop malignancy by age 30 years)
      2. Aggressive nature of malignancy (squamous cell carcinoma)
5. Kindler syndrome (Sawamura et al. 2010)
   1. Autosomal recessive inheritance
   2. A subtype of EB
   3. The pathogenesis of Kindler syndrome involves loss-of-function mutations in a newly recognized actin cytoskeleton-associated protein, now known as fermitin family homolog 1 and encoded by the gene *FERMT1* (Jobard et al. 2003)
   4. Trauma-induced blistering
   5. Poikiloderma
   6. Skin atrophy
   7. Mucosal inflammation
   8. Varying degrees of photosensitivity
6. Differential diagnosis of inherited EB (in neonates and small children) (Fine 2010)
   1. Inherited or congenital disorders
      1. Epidermolytic hyperkeratosis (bullous congenital ichthyosiform erythro-derma)
      2. Ichthyosis bullosa of Siemens
      3. Peeling skin syndrome
      4. Pachyonychia congenita
      5. Congenital porphyrias
      6. Acrodermatitis enteropathica
      7. Incontinentia pigmenti
      8. Ectodermal dysplasia (ED)
      9. AEC syndrome (Hay-Wells syndrome)
      10. Congenital absence of skin (cutis aplasia)
      11. Congenital erosive dermatosis with reticulate supple scarring
   2. Acquired disorders
      1. Immunobullous disorders
         1. EB acquisita
         2. Linear IgA dermatosis
         3. Bullous pemphigoid
         4. Cicatricial pemphigoid
         5. Neonatal herpes gestationis
         6. Pemphigus
      2. Infectious diseases
         1. Herpes simplex
         2. Staphylococcal scalded skin syndrome
         3. Bullous impetigo
      3. Other diseases or conditions
         1. Bullous mastocytosis
         2. Traumatic blisters (sucking; other)

Diagnostic Investigations

1. Level of blister formation in each major EB type (Fine 2010)
    1. EB simplex: intraepidermal
    2. Junctional EB: intra-lamina lucida
    3. Dystrophic EB: sub-lamina densa
    4. Kindler syndrome: multiple levels (intra-lamina lucida and sub-lamina densa)
2. Radiographs: distended stomach, filled with air in junctional EB with pyloric atresia
3. EM of skin biopsy (Pai and Marinkovich 2002)
    1. A gold standard of laboratory diagnosis
        1. To determine the level at which blistering occurs
        2. To obtain additional information on the morphology of various basement membrane zone components
    2. Epidermolysis bullosa simplex
        1. Cytolysis of the basal cells
        2. Distinctive clumping of the keratin tonofilaments
    3. Junctional epidermolysis bullosa: rudimentary hemidesmosomes
    4. Dystrophic epidermolysis bullosa: absent or altered anchoring fibrils
    5. Hemidesmosomal epidermolysis bullosa: separation at the level of hemidesmosome just inside the basal keratinocytes
4. Transmission electron microscopy findings among selected EB subtypes (Fine 2010)
    1. EB simplex (suprabasal) (EBS)
        1. EB simplex superficialis: subcorneal cleavage
        2. Lethal acantholytic EB:
            1. Suprabasal cleavage
            2. Acantholysis
            3. Perinuclear retraction of keratin filaments
        3. EBS, plakophilin deficiency:
            1. Mid-epidermis cleavage
            2. Perinuclear retraction of keratin filaments
            3. Small suprabasal desmosomes
    2. EBS (basal)
        1. EBS, localized: basal keratinocyte cleavage
        2. EBS, Dowling-Meara
            1. Basal keratinocyte cleavage
            2. Clumped keratin filaments
        3. EBS, generalized other: basal keratinocyte cleavage
        4. EBS, autosomal recessive
            1. Basal keratinocyte cleavage
            2. Absent or reduced keratin filaments within basal keratinocytes
    3. Junctional EB (JEB)
        1. JEB, Herlitz
            1. Intra-lamina lucida cleavage
            2. Markedly reduced or absent hemidesmosomes
            3. Absent subbasal dense plates
            4. Absent anchoring filaments
        2. JEB, non-Herlitz
            1. Intra-lamina lucida cleavage
            2. Hemidesmosomes may be normal or reduced in size and number
        3. JEB with pyloric atresia
            1. Intra-lamina lucida cleavage
            2. Small hemidesmosome plaques with attenuated subbasal dense plates
    4. Dominant dystrophic EB (DDEB)
        1. DDEB, generalized
            1. Sub-lamina densa cleavage
            2. Normal or reduced numbers of anchoring fibrils
        2. DDEB, bullous dermolysis of the newborn
            1. Sub-lamina densa cleavage
            2. Electron-sense stellate shaped bodies within basal keratinocytes
            3. Reduced numbers of anchoring fibrils
    5. Recessive dystrophic EB (RDEB)
        1. RDEB, severe generalized
            1. Sub-lamina densa cleavage
            2. Absent or rudimentary appearing anchoring fibrils
        2. RDEB, generalized other (generalized mitis)
            1. Sub-lamina densa cleavage

2. Reduced or rudimentary appearing anchoring fibrils

5. Immunofluorescent microscopy (Pai and Marinkovich 2002)
   1. Provide additional information on the level of blistering
   2. Provide important clue to the underlying molecular defects
   3. Antibodies against intracellular hemidesmosomal component such as BP230 and a lamina densa protein such as type IV collagen
      1. Samples from EBS: both antibodies localized to the floor of the blister
      2. Samples from JEB
         1. Antibodies against BP230 localized to the roof of the blister
         2. Antibodies against type IV collagen localized to the floor
      3. Samples from DEB: both antibodies localized to the roof of the blister
   4. Samples lacking staining with antibodies specific to laminin 5 support a JEB diagnosis
   5. Samples lacking staining with antibodies specific to type VII collagen support a DEB diagnosis
   6. Absence of staining for BP180 supports a diagnosis of generalized atrophic benign epidermolysis bullosa
6. Laboratory approach to epidermolysis bullosa (Castiglia and Zambruno 2010)
   1. At first use of immunofluorescence epitope mapping (IFM) and transmission electron microscopy (TEM) examination of a skin biopsy to determine the level of skin cleavage and the presence of morphologic alterations of epithelial adhesion structures and the defective expression of specific protein components
   2. IFM and TEM enable definition of the major EB type and, in most cases, the subtype and identification of the protein component targeted by the mutations
   3. These analyses define the candidate genes for mutation screening and they must precede molecular testing, which should be primarily considered when:
      1. Prenatal or preimplantation diagnosis is being planned
      2. The mode of genetic transmission cannot be delineated from the family pedigree in combination with IFM and TEM findings
      3. Gene-replacement therapy protocol is foreseen
   7. Linkage analysis of linked markers within or flanking the particular EB gene in families in which the inheritance pattern is known
   8. Mutation detection for all forms of epidermolysis bullosa
      1. Mutation analysis
      2. Sequence analysis
   9. Genetic testing for EB: the perfect application for NGS technology, as there are many candidate genes (some of which are very complex), large deletions are relatively rare, and if the phenotype is consistent with the inherited form of EB (neonatal onset and a fragile skin phenotype), mutations are reliably disclosed (Takeichi et al. 2013, 2015; Poulter et al. 2014; Nagai et al. 2015; Pfendner 2015)
   10. Lethal acantholytic epidermolysis bullosa (Bolling et al. 2010)
      1. Electron microscopy
         1. Loss of keratin filament insertion and
         2. Loss of the inner dense plaque
      2. A panel of antibodies directed against the desmoplakin C-terminus and the N-terminus/rod domain for immunofluorescence microscopy on a representative fresh frozen skin sample can provide an early diagnosis

Genetic Counseling

1. Recurrence risk
   1. Patient's sib
      1. Autosomal dominant
         1. 50% if a parent is affected
         2. Low recurrent risk when the parents are clinically unaffected
         3. Low recurrent risk but greater than that of the general population because

of the possibility of germline mosaicism when the disease-causing mutation cannot be detected in the DNA of either parent
4. Parental germline mosaicism have been reported in both EBS (Nagao-Watanabe et al. 2004) and DEB (Rouan et al. 1998; Cserhalmi-Friedman et al. 1999, 2001; van den Akker et al. 2015)

2. Autosomal recessive
1. Carrier status of parents needs to be confirmed by molecular genetic testing because germline mosaicism and uniparental isodisomy have been reported (Takizawa et al. 2000; Cserhalmi-Friedman et al. 2002; Fassihi et al. 2005)
2. Recurrence risk: 25%

2. Patient's offspring
1. Autosomal dominant
1. A 50% risk of inheriting the mutation
2. A 75% risk of having at least one mutation in the rare instance in which both parents have an autosomal dominant mutation such as in consanguineous union
2. Autosomal recessive: recurrence risk not increased unless the spouse is a carrier or affected

2. Prenatal diagnosis (Eady 2001; Fassihi and McGrath 2010)
1. Fetal skin biopsy with EM analysis and/or immunohistochemistry with following drawbacks
1. Drawbacks
1. Fetal biopsy can only be obtained fairly late in gestation ($\geq$17 weeks)
2. A relatively high rate of miscarriage
3. Fetal status can only be determined by an expert in the ultrastructure of fetal skin who is qualified to make the diagnosis
2. An alternative option for rare families in which mutations cannot be identified and linked markers are not available to be used for prenatal diagnosis
2. Fetal skin biopsy at 20 weeks' gestation in a woman at risk for a child with the lethal skin-blistering disorder junctional epidermolysis bullosa (Herlitz) confirmed an affected fetus (McGrath et al. 1995)
3. Prenatal diagnosis of EB letalis made by electron microscopy of a biopsy specimen of fetal skin obtained under direct vision by fetoscopy at 18 weeks gestation (Rodeck et al. 1980)
4. Villous trophoblasts, sampled during the first trimester, display immunoreactivity to $\alpha_6\beta_4$ integrin and plectin, thereby permitting diagnosis/exclusion of EB associated with pyloric atresia through tissue diagnosis (D'Alessio et al. 2008)
5. Mutation detection on fetal DNA obtained by amniocentesis or CVS for all forms of epidermolysis bullosa (Pfendner et al. 2003)
1. Before any prenatal test, samples from both parents and any previous affected siblings are analyzed for pathogenic mutations
2. In autosomal recessive EB, ideally both parents must be shown to be heterozygous carriers of the pathogenic mutation (s)
3. The possibility of de novo mutations, nonpaternity, and uniparental disomy (the inheritance of both copies of a chromosome pair from just one parent) should be excluded before considering the suitability of the prenatal test
6. Gene diagnosis and prenatal genetic diagnosis of a case of dystrophic epidermolysis bullosa family caused by gonadosomatic mosaicism for the *COL7A1* mutation p. Gly2043Arg in the pregnant mother (Shen et al. 2015)
7. Linkage analysis by linked markers within or flanking the *COL7A1* gene in several DEB families in which the inheritance pattern was known
8. Probability of parental germline mosaicism should always be kept in mind, and the option of prenatal diagnosis should be discussed (Cserhalmi-Friedman

et al. 2001, 2002; van den Akker et al. 2015)
9. Preimplantation genetic diagnosis, an alternative to first-trimester prenatal diagnosis
    1. Involves in vitro fertilization, usually by intracytoplasmic sperm injection
    2. Followed by the biopsy of a single cell from the eight-cell blastocysts (embryo)
    3. Using complex polymerase chain reaction analysis to determine whether DNA from the single cell caries the parental mutations

3. Management (Herod et al. 2002; Bello et al. 2003; Hachem et al. 2014; Soro et al. 2015)
    1. A multidisciplinary team approach, tailored to the severity and extent of skin involvement
    2. Blister management and dressing technique
        1. Avoidance of trauma as a primary goal
        2. Puncture fresh blisters with a sterile needle and drain blister fluid with the blister roof left in situ so that the blister fluid cannot extend
        3. Use white petrolatum-impregnated gauzes, hydrogels, fenestrated silicone dressings, or absorbent foam silicone dressings for open wounds
        4. Keep intravenous lines in place by using soft roller-gauze bandages
        5. Avoid dressing with adhesive tapes
        6. Prevention and treatment of infections
    3. Prevention and treatment of complications (Pai and Marinkovich 2002)
        1. Change dressing regularly
            1. To control blistering and infection
            2. To prevent the debilitating contractures secondary to bullae formation in dystrophic EB
        2. Physiotherapy
            1. To maintain mobility
            2. To decrease contracture formation
        3. Corrective surgery recommended for digital fusion (mitten pseudosyndactyly) and contractures
        4. Nutritional support
    5. Gastrointestinal management
        1. Dilatation of esophageal strictures
        2. Colonic interposition for advanced cases of strictures
        3. Gastrostomy tube insertion to provide nutrition
        4. Laxatives and increased dietary fiber for constipation, anal fissures, and perianal ulceration
    6. Care for eye lesions (Tong et al. 1999)
        1. Ophthalmic complications: most severe in the dystrophic recessive and junctional subtypes
        2. Moisture chambers and ocular lubricants
        3. Treat corneal erosions with antibacterial ointments and use of cycloplegic agents to reduce ciliary spasms and provide comfort
    7. Oral care
        1. Good oral hygiene
        2. Gentle cleaning of the mucosal surfaces with normal saline rinses
        3. Softest brush for regular cleansing
4. Pain management (Herod et al. 2002)
    1. Acute phase: experience considerable pain and discomfort caused by the expanding and often tense bulla
    2. Chronic wounds: experience considerable pain caused by chronic wounds with denuded areas of skin and by therapeutic procedures
    3. Analgesics
        1. Combination of paracetamol and ibuprofen or diclofenac for dressing changes associated with small wounds
        2. Potent analgesia and sedation required for large dressing changes (oral morphine solution and midazolam)
5. Management of anesthesia and surgery: should be undertaken in specialized centers familiar with the many complex aspects of EB care
6. Outcome after surgical repair of junctional epidermolysis bullosa-pyloric atresia syndrome (Dank et al. 1999): The poor

prognosis of this condition must be considered when decisions are made regarding surgical correction. Attempting surgical correction may be warranted in individual circumstances, but withholding surgical intervention and providing palliative support is an acceptable alternative. However, successful repair of PA was performed after appropriate stabilization in three children with long-term survival (Hayashi et al. 1991)

7. Tumor detection in recessively inherited DEB
8. Advanced therapy to treat hard to heal wounds
    1. Cultured keratinocytes
    2. Acellular dermal allograft plus ultrathin autografts
    3. Living dermal skin substitute
    4. Living bilayered skin equivalents
        1. Composite cultured skin (CCS)
        2. Graft skin
        3. Dermagraft
9. Feasibility of ex-vivo gene therapy in generalized non-Herlitz JEB (Mavilio et al. 2006)
10. Clinical trials based on the use of (i) allogenic fibroblasts for local RDEB wound care (Petrof et al. 2013; Venugopal et al. 2013) and (ii) allogenic hematopoietic stem cell/mesenchymal cell transplantation for severe RDEB forms (Tolar and Wagner 2013) have been recently described. In particular, hematopoietic stem cells transplantation has been reported to result in significant disease improvement, but not cure, in the majority of treated patients
11. Grafting of gene-corrected skin stem cells: still the most promising approach for permanent treatment of chronic wounds in EB patients (Murauer et al. 2015)

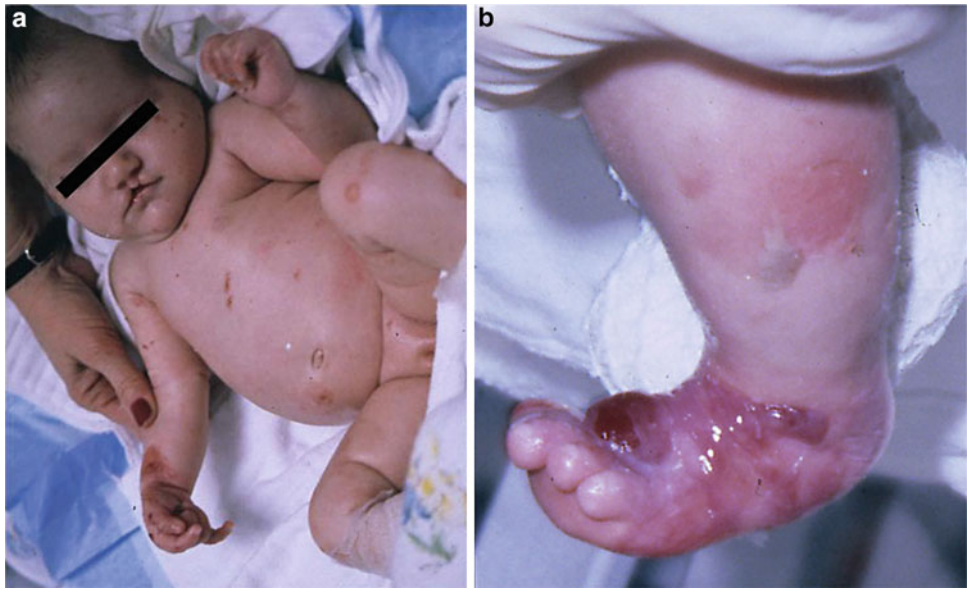

Fig. 1 (**a**, **b**) An infant (**a**) with epidermolysis bullosa showing large blisters on the foot (**b**) and smaller blisters on other part of the body (**a**)

Fig. 2 (**a**–**d**) A 19-year-old female with recessively inherited dystrophic epidermolysis bullosa (Hallopeau-Siemens type) who was born with generalized blisters involving skin and mucosa, especially blisters and skin sloughing on the fingers and legs (**a, b**). She showed excessive fragile skin leading to blisters with minimal trauma (**c**), excessive scarring leading to contractures of the right foot, and fusion of first and second toe on the right foot requiring surgical separation. She also had syndactyly of the second, third, and fourth toes of the left foot. The lesions were extremely itchy and painful and more severe on the lower extremity (**c, d**). At the time of these photos, the patient still had swallowing difficulty secondary to blistering lesion in the throat

Fig. 3 This infant was born with blisters on his hands, fingers, ankles, feet, toes, and oral mucosa, and part of the body. A biopsy of the lesion was consistent with dystrophic epidermolysis bullosa. In addition, he had a single umbilical artery, esophageal atresia, a single kidney, penile hypospadias, and unilateral preaxial polydactyly. At 12-weeks of age, he still showed scars on the oral mucosa and the chest and dystrophic lesions on the fingers

Epidermolytic Palmoplantar Keratoderma

Contents

Epidermolytic palmoplantar keratoderma (EPPK), first described by Vörner in 1901 (Vörner 1901), may be the most common form of diffuse keratoderma and is characterized by keratosis restricted to the palms and soles. The disease is also known as keratosis palmaris et plantaris familiaris. The estimated incidence is at least 4.4 per 100,000 in Northern Ireland (Covello et al. 1998).

Synonyms and Related Disorders

Keratosis of Greither; Keratosis palmaris et plantaris; Localized epidermolytic hyperkeratosis; Vörner type palmoplantar keratoderma

Genetics/Basic Defects

1. Inheritance:
    1. Autosomal dominant
    2. Highly penetrant
2. Cause
    1. Keratin 9 (K9)
        1. A type 1 keratin gene (*KRT9*, located at 17q12-q21) (Reis et al. 1992, 1994; Stevens et al. 1996), a type 1 keratin expressed exclusively in the suprabasal keratinocytes of the palmoplantar epidermis
        2. Over 20 distinct pathogenic mutations in KRT9 have been identified in various ethnic kindreds with EPPK (Coleman et al. 1999; He et al. 2004; Chen et al. 2009; Liu et al. 2012; Liang et al. 2014)
    2. Mutations in keratin 1 gene (*KRT1*) underlie mild EPPK (Terron-Kwiatkowski et al. 2002, 2006)
3. Disorders of keratin genes (Knöbel et al. 2015)
    1. Mutations in *KRT5* or *KRT14*
        1. Various subtypes of epidermolysis bullosa simplex (EBS)
        2. EBS generalized severe (formerly EBS Dowling-Meara): considered the most debilitating form of EBS with extensive blistering from birth (Fine et al. 2014)
        3. EBS localized (formerly Weber-Cockayne): the mildest form with onset in childhood and predominantly confined to palms and sole
        4. Rare variants including autosomal recessive EBS
    2. *KRT1* or *KRT10* mutations
        1. Autosomal dominant: epidermolytic ichthyosis (also known as epidermolytic

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_82

hyperkeratosis), bullous congenital ichthyosiform erythroderma (characterized by erythroderma, hyperkeratosis, and blistering of the upper skin layer) (Arin 2009; Oji et al. 2010), ichthyosis hystrix of Curth-Macklin (*KRT1* mutations, characterized by generalized or localized verrucous or spiky hyperkeratosis without blistering (Arin 2009)), and congenital reticular ichthyosiform erythroderma (KRT10 mutation, characterized by small patches of normal skin within erythroderma that increase in size over time)
    2. Autosomal recessive *KRT10* mutations (Gutierrez et al. 2013)
3. *KRT6A*, *KRT6B*, *KRT6C*, *KRT16*, or *KRT17* mutations: pachyonychia congenita (characterized by a painful and debilitating plantar keratoderma, variable hypertrophic nail dystrophy, oral leukokeratosis, and epidermal cysts) (Wilson et al. 2014)
4. *KRT9* mutations
    1. Palmoplantar keratoderma
    2. Epidermolytic palmoplantar keratoderma (Chamcheu et al. 2011; Lane and McLean 2004)

Clinical Features

1. Characteristic hyperkeratosis (Covello et al. 1998)
    1. Early onset: present at birth or during the first months of life
    2. Diffuse thick yellowish hyperkeratosis, distinctly limited to the palms and soles, with sharply bordered erythematous margins (virtually diagnostic of EPPK) (Chamcheu et al. 2011)
    3. The absence of associated features
2. Differential diagnosis (Lucker et al. 1994; Corden and McLean 1996; Ratnavel and Griffiths 1997; Lee et al. 2008)
    1. Diffuse hereditary PPK without associated features (Hatsell et al. 2001; Kingsbery 2014)
        1. Diffuse nonepidermolytic PPK (NEPPK)
            1. NEPPK: an autosomal dominant disorder.
            2. Clinically difficult to distinguish between EPPK and NEPPK.
            3. Histologically, EPPK shows epidermolysis of keratinocytes in the suprabasal layers, a characteristic not observed in NEPPK.
            4. In mild cases of EPPK, diagnosis can still be problematic as detection of epidermolysis can be difficult.
        2. Progressive PPK
            1. Hyperkeratosis extends onto the dorsa of the hands and the feet with characteristic involvement of the Achilles tendon.
            2. Hyperhidrosis common.
            3. Intrafamilial phenotypic variation common.
            4. Course of the disease: worsens during childhood, becomes static after puberty, and improves in the fifth decade of life.
        3. Gamborg-Nielsen PPK
            1. An autosomal recessive disorder.
            2. Severe form of PPK delineated in two families with six patients in Sweden.
            3. Thick, diffuse keratoderma with knuckle pads.
            4. Occasional keratosis on the dorsa of the hands.
            5. Mutilating changes due to constricting bands surrounding the fingers have been described.
    2. Diffuse hereditary PPK with associated features
        1. Mal de Meleda
            1. Described initially in inhabitants of the Adriatic Island of Meleda (Mljet)
            2. An autosomal recessive disorder

3. Diffuse, thick keratoderma with prominent erythematous border extending onto the dorsa of the hands and the feet
4. Constricting bands around digits resulting in spontaneous amputation
5. Well-circumscribed psoriasis-like plaques or lichenoid patches on the knees and the elbows
6. Hyperhidrosis
7. Periorbital erythema and hyperkeratosis
8. Nail changes (koilonychias, subungual hyperkeratosis)
9. Other associated features (lingua plicata, syndactyly, hair on the palms and the soles, high-arched palate, left handedness)

2. Vohwinkel PPK mutilans
   1. An autosomal dominant disorder
   2. Honeycomb-like keratosis of the palms and soles in infancy
   3. Constricting fibrous bands on the digits, leading to progressive strangulation and autoamputation
   4. Starfish-shaped keratosis on the dorsa of the fingers and the knees
   5. Other associated features (alopecia, deafness, spastic paraplegia, myopathy, ichthyosiform dermatosis, and nail abnormalities)
3. Olmsted mutilating PPK with periorificial keratotic plaques (Olmsted syndrome) (Da Rosa Santos et al. 1997; Tao et al. 2008)
   1. An autosomal dominant disorder
   2. Onset in the first year of life
   3. Symmetric, sharply circumscribed PPK, surrounded by erythema with flexion deformities of the digits, leading to constriction and spontaneous amputation (Poulin et al. 1984)
   4. The presence of hyperkeratotic plaques with a periorificial pattern (Atherton et al. 1990; Lucker and Steijlen 1994)
   5. Onychodystrophy
   6. Universal congenital alopecia
   7. Oral leukokeratosis
   8. Joint hyperlaxity
4. PPK with sclerodactyly
   1. An autosomal dominant disorder
   2. Sclerodactyly
   3. Diffuse keratoderma more marked on the soles than the palms
   4. Nail abnormalities
   5. Hypohidrosis
   6. Associated with squamous cell carcinoma
5. PPK with periodontitis
   1. An autosomal recessive disorder.
   2. Diffuse transgrediens palmoplantar dermatosis.
   3. Periodontosis, unless treated, results in severe gingivitis and loss of teeth by age 5 years.
   4. Increased susceptibility to infection.
   5. Scaly, erythematous lesions often observed over the knees, the elbows, and the interphalangeal joints.
   6. Hyperhidrosis with malodor.
6. Clouston hidrotic ectodermal dysplasia
   1. Diffuse, papillomatous PPK
   2. Nail dystrophy
   3. Universal sparsity of hair
   4. Other associated features (sensorineural deafness, polydactyly, syndactyly, finger clubbing, mental retardation, dwarfism, photophobia, and strabismus)
7. Diffuse NEPPK and sensorineural deafness
   1. An autosomal dominant disorder.
   2. Diffuse palmoplantar hyperkeratosis.
   3. Associated with a slowly progressive, bilateral, high-frequency hearing loss.
   4. Deafness precedes the skin changes.

3. Focal (nummular) PPK without associated features
   1. Focal NEPPK
      1. An autosomal dominant disorder

2. Palmar keratosis with a nummular, linear, membranaceous, fissured, or periungual configuration
3. Plantar keratosis with a nummular appearance, localized to pressure points

2. Focal epidermolytic PPK
   1. An autosomal dominant disorder
   2. Nummular keratotic lesions, located mainly on plantar pressure points
   3. Painful lesions
3. Siemens PPK areata/striata
   1. An autosomal dominant disorder
   2. Marked variable phenotypic expression
   3. Marked erythema initially, followed by islands of linear hyperkeratosis

4. Focal (nummular) hereditary PPK with associated features
   1. Oculocutaneous tyrosinemia (tyrosinemia type II)
      1. Focal, painful PPK
      2. Bilateral, pseudoherpetic corneal ulceration, leading to corneal scarring and glaucoma
      3. Mental retardation
      4. Occasional hyperkeratotic lesions on the elbows, knees, and tongue
      5. Hyperhidrosis
      6. Occasional bullous lesions
   2. Pachyonychia congenita
      1. Autosomal recessive disorder
      2. Localized areas of hyperkeratosis on the palms and the soles
      3. Discoloration and thickening of the nails
   3. Keratosis palmaris and plantaris with carcinoma of the esophagus
      1. Autosomal dominant disorder
      2. Age of onset: 5–15 years
      3. Focal PPK
      4. Increased susceptibility to developing carcinoma of the esophagus (38-fold increase)
      5. Variable oral leukokeratosis and follicular keratosis
   4. Focal palmoplantar and oral mucosa hyperkeratosis
      1. Autosomal dominant disorder
      2. Focal PPK, especially on weight-bearing areas
      3. Oral hyperkeratosis
      4. Increased severity with age
      5. Subungual and circumungual hyperkeratosis

5. Papular PPK without associated features
   1. Keratosis palmoplantaris punctata
      1. Autosomal dominant disorder
      2. Asymptomatic, tiny hyperkeratotic papules present on the palmoplantar surface
      3. The absence of associated features in most patients
      4. Spastic paralysis, ankylosing spondylitis, facial sebaceous hyperplasia reported
      5. Possible association with gastrointestinal malignancy
   2. Acrokeratoelastoidosis
      1. Autosomal dominant disorder
      2. Round or oval, yellowish, hyperkeratotic papules that can appear umbilicated
      3. Distribution of the lesions: along the border of the palms and the soles
      4. Associated hyperhidrosis
   3. Focal acral hyperkeratosis
      1. Autosomal dominant disorder
      2. Condition similar to acrokeratoelastoidosis
      3. Insidious onset in childhood, reaching maximum in early life
      4. Race: African origin

6. Papular PPK with associated features
   1. Rare single pedigree syndromes
      1. Syndrome of cystic eyelids, punctate PPK, hypotrichosis, and hypodontia (Schöpf-Schulz-Passarge syndrome)
      2. Punctate PPK with ankylosing spondylitis
      3. Punctate PPK with facial sebaceous hyperplasia
      4. Punctate PPK with spastic paralysis
      5. PPK with lipomata
   2. Punctate PPK and cancer

7. Acquired palmoplantar keratoderma
    1. Inflammatory and reactive dermatoses
        1. Hyperkeratotic eczema
        2. Psoriasis
        3. Reiter syndrome
        4. Lichen planus
        5. Pityriasis rubra pilaris
        6. Lupus erythematosus
        7. Callosities
        8. Darier disease
    2. Infective causes
        1. Dermatophytes
        2. Viral (human papillomavirus) warts mimicking keratoderma
        3. AIDS-related psoriasis with discrete keratotic pustular keratoderma
        4. Late secondary syphilis in patients with HIV with diffuse, symmetric keratoderma or papular PPK
        5. Yaws
        6. Leprosy
    3. Drugs
        1. Chronic arsenic exposure with multiple, irregular, warty keratosis
        2. Lodine: manifestation of drug hypersensitivity
    4. Cutaneous features of systemic disease
        1. Myoedema with hyperkeratosis
        2. Diabetes with discrete plantar keratosis
        3. Cutaneous T cell lymphoma with subungual hyperkeratosis
    5. Haxthausen keratoderma climactericum
        1. Onset in the 40s
        2. Initial lesion: pressure areas on the soles
        3. Erythema and hyperkeratosis with fissuring making walking painful
        4. Minimal pruritus
        5. Discrete and centrally confined palmar involvement
    6. Keratoderma associated with internal malignancy
        1. Keratoderma as a paraneoplastic phenomenon, such as acrokeratosis paraneoplastica of Bazex associated with squamous cell carcinoma of the upper gastrointestinal tract and acanthosis palmaris associated with gastric or pulmonary malignancy in 90% of cases
        2. Keratoderma as evidence of predisposition to malignancy such as late-onset punctate keratoderma associated with cutaneous and internal malignancy
    8. Syndromes with PPK as associated features
        1. Basal cell nevus syndrome
        2. Congenital bullous ichthyosiform erythroderma
        3. Congenital nonbullous ichthyosiform erythroderma
        4. Darier disease
        5. Epidermodysplasia verruciformis
        6. Epidermolysis bullosa herpetiformis
        7. Ichthyosis vulgaris
        8. Incontinentia pigmenti
        9. Keratitis, ichthyosis, and deafness (KID) syndrome
        10. Lamellar ichthyosis

Diagnostic Investigations

1. Histology and ultrastructures: cytolysis of keratinocytes and abnormal aggregation of tonofilaments in the suprabasal layers of the epidermis (Navsaria et al. 1995)
2. Molecular genetic analysis
    1. *KRT9* mutation analysis
        1. Sequencing of entire coding region
        2. Sequencing of select exons
        3. Targeted mutation analysis
    2. *KRT1* mutation analysis for patients with no mutations in *KRT9*

Genetic Counseling

1. Recurrence risk
    1. Patient's sib: not increased unless a parent is affected in which case there is a 50% risk
    2. Patient's offspring: 50%

2. Prenatal diagnosis
    1. Not usually requested because of mild nature of the disease
    2. Possible to pregnancy at risk, provided the disease-causing mutation has been identified in the proband
    3. KRT9 gene mutation as a reliable indicator in the prenatal diagnosis of EPK (Ke et al. 2014)
    4. Accomplished in a Chinese kindred affected by EPPK for detection of c. T470C (p.M157T) of the keratin 9 gene from fetal DNA obtained by amniocentesis (Chen et al. 2009)
3. Management
    1. Topical keratolytics
    2. Topical retinoids such as tretinoin

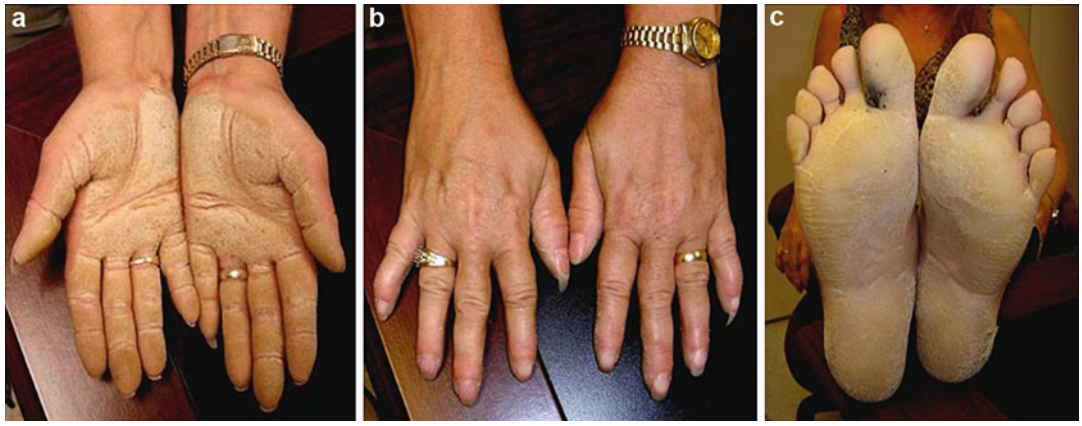

Fig. 1 (**a**–**c**) A 47-year-old woman with epidermolytic palmoplantar keratoderma showing diffuse keratoderma affecting both the palms and the soles. The keratoderma had erythematous border at the margins of both palms and soles and was completely restricted to the palms and soles. The dorsa of the hands and soles were spared. This patient has multiple affected relatives in several generations

Fig. 2 This 17-year-old girl was seen for hyperkeratosis of the palms and soles associated with severe nail hyperplasia of the toes. She has mental retardation and short stature. Clinically, she has type IV epidermolytic palmoplantar keratoderma with pachyonychia congenita

Fig. 3 She has marked midfacial hypoplasia

Fig. 4 Diffuse *thick* yellowish hyperkeratosis was noted on her palms. Her soles also have same *thick* yellowish hyperkeratosis

Fig. 5 Her toenails show subungual keratinous mass pushing the nail bed upward

Fig. 6 (**a**–**d**) An African-American female presented with epidermolytic palmoplantar keratoderma affecting both the palms (**a**, **b**) and soles (**c**, **d**)

Fig. 7 This newborn was suspected to have epidermolytic hyperkeratosis. *KRT10* mutation hot spot analysis showed a heterozygous T>G (L153P) mutation in exon 1 of the *KRT10* gene. The presence of the L153P mutation in the *KRT10* gene confirms the clinical diagnosis of epidermolytic hyperkeratosis

Faciogenital (Faciodigitogenital) Dysplasia

Contents

Faciogenital dysplasia (FGDY) was first described by Aarskog in 1970 (Aarskog 1970) as a familial syndrome of short stature associated with facial and genital anomalies. The occurrence of ligamentous laxity was emphasized by Scott in 1971 (Scott 1971). The syndrome is also known as Aarskog syndrome, Aarskog-Scott syndrome, and faciodigitogenital syndrome (Sugarman et al. 1973).

Synonyms and Related Disorders

Aarskog syndrome; Aarskog-like syndrome; Aarskog-Scott syndrome

Genetics/Basic Defects

1. Aarskog-Scott syndrome (Orrico et al. 2010)
    1. X-linked recessive inheritance (Archibald and German 1975; Berman et al. 1974, 1975; Escobar and Weaver 1978; Bawle et al. 1984) with occasional partial expression in the heterozygote
    2. X-linked dominant with full male–female expression (Tyrkus et al. 1980)
    3. The *FGDY1* gene (Schwartz et al. 2000): mapped to the pericentromeric region of the X chromosome (Stevenson et al. 1994) by the observation of an X;8 translocation in an affected mother and son (Pasteris et al. 1997) (breakpoint at Xp11.21) (Glover et al. 1993); encoding a guanine nucleotide exchange factor (Estrada et al. 2001) that specifically activates the P21 GTPase Cdc42, a member of the Rho (Ras homology) family of GTPase proteins (Pasteris et al. 1994; Zheng et al. 1996; Gorski et al. 2000)
    4. Caused by mutations in the *FGDY* gene (*FGDY1*) affecting multiple skeletal structures including craniofacial bones, vertebrae, ribs, long bones, and phalanges
    5. First case of deletion of *FGD1* gene: reported in a boy with Aarskog-Scott syndrome (Bedoyan et al. 2009)
    6. Unusual facies, joint hypermobility, genital anomaly, and short stature (Bartsocas and Dimitriou 1975)
2. Aarskog syndrome: autosomal dominant (Grier et al. 1984; van de Vooren et al. 1983)
3. Aarskog-like syndrome (faciodigitogenital syndrome): autosomal dominant (Teebi et al. 1988)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_83

Clinical Features

1. Typical triad of the syndrome (Furukawa et al. 1972; Funderburk and Crandall 1974; Berry et al. 1980; Porteous and Goudie 1991; Aten et al. 2013)
    1. Facial appearance (Nielson 1988)
        1. Rounded facies
        2. Prominent metopic ridge
        3. Widow's peak hair anomaly
        4. Ocular hypertelorism
        5. Ptosis
        6. Antimongoloid obliquity of palpebral fissures
        7. Small and short nose
        8. Anteverted nares
        9. Broad nasal bridge
        10. Broad long philtrum
        11. Maxillary and mandibular hypoplasia
        12. Slight crease below lower lip
        13. Low-set ears with fleshy earlobes and incomplete outfolding of upper helices
        14. Wide phenotypic variability with severe craniofacial dysplasia (Volter et al. 2014)
    2. Digital anomalies
        1. Hands
            1. Short and broad hands
            2. Hypermobility of fingers
            3. Cutaneous syndactyly (interdigital webbing)
            4. Clinodactyly with hypoplasia of middle phalanges
            5. Transverse palmar crease
        2. Feet
            1. Short and broad feet
            2. Bulbous toes
            3. Metatarsus varus
            4. Hypoplasia of the middle or terminal phalanges
    3. Genital abnormalities
        1. Shawl scrotum (scrotal folds encircling the base of the penis): most frequently responsible for ascertainment (Duncan et al. 1977)
        2. Cryptorchidism
        3. Phimosis
        4. Hypoplasia
        5. Renal hypoplasia
2. Growth
    1. Failure to thrive
    2. Delayed puberty
    3. Slight to moderate (disproportionate acromelic) short stature (71%)
3. Intelligence and behavioral disorders (Logie and Porteous 1998)
    1. Most individuals with normal intelligence: hyperactive and attention deficits present in 61% of these individuals, which usually regress after 12–14 years of age
    2. Individuals with subnormal to mentally retarded (30%): hyperactive and attention deficits present in 84% of these individuals
4. Dental abnormalities (Halse et al. 1979; Reddy et al. 1999)
    1. Hypodontia
    2. Retarded dental eruption
    3. Orthodontic problems
5. Ocular features (Kirkham et al. 1975; Brodsky et al. 1990)
    1. Strabismus
    2. Nystagmus
    3. Amblyopia
    4. Bilateral blepharoptosis
    5. Astigmatism
    6. Hyperopia
    7. Anisometropia
    8. Corneal enlargement
    9. Deficient ocular elevation
    10. Blue sclera
    11. Posterior embryotoxon
    12. Ophthalmoplegia (Melnick and Shields 1976)
    13. Tortuosity of the retinal vessels (Pizio et al. 1994)
6. Musculoskeletal anomalies
    1. Cervical vertebral anomalies
    2. Spina bifida occulta
    3. Mild pectus excavatum

4. Genu recurvatum
5. Joint restriction
6. Prominent umbilicus
7. Inguinal hernias
8. Myopathy and distal arthropathy (Al-Semari et al. 2013)

7. Other rare signs
    1. Congenital heart defects (Fernandez et al. 1994)
    2. Gastrointestinal obstruction and volvulus in a few patients
    3. Rare perinatal occurrence of severe cerebrovascular accidents, resulting in severe neurological deficit with spastic hemiplegia (Fryns and Descheemaker 1995)
8. Phenotypic variability: wide between mother and sons and between sibs (Teebi et al. 1993)
9. Clinical variability and changing phenotype with age (Fryns 1992)
10. Carrier females often present with minor manifestations of disorder, especially relatively short stature and subtle craniofacial anomalies (Fryns et al. 1978; Hoo 1979; Pasteris et al. 1997)

Diagnostic Investigations

1. Ophthalmic examination
2. Radiography (Lizcano-Gil et al. 1994)
    1. Ocular hypertelorism
    2. Short tubular bones with widened metaphysis
    3. Brachydactyly
    4. Clinodactyly of fifth fingers
    5. Hypoplastic middle phalanges
    6. Mild interdigital webbing
    7. Cubitus valgus
    8. Splayed toes with bulbous tips
    9. Metatarsus adductus
    10. Broad flat feet
    11. Cervical vertebral anomalies
        1. Odontoid hypoplasia
        2. Fused cervical vertebrae
        3. Spina bifida occulta
    12. Scoliosis
    13. Additional pairs of ribs
    14. Retarded bone age
3. Mutation analysis: by sequencing entire coding region of *FGD1* gene available clinically
4. Application of exome sequencing in a diagnostic setting should give a significant increase in the detection of pathogenic variants by partially covering the intron–exon flanking regions. Ultimately, only full-genome sequencing will guarantee that all possible regions are taken into account (Aten et al. 2013)

Genetic Counseling

1. Recurrence risk for X-linked recessive inheritance (Aarskog-Scott syndrome)
    1. Patient's sib: 50% risk of having affected brothers if the mother is a carrier; otherwise recurrence risk is not increased
    2. Patient's offspring: 50 of his daughters to be carriers; no increased risk to his sons
2. Prenatal diagnosis
    1. Ultrasonography (Sepulveda et al. 1999): possible with a positive family history of a previously affected child by demonstrating hydrops, ocular hypertelorism, short long bones, vertebral defects, and digital anomalies in a male fetus
    2. Mutation analysis of fetal DNA from amniocytes or CVS provided the mutation has been previously identified in the proband
3. Management
    1. Supportive management
    2. Ophthalmological evaluation of the ocular problems for treatable causes of visual loss
    3. Surgery for cryptorchidism and inguinal hernia
    4. Reports of growth hormone treatment indicate a positive effect on growth and adult height in treated patients (Petryk et al. 1999)

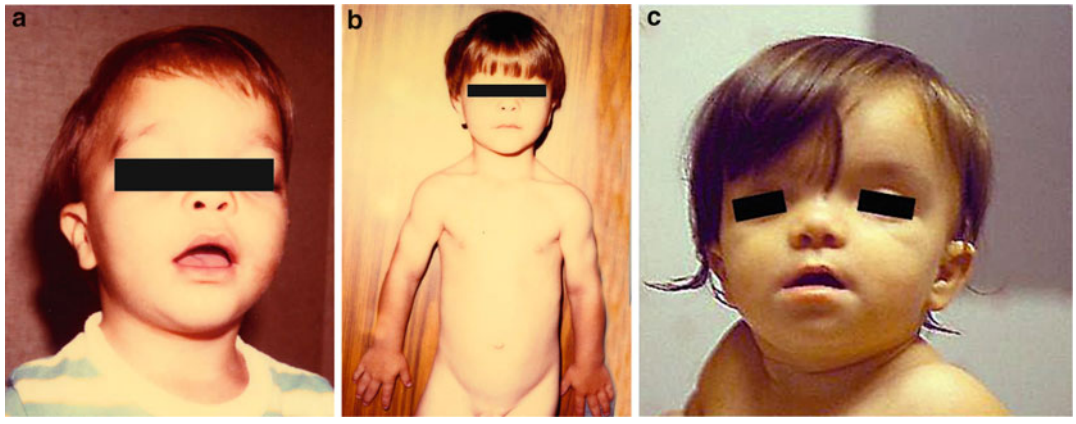

Fig. 1 (**a**–**c**) Two patients (*top* two photos (**a**, **b**) are same patient, **c**) with faciogenital dysplasia showing short stature, round face, broad forehead, hypertelorism, mild ptosis, short nose with anteverted nostrils, long philtrum, low-set ears, and broad hands with webbing of fingers

Fig. 2 (**a**–**d**) Shawl scrotums observed in four patients (**a**-**d**) with faciogenital dysplasia

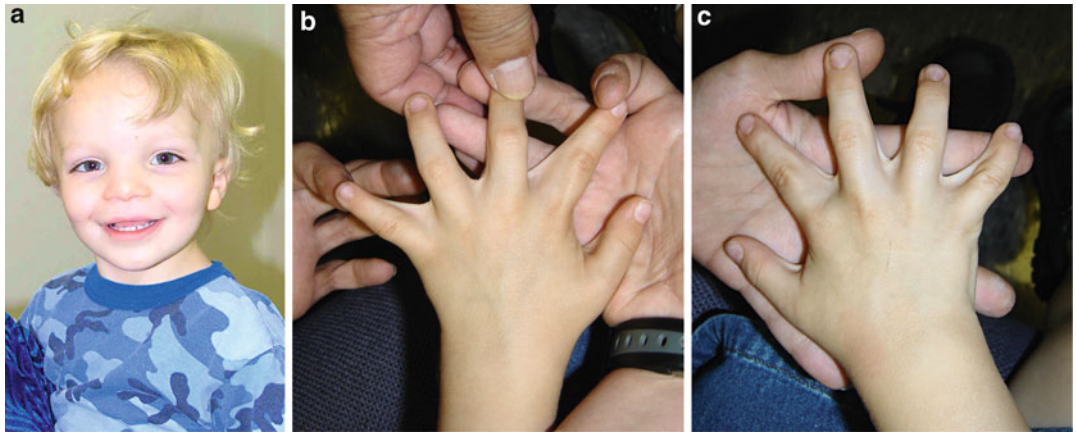

Fig. 3 (**a**–**c**) A 3-year-old boy with faciogenital syndrome showing typical facial features (round face, prominent metopic ridge, ocular hypertelorism, low-set ears) (**a**) and digital anomalies (short and broad hands and cutaneous syndactyly) (**b**, **c**)

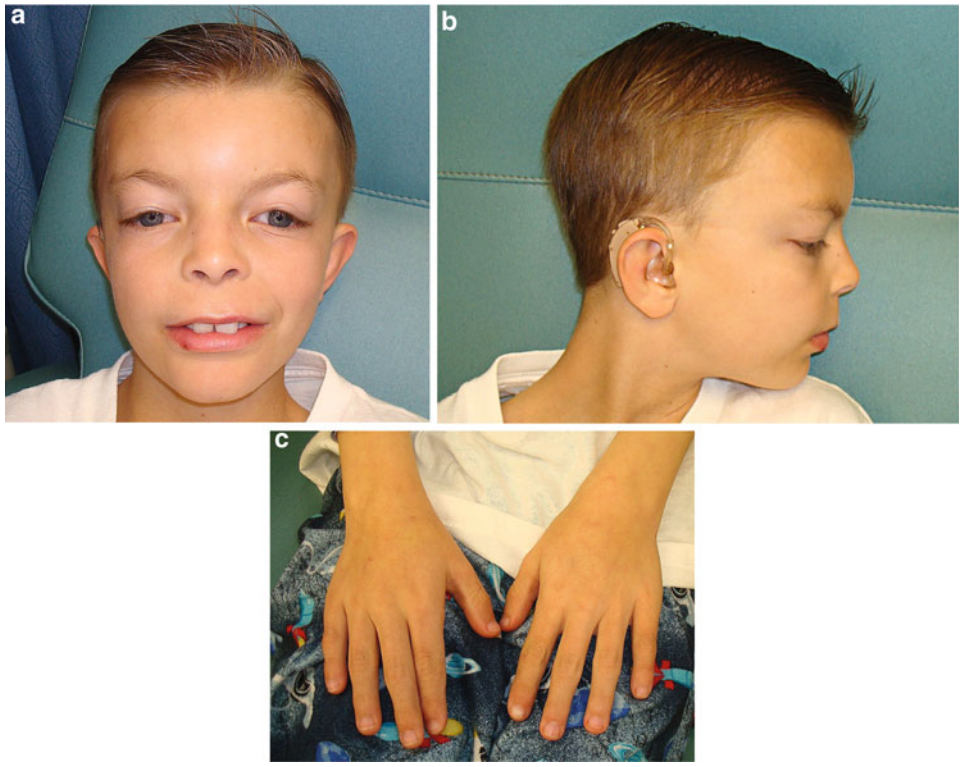

Fig. 4 (**a**–**c**) A 12-year-old boy was evaluated for short stature. On physical examination, he had ocular hypertelorism, ptosis, antimongoloid palpebral fissures, long philtrum (**a**, **b**), short and broad hands, and shawl scrotum. DNA sequencing identified a one basepair insertion at nucleotide 527 of the *FGDI* gene (c.527insC). This change is expected to cause a shift in the reading frame resulting in a truncated protein. This result is consistent with a diagnosis of Aarskog syndrome. In addition, he had sensorineural hearing loss. DNA sequence analysis indicated normal GJB2, connexin 26 (Cx26) gene

Fig. 5 His mother showed ocular hypertelorism, ptosis, and a long philtrum. She may represent a carrier with partial expression. Unfortunately, *FGS1* gene sequencing was not performed

Facioscapulohumeral Muscular Dystrophy

Contents

Facioscapulohumeral muscular dystrophy (FSHD) is the third most common neuromuscular disorder after Duchenne muscular dystrophy and myotonic dystrophy (Upadhyaya and Cooper 2002). It is characterized by progressive weakness and atrophy of the facial and shoulder girdle muscles. The other muscles are also involved. Its prevalence is estimated to be 1 in 20,000 in Europe (Lunt and Harper 1991).

Genetics/Basic Defects

1. Inheritance
    1. Autosomal dominant
    2. Almost complete penetrance (95%)
2. FSHD1
    1. *FSHD1 gene*: mapped to the subtelomeric region of chromosome 4q35.
    2. Closely linked to the highly polymorphic locus D4F104S1.
    3. Deletion of 3.3 kb tandemly repeated D4Z4 within the *Eco*RI fragment on chromosome 4q35 (van Deutekom et al. 1996): associated with the disease in 85–95% of FSHD families (Lunt et al. 1995).
    4. The deletion is pathogenic only when it is hypomethylated and resides in a 4qA161 allele (Lemmers et al. 2007).
    5. Candidate genes for FSHD not yet elucidated.
    6. Nature of the precise mutation: still unknown.
    7. Approximately 5% of FSHD families fail to exhibit linkage to 4q35, presumably indicating the presence of a second *FSHD1* locus (Upadhyaya et al. 1999).
    8. Germline mosaicism in 4q35 FSHD1A occurring predominantly in oogenesis (Köhler et al. 1996).
    9. Evidence of anticipation and association of deletion size with severity in FSHD (Tawil et al. 1996).
3. FSHD2 (Sacconi et al. 2015)
    1. A small proportion of patients (around 5–10%) with features of FSHD do not harbor a contraction of the 4q35 D4Z4 array, and they often have a complex pattern of inheritance. The molecular basis of this second form of FSHD is termed FSHD2.
    2. FSHD2 gene *SMCHD1*: a modifier of disease severity in families affected by DSHD1 (Sacconi et al. 2013)
4. Genotype-phenotype correlation
    1. Patients with a large gene deletion

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_84

1. Tendency to have a higher chance of exhibiting severe clinical phenotypes (Tawil et al. 1998)
2. Higher chance of central nervous system abnormalities

2. Patients with small *Eco*RI fragments
   1. Tendency to have earlier-onset disease
   2. More rapid progression
3. Correlation between the size of the disease-associated 4q35-*Eco*RI fragment and the following parameters:
   1. Age at onset of symptoms.
   2. Age at loss of ambulation.
   3. Muscle strength as measured by quantitative isometric myometry.
4. Prognosis varies with the length of the p13E-11 fragment (i.e., the number of *Kpn*I repeat units spared by the deletion) (Ricci et al. 1999).
   1. Patients with very short fragments (1–2 *Kpn*I repeats left): 100% probability of developing a severe form of the disease.
   2. Patients carrying fragments of 16–20 kb (3–4 *Kpn*I repeats left): probability decreases to 54%.
   3. Patients carrying fragments larger than 20 kb (>4 repeats left): probability drops to 21% or less and also they are compatible with asymptomatic conditions in adult age.
5. De novo mutations
   1. Association with smaller *Eco*RI fragments (on average) than those segregating in families
   2. Tendency of patients with de novo mutations to have findings the more severe end of the phenotypic spectrum
6. Reduced penetrance in females bearing the FSHD small fragment as compared to the penetrance in males with the FSHD small fragment
7. Germinal mosaicism (Upadhyaya et al. 1995)

5. Categories of FSHD (Padberg and van Engelen 2009)
   1. Severe disease, infantile form, onset usually before the age of 10 years with one to three residual D4Z4 repeats
   2. Moderate disease or classical phenotype with four to seven repeats and with a widely variable course, encompassing a large percentage of asymptomatic carriers older than 50 years and 60% lower limb involvement with 20% wheelchair use after this age
   3. Mild disease with eight to ten residual D4Z4 repeats, probably with frequent nonpenetrant gene carriers and muscle involvement limited to the upper limbs

Clinical Features

1. Marked clinical variability
   1. Age at onset
      1. Usually between the first and second decade
      2. Progress gradually over time
   2. Pattern of muscle involvement
      1. Progressive weakness and atrophy of the facial and shoulder girdle muscles
      2. Other muscles affected in a specific order
         1. Abdominal muscles involved first
         2. Followed by foot-extensor and upper arm muscles
         3. Finally involving pelvic girdle and lower arm muscles
   3. Intrafamilial variability
   4. Interfamilial variability
   5. Phenotype ranging from almost asymptomatic forms to more severe wheelchair-bound forms
2. A distinctive distribution of progressive muscular weakness involving the following muscles (Kissel 1999)
   1. Facial muscles
      1. Typically involved:
         1. Orbicularis oculi
         2. Orbicularis oris
      2. Clinical signs
         1. Often asymmetric involvement
         2. Facial weakness
         3. Unable to turn up the corners of the mouth when smiling
         4. Difficulty in whistling

5. Unable to purse lips
6. Sleeping with eyes partially open, the most common early sign
7. Bury eyelashes when attempting to close eyelids tightly
8. Sparing of extraocular, eyelid, and bulbar muscles

2. Scapular stabilizer muscles
   1. Affected muscles
      1. Latissimus dorsi
      2. Trapezius
      3. Rhomboids
      4. Serratus anterior
   2. Clinical signs
      1. Sloping shoulder posture at rest
      2. Anterior axillary folds
      3. Straight (horizontally placed) clavicles
      4. Pectoral muscle atrophy
      5. Scapular winging, the most common initial finding
      6. Preferential weakness of the lower trapezius muscle, resulting in characteristic upward movement of the scapula when attempting to flex or abduct the arms
3. Proximal arm muscles
   1. Biceps and triceps selectively involved, resulting in atrophy of the upper arm
   2. Distal progression of wasting and weakness of upper arm muscles, leading to eventual weakness of wrist and finger extensors
   3. Deltoids minimally affected until late in the disease
   4. Sparing of the forearm muscles, resulting in so-called "popeye arms" appearance
4. Abdominal muscles
   1. Abdominal muscle weakness resulting in:
      1. Protuberance of the abdomen
      2. Exaggerated lumbar lordosis
   2. Selective involvement of the lower abdominal muscles, resulting in Beevor's sign (upward displacement or occasionally downward movement of the umbilicus upon flexion of the neck in a supine position)
      1. Present in 90% of patients.
      2. Helpful early sign in patients with equivocal findings, as it is rarely found in other muscle disorders.
      3. Positive Beevor's sign may be caused by spinal cord injury at or below the level of Th10 (Eger et al. 2010).
5. Lower extremity muscles
   1. Anterior compartment muscles of the distal leg (anterior tibial and peroneal muscles)
      1. Usually the first and most severely affected
      2. Resulting in the typical complaints of a foot slap while walking or frank foot drop
      3. Frequent tripping or unstable walking, particularly on uneven ground
   2. Pelvic girdle muscles
      1. Less common
      2. Involving hip flexors and hip abductors
      3. Resulting in early and relatively severe gait involvement

3. Degree of muscle involvement
   1. Extremely variable
   2. Wide range of muscle involvement
      1. Very mildly affected patients unaware of the disease symptoms
      2. Isolated facial weakness
      3. Severe generalized weakness
      4. Eventually requiring a wheelchair in approximately 20% of patients
   3. Sex difference in penetrance: males more severely affected than females
4. Clinical course of muscle involvement
   1. Early involvement of facial and scapular muscles with eventual spreading to pelvic and lower limb muscles
   2. A slowly progressive course
   3. A stepwise course with periods of rapid deterioration occurring against a background of stability
   4. Aggravation of muscle weakness during pregnancy but recover quickly in the puerperium

5. Bulbar and pharyngeal muscles, extraocular muscles, and respiratory muscles typically spared
5. Extra-muscular involvement (uncommon)
    1. Coats syndrome (Fitzsimons 1999)
        1. Neurosensory hearing loss (64%)
        2. Retinal vasculopathy (49–75%)
            1. Tortuosity of retinal arterioles (microaneurysms)
            2. Telangiectasia
    2. Mental impairment
    3. Cardiac involvement (5%)
        1. Conduction defects
        2. Supraventricular arrhythmia
    4. Neurologic manifestations
        1. Preserved sensation
        2. Often diminished reflexes
6. Diagnostic criteria include the following four main elements: The diagnosis of FSHD often remains a clinical diagnosis (Kissel 1999).
    1. Onset of disease in the facial or shoulder girdle muscles, sparing the eyes, pharynx, tongue, and heart
    2. Facial weakness in more than 50% of affected family members
    3. Autosomal dominant inheritance in familial cases
    4. Evidence of myopathic disease by electrodiagnostic studies and muscle biopsy in at least one affected family member
    5. In the absence of (Statland and Tawil 2014):
        1. Ptosis, weakness of extraocular muscles, or bulbar weakness
        2. Electromyography in a patient or affected family member showing myotonia or neurogenic changes

Diagnostic Investigations

1. Increase of seven serum biomarkers (no difference detected between FSHD types 1 and 2 for these markers (Statland et al. 2014))
    1. Creatine kinase
    2. Myoglobin
    3. Plasminogen pathway markers (tissue-type plasminogen activator)
    4. Vitronectin
    5. Inflammatory marker chemokine ligand 2
    6. Inflammatory marker CD40 ligand
    7. Epidermal growth factor
2. Serum creatine kinase (CK)
    1. Normal to elevated levels: raised level in only 80% of affected males under 40 years and 48% of affected women (Lunt and Harper 1991)
    2. Usually not exceeding three to five times the upper limit of the normal range
3. Audiogram for sensorineural hearing loss
4. Fluorescein angiography to demonstrate retinal vasculopathy
5. EMG: nonspecific myopathic features
    1. Fibrillations
    2. Positive waves in resting muscle
    3. Early recruitment of short-duration motor unit action potentials
6. Muscle biopsy: nonspecific features
    1. Underlying process: myopathic and help to exclude the following primary muscle diseases that can present with a FSHD-like phenotype (Kissel 1999)
        1. Congenital myopathies
            1. Nemaline (rod) myopathy
            2. Centronuclear myopathy
        2. Inflammatory myopathies
            1. Polymyositis
            2. Inclusion body myositis
        3. Other dystrophies
            1. Scapuloperoneal dystrophy
            2. Limb-girdle dystrophy
        4. Others: desmin storage myopathy
    2. Increased variation in fiber size
    3. Increased internalized nuclei
    4. Variable degrees of endomysial inflammatory cells
    5. Angulated “neuropathic-like” myofibers
    6. Mononuclear inflammatory reaction (75%)
7. Molecular genetic testing (Kissel 1999)
    1. Molecular confirmation of FSH may be sought (Fitzsimons 1999):
        1. To exclude another form of dystrophy

2. To exclude nonpenetrant carrier status in an adult
3. To diagnose the FSH status of a fetus
4. Useful in infants who present sporadically with deafness combined with facial immobility

2. Mutation analysis
   1. Combination of double digestion with *Eco*RI and *Bln*I followed by pulsed field gel electrophoresis: the most reliable molecular protocol for distinguishing patients with FSHD (Orrell et al. 1999).
   2. Detection of the short fragment in affected individuals.
      1. High sensitivity and specificity of the 4q35 deletion for FSHD.
      2. Using probe p13E-11 (D4F104S1), which hybridized to 4q35, to detect small *Eco*RI digestion fragments (Felice and Moore 2001).
      3. Deletion within the D4Z4 repeat region of chromosome 4q35 (demonstrable short fragment), observed in 95% of patients clinically affected with FSHD, whether familial or sporadic.
      4. Approximately 98% of patients with such a short fragment have clinically demonstrable FSHD.
      5. Confirms the diagnosis with a high degree of certainty.
   3. Large deletions in the 4q35 region (producing a smaller short fragment).
      1. Associated with more severe expression of the disease
      2. Manifest earlier onset of disease
      3. More severe degree of weakness
      4. Shorter fragment size generally associated with sporadic cases with an earlier age of onset than with familial cases
   4. Variability in fragment size: unable to explain the significant clinical variability sometimes seen within FSHD families, since the deletion size appears to remain stable from generation to generation.
   5. Findings of a short but less intensively hybridizing p13E-11/*Eco*RI/*Bln*I fragment strongly suggest germinal mosaicism. Minor clinical signs in parents may point toward germline mosaicism.
3. Genetic diagnosis (Tawil et al. 2010)
   1. The large majority (>95%) of patients with FSHD have a partially deleted D4Z4 repeat array on one of their chromosomes 4 (FSHD1).
   2. This repeat array is polymorphic in copy number, with alleles varying between 11 and 100 units in the general population.
   3. Patients with FSHD1 carry one allele with one to ten D4Z4 units (Tawil and van der Maarel 2006).
   4. In order to be pathogenic, this shortened D4Z4 repeat array needs to reside on the 4qA background of chromosome 4.
4. Absence of identifiable D4Z4 deletions in approximately 5% of individuals with FSHD

Genetic Counseling

1. Recurrence risk
   1. Patient's sib
      1. Ten percent risk for a sib of a de novo case being a carrier. The figure of 10% is based on the observation that both somatic and germinal mosaics are detected, indicating that both types of mutations occur early in embryogenesis and therefore will give rise to a high percentage of mutated germ cells (Bakker et al. 1996).
      2. Fifty percent recurrence risk if a parent is affected.
   2. Patient's offspring: each offspring of an affected individual having a 50% chance of inheriting the deleted region within the D4Z4 repeat motif for FSHD
2. Prenatal diagnosis (Tawil et al. 2010)
   1. Available for fetuses at 50% risk for FSHD

2. Molecular genetic testing: follow a de novo mutation in a subsequent generation by analyzing DNA extracted from fetal cells obtained by (Bakker et al. 1996):
    1. CVS: preferred over amniocentesis since genetic diagnosis for FSHD can take several weeks to complete
    2. Amniocentesis
3. Conditions for inclusion for prenatal diagnosis
    1. Confirmed FSHD1 in the family
    2. Availability of DNA from parents and index case
4. Preimplantation genetic diagnosis (PGD)
    1. Southern blot genetic test: not applicable to single-cell PGD.
    2. Consequently, the disease-associated D4Z4 repeat can only be detected indirectly with the use of polymorphic markers, but the relatively high recombination frequency and the availability of few polymorphic markers specific for the region proximal to D4Z4 hamper PGD significantly.

3. Management (Kissel 1999; Lemmers and van der Maarel 2014)
    1. Lack of effective treatment
    2. Unpredictability of the clinical course
    3. Management of pain in the shoulders, back, abdomen, and leg
        1. Use of nonsteroidal anti-inflammatory drugs
        2. Range-of-motion exercise
        3. Gentle stretching through a physical therapy program
    4. Physiotherapy (Eggers et al. 1993)
    5. Supportive treatment of complications from progressive weakness
        1. Judicial use of bracing
        2. Ankle and foot orthoses to improve mobility and prevent falls in patients with foot drop
        3. Surgical fixation of the scapula to the chest wall (thoracoscapular fusion) or to the ribs (scapulocostal fusion)
            1. Often improving range of motion of the arms
            2. Short-lived effect in patients with rapidly progressive disease
    6. Pharmacologic treatment
        1. Limited to the use of corticosteroids in patients with evidence of inflammation on muscle biopsy
        2. Possible effect of albuterol, a β2-adrenergic agent (Sripathi 2014)
            1. Improvement of lean body mass
            2. Modest improvement in strength
    7. Treat respiratory dysfunction which occurs in <1% of patients with FSHD (Wohlgemuth et al. 2004)
    8. Treat cardiac dysfunction which is seen in about 5% of patients (Laforet et al. 1998)
    9. Pregnancy in FSHD
        1. Pregnancy outcomes in FSHD are generally good although two case series have conflicting reports about an increased incidence of operative deliveries and preterm births (Rudnik-Schoneborn et al. 1997; Ciafaloni et al. 2006).
        2. Pregnant women with FSHD be followed by high-risk obstetricians and that delivery occurs in a center that can provide comprehensive perinatal care.
        3. Additionally, it is recommended that pregnant women with FSHD and reduced lung function have serial monitoring of their FVC during the course of their pregnancy.
    10. Required assistance in caring the infants after delivery due to weakness in the shoulder girdle
    11. Evidence-based guideline for evaluation, diagnosis, and management of facioscapulohumeral muscular dystrophy (Tawil et al. 2015)
        1. Available genetic testing for FSHD type 1 is highly sensitive and specific.
        2. Although respiratory insufficiency occurs rarely in FSHD, patients with severe FSHD should have routine pulmonary function testing.
        3. Routine cardiac screening is not necessary in patients with FSHD without cardiac symptoms.

4. Symptomatic retinal vascular disease is very rare in FSHD. Exudative retinopathy, however, is potentially preventable, and patients with large deletions should be screened through dilated indirect ophthalmoscopy.
5. The prevalence of clinically relevant hearing loss is not clear. In clinical practice, patients with childhood-onset FSHD may have significant hearing loss. Because undetected hearing loss may impair language development, screening through audiometry is recommended for such patients.
6. Musculoskeletal pain is common in FSHD, and treating physicians should routinely inquire about pain.
7. There is at present no effective pharmacologic intervention in FSHD.
8. Available studies suggest that scapular fixation is safe and effective. Surgical scapular fixation might be cautiously offered to selected patients.
9. Aerobic exercise in FSHD appears to be safe and potentially beneficial. On the basis of the evidence, patients with FSHD might be encouraged to engage in low-intensity aerobic exercises.

Fig. 1 A child with FSHD showing periscapular wasting and weakness resulting in scapular winging and inability to abduct the arm above the horizon

Fig. 3 An adult with FSHD showing facial weakness and inability to smile, purse the lips, and whistle

Fig. 2 An adult with FSHD showing scapular winging and wasting of proximal arm muscles

Fig. 4 (**a**–**c**) A 14-year-old boy with FSHD showing sloping shoulders, inability to raise arms above shoulders, and inability to close his eyelids completely. In addition, he had difficulty in pursing the lips and could not whistle (onset at about 2 years of age). His CPK was 1,295 (normal, 0–200 U/L). Molecular genetic analysis revealed FSHD allele 1 of 18 kb and FSHD allele 2 of >48 kb (FSHD deletion, 12–37; marginal, 38–41; no deletion, ≥42). The mother and several other family members are also affected

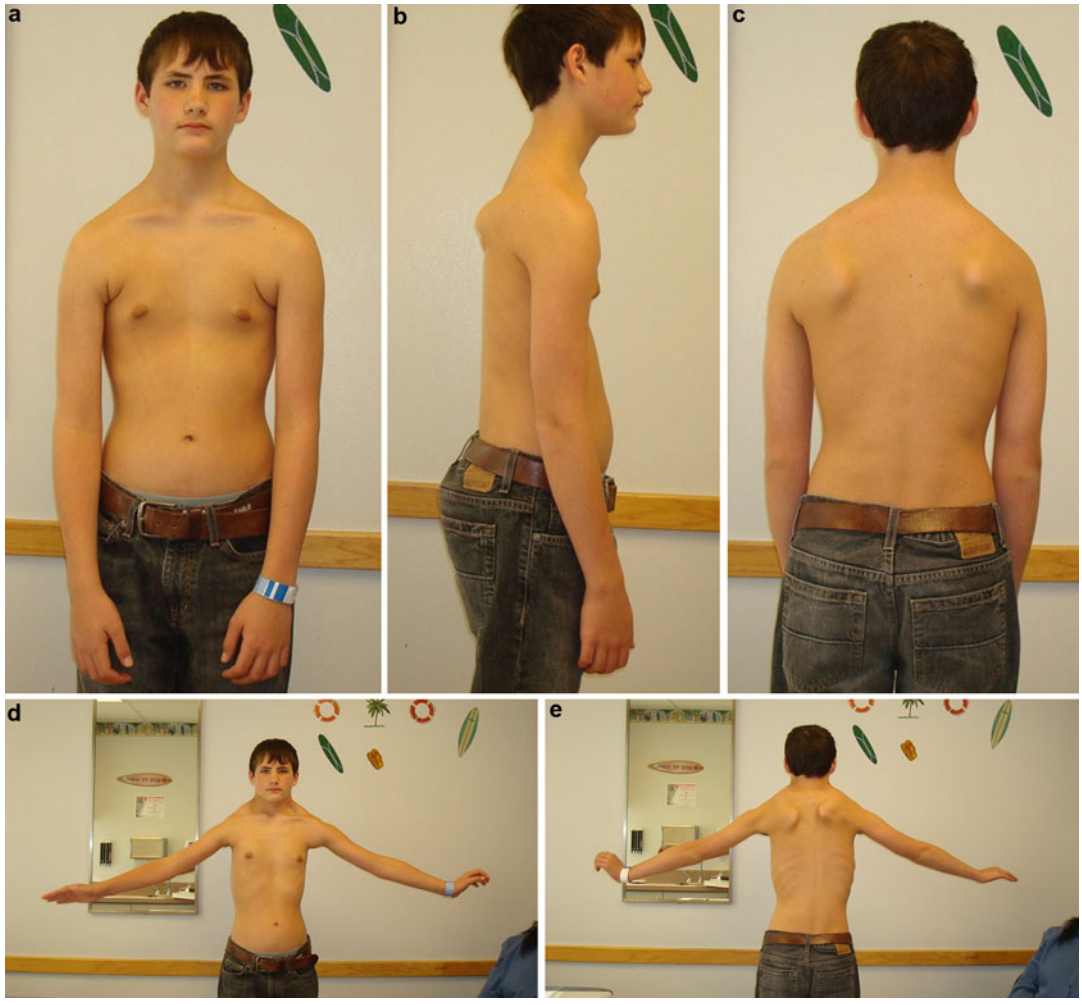

Fig. 5 (**a**–**e**) A 13-year-old boy was evaluated for his scapula deformities. He could not purse his lips, whistle, or smile. He could not raise his arms above his shoulders for the last 6 months. He had an elevated CK of 717 (normal, 35–232). On physical examination, he was noted to have sloping shoulder posture at rest, winging scapular, pectoral muscle atrophy, and mild atrophy of the upper arms. Molecular genetic testing revealed an FSHD gene mutation with allele 1 of 13 kb and allele 2 of >48 kb consistent with the diagnosis of facioscapulohumeral muscular dystrophy

Fig. 6 This 19-year-old female was evaluated for inability to raise arms above shoulders. Molecular genetic analysis revealed FSHD allele 1 of 22 kb (FSHD deletion mutation) and FSHD allele 2 of >48 kb (normal allele), confirming the clinical diagnosis of facioscapulohumeral muscular dystrophy

Familial Adenomatous Polyposis

Contents

Germline mutations in the adenomatous polyposis coli (*APC*) gene cause the most common form of hereditary polyposis syndromes termed "familial adenomatous polyposis (FAP)." The incidence is approximately 1 in 8,300 to 1 in 13,000 live births (Bisgaard et al. 1994).

Synonyms and Related Disorders

Adenomatous intestinal polyposis; Attenuated FAP; Familial colorectal cancer syndromes; Familial polyposis of the colon (familial polyposis coli); Gardner syndrome; Hereditary gastrointestinal cancer syndrome; Hereditary mixed polyposis; Hereditary polyposis syndrome; Juvenile polyposis; Lynch syndrome; MYH-associated polyposis; Peutz-Jeghers syndrome; Polymerase proofreading polyposis; PTEN hamartoma tumor (Cowden) syndrome; Serrated polyposis; Turcot syndrome

Genetics/Basic Defects

1. Inheritance
    1. Autosomal dominant (AD) with high penetrance (80–100%)
    2. Spontaneous mutations account for approximately 30% of cases
2. Caused by germline mutations in the adenomatous polyposis coli (*APC*) gene on chromosome 5q21 (Leppert et al. 1987; Lynch and Hoops 2002)
    1. More than 300 different disease-causing mutations of the *APC* gene are currently identified
    2. Nonsense or frameshift mutations that result in a truncated protein in nearly all of the germline mutations in APC
    3. Nearly 80% of FAP families have identifiable germline mutations in one allele of *APC* in affected individuals
    4. Similar high incidence of germline mutations is seen in the FAP variant, Gardner syndrome
3. *APC* gene
    1. A large gene consisting of approximately 6 kb in length
    2. A tumor suppressor gene encoding for a 2,843-amino acid protein with a putative role in:
        1. Cell adhesion
        2. Signal transduction
        3. Transcriptional activation

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_85

3. The causative germline defect of *APC* gene predisposes to the following conditions (Gebert et al. 1999):
    1. FAP
    2. Nearly obligatory colorectal cancers
4. Loss of second *APC* allele either by somatic mutation or loss of heterozygosity in the earliest premalignant lesions:
    1. Dysplastic aberrant crypt foci
    2. Small adenomatous polyps
5. Adenoma formation (Robbins and Itzkowitz 2002)
    1. Beginning with loss of function of the APC tumor suppressor gene
    2. Followed by activation of the K-ras oncogene
    3. Subsequent loss of function of genes on chromosome 18q and inactivation of p53 ushers in malignant degeneration
6. The site of APC gene mutation is associated with pigmented ocular fundus lesions (codons 542–1309) and predisposition to multiplicity of extraintestinal manifestations (codons 1465, 1546, and 2621) (Giardiello et al. 1997)

4. Colorectal carcinogenesis: involves two principal pathways (Robbins and Itzkowitz 2002):
    1. Chromosomal instability
        1. Deletion of portions of a chromosome results in loss of specific genes and abnormal amounts of DNA per cell (aneuploidy). This pathway accounts for:
            1. All cases of colorectal cancers associated with FAP
            2. Nearly 85% of sporadic colorectal cancers
        2. The pathway of *c-myc* and *β-catenin* as downstream targets appears to impact on the kinetochore and microtubule attachment
        3. Mutations in *APC* interfere with the way that epithelial cells divide and distribute their nuclear DNA
        4. Mutations in the APC tumor suppressor gene cause chromosomal instability (Fodde et al. 2001)
    2. Microsatellite instability
        1. Produced by defects of the DNA base mismatch repair system
        2. This pathway accounts for:
            1. 15% of sporadic colorectal cancers
            2. Most cases of hereditary nonpolyposis colorectal cancer
5. Genotype-phenotype correlation
    1. FAP phenotype expressed in an individual depends in part on the site of the germline *APC* mutation
        1. Attenuated familial adenomatous polyposis coli occurs when there is a truncating mutation in the extreme ends of the *APC* coding sequence (Spirio et al. 1993; Soravia et al. 1998)
        2. Germline mutations in the 3′ part of APC exon 15 do not result in truncated proteins and are associated with attenuated adenomatous polyposis coli (Van der Luijt et al. 1996)
        3. Mutations between codons 169 and 1,393 resulting in classic FAP
        4. Mutations between codons 1,250 and 1,464, especially around codon 1,300, resulting in profuse colorectal polyposis and earlier onset of gastrointestinal polyps (Nagase et al. 1992)
        5. Retinal lesions (congenital hypertrophy of the retinal pigment epithelium, a condition present at any age in 60% of FAP families) occur only with mutations between codons 457 and 1,444 (Lynch and Hoops 2002; Cruz-Correa and Giardiello 2003)
        6. Up to 60% of patients with mutations between codons 1,445 and 1,580 result in desmoids (Leggett 2002)
    2. Limited clinical application of genotype-phenotype correlation: Considerable phenotypic variability exists even among individuals and families with identical genotypic mutations
6. Familial colorectal cancer syndromes (Novelli 2015; Syngal et al. 2015)
    1. FAP
    2. Attenuated FAP

3. Lynch syndrome (AD) (*MLH1*, 3p21.3; *PMS2*, 7p22.1; *MSH2*, 2p21; *MSH6*, 2p16.3)
    1. Polyp type(s): conventional adenomas
    2. Extraintestinal features: endometrial adenocarcinoma, transitional cell carcinoma of upper urogenital tract, ovarian carcinoma, pancreatobiliary carcinoma, brain tumors, skin tumors
4. MYH-associated polyposis (autosomal recessive) (*MUTYH*, 1p34.3)
    1. Polyp type(s): conventional adenomas, serrated polyps
    2. Extraintestinal features: Some FAP-type extraintestinal features but at low incidence
5. Serrated polyposis (unknown)
    1. Polyp type(s): serrated polyps (conventional adenomas)
    2. Extraintestinal features: none
6. Hereditary mixed polyposis (AD) (*GREM1*, 15q13.3)
    1. Polyp type(s): conventional adenomas, serrated polyps, hamartomas (juvenile polyps)
    2. Extraintestinal features: none
7. Polymerase proofreading polyposis (AD) (*POLE*, 12q24.3; *POLD1*, 19q13.33)
    1. Polyp type(s): conventional adenomas
    2. Extraintestinal features: endometrial carcinomas, ?brain tumors
8. Peutz-Jeghers syndrome (AD) (*STK11*, 19p13.3)
    1. Polyp type(s): hamartomas (polyps)
    2. Extraintestinal features: carcinomas in many organs
9. Juvenile polyposis (AD) (*SMAD4*, 18q21.1; *BMPR1A*, 10q23)
    1. Polyp type(s): hamartomas (juvenile polyps)
    2. Extraintestinal features: none
10. PTEN hamartoma tumor (Cowden) syndrome (AD) (*PTEN*, 10q23)
    1. Polyp type(s): conventional adenomas, hyperplastic polyps, hamartomas, ganglioneuromas, inflammatory polyps
    2. Extraintestinal features: breast carcinoma
11. Constitutional mismatch repair deficiency (autosomal recessive) (*MLH1*, 3p21.3; *PMS2*, 7p22.1; *MSH2*, 2p21; *MSH6*, 2p16.3)
    1. Polyp type(s): conventional adenomas
    2. Extraintestinal features: Cafe-au-lait spots, high-grade brain tumors, leukemias/lymphomas

Clinical Features

1. Spectrum of disease activity (Half et al. 2009)
    1. Attenuated FAP (AFAP): mild form of FAP
        1. Fewer number of adenomatous polyps: less than 100
        2. A later age of adenoma development and onset for colorectal cancers
    2. Fulminant FAP
        1. With hundreds to thousands of polyps at a young age
        2. A nearly 100% risk of developing colorectal cancers by the age of 40
2. Usually asymptomatic until puberty when colonic polyps begin to develop, the adenomas become large and numerous so as to cause rectal bleeding or even anemia
3. Average age of onset of polyps: 25 years
4. Presenting signs and symptoms
    1. Rectal bleeding: the most common symptom
    2. Anemia
    3. Abdominal pain
    4. Change in bowel habits, constipation, or diarrhea, occurring approximately 8 years later
    5. Palpable abdominal masses
    6. Weight loss
    7. Above signs and symptoms in young patients can lead to rectosigmoid examination and identification of polyps suggestive of FAP

5. Relative and approximate contributions of familial causes to the incidence of colorectal cancer (Half et al. 2009)
    1. About 85% of cases are sporadic
    2. Approximately 10% are familial cancer
    3. Three to five percent are hereditary nonpolyposis colorectal cancer (Lynch syndrome)
    4. Less than one percent are FAP, familial juvenile polyposis, and Peutz-Jeghers syndrome
6. Colonic manifestations of FAP
    1. Characterized by the presence of hundreds to thousands of colorectal adenomas of different sizes. Today, this is rarely seen in countries with well-developed public health services
    2. In the majority of patients, polyps begin to develop during childhood, mostly in the distal colon (rectosigmoid) as small intramucosal nodules
    3. By the time of adolescence, the polyps are usually identified throughout the colon and, thereafter, increase in size and numbers
    4. About half of FAP patients develop adenomas by 15 years of age and 95% by age 35 years (Petersen et al. 1991)
    5. Generally, cancers start to develop a decade after the appearance of the polyps. So, if the colon is left intact, the majority of patients with FAP eventually develop CRC by the ages 40–50 years
    6. Although uncommon, colorectal cancers can develop in children or in older adults
    7. Other gastrointestinal manifestations
        1. Gastric polyps (fundic gland polyps) develop in the stomach in 90% of patients with FAP
            1. Typically benign
            2. Adenomatous in rare cases
            3. An increased rate of gastric cancer in some kindreds
            4. Gastric cancer occur more frequently than duodenal cancer in Japanese FAP kindreds (Opposite is true for FAP kindreds with European Caucasian descent)
            5. Gastric adenomas occur in 50% of Japanese FAP kindreds
        2. Duodenal or periampullary (Bjork et al. 2001) adenomatous polyps (5–10% lifetime risk)
            1. May progress to cancer
            2. Five percent of these patients develop malignant transformation within 20 years after the onset of polyps
        3. Other small intestinal tract polyps: rare
    8. Adenomas of the ileal pouch may follow proctocolectomy
7. Extraintestinal (extracolonic) manifestations (Parks et al. 1970; Gebert et al. 1986)
    1. Pancreatic (2%) and biliary tract cancers: rare
    2. Adrenal adenomas: rare
    3. Papillary thyroid carcinomas
        1. Affect about 1–2% of patients with FAP
        2. A hundred-fold increased risk in the women with FAP
        3. Activation of *ret/ptc1* oncogene in FAP-associated thyroid papillary carcinomas (Cetta et al. 1998)
    4. Hepatoblastomas: a 1–3% risk of developing hepatoblastomas from birth until 6 years of age in infants and children who are at risk or known APC mutation carriers (Hughes and Michels 1992)
    5. Brain (medulloblastoma, glioblastoma) (<1%) (Cohen 1982)
    6. Osteomas (Jagelman 1987)
    7. Congenital hypertrophy of retinal pigment epithelium
        1. Multiple and bilateral lesions: a sensitive phenotypic marker that can direct clinical screening tests prior to or in lieu of genetic screening in an at-risk member of an FAP kindred
        2. Generally a benign condition but low-grade adenocarcinoma of the retina has been reported in several individuals with this condition

8. Dental abnormalities
    1. Unerupted teeth
    2. Congenital absence of one or more teeth
    3. Supernumerary teeth
    4. Dentigerous cysts
    5. Odontomas
9. Cutaneous lesions: rarely malignant
    1. Fibromas
    2. Lipomas
    3. Sebaceous and epidermoid cysts
    4. Nasopharyngeal angiofibromas

8. Desmoid tumors (Gebert et al. 1986; Jones et al. 1986; Clark et al. 1999)
    1. Also known as mesenteric fibromatosis
    2. A relatively common complication of FAP (Klemmer et al. 1987; Sturt and Clark 2006)
        1. A lifetime risk for men: 8%
        2. A lifetime risk for women: 13%
    3. No metastatic potential but can be both life threatening or problematic in treatment when the lesions slowly expand:
        1. To involve the intra-abdominal cavity
        2. To surround the nervous or vascular systems
    4. Conditions which may accelerate the growth:
        1. Surgery
        2. Estrogen receptor antagonists
        3. Radiation
        4. Chemotherapy
    5. Common recurrence
    6. Desmoids may follow a slow but unrelenting course with a lethal outcome (Herrera-Ornelas et al. 1987)
9. FAP variants (Lynch et al. 1979)
    1. Gardner syndrome
        1. Refers to FAP with additional extraintestinal phenotypic manifestations accompanying colonic polyposis
            1. Osteomas
            2. Sebaceous cysts
            3. Lipomas
            4. Desmoids
            5. Dental abnormalities
        2. Caused by mutations in the *APC* gene
    2. Attenuated FAP
        1. Characterized by the development of significantly fewer colonic adenomas (<100)
        2. Typically right-sided polyps
        3. Seventy percent of patients develop colorectal cancers by age 65 if polypectomy is not performed
        4. Presence of fundic gland polyps, a clue to the possible diagnosis of AFAP
    3. Turcot syndrome
        1. Characterized by medulloblastoma in association with colonic polyposis and colorectal cancers
        2. Caused by germline *APC* mutations
        3. Variable inter- and intrafamilial phenotypic expression

10. Differential diagnosis with two other main polyposis syndromes (Lynch et al. 1979) and one nonpolyposis syndrome, all of which are associated with an increased risk of GI cancer, especially colorectal cancer (Järvinen 2003)
    1. Juvenile polyposis
        1. An autosomal dominant disorder
        2. Caused by at least two separate genes
            1. *SMAD4*/*DPC4* in chromosome 18q21
            2. *BMPR1A*/*ALK3* in chromosome 10q21-22
        3. Characterized by multiple juvenile polyps of the colorectum
        4. Also involves the stomach and the small intestine
        5. Large polyps
            1. Commonly lobulated
            2. Adenomatous dysplasia in 50% of cases, giving rise to the increased risk of colorectal cancer (Järvinen and Franssila 1984)
        6. The APC gene mutation of familial juvenile polyposis suggests a genetic relationship with familial adenomatous polyposis (Kim et al. 1997)
    2. Peutz-Jeghers polyposis
        1. An autosomal dominant disorder
        2. Caused by mutations of the *LKB1* gene on 19p13.3

3. Characteristics
    1. Mucocutaneous melanin pigmentation
    2. Hamartomatous intestinal polyposis
4. Sites of polyps
    1. Affect small intestine preferentially
    2. Also affect stomach and large intestine

3. Hereditary nonpolyposis colorectal cancer syndrome (Lynch syndrome)
    1. An autosomal dominant disorder
    2. Caused by mutations of three DNA mismatch repair genes
        1. *MSH2* (2p21-23)
        2. *MLH1* (3p21)
        3. *MSH6* (2p16)
    3. More common than the polyposis syndromes
    4. Predominant tumors
        1. Colorectal cancer
        2. Endometrial cancer
    5. Other cancer types: cancers of the stomach, ovary, ureter and renal pelvis, bile ducts, kidney, small intestine, and brain tumors

Diagnostic Investigations

1. Basis of diagnosis of classic FAP (Eccles et al. 1997; Gebert et al. 1999)
    1. Suggestive family history
    2. Clinical findings
    3. Confirmed by genetic testing whenever possible
2. Screening in FAP (Boardman 2002)
    1. Colonoscopic examination for at risk and *APC* mutation carriers, initiate at 10–12 years of age
    2. Flexible sigmoidoscopy for at-risk individuals with unknown mutation status
        1. Annually from age 10 to 15
        2. Biennially from age 26 to 35
        3. Every third year from age 36 to 50
    3. Upper GI tract endoscopy for at-risk individuals with colorectal polyps and known gene carriers. Recent progress in endoscopic technology, including high-resolution endoscopy, capsule endoscopy, and double-balloon endoscopy, has made possible more detailed and wide-ranging investigation of the gastrointestinal tract (Aihara et al. 2014)
    4. Annual physical examination to assess thyroid nodules
    5. Hepatoblastoma screening in children with FAP (at risk or mutation-positive carriers until age 6)
        1. Annual screening by liver ultrasonography
        2. Annual serum α-fetoprotein levels
    6. Medulloblastoma screening: brain imaging for symptomatic or known Turcot syndrome kindreds
    7. Imagings (King et al. 2000)
        1. CT scan for desmoid tumors of the mesentery
        2. MRI to delineate vascular involvement and to predict desmoid growth
3. Screening in AFAP
    1. Colonoscopy required for individual at risk for AFAP
    2. Continued screening in the individual with AFAP because of the later age of onset of polyps
4. Detection of FAP in known kindreds
    1. Retinoscopy: Presence of more than three pigmented ocular fundic lesions confirms the diagnosis of FAP
    2. Flexible sigmoidoscopy
    3. Presymptomatic *APC* gene testing (Park et al. 1994)
        1. Indications (Leggett 2002)
            1. Children and siblings of affected individuals with FAP or AFAP: usually delayed until the early teenage years (10 years or older) when screening by flexible sigmoidoscopy would normally commence
            2. Patients with an unusually high number of colorectal adenomas for their age but not enough to be clinically diagnostic of classical FAP ($\geq$20 cumulative colorectal adenomas, suspected AFAP)
            3. $\geq$100 colorectal adenomas

2. Methods (Boardman 2002)
    1. Protein truncation testing of peripheral blood lymphocytes: detects *APC* mutation in more than 80–90% of affected families
    2. Conformation strand gel electrophoresis
    3. Single-strand conformation polymorphism
    4. Direct sequencing
    5. Linkage analysis to markers on chromosome 5q
3. Germline *APC* testing: the most efficient means for identifying gene carriers within an FAP kindred
4. Direct sequencing targeted at the known region of the *APC* gene if a mutation has already been detected within one member of a kindred
    1. Cost effective
    2. Nearly 90% accurate means of *APC* testing

5. Genetic tests for *MUTYH* (Half et al. 2009)
    1. A subset of patients that presents with clinical AFAP harbor a recessive disorder caused by the inheritance of mutations in the base-excision-repair gene *MUTYH* (Castellsagué et al. 2008)
    2. *MUTYH* mutation causes the polyposis condition known as *MUTYH* attenuated FAP (MAP)
    3. It is recessively inherited and patients have either a homozygous or compound heterozygous germline mutations of the *MUTYH* gene
    4. Recommended for all patients who have tens to hundreds of colorectal adenomas with no identified germline mutation in the *APC* gene and with a family history compatible with an autosomal recessive and rarely autosomal dominant modes of inheritance
    5. Therefore, DNA screening of the *MUTYH* gene should look for both heterozygous and homozygous mutations (Olschwang et al. 2007)
6. Despite technological advances, APC gene size, allelic and locus heterogeneity, and multiple mutational disease-causing mechanisms (truncations, deletions, duplications, splicing alterations, missense alterations, and others yet unknown) continue to make the detection of disease-causing mutations in patients with colorectal adenomatous polyposis challenging (Kerr et al. 2013)
7. Next-generation sequencing (NGS) technology can be included as an adequate diagnostic method for the identification of intragenic mutation testing of familial colorectal cancer syndromes, complemented in the mutation-negative cases with a reduced number of Sanger sequences to resolve the DNA regions not adequately assessed by NGS (Simbolo et al. 2015)

Genetic Counseling

1. Recurrence risk for autosomal dominant inheritance
    1. Patient's sib
        1. Not increased in a de novo case
        2. 50% if a parent is affected
    2. Patient's offspring: a 50% risk of inheriting the condition and virtually all children who inherit the condition will develop polyposis (Leggett 2002)
2. Prenatal diagnosis
    1. Molecular genetic testing of the *APC* gene on fetal DNA obtained from amniocentesis or CVS for fetuses at 50% risk for FAP if a clinically diagnosed relative has an identified disease-causing *APC* gene alteration
    2. Linkage analysis if the family is informative for linked markers
    3. Preimplantation genetic diagnosis (Ao et al. 1998)
3. Management (Boardman 2002)
    1. Surveillance: In patients with FAP and FAP variants including Gardner syndrome, Turcot syndrome, and attenuated FAP, the main goal of surveillance is to detect the colorectal cancer in early stages (Leoz et al. 2015), combining molecular and clinical approaches (Gebert et al. 1999)

2. Pre- and post-test genetic counseling
    1. A pretest counseling session covering:
        1. The nature of the disease itself
        2. The genetic aspects
        3. The implications of positive and negative test results on future screenings
        4. On insurability and family relationships
    2. A post-test counseling session
        1. Disclosure of the results
        2. Addressing psychological consequences
3. Potential consequences of genetic testing for hereditary colorectal cancer (Trimbath and Giardiello 2002)
    1. Positive consequences if the result is gene positive (the disease-causing mutation detected)
        1. Removal of uncertainty
        2. Early detection of polyps and prevention of cancer
        3. Greater ability to plan the future including family and career decisions
        4. Increased compliance with colonic screening/surveillance
        5. Greater choice of surgical and medical management
    2. Negative consequences if the result is gene positive (the disease-causing mutation detected)
        1. Psychological distress, including anxiety, depression, anger, or denial
        2. Changes in family psychosocial dynamics
        3. Stigmatization
        4. Increased fear about surgery or death
        5. Children at 50% risk of disease
        6. Guilt/worry about children
        7. Colon surgery and possible lifestyle changes
    3. Positive consequences if the result is gene negative (truly negative for gene mutation identified in family)
        1. Removal of uncertainty
        2. Children not at risk
        3. Fewer medical exams and costs
        4. Better insurability
    4. Negative consequences if the result is gene negative (truly negative for gene mutation identified in family)
        1. Survival guilt (guilt about being unaffected when other family members are affected)
        2. Changes in family psychosocial dynamics
    5. Negative consequences if the result is inconclusive (no pedigree mutation found or variant of unknown significance)
        1. False sense of security
        2. Does not rule out risk for disease
        3. Need for continued screening
        4. Confusion/anxiety
4. FAP (Forbes et al. 1987)
    1. Prophylactic surgery remains the best means to minimize the risk of developing colorectal cancers
    2. Laparoscopic prophylactic treatment for FAP can be performed safely and effectively with the advantage of minimal invasion by experienced surgeons (Huang et al. 2015)
    3. Consider colectomy (Giardiello et al. 2002)
        1. By late teen years for cancer prophylaxis for both gene carriers and at-risk individuals with polyposis
        2. Without colectomy, colorectal cancer is inevitable, appearing approximately 10–15 years after the onset of polyposis
    4. Total colectomy with ileorectal anastomosis remains the operation of choice for the majority of patients with FPC, but a total colectomy with ileal reservoir and ileo-anal anastomosis is appropriate in some cases (Aitken et al. 1986)
    5. Specific surgical recommendation (Heimann et al. 1986)
        1. Proctocolectomy with mucosectomy
        2. Ileal pouch anal anastomoses
        3. Ileorectal anastomosis
    6. Surgical removal of osteomas for cosmetic reasons

7. Treatments for desmoid tumors
    1. Surgical excision: associated with high rates of recurrence
    2. Nonsteroidal anti-inflammatory drugs (sulindac, celecoxib) (use before colectomy): remains experimental
    3. Antiestrogens
    4. Cytotoxic chemotherapy
    5. Radiation
    6. For intra-abdominal desmoid tumors: chemotherapy as a first choice treatment and reserve surgery when it is impossible or when desmoid tumors are life threatening (Desurmont et al. 2015)
8. Celecoxib (sulindac), a selective cyclooxygenase-2 (prostaglandin synthetase) inhibitor (Lipsky 1999; Corredor et al. 2001)
    1. Reduces by 28% the mean number of polyps in adult patients with FAP
    2. Potential use of this class of drugs as chemopreventive and therapeutic agents: subject of intense current investigation (Giardiello et al. 2002)

5. AFAP
    1. Endoscopy and polypectomy
    2. Surgery: ileorectostomy rather than ileal pouch anal anastomosis is recommended because the rectum is relatively spared by polyposis
        1. For recurrent, numerous polyposis
        2. For the presence of aggressive histologic features
    3. Continued need for annual endoscopic evaluation of the rectal remnant
6. Prognosis (Half et al. 2009)
    1. Most patients with clinical FAP can be identified and have their diagnosis confirmed by genetic testing
    2. Individuals with FAP carry a 100% risk of colorectal cancer that is reduced almost absolutely when patients enter a screening and treatment program
    3. Once proctocolectomy has been performed, the risk of ampullary and duodenal cancer is significant and requires lifelong upper gastrointestinal surveillance that has been shown to save lives of FAP patients
    4. Desmoids need to be identified early while small and not causing local perturbations
    5. Duodenal cancer and desmoids are the two main causes of mortality after total colectomy has removed the risk for CRC
    6. The sociological, psychological, and physiological issues related to the diagnosis and treatment of FAP need to be addressed
    7. The colectomy and ensuing change in bowel habits frequently lead to dietary changes that can be unbalanced and lead to vitamin-mineral deficiencies

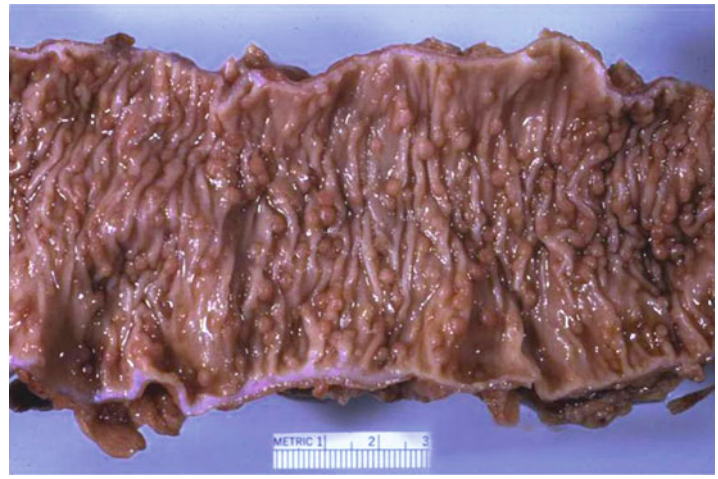

Fig. 1 Colon of an 8-year-old girl with familial adenomatous polyposis. Numerous small polyps were present on the mucosal surface of the entire colon. The polyps measured up to 3 mm in size. Occasional polyps had a slender stalk, up to 2 mm in length. Histologically, the polyps were of tubular (adenomatous) type

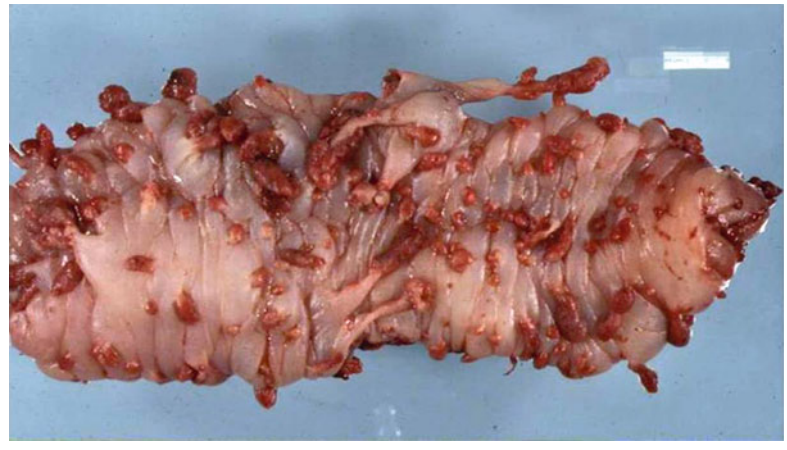

Fig. 2 A segment of colon showing juvenile polyposis. The polyps are large and lobulated. Stalks are present in some of them. The number of polyps is not as numerous as seen in Fig. 1 (AFP)

Fig. 3 A 50-year-old female had a history of multiple removals of numerous pedunculated and sessile polyps (adenomatous) during past 12 years. Her mother was diagnosed with colon cancers and had most colon surgically removed. Molecular testing of the patient showed intron 3 alteration [IVS3(−3)T > A]. Aberrations within the intron can affect normal splicing of RNA. Whether this is a disease-causing mutation or a normal variant cannot be determined without determination of the mother's DNA status

Familial Hyperlysinemia

Contents

Familial hyperlysinemia is an inborn error of metabolism caused by a defect in the bifunctional protein α-aminoadipic semialdehyde synthase (Woody 1964; Markovitz et al. 1984; Sacksteder et al. 2000; Cox 2001).

Synonyms and Related Disorders

Alpha-aminoadipic semialdehyde synthase deficiency; L-lysine NAD-oxido-reductase deficiency; Lysine alpha-ketoglutarate reductase deficiency

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. A heterogeneous group of at least four disorders
    1. Caused by mutations in the gene (mapped to 7q31.3) encoding α-aminoadipic semialdehyde synthase (AASS), the bifunctional protein that contains both lysine-ketoglutarate reductase (LKR) and saccharopine dehydrogenase (SDH) activity.
    2. Deficiency in lysine-ketoglutarate reductase (LKR) and/or saccharopine dehydrogenase (SDH) activities leads to a clinical phenotype characterized by hyperlysinemia, lysinuria, and variable saccharopinuria.
    3. Deficiency in saccharopine oxidoreductase activity, along with deficient LKR and SDH activities, is also observed in children with familial hyperlysinemia (Dancis et al. 1969, 1976, 1979).
    4. Mitochondrial NADP(H) deficiency due to a mutation in NADK2 causes dienoyl-CoA reductase deficiency with hyperlysinemia (Houten et al. 2014).

Clinical Features

1. Generally considered a benign metabolic variant
2. The more severe neurological disease course in two patients with a contiguous deletion syndrome may be explained by the additional loss of *PTPRZ1* (Houten et al. 2013)
3. Mental retardation of varying degree (Woody 1964; Ghadimi et al. 1965, 1967; Armstrong and Robinow 1967)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_86

4. Other neuromuscular manifestations
    1. Poor muscle tone (hypotonia)
    2. Muscle weakness
    3. Clumsy hand movements
    4. Cross adductor reflexes
    5. Ankles clonus
    6. High-arched feet
    7. Awkward gait
    8. Hyperactive deep tendon reflexes
    9. Seizures
    10. Progressive spastic paraparesis/diplegia (Yiannikas and Cordato 1996)
5. Developmental delay, especially speech delay
6. Hyperactive behavior
7. Ligamentous laxity
8. Ocular manifestations (Smith et al. 1971)
    1. Bilateral subluxated lenses (ectopia lentis)
    2. Lateral rectus muscle paresis
    3. Bilateral spherophakia
9. Hyperlysinemia alone may not be associated with a clinical phenotype (Woody et al. 1966; Van Gelderen and Teijema 1973; Özalp et al. 1981; Dancis et al. 1983)
10. Differential diagnosis
    1. Hyperlysinemia: periodic hyperlysinemia with ammonia intoxication
    2. Ectopia lentis
        1. Marfan syndrome
        2. Homocystinuria
        3. Weill-Marchesani syndrome
        4. Ehlers-Danlos syndromes
        5. Dominant and recessive forms of inherited subluxation of the lens

Diagnostic Investigations

1. Plasma amino acid quantitative analysis: hyperlysinemia (Simell et al. 1972)
2. Urinary amino acid quantitative analysis: hyperlysinuria (Armstrong and Robinow 1967; Woody and Ong 1967)
3. Urinary organic acid analysis: variable saccharopinuria (Carson et al. 1968)
4. Excretion of pipecolic acid by infants and by patients with hyperlysinemia (Woody and Pupene 1970)
5. Excretion of hypusine by children and by patients with familial hyperlysinemia (Woody and Pupene 1973)
6. Cultured skin fibroblasts: absent lysine-ketoglutarate reductase and saccharopine dehydrogenase activities (Cederbaum et al. 1979)
7. Molecular genetic study: homozygous deletion in *AASS* gene
8. EEG for seizures

Genetic Counseling

1. Recurrence risk
    1. Patient's sib: 25%
    2. Patient's offspring: not increased unless the spouse is a carrier in which case 50% of the offspring will be affected
2. Prenatal diagnosis has not been reported
3. Management
    1. Dietary control with reduction in lysine intake (Tondo et al. 2013): two children with hyperlysinemia type I and neurological impairment in which implementation of lysine-restricted diet achieved a mild improvement of some signs but did not reverse cognitive impairment. The moderate decrease of plasma lysine concentrations after dietary treatment supports the need of increase in lysine restriction.
    2. Other supportive therapies

Fig. 1 A 27-year-old female with hyperlysinemia showing global delay, spasticity, rigidity, and multiple joint contractures. She was diagnosed to have hyperlysinemia since about 1 1/2 years of age with markedly elevated serum lysine of 1,618 μM (45–144). As a neonate, she had frequent emesis and noted to be stiff and irritable with progressive developmental delay. She began to walk with a ramp and rails until approximately 4 years of age when she started to develop increased spasticity and significant scissoring, necessitating adductor release. On the recent plasma amino acid analysis, lysine was markedly elevated at 1,252 μM (41–225)

Familial Mediterranean Fever

Contents

Familial Mediterranean fever (FMF), also known as an autoinflammatory syndrome, is the most frequent periodic fever syndrome, affecting not only eastern Mediterranean people such as non-Ashkenazi Jews, Armenians, Arabs, and Turks but also reported throughout the world's populations (Papadopoulos et al. 2008; Guz et al. 2009).

Synonyms and Related Disorders

Autoinflammatory diseases (Hausmann and Dedeoglu 2013); Hereditary periodic fever syndromes; Recurrent hereditary polyserositis

Genetics/Basic Defects

1. An autosomal recessive disorder caused by missense mutations in the *MEFV* gene, located on the short arm of chromosome 16 (16p13.3). The *MEFV* gene is responsible for encoding a protein called pyrin or marenostrin
2. Pathogenesis
    1. Partially elucidated only after the identification of pyrin or marenostrin
    2. A new macromolecular complex, called inflammasome, seems to play a major role in the control of inflammation and it might be involved in the pathogenesis of FMF
3. Role of pyrin in innate immunity (Manukyan and Aminov 2016)
    1. Formation of several supramolecular structures and inflammasome assembly
    2. Sensing various intracellular danger signals
    3. Mounting the innate immune responses
    4. Resolution of inflammation
4. Phenotype expression of the FMF should depend on the presence of a homozygote or heterozygote genotype for the *MEFV* gene mutations
5. Genotype-phenotype correlation, however, is complex due to influence of genotype and the ethnic and environmental factors, playing a role in the clinical outcome with a very wide clinical spectrum

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_87

6. Etiology of the periodicity and the self-limited nature remains largely unexplained
7. These rare conditions are collectively named
8. "Hereditary periodic fever syndromes" (HPFS) and protean pathogenetic mechanisms combined with several clinical phenotypes characterize at least four distinct conditions (Rigante et al. 2016):
    1. Familial Mediterranean fever: the prototype and the most widely recognized among HPFS, inherited as an autosomal recessive disorder showing recurrent dysregulated inflammatory processes, caused by an abnormal interaction between cytoskeleton and inflammasome, a key-signaling platform that releases interleukin-1β (IL-1β)
    2. The group of cryopyrin-associated periodic syndrome: upsets directly the production of IL-1β, with a dominant pattern of inheritance
    3. Tumor necrosis factor receptor-associated periodic syndrome: an autosomal dominant disorder subverting the functions and traffic of a cell membrane protein
    4. Mevalonate kinase deficiency: an autosomal recessive metabolic disorder halting the biosynthesis of cholesterol
    5. *MEFV*, *NLRP3*, *TNFRSF1A*, and *MVK* are respectively the four causing genes of these conditions, all resulting in excessive IL-1β signaling, though the encoded proteins act at different levels in cytoskeletal filament organization, apoptosis, and activation of the IL-1β-structured inflammasome

Clinical Features

1. Clinical manifestations (Fonnesu et al. 2009; Ozel et al. 2000)
    1. Onset of the disease: occurs before the age of 30 in almost all patients
    2. Recurrent attacks
        1. Last 1–4 days on average
        2. Resolve spontaneously with a frequency varying from once a week to once every 3–4 months or, sometimes, years
        3. Severity and frequency of attacks have an inter- and intra-individual variations
    3. Presence of fever: absent in rare cases
    4. Gastrointestinal symptoms
        1. Abdominal pain: localized or diffuse
        2. Stypsis/diarrhea
        3. Associated disease
    5. Musculoskeletal symptoms
        1. Arthralgia: transient or abortive
        2. Arthritis
            1. Acute asymmetric nondegenerative mono/oligoarthritis
            2. Protracted arthritis
            3. Chronic degenerative arthritis
            4. Migrating polyarthritis: usually induced by exertion
        3. Myalgias
        4. HLA-B27 negative sacroiliitis during the prodromes or the attack
        5. Seronegative spondyloarthropathy (Borman et al. 2009)
    6. Cardiopulmonary symptoms
        1. Pleuritis
        2. Pericarditis
    7. Cutaneous symptoms: erysipelas-like erythema
    8. Vasculitis
        1. Henoch-Schoenlein purpura
        2. Polyarteritis nodosa
        3. Behcet disease
    9. Other manifestations
        1. Acute orchitis
        2. Mollaret's meningitis
        3. Splenomegaly
        4. Retinopathy
2. Known trigger factors
    1. Physical and emotional stress
    2. Exposure to cold
    3. Fat-rich meals
    4. Banal infections
    5. Drugs such as cisplatin
    6. Menstrual cycle

7. Presence of *Helicobacter pylori*

3. Secondary amyloidosis: the most devastating and important long-term complication
   1. Predominantly renal
   2. Genetic risk factors
      1. Genetic factors linked to *MEFV* gene
      2. Genetic factors linked to modifier genes (Seroamyloid A gene – SAA – and major histocompatibility complex class 1 chain-related A gene – MICA)
   3. Nongenetic factors
      1. Male gender: males four times higher than in females
      2. Environmental factors: country identified as the primary risk factor for renal amyloidosis (e.g., Armenians residing in Armenia have higher incidence than those who reside in the USA)
4. Two phenotypes of FMF (Shohat et al. 2014)
   1. FMF type I
      1. Characterized by recurrent short episodes of inflammation and serositis including:
         1. Fever
         2. Peritonitis
         3. Synovitis
         4. Pleuritis
         5. Rarely pericarditis and meningitis
      2. Inter-individual and intra-familial variation of symptoms
      3. Amyloidosis which can lead to renal failure is the most severe complication of FMF type I
   2. FMF type II: characterized by amyloidosis as the first clinical manifestation of disease in an otherwise asymptomatic individual (Pras 1998; Langevitz et al. 1999; Shohat et al. 1999; Koné Paut et al. 2000)
5. Differential diagnosis (Lidar and Livneh 2007; Portincasa et al. 2013)
   1. Abdominal attacks (recurrent peritonitis)
      1. Appendicitis
      2. Diverticulitis
      3. Cholecystitis
      4. Pyelonephritis
      5. Pelvic inflammatory disease
      6. Pancreatitis
   2. Recurrent abdominal attacks (without peritonitis)
      1. Peptic disease
      2. Renal colic
      3. Endometriosis
      4. Menstruation pain
      5. Irritable bowel syndrome
   3. Chest attacks (recurrent pleuritic chest pain)
      1. Pulmonary embolism
      2. Pleuritis (idiopathic, infectious, autoimmune)
      3. Pericarditis (idiopathic, infectious, autoimmune)
   4. Joint attacks (recurrent synovitis)
      1. Gout
      2. Pseudogout
      3. Spondyloarthropathy
      4. Juvenile idiopathic arthritis
   5. Febrile attacks (recurrent)
      1. Lymphoma
      2. Infections (malaria, relapsing fever)
      3. PFAPA (periodic fever, aphthous stomatitis, pharyngitis, adenopathy) (Thomas et al. 1999)
   6. Non-FMF inflammatory disorders (Ozen 2003)
      1. Inflammatory bowel disease
      2. Hyper IgD syndrome
      3. Tumor necrosis factor receptor-associated periodic fever syndrome
      4. Acute intermittent porphyria
      5. Familial cold urticaria or familial cold autoinflammatory syndrome
   7. Systemic lupus erythematosus

8. Adult Still's disease
9. Muckle-Wells syndrome
10. Chronic infantile neurological cutaneous arthropathy
11. Neonatal onset multisystem inflammatory disease syndrome
12. Clinical criteria of periodic fever-aphthous stomatitis, pharyngitis, cervical adenitis (Ahmadinejad et al. 2014)
    1. Regulatory recurring fevers with an early age of onset (<5 years of age)
    2. Symptoms in the absence of upper respiratory tract infection with at least one of the following clinical signs:
       1. Aphthous stomatitis
       2. Cervical lymphadenitis
       3. Pharyngitis
    3. Exclusion of cyclic neutropenia, completely asymptomatic interval between episodes, normal growth, and development

Diagnostic Investigations

1. Tel Hashomer diagnostic criteria (Sohar et al. 1967; Livneh et al. 1997; Sohar and Gafni 1997; Portincasa et al. 2013; Giancane et al. 2015; Sönmez et al. 2016)
   1. Major criteria
      1. Recurrent febrile episodes accompanied by peritonitis, synovitis, or pleuritis serositis
      2. Amyloidosis of AA type without predisposing disease
      3. Favorable response to continuous colchicine treatment
   2. Minor criteria
      1. Recurrent febrile episodes
      2. Erysipela-like erythema
      3. First-degree relatives affected by FMF
   3. Definitive diagnosis: two major criteria or one major criterion and two minor criteria
   4. Probable diagnosis: one major criterion and one minor criterion
2. Tel Hashomer revised diagnostic criteria (Fonnesu et al. 2009)
   1. Presence of typical attacks
      1. Fever
      2. Serositis
   2. Positive response to colchicine
3. Livneh criteria for the diagnosis of FMF (Lidar and Livneh 2007; Livneh et al. 1997; Portincasa et al. 2013; Giancane et al. 2015; Sönmez et al. 2016)
   1. Major criteria: typical attacks (recurrent, febrile, and short)
      1. Peritonitis (generalized)
      2. Pleuritis (unilateral) or pericarditis
      3. Monoarthritis (hip, knee, ankle)
      4. Fever alone
   2. Minor criteria
      1. Incomplete (painful and recurrent) attacks involving one or more of the following sites:
         1. Abdomen
         2. Chest
         3. Joint
      2. Exertional leg pain
      3. Favorable response to colchicine
   3. Supportive criteria
      1. Family history of familial Mediterranean fever
      2. Appropriate ethnic origin
      3. Age <20 years at disease onset
      4. Features of attacks
         1. Severe, requiring bed rest
         2. Spontaneous remission
         3. Symptom-free interval
         4. Transient inflammatory response with one or more abnormal test result(s) for white blood cell count, erythrocyte sedimentation rate, serum amyloid A, and/or fibrinogen
      5. Episodic proteinuria/hematuria
      6. Unproductive laparotomy or removal of "white" appendix
      7. Consanguinity of parents
   4. Requirements for diagnosis of FMF
      1. Greater than or equal to one major criteria, or
      2. Greater than or equal to two minor criteria, or

3. One minor plus >5 supportive criteria
4. Modified diagnostic criteria for PFAPA (Thomas et al. 1999)
   1. Regularly recurring fevers with an early age of onset (<5 years)
   2. Constitutional symptoms in the absence of upper respiratory infection with at least one of the following clinical signs:
      1. Aphthous stomatitis
      2. Cervical lymphadenitis
      3. Pharyngitis
   3. Exclusion of cyclic neutropenia
   4. Completely asymptomatic intervals between episodes
   5. Normal growth and development
5. General clinical laboratory findings: No common biomarker or imaging study is specific for FMF (Portincasa et al. 2013)
   1. Leukocytosis
   2. Leukopenia: associated with colchicine treatment
   3. Elevated acute-phase reactant proteins such as erythrocyte sedimentation rate, C-reactive protein, fibrinogen, haptoglobin, C3, C4, and serum amyloid A (SAA) protein, interleukin-6, and tumor necrosis factor-alpha during attack (Guz et al. 2009)
   4. Urinalysis for the presence of proteinuria which may be present in between attacks when renal amyloidosis has developed
   5. Synovial fluid leucocyte count can be elevated during febrile attacks (up to 1,000,000/μL) and consists mainly of neutrophils
6. Diagnostic algorithm (Lidar and Livneh 2007)
   1. Clinical criteria
   2. Results of MEFV mutation analysis
   3. Therapeutic trial, monitored by clinical response and SAA levels
7. Renal biopsy: indicated in all FMF patients who develop proteinuria or nephrotic syndrome
8. Molecular genetic study of the MEFV gene to confirm the diagnosis
9. Recommendations for familial Mediterranean fever (FMF) genetic diagnosis (Giancane et al. 2015)
   1. FMF is a clinical diagnosis, which can be supported but not excluded by genetic testing
   2. Consider patients homozygous for M694V at risk of developing, with very high probability, a severe phenotype
   3. FMF patients carrying two of the common mutated alleles (homozygotes or compound heterozygotes), especially for M694V mutation or mutations at position 680–694 on exon 10, must be considered at risk of having a more severe disease
   4. The E148Q variant is common of unknown pathogenic significance and, as the only *MEFV* variant, does not support the diagnosis of FMF
   5. Patients homozygous for M694V mutation are at risk of early onset disease
   6. Individuals homozygous for M694V who are not reporting symptoms should be evaluated and followed closely in order to consider therapy
   7. For individuals with two pathogenic mutations for FMF who do not report symptoms, if there are risk factors for AA amyloidosis (such as the country, family history, and persistently elevated inflammatory markers, particularly serum amyloid A protein), close follow-up should be started and treatment considered
   8. Consultation with an autoinflammatory disease specialist may be helpful in order to aid in the indication and interpretation of the genetic testing and diagnosis

Genetic Counseling

1. Recurrence risk
   1. Both parents carrying at least one *MEFV* gene mutation
   2. Patient's sib
      1. Twenty-five percent with MFM
      2. Fifty percent with MFM carrier
   3. Patient's offspring
      1. All offspring inherit one *MEFV* gene mutation from the proband

   2. Low recurrence risk unless the spouse is affected or a carrier of *MEFV* gene mutation
2. Prenatal diagnosis (Shohat et al. 2014)
   1. Possible for pregnancies at increased risk by analysis of DNA extracted from fetal cells obtained by amniocentesis or chorionic villus sampling, giving that both disease-causing alleles of an affected family member must be identified or linkage established in the family before prenatal testing can be performed
   2. Prenatal diagnosis of FMF, a treatable condition associated with a good prognosis with early treatment, may be controversial if the testing is being considered for the purpose of pregnancy termination rather than early diagnosis
3. Management (Guz et al. 2009; Portincasa et al. 2013)
   1. Colchicine (lifelong therapy): currently the only effective treatment of familial Mediterranean fever (Fonnesu et al. 2009)
      1. Should be introduced as soon as the diagnosis is made and continued for life
      2. Reduces the attack frequency, severity, and duration in most FMF patients
      3. Can prevent, arrest, and even reverse renal amyloidosis, even if it fails to stop the attacks (Lidar et al. 2004; Kallinich et al. 2007)
      4. Also recommended for treatment of amyloidosis
      5. Higher colchicines dosage, up to 2 mg/day, may be needed in high-risk patients such as after kidney transplantation or patients with amyloidosis
   2. Anakinra can be an effective and safe adjunctive drug to colchicine for prevention of FMF attacks in colchicine-refractory patients, even after kidney transplantation (Celebi et al. 2014)
   3. Anti-interleukin-1 (IL-1) targeting drugs seem safe and effective therapies in colchicine-resistant FMF (Cetin et al. 2015)
   4. No effective mean to treat acute attacks of FMF
      1. Methylprednisolone may relieve abdominal pain and tenderness (Erken et al. 2008), although steroids in general play no role
      2. Interferon (IFN)-α injection at the earliest signs of an attack may provide some benefit (Tunca et al. 2004; Tweezer-Zaks et al. 2008)
   5. Controversy in treating asymptomatic individuals with mutations in the *MEFV* gene who may or may not develop FMF in the future
   6. Prognosis of FMF: normal if AA amyloidosis is prevented (Portincasa et al. 2013)

Fig. 1 A 40-year-old female was diagnosed to have familial Mediterranean fever. She had a history of low grade fever, abdominal pain, joint pain, and peritonitis. She responded well to colchicine treatment. She is a compound heterozygote for two different mutations: MM680I and V726A, in exon 10 of the *MEFV* gene which confirms the clinical diagnosis. Her brother and sister are similarly affected. Her 5-year-old daughter was found to be heterozygous for the V726A FMF mutation. The parents are from Egypt

Fanconi Anemia

Contents

In 1927, Fanconi (1927) described a familial form of aplastic anemia in three brothers with short stature, hypogonadism, and skin pigmentation. It is the most common inherited form of aplastic anemia, affecting 1 in 100,000 to 1 in 200,000 live births (Ahmad et al. 2002; Rosenberg et al. 2011). The carrier frequency is estimated as 1 in 300 (Erdmann 2003) in Europe and the United States. Founder mutations have been described in Ashkenazi Jews, who have carrier frequency of 1 in 89 (Tischkowitz and Hodgson 2003).

Synonyms and Related Disorders

Chromosome breakup syndrome; Constitutional aplastic anemia; DNA repair disorder; Fanconi pancytopenia; Inherited aplastic anemia; Inherited bone marrow failure syndrome; Inherited pancytopenia; Premalignant disorder

Genetics/Basic Defects

1. Inheritance: genetically and phenotypically heterogeneous
    1. Autosomal recessive
    2. X-linked recessive (*FANCB* mutation)
2. Presence of at least 16 complementation groups delineated by cell fusion studies (Dokal 2000; Blom et al. 2004; Alter and Kupfer 2013; Schneider et al. 2015)
    1. FA-A (65–70%)
    2. FA-B (<2%)
    3. FA-C (10–15%)
    4. FA-D1 (*BRCA2*)
    5. FA-D2
    6. FA-E (2–5%)
    7. FA-F (<2%)
    8. FA-G (10%)
    9. FA-I
    10. FA-J (*BRIP1/BACH1*)
    11. FA-L
    12. FA-M
    13. FA-N (*PALB2*)
    14. FA-O (*RAD51C*)
    15. FA-P (*SLX4*)
    16. FA-Q (*XPF*)
3. The FA pathway is composed of at least 16 genes. Each of these genes, when biallelically mutated, causes FA (Green and Kupfer 2009; Alter and Kupfer 2013; Schneider et al. 2015):

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,

11. *FANCL*, mapped to 2p16.1
12. *FANCM*, mapped to 14q21.3
13. *FANCN*, mapped to 16p12
14. *FANCO*, mapped to 17q22
15. *FANCP*, mapped to 16p13
16. *FANCQ*, mapped to 16p13.12

4. A candidate gene approach leads to the breast cancer susceptibility gene BRCA2 as the gene defective in FA-D1 patients. The Fanconi-BRCA pathway is activated in response to certain kinds of DNA damage, particularly DNA agents that cause double-strand breaks in DNA such as ultraviolet light, ionizing radiation, and cisplatin.
5. FA cells are hypersensitive to cross-linking agents such as diepoxybutane (DEB) (increased chromosome breakage and rearrangement) (Esmer et al. 2004), nitrogen mustard (NTM) (Deviren et al. 2003), and mitomycin C (MMC) (radial figures) (Cervenka et al. 1981): induction of chromosomal aberrations (breaks and rearrangements) (Blom et al. 2004)
6. Mosaicism (Lo Ten Foe et al. 1997)
   1. Not infrequent in Fanconi anemia
   2. Presence of two populations of lymphocytes in mosaic Fanconi anemia patients
      1. One being hypersensitive to the clastogen
      2. The other normal
   3. Phenotypic reversion to normal
      1. Correlated with intragenic homologous recombination in compound heterozygous patients giving rise to the segregation of a wild-type allele at the disease locus.
      2. The resulting cells are thus essentially cured from the disease.
      3. Progeny from a reverted stem cell expected to have a proliferative advantage over affected cells and thus may gradually expand and take over hematopoiesis.
   4. Patients with a high proportion of reverted cells may be falsely diagnosed as negatives.
7. Defective FA functional pathway
   1. Defective DNA repair
   2. Prolonged G2/M transition in the cell cycle
   3. Increased oxygen sensitivity
   4. Abnormally regulated apoptosis and accelerated telomere shortening
   5. Defective hemopoiesis

Clinical Features

1. Variable clinical expression and severity (Fanconi 1967; Schroeder et al. 1976; Alter 1993; Giampietro et al. 1993; 1997)
2. Hematological abnormalities secondary to bone marrow failure (>90%)
   1. Clinical hallmark of Fanconi anemia
   2. Usually starting in childhood
   3. Increased incidence of aplastic anemia, myelodysplastic syndrome, and acute myeloid leukemia
   4. Initial presentation
      1. Pallor
      2. Bleeding
      3. Recurrent infections
   5. Thrombocytopenia or leukopenia typically preceding anemia
   6. Severe progressive pancytopenia due to loss of hematopoietic stem cells: the cardinal clinical feature
   7. Increased risk of infections due to neutropenia
   8. Sweet syndrome (neutrophilic skin infiltration) reported in a few patients with Fanconi anemia and myelodysplastic syndrome
3. Diverse congenital abnormalities (Zierhut et al. 2014)

1. Endocrine (79%)
    1. Intrauterine growth retardation/short stature
    2. Hypothyroidism
    3. Diabetes
    4. Growth hormone deficiency
    5. Decreased fertility
2. Upper limb anomalies (70% of all skeletal defects)
    1. Mainly radius and thumb abnormalities
        1. Absent, hypoplastic, or supernumerary thumbs with hypoplastic thenar eminence
        2. Absent, hypoplastic radii, and ulnae associated with abnormal thumbs
        3. Absent first metacarpal
    2. Hypoplastic thenar eminence
    3. Dysplastic ulnar
    4. Clinodactyly
    5. Polydactyly
    6. Short fingers
    7. Transverse palmar crease
3. Other skeletal abnormalities
    1. Microcephaly
    2. Micrognathia
    3. Triangular face
    4. Short webbed neck with low hairline
    5. Sprengel deformity/Klippel-Feil anomaly
    6. Spine anomalies
        1. Spina bifida
        2. Scoliosis
        3. Abnormal ribs
        4. Sacrococcygeal sinus
        5. Other vertebral anomalies
    7. Lower limb anomalies
        1. Toe syndactyly
        2. Pes planus
        3. Abnormal toes
        4. Congenital hip dislocation
4. Skin pigmentary changes (40%)
    1. Generalized hyperpigmentation
    2. Café au lait spots
    3. Hypopigmentation
5. Eye anomalies (20%)
    1. Microphthalmia
    2. Strabismus
    3. Epicanthal folds
    4. Hypertelorism/hypotelorism
    5. Ptosis
    6. Cataracts
    7. Epiphora
    8. Nystagmus
    9. Astigmatism
6. Ear anomalies (15%)
    1. Deafness (11%), usually conductive secondary to middle ear abnormalities
    2. Abnormal pinna
    3. Stenosis or atresia of the external auditory meatus
    4. Low-set ears
7. Heart disease (6%)
    1. Congenital heart disease
        1. Patent ductus arteriosus
        2. Ventricular septal defect
        3. Pulmonary stenosis
        4. Aortic coarctation
    2. Cardiomyopathy
8. Renal anomalies (20%)
    1. Kidney
        1. Ectopic kidney
        2. Pelvic kidneys
        3. Horseshoe kidneys
        4. Hypoplastic/aplastic/dysplastic kidneys
    2. Collecting system (hydronephrosis, hydroureter, reflux)
    3. Abnormal artery
9. Gastrointestinal problems (5–7%)
    1. Atresia
        1. Esophagus (7%)
        2. Duodenum
        3. Jejunum
    2. Tracheoesophageal fistula
    3. Anteriorly placed anus
    4. Imperforate anus
    5. Persistent cloaca
    6. Meckel diverticulum
    7. Umbilical hernia
    8. Abnormal biliary ducts
    9. Megacolon
    10. Abdominal diastasis
    11. Budd-Chiari syndrome
    12. Annular pancreas

10. CNS abnormalities
    1. Microcephaly
    2. Hydrocephalus
    3. Absent septum pellucidum
    4. Neural tube defects
11. Hypogonadism in males (25%).
    1. Underdeveloped gonads.
    2. Cryptorchidism.
    3. Hypospadias.
    4. Micropenis.
    5. Defective spermatogenesis (infertility).
    6. A few males with Fanconi anemia fathered children.
12. Hypogonadism in females (2%)
    1. Hypogenitalia
    2. Bicornuate uterus
    3. Absent uterus or vagina
    4. Ovarian atresia
    5. Delayed menarche
    6. Irregular menses
    7. Early menopause
    8. Successful pregnancies with live-born children observed
13. Absence of obvious congenital abnormalities in approximately 33% of patients with Fanconi anemia

4. Predisposition to malignancy (Alter 1996, 2003; Rosenberg et al. 2003)
    1. Hematologic tumors (60%)
        1. Acute myelogenous leukemia (30%)
        2. Myelodysplastic syndrome (26%)
        3. Acute lymphocytic leukemia
        4. Chronic myelomonocytic leukemia
        5. Burkitt lymphoma
    2. Non-hematologic tumors (40%)
        1. Liver tumors (9%)
            1. Adenoma
            2. Hepatocellular carcinoma
            3. Adenocarcinoma
        2. Brain tumor (2%)
            1. Medulloblastoma
            2. Astrocytomas
        3. Renal tumors (3%)
            1. Wilms tumor
            2. Renal cell carcinoma
            3. Nephroblastoma
        4. Squamous cell carcinoma (20%)
            1. Head and neck
            2. Vulvar
            3. Cervix
            4. Cutaneous
            5. Anus
            6. Esophagus
        5. Miscellaneous tumors (6%)
            1. Breast carcinoma
            2. Basal cell carcinoma
            3. Neuroblastoma
            4. Desmoid tumor
            5. Gonadoblastoma
            6. Melanoma
            7. Neurilemmomas
            8. Osteogenic sarcoma
5. Cumulative probability of developing leukemia, liver tumors, and solid tumors in FA patients
    1. Close to 40% by age 30
    2. About 50% by age 45
    3. An astounding 76% by age 45
6. Prognosis (Kutler et al. 2002)
    1. Mean survival: 16 years
    2. Main causes of death
        1. Pancytopenia which develops in the first decade of life
        2. Associated progressive microcytosis
        3. Extremely high probability of developing bone marrow failure
        4. A predisposition to malignancy, particularly acute myeloid leukemia and aplastic anemia
7. A guideline of the indications for testing for FA (Wu 2013)
    1. Definite.
        1. Sibling with FA with following:
        2. Aplastic anemia
        3. Characteristic birth defects, particularly one or more of abnormal radii and/or thumbs; renal structural anomalies; microphthalmia, microcephaly, café au lait spots, and features of VACTERL-H such as tracheoesophageal fistula, imperforate anus, and others
        4. Spontaneous chromosome breaks
        5. Primary MDS (at a young age)
        6. Primary AML (at a young age)

7. Unusual sensitivity to chemo- or radiotherapy
8. Cancer typical of FA at an atypical age
9. Family history consistent with FA or with cancer (e.g., breast cancer)

2. Consider.
   1. Single cytopenias with following:
   2. Macrocytosis unexplained by B12 or folate deficiency
   3. Liver tumors without alcohol or hepatitis
   4. Premature ovarian failure <30 years old
   5. Diminished ovarian reserve <30 years old
   6. Brain tumor <5 years old
   7. Wilms tumor <4 years old
   8. Increased Hb F not otherwise explained
   9. Male (or female) infertility
   10. Liver adenomas or hepatomas without alcohol or hepatitis

8. Differential diagnosis (Tischkowitz and Hodgson 2003; Alter 2014)
   1. VATER/VACTERL association overlap with FA (Giampietro et al. 1993)
      1. Vertebral defects
      2. Tracheoesophageal atresia
      3. Renal defects
      4. Radial ray defects
   2. Dyskeratosis congenita
      1. Aplastic anemia
      2. AML
      3. Squamous cell carcinomas
   3. Diamond-Blackfan anemia (Aase syndrome)
      1. Defective erythroid progenitor maturation
      2. Normochromic or macrocytic anemia
      3. AML
      4. Osteosarcomas
      5. Congenital malformations in over one third of patients
         1. Head (micrognathia, cleft lip)
         2. Upper limb defects
         3. Genitourinary anomalies
      6. A heterogeneous disorder
         1. Sporadic in most cases
         2. Autosomal dominant in some cases
         3. Rarely autosomal recessive inheritance
   4. Shwachman-Diamond syndrome
      1. Neutropenia
      2. AML
   5. Nijmegen breakage syndrome
      1. A rare autosomal recessive disorder
      2. Resulting from mutations in *NBS1*, which codes for the nibrin protein
      3. Clinical characteristics
         1. Immune deficiency
         2. Microcephaly
         3. Hypersensitivity to ionizing radiation
   6. Other chromosomal breakage syndromes (Bloom syndrome, ataxia-telangiectasia)
      1. Also exhibit high rates of spontaneous chromosomal breakage.
      2. Only FA cells exhibit increased chromosomal breakage in response to DEB.
   7. Severe congenital neutropenia
      1. Neutropenia
      2. AML
   8. Amegakaryocytic thrombocytopenia
      1. Thrombocytopenia
      2. AML
   9. Thrombocytopenia-absent radii (TAR) syndrome
      1. Thrombocytopenia
      2. AML
   10. Holt-Oram syndrome

Diagnostic Investigations

1. Difficult to diagnose FA because of phenotypic diversity.
2. Hematologic investigation.
   1. Progressive decrease in peripheral blood counts, often present by 7–8 years of age:
      1. Thrombocytopenia
      2. Leukopenia
      3. Anemia

2. Macrocytic red blood cells, often with increased fetal hemoglobin.
3. Generally increased serum erythropoietin concentration.
4. Hypocellular or dysplastic bone marrow.
5. Bone marrow failure with pancytopenia.
6. Bone marrow cytogenetic testing: Cytogenetic abnormalities may progress to leukemia or myelodysplastic syndrome (MDS) (Alter et al. 2000).
7. Clonal amplifications of chromosome 3q26-q29 were reported in association with an increased risk of progression to MDS or acute myelogenous leukemia (AML) (Tonnies et al 2003, Cioc et al 2010).

3. Individuals with FA should be routinely screened for endocrine abnormalities, including evaluation of growth; glucose, insulin, and lipid metabolism; thyroid function; puberty; gonadal function; and bone mineral metabolism (Petryk et al. 2015).
4. DEB testing: (Auerbach et al. 1986, 1989)
   1. Tenfold to 100-fold increased chromosomal breakage (breaks, rearrangements, radials, exchanges) of Fanconi anemia cells after incubation of the patient's cells with chemical clastogen, DEB, a bifunctional DNA interstrand cross-linking agent (Auerbach 1993)
   2. Highly sensitive and specific test for Fanconi anemia
   3. Allowing diagnosis of Fanconi anemia in persons with diverse clinical features including those without clinically detectable congenital abnormalities
   4. Used successfully in prenatal diagnosis of Fanconi anemia
   5. Remains underutilized mainly because there are some clinical conditions in which FA is not usually suspected
   6. Disadvantage
      1. Requires a high degree of cytogenetic expertise and meticulous attention to cell culture and safety conditions
      2. Fails to distinguish among Fanconi anemia patients in different complementation groups
      3. Fails to identify heterozygote carriers of mutant Fanconi anemia genes
5. Immunoblot assay of FANCD2 protein monoubiquitination (Shimamura et al. 2002).
6. Cell cycle arrest in G2 phase induced by MMC (Seyschab et al. 1995; Pulsipher et al. 1998).
   1. Alternative to cytogenetic testing
   2. Diagnostic potential of the cell cycle test for Fanconi anemia
   3. Based on the observation that Fanconi anemia cells experience difficulties in traversing the S and G2 compartments of the cell cycle
   4. Limitation of cell cycle test
      1. Applicable only to nonleukemic cells
      2. Confirmatory DEB studies required in cases with evidence for G2-phase arrest
7. Molecular genetic testing (Alter and Kupter 2013; Zierhut et al. 2014):
   1. Used primarily for carrier detection and prenatal diagnosis
   2. Complicated by the presence of 13 genes, which are responsible for the 13 FA complementation groups [A, B, C, D1 (BRCA2), D2, E, F, G, I, J, L, M, and N]
   3. Complementation testing
      1. Traditionally, complementation group testing was the first tier of testing following a positive chromosome breakage assay.
      2. Complementation testing assesses each FA protein individually to identify the dysfunctional protein in an individual with FA; however, this testing cannot provide information about the location or type of mutation (Chandra et al. 2005).
      3. If a dysfunctional protein is identified, single-gene sequencing and, if necessary, deletion/duplication analysis of the corresponding gene are completed (Ameziane et al. 2008). This process can be both expensive and time consuming (Ameziane et al. 2012) and has been replaced by newer genetic testing technologies.
   4. Linkage analysis once a family has been assigned to a complementation group by a

functional assay or by the detection of a specific mutant allele using highly polymorphic microsatellite markers located in close proximity to both FAA and FAAC genes
    1. Used for carrier detection
    2. Used for prenatal diagnosis
5. Sequence analysis for *FANCA*, *FANCB*, *FANCC*, *FANCE*, *FANCF*, *FANCG*, and *FANCI*
6. Mutation analysis for the common Ashkenazi Jewish *FANCC* mutation (IVS4 + 4A > T)
7. Targeted mutation analysis
    1. Helpful in testing patients with an ethnic background that has well-established founder mutation(s)
    2. Further, if the mutations are known for an individual affected with FA, targeted mutation analysis can help facilitate in other relatives for diagnostic testing, carrier testing, prenatal testing, and preimplantation genetic diagnosis
8. Single-gene sequencing: likely used mostly for testing partners of individuals with FA or carriers of an FA mutation.
9. Deletion/duplication analysis (Wu 2013):
    1. To detect deletions of one or more exons or of an entire gene of any suspected case of FA.
    2. The next-generation sequencing technology has enabled an effective and faster molecular diagnostic approach for FA gene studies in which it is able to perform the mutation analysis for FA genes without the requirement of complementation group testing step in which the living cells are required.
    3. Recently, Ameziane et al. (2012) applied the next-generation sequencing approach to identify *BRCA2*, *FANCD2*, *FANCI*, and *FANCL* mutations in novel unclassified FA patients.
10. Fanconi anemia panel testing:
    1. Testing of all FA genes simultaneously can now be accomplished through panel testing using next-generation sequencing technologies.
    2. It has many benefits over other testing methods, including reduced cost and turnaround times and, for some platforms, the ability to identify mutations in the deep intronic regions that are not typically detected in Sanger sequencing (Ameziane et al. 2012).
    3. It is recommended that families be offered panel testing for the known FA genes following a positive chromosome breakage study.
    4. If the panel does not include FANCD1/BRCA2 or if the phenotype is consistent with the more severe features typically seen in patients with mutations in FANCD1/BRCA2, testing should be ordered through a separate lab that can perform single-gene sequencing.
11. Comparative genomic hybridization and multiplex ligation-dependent probe amplification:
    1. While next-generation sequencing for FA significantly improves the testing process, it typically cannot detect all large deletions, duplications, and insertions that can account for up to one third of all FA mutations.
    2. Comparative genomic hybridization or multiplex ligation-dependent probe amplification may be an important part of the testing process (Knies et al. 2012).
    3. This testing can precede or follow next-generation sequencing if the panel testing does not include this analysis.

8. Cancer surveillance
    1. Annual bone marrow examination provides early evidence for myelodysplastic syndrome or leukemia:
        1. Aspirate for cell types.
        2. Biopsies for cellularity
        3. Cytogenetics

2. Liver function tests and ultrasound examinations to identify adenomas or hepatomas before becoming symptomatic.
3. Screening for solid tumors: more complex because of multiplicity of cancer types:
    1. Direct visualization of the oropharynx and fiber-optic endoscopy for screening for aerodigestive cancers and precancerous lesions
    2. Gynecologic examinations for vulvar and cervical tumors beginning with menarche

Genetic Counseling

1. Recurrence risk (Alter and Kupfer 2013)
    1. Patient's sib:
        1. Autosomal recessive inheritance in all but one of the FA complementation groups
            1. Twenty-five percent chance of inheriting both mutation alleles and being affected
            2. Two third chance of being carriers in unaffected sibs who have a normal DEB test
        2. X-linked recessive inheritance (FANCB mutation)
            1. Risk to sibs depends upon the carrier status of the mother.
            2. Fifty percent of male sibs who inherit the mutation will be affected.
            3. Female sibs who inherit the mutation will be carriers and will usually not be affected.
            4. Risk to sibs is low but greater than that of the general population because of the possibility of germline mosaicism if the disease-causing mutation cannot be detected in the DNA extracted from leukocytes of the mother of the only affected male in the family.
    2. Patient's offspring: recurrence risk not increased unless the spouse is a carrier, in which case 50% of offspring will be affected; otherwise all offspring of the affected parent will be carriers who will be asymptomatic.
2. Prenatal diagnosis
    1. Prenatal ultrasonography to evaluate fetal anomalies consistent with FA
    2. Prenatal diagnosis available to at-risk families by CVS, amniocentesis, or cordocentesis
        1. Demonstration of chromosome instability by DEB test (Auerbach et al. 1986)
        2. The fetus at risk is shown to suffer from FA on the grounds of excessive chromosome breakage, both spontaneous and MMC induced, in fetal blood culture (Shipley et al. 1984)
        3. Molecular genetic testing of FA gene (*FANCA*, *FANCB*, *FANCC*, *FANCE*, *FANCF*, *FANCG*, and *FANCI*) mutations if the disease-causing mutations are previously characterized in a given family
        4. Preimplantation genetic diagnosis possible for families in which the disease-causing mutations have been identified by using molecular methods, resulting in implantation of an embryo without FA mutations (Verlinsky et al. 2001; Bielorai et al. 2004; Grewal et al. 2004)
3. Management
    1. Supportive care:
        1. Developmental assessment
        2. HLA typing of the patient, sibs, and parents in anticipation of possible bone marrow transplantation
        3. Full blood typing
        4. Packed red blood cell transfusions for symptomatic anemia
        5. Platelet transfusions for symptomatic thrombocytopenia
        6. Antimicrobials for secondary infections
    2. Surgical care:
        1. Splinting and hand surgery indicated for thumb and radial anomalies
        2. Surgery for congenital heart defects and gastrointestinal anomalies such as TE fistula

3. Transient response:
    1. Androgens (oxymetholone) shown to improve the blood counts in approximately 50% of patients
    2. Corticosteroids
    3. Cytokines
    4. Granulocyte-macrophage colony-stimulating factor and granulocyte colony-stimulating factor (shown to improve the neutrophil count in some patients) for symptomatic neutropenia
4. Hematopoietic stem cell transplantation may cure sibling's aplastic anemia and prevent myelodysplastic syndrome or leukemia (Lipton 2016):
    1. Peripheral blood stem cells
    2. Allogenic bone marrow transplant with a histocompatible sibling donor: treatment of choice
    3. Umbilical cord blood offers a potential source of hematopoiesis stem cells for Fanconi anemia patients without sibling matches
5. FA patients are uniquely hypersensitive to hematopoietic stem cell transplantation (HSCT) conditioning agents due to the underlying chromosomal instability. HSCT has shown important progress in the last years, especially after the introduction of fludarabine and the reduction of cyclophosphamide in the preparative regimen. For patients with HLA-identical related donors, HSCT should be performed as first-line therapy; for patients with alternative donors, HSCT remains a therapy with increased morbidity and mortality (Schifferli and Kühne 2015).
6. Successful transplantation obtained by using in vitro fertilization and preimplantation genetic diagnosis of hematopoietic stem cells from a donor selected on the basis of specific, desirable disease and HLA characteristics (Grewal et al. 2004):
    1. Select embryos which are HLA identical to the patient and unaffected by FA for intrauterine transfer and let the pregnancy continue to term.
    2. Obtain the umbilical cord blood from the healthy newborn infant and use it as the source of HLA-identical hematopoietic stem cells to reconstitute normal hematopoiesis in the affected sibling.
7. Follow-up surveillance for solid malignancies.
8. The genetic characterization of patients with FA is essential for developing therapies, including hematopoietic stem cell transplantation from a savior sibling donor after embryo selection, gene therapy, or genome editing using genetic recombination or engineered nucleases (Bogliolo and Surrallés 2015).
8. The genetic characterization of patients with FA is essential for developing therapies, including hematopoietic stem cell transplantation from a savior sibling donor after embryo selection, gene therapy, or genome editing using genetic recombination or engineered nucleases (Bogliolo and Surrallés 2015).
9. Gene therapy not currently available (Liu et al. 1994)

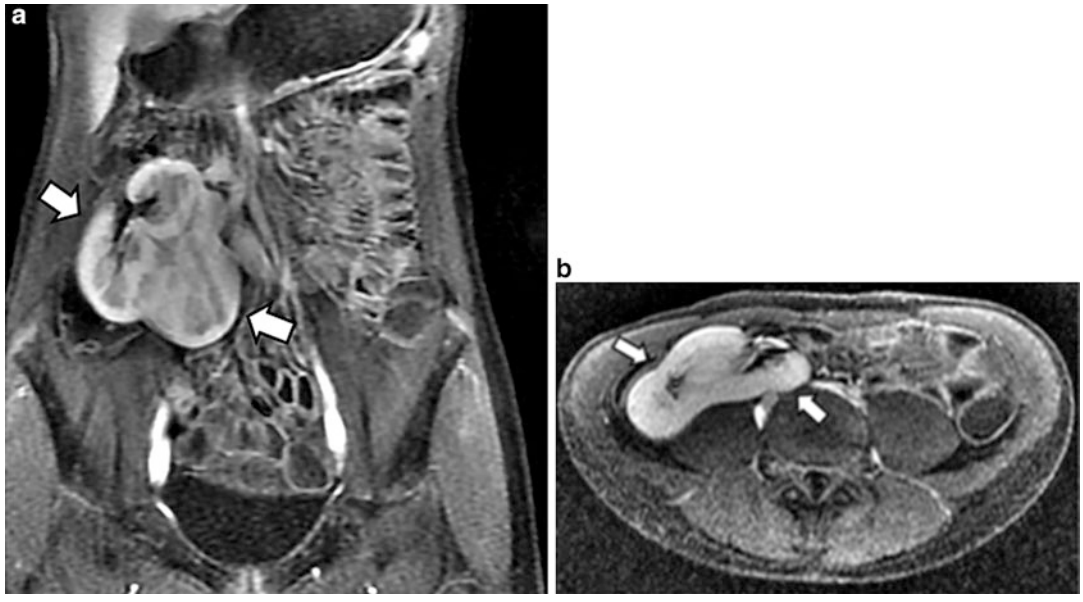

Fig. 3 (**a, b**) A 14-year-old boy has a history of short stature, undescended testis, and hematologic abnormalities and chromosome breakage. DEB stress studies showed findings consistent with fanconi anemia. C1MR1 (**a**) and C1MR4 (**b**) demonstrated crossed fused renal ectopia in the right mid-abdomen (*arrows*). Bilateral renal fossae are empty (Courtesy of Dr. Grace Guo)

Feingold Syndrome

Contents

Feingold in 1975 originally described a father, son, and grandmother with microcephaly, hand abnormalities, tracheoesophageal fistula, duodenal atresia, and normal intelligence. Later in 1978, Feingold reported a mother and daughter with similar findings except for the absence of tracheoesophageal fistula and duodenal atresia.

Synonyms and Related Disorders

Feingold syndrome 1 (oculodigitoesophagoduodenal (ODED) syndrome); Feingold syndrome 2 (brachydactyly with short stature and microcephaly due to hemizygous deletion of the *MIR17HG* gene on chromosome 13q31.3); Microcephaly mesobrachyphalangy-tracheoesophageal fistula syndrome; Microcephaly-digital anomalies-normal intelligence syndrome; Microcephaly-oculo-digito-esophageal-duodenal (MODED) syndrome

Genetics/Basic Defects

1. Feingold syndrome 1
   1. Autosomal dominant inheritance with full penetrance and variable expressivity.
   2. Caused by mutations in the neuroblastoma-derived V-myc avian myelocytomatosis viral-related oncogene (*MYCN*) maps to 2p24.3 (Teszas et al. 2006; Blaumeiser et al. 2008).
   3. MYCN haploinsufficiency is associated with reduced brain size and intestinal atresias in Feingold syndrome (van Bokhoven et al. 2005).
2. Feingold syndrome 2
   1. Identification of germline hemizygous deletion of the microRNA 17 host gene (*MIR17HG*), maps in 13q31.3, has been described in two individuals with microcephaly, short stature, and digital anomalies (Feingold syndrome 2) (de Pontual et al. 2011).
   2. *MIR17HG* locus is considered as the best candidate to explain the skeletal abnormalities and digital malformations observed in

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_258

patients with Feingold syndrome 2 (Tassano et al. 2013).

Clinical Features

1. Feingold syndrome 1
   1. Clinical features (Fig. 1) (Celli et al. 2003; Marcelis et al. 2008)
      1. Digital anomalies: the most constant findings
         1. Brachymesophalangy (shortening of the 2nd and 5th middle phalanges of the hand with clinodactyly of the 5th finger) (100%)
         2. Toe syndactyly (2–3 and/or 4–5) (97%)
         3. Thumb hypoplasia (17%)
      2. Microcephaly (89%)
      3. Facial dysmorphism
         1. Short palpebral fissures (73%)
         2. Micrognathia (32%)
      4. Mild learning deficit (51%)
      5. Atresia
         1. Gastrointestinal (55%)
         2. Esophageal atresia (32%)
         3. Duodenal atresia (31%)
         4. Jejunal (3%)
         5. Anal (2%)
         6. Multiple (12%)
      6. Short stature (<10th centile) (60%)
      7. Renal abnormalities (18%)
      8. Cardiac abnormalities (15%)
      9. Deafness (10%)
      10. Asplenial/polysplenia (0.25%)
   2. Differential diagnosis
      1. "▶ VATER (VACTERL) Association": please see the chapter.
      2. "▶ CHARGE Syndrome": please see the chapter.
      3. "▶ Fanconi Anemia" (thumb hypoplasia and other congenital anomalies): please see the chapter.
      4. Brachydactyly type A4: please see the chapter "▶ Brachydactyly."
2. Feingold syndrome 2 (De Pontual et al. 2011; Tassano et al. 2013)
   1. Growth and psychomotor retardation
   2. Short stature
   3. Microcephaly
   4. Mild generalized hypotonia
   5. Mild facial dysmorphisms
      1. Epicanthus
      2. Short palpebral fissures
   6. Digital abnormalities (brachymesophalangy)
      1. Brachydactyly or brachymesophalangy of the second and fifth fingers
      2. Hypoplastic thumbs of variable severity
      3. Clinodactyly of 5th fingers
      4. Cutaneous syndactyly of the toes
      5. Clinodactyly of 3rd toes
   7. Lack of gastrointestinal abnormalities and short palpebral fissures

Diagnostic Investigations

1. Radiology for microcephaly and digital abnormalities
2. Echocardiogram for cardiac evaluation
3. Renal ultrasound for renal abnormalities
4. Audiometry for hearing loss
5. Cytogenetics/CGH microarray analysis
   1. Feingold syndrome 1: microdeletion of 2p23-p24
   2. Feingold syndrome 2: del(13)(q31.1q32.1)
6. *MYCN* analysis: presence of brachymesophalangy and toe syndactyly in combination with microcephaly sufficient to justify MYCN analysis to confirm mutation or deletion (Marcelis et al. 2008)

Genetic Counseling

1. Recurrence risk: autosomal dominant inheritance
   1. Patient's sib: not increased unless a parent is affected or having gonadal mosaicism
   2. Patient's offspring: 50%
2. Prenatal diagnosis and preimplantation genetic diagnosis for at-risk pregnancies require prior identification of the disease-causing mutation in the family.

3. Management
    1. Surgery for gastrointestinal atresia
    2. Management of cardiac and renal anomalies

Fig. 1 A 10-month-old Caucasian male was evaluated for microcephaly with a head size of 41.8 cm. Other craniofacial features include prominent nasal bridge with retrognathia and slightly prominent ears. There was partial syndactyly on the 2nd and the 3rd toes on both feet and the fourth and the fifth toes on the right foot. He also has pyelectasis on his renal ultrasound. Chromosomal microarray analysis showed a microdeletion of 2p24.3-p24.2 which includes six genes, one of which is MYCN. Heterozygous mutations or deletions of that gene are associated with Feingold syndrome type I. (Courtesy of Dr. Susonne Ursin)

Femoral Hypoplasia: Unusual Facies Syndrome

Contents

In 1973, Daentl et al. (1973) delineate a distinctive pattern of malformation which includes femoral hypoplasia and unusual facies in four unrelated individuals. The syndrome is also known as femoral facial syndrome.

Synonyms and Related Disorders

Femoral facial syndrome

Genetics/Basic Defects

1. Inheritance/etiology (Burn et al. 1984)
    1. Sporadic in most cases
    2. Familial cases with autosomal dominant inheritance reported (Lampert 1980; Robinow et al. 1995)
    3. Multifactorial trait in some families (Lord and Beighton 1981)
    4. Maternal/gestational diabetes causative in more than 20% of the reported cases (Johnson et al. 1983; Burn et al. 1984; Giacoia and Tunnessen 1996; Hinson et al. 1996)
    5. Genetic contribution suspected in affected children born to non-diabetic mothers
    6. A report of a girl with femoral facial syndrome and a de novo complex chromosome rearrangement: The duplication 2q37.2 could be causative for the femoral hypoplasia phenotype (Spielmann et al. 2016).
2. Possible causes
    1. Fetal constraint (deformation) due to severe oligohydramnios
    2. Maternal diabetes (disruption)
    3. Undetermined etiology

Clinical Features

1. Characteristic facial features (Daentl et al. 1973)
    1. Up-slanting eyes
    2. A short nose with broad tip
    3. Elongated philtrum
    4. Thin upper lip
    5. Micrognathia
    6. Cleft palate
    7. Low-set ears
2. Hypoplasia/aplasia of the femurs
    1. Usually asymmetric

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_89

2. Presence of some degree of shortened lower extremities in most cases
3. Variable shortening of the lower extremities depending on the absence or degree of hypoplasia of the femurs, with or without absent fibulas
4. Complete absence of the femur: very rare in femoral facies syndrome (Johnson et al. 1983; Bum et al. 1984; Ahmed et al. 2015)

3. Short stature due to reduced length of the lower extremities
4. Normal intelligence
5. Other anomalies
    1. Club foot in most cases
    2. Occasional preaxial polydactyly (Baraitser et al. 1994)/syndactyly
    3. Sprengel's deformity
    4. Upper extremity hypoplasia
    5. Restricted motion of the elbows
    6. Stiff shoulders
    7. Pelvic and spinal abnormalities
    8. Inguinal hernia
    9. Genitourinary anomalies
        1. Hypoplastic/dysplastic kidneys
        2. Polycystic kidneys
        3. Cryptorchidism
        4. Genital hypoplasia
            1. Hypoplastic penis
            2. Hypoplastic labia majora
        5. Inferiorly placed kidneys
        6. Septated urinary bladder
    10. Rare cardiovascular anomalies
        1. Ventricular septal defect
        2. Pulmonary stenosis
        3. Truncus arteriosus
    11. Caudal dysplasia (Riedel and Froster-Iskenius 1985)
6. Differential diagnosis (Pryde et al. 2003)
    1. Kyphomelic dysplasia (Pitt 1986)
        1. Femur
            1. Symmetrically short
            2. Severe bowing
        2. Other long bones
            1. Mild shortening
            2. Minimal bowing
        3. Genitourinary: no abnormalities
        4. Face: micrognathia
        5. Scapulae: normal
        6. Others
            1. Mild small thorax
            2. Male sex predilection
        7. Prognosis
            1. Good developmental prognosis
            2. Ambulatory
        8. Genetics: autosomal recessive
    2. Campomelic dysplasia
        1. Femur
            1. Symmetric mild shortening
            2. Moderate-to-severe bowing/amputation
        2. Other long bones
            1. Tibial bowing more marked than femora bowing
            2. Hypoplastic fibulae
        3. Genitourinary
            1. Ambiguous genitalia
            2. Sex reversal in XY
        4. Face
            1. Micrognathia
            2. Cleft palate
        5. Scapulae: hypoplastic
        6. Others
            1. Occasional lateral ventriculomegaly
            2. Cardiac anomalies
            3. Talipes
        7. Prognosis
            1. Often lethal in early infancy
            2. Survivors often severely disabled
        8. Genetics
            1. Autosomal dominant
            2. *SOX*-9 mutations
    3. Antley-Bixler syndrome
        1. Femur; symmetric short, severely bowing
        2. Other long bones
            1. Radiohumeral synostosis
            2. Joint contractures
        3. Genitourinary: occasional abnormalities
        4. Face
            1. Frontal bossing
            2. Depressed nasal bridge
        5. Scapulae: severely hypoplastic

6. Others
   1. Craniosynostosis
   2. Arachnodactyly
7. Prognosis
   1. Occasional death
   2. Normal neurodevelopment
   3. Severe orthopedic disability
8. Genetics: autosomal recessive

Diagnostic Investigations

1. Radiography
   1. Mandibular hypoplasia
   2. Femoral hypoplasia including proximal femoral focal deficiency and hypoplastic fibulae (Sorge et al. 1995)
   3. Less frequent thoracocostovertebral anomalies
      1. Thorax: congenital elevation of the scapula (Sprengel's deformity)
      2. Ribs
         1. Absent
         2. Hypoplastic
         3. Fused
      3. Spine
         1. Dysplastic vertebrae
         2. Scoliosis
         3. Hemivertebrae
         4. Spina bifida occulta
         5. Lumbar scoliosis
         6. Sacral dysgenesis
      4. Pelvis
         1. Small iliac wings
         2. Wide obturator foramen
         3. Hypoplasia/aplasia of the acetabula with dislocation of the hips
   4. Less frequent upper extremity anomalies
      1. Hypoplasia of the humerus
      2. Radiohumeral/radioulnar synostosis
      3. Ulnar deviation of the hands
2. Histopathology
   1. Femur from one infant showed hyaline cartilage with foci of fibrous dysplasia.
   2. A disorganized growth plate and relative decrease in the resting cartilage matrix in another patient (Urban et al. 1997).

Genetic Counseling

1. Recurrence risk
   1. Patient's sib
      1. Sporadic cases: not increased.
      2. Autosomal dominant inheritance: not increased unless one of the parents is affected.
      3. Maternal diabetes: Risk is significantly increased.
   2. Patient's offspring: 50% if the patient has the autosomal dominant form of the syndrome
2. Prenatal diagnosis possible by ultrasonography (Tadmor et al. 1993; Robinow et al. 1995; Gonçalves et al. 1996; Hinson et al. 1996; Campbell and Vujanic 1997; Gillerot et al. 1997; Urban et al. 1997; Filly et al. 2004; Paladini et al. 2007; Ho et al. 2008; Figureoa et al. 2009; Nowaczyk et al. 2010; Castro et al. 2014)
   1. Micrognathia
   2. Cleft palate
   3. Other facial features
   4. Short, bowed femora
3. Management
   1. Cleft palate repair
   2. Care for cardiovascular and genitourinary complications
   3. Orthopedic management of limb deformity and hip dysplasia

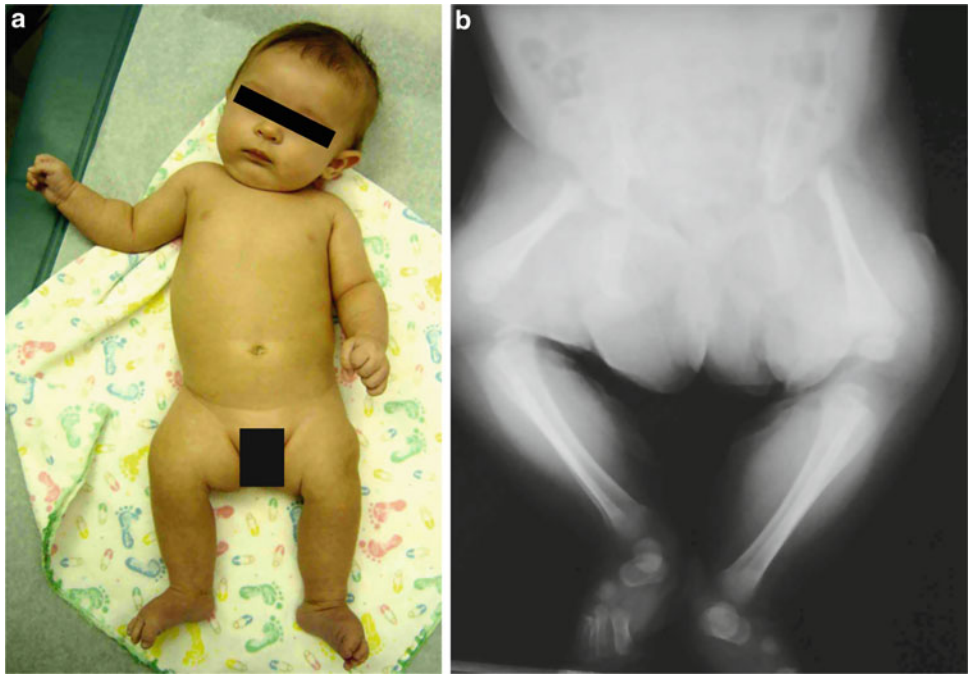

Fig. 1 (**a**, **b**) A 3-month-old infant with femoral hypoplasia – unusual facies syndrome showing short nose, long philtrum, thin upper lip, micrognathia, low-set ears, and marked bilateral rhizomelic shortening of the lower extremities. The radiograph showed hip dysplasia and bilateral proximal femoral hypoplasia

Fig. 2 This 8-month-old girl was diagnosed with femoral hypoplasia-unusual facies syndrome. The pelvic radiography demonstrates type D right proximal focal femoral deficiency. The left femur is also diffusely hypoplastic, particularly the proximal end. Marked acetabular dysplasia was present bilaterally (Courtesy of Dr. Grace Guo)

Fetal Akinesia Deformation Sequence

Contents

Fetal akinesia deformation sequence (FADS) refers to the condition of decreased intrauterine fetal movement and its consequent manifestations of multiple joint contractures, pulmonary hypoplasia, and abnormal face present at birth. It is also known as Pena-Shokeir phenotype (Hall 2009). The incidence is estimated to be 1 in 12,000, reflecting causal heterogeneity.

Synonyms and Related Disorders

Arthrogryposis multiplex congenita with pulmonary hypoplasia; Fetal akinesia sequence; Pena-Shokeir phenotype

Genetics/Basic Defects

1. Genetics:
    1. Sporadic in majority of cases
    2. Familial cases:
        1. Autosomal recessive inheritance (Bacino et al. 1993; Bisceglia et al. 1987; Vuopala et al. 1995b)
        2. Possible X-linked recessive inheritance
2. Heterogeneous causes (Beemer 1990):
    1. Inadequacy of the intrauterine fetal environment:
        1. Etiologic factors:
            1. Ovarian cyst
            2. Bicornuate uterus
            3. Umbilical cord wrapping
            4. Twins
            5. Extrauterine pregnancy
            6. Insufficient placental circulation
            7. Maternal tetanus, drug treatment
            8. Amniotic bands
        2. Oligohydramnios sequence (Rodriguez and Palacios 1991):
            1. Facial deformities (Potter's facies)
            2. Arthrogryposis
            3. Lung hypoplasia
        3. Types of defects determined by the timing of constraint:
            1. Early in pregnancy leading to limb reduction defects, syndactyly, and polydactyly.
            2. Later in pregnancy (third trimester) leading to genu recurvatum, dislocated hips, and deviated wrists.
            3. Various developmental defects occurring earlier in the upper than in the lower limbs.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_90

4. Embryonic onset of immobility interferes with limb development and results in joint fixation and pterygium formation, in contrast to fetal-onset immobility, which causes joint contractures alone (Davis and Kalousek 1988).

2. Pena-Shokeir phenotype or sequence (Hall 1986, 2009):
   1. Pena-Shokeir syndrome:
      1. Originally described by Pena and Shokeir in 1974 (Pena and Shokeir 1974a).
      2. Syndrome consisting of camptodactyly, multiple ankyloses, facial anomalies, pulmonary hypoplasia, and lethal outcome.
      3. Currently the term "Pena-Shokeir phenotype or sequence" is recommended instead of Pena-Shokeir syndrome.
      4. This form clearly exists as an autosomal recessive trait with frequent consanguinity and even incest reported.
   2. Curarization of fetal rats during pregnancy (study by Moessinger 1983) resulted in better understanding of fetal akinesia deformation sequence with the following features almost identical with those described in the Pena-Shokeir syndrome:
      1. Multiple contractures or arthrogryposis
      2. Pulmonary hypoplasia
      3. Craniofacial anomalies
      4. Polyhydramnios
      5. Intrauterine growth retardation
      6. Short umbilical cord
   3. Currently the term "Pena-Shokeir phenotype or sequence" is recommended instead of "Pena-Shokeir syndrome."

3. Fetal akinesia not associated with primary malformations (Grubben et al. 1990; Porter 1995):
   1. Mechanical causes:
      1. Oligohydramnios
      2. Polyhydramnios
      3. Premature rupture of the membrane
      4. Chorioamnionitis
   2. Congenital infections:
      1. Rubella
      2. CMV
      3. Toxoplasmosis
   3. Physical or chemical agents:
      1. Toxic agents
      2. Drugs
      3. X-rays
      4. Hyperthermia
   4. Fetal hypoxia:
      1. Fetal anemia:
         1. Blood loss
         2. Hemolysis
      2. Compression of umbilical cord
      3. Placental insufficiency
      4. Severe toxemia
   5. Maternal myasthenia gravis

4. Role of fetal akinesia in heterogeneous syndromes and conditions (Grubben et al. 1990):
   1. Cerebro-oculo-facio-skeletal (COFS) syndrome (Pena and Shokeir 1974b)
   2. Potter sequence
   3. Neu-Laxova syndrome
   4. Syndrome described by Herva et al. (1985)
   5. Osteochondrodysplasias:
      1. Thanatophoric dysplasia
      2. Achondrogenesis
      3. Diastrophic dysplasia
   6. Lethal multiple pterygium syndrome (LMPS) (Chen et al. 1984; Hall 1984; Moerman and Fryns 1990)
   7. CNS anomalies:
      1. Hydranencephaly
      2. Dandy-Walker malformation with hydrocephalus
      3. Schizencephaly
      4. Olivopontocerebellar degeneration
   8. Skin/connective tissue disorders:
      1. Restrictive dermopathy
      2. Epidermolysis bullosa
      3. Congenital ichthyosis
   9. Metabolic disorders:
      1. Lysosomal storage disorders
      2. Generalized gangliosidosis syndrome type I
      3. Glycogenosis type VII (Moerman et al. 1995)
   10. Known single-gene disorders affecting the spinal cord, peripheral nerves,

neuromuscular junction, or skeletal muscles that result in fetal akinesia (Ravenscroft et al. 2011):

1. Fetal akinesia due to mutations in genes involved in motor neuron development and survival:
    1. Survival motor neuron 1 (*SMN1*)
    2. Epidermal growth factor receptor 3 (*ERBB3*)
    3. mRNA export mediator GLE1 (*GLE1*)
    4. Phosphatidylinositol-4-phosphate 5-kinase, type I, gamma (*PIP5K1C*)
    5. Trisomy 1q
    6. Ubiquitin-activating enzyme 1 (*UBE1*)
2. Fetal akinesia due to mutations in genes affecting the peripheral nerves
3. Fetal akinesia due to mutations in genes encoding components of the neuromuscular junction:
    1. The acetylcholine receptor (AChR): a and d subunits (*CHRNA1* and *CHRND*), γ subunit (*CHRNG*), and antibodies to the γ subunit of the AChR
    2. Contactin-1 (*CNTN1*)
    3. Downstream of kinase-7/muscle intrinsic activator of MUSK (*DOK7*) (Wilbe et al. 2015)
    4. Nesprin-1/synaptic nuclear envelope protein-1 (*SYNE1*)
    5. Rapsyn (*RAPSN*)
4. Fetal akinesia due to mutations in genes encoding adult skeletal muscle proteins:
    1. Actin, skeletal muscle alpha (*ACTA1*)
    2. Amphiphysin 2 (*BIN1*)
    3. Dystrophia myotonica protein kinase (*DMPK*)
    4. Fukutin-related protein (*FKRP*)
    5. Lamin A/C (*LMNA*)
    6. Myotubularin (*MTM1*)
    7. Nebulin (*NEB*)
    8. Ryanodine receptor 1 (*RYR1*)
    9. Tropomyosin, slow beta (*TPM2*)
    10. Troponin I, fast skeletal muscle (*TNNI2*)
    11. Troponin T, fast skeletal muscle (*TNNT3*)
5. Fetal akinesia due to mutations in genes encoding fetally expressed myostructural proteins:
    1. Myosin heavy chain, embryonic (*MYH3*)
    2. Myosin heavy chain, perinatal (*MYH8*)
    3. Myosin-binding protein C1, skeletal muscle slow type (*MYBPC1*)
    4. Utrophin (*UTRN*)
6. Fetal akinesia associated with other genes:
    1. Fibroblast growth factor receptor 2 (*FGFR2*)
    2. Glycogen branching enzyme (*GBE1*)
7. Examples of neuromuscular disorders:
    1. Congenital muscular dystrophy
    2. Congenital myotonic dystrophy
    3. Congenital spinal muscular atrophy
    4. Central core disease
    5. Nemaline myopathy
    6. Others

11. Other disorders causing restrictive fetal akinesia:
    1. Loss of anterior horn cells
    2. Radical disease
    3. Peripheral neuropathy
    4. Congenital myasthenia gravis
    5. Amyoplasia congenita
    6. Prader-Willi syndrome
    7. Cohen syndrome
    8. Angelman syndrome
    9. Neurofibromatosis I
    10. Moebius syndrome
    11. Bilateral dislocation of the hips
    12. Exstrophy of the cloaca and bladder
    13. Chromosome abnormalities:
        1. Fetal triploidy
        2. Trisomies 4p, 9, 9q, 9p, 10q, 11q, proximal 14, proximal 15, and 18
        3. Monosomies 4p and 13q

14. Miscellaneous:
    1. Cornelia de Lange syndrome
    2. Catel-Manzke syndrome
    3. Opitz-Frias syndrome
    4. Bowen-Conradi syndrome
    5. Marden-Walker syndrome
5. Pathogenesis of fetal akinesia sequence (Hageman et al. 1987; Witters et al. 2002):
    1. Spinal cord lesions observed most often (28%)
    2. Brain lesions (19%)
    3. Miscellaneous or connective tissue disorders (11%)
    4. Combined brain and spinal cord lesions (9%)
    5. Mechanical restriction (7%)
    6. Muscle disorders (5%)
    7. Peripheral neuropathy and myasthenia gravis (1%)
    8. No underlying defect observed in 14% of cases
6. Molecular basis of lethal fetal akinesia phenotype (Vogt et al. 2008, 2009):
    1. Mutations in the acetylcholine receptor (AChR) subunits *CHRNA1*, *CHRNB1*, *CHRND*, and rapsyn (*RAPSN*) can also result in a multiple pterygium syndrome (MPS)/FADS phenotype.
    2. Whereas incomplete loss of *DOK7* function may cause congenital myasthenia, more severe loss of function can result in a lethal fetal akinesia phenotype.
7. Mutations in the fetally expressed g subunit (CHRNG) of AChR were found in two FADS disorders, lethal multiple pterygium syndrome (LMPS) and Escobar syndrome. Other AChR subunits α1, β1, and δ (CHRNA1, CHRNB1, CHRND) as well as receptor-associated protein of the synapse (RAPSN) previously revealed missense or compound nonsense-missense mutations in viable congenital myasthenic syndrome (Michalk et al. 2008).
8. Fetal akinesia deformation sequence due to a congenital disorder of glycosylation: characteristic features of the fetal akinesia sequence with other unique features, including joint contractures, cataracts, hypotonia, vermian hypoplasia, and consanguinity, which was found to have CDG-DPAGT1 (Ganetzky et al. 2015).

Clinical Features

1. Pregnancy history (Grubben et al. 1990):
    1. Feeble fetal movement (limitation of fetal movement) (Hammond and Donnenfeld 1995)
    2. Polyhydramnios
    3. Oligohydramnios
    4. Craniofacial abnormalities:
        1. Ocular hypertelorism
        2. Micrognathia
        3. Low-set ears
        4. Depressed nasal tip
        5. Short neck
    5. Limb anomalies:
        1. Lack of normal growth
        2. Limitation of joint movement
        3. Abnormal shape
        4. Abnormal position
        5. Decreased bone calcification
        6. Multiple perinatal fractures (Chen et al. 1995)
2. Phenotype present at birth (Mease et al. 1976):
    1. Multiple joint contractures
    2. Limb pterygia
    3. Craniofacial abnormalities
    4. Pulmonary hypoplasia
    5. Short umbilical cord
    6. Growth retardation
3. Lethal outcome with pulmonary hypoplasia
4. Identifiable familial forms of Pena-Shokeir phenotype/fetal akinesia deformation sequence:
    1. Classic Pena-Shokeir syndrome (type I):
        1. Classic signs of fetal akinesia deformation sequence (lack of normal fetal movement in utero):
            1. Intrauterine growth retardation
            2. Joint contractures
            3. Short gait
            4. Short umbilical cord
            5. Pulmonary hypoplasia

6. Characteristic facial features: hypertelorism, prominent nasal bridge, posteriorly rotated low-set ears, depressed tip of the nose, micrognathia, and cleft palate (probably related to micrognathia and lack of in utero tongue movement)
2. Sticklike limbs with flexion or extension contractures
3. Feet usually in severe equinovarus position but rocker bottom feet may be present
4. Elbows usually flexed
5. Hypoplastic dermatoglyphics
6. Normal CNS and most skeletal muscle, although muscle biopsies often show disuse atrophy, no myopathy changes, and rarely fatty, fibrous replacement
7. Other often reported features:
    1. Disproportionately large head
    2. Short limbs
    3. Thin ribs and long bones
    4. Clenched hands
    5. Ankylosis of large joints
    6. Thoracic kyphosis

2. Lower motor neuron disorder with generalized decrease in anterior horn cells (Chen type) (Chen et al. 1983):
    1. Intrauterine growth retardation.
    2. Polyhydramnios.
    3. Lack of fetal movement in the early second trimester.
    4. Pulmonary hypoplasia.
    5. Characteristic facial appearance:
        1. Nasal bridge: depressed or high
        2. Long philtrum
        3. Small mouth
    6. Limb abnormalities:
        1. Flexion contractures
        2. Hyperextended and overlapping distal phalanges
        3. Ulnar deviation of fingers
        4. Radioulnar synostosis
        5. Clubfeet
    7. Other findings:
        1. Mild kyphosis
        2. Hypoplastic adrenals
    8. Small muscles with disuse atrophy.
    9. Cases reported by Abe et al. (1989), Moerman et al. (1983), Moerman and Fryns (1990), and possibly Imamura et al. (1981) and Gullino et al. (1993) appear to have this subtype.
3. Lethal congenital contracture syndrome type I (LCCS-1) (GLE mRNA export mediator gene mapped at 9q34) (Herva et al. 1985, 1988; Vuopala et al. 1994):
    1. An autosomal recessive disorder frequently seen in Finland
    2. Intrauterine growth retardation
    3. Pulmonary hypoplasia
    4. Micrognathia
    5. Short neck
    6. Thin ribs
    7. Thin, sticklike limbs which may fracture, associated with decreased muscle mass
    8. Extended legs, often with flexed arms
    9. Dislocated hips always present
    10. Striking and characteristic feature: decrease of anterior horn cells in the ventral part of the spinal cord with normal cerebellum
    11. Prenatal diagnosis possible by molecular testing of mutations in the messenger RNA export mediator GLE (*GLE1*) (Nousiainen et al. 2008)
4. Lethal congenital contracture syndrome type II (LCCS-2) (Landau et al. 2003):
    1. Described in two Israeli Bedouin consanguineous kindreds
    2. Clinical features:
        1. Extended elbows
        2. Flexed knees
        3. Mild IGUR
        4. Micrognathia
        5. Hydronephrosis
        6. Distended bladders
    3. Generally decreased anterior horn cells in the spinal cord and muscle wasting suggesting a neuropathic etiology
    4. *ERBB3* gene mapped at 12q13

5. Lethal congenital contracture syndrome type III (LCCS-3):
    1. Represented by a large consanguineous Israeli Bedouin kindred
    2. Clinical features identical to LCCS-2 without bladder involvement
    3. *PIP5K1C* gene mapped at 19p13
6. Lethal lower motor neuron deficiency (Vuopala et al. 1995a):
    1. Described in 11 families.
    2. Considered to be a disorder of the degeneration of anterior horn cells leading to lethality.
    3. Clinical features:
        1. Legs and arm: hyperextended or flexed
        2. Mild IUGR
        3. Usually born near the term
        4. Craniofacial: micrognathia, high nasal bridge, underdeveloped nasal tip, posteriorly rotated ears, and short neck
        5. Early death due to respiratory failure
    4. This disorder mapped to 5q.
7. Families with apparent increase in monozygotic (MZ) twinning (Chen et al. 1983; Lindhout et al. 1985; Ho 2000):
    1. Affected twins and affected singletons occur in the same families.
    2. Clinical features:
        1. Polyhydramnios
        2. Increased fetal movement signal problems
        3. Severe pulmonary hypoplasia
        4. IUGR
        5. Mildly webbed necks
        6. Multiple flexion contractures including camptodactyly and clubfeet
        7. Relatively large head compared to short trunk
        8. Triangular face
        9. Ocular hypertelorism
        10. Clenched jaw
        11. Posteriorly angulated ears
    3. Other features in some affected infants
    4. Relationship between MZ twinning and this type of PSP/FADS:
        1. Unclear.
        2. Potentially they are cases of classic Pena-Shokeir syndrome.
8. Normal in utero growth, macrocephaly, and Pena-Shokeir phenotype (Lammer type):
    1. Affected brothers described by Lammer et al. (1989)
    2. Clinical features:
        1. Normal intrauterine growth
        2. Died with severe pulmonary hypoplasia
        3. Trismus
        4. Micrognathia
        5. Hydronephrosis
        6. Macrocephaly
        7. Choanal atresia in one brother
9. Absence of pyramidal cells, immature CNS development, adducted thumbs, kyphoscoliosis, and severe pulmonary hypoplasia (Biscegli type):
    1. Described in a consanguineous family
    2. Clinical features:
        1. Polyhydramnios
        2. IUGR
        3. Immaturity or delayed development of the CNS
        4. Marked ocular hypertelorism
        5. Hypoplasia and atrophy of skeletal muscles
        6. Extension contractures of arms and legs
        7. Camptodactyly with abducted thumbs
        8. Clubfeet
        9. Marked congenital kyphoscoliosis
10. CNS dysgenesis and degeneration, seizures, trismus, and abdominal wall herniation (Erdl type):
    1. Sibs described by Erdl et al. (1989)
    2. Clinical features:
        1. IUGR
        2. Extended knees
        3. Trismus
        4. Seizures (intrauterine and after birth)
        5. Generalized edema at birth

6. Severe lung hypoplasia
7. Died shortly after birth
8. Abdominal herniation (muscle defect) in the first sib
9. A short and extremely thin umbilical cord
10. Left lung trilobation and large thyroid and adrenal glands
11. Polyhydramnios
12. Fetal hydrops at 30–34 weeks of gestation
13. CNS abnormalities: internal hydrocephalus, hypoplasia of basal ganglia, reduced or degenerating anterior horn cells, and other dystrophic brainstem and cerebellar changes

11. Skeletal muscle maturation defect:
    1. Finnish female siblings described by Vuopala et al. (1994)
    2. Clinical features:
        1. Polyhydramnios
        2. Severe pulmonary hypoplasia
        3. Congenital scoliosis
        4. Normal birth weight for gestation
        5. Edema
        6. One sib stillborn and other lived only 7 weeks
        7. Normal CNS
        8. Skeletal muscle immature with small muscle fibers and prominent atypical spindles
12. Pyramidal tract degeneration:
    1. Two female sibs described by Vuopala et al. (1994)
    2. Pena-Shokeir phenotype
    3. Presence of pyramidal tract degeneration
    4. Normal brain in one sib
    5. Holoprosencephaly in other sibs
    6. May represent an upper motor neuron disorder or a variation on holoprosencephaly
13. In utero seizures and scoliosis, together with cerebral and cerebellar hypoplasia in males (Persutte type):
    1. Two male sibs in a consanguineous family described by Persutte et al. (1988).
    2. Clinical features:
        1. Congenital scoliosis apparent at 18 weeks of gestation
        2. Decreased fetal movement
        3. Polyhydramnios
        4. IUGR
        5. Severe pulmonary hypoplasia leading to death within a few minutes after birth
        6. Flexion contractures
        7. Relatively large head
        8. Short neck
        9. Small low-placed ears
        10. CNS anomalies: agenesis of the corpus callosum and septum pellucida, hydrocephaly, hypoplastic cerebellum, and brain stem
    3. A family of male sibs with similar structural anomalies was described by Skrupski et al. (1996).
    4. This disorder could be X-linked recessive.
14. Microphthalmia, microtia, and normal birth size (Thomas type):
    1. Two male sibs described by Thomas et al. (1993)
    2. Clinical features:
        1. Polyhydramnios.
        2. Normal size at birth.
        3. Multiple congenital contractures.
        4. Died of respiratory insufficiency.
        5. Persistent truncus arteriosus.
        6. Microphthalmia.
        7. Microtia.
        8. One had duodenal atresia, hydronephrosis, and dilated bladder.
15. Olivopontocerebellar hypoplasia:
    1. A family of three siblings reported by Goutieres et al. (1977)
    2. Clinical features:
        1. Contractures
        2. Anterior horn disease
        3. Olivopontocerebellar hypoplasia

4. Death shortly after birth due to pulmonary hypoplasia

16. Failure to myelinate peripheral nerve:
    1. Affected male and female siblings reported by Pena et al. (1968)
    2. Clinical features:
        1. Multiple congenital contractures
        2. Lack of myelination of the peripheral nerve
17. Holoprosencephaly with hypokinesia and congenital contractures in an X-linked recessive pattern of inheritance:
    1. First reported by Morse et al. (1987) and then by Hockey et al. (1988)
    2. Other clinical findings with typical features of FADS
18. Hydranencephaly, calcification of the basal ganglion, and proliferative vasculopathy (Fowler type):
    1. Families reported by Fowler et al. (1972), Harper and Hockey (1983), and Harding et al. (1995)
    2. Clinical findings:
        1. Polyhydramnios
        2. Lack of fetal movements
        3. Generalized edema
        4. Cleft palate
        5. Pterygia of large joints
19. Calcification of leptomeninges, the surface of cerebral convolutions, neurons, muscles, and vessels (Illum type):
    1. A family of male and female siblings reported by Illum et al. (1988)
    2. Other clinical findings:
        1. Multiple congenital contractures
        2. Camptodactyly with ulnar flare and clubfeet
        3. Round face, depressed nasal bridge, long philtrum, short nose, puckered mouth, a deep horizontal crease below the lower lip, and trismus
        4. Early lethality
20. Familial intrauterine anoxia and/or ischemia and PSP/FADS can be associated with the following situations:
    1. Maternal cocaine
    2. Monozygotic twins at increased risk for this type of change because of their vascular connection
    3. Polymicrogyri
    4. Oligogyri
    5. Atrophy of the cerebellum and cerebrum
    6. Cerebral neuronal loss and gliosis
    7. Cyst of the brain
    8. Heterotopia
    9. Decreased number of anterior horn cells with ferrigination
    10. Dilated ventricles with calcification
21. A newly recognizable subtype of FADS with bulbous digital tips, prominent digit pads, and cerebellar anomalies and that highlights the phenotypic diversity of syndromes with multiple congenital contractures manifesting in utero (Nayak et al. 2014)

Diagnostic Investigations

1. Radiography:
    1. Thin tubular bones
    2. Gracile ribs
    3. Multiple fractures possible at mid-diaphyses of humeri, distal diaphyses of femora, proximal diaphyses of tibiae and fibulae
    4. Camptodactyly
2. Histopathologic and other laboratory studies:
    1. Trophoblastic inclusions in the chorionic villi of the placenta:
        1. Triploidy
        2. Lethal multiple pterygium syndrome
    2. Lung hypoplasia
    3. Bones:
        1. Unremarkable resting cartilage
        2. Normal cartilage cell columns at the chondro-osseous junctions
        3. Marrow bony spicules often unusually thin and underossified
        4. Irregular and focal areas of extreme diaphyseal thinning: a consistent finding

4. CNS, muscles, and other organ systems
5. Biochemical studies for lysosomal storage disease
6. Analysis for chromosome abnormality

3. Molecular genetic diagnosis:
   1. *DOK7*- and *RAPSN*-related fetal akinesia deformation sequence available clinically.
   2. The potential of the whole exome sequencing will be crucial to identifying the unknown genetic bases of fetal akinesia (Ravenscroft et al. 2011).

Genetic Counseling

1. Recurrence risk:
   1. Patient's sib:
      1. Autosomal recessive inheritance, 25%
      2. A recurrence risk of 10–15% suggested in the nonfamilial sporadic cases
   2. Patient's offspring: a lethal entity not surviving to reproductive age
2. Prenatal diagnosis by ultrasonography (Ohlsson et al. 1988; Yfantis et al. 2002; Ruano et al. 2003; Hellmund et al. 2016) in high-risk pregnancies after the birth of a previous child with a heritable (mostly autosomal recessive) form of fetal akinesia sequence:
   1. Marked decreased fetal activity:
      1. Restricted limb movements
      2. Decreased fetal chest movements
   2. Hydramnios/oligohydramnios.
   3. Intrauterine growth retardation.
   4. Hydrops noted in some affected babies late in pregnancy.
   5. Nuchal edema.
   6. Abnormal profile:
      1. Micro-/retrognathia
      2. Flat profile
      3. Edema of the forehead
      4. Permanently open mouth
      5. Not visualized because of hydrops
   7. Absent/minimal filling of the stomach.
   8. Thorax hypoplasia/narrow thorax.
   9. Scoliosis.
   10. Permanent opisthotonus.
   11. Fixation of the elbow joint, wrist, fingers, knee joint, and ankle joint.
   12. Pterygia.
   13. Some affected babies often die in utero if not shortly following birth.
   14. Other echographic abnormalities associated with fetal akinesia:
      1. Brain:
         1. Microcephaly
         2. Holoprosencephaly
         3. Hydranencephaly
         4. Meningomyelocele
         5. Lissencephaly
         6. Dilated ventricles
         7. Absence of septum pellucidum
      2. Spinal cord: sacrococcygeal agenesis
      3. Gastrointestinal tract:
         1. Omphalocele
         2. Gastroschisis
      4. Renal:
         1. Bilateral renal agenesis
         2. Renal malformations
      5. Craniofacial:
         1. Hypertelorism
         2. Hypotelorism
         3. Micrognathia
         4. Cleft palate
      6. Limbs:
         1. Contractures (arthrogryposis)
         2. Camptodactyly
         3. Webbing
         4. Syndactyly
         5. Polydactyly
         6. Overlapping fingers and toes
         7. Abnormal position
         8. Clubfoot
         9. Partial absence or shortness
      7. Cardiopulmonary:
         1. Pulmonary hypoplasia
         2. Cardiac defects
   15. Prenatal MR imaging in Pena-Shokeir syndrome: to look for associated neurological malformation (Persutte et al. 1988; Senocak et al. 2009; Gupta et al. 2011; Nemec et al. 2011).
3. Management: no effective treatment for pulmonary hypoplasia

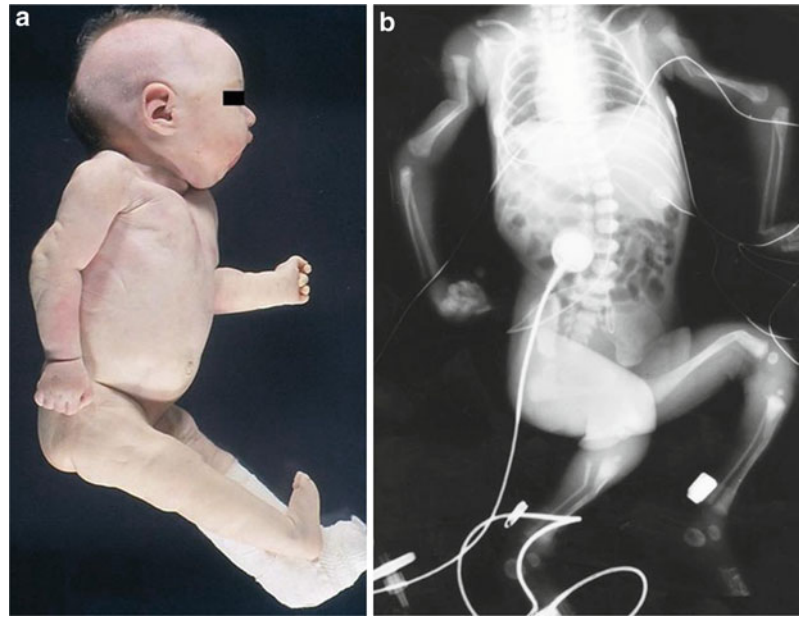

Fig. 1 (**a**, **b**) A neonate with fetal akinesia sequence showing micro-/retrognathia, short neck, narrow thorax, flexion contractures of hips, fixed extension of the right knee, and inverted and rotated feet. The radiograph showed gracile ribs; thin long bones with multiple fractures at mid-diaphyses of humeri, distal diaphysis of femora, and proximal diaphyses of both tibiae and the left fibula; and clubhands

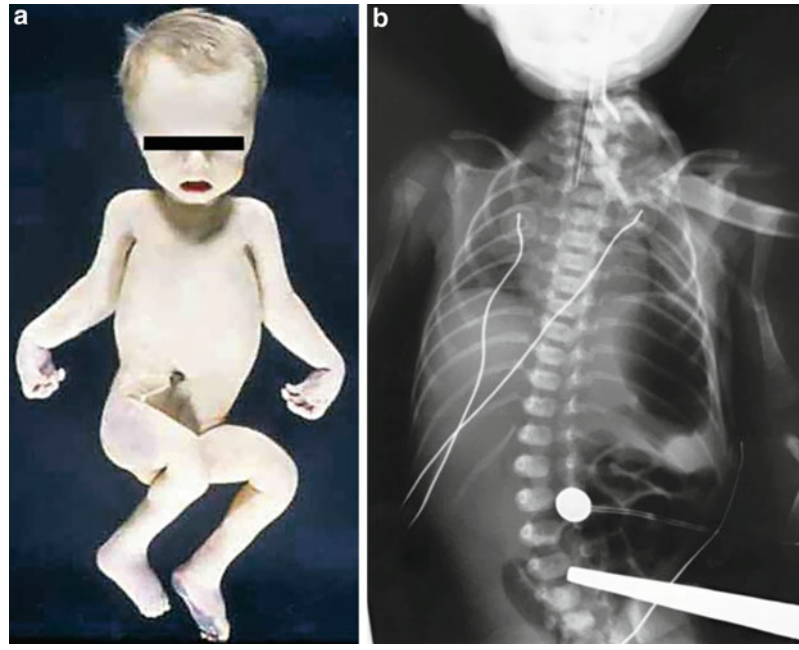

Fig. 2 (**a**, **b**) A neonate with fetal akinesia sequence showing micrognathia and multiple contractures. The radiograph showed gracile ribs and fractures at mid-diaphyses of humeri

Fig. 3 (**a**, **b**) A neonate with Pena-Shokeir sequence (Chen type) showing hypertelorism; a short nose with depressed nasal bridge; long philtrum; a small and recessed jaw; low-set malformed ears; a short neck; clenched hands; multiple contractures at the hip, elbows, knees, and ankles; and clubfeet. The infant had scalp edema and pulmonary hypoplasia. Neuromuscular histology showed lower motor neuron disorder with generalized decrease in anterior horn cells

Fig. 4 Radiographic study of the infant showed gracile ribs; thin long bones; and multiple contractures at the hip, elbows, knees, and ankles; and clubfeet

Fig. 5 Prenatal ultrasonography showed hydramnios, retrognathia, low-set ears, scalp edema, and flexion contractures at the elbows and knees

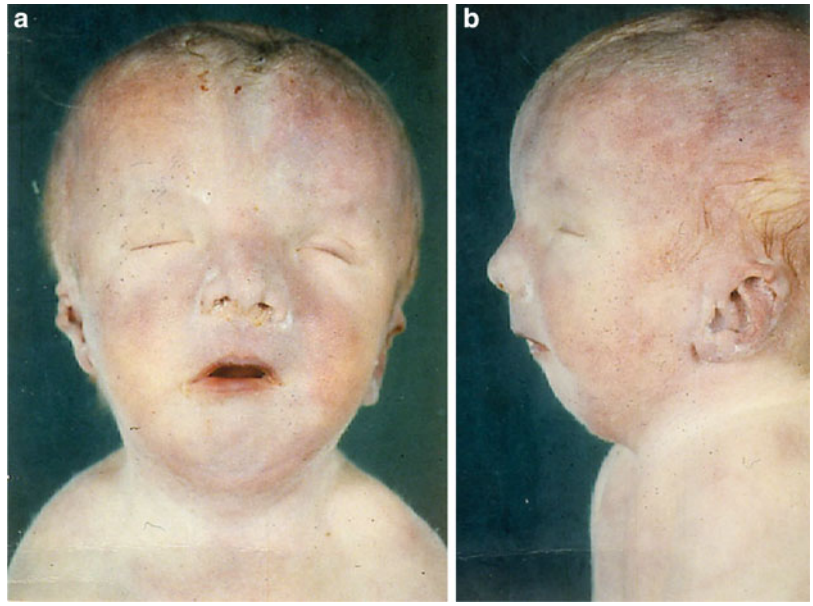

Fig. 6 (**a**, **b**) An infant in a family with MZ twinning. Note small jaw, ocular hypertelorism, antimongoloid slant of the palpebral fissures, high bridge of the nose, posteriorly rotated large ears, triangular-shaped face, and short-appearing mildly webbed neck

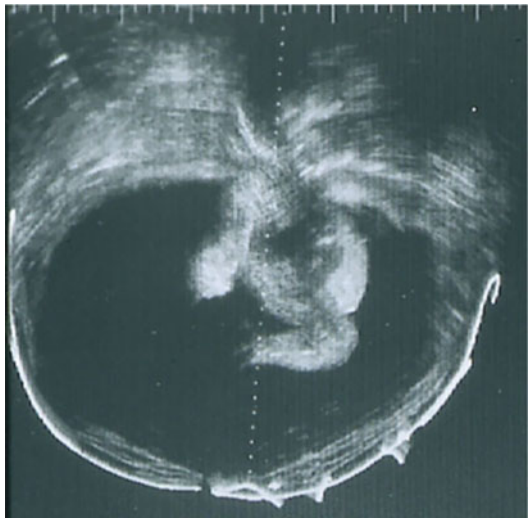

Fig. 7 Prenatal ultrasound of this fetus showed polyhydramnios, IUGR, and flexion contractures of the knees

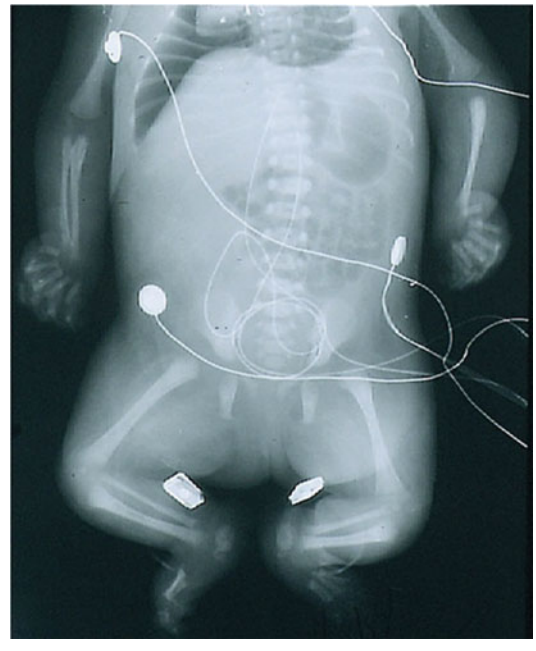

Fig. 8 Radiograph showed gracile ribs, thin long bones, flexion contractures at the elbows and knees, and clenched hands

Fetal Alcohol Spectrum Disorders

Contents

In 1973, Jones et al. described, in the American medical literature, a constellation of features in children born to alcoholic mothers, now known as fetal alcohol syndrome (FAS). In 1996, the Institute of Medicine further defined criteria of FAS and proposed two new terms, alcohol-related neurodevelopmental disorder (ARND) and alcohol-related birth defects (ARBDs), to include structural CNS and cognitive abnormalities in children in whom fetal exposure to alcohol has been confirmed.

It is established that prenatal exposure to alcohol produces a range of morphological and cognitive-behavioral outcomes in the offspring, commonly referred to as fetal alcohol spectrum disorder (FASD) (Kodituwakku 2007). Fetal alcohol syndrome refers to severely affected children on the spectrum displaying a pattern of altered growth and morphogenesis, characterized by prenatal and postnatal growth retardation, craniofacial anomalies, abnormal brain function reflected by cognitive deficits, and developmental delays. The majority of children (about three times as many children as those with FAS) with substantial prenatal alcohol exposure show only some of the abovementioned features (Sampson et al. 1997), commonly referred to having fetal alcohol effects (FAEs). The term FAE, however, has been replaced by two new terms: ARND and ARBD.

The incidence of FAS in the United States is estimated to be about 1–3 per 1,000 live births. The incidence is higher in certain population, such as Native Americans (Gleason 2001).

Synonyms and Related Disorders

Alcohol-related birth defects (ARBDs); Alcohol-related neurodevelopmental disorder (ARND); Fetal alcohol effect; Fetal alcohol syndrome; Partial fetal alcohol syndrome

Genetics/Basic Defects

1. Genetics (Thackray and Tifft 2001):
    1. Genetic susceptibility:
        1. Observation of differences in the severity and spectrum of FAS based on genetic background.
        2. Higher concordance of FAS in monozygotic twins than in dizygotic twins supports the concept of genetic factors in the fetal effects of alcohol.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_91

2. Possible mechanism of heritable susceptibility to FAS – genetically encoded differences in alcohol dehydrogenase, the enzyme responsible for metabolizing alcohol in the liver:
    1. The mother of children with FAS: possibly with less functional enzyme resulting in higher peak blood alcohol concentration after the ingestion of alcohol.
    2. Fetuses with FAS: possibly with deficient alcohol dehydrogenase activity and thus less tolerance to elevated maternal alcohol levels.
2. Pathogenesis (Erb and Andresen 1978; Thackray and Tifft 2001):
    1. Clinical features of FAS: result from exposure of the developing fetus to toxic levels of alcohol and its metabolites at critical periods in development.
    2. Specific pathophysiology unknown: may involve free radical formation that causes cellular damage in the developing tissues of the fetus.
    3. Exposure in the first trimester:
        1. Affects organogenesis and craniofacial development, leading to minor and major malformations such as the characteristic facial features and ARBD.
        2. Excessive cell death in the midline of the developing embryo may account for the development of these facial features.
    4. Continuous use of alcohol by the mother later in pregnancy resulting in low birth weight and affecting postnatal growth.
    5. Alcohol exposure at varying times in pregnancy may result in similar CNS neurodevelopmental effects.
    6. Detrimental defects on the fetus when there is concomitant maternal use of other drugs (marijuana, nicotine, caffeine).
3. Key risk factors for alcohol-induced brain damage:
    1. Peak blood alcohol concentration rather than the length of alcohol exposure: the critical variable in determining the risk for adverse effects on brain development.
    2. Cessation of drinking alcohol at any time during pregnancy likely to be beneficial on the developing brain.
    3. The cerebellum particularly vulnerable to alcohol-induced growth restriction as well as neuronal loss following alcohol exposure during the brain growth spurt (third trimester in humans).
    4. Heavy alcohol consumption during the first trimester associated strongly with craniofacial abnormalities in humans.
4. A potential molecular target for morphological defects of fetal alcohol syndrome: Kir2.1 (Bates 2013).
5. Potential role of endocannabinoid signaling (Basavarajappa 2015):
    1. Several molecular mechanisms are expected to contribute to the damaging effects of prenatal alcohol exposure on the developing fetus.
    2. These events including endocannabinoid mechanisms contribute to impaired development and function of neuronal communication and circuit formation.
    3. These alcohol-induced deficits result in long-lasting abnormalities in neuronal plasticity and learning and memory and can explain many of the neurobehavioral abnormalities found in FASD.
6. Epigenetic mechanisms in developmental alcohol-induced neurobehavioral deficits (Mead and Sarkar 2014; Basavarajappa and Subbanna 2016):
    1. Several epigenetic mechanisms are suggested to contribute to the harmful consequences of alcohol abuse during pregnancy in the developing fetus.
    2. Epigenetic modifications, such as altered DNA methylation, specific histone protein modification, and dysregulation of miRNA, in response to developmental alcohol exposure, can contribute to impaired neurogenesis, neuronal communication, and neural circuit assembly.
    3. These alcohol-induced neuronal deficits can be long-lasting and could result in

abnormalities in synaptic plasticity and cognitive function and can provide bases for many of the neurobehavioral abnormalities found in FASD.

Clinical Features

1. Characteristic craniofacial features in the young child (Jones and Smith 1973, 1975; Clarren and Smith 1978; Clarren 1981; Colangelo and Jones 1982; Gleason 2001; Moore et al. 2002; Jones 2003):
    1. Discriminating features:
        1. Short palpebral fissures (Miller et al. 1981)
        2. Flat midface
        3. Indistinct (smooth, flat) philtrum
        4. Thin upper lip
    2. Associated features:
        1. Epicanthal folds
        2. Low nasal bridge
        3. Minor ear anomalies
        4. Short nose
        5. Micrognathia
2. Growth retardation (Hanson et al. 1976; Jones et al. 1976; Jones 1986):
    1. Low birth weight for gestational age (prenatal growth deficiency) (97%)
    2. Decelerating weight over time not due to nutrition (postnatal growth deficiency) (97%)
    3. Disproportionate low weight to height
3. Alcohol-related birth defects (ARBDs) – birth defects associated with in utero alcohol exposure:
    1. Ocular abnormalities (Strömland 1987; Strömland and Hellström 1996):
        1. Strabismus
        2. Retinal vascular anomalies
        3. Optical nerve hypoplasia
        4. Refractive problems secondary to small globes
        5. Coloboma
    2. Cardiovascular abnormalities:
        1. Atrial septal defect
        2. Ventricular septal defect
        3. Aberrant great vessels
        4. Tetralogy of Fallot
    3. Hepatic abnormality: extrahepatic biliary atresia
    4. Skeletal abnormalities (Gonzalez 1979; Spiegel et al. 1979):
        1. Hypoplastic nails
        2. Shortened fifth digits
        3. Radioulnar synostosis
        4. Flexion contractures
        5. Camptodactyly
        6. Clinodactyly
        7. Pectus excavatum/carinatum
        8. Klippel-Feil syndrome
        9. Hemivertebrae
        10. Scoliosis
    5. Muscular abnormalities:
        1. Hernias:
            1. Diaphragm
            2. Umbilicus
            3. Inguinal
        2. Diastasis recti
    6. Renal abnormalities:
        1. Aplastic/dysplastic/hypoplastic kidneys
        2. Horseshoe kidneys
        3. Ureteral duplications
        4. Megaureter
        5. Hydronephrosis
        6. Cystic diverticula
        7. Vesicovaginal fistula
    7. Genital abnormalities:
        1. Hypospadias
        2. Labial hypoplasia
    8. Cutaneous abnormalities:
        1. Hemangiomas
        2. Hirsutism
    9. Auditory abnormalities (Church and Abel 1998):
        1. Conductive hearing loss
        2. Neurosensory hearing loss
    10. Neuroendocrine abnormalities:
        1. Altered hypothalamic-pituitary-adrenocortical axis-heightened stress response
        2. Abnormal thyroid function
    11. Other abnormalities: include virtually any malformation

4. Alcohol-related neurodevelopmental disorder (ARND):
    1. Structural CNS abnormalities associated with in utero alcohol exposure:
        1. Microcephaly
        2. Microencephaly
        3. Decreased size of the cerebrum, cerebellum, basal ganglia, and diencephalons
        4. Partial or complete agenesis of the corpus callosum
        5. Neuroglial heterotopia
        6. Dendritic neuronal abnormalities
        7. Holoprosencephaly sequence
        8. Anencephaly
        9. Porencephaly
        10. Ventricular enlargement
        11. Dandy-Walker malformation
    2. Neurologic abnormalities associated with in utero alcohol exposure:
        1. Impaired fine motor skills
        2. Deficits in balance
        3. Poor tandem gait
        4. Neurosensory hearing loss
        5. Poor hand-eye coordination
        6. Hypotonia
    3. Neurobehavioral abnormalities associated with in utero alcohol exposure (Streissguth et al. 1991; Olson et al. 1997; Abel 1980):
        1. Learning disabilities
        2. Decreased IQ scores (Streissguth et al. 1978)
        3. Mental retardation
        4. Attention deficit/hyperactivity disorder (Spohr and Steinhausen 1984)
        5. Poor impulse control
        6. Problems in memory, attention, or judgment
        7. Problems in social perception
        8. Deficits in higher-level receptive or expressive language: speech and language abnormalities (Iosub et al. 1981)
        9. Poor capacity for abstraction or metacognition
        10. Autism
        11. Adult mental illness:
            1. Alcohol or drug dependence
            2. Psychotic disorders
            3. Avoidant, antisocial, or dependent personality disorder
            4. Depression
            5. Suicide
        12. Alcohol or drug dependence
        13. Psychotic disorders
        14. Avoidant, antisocial, or dependent personality disorder
        15. Depression
        16. Suicide
5. Neuropsychological abnormalities found in individuals with fetal alcohol spectrum disorders (FASDs) when compared to typically developing children (Basavarajappa 2015):
    1. General intelligence: lower IQ (~70)
    2. Executive function: impaired executive functions such as planning, fluency, and working memory
    3. Learning and memory:
        1. Verbal: impaired initial learning without affecting retention of information already learned due to implicit learning strategies
        2. Nonverbal: impaired nonverbal learning and memory but impairment of retention of information is inconsistent
    4. Motor function: deficits in motor abilities and visual-motor tasks
    5. Attention and hyperactivity: deficits in attention and exhibit hyperactivity
6. Neonatal alcohol withdrawal signs:
    1. Hypoglycemia
    2. Irritability
    3. Tremors
    4. Seizures
    5. Autonomic dysregulation, including temperature instability
    6. Blood pressure abnormalities:
        1. Hypotension
        2. Hypertension
    7. Excessive glucocorticoid release
    8. Altered behavioral state organization
7. Medical risks for women who drink alcohol (Bradley et al. 1998):
    1. Increased mortality and breast cancer in women who drink more than two drinks daily

2. Increased menstrual symptoms, hypertension, and stroke in women with higher levels of alcohol consumption
3. Increased infertility and spontaneous abortion in women who drink heavily
4. Adverse fetal effects after variable amounts of alcohol consumption, making any alcohol use during pregnancy potentially harmful

Diagnostic Investigations

1. Diagnosis of FAS based on clinical features in the setting of maternal alcohol use
2. Radiography for skeletal abnormalities
3. Neuroimaging in FASD (Norman et al. 2009):
    1. MRI imagings for CNS abnormalities:
        1. Overall reduction in brain volume
        2. CNS disorganization
        3. Wide range of structural abnormalities (Johnson et al. 1996):
            1. Corpus callosum agenesis/hypoplasia
            2. Cavum septi pellucidi and cavum vergae
            3. Ventriculomegaly
            4. Hypoplasia of inferior olivary eminences
            5. Small brain stem
            6. Micrencephaly
    2. Neuroimaging techniques:
        1. Regional increases in cortical thickness and gray matter volume
        2. Decreased volume and disorganization of white matter in individuals
    3. Functional imaging studies: functional and neurochemical differences in those prenatally exposed to alcohol
4. Echocardiography for cardiovascular anomalies
5. Ultrasound for renal abnormalities
6. Neurologic and neurobehavioral evaluations

Genetic Counseling

1. Recurrence risk:
    1. Patient's sib: high if the mother abuses alcohol during the pregnancy
    2. Patient's offspring: high if the affected woman abuses alcohol during her pregnancy
2. Prenatal diagnosis:
    1. Low maternal serum alpha-fetoprotein and low pregnancy-specific β_1-glycoprotein observed in one report possibly reflecting primary or secondary effects of ethanol abuse in pregnancy and possibly useful in predicting fetal alcohol syndrome (Halmesmäki et al. 1986)
    2. Prenatal ultrasound examination recommended for pregnant women who drink to detect fetal growth retardation and various birth defects associated with in utero alcohol exposure
3. Management (Thackray and Tifft 2001):
    1. Beneficial effects of early diagnosis of FAS on medical intervention of affected infants and children
    2. Management of issues (medical and surgical interventions) regarding specific birth defects.
    3. Implementation of resource programs for developmental delay, functional abilities, speech abilities, and social/behavioral interactions
    4. Appropriate interventions with educational evaluation and support and community resources such as the National Organization on Fetal Alcohol Syndrome (NOFAS)
    5. Evaluation and management of the siblings who also have FAS
    6. Prevention of alcohol-induced fetal brain damage (American Academy of Pediatrics Committee on Substance Abuse and Committee on Children with Disabilities 2000):
        1. Abstinence recommended for pregnant women and for those planning pregnancy since there is no known safe amount of alcohol consumption during pregnancy
        2. High-quality educational programs regarding the deleterious effects of alcohol on the unborn child
        3. High awareness of FAS and ARND and their prevention by health-care professionals

4. Appropriate support services including prevention of recurrence for parents and children diagnosed as having FAS or ARND

Fetal Hydantoin Syndrome

Contents

Fetal hydantoin syndrome is by far the best-characterized malformation complexes induced by anticonvulsant drugs used to treat maternal epilepsy.

Genetics/Basic Defects

1. Cause: maternal exposure to hydantoin anticonvulsant
2. Effect of prenatal exposure to hydantoin (Hanson et al. 1976; Buehler et al. 1994):
   1. Fetal hydantoin syndrome in 11% of cases
   2. Fetal hydantoin effect in an additional 31% of cases
3. Teratogenicity of hydantoin:
   1. Mediated not by the parent compound but by toxic intermediary metabolites that are produced during the biotransformation of the parent compound
   2. Epoxide (oxidative intermediates) – the primary teratogenic agent of phenytoin:
      1. Thought to occur before the formation of the dihydrodiol metabolite in a reaction catalyzed by the enzyme epoxide hydrolase
      2. Highly reactive and capable of covalently binding to embryonic or fetal nucleic acids, which at critical periods of embryogenesis are theoretically capable of disrupting normal development

Clinical Features

1. Eleven percent of infants exposed prenatally to hydantoin classified as having the fetal hydantoin syndrome
2. The presence of variable patterns of malformations (Bustamante and Stumpff 1978; Robinow 1984)
3. Classic features (Hanson 1986):
   1. Growth and development:
      1. Developmental delay
      2. Mild to moderate mental retardation
      3. Prenatal and postnatal growth deficiencies
      4. Microcephaly
   2. Craniofacial anomalies (Hanson and Smith 1975; Kousseff et al. 1981):
      1. Ridging of the metopic suture
      2. Broad and low nasal bridge
      3. Ocular defects (Hampton and Krepostman 1981):

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_92

1. Hypertelorism
2. Ptosis
3. Strabismus
4. Wide epicanthal folds
5. Congenital glaucoma
6. Retinoschisis
7. Nasolacrimal duct deformity and agenesis
8. Coloboma of the iris and choroid

4. Short upturned nose
5. Low-set abnormal ears
6. Wide mouth with prominent lips
7. Long philtrum
8. Wide alveolar ridges
9. Cleft lip and/or palate

3. Limb defects (Smith 1977; Sabry and Farag 1996):
   1. Hypoplasia of distal phalanges and nails (most characteristic feature) (Nagy 1981; Verdeguer et al. 1988)
   2. A finger-like thumb
   3. Hyperphalangism
   4. Adactyly/absent nails
   5. Acheiria (congenital absence of one or two hands)
   6. Positional limb defects:
      1. Calcaneovalgus deformity
      2. Pes cavus
   7. Abnormal palmar creases
4. Less frequently observed abnormalities:
   1. Neck webbing
   2. Low hairline
   3. Cardiovascular anomalies:
      1. Aortic coarctation
      2. Patent ductus arteriosus
      3. Septal defects
   4. Gastrointestinal abnormalities:
      1. Pyloric stenosis
      2. Duodenal atresia
   5. Renal defects
   6. Genital abnormalities in males:
      1. Hypospadias
      2. Bifid or shawl scrotum
   7. Hernias:
      1. Diaphragmatic hernia
      2. Umbilical hernia
      3. Inguinal hernias
   8. Other skeletal anomalies (Kogutt and Young 1984):
      1. Spinal anomalies:
         1. Scoliosis
         2. Segmentation defects of vertebral bodies
      2. Rib and sternal anomalies
      3. Hip dislocation
   9. Occasional tumor association:
      1. Neuroblastoma
      2. Melanotic neuroectodermal tumor of infancy
   10. Single umbilical artery

Diagnostic Investigations

1. Radiography for skeletal defects
2. Echocardiography for associated congenital heart defect
3. Renal ultrasound for renal defects
4. Developmental evaluation

Genetic Counseling

1. Recurrence risk:
   1. Patient's sib: minimal in the absence of maternal exposure to hydantoin during pregnancy
   2. Patient's offspring: minimal in the absence of maternal exposure to hydantoin during pregnancy
2. Prenatal diagnosis: prenatal ultrasound examination recommended for pregnant women who take hydantoin anticonvulsant to detect fetal growth retardation and various birth defects associated with in utero hydantoin exposure
3. Prenatal risk prediction of fetal hydantoin syndrome (Buehler et al. 1993):
   1. Not recommending chorionic-villus sampling
   2. Not recommending the use of placental cultures

4. Management:
    1. Management of issues (medical and surgical interventions) regarding specific birth defects
    2. Implementation of resource programs for developmental delay, functional abilities, speech abilities, and social/behavioral interactions
    3. Appropriate interventions with educational evaluation and support
    4. Avoid hydantoin anticonvulsant during pregnancy

Fibrodysplasia Ossificans Progressiva

Contents

Fibrodysplasia ossificans progressiva (FOP), an extremely rare and catastrophic genetic disorder of progressive heterotopic ossification, is the most disabling condition of extraskeletal ossification known to mankind. It is also known as myositis ossificans progressiva. The incidence of FOP was estimated to be approximately 1 in 1.64 million (Connor and Evans 1982b).

Synonyms and Related Disorders

Myositis ossificans progressiva

Genetics/Basic Defects

1. Inheritance
   1. Usually sporadic in occurrence: very few affected individuals have children because of the devastating nature of the disease
   2. Autosomal dominant inheritance (Connor et al. 1993; Kaplan et al. 1993; Pachajoa and Botero 2015; Pawar et al. 2015)
      1. Complete penetrance
      2. Variable expression
      3. FOP in two half sisters: evidence of maternal mosaicism (Janoff et al. 1996)
      4. Phenotypic and molecular heterogeneity in FOP (Virdi et al. 1999)
2. Cause (Shore et al. 2006)
   1. FOP is caused by a recurrent heterozygous mutation (c.617G>A; p.R206H) of codon 206 in the glycine-serine (GS) activation domain of activin receptor 1A (ACVR1)/activin-like kinase 2 (ALK2) (Herrera-Esparza et al. 2013), a highly conserved BMP (bone morphogenetic protein) type I receptor, in all sporadic and familial cases of classically affected individuals worldwide, making this one of the most highly specific disease-causing mutations in the human genome (Kaplan et al. 2007).
   2. Not all FOP cases are caused by the common mutation, as there are several FOP variants with varying phenotypes (Faruqi et al. 2014).
   3. Overexpression of a potent bone-inducing morphogen, bone morphogenetic protein 4 (BMP4), in lymphocytes is associated with the disabling ectopic osteogenesis of FOP (Shafritz et al. 1996).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_93

4. Noggin gene (*NOG*) mutations in FOP (Lucotte et al. 1999; Sémonin et al. 2001).
5. Chromosomal locus for the *FOP* gene:
    1. 2q23-24 by genome-wide linkage analysis
    2. 4q27-31 (Feldman et al. 2000)
    3. 17q21-22 (Lucotte et al. 2000)

3. The presence of two skeletons in patients with FOP (Mahboubi et al. 2001)
    1. A normotopic bone formation during embryogenesis
        1. Grossly normal normotopic skeleton
        2. Exceptions
            1. Segmentation defects in the cervical spine
            2. Malformation of the great toes at birth due to shortening of the first metatarsal and proximal phalanx
            3. Monophalangic great toes due to synostosis: the earliest phenotypic feature of fibrodysplasia ossificans progressiva
    2. A heterotopic bone formation following birth
        1. Usually beginning in the first decade of life
        2. Progressing in characteristic anatomic patterns
        3. Typically involving the upper back and neck
        4. Heralded by large painful swellings of the highly vascular fibroproliferative tissue involving ligaments, tendons, and skeletal muscle, often following minor trauma
        5. Early swelling regresses spontaneously but often matures to true heterotopic bone
4. Pathogenesis
    1. p.R206H mutation in the *ACVR1* gene enhances ACVR1 activation and disrupts the highly conserved BMP signaling pathway (Groppe et al. 2007).
    2. When triggered by an inflammatory stimulus, some normal-functioning connective tissue may metamorphose into heterotopic bone (Kaplan et al. 2008).
5. Genotype-phenotype correlation (Hüning and Gillessen-Kaesbach 2014)
    1. Individuals with the "classical" p.R206H mutation have an early onset of ossifications (during childhood) that can be triggered by trauma. The course of the disease is usually severe and leads to immobility at early age.
    2. Also patients with the mutations p.G328W and p.G328E show early disease onset and severe progression, but the ossifications seem not to be influenced by trauma.
    3. Individuals with the mutation p.G356D seem to have later onset of the disease, which could, however, progress quickly.
    4. Also the mutations p.G328W and p.G328E are probably associated with early onset and severe disease course but do not seem to be triggered by trauma.
    5. Interestingly, the amino acid change p.G328R in the same codon seems to be associated with a mild disease course and late onset, but ossifications show a high correlation with injury or surgical intervention.
    6. The amino acid changes p.R258S, p.R375P, and p.L196P seem to be associated with a milder phenotype with less influence on life quality than in patients with other mutations.
6. Precipitating factors for ectopic ossification (Connor and Evans 1982c; Kocyigit et al. 2001)
    1. Biopsies of lumps
    2. Intramuscular injections
    3. Dental therapy
    4. Prolonged pressure on the body, such as tight clothing
    5. Aggressive physical therapy
    6. Falls
    7. Injuries to muscle
    8. Exacerbation of bone formation common in response to surgery and other tissue trauma

9. Operation to excise ectopic bone
10. Careless venipuncture

Clinical Features

1. Appears to be normal at birth except for telltale malformations of the great toes (Kaplan et al. 2005)
2. Extraskeletal abnormalities (100%) (Connor and Evans 1982c)
   1. Progressive widespread heterotopic ossification of muscles, tendons, ligaments, aponeurosis, and fascia. The heterotopic bony masses lead to progressive immobility/disability (100%).
   2. Onset: about 4 years of age in majority of patients (Rogers and Geho 1979).
   3. Typical course of lesional progression at any site (Mahboubi et al. 2001)
      1. Early lesions during the first few weeks: characterized by pain, erythema, swelling, warmth, and tenderness
      2. Intermediate lesions after several weeks
         1. Swelling beginning to subside
         2. Decrease in pain, tenderness, and erythema
      3. Late lesions after approximately 12 weeks
         1. Disappearance of swelling.
         2. A hard, non-tender lesion remains. It is roentgenographically a new area of heterotopic ossification.
   4. Characteristic anatomical progression of heterotopic bone formation (Cohen et al. 1993; Mahboubi et al. 2001)
      1. Typical earliest involvement: dorsal, axial, cranial, and proximal regions of the body.
      2. Later involvement: ventral, appendicular, caudal, and distal regions of the body.
      3. Painful swelling of muscle (myositis) leading to ossification began at mean age of 4.6 years (0–16 years) initially in the neck and upper spine and later around the hips, other major joints, and jaw (Smith 1998).
5. Proximal medial tibial osteochondromas (>90%)
6. Variation in size of soft tissue nodules involving the neck and back: often the first indication of heterotopic ossification in a child
7. Progressive ankylosis:
   1. Shoulder joints
   2. Elbow joints
   3. Hip joints
   4. Knee joints
   5. Neck (>90%): painful swelling or stiffness of the neck in most patients
   6. Spine:
      1. Leading to complete fusion
      2. Mimicking ankylosing spondylitis
      3. Pain and stiffness of the spine present in most patients
   7. Muscles of mastication – ankylosis of the temporomandibular joint by the progressively ossifying lesion (Cramer et al. 1981)
      1. Leading to limited mouth opening
      2. Inability to feed orally
      3. Poor oral hygiene
      4. Subsequent cachexia
8. Severe restrictive pulmonary disease (Kaplan and Glaser 2005)
   1. Causes
      1. Kyphoscoliosis of the thoracolumbar spine
      2. Ankylosis of costovertebral joints
      3. Ossification of the chest wall with resultant dependence on diaphragm for respiration
   2. Severely reduced lung volume
   3. Constrictive airway dysfunction developing over time
   4. Recurrent pulmonary infections secondary to ineffective cough: a common cause of death in the third or fourth decade
9. Eventual confinement to wheelchair

3. Congenital malformation (microdactylia) of the great toes (>95%) and thumbs (50%)
    1. Association with congenital great toe malformation – abnormal hallux, hallux valgus (Schroeder and Zasloff 1980; Cohen 2002)
        1. Mainly short big toes with single phalanx (a cartilaginous anlage of the first metatarsal and proximal phalanx) present at birth
        2. An important early diagnostic clue
    2. Shortened thumbs
    3. Clinodactyly of the fifth fingers
4. Other features
    1. Patients with FOP are prone to fractures with poor outcome.
    2. Occasional baldness.
    3. Conductive hearing loss (∼50%) secondary to calcification and fusion of the ligaments, tendons, and bones of the middle ear.
    4. Markedly reduced reproductive fitness.
    5. Life-threatening complications caused by thoracic insufficiency syndrome (95%) due to:
        1. Costovertebral malformations with orthotopic ankylosis of the costovertebral joints
        2. Ossification of intercostals muscles, paravertebral muscles, and aponeuroses
        3. Progressive spinal deformity
            1. Kyphoscoliosis
            2. Thoracic kyphosis
        4. Pneumonia
        5. Right-sided congestive heart failure
    6. Reduced life span but most patients survive to adulthood.
5. Natural history
    1. Mobility becomes more restricted as the disease advances.
    2. A life-long rigid immobility caused by the progressive metamorphosis of skeletal muscle and soft connective tissue into a second skeleton of heterotopic bone.
    3. Typically confined to bed or wheelchair by early 30s.
6. Diagnostic criteria (Kartal-Kaess et al. 2010)
    1. Major characteristics
        1. Congenital malformation of the great toes (earliest phenotypic feature)
        2. Progressive extraskeletal bone formation (episodic, begin during childhood)
        3. Heterozygous *ACVR1* mutation
    2. Other features
        1. Early stage lesions associated with soft tissue swellings and inflammation in characteristic anatomic patterns
        2. Predictable regional pattern of heterotopic ossification
        3. Cervical spine fusions
        4. Short/broad femoral necks
        5. Osteochondromas
        6. Conductive hearing loss
7. Differential diagnosis of heterotopic ossification (Blaszczyk et al. 2003; Kartal-Kaess et al. 2010)
    1. Progressive osseous heteroplasia (Shore and Kaplan 2005)
        1. Presence of cutaneous ossification
        2. Absence of congenital malformations of the skeleton
        3. Absence of inflammatory tumor-like swellings
        4. Asymmetric mosaic distribution of lesions
        5. Absence of predictable regional patterns of heterotopic ossification
        6. Presence of dominance of intramembranous rather than endochondral ossification
        7. Inherited only paternally
        8. Carries inactivating mutations of the *GNAS* gene, a gene that is regulated through genomic imprinting and allele-specific gene expression
    2. Post-traumatic: myositis ossificans circumscripta
    3. Neurogenic
        1. After head trauma or spinal cord injury
        2. After long coma
    4. Postsurgical: after total joint arthroplasties
    5. Reactive
        1. Bizarre parosteal osteochondromatous proliferation
        2. Florid reactive periostitis
        3. Subungual exostosis
    6. Neoplasms
        1. Sarcoma
        2. Malignant fibrous histiocytoma

7. Degenerative processes
8. Albright hereditary osteodystrophy

Diagnostic Investigations

1. Radiography (Bridges et al. 1994)
    1. Extraskeletal ossification
        1. Progressive widespread heterotopic ossification of muscles, tendons, ligaments, and fascia
        2. Ankylosis
            1. Shoulder joints
            2. Elbow joints
            3. Hip joints: prevent ability to ambulate
            4. Knee joints
            5. Muscles of mastication
        3. Osseous bridging between the axial and appendicular skeleton might be seen in advanced stages (Al-Salmi et al. 2014).
    2. Phalangeal abnormalities
        1. Characteristically affecting the great toes
            1. Shortened first digits
            2. Delta-shaped proximal phalanges
            3. Often monophalangism with the absence of the interphalangeal joint of the great toes
        2. Shortened thumbs
        3. Clinodactyly of the fifth fingers
    3. Less common congenital malformations
        1. Small vertebral bodies and enlarged pedicles in early childhood (Connor and Smith 1982)
        2. Variable degrees of vertebral fusion, especially apophyseal joint fusion in late childhood
        3. Short, broad femoral necks
        4. Ossification of ligamentous insertions producing exostoses of the proximal tibia
        5. Delay in skeletal maturation
        6. Enchondroma formation
        7. Association with synovial chondromatosis
    4. Skeletal changes in FOP are the consequences of soft tissue ossification and that the condition is not primarily bone dysplasia (Cremin et al. 1982).
2. Bone scintigraphy (radionuclide imaging) (Tulchinsky 2007; Pawar et al. 2015)
    1. A very sensitive technique for new bone formation in FOP
    2. Reveals multiple foci of increased uptake in connective tissue at characteristic locations (ligaments, tendons, muscles), in combination with pathognomonic microdactyly of the great toes (or thumbs): highly specific
3. CT scan
    1. Useful for diagnosis because CT scan is very sensitive for calcification
    2. Soft tissue swelling in the fascial planes and muscle in the early course of FOP
    3. Evidence of soft tissue calcification, typically in the form of shell seen within days to a few weeks
    4. Calcification appearing as spicules (Carter et al. 1989) in the soft tissue or in thin planes along the fascia often encircling muscle
    5. Able to delineate the presence or absence of bone destruction, differentiating FOP from invasive processes such as infection and tumor
4. MRI: a sensitive imaging technique for soft tissue abnormalities but not particularly useful for diagnosis.
5. Ultrasonography to demonstrate echogenic and shadowing mass.
6. Audiography: mixed-type hearing loss with prominent conductive component.
7. Histopathology (Mahboubi et al. 2001)
    1. Earliest finding: an intense perivascular lymphocytic infiltration
    2. Followed by death of skeletal muscle and replacement by a highly vascular fibroproliferative soft tissue, which rapidly progresses through an endochondral process to form heterotopic bone
8. Molecular genetic diagnosis – mutational screening of *ACVR1* gene
    1. Detection of a specific heterozygous mutation (c.617G>A; p.R206H) in the activin A type I receptor gene (*ACVR1*) in all classically affected individuals

2. Detection of a variant FOP phenotype (c.983G > A; p.G328E) (Carvalho et al. 2010)
3. Atypical fibrodysplasia ossificans progressiva diagnosed by whole exome sequencing (Liu et al. 2015)

9. Definitive genetic testing of FOP is now available and can confirm a diagnosis of FOP prior to the appearance of heterotopic ossification. Clinical suspicion of FOP early in life on the basis of malformed great toes can lead to early clinical diagnosis, confirmatory diagnostic genetic testing (if appropriate), and the avoidance of harmful diagnostic and treatment procedures (Pignolo et al. 2013).

Genetic Counseling

1. Recurrence risk (Delatycki and Rogers 1998)
   1. Patient's sib: not increased unless a parent is affected or has gonadal mosaicism (a low recurrence risk) (Janoff et al. 1996)
   2. Patient's offspring: 50%
2. Prenatal diagnosis
   1. Ultrasonography: bilateral hallux valgus on ultrasound, a clue for the first prenatal diagnosis of FOP. Genetic testing for FOP revealed that the fetus was heterozygote for the recurrent de novo mutation responsible for FOP in exon 6 of *ACVR1* gene – c.617G>A, p.Arg206His (Maftei et al. 2015).
   2. Possible by molecular genetic testing of the *ACVR1* gene on fetal DNA obtained from amniocentesis or CVS (chorionic villus sampling) for fetuses at 50% risk for FOP if a clinically diagnosed relative has an identified disease-causing *ACVR1* gene alteration.
3. Management (Kocyigit et al. 2001; Taslimi et al. 2015)
   1. No effective treatment available.
   2. Mainly focused in prophylactic approaches, symptomatic management, and optimization of function.
   3. FOP can often be recognized in children with or without previously affected family members at birth or in early years before the onset of heterotopic ossifications because of the presence of shortening of the great toe and short thumbs.
4. Early recognition allows protection of the child from injuries
   1. Avoid multiple biopsies, trauma, intramuscular injections, and dysfunctional IV catheters to prevent precipitating the heterotopic ossification and exacerbating the disease.
   2. Prevention of influenza-like illnesses.
   3. Minimal soft tissue trauma during routine dental care may precipitate permanent ankylosis of the jaw.
5. Alleviate pain during episodic flare-ups (Faruqi et al. 2014).
6. Should not be subjected to excessive stretching of the jaw in dental procedures, as well as injection of local anesthesia especially mandibular block.
7. Intramuscular injections should be avoided.
8. Vaccinations should be administered subcutaneously.
9. Venipuncture and IV administration of drugs pose minimal risk.
10. Prevention of falling and improving household safety are crucial.
11. Orotracheal intubation can traumatize the TMJ (temporomandibular joint) joints and result in disease flare-up. Instead, an awake fiber-optic nasotracheal intubation should be used by an expert anesthesiologist under light sedation.
12. Physical therapy in general not recommended as stretching of the soft tissues around a joint can lead to a painful flare-up.
13. Steroids, nonsteroid anti-inflammatory agents, disodium etidronate (Rogers and Geho 1979; Brantus and Meunier 1998), warfarin, and radiotherapy
    1. Used to halt the progression of disease
    2. Without proven benefit

14. Isotretinoin
    1. Principle based on its ability to inhibit differentiation of the mesenchymal tissue into the cartilage and bone
    2. Questionable benefit to decrease the incidence of heterotopic ossification at uninvolved anatomical sites
15. Etidronate (aminobisphosphonates) (Hall et al. 1979)
    1. Blocks ectopic calcification and is approved by Food and Drug Administration for treatment of postoperative heterotopic ossification.
    2. Short-term effect of bone metabolism shows diminished bone turnover rate.
    3. Long-term effect on ectopic calcification is unchanged in most cases with few exceptions.
16. Primary therapy for the debilitating disease – supportive care
    1. Active range-of-motion exercises encouraged if the movements are comfortable.
    2. Available adaptations or modifications prescribed to a disabled patient with FOP to achieve functional independence in the home and community (Levy et al. 1999)
        1. Shoes
        2. Canes
        3. Power wheelchairs
17. Avoid trauma
18. Surgery
    1. Nearly always contraindicated since new heterotopic ossification occurs at the operative site (Connor and Evans 1982a)
    2. Surgical removal of heterotopic bone
        1. Ineffective
        2. Leading to catastrophic exacerbation of the disease
    3. Existence of intercurrent problems occasionally requiring surgery
19. Anesthesia (Liu et al. 2014)
    1. Presenting numerous difficulties to the anesthesiologist including cervical spine ankylosis and restrictive pulmonary disease (thoracic insufficiency).
    2. Avoid tissue trauma in the form of local anesthetic injections.
    3. Presence of anatomical airway abnormalities.
    4. Alternative methods preferred.
        1. Nebulized lidocaine
        2. IV sedation
        3. Nasotracheal intubation
    5. Proper positioning and padding perioperatively
    6. Vigorous chest physiotherapy and pulmonary toilet postoperatively

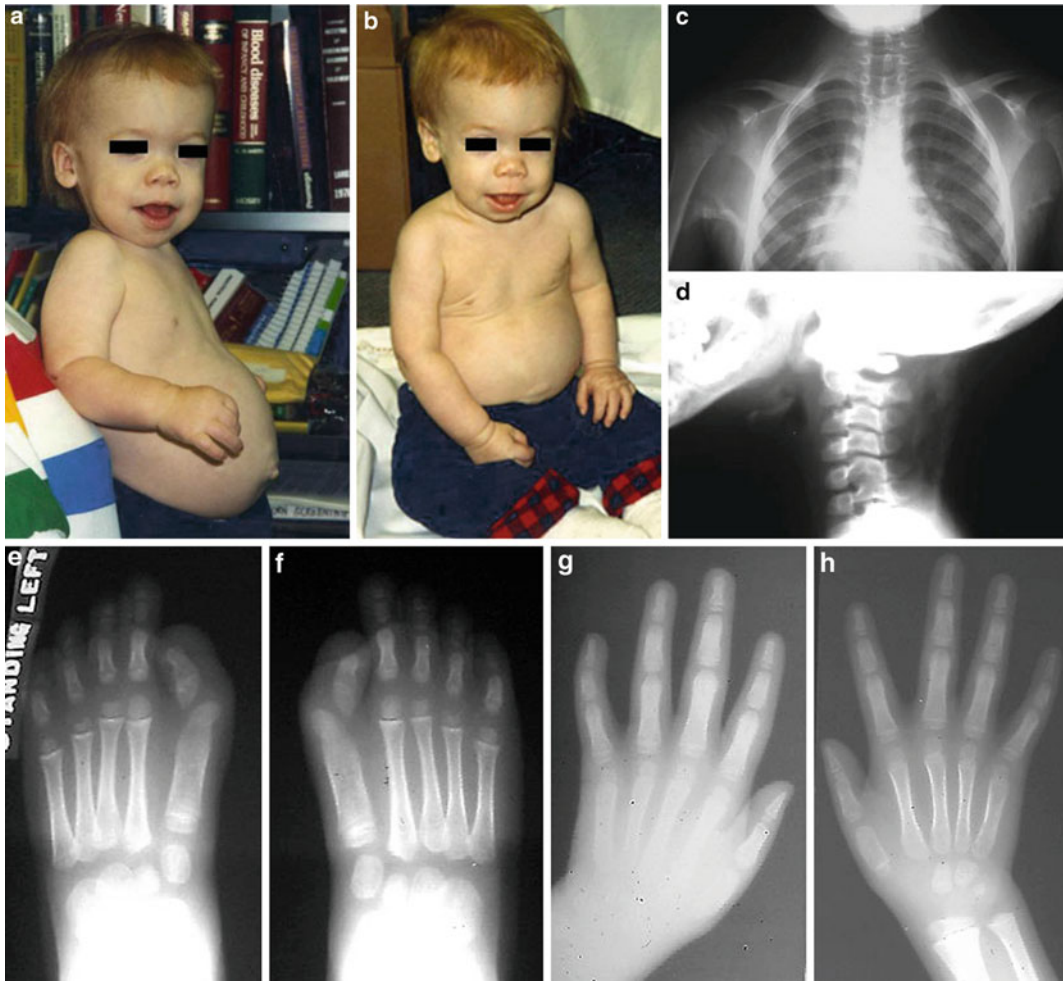

Fig. 1 (**a**–**h**) A boy (**a**, **b**) with fibrodysplasia ossificans progressiva showing a stiff neck, a narrow chest, and inability to raise arms upward due to ossification of the soft tissues on the back of the neck (**d**), the lateral chest wall, and the axillary region (**c**), illustrated by the neck, chest, and pelvic radiographs. The radiographs of both feet (**e**, **f**) showed shortened first toes and hallux valgus with delta-shaped proximal phalanges, monophalangism with the absence of the interphalangeal joint of the great toes. The radiographs of both hands (**g**, **h**) showed shortening of the first metacarpals and the middle phalanx of the fifth fingers with clinodactyly

Fig. 2 A 14-year-old girl with fibrodysplasia ossificans progressiva was seen because of swelling and pain on the upper thigh, especially on the *left*. The pelvic radiograph showed extensive heterotopic calcifications on the inner upper thighs, worse on the *left*. Her father was also affected

Fibular Hemimelia

Contents

Fibular hemimelia is a rare congenital malformation of the lower limbs. It is also the most common congenital long bone deficiency and occurs more frequently than congenital anomalies of the radial, femoral, and tibial bones (Boakes et al. 1991). Fibular hemimelia syndrome includes a wide range of disorders, from an isolated shortening of the fibula up to its complete deficiency, with associated deformities of the foot, shin, and thigh (Oberc and Sulko 2013). The incidence is 7.4–20 per 1,000,000 live births (Rogala et al. 1974; Froster and Baird 1993).

Synonyms and Related Disorders

Cayler cardiofacial syndrome; Congenital fibular deficiency; Fibular hypoplasia or aplasia

Genetics/Basic Defects

1. Etiology:
   1. Most cases:
      1. Sporadic and isolated events
      2. Nonsyndromic
      3. Absence of positive family history
   2. Only 0.8% of 493 cases reviewed were associated with nonskeletal malformations, including two neural tube defects, one cardiac anomaly, and one renal anomaly (Lewin and Opitz 1986).
   3. Disruptions during the critical period of embryonic limb development (5–8 weeks of gestation) can result in a variety of limb deficiencies giving rise to varying degrees of fibular hypoplasia or aplasia.
   4. Vascular dysgenesis, viral infections, trauma, and environmental influences have been suggested as possible causes.
2. Vascular anomalies (absent peroneal artery detected by CT angiography) were observed in the dysplastic limb in three patients reported by Huda et al. (2014). These three patients with different presentations all have absent fibula and peroneal artery on the same extremity which suggests an association with a possible causal relationship. Most authors speculated that the absent fibula might be due to vascular insult in early embryogenesis during the 4–7

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_259

weeks of gestation. Huda et al. speculate that the absent peroneal artery is secondary to absent fibular bud.

Clinical Features

1. Possible components of the complex malformation of fibular hemimelia (Birch et al. 2011) (Figs. 1–4):
    1. Femur:
        1. Shortening: the most common associated disorder (about 50 % of cases)
        2. Varus or valgus femoral neck
        3. Acetabular dysplasia
        4. External rotational deformity (retroversion)
        5. Hypoplastic lateral condyle
    2. Tibia: shortening
    3. Knee:
        1. Genu valgum
        2. Anterior cruciate ligament deficiency
        3. Anteroposterior instability of the knee
        4. Flexion contracture
    4. Ankle:
        1. Valgus deformity
        2. Ball-and-socket mortise
        3. Planar mortise
        4. Instability/dislocation
    5. Foot:
        1. Tarsal coalition
        2. Absent lateral rays
        3. Hypoplasia
        4. Equinovarus (clubfoot)
    6. Other associated anomalies:
        1. Scoliosis
        2. Roberts syndrome
        3. Upper extremity:
            1. Ulnar hemimelia
            2. Amelia
            3. Syndactyly
2. Classifications:
    1. Most classifications of congenital fibular deficiency are based primarily on the radiographic preservation of the fibula rather than on the overall clinical severity of the limb deficiency.
    2. Classification by Coventry and Johnson (1952): approximately 30 % of patients with bilateral involvement:
        1. Type I (hypoplastic fibula)
        2. Type II (rudimentary or absent fibula)
        3. Type III (bilateral fibular deficiency or the presence of "associated anomalies")
    3. Classification of fibular length deficiency by Achterman and Kalamchi (1979):
        1. Type I (minimal hypoplasia of the fibula)
        2. Type II (complete absence of the fibula)
    4. Classification of fibular aplasia by Courtens et al. (2005):
        1. Unilateral/bilateral
        2. Sporadic/familial
        3. Isolated versus syndromal
    5. Classification by Birch et al. (2011):
        1. Based on the clinical appearance of the foot and the extent of limb shortening as a percentage of the contralateral limb on radiographs
        2. Provides an opportunity to anticipate the extent of deformity at skeletal maturity and to estimate the scope of treatment necessary to reconstruct limb deformity
3. Differential diagnosis of fibular aplasia (Ekbote and Danda 2012):
    1. Autosomal dominant disorders:
        1. Fibular aplasia with ectrodactyly (Gieruszczak-Bialek et al. 2006)
        2. Fibular aplasia, tibial campomelia, and oligosyndactyly (FATCO) syndrome: proposed autosomal dominant inheritance and so far has an unknown molecular basis
        3. Reinhardt-Pfeiffer mesomelic dysplasia (mesomelic dwarfism of hypoplastic ulna and fibula type)
        4. Split hand/foot malformation with long bone deficiency I
    2. Autosomal recessive disorders:
        1. Absence of ulna and fibula with severe limb deficiency:
            1. Also called Al-Awadi/Raas-Rothschild syndrome, limb/pelvis-hypoplasia/aplasia syndrome, or Schinzel phocomelia syndrome

2. Caused by homozygous mutation in the *WNT7α* gene on chromosome 3p25
2. Fuhrmann syndrome (fibular aplasia or hypoplasia, femoral bowing, and poly-, syn-, and oligodactyly)
3. Congenital absence of the fibula and craniosynostosis
4. Femur-fibula-ulna syndrome
5. SC Roberts syndrome
3. Aneuploidy: del(21q) syndrome

Diagnostic Investigations

1. Skeletal Survey (Fig. 1b, 1c, 1d and Fig. 2)
2. 3D volume rendering reconstruction of the lower extremities (Fig. 3a and Fig. 4)
3. Computerized tomography angiogram of the lower extremities (Fig. 3b and 3c)

Genetic Counseling

1. Recurrence risk: depending on the etiology and the mode of inheritance:
   1. Patient's sib:
      1. Isolated: not increased
      2. Autosomal dominant inheritance: not increased unless a parent is affected
      3. Autosomal recessive inheritance: 25 %
   2. Patient's offspring:
      1. Isolated: unknown
      2. Autosomal dominant inheritance: 50 %
      3. Autosomal recessive inheritance: not increased unless the spouse is a carrier
2. Prenatal diagnosis:
   1. 2D ultrasonography:
      1. Isolated unilateral or bilateral complete fibular deficiency can be diagnosed antenatally (Abel et al. 2002).
      2. This condition may occur in the presence of other congenital anomalies.
      3. A comprehensive fetal anatomic survey, including examination of all long bones, is essential.
   2. 3- and 4-dimensional sonography to better image and characterize the defect (Monteagudo et al. 2006)
3. Management (Obec and Sulko 2013):
   1. The treatment should be individualized and based on the severity of the deformity.
   2. A multidisciplinary approach.
   3. Conservative management:
      1. Type IA
      2. Predicted shortening <2 cm at maturity
      3. Functional foot with more than three rays
   4. Operation approach:
      1. Elongation:
         1. Type IA or IB
         2. Functional foot with more than three rays
         3. Leg shortening <5 cm at birth
         4. Leg shortening <10 cm in the 9th year of life
      2. Epiphysiodesis:
         1. Leg shortening <5 cm in the 9th year of life
         2. Residual shortening after elongation
      3. Amputation:
         1. Type II with nonfunctional foot with < or = 3 rays
         2. Shortening >5 cm at birth
         3. Predicted shortening above 25 cm at maturity

Fig. 1 (**a**–**d**) This 3-year-old girl was evaluated for short right lower leg (**a**, **b**). The AP view radiograph of both lower extremities showed absence of right fibula with shortened right tibia. In contrast the left lower extremity was normal (**c**). She has undergone realignment of her right tibia and her right foot in the past. Lateral view radiograph of the right lower leg and foot showed anterior bowing of the tibia and bone fusion of the talus and the calcaneus (**c**). AP view of the right foot showed three rays, a normal-looking first ray and two other rays consisting of metatarsals and phalanges (**d**). She was using an AFO on a regular basis and the foot position has been well maintained, according to the family. She walks well and is extremely active and not complaining of any discomfort. She has not had any recent medical or surgical problems (Courtesy of Dr. Grace Guo)

Fig. 2 (**a**, **b**) This 3-year-old male was evaluated for short right lower leg. He was born 5 days post-due date via spontaneous vaginal delivery to a 21-year-old gravida 3, para 2, AB 1 mother. He was noted to have a short leg consistent with fibular hemimelia shown on radiographs. There was absence of the right fibula. The tibia was foreshortened and broadened, with medial bowing. The right foot presented with four rays (**a**). Lateral imaging of the right lower leg showed anterior bowing of the tibia with flatfoot deformity of the foot (**b**). There was parallelism of the talus and calcaneus. Fibular hemimelia was seen on prenatal ultrasounds. After birth, he did well and went home the next day with mom. He weighed seven pounds two ounces at birth. He was lost to follow-up (Courtesy of Dr. Grace Guo)

Fig. 3 The baby girl was born at 37 weeks of gestation via elective cesarean section. Prenatal ultrasounds showed lumbosacral meningocele and hydrocephalus. FISH analysis of the amniotic fluid was unremarkable. At birth, multiple abnormalities were noted including a lumbosacral meningomyelocele, length discrepancy of the lower extremities, and bilateral clubbing of the feet. Cranial ultrasound showed dilatation of lateral and third ventricles. Renal ultrasound demonstrated bilateral hydronephrosis. Frontal skeletal radiograph showed limb length discrepancy, absent left fibula, deformed bowed distal tibiae, and bilateral club feet. 3D reconstruction of both lower extremities demonstrated absence of the left fibula with shortened, hypoplastic left femur and tibia (shown here). Diffuse muscular atrophy was present in the soft tissue algorithm. Axial CT angiography of the left lower extremity revealed three vessels on the right, namely, the peroneal artery and anterior and posterior tibial arteries, but only two vessels on the left side, namely, the anterior and posterior tibial arteries with absence of peroneal artery (not shown). Curve maximum intensity projection (MIP) reconstruction of the left leg demonstrated patent anterior and posterior tibialis arteries (not shown). The peroneal artery is absent. She was discharged home at 2 weeks of age with follow-up by her pediatrician and orthopedic surgeon (Huda et al. Hemimelia and absence of the peroneal artery. Journal of Perinatology) (Courtesy of Dr. Hassan Ibrahim)

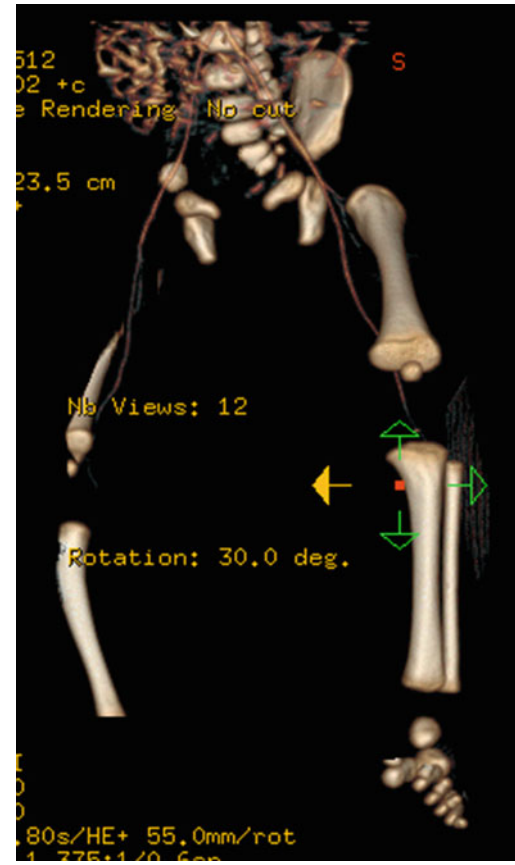

Fig. 4 This female newborn was delivered at 34 weeks of gestation via cesarean section complicated by polyhydramnios. Amniocentesis showed 46, XX. The face was asymmetric during crying. Echocardiogram showed a subaortic perimembranous ventricular septal defect (VSD). The baby was noted to have shorter right leg, absent right foot, absent thumb, and clinodactyly with a longer 4th finger. Skeletal survey showed a hypoplastic right first rib, partial fusion of the right radius and ulna, a shorter right radius, and also the absent right thumb with a corresponding absence of the first metacarpal bone. Frontal skeletal radiograph showed a congenital anomaly of the right lower extremity with unilateral fibula and foot agenesis. Soft tissue atrophy/hypoplasia of the leg is also seen. The figure here showed frontal 3D volume rendering reconstruction of both lower extremities demonstrating absence of the right fibula and foot. A computerized tomography angiogram of the lower extremities revealed normal popliteal arteries on both sides with an absent peroneal artery on the right side (not shown). She received prosthesis for the right lower extremity subsequently. The combination of absent depressor anguli oris along with the VSD prompted consideration of the possibility of Cayler cardiofacial syndrome in this patient (Courtesy of Dr. Hassan Ibrahim)

Finlay-Marks Syndrome

Contents

In *1978*, Finlay and Marks described the association of scalp defect, malformed ears, and the absence of nipples in a family. The association is also known as scalp-ear-nipple syndrome.

Synonyms and Related Disorders

Scalp-ear-nipple syndrome

Genetics/Basic Defects

1. Inheritance
   1. Autosomal dominant in most reports (Marneros et al. 2013)
   2. Severe autosomal recessive form: two children from an inbred Arab family with features suggestive of scalp-ear-nipple syndrome (Al-Gazali et al. 2007)
   3. Possible autosomal recessive form in an consanguineous family with three affected siblings with a propositus having excess of soft tissue on the nasofrontal region, widely spaced teeth, cupped protruding ears, and absent nipples (Morales-Peralta et al. 2014). Also a report of two affected siblings born to non-affected parents (Naik et al. 2012)
2. Lymphoid enhancer factor-1 (*Lef-1*), mapped to chromosome 4q23-q25 (Milatovich et al. 1991): identified as a candidate gene for scalp-ear-nipple syndrome (van Steensel et al. 1999)
   1. *Lef-1*: an HMG-domain DNA-binding protein expressed in the neural crest, mesencephalon, tooth germs, and other sites during embryogenesis.
   2. Homozygous deficiency of this gene causing postnatal lethality in mice.
   3. Mutant mice lacking teeth, mammary glands, whiskers, and hair.
   4. Lack of hair, missing teeth, and aplasia of breast tissue suggest that *Lef-1* may be a candidate gene for scalp-ear-nipple syndrome.
3. Mutations in KCTD1 cause scalp-ear-nipple syndrome (Marneros et al. 2013)

Clinical Features

1. Scalp abnormalities (Aase and Wilroy 1988; Le Merrer et al. 1991; Edwards et al. 1994; Plessis et al. 1997; Picard et al. 1999; Taniai et al. 2004)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_94

1. Raised firm nodules over the scalp in the occipital region, not covered by hairs
2. The areas: raw at birth and heal during childhood
3. Crumpled scalp over occipital region

2. External ear abnormalities
   1. Hypoplastic tragus, antitragus, and lobule
   2. Over-folding of the superior helix
   3. Flattening of the antihelix
3. Athelia (absent breasts and nipples)
   1. Rudimentary or absent nipples (Tawil and Najjar 1968)
   2. Breast hypoplasia or aplasia
   3. Can be part of syndromes including other congenital or ectodermal anomalies, such as limb-mammary syndrome or ectodermal dysplasias (Borck et al. 2014)
4. Other reported features
   1. Ectodermal dysplasia features
      1. Dental anomalies
         1. Widely spaced teeth
         2. Missing secondary teeth
         3. Neonatal teeth (Berman and Silverstone 1975)
      2. Reduction of axillary apocrine secretion and axillary hair growth
      3. Hypohidrosis
      4. Nail dysplasia
   2. Aplasia cutis vertices
   3. Renal hypoplasia
   4. Hypospadias
   5. Pyeloureteral duplication
   6. Cataract
   7. Coloboma of the iris (de Macena Sobreira et al. 2006)
   8. Hypertension
   9. Diabetes mellitus
   10. Partial syndactyly
5. Hypotonia and developmental delay in severe autosomal recessive form

Diagnostic Investigations

1. No specific laboratory tests available
2. Histology of scalp defect resembling aplasia cutis congenita (Finlay and Marks 1978)
   1. An excess of normal-appearing connective tissue
   2. Lack pilosebaceous elements
3. Renal sonography for renal hypoplasia
4. Diagnosis primarily by clinical features

Genetic Counseling

1. Recurrence risk
   1. Autosomal dominant
      1. Patient's sib: low unless a parent is affected.
      2. Patient's offspring: 50%
   2. Autosomal recessive
      1. Patient's sib: 25%
      2. Patient's offspring: not increased unless the spouse is a carrier.
2. Prenatal diagnosis: not been reported
3. Management: primarily supportive

Fig. 1 A 7-month-old boy with Finlay-Marks syndrome showing absence of nipples and abnormal ears. He also had scanty eyebrows and eyelashes, neonatal teeth, which were extracted, nasolacrimal duct stenosis, and lumpy scalp on the occiput region

Floppy Infant

Contents

A floppy infant is an infant with poor muscle tone affecting the limbs, trunk, and the craniofacial musculature. The causes are numerous (heterogeneous etiologies) and the work-up in many instances can be complex. The task of evaluating infants with hypotonia is difficult and complex.

Synonyms and Related Disorders

Congenital hypotonia

Genetics/Basic Defects

1. Heterogeneous causes of hypotonia (Stiefel 1996; Richer et al. 2001; Johnston 2003; Prasad and Prasad 2003, 2011; Igarash 2004)
    1. Chromosome disorders: central hypotonia
        1. Aneuploidy: Down syndrome (one of the most frequently encountered cause of neonatal hypotonia)
        2. Microdeletions: Prader-Willi syndrome (neonatal hypotonia, feeding problems, and failure to thrive with later onset of hyperphagia and obesity)
        3. Subtelomeric cryptic deletions (relatively new category of disorders that account for unexplained mental retardation): terminal 22q13.3 deletion syndrome (neonatal hypotonia can be a prominent feature)
2. CNS malformations/encephalopathies (associated with profound neonatal hypotonia)
    1. Congenital CNS malformations
        1. Lissencephaly
        2. Holoprosencephaly
    2. Acquired CNS disorders
        1. Birth trauma
        2. Hypoxic-ischemic encephalopathy
        3. Spinal cord injury
3. Disorders affecting anterior horn cells and peripheral nerves
    1. Spinal muscular atrophy (SMA1) (Werdnig-Hoffman disease): generalized weakness, often spares the diaphragm, facial muscles, pelvis, and sphincters
    2. Charcot-Marie-Tooth disease
        1. CMT1A
        2. CMT4E (congenital hypomyelination syndrome)
        3. Dejerine-Sottas syndrome (CMT3)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_95

4. Neuromuscular junction disorders
    1. Transient myasthenic syndrome.
    2. Hypermagnesemia of the newborn.
    3. Infantile botulism.
    4. Congenital myasthenic syndromes (neuromuscular junction disorders): bulbar oculomotor muscles exhibit greater degree of involvement (neonatal hypotonia, easy fatigability, recurrent aspiration, feeding difficulty, cyanosis, and apnea).
        1. Congenital myasthenic with episodic apnea
        2. Slow-channel and fast-channel syndromes
        3. Endplate cholinesterase deficiency
5. Congenital muscular dystrophies (CMD) (Brown et al. 2006) and myopathies: hypoactive reflexes. For example:
    1. Classical congenital muscular dystrophy
    2. Fukuyama muscular dystrophy
    3. Walker-Warburg syndrome
    4. Muscle-eye-brain disease
    5. Ullrich congenital muscular dystrophy
    6. Bethlem myopathy
    7. Rigid spine-muscular dystrophy (SEPN1 selenoprotein deficiency)
    8. Congenital myotonic dystrophy
        1. Triplet repeat CTG expansion of the *DMPK* and *SIX5* genes
        2. Abnormal splicing of chloride channels mRNA leading to the myotonia
6. Congenital myopathies (Taratuto 2002): prominent weakness. For example:
    1. Central core myopathy
    2. Nemaline myopathy
    3. Myotubular (centronuclear) myopathy
    4. Multicore myopathy
    5. Congenital myopathy with fiber-type disproportion
7. Metabolic disorders/myopathies: proximal musculature weakness. For example:
    1. Acid maltase deficiency (Pompe disease) (Howell et al. 2006)
    2. Pyruvate dehydrogenase complex deficiency
    3. Pyruvate carboxylase deficiency
    4. Respiratory chain defects (mitochondrial disorder)
    5. Zellweger syndrome
    6. Smith-Lemli-Opitz syndrome
    7. Congenital disorders of glycosylation
    8. Phosphomannomutase-2 deficiency
8. Combined CNS and motor unit disorder
    1. Metachromatic leukodystrophy
    2. Giant axonal neuropathy
    3. Familial dysautonomia
    4. Mitochondrial encephalopathy
    5. Congenital muscular dystrophies
9. Congenital hypotonia with a favorable outcome (benign congenital hypotonia): characterized by an early neonatal onset and a benign clinical course, no longer considered as a specific diagnostic entity
10. Acute and systemic diseases especially in the newborn period
    1. Sepsis
    2. Congestive heart failure
11. Chronic
    1. Hypothyroidism
    2. Connective tissue disorder

2. Localization of hypotonia in the floppy infant (Bodensteiner 2008)
    1. Supraspinal/suprasegmental hypotonia in which deep tendon reflexes are preserved:
        1. Central hypotonia caused by brain lesions
            1. Sepsis
            2. Congenital heart failure
            3. Hypoxic-ischemic encephalopathy
        2. Syndromic central hypotonia caused by brainstem lesions (extensive list of etiologic possibilities associated with constellation of dysmorphic features)

3. Nonsyndromic central hypotonia
    1. Cerebral dysgenesis (developmental anomalies of the brain).
    2. Grossly normal brain by MRI includes myelination within normal range, normal development (essential hypotonia), delayed myelination, motor delay only (usually catch up to peers in tone and development by school age), developmental delay (may later be diagnosed as nonsyndromic mental retardation, frequently labeled as autistic), or global developmental delay (usually do not catch up intellectually and cognitively to peer by school age).
4. Central hypotonia caused by craniocervical junction lesions
    1. Spinal cord injury (critically ill infant with severe hypotonia at first and the nature of the injury is not usually suspected until the development of the hyperactive reflexes and the lack of the expected maturation of the corticospinal tract influences on the motor unit).
    2. Chiari I malformation (may be an isolated finding that may cause hypotonia early on by compression of the lower brainstem at the level of the foramen magnum).
    3. Chiari II malformation (usually associated with spina bifida and easily suspected).

2. Segmental or motor unit hypotonia in which deep tendon reflexes are depressed or lost
    1. Anterior horn cell (spinal muscular atrophy)
    2. Peripheral nerve (hereditary motor sensory neuropathy)
    3. Neuromuscular junction
        1. Myasthenia gravis
        2. Congenital myasthenic syndromes
        3. Botulism
    4. Muscle
        1. Congenital myopathies
        2. Metabolic myopathies
        3. Neonatal presentation of muscular dystrophy

Clinical Features

1. Hypotonia (decreased or loss of muscle tone)
    1. Full abduction and external rotation of the legs.
    2. Flaccid extension of the arms.
    3. Prominent head lag on pull to sit (normally diminished or absent by about 2 months of age): “Pull to sit” maneuver tests axial tone of the neck and back and appendicular tone of the shoulder and arms and also tests strength to some extent. Normal response from the infant being tested is to resist the pull on the arms and shoulder.
    4. Scarf sign: Produced by grasping the supine infant’s hand and pulling it across the chest and bring the baby’s elbow well beyond the baby’s chin and the midline of the chest before encountering the resistance. The maneuver tests the appendicular tone in the shoulder and is somewhat sensitive to the gestational age of the infant, the degree of laxity of the ligaments, and the state of alertness of the child.
    5. Shoulder suspension test: Produced by picking the infant up holding under the infant’s arms and observe the tendency of the hypotonic infant to slip through the examiner’s hands. The maneuver tests the appendicular tone but also gives some indication of head control (axial) as well as strength.
    6. Ventral suspension test: Produced by lifting off the infant from the table by examiner’s one hand under the infant’s chest and abdomen and observe the

hypotonic infant unable to lift the head above the horizontal plane and unable to flex the arms and legs.

2. Central hypotonia (disorders of central nervous system that cause decreased tone by interrupting pathways involved in the modulation) with following general characteristics:
    1. Hypotonia
    2. Obtundation
    3. Neonatal seizures
    4. Hyperactive deep tendon reflexes
    5. Neonatal encephalopathy
    6. Clinical or neuroimaging evidence for hypoxia-ischemia
3. Peripheral hypotonia (disorders of the motor unit)
    1. General characteristics.
        1. Hypotonia (absence of features of central hypotonia)
        2. Areflexia or diminished reflexes
        3. Convincing weakness
        4. Decreased antigravity limb movements
        5. Weak cry
        6. Weak suck
        7. Fasciculations
        8. External ophthalmoplegia
        9. Alert look
        10. Arthrogryposis
    2. Anterior horn cell disease.
        1. SMA: the most common serious cause of hypotonia in the infant and child
        2. Very few conditions other than SMA that would result in widespread denervation on EMG in the clinical setting of hypotonia and weakness in infancy
        3. Muscle biopsy no longer necessary to make the diagnosis of SMA in the clinical situation
    3. Peripheral nerve diseases, such as CMT, rarely cause hypotonia in infancy.
    4. Neuromuscular junction disease.
        1. Not a common cause of hypotonia in infancy
        2. The only category of motor unit disease in which the reflexes may be preserved
    3. Neonatal myasthenia gravis
        1. Uncommon cause of hypotonia in infancy in recent years
        2. Caused by antibodies to the acetylcholine receptor (AchR) which are passively transferred to the infant by the mother who has autoimmune myasthenia gravis
    4. Congenital myasthenic syndromes
        1. Much more common cause of hypotonia in infancy.
        2. Caused by genetic defects of neuromuscular transmission resulting in a decrease in the safety margin in neuromuscular transmission.
        3. Manifest clinically by easy fatigability and weakness to variable degree depending on the severity of the defect in transmission.
        4. Diagnosis based on fatigue with exercise.
        5. Affected infants may be very sensitive to neuromuscular blocking agents and may respond to AchE antagonists.
    5. Selected congenital myasthenic syndromes
        1. AchR deficiency: early onset, variable severity, ptosis, extraocular palsy, and involvement of the bulbar, arm, and legs.
        2. Slow-channel syndrome: selective severe weakness of the neck, wrist, and finger extensor, variable onset and severity, and common, often progressive ventilatory problems.
        3. Fast-channel syndrome: variable onset and severity and may respond to AchE inhibitors.
        4. Endplate rapsyn deficiency: early onset with hypotonia, respiratory failure, apnea, and arthrogryposis.
        5. Congenital myasthenia syndrome with episodic apnea: early respiratory failure, episodic apnea, improvement with age, and may respond to AchE inhibitors.
        6. Endplate acetylcholinesterase deficiency: ophthalmoparesis, severe

axial musculature weakness, slow papillary responses.

5. Abnormalities of muscle structure or function
    1. A major cause of motor unit hypotonia, second only to SMA in overall frequency
    2. Congenital myopathies
        1. More likely than Duchenne muscular dystrophy as a cause of hypotonia in the first year.
        2. Comprised of a group of muscle diseases that typically only slowly progressive over time, although present at birth with variable severity.
        3. Classical congenital myopathies (central core disease, nemaline myopathy, centronuclear myopathy) (Riggs et al. 2003).
        4. Other well-established congenital myopathies (multicore, congenital myopathy with fiber-type disproportion (CFTD), reducing body, fingerprint, cytoplasmic body).
        5. Congenital muscular dystrophies (CMD): CMD is an important subgroup of congenital myopathies. The conditions are usually present at birth, often quite severe with muscle weakness, wasting, respiratory difficulty, and contractures, with variable involvement of the brain, eyes, and other tissues. Muscle biopsies show dystrophic muscle with muscle fiber necrosis and regeneration with replacement of muscle with fibrous and fatty connective tissue. The CMD is typically subdivided into two categories: those with brain involvement (syndromic CMD, comprised of merosin-deficient CMD, CMD with partial merosin deficiency, CMD 1C, CMD with ITGA7 mutations, CMD with spine rigidity) and those without brain involvement (nonsyndromic CMD, comprised of Fukuyama CMD, muscle-eye-brain disease, Walker-Warburg syndrome 2, congenital muscular dystrophy).
    3. Central core disease
        1. Variable presentation
        2. Somatic abnormalities
        3. Characteristic malignant hyperthermia
        4. Occasional cardiomyopathy
    4. Nemaline myopathy
        1. Variable presentation
        2. Somatic abnormalities (infantile)
        3. Muscle wasting
        4. Ocular muscle weakness
        5. Adult onset of pain/cramp
        6. Rare cardiomyopathy
    5. Centronuclear (myotubular) myopathy
        1. Variable presentation
        2. Somatic abnormalities (infantile)
        3. Muscle wasting
        4. Ocular muscle weakness with ptosis
    6. Multicore myopathy
        1. Mild early presentation
        2. Somatic abnormalities
        3. Ocular muscle weakness with ptosis
        4. Malignant hyperthermia reported
        5. Cardiomyopathy reported
    7. Congenital myopathy with fiber-type disproportion (CFTD)
        1. Variable presentation
        2. Muscle wasting
        3. Somatic abnormalities
        4. Stiffness
        5. Mental retardation
    8. Reducing body myopathy (X-linked)
        1. Variable presentation
        2. Somatic abnormalities
        3. Ocular muscle weakness with ptosis
        4. Cardiomyopathy reported
    9. Fingerprint body myopathy
        1. Mild early presentation
        2. Muscle wasting
        3. Somatic abnormalities
        4. Mental retardation

10. Cytoplasmic inclusion body myopathy
    1. Early, moderate to severe onset
    2. Somatic abnormalities
    3. Cardiomyopathy
11. Merosin-deficient DMD
    1. Severe manifestation
    2. Hypotonia
    3. Global weakness
    4. Contractures
    5. Scoliosis
    6. Inability to walk
    7. Normal intelligence
    8. Abnormal white matter signal (MRI)
12. CMD with partial merosin deficiency
    1. Milder manifestation
    2. Ability to walk in most cases
    3. Cardiomyopathy
    4. Contractures of elbow, knees, and fingers
    5. Normal intelligence
    6. Normal MRI of the brain
13. CMD type 1C
    1. Severe weakness
    2. Global involvement
    3. Contractures of elbow, knees, fingers
    4. Cardiomyopathy
    5. Normal intelligence
    6. Normal MRI of the brain
14. CMD with *ITGA7* mutation
    1. Proximal muscle weakness
    2. Torticolis
    3. Congenital hip dislocation
15. CMD with spine rigidity
    1. Rigid spine, elbows, hips, and ankles
    2. Progressive sleep hypoventilation
16. Ullrich CMD
    1. Global weakness with contractures
    2. Distal hyperextensibility
    3. Calf atrophy
    4. Normal intelligence
17. Fukuyama CMD
    1. Severe generalized weakness
    2. Contractures
    3. Cobblestone lissencephaly
18. Muscle-eye-brain disease
    1. Mild presentation early (ability to walk in some cases but lose walking by age 20)
    2. Eye malformations (without cataracts)
    3. Hydrocephalus
    4. White matter abnormality (MRI)
    5. Cobblestone lissencephaly
19. Walker-Warburg syndrome
    1. Severe generalized weakness
    2. Contractures at elbows only
    3. Lissencephaly
    4. Dandy-Walker malformation or cerebellar hypoplasia and flat pons (MRI)
    5. Early demise
20. CMD 1D
    1. Global delay
    2. Proximal weakness greater than distal weakness
    3. Muscle hypertrophy
    4. Facial sparing
    5. White matter changes (MRI)

4. Differentiating congenital hypotonia of central versus peripheral origin (Harris 2008)
    1. Weakness
        1. Central: mild to moderate
        2. Peripheral: significant (“paralytic”)
    2. Deep tendon reflexes
        1. Central: decreased or increased
        2. Peripheral: absent
    3. Placing reactions
        1. Central: sluggish or slow
        2. Peripheral: absent
    4. Motor delays
        1. Central: present
        2. Peripheral: present
    5. Antigravity movements in prone and supine
        1. Central: some but less than a typical infant
        2. Peripheral: often absent
    6. Pull to sit
        1. Central: some head lag (more so than typical infant)
        2. Peripheral: marked head lag

7. Cognition/affect
    1. Central: delayed
    2. Peripheral: typical
8. Ability to "build up" tone, e.g., tapping under knees with infant in supine to assist them in holding hips in adduction
    1. Central: present
    2. Peripheral: absent

5. Pattern of muscle weakness and localization in the floppy infant (Prasad and Prasad 2003)
    1. Central nervous system
        1. Corresponding disorders
            1. Chromosome disorders
            2. Inborn errors of metabolism
            3. Cerebral dysgenesis
            4. Cerebral/spinal cord trauma
        2. Pattern of weakness and involvement
            1. Central hypotonia
            2. More prominent axial weakness
            3. Hyperactive reflexes
    2. Motor neuron
        1. Corresponding disorders (SMA)
        2. Pattern of weakness and involvement (generalized weakness, often sparing diaphragm, facial muscles, pelvis, and sphincters)
    3. Nerve
        1. Corresponding disorders: peripheral neuropathies
        2. Pattern of weakness and involvement (weakness with wasting involving distal muscle)
    4. Neuromuscular junction
        1. Corresponding disorders
            1. Myasthenia syndrome
            2. Infantile botulism
        2. Pattern of weakness and involvement (weakness with greater involvement of bulbar and oculomotor muscles)
    5. Muscle
        1. Corresponding disorders
            1. Congenital myopathies
            2. Metabolic myopathies
            3. CMD
            4. Congenital myotonic dystrophy
        2. Pattern of weakness and involvement
            1. Prominent weakness
            2. Proximal musculature
            3. Hypoactive reflexes
            4. Joint contractures
6. Congenital hypotonia with a favorable outcome (benign congenital hypotonia) (Shuper et al. 1987; Parush et al. 1998; Carboni et al. 2002)
    1. No longer considered as a specific diagnostic entity
    2. The term applied to a group of patients in whom a specific diagnosis cannot be made despite best effort in work-up
    3. Common features
        1. Generalized hypotonia since birth
        2. Mild delayed or normal developmental milestones
        3. Active movement with preserved reflexes
        4. Significant joint laxity or hypermobility
        5. Normal investigations (muscle enzymes, EMG, nerve conduction studies, muscle biopsy)
        6. Favorable outcome common
7. Other diagnostic features
    1. Areflexia, decreased limb movement, and demonstration of denervation on EMG suggest anterior horn cell disorders such as SMA type I.
    2. Decreased conduction velocities on nerve conduction test suggest a demyelinating neuropathies such as Charcot-Marie-Tooth (CMT) type 2 (also known as Dejerine-Sottas disease), congenital hypomyelinating neuropathy (CMT 4E), and other subtypes of CMT4.
    3. Demonstration of cerebral myelin abnormalities and peripheral demyelination suggest Pelizaeus-Merzbacher disease or other known leukodystrophies such as Krabbe disease.
    4. Pompe disease (acid maltase deficiency) (Hebert et al. 2015).
        1. A mutation in the gene responsible for production of lysosomal alpha-1,4- glucosidase (GAA), an enzyme responsible for glycogen breakdown, leads to decreased enzyme activity resulting in glycogen buildup in the body, with the heart and skeletal muscles being most severely affected.

2. Can be easily mistaken for a primary myopathy in the first year.
3. Major differential clinical features.
    1. A large heart
    2. Firm skeletal muscles secondary to glycogen stored in the muscle fibers
    3. Distinctive EMG findings

8. Differential diagnosis of hypotonia based on specific associated features (Dubowitz 1985)
    1. Hypotonia and respiratory difficulties
        1. Muscular disorders
            1. Spinal muscular atrophy
            2. Myotonic dystrophy
            3. Myotubular myopathy (especially X-linked form)
            4. Nemaline myopathy
            5. Congenital muscular dystrophy
            6. Other
        2. Nonmuscular disorders
            1. Intracranial hemorrhage
            2. Intracranial ischemia
    2. Hypotonia and facial weakness: muscular disorders
        1. Congenital myotonic dystrophy
        2. Myotubular myopathy
        3. Congenital muscular dystrophy
        4. Congenital facial diplegia syndrome
    3. Hypotonia and swallowing difficulty
        1. Muscular disorders
            1. Spinal muscular atrophy
            2. Myotubular myopathy
            3. Myotonic dystrophy
            4. Myasthenia gravis (neonatal)
        2. Nonmuscular disorders
            1. Prader-Willi syndrome
            2. Intracranial hemorrhage
            3. Intracranial ischemia
    4. Hypotonia and ptosis/ophthalmoplegia: muscular disorders
        1. Myotubular myopathy
        2. Mitochondrial myopathy
        3. Myotonic dystrophy
        4. Congenital muscular dystrophy
        5. Myasthenia gravis
    5. Hypotonia and arthrogryposis
        1. Muscular disorders
            1. Congenital muscular dystrophy
            2. Myotonic dystrophy
            3. Congenital fiber-type disproportion
            4. Denervation syndromes
        2. Nonmuscular disorders
            1. Oligohydramnios
            2. Bicornuate uterus
            3. Renal agenesis
    6. Hypotonia and CNS dysfunction/convulsions
        1. Hypoxic-ischemic encephalopathy
        2. Intracranial hemorrhage
        3. Intracranial ischemia
        4. Organic acidurias
        5. Mitochondrial encephalopathies
        6. Zellweger disease
        7. Other rare metabolic disorders

Diagnostic Investigations

1. A stepwise approach to the evaluation of a neonate with hypotonia (modified from Paro-Panjan and Neubauer 2004)
    1. Step 1 comprised of history taking and physical examination
        1. Family history (FH)
            1. Drug or teratogen exposure
            2. Breech presentation
            3. Reduced fetal movements
            4. Polyhydramnios
            5. Maternal diseases such as diabetes and epilepsy
            6. Parental age
            7. Neuromuscular disease
            8. Affected siblings
        2. Prenatal history
            1. Decreased fetal movement
            2. Abnormal ultrasonographic findings such as hydrocephalus or polyhydramnios
            3. Possible evidence for hypoxic-ischemic insult, either in utero or during birth: detail perinatal birth trauma, birth anoxia, delivery complications, low APGAR scores (lower scores for

tone, reflexes, and respiratory effort), and onset of hypotonia
3. Neonatal history
1. A shortened umbilical cord and abnormal fetal presentation: reflects poor fetal movement or immobility.
2. Infants requiring ventilator assistance soon after birth to maintain respiration in addition to hypotonia: suggest the presence of significant muscle weakness.
3. In addition to hypotonia, infants with severe CNS abnormalities develop signs of impairment in level of consciousness, feeding difficulties, seizures, apneas, abnormal posturing, abnormalities of ocular movements, and of brain stem reflexes.
4. Presence of congenital malformations in other organ systems, deformations, and craniofacial dysmorphic features: need to establish a syndromic diagnosis.
4. Postnatal history
5. Clinical and neurological examinations
2. Step 2 comprised of neurological imaging tests: important to determine whether there is evidence for a cerebral lesion contributing to hypotonia
1. Computed tomography (CT)
2. Magnetic resonance imaging (MRI)
3. Step 3 comprised careful search of dysmorphology databases
4. Step 4 comprised of karyotyping with fluorescence in situ hybridization (FISH) for chromosome anomalies
5. Step 5 comprised of biochemical investigations for inborn errors of metabolism
6. Step 6 comprised of other specific studies
1. Specific nerve and muscle investigations
1. Serum kinase levels
2. Electromyography
3. Nerve conduction velocities
2. DNA markers
1. Spinal muscular atrophy
2. Congenital myotonic dystrophy
3. Duchenne muscular dystrophy
3. Muscle and nerve biopsy with mitochondrial enzymes

2. Initial work-up of the floppy infant based on clinical presentation, localization, and diagnostic yield (Prasad and Prasad 2003)
1. Clinical history and physical examination
1. Central hypotonia
1. Hypotonia
2. Obtundation
3. Seizures
4. Hyperactive deep tendon reflexes
2. Disorders of the lower motor unit
1. Hypotonia
2. Weakness
3. Areflexia
4. Fasciculations
5. Weak cry
6. Weak suck
7. External ophthalmoplegia
8. Alert look
9. Arthrogryposis
2. Multidisciplinary assessment including pedigree/family history and targeted investigations
1. CT/MRI, EEG, and infection screen (CSF, blood)
1. Birth trauma
2. Hypoxic-ischemic encephalopathy
3. Sepsis
4. Cerebral dysgenesis
2. Genetic studies (karyotyping, FISH, methylation studies, mutation analysis)
1. Chromosomal rearrangements
2. Prader-Willi syndrome
3. Congenital myotonic dystrophy
4. Subtelomeric deletions
3. Creatine kinase assay, electrophysiology, nerve conduction studies, and EMG
1. Nerve biopsy and/or direct mutation analysis (inherited neuropathies, disorders of neuromuscular junction)
2. Muscle biopsy followed by DNA-based mutation analysis when available (congenital muscular dystrophy, congenital myopathies)

3. Investigation scheme in the floppy infant with multisystem involvement (Prasad and Prasad 2003)
    1. Cranial MRI, echocardiography, abdominal ultrasound, and ophthalmic examinations for infants with hypotonia plus manifestations
        1. CNS obtundation
        2. Abnormal odors
        3. Seizures
        4. Craniofacial dysmorphisms
        5. Cataracts
        6. Hepatomegaly
        7. Renal cysts
        8. Retinopathy
        9. Arthrogryposis
        10. Lipodystrophy
    2. Plasma lactate levels, mt DNA mutations, DNA depletion studies, respiratory chain analysis (muscle), DNA-based mutation analysis for mitochondrial, and "energy deficient" encephalopathies (e.g., congenital lactic acidosis)
    3. Plasma ammonia, amino acids (blood, urine), urine organic acids, blood acylcarnitine profile, plasma uric acid, urinary sulfites, enzyme assays in skin fibroblasts for aminoacidopathies, organic acidemias, and sulfite oxidation/molybdenum cofactor deficiency
    4. Lysosomal enzyme assay in WBC, skin biopsy (EM for inclusion), and skin fibroblast culture + enzyme assays for lysosomal disorders (e.g., Pompe disease)
    5. Phytanic acid and plasma VLCFA for peroxisomal disorders (e.g., Zellweger syndrome)
    6. Isoimmune electrophoresis for transferrin for congenital disorders of glycosylation
    7. 7-Dehydrocholesterol for Smith-Lemli-Opitz syndrome
4. Cytogenetic analyses (Zand and Zackai 2004): for floppy infants with dysmorphic features and/or multiple congenital anomalies
    1. Aneuploidy disorders such as Down syndrome
    2. Microdeletion disorders such as Prader-Willi syndrome
        1. Methylation patterns study to determine the presence of PWS
        2. FISH and mutation analysis to identify the class of mutation
    3. Subtelomeric deletion disorders: easily detected using in situ hybridization using chromosomal telomeric probes
5. Molecular analyses: genetic testing aid significantly in timely diagnosis for a critically ill newborn and allow for anticipation of medical interventions by the multidisciplinary team caring for the infant
    1. Chromosomal microarray studies
    2. Mutation or deletion analysis of the survival motor neuron gene (*SMN*) for SMA
        1. All patients with SMA have deletions or mutations of *SMN1* (also known as *SMN t*, the telomeric copy of *SMN* gene). Homozygous deletion of exon 7 in the telomeric survival motor neuron gene found in 95% of SMA type I patients
        2. The major phenotype determinant is the presence of the number of copies of *SMN2* (also known as *SMN c*, the centromeric copy of *SMN* gene)
            1. One copy: likely to produce SMA1
            2. No copy of SMA1: likely results in spontaneous abortion or fetal wastage
            3. Five or six copies: likely allow normal survival with little or no progressive weakness
    3. Mutation analysis in CMT hereditary motor sensory neuropathies
        1. CMT 1A: mutations in the peripheral myelin protein-22 gene
        2. CMT 1B: mutation in the myelin protein zero gene
        3. CMT 2B: mutation in the RAS-associated protein RAB7
        4. CMT 4A: mutation in the ganglioside-induced differentiation-associated protein-1 gene
        5. CMT-X1: mutation in the connexin-32 gene

4. Mutation analysis for disorders of neuromuscular junction (congenital myasthenic syndromes)
    1. Congenital myasthenia with episodic apnea
    2. Slow-channel and fast-channel syndrome
    3. End plate cholinesterase deficiency
5. Mutation analysis for disorders with prominent muscle involvement
    1. Bethlem myopathy
    2. Triplet repeat CTG expansion of the DM protein kinase mutations (>37)
    3. Congenital DM protein kinase repeat expansion (>750)
6. Gene sequencing, mutation analysis, or mutation scanning
    1. Dystrophinopathies
    2. Muscular dystrophies
    3. Myopathies
7. mtDNA mutation analysis or mutation analysis in nuclear gene for mitochondrial disorders

6. Electrophysiological studies (Darras and Jones 2000)
    1. Needle electromyogram (EMG)
        1. Neurogenic changes.
            1. Spontaneous fibrillation at rest
            2. Long-duration polyphasic motor unit potentials
            3. Decreased interference pattern
        2. Myopathic changes: consider muscle biopsy.
            1. Low-amplitude, short-duration polyphasic
            2. Normal interference pattern
        3. Myopathy plus muscle irritability (large amplitude of CMAPs, increased insertional activity) should consider Pompe disease (acid maltase enzyme assay).
        4. Demonstration of denervation on EMG (large amplitude of CMAPs, fasciculation, positive sharp wave) should prompt investigation for anterior horn cell disorders (proceed to SMA genetic test, SMN type I and type II copy number).
    2. Motor and sensory nerve conduction studies (NCS): decreased nerve conduction velocities on NCS suggest a demyelinating neuropathy
7. Pathologic studies of muscles (muscle biopsy) (Darras and Jones 2000):
    1. The most useful test in the diagnosis of motor unit hypotonia.
    2. Used much less often today with the availability of specific gene test for many of the conditions under consideration.
    3. A sequential scheme for the proper use of the muscle biopsy.
        1. Nonspecific myopathy: consider myotonic, dystrophinopathy, and other congenital myopathy.
        2. Characteristic pathology.
            1. Central core disease
            2. Nemaline rod myopathy
            3. Centronuclear myopathy
        3. Dystrophic muscle.
            1. Brain involvement: consider muscle-eye-brain disease, Fukuyama congenital muscular dystrophy, and Walker-Warberg syndrome.
            2. Without brain involvement: consider histoimmunological stain for merosin-deficient and merosin-positive muscular dystrophies.
    4. SMA: extensive large grouped atrophy involving both type I and type II fibers and scattered clusters of enlarged type I fibers.
    5. Congenital muscular dystrophy: considerable variations in fiber size with extensive fatty infiltration.
    6. Glycogen storage disease: vacuolar myopathy with muscle fibers containing type vacuoles of varying sizes.
    7. Central nuclear myopathy: presence of central nucleus in the majority of muscle.
    8. Central core myopathy: deficient oxidative enzyme in the center of many fibers.
    9. Nemaline myopathy: muscle fibers with thickened striations and aggregates of rod bodies.

10. Congenital fiber-type disproportions: increased number of small lightly stained type I fibers and reduced number of larger darkly stained type II fibers.

8. Biochemical studies
    1. Muscle enzymes (creatine kinase)
        1. Rarely helpful in work-up of a floppy infant
        2. Elevated in:
            1. Congenital muscular dystrophies
            2. Some forms of congenital myopathies
    2. Inborn errors of metabolism screening
        1. Categories of biochemical defects
            1. Toxic encephalopathies
            2. Energy deficient encephalopathies
            3. Disorders affecting intracellular processing of complex molecules
        2. Blood ammonia
            1. Urea cycle defects
            2. Organic acidemias
            3. Fatty acid oxidation disorders
        3. Lactate (blood, urine, CSF)
            1. Carbohydrate metabolism disorders
            2. Mitochondrial disease
        4. Blood and urine quantitative analysis of amino acids for aminoacidopathies
        5. Blood organic acid and acylcarnitine profiles using tandem mass spectrometry
            1. Organic acidemias
            2. Fatty acid oxidation defects
        6. Plasma very long chain fatty acids (VLCFA) for peroxisomal disorders
        7. Transferrin (low in glycosylation disorders)
        8. Blood 7-dehydrocholesterol (elevated in Smith-Lemli-Opitz syndrome)
9. Cranial ultrasound or CT studies (Rumack 1985): to detect CNS lesions causing infantile hypotonia
    1. Hypoxic-ischemic encephalopathy
        1. Fetal or neonatal hypoxia
        2. Sudden infant death syndrome
        3. Infarction from other causes
    2. Neonatal intracranial hemorrhage
        1. Subependymal hemorrhage (premature infants)
        2. Subarachnoid hemorrhage or atypical intracranial hemorrhage (term infants)
    3. Intracranial infection
        1. Prenatal
            1. Cytomegalovirus
            2. Toxoplasmosis
            3. Herpes
            4. Rubella
        2. Neonatal and infant: bacterial
    4. Trauma
        1. Subdural hematoma
        2. Epidural hematoma
        3. Parenchymal hemorrhage or edema
10. Cranial CT/MRI studies
    1. Structural malformations
    2. Altered signals
        1. White matter: laminin deficiency
        2. Basal ganglia: mitochondrial cytopathies
        3. Brain stem and cerebellar abnormalities
            1. Joubert syndrome
            2. Pontocerebellar hypoplasia
11. Genetic testing in neuromuscular diseases (Krajewski and Shy 2004)
    1. Polymerase chain reaction (PCR)
    2. Mutation analysis
    3. Sequence analysis
    4. Restriction fragment length polymorphism (RFLP)
    5. Single-strand conformational polymorphism (SSCP)
    6. Denaturing gradient high-performance liquid chromatography
    7. Cytogenetics and fluorescent in situ hybridization
    8. Southern blotting
    9. RNA analysis
    10. Linkage analysis
12. Genetic evaluation in floppy infant (Jain and Jayawant 2011)
    1. Recently, array CGH (comparative genomic hybridization) has come up as a powerful diagnostic tool having detection rate of 5–17% in cases of normal karyotype.

2. Exon sequencing is promising in detecting causal genetic variants of rare monogenic disorders.
3. Newborn screening using tandem mass spectrometry can be helpful for metabolic disorders.
4. Recent advances in genetics have uncovered new conditions causing hypotonia and weakness such as congenital myasthenic syndromes and spinal muscular atrophy variants.

13. Differential diagnosis of hypotonia (Sparks 2015)
    1. Central hypotonia
        1. Hypoxic-ischemic encephalopathy
            1. Premature birth
            2. Difficult delivery
            3. Brain MRI
        2. Intracranial hemorrhage
            1. Brain MRI
        3. Cerebral malformations
            1. May be noted on prenatal ultrasonography
            2. Brain MRI
        4. Chromosomal abnormalities
            1. Dysmorphic features
            2. Congenital malformations
            3. Karyotype/array CGH
        5. Congenital infections
            1. Prenatal history
            2. Infectious cultures/evaluation
        6. Acquired infections
            1. Infectious cultures
        7. Peroxisomal disorders
            1. Dysmorphic features
            2. Very long chain fatty acids
        8. Inborn errors of metabolism
            1. Metabolic acidosis (hyperammonemia, hypoglycemia, lactic acidosis)
        9. Maternal and infant drug effects
            1. Prenatal and perinatal history of drug exposure
            2. Toxicology screen
    2. Spinal cord lesions
        1. Birth trauma
            1. History of trauma
        2. Hypoxic-ischemic encephalopathy
            1. Brain MRI
        3. Syringomyelia
            1. Spine MRI
    3. Anterior horn cell disease
        1. Spinal muscular atrophy
            1. Diminished/absent deep tendon
            2. Reflexes
            3. Muscle fasciculations
            4. *SMN1* copy number analysis
    4. Neuromuscular junction diseases
        1. Myasthenia gravis (transient acquired neonatal myasthenia, congenital myasthenia gravis)
            1. Easy fatigability.
            2. Recurrent aspiration.
            3. Feeding difficulty.
            4. EMG.
            5. Responds to anticholinesterase inhibitors.
            6. ECG may show heart block.
        2. Infantile botulism
            1. Facial weakness and pupillary abnormality
            2. Presence of toxin in food
        3. Drug toxicity (magnesium, aminoglycosides)
            1. History of drug exposure
            2. Plasma and urine drug levels
    5. Peripheral nerve diseases
        1. Hereditary motor and sensory neuropathies
            1. Diminished/absent DTRs.
            2. Absent Babinski and infantile reflexes.
            3. EMG/NCV may be helpful.
            4. DNA sequencing.
        2. Congenital hypomyelinating neuropathy
            1. FH
            2. DNA sequencing
        3. Giant axonal neuropathy
            1. FH
            2. DNA sequencing
    6. Muscle diseases
        1. Muscular dystrophies
            1. FH.

2. May have elevated serum CK and aldolase.
3. ALT and AST may be elevated from muscle rather than liver.
4. Muscle biopsy.

2. Congenital myopathies
   1. FH
   2. Muscle biopsy
3. Metabolic myopathies
   1. FH
   2. May have elevated serum CK, aldolase, ALT, and AST
   3. Muscle biopsy
4. Congenital myotonic dystrophy
   1. FH and maternal myotonia
   2. CTG-repeat analysis of *DMPK*

7. Microdeletion syndromes (Prasad and Prasad 2011)
   1. Clinical features: hypotonia in association with specific phenotypes
      1. Facial dysmorphisms
      2. Supravalvular aortic stenosis (in Williams syndrome)
   2. Disorders: 1p36, 22q13, 22q11.2, Williams syndrome, Smith-Magenis syndrome, and Wolf-Hirschhorn syndrome
   3. Laboratory testing: array CGH
   4. Genetic basis/inheritance: continuous gene syndrome

Genetic Counseling

1. Recurrence risk: depends on underline etiology
   1. Patient's sib
      1. Autosomal recessive (e.g., spinal muscular atrophy, congenital muscular dystrophy): 25%.
      2. Autosomal dominant (e.g., congenital myotonic dystrophy): not increased unless a parent is affected.
      3. X-linked recessive (e.g., severe infantile form of myotubular myopathy): 50% of male sibs affected if the mother is a carrier.
      4. Mitochondrial: all sibs are at risk of being affected if the mother has the mitochondrial DNA mutation.
      5. Chromosomal: increased risk, especially a parent is a translocation carrier.
   2. Patient's offspring
      1. Autosomal recessive: not increased unless the spouse is also a carrier.
      2. Autosomal dominant: 50%.
      3. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal.
      4. Mitochondrial:
         1. Offspring of males with a mtDNA mutation are not at risk.
         2. All offspring of females with a mtDNA mutation are at risk of inheriting the mutation.
         3. A female harboring a heteroplasmic mtDNA point mutation may transmit a variable amount of mutant mtDNA to her offspring, resulting in considerable clinical variability among sibs within the same nuclear family (Poulton and Turnbull 2000; Chinnery 2006).
      5. Chromosomal: an increased risk.
2. Prenatal diagnosis as well as preimplantation genetic diagnosis in certain cases (Prasad and Prasad 2011)
3. Management (Pediatric Care Online 2008)
   1. Supportive treatment in most causes of hypotonia.
   2. Multidisciplinary team approach for coordination of interventions.
   3. Infantile progressive spinal muscular atrophy.
      1. Physical therapy
      2. Respiratory therapy
      3. Nutritional support as needed
      4. Scoliosis treatments:
         1. Body jacket
         2. Molded back support
         3. Surgery
         4. Motorized wheelchair for children with type II at approximately 2–3 years of age

4. Peripheral nerve disorders: bracing for children with foot drop.
5. Neuromuscular junction disorders: hospitalization, with respiratory and nutritional support as needed.
    1. Passively acquired autoimmune myasthenia gravis (transient neonatal myasthenia): give pyridostigmine until asymptomatic and then taper over 1–2 weeks.
    2. Acquired autoimmune myasthenia gravis (juvenile myasthenia).
        1. Anticholinesterase drugs
        2. Immunosuppressive treatment
        3. Intravenous γ-globulin
        4. Corticosteroids
        5. Thymectomy
    3. Nonautoimmune myasthenic syndromes (congenital myasthenia gravis).
        1. Anticholinesterase inhibitors
        2. Corticosteroids
        3. Diaminopyridine (experimental)
    4. Infantile botulism: antibotulism immune globulin may be therapeutic.
6. Myopathies.
    1. Infantile form of myotonic dystrophy-type hypotonia
        1. Assisted ventilation as indicated
        2. Gastrostomy tube feedings as indicated
    2. Glycogen storage disease: consider enzyme replacement therapy (myozyme) (prognosis dismal without such therapy).
7. Some of recent advances in genetics have allowed for specific therapeutic interventions (Jain and Jayawant 2011).
    1. Use of acetylcholinesterase inhibitors, 3,4-diaminopyridine and ephedrine, salbutamol, or fluoxetine in some congenital myasthenic syndromes.
    2. Antisense oligonucleotide therapy has been under trial for Duchenne muscular dystrophy.
    3. Enzyme replacement therapy (myozyme) for infantile Pompe disease.

Fragile X Syndrome

Contents

Fragile X syndrome is the most common form of heritable intellectual disability, affecting approximately 1 in 1,250 males and 1 in 2,000 females (Webb 1989). The prevalence appears to be 1 in 4,000–6,000 males and 1 in 8,000–10,000 females. Martin and Bell first documented X-linked mental retardation in 1943. Subsequent identification of a fragile site on the long arm of the X chromosome (Lubs 1969), discovery of cell culture medium-dependent fragile site, and recognition of a unique constellation of physical features served to distinguish fragile X syndrome from other X-linked mental retardation syndromes.

Verkerk et al. (1991) identified a single gene that was associated with symptoms of the disorder. The gene, known as fragile X mental retardation gene 1 (*FMR1*), exhibited a novel form of mutation, a sequence of three nucleotides (CGG) that was repeated many times in patients with fragile X syndrome.

Synonyms and Related Disorders

Fragile X mental retardation syndrome; Fragile X spectrum disorders; Marker X syndrome; Martin-Bell syndrome; X-linked mental retardation and macroorchidism

Genetics/Basic Defects

1. Inheritance not conforming to usual rules governing X-linked traits
    1. Presence of asymptomatic transmitting males
    2. Presence of affected female carriers who inherited the gene
2. Caused by mutations in a trinucleotide $(CGG)_n$ repeat found in the coding region of the *FMR1* gene, mapped to Xq27.3 (De Boulle et al. 1993)
    1. Expanded CGG repeats >200 (full mutation): associated with fragile X syndrome.
    2. High repeat number (full mutation) leads to hypermethylation of an upstream promoter region and subsequent silencing (inactivating) of the *FMR1* gene.
    3. Fragile X premutation.
        1. A small expansion (premutation): between 55 and 200 CGG repeats
        2. Usually not associated with cognitive deficits

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_96

4. Expansion to a full mutation from the premutation in normal carriers occurs only when it is transmitted by a female.
5. Presence of anticipation phenomenon.

3. The Sherman paradox (Laxova 1994)
   1. A perplexing and confusing fragile X pedigree pattern was discovered during the mid-1980s by Sherman et al. (1984, 1985) who discovered the large discrepancy in risks for mental retardation within fragile X families containing transmitting males. This phenomenon was termed the "Sherman paradox" by Opitz (1986).
      1. 20% of males within fragile X families who carried the mutation are unaffected clinically and intellectually and became known as transmitting males.
      2. An increasing risk of mental retardation in grandsons of normal transmitting males: a special form of genetic anticipation (the increase in disease severity through successive generations).
      3. About a third of obligate carrier females are mentally impaired.
      4. More than half of known carrier females are either mildly impaired or expressed the fragile site on one of their X chromosomes.
   2. Possible explanations of the Sherman paradox.
      1. An unaffected transmitting male who inherits a premutation from his unaffected carrier mother, who has 50–200 repeats but probably a number closer to the lower end of the premutation range.
      2. Offspring of a carrier mother with the number of repeats still within the premutation range, even if amplification occurs during oogenesis.
      3. Transmission of the premutation to the daughters by the transmitting male. No amplification has occurred during spermatogenesis; hence, the daughters also have a premutation and are unaffected.
      4. Amplification to more than 200 repeats occurs during oogenesis of the transmitting male's daughters whose sons will receive a null mutation and be affected and their daughters may or may not be affected.
      5. The risk of expansion during oogenesis to the full mutation associated with mental retraction increases with the number of repeats, and this variation in risk accounts for the Sherman paradox (Fu et al. 1991).
4. Genotypic-phenotypic correlations (Kaufmann and Reiss 1999)
   1. Fragile X full mutation and mental retardation with a wide spectrum of phenotypic effects in both sexes
      1. Mental retardation in 100% of males
      2. Usually a milder form of retardation in 60% of females
   2. Large CGG amplification
      1. Associated with hypermethylation
      2. Almost invariably correlated with the most severe fragile X phenotype
      3. Seen in males with the full mutation pattern
   3. Premutation expansions that are not usually accompanied by methylation: minimal or no neurologic repercussion
   4. Correlation of methylation in *FMR1* expression and cognitive function
      1. Individuals with full mutation without methylation scored better than those with full mutation and complete methylation
      2. Individuals with full mutation and partial methylation showed intermediate values
   5. Presence of the *FMR1* protein (FMRP) responsible for:
      1. Lack of neurologic abnormalities in individuals with premutation
      2. Milder phenotype of males having full mutation without full methylation
5. Pathogenesis
   1. A consequence of the absence or deficit of the FMRP (de Vries et al. 1998)
   2. Absence of FMRP in the brain: the likely cause of mental retardation in patients with fragile X syndrome

6. Genetic and environmental influences on the cognitive outcomes of children with fragile X syndrome (Dyer-Friedman et al. 2002)

Clinical Features

1. Affected males (Hagerman and Cronister 1996)
    1. CNS involvement
        1. Delayed developmental milestones
        2. Mild to severe mental retardation
        3. Difficulty with abstract thinking, sequential processing, mathematics, short-term memory, and visual motor coordination
        4. Seizures
    2. Connective tissue dysplasia (Davids et al. 1990)
        1. Hyperextensible finger joints
        2. Double-jointed thumbs
        3. Flat feet
        4. High-arched palate
        5. Mitral valve prolapse (55%, diagnosed by echocardiography)
        6. Dilatation of the ascending aorta
        7. Inguinal hernia
        8. Soft and velvet-like skin
    3. Typical facial features
        1. Long face
        2. Prominent forehead
        3. Prominent/long ears
        4. Prominent jaw
    4. Other features
        1. Macroorchidism present in over 80% of adult fra(X) males
        2. Pectus excavatum
        3. Scoliosis
        4. Strabismus
        5. Recurrent otitis media in early childhood
        6. Reproduction documented but rare because of significant mental retardation
    5. Behavior abnormalities (Dykens et al. 1994; Kau et al. 2002)
        1. Stereotyped with odd mannerisms (hand flapping/biting)
        2. Tactile defensiveness
        3. Poor eye contact (excessive shyness)
        4. Attention deficit/hyperactivity disorder
            1. Hyperactivity
            2. Temper tantrums
            3. Distractibility
            4. Mood lability
        5. Speech disorder
            1. Perseveration
            2. Litany speech
            3. Echolalia
        6. Autism
        7. Autistic-like features
        8. Schizotypal personality disorder
        9. Anxiety disorder
2. Females heterozygous for full mutation alleles (Hagerman et al. 1992)
    1. Fifty percentage with cognitive deficits with learning disabilities, borderline IQ, or mental retardation
    2. Fifty percentage with normal intellectual function
3. Females heterozygous for premutation alleles (carriers) at risk for premature ovarian failure (early onset of menopause before age 40 years) (*FMR1*-related premature ovarian failure) (Hagerman et al. 1998; Holden et al. 1999; Bardoni et al. 2000; Kenneson and Warren 2001)
4. Fragile X-associated tremor/ataxia syndrome (FXTAS) (Saul and Tarleton 2012; Hagerman and Hagerman 2013)
    1. Carriers of the fragile X premutation may develop a neurodegenerative disease called FXTAS (Brown and Stanfield 2015).
    2. Established and expanded features of FXTAS.
        1. Autonomic problems
            1. Constipation/irritable bowel syndrome
            2. Erectile dysfunction
            3. Problems swallowing
            4. Gastrointestinal reflux
            5. Orthostatic hypotension
            6. Hypertension
            7. Urinary urgency and incontinence
            8. Cardiac arrhythmia
            9. Dizzy spells or vertigo

2. Sensory
    1. Olfactory dysfunction
    2. Hearing loss
    3. Neuropathy
3. Sleep problems
    1. Insomnia
    2. Sleep apnea
    3. Daytime sleeping
4. Motor symptoms
    1. Tremor or ataxia
    2. Muscle weakness
    3. Parkinsonism
5. Psychiatric
    1. Depression or anxiety
    2. Irritability
6. Chronic pain
    1. Fibromyalgia
    2. Neuropathic pain
7. Immune-mediated disorder
    1. Hypothyroidism
    2. Fibromyalgia

3. A definite diagnosis based on the following four observations (major criteria)
    1. Molecular: presence of FMR1 premutation (55–200 CGG repeats)
    2. Radiological: white matter lesions on MRI in the middle cerebellar peduncles and/or brain stem (the major neuroradiologic sign)
    3. Clinical: presence of two major clinical signs
        1. Intention tremor
        2. Gait ataxia
    4. Neuropathological: FXTAS inclusions
4. Other minor clinical criteria
    1. Clinical
        1. Parkinsonism
        2. Moderate to severe short-term memory deficits
        3. Executive cognitive function deficits
    2. Radiological
        1. MRI white matter lesions in cerebral white matter
        2. Moderate-to-severe generalized atrophy
5. Diagnostic category: presence of expanded CGG repeat (molecular)
    1. Definite: presence of one major radiological sign plus (i) one major clinical symptom or (ii) the presence of FXTAS inclusions
    2. Probable: presence of one major radiological sign and one minor clinical symptom, or two major clinical symptoms
    3. Possible: presence of one minor radiological sign and one major clinical symptom
5. Fragile X spectrum disorders (FXSD) (Lozano et al. 2014): FXSD should be used to include the wide range of overlapping phenotypes observed in affected individuals with *FMR1* mutations
    1. Fragile X-associated primary ovarian insufficiency.
    2. Fragile X-associated tremor/ataxia syndrome.
    3. Developmental problems including ASD and ADHD especially in boys and psychopathology including anxiety and depression in children and adults.
    4. Some premutation carriers can have a deficit of FMRP and some unmethylated full mutation individuals can have elevated FMR1 mRNA that is considered a premutation problem.

Diagnostic Investigations

1. Pedigree analysis.
2. Karyotyping of cells grown in folate- or thymidine-depleted cell culture media.
    1. A “fragile” site on one of the X chromosomes (Xq27.3) that appeared as a constriction on the distal long arm in many patients
    2. Cells exhibiting fragile X chromosome: 5–50%
    3. Cytogenetic studies now rendered obsolete by direct DNA testing
3. Indications for molecular genetic testing (Park et al. 1994).

1. Individuals of either sex with mental retardation, developmental delay, or autism
    1. Any physical or behavioral characteristics of fragile X syndrome
    2. A family history of fragile X syndrome
    3. Male or female relatives with undiagnosed mental retardation
2. Individuals seeking reproductive counseling who have a family history of fragile X syndrome or undiagnosed mental retardation
3. Fetus of a known carrier mother
4. Patients with cytogenetic fragile X test result discordant with phenotype
    1. Patients with a strong clinical impression of being affected with or carrier of fragile X syndrome but had a negative or ambiguous cytogenetic test result
    2. Patients with an atypical phenotype of fragile X syndrome but had a positive cytogenetic test result

4. Prenatal carrier testing for fragile X (Musci and Moyer 2010).
    1. Carrier testing is recommended for:
        1. Women with a family history of FXS
        2. Women with ovarian insufficiency
        3. Women with a family history of undiagnosed mental retardation, developmental delay, or autism.
    2. Testing for premutations is also recommended in men and women with late-onset intention tremor and cerebellar ataxia, especially those individuals with a family history of FXS, unknown mental retardation, and movement disorders.
5. Direct DNA analysis for point mutation or deletion in *FMR1* gene (Saul and Tarleton 2012).
    1. Targeted mutation analysis: mutation analysis to determine the CGG repeat size (mutation detection rate >99%).
        1. Southern blot hybridization
        2. Polymerase chain reaction (PCR)
        3. AGG trinucleotide repeat genotyping
    2. Methylation analysis by Southern blot analysis to determine the *FMR1* methylation status, independent of measuring the number of CGG repeats.
    3. Sequence analysis: very few individuals with fragile X syndrome have been identified with an intragenic *FMR1* mutation.
    4. Deletion/duplication analysis: fewer than 1% of individuals with fragile X syndrome have a partial or full deletion of FMR1 (Hammond et al. 1997).
6. Types of *FMR1* repeat expansion mutations (Tarleton and Saul 1993; Saul and Tarleton 2012).
    1. Normal alleles: 5–40 CGG repeats
        1. Stably transmitted without any increase or decrease in repeat number.
        2. In stable normal alleles, the CGG region is interrupted by an AGG triplet after every nine or ten CGG repeats. These AGG triplets are believed to maintain repeat integrity by preventing DNA strand slippage during replication.
        3. Normal alleles with more than 35 CGG repeats are associated with increased risk of *FMR1*-related premature ovarian failure.
    2. Mutable normal alleles (intermediate alleles, also termed "gray zone"): broadly defined as 41–58 repeats (no consensus exists regarding the precise size)
    3. Premutation alleles
        1. 59–200 CGG repeats.
        2. Methylation status of *FMR1*: premutation alleles are usually unmethylated and FMRP production is normal.
        3. Therefore, individuals (males or females) with premutation are clinically unaffected (Caskey et al. 1992).
        4. Do convey increased risk for FXTAS and POF, because of:
            1. Potential repeat instability upon transmission of premutation alleles.
            2. Women with alleles in this range are considered to be at risk of having

children affected with fragile X syndrome.

4. Full mutation alleles
   1. >200 CGG (several hundreds to several thousands) repeats. Expansion of the repeat more than 200 generally results in hypermethylation of both the CpG island and the CGG repeat within the *FMR1* gene.
   2. Methylation status of *FMR1*: completely methylated.
   3. Males: affected.
   4. Females: affected in about 50% of cases; unaffected in about 50% of cases.
5. Mosaicism
   1. Number of CGG repeats varies between premutation and full mutation in different cell lines.
   2. Methylation status of *FMR1*: partially methylated (unmethylated in the premutation cell line and methylated in the full mutation cell line).
   3. Males: affected but may function higher than individuals with full mutation.
   4. Females: highly variable clinical expression ranging from normal intellect to affected.
6. Methylation mosaicism
   1. Number of CGG repeats >200
   2. Methylation status of *FMR1* gene: partially methylated (mixture of methylated and unmethylated cell lines)
   3. Males: affected but may function higher than individuals with full mutation
   4. Females: highly variable clinical expression ranging from normal intellect to affected
7. Unmethylated full mutation
   1. Number of CGG repeats >200.
   2. Methylation status of *FMR1* gene: unmethylated.
   3. High functioning fragile X males (Hagerman et al. 1994): nearly all are affected but may have high functioning mental retardation to low normal intellect.
   4. Females: highly variable clinical expression ranging from normal intellect to affected.
7. Immunocytochemical tests based on the direct detection of FMRP using monospecific antibodies (Willemsen and Oostra 2000; Oostra and Willemsen 2001). This FMRP detection assay is based on the presence of FMRP in cells from unaffected individuals and its absence in cells from patients with fragile X syndrome. This assay is proven to be a reliable alternative method to identify male patients with fragile X syndrome. The new test on hair roots is suitable for use in large screening programs among males. The immunocytochemical tests can also be used in patients with mosaic pattern, affected premutation males, and intragenic mutations.
8. Functional neuroimaging (fMRI) of fragile X premutation carriers (Brown and Stanfield 2015).
   1. Given the complex nature of the premutation and FXTAS, functional imaging in particular can be further utilized to probe a broad range of clinically relevant features.
   2. For example, analysis of emotional processing may help to unravel the neurodevelopmental aspects of the premutation.
9. Molecular genetic testing (Oostra et al. 1993; Brown 1995; Naber 1995; Crawford et al. 2001).
   1. Targeted mutation analysis
      1. PCR analysis
      2. Southern blot analysis (Rousseau et al. 1991)
   2. Methylation status/analysis (Das et al. 1997)
   3. Sequence analysis
   4. Deletion/duplication analysis
   5. FISH analysis
   6. X-chromosome inactivation

Genetic Counseling

1. Recurrence risk: adequate genetic counseling depends on accurate diagnosis at the molecular level.

1. Individuals identified as noncarriers: the zero risk of transmitting fragile X syndrome to the next generation
2. Individuals identified as carriers: the risk of having children with fragile X syndrome depending on the sex of the carrier parent, the sex of the child, and the size of the CGG repeats.
    1. Premutation carrier males: considered "transmitting males." All daughters of transmitting males are unaffected premutation carriers. However, the grandsons and granddaughters of a transmitting male are at risk for developing fragile X syndrome.
    2. All mothers of a child with *FMR1* full mutation (expansion >200 CGG trinucleotide repeats) are considered carriers of an *FMR1* gene expansion (either full mutation or premutation and may be affected).
    3. Females with premutation (Kallinen et al. 2000; Nolin et al. 2003): an increased risk of passing on the full mutation and having offspring with the fragile X phenotype (the fragile X premutation can expand to the full mutation during maternal meiosis) (Warren and Nelson 1994).
    4. Carrier males who may reproduce: essentially zero risk of having male offspring with fragile X syndrome, since all their sons receive their Y chromosome [except in the rare instance of the fragile X chromosome coming into the family from the other source (mother)]. All the daughters of male carriers will have premutations regardless of the size of paternal amplifications and will not have fragile X syndrome. Only a few reports with premutation males have full mutation daughters.
3. Females with full mutation: her offspring, if they inherit the fragile X locus, all will have full mutation.
    1. All her sons will have fragile X syndrome.
    2. About 50–60% of her daughters will have fragile X syndrome, exceeding the 35% applicable to all female carriers of the fragile X chromosome. Affected females generally have less severe intellectual disability than found in affected males.
    4. Males with full mutations.
        1. Mentally retarded
        2. Generally do not reproduce
2. Risks to pregnant women with an expanded *FMR1* gene.
    1. A repeat size of 40–59: safe (0% risk) with no fetal full mutations
    2. A repeat size of 60–80: low risk (14%) of full mutation in the fetus
    3. A repeat size of over 80–100: a significant increase in risk (89%) of developing full mutation in the fetus
    4. A repeat size of 100–200: 100% risk of developing full mutation in the fetus
3. Prenatal diagnosis by amniocentesis or CVS (Saul and Tarleton 2012).
    1. Available to at-risk pregnancies: requires prior confirmation of the presence of an expanded (or altered) *FMR1* allele in the family
    2. Prenatal diagnosis using direct DNA analysis to women discovered to be premutation carriers
    3. The limitation: inability to accurately predict phenotype in female fetuses with full mutation
    4. CVS: follow-up amniocentesis or testing using PCR, necessary to determine the size of the *FMR1* alleles in a methylation-independent manner
4. Prenatal identification of male or female fetuses with a premutation fragile X allele of a premutation carrier woman (Musci and Moyer 2010).
    1. The mother has knowledge of the repeat size and gender of her fetus.
    2. The fetus does not carry a full mutation but instead has inherited an allele in the premutation range.
    3. Involves disclosure of information pertaining to the risk that the fetus may have to develop 2 adult-onset conditions, fragile X-associated primary ovarian insufficiency (FXPOI) and FXTAS.

5. Prenatal Identification of female fetuses with a full mutation of a premutation carrier woman (Musci and Moyer 2010).
    1. Identification of female fetuses with full mutations (>200) can pose a significant counseling challenge and a difficult set of choices for the parents.
    2. As anticipated for X-linked conditions, skewed X inactivation may modify the clinical phenotype of FXS in female carriers.
    3. In general, up to 50% of females with a full mutation allele will be significantly affected with cognitive and behavioral features of FXS (Sherman et al. 2005).
    4. Ultimately, for those women identified as carrying a female fetus with a full mutation, uncertainty about the resulting phenotype may certainly produce anxiety.
6. Prenatal identification of female fetuses with a full mutation (Musci and Moyer 2010).
    1. Genetic counseling for individuals shown to have an intermediate allele has proven especially challenging.
    2. This repeat range (45–54), often referred to as the "gray zone," can cause moderate anxiety in patients because this result is not called "normal," and intermediate repeat sizes may be unstable and can expand in subsequent generations.
    3. To date, there have been no reports of a CGG repeat of less than 56 expanding into a full mutation in a single generation.
7. Preimplantation genetic diagnosis (Saul and Tarleton 2012): available to at-risk pregnancies in which prior confirmation of the presence of an expanded (or altered) *FMR1* allele was identified in the family.
8. Management (Hagerman and Silverman 1991; Goldson and Hagerman 1992; American Academy of Pediatrics 1996; Hagerman 2001).
    1. To date, no drug is approved for the treatment of fragile X syndrome although many drugs are used to manage challenging behaviors from a symptomatic perspective in this population. A wide array of drug mechanisms is currently being assessed in FXS clinical study, although most are still in early phases (Davenport et al. 2016).
    2. Psychopharmacologic treatment with medications such as stimulants for attention and hyperactivity, selective serotonin reuptake inhibitors for anxiety, alpha-agonists for hyperactivity and overarousal, and antipsychotics for irritable and aggressive behaviors appear to be helpful by assessment in a clinical setting in approximately 50–70% of patients (Berry-Kravis et al. 2012).
    3. Emerging pharmacological treatment options (symptoms-based treatments) for fragile x syndrome (Schaefer et al. 2015).
        1. ADHD treatments: Overall, clinical treatment of ADHD symptoms in the context of FXS continues to focus on stimulant usage. Published data supporting use of agents approved by the FDA, including atomoxetine, clonidine, and guanfacine, specifically in persons with FXS, remains limited. Use of novel agents such as L-acetylcarnitine (LAC) or valproic acid (VPA) remains limited in the clinical setting for symptoms and behaviors of ADHD in this population.
        2. Sleep treatments: melatonin treatment leads to significantly longer sleep duration, shorter sleep latency, and earlier onset of sleep.
        3. Anxiety treatments: Oxytocin (OT) is a hormone produced in the hypothalamus that could diminish stress-induced behavior. Despite limited published data, selective serotonin reuptake inhibitor (SSRI) use targeting anxiety in persons with FXS is widespread. Clinical consensus on FXS appears to hold that SSRIs may be better tolerated in persons with FXS compared with youth with idiopathic ASD, where SSRI controlled trials have noted significant adverse effect rates and a lack of efficacy targeting repetitive behavior.

4. Irritability treatments: Atypical or newer-generation antipsychotics are often used by clinicians to treat the irritability associated with FXS. Despite their high rate of clinical use, there has been little systematic study of the efficacy of these antipsychotics within the FXS population.
4. Early intervention programs for developmental delay including speech and language therapies, physical therapy, and occupational therapy.
5. Behavioral interventions including psychopharmacological therapy.
6. Special educations.
7. Vocational planning.
8. Anticonvulsants for seizure control.
9. Prophylactic antibiotics for surgical or dental procedures in patients with mitral valve prolapse.
10. Orthopedic care for joint dislocations, flat feet, and scoliosis.

Fig. 1 Two brothers with fragile X syndrome showing large ears, accompanied by their mother

Fig. 2 A pair of brothers with fragile X syndrome showing a long face with large ears

Fig. 3 Another pair of male siblings with fragile X syndrome

Fig. 4 A chromosome spread showing a fragile X chromosome (*arrow*)

Fig. 5 (**a**–**d**) A large family affected by fragile X syndrome. The first boy (**a**, age 15) is the most affected one with CGG repeats of >1,500. He was not toilet trained until age 5 or 6 years. He never spoke until after auditory training. He may watch TV for 6–8 h straight and get agitated if someone approaches him. The brother (**b**, age 10) and sister (**c**, age 16) have CGG repeats of 1,200 and 600, respectively. Another sister (**d**) is a carrier with CGG repeats of 110 who has four children. The daughter (age 3, the first one from the *left*) has CGG repeats of 700. She has a long face with prominent ears, a high-arched palate, and flat feet. She suffers from hyperactivity, tactile/oral/olfactory defensiveness, gaze aversion, poor postural alignment, food cramming, hand biting, excessive drooling, poor self-regulation, and speech difficulties including echolalia. The other three children are normal with normal CGG repeats. The maternal grandmother has CGG repeats of 126

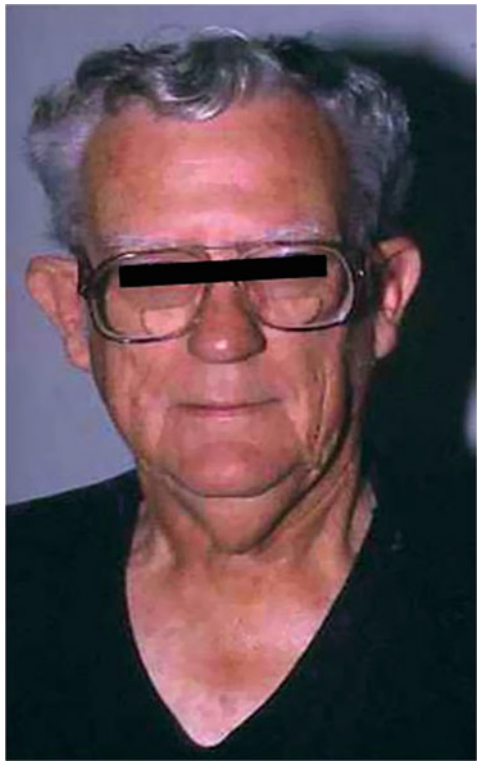

Fig. 6 A 66-year-old male with fragile X syndrome. The patient has mental retardation, a long face with large ears, and macroorchidism. Molecular analysis revealed CGG repeats of about 400

Fig. 7 A 46-year-old male with methylation mosaic fragile X syndrome (mixture of methylated full mutation allele of approximately 450 repeats in some cells and unmethylated premutation size allele of approximately 200 repeats in some cells). He is tall and has mental retardation, a long narrow face, slightly large ears, and macroorchidism

Fraser Syndrome

Contents

Fraser syndrome is a malformation syndrome characterized by cryptophthalmos ("hidden eye," a term coined by Zehender et al. 1872), cutaneous syndactyly, and anomalies of the genitourinary system. It was first described by Fraser in 1962. It is also known as cryptophthalmos-syndactyly syndrome, cryptophthalmos syndrome, or Fraser cryptophthalmos syndrome. Fraser syndrome occurs with a minimal estimated frequency of 0.43 per 100,000 live-born infants and 11.06 per 1,000,000 stillbirths (Martínez-Frías et al. 1998).

Synonyms and Related Disorders

Cryptophthalmos with other malformations; Cryptophthalmos-syndactyly syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Azevedo et al. 1973; Francannet et al. 1990; Barisic et al. 2013)
2. Caused by mutations in *FRAS1* and FRAS1-related extracellular matrix protein 2 (*FREM2*) genes:
    1. *FRAS1* gene, encoding a putative extracellular matrix (ECM) protein, located on the long arm of chromosome 4 (4q21)
    2. *FREM2* gene located on the long arm of chromosome 13 (13q13.3)
3. Mutations in *GRIP1*, which encodes a cytoplasmic scaffolding protein required for proper Fras1 localization at the basal membrane (Takamiya et al. 2004; Long et al. 2008), result in classical Fraser syndrome (Vogel et al. 2012; Schanze et al. 2014)
4. Genotype-phenotype correlations (van Haelst et al. 2008):
    1. Patients with an *FRAS1* mutation:
        1. More frequently skull ossification defects
        2. Low insertion of the umbilical cord
    2. Mutations were identified in only 43% of the cases suggesting that other genes syntenic to murine genes causing blebbing

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_97

may be responsible for Fraser syndrome as well.

5. Familial cases (56%):
   1. Presence of consanguinity, estimated to be as high as 15%
   2. Multiple affected sibs born to the same parents (Slavotinek and Tifft 2002; Singh et al. 2007)
6. Three forms of cryptophthalmos, classified based on ophthalmic findings (Francois 1969):
   1. Complete (typical) cryptophthalmos:
      1. The eyelids replaced by a sheet of skin running from forehead to cheek with absence or poor development of the eyebrow
      2. Absence of the eyelashes or the gland structures
      3. The elevated skin covering the globe moves when eye movements occur
      4. The skin adherent to the underlying cornea
      5. Absence of the conjunctival sac
      6. Microphthalmia usually present
      7. Often associated with numerous congenital abnormalities, including anomalies of the head, ears, nose, and genitalia, and syndactyly. This pattern of anomalies is termed Fraser syndrome (Ferri and Harvey 1999)
   2. Incomplete (atypical) cryptophthalmos:
      1. Presence of rudimentary eyelids
      2. Lateral placement of a small conjunctival sac
      3. The palpebral aperture about one-third of normal length
      4. Usually small globe, covered almost completely by the skin
   3. Abortive form or congenital symblepharon:
      1. The upper eyelids, without a defined margin, cover and adhere to up to 75% of the upper cornea
      2. Absence of punctum in the eyelid
      3. Absence of the upper conjunctival fornix
      4. Free part of the cornea often keratinized or opaque
      5. Globes: usually normal or small size
7. Pathogenesis (Ferri and Harvey 1999):
   1. Primary failure of differentiation during embryogenesis
   2. Compression of the amniochorionic band
   3. Intrauterine inflammation
   4. Failure of lid fold development
   5. Inactivation of glutamate receptor interacting protein 1 (GRIP1), a cytoplasmic multi-PDZ scaffolding protein, leads to the formation of subepidermal hemorrhagic blisters, renal agenesis, syndactyly or polydactyly, and permanent fusion of eyelids (cryptophthalmos), Fraser syndrome-like defects in mice (Takamiya et al. 2004)

Clinical Features

1. Intrafamilial clinical heterogeneity (Chattopadhyay et al. 1993; Slavotinek and Tifft 2002)
2. Eyes:
   1. Cryptophthalmos (a developmental anomaly in which the skin is continuous over the eyeballs without any indication of the formation of eyelids): the most common feature of Fraser syndrome (84–93%) (Gattuso et al. 1987):
      1. Bilateral (more common) or unilateral
      2. Total or partial
   2. Microphthalmia
   3. Absent or malformed lacrimal ducts
   4. Ocular hypertelorism
   5. Coloboma of the upper eyelid
   6. Supernumerary eyebrows
   7. Blindness
3. Head: unusually low lateral hairline on temples extending to lateral eyebrow
4. Nose:
   1. Hypoplastic and notched nares
   2. Broad nasal bridge
   3. Midline nasal cleavage
   4. Choanal atresia

5. Mouth:
    1. Cleft lip
    2. Cleft palate
    3. High-arched palate
    4. Crowding of the teeth
6. Ears:
    1. Malformation of middle and external ears (cup shaped and low set)
    2. Microtia
    3. Low-set ears
    4. Absent pinna
    5. Skin of the upper helix contiguous with scalp
    6. Conductive hearing loss
7. Laryngeal stenosis/atresia
8. Chest: widely spaced nipples
9. Lungs:
    1. Lung hyperplasia (Stevens et al. 1994)
    2. Lung hypoplasia
10. Cardiac anomalies (Thapa and Bhattachakya 2008):
    1. Hypertrophy of the left ventricle
    2. A variant of Ebstein anomaly
    3. Coarctation of the aorta
    4. Atrial septal defect
    5. Interventricular communication
    6. Truncus arteriosus
    7. Ventricular septal defect
    8. Complex heart disease
    9. PDA
    10. Patent foramen ovale
    11. Dextrocardia
    12. Transposition of the great vessels
    13. Partial anomalous pulmonary venous connection
11. Gastrointestinal anomalies (Slavotinek and Tifft 2002):
    1. Imperforate anus
    2. Anal atresia and anal stenosis
    3. Rectal atresia
    4. Displaced anus
    5. Umbilical hernia
    6. Intestinal malrotation
    7. Colonic atresia
12. Urogenital anomalies (Codere et al. 1981; Burn and Marwood 1982; Francannet et al. 1990):
    1. Renal agenesis/hypoplasia:
        1. Unilateral
        2. Bilateral
        3. Hypoplastic bladder
    2. Male genital anomalies:
        1. Small penis
        2. Hypospadias
        3. Cryptorchidism
    3. Female urogenital anomalies:
        1. Anterior urethral atresia (Andiran et al. 1999)
        2. Bicornuate uterus
        3. Uterine hypoplasia
        4. Vaginal atresia
        5. Hypoplastic labia majora
        6. Clitoral enlargement
        7. Gonadal dysgenesis/gonadoblastoma (Greenberg et al. 1986)
13. Limbs: syndactyly of the fingers (cutaneous in 54% of cases) and toes
14. CNS involvement:
    1. Mental retardation
    2. Microcephaly
    3. Meningomyelocele
    4. Encephalocele
15. Natural history:
    1. Stillborn: 25% of affected infants
    2. Additional 20% of affected infants die before 1 year of age
    3. Survival to 96 years of age reported (Impallomeni et al. 2006)
    4. Commonest causes of death:
        1. CNS malformations
        2. Laryngeal stenosis or atresia
        3. Respiratory insufficiency
        4. Obstructive uropathy or bilateral renal agenesis
16. Diagnostic criteria (Thomas et al. 1986) requires at least two major and one minor or one major and four minor criteria for the diagnosis:
    1. Major criteria:
        1. Cryptophthalmos
        2. Syndactyly

3. Abnormal genitalia
4. Sib with Fraser syndrome

2. Minor criteria:
   1. Congenital malformation of nose
   2. Congenital malformation of ears
   3. Congenital malformation of larynx
   4. Cleft lip/palate
   5. Skeletal defects
   6. Umbilical hernia
   7. Renal agenesis
   8. Mental retardation

17. Revised diagnostic criteria for Fraser syndrome (van Haelst et al. 2007) requires either three major, or two major and two minor, or one major and three minor diagnostic criteria present in a patient:
    1. Major criteria:
       1. Syndactyly
       2. Cryptophthalmos spectrum
       3. Urinary tract abnormalities
       4. Ambiguous genitalia
       5. Laryngeal and tracheal anomalies
       6. Positive family history
    2. Minor criteria:
       1. Anorectal defects
       2. Dysplastic ears
       3. Skull ossification defects
       4. Umbilical abnormalities
       5. Nasal anomalies

Diagnostic Investigations

1. Radiography:
   1. Poor ossification of the calvarium
   2. Orbital structures
   3. Pulmonary hypoplasia
   4. Diastasis of the symphysis pubis
   5. Syndactyly
2. Renal ultrasound for renal anomalies
3. Hearing test
4. CT (De Bernardo et al. 2015):
   1. Unilateral microphthalmos
   2. Ocular globe inhomogeneous for structure and signals
   3. Thin optic nerve
   4. Presence of a malformation-like coloboma into the ocular globe with cysts
   5. A small calcification of the parietal anterior
   6. An incomplete myelination of the brain
5. MRI:
   1. Intracranial malformations: parietooccipital flattening, absent eyelids and eyelashes, and abnormal left tentorium traversing the left occipital lobe (Yesilkaya et al. 2012)
   2. Developing unilateral optic nerve and visual cortex (De Bernardo et al. 2015)
6. Molecular genetic testing (van Haelst et al. 2008; Shafeghati et al. 2008):
   1. Linkage analysis in consanguineous families indicated possible linkage to *FRAS1* and *FREM2* in 60% of the cases
   2. Mutation analysis identified 11 new mutations in *FRAS1* and one *FREM2* mutation
   3. Molecular genetic test: mutation c.[5752dup];[8544 + 1G > T] p.[(Cy51918fs)] in the *FREM2* gene (De Bernardo et al. 2015)

Genetic Counseling

1. Recurrence risk:
   1. Patient's sibs: 25%
   2. Patient's offspring: recurrence risk not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis:
   1. Prenatal diagnosis made in the follow-up of a pregnancy with a previous sibling having had the same syndrome (Feldman et al. 1985; Ramsing et al. 1990; Schauer et al. 1990; Fryns et al. 1997; Berg et al. 2001; Rousseau et al. 2002; Vijayaraghavan et al. 2005).
   2. Prenatal diagnosis made in families with a negative history (Boyd et al. 1988; Serville et al. 1989; Maruotti et al. 2004)

3. Prenatal ultrasonography:
    1. Most cases of Fraser syndrome (85%) are suspected prenatally, often due to the presence of the association of renal agenesis and cryptophthalmos (Barisic et al. 2013).
    2. Major findings:
        1. Cryptophthalmos
        2. Microphthalmia
        3. Syndactyly
        4. Ambiguous genitalia
    3. Other findings:
        1. Oligohydramnios
        2. Ear defects
        3. Renal abnormalities or agenesis
        4. Uropathy
        5. Hyperechogenic lungs
        6. Laryngeal stenosis/atresia (Balci 1999)
        7. Ascites
        8. Intrauterine growth retardation
        9. Polyhydramnios
    4. A combination of prenatal ultrasonography and fetoscopy (Gattuso et al. 1987; Kabra et al. 2000)
    5. Exome sequencing for prenatal diagnosis of fetuses with sonographic abnormalities (Drury et al. 2015)
3. Management:
    1. Immediate ocular management: frequent use of artificial tears to maintain corneal luster and clarity (Dinno et al. 1974).
    2. Intubation or tracheotomy to provide an adequate airway when laryngeal atresia/stenosis is present. Final repair of the laryngeal stenosis is deferred until about 1–2 years of age when adequate thyroid cartilage development has occurred (Karas and Respler 1995).
    3. A relatively high incidence of difficult or impossible tracheal intubation (20%) due to glottic stenosis (Mathers et al. 2014).
    4. Surgical correction of associated anomalies.
    5. Goals of reconstruction, considering the poor probability of restoring visual function (Ferri and Harvey 1999):
        1. To protect the cornea (if present) from infection and ulceration
        2. To enhance cosmetic appearance
        3. To preserve the globe
    6. Surgical treatment of congenital symblepharon variant (Brazier et al. 1986):
        1. Lid rotation flap
        2. Rotation incisions
        3. Rotation of medial end of lower lid
        4. Skin edges suture
    7. Surgical treatment at a later age (Dibben et al. 1997):
        1. Reconstruction in partial cryptophthalmos:
            1. Dissection of the eyelids from the cornea
            2. Reconstruction of the conjunctival fornices with buccal mucosa
            3. Repair the upper lid coloboma in a flap reconstruction using the inferior eyelid margin
        2. Reconstruction without grafting in complete cryptophthalmos (Ferri and Harvey 1999)
        3. Reconstruction of unilateral incomplete cryptophthalmos (Tran et al. 2015):
            1. An evisceration with orbital implant and reconstruction of the eyelids and fornices using the preexisting scleral remnant
            2. Custom ocular prosthetic fitting was performed 5 weeks postoperatively.
            3. The prosthesis was successfully retained at 4-year follow-up
    8. Surgical strategy for correction of cryptophthalmos (Saleh et al. 2009):
        1. The main indication for early surgery: presence or risk of corneal exposure in eyes with visual potential, as may occur in abortive cryptophthalmos
        2. Surgery deferred for painless eyes with no potential for vision and where there is a low risk of corneal exposure. These include:

1. Complete cryptophthalmos
2. Incomplete cryptophthalmos with completely keratinized corneas
3. Patients without corneal exposure

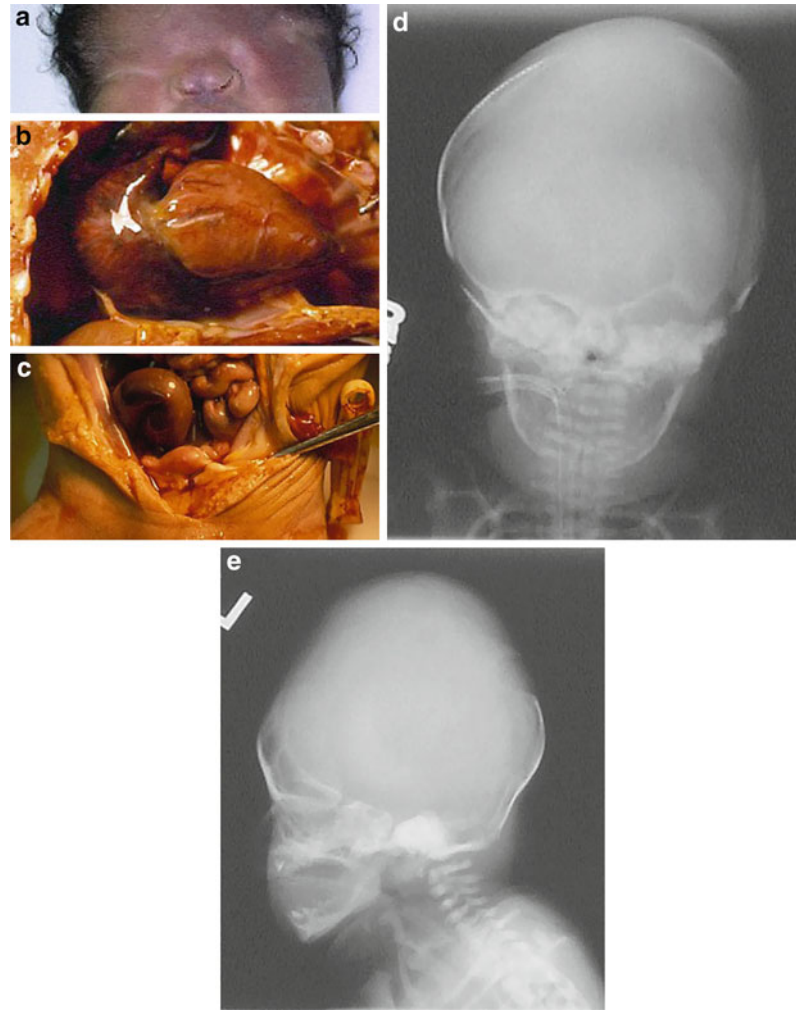

Fig. 1 (**a**–**e**) An infant with Fraser cryptophthalmos syndrome showing fused eyelids, lateral hair extending to lateral eyebrows, ocular hypertelorism, notched nares (**a**), and a tracheostomy site for management of laryngeal stenosis. Postmortem photos show lung hypoplasia (**b**), a small uterus (**c**), and clitoral hypertrophy. The skull radiographs (**d**, **e**) show poorly ossified calvarium

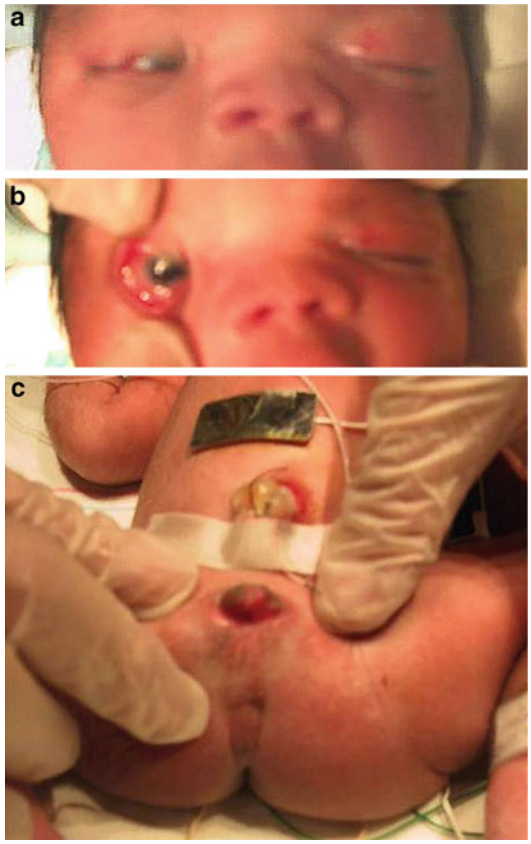

Fig. 2 (**a**–**c**) The sibling of the previous infant with Fraser syndrome showing microphthalmia, partial fusions of eyelids, ocular hypertelorism (**a**, **b**), genitourinary anomalies (**c**), and partial syndactyly of the toes. Variability of expression is illustrated in these two sibs

Freeman-Sheldon Syndrome

Contents

In 1938, Freeman and Sheldon described a syndrome characterized by a whistling face with a long philtrum, a puckered mouth, microstomia, H-shaped cutaneous dimpling on the chin, multiple joint contractures with camptodactyly, ulnar deviation of the fingers, bilateral talipes equinovarus, and kyphoscoliosis. Freeman-Sheldon syndrome (FSS) is the most severe of the distal arthrogryposes with the striking contractures of the orofacial muscles. The syndrome is also known as distal arthrogryposis (DA) type 2A, craniocarpotarsal dysplasia, or "whistling face" syndrome (Lev et al. 2000).

Synonyms and Related Disorders

Craniocarpotarsal dysplasia; "Whistling face" syndrome

Genetics/Basic Defects

1. Caused by mutations in embryonic myosin heavy chain gene (*MYH3*) (Toydemir et al. 2006). Sheldon-Hall syndrome (SHS) is known to be caused by mutations in either *MYH3*, *TNNT2* (Li et al. 2013), or *TNNT3* (Toydemir and Bamshad 2009)
2. Genetic heterogeneity (Sánchez and Kaminker 1986; Lev et al. 2000)
    1. Autosomal dominant inheritance (Malkawi and Tarawneh 1983; Marasovich et al. 1989; Gross-Kieselstein et al. 1971; Wettstein et al. 1980)
        1. Usually with normal psychomotor development, although mild motor delay attributable to joint anomalies might be present
        2. A variant of autosomal dominant inheritance, mapped to chromosome 11p15.5-pter (Krakowiak et al. 1997)
    2. Autosomal recessive inheritance (Kousseff et al. 1982; Fitzsimmons et al. 1984; Dallapiccola et al. 1989; Alves and Azevedo 1977): severe developmental retardation reported in a few patients
3. Pathogenesis
    1. Considered a form of distal arthrogryposis (Hall et al. 1982)
        1. Closely related to distal arthrogryposis type 1

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_98

1. Similar limb phenotypes but distinguished only by differences in facial morphology
2. Reports of families in which different individuals were diagnosed with distal arthrogryposis type 1 or Freeman-Sheldon syndrome

2. Proposed to classify Freeman-Sheldon syndrome as distal arthrogryposis type 2 (a distinct disorder from distal arthrogryposis type 1 with overlapping phenotypes) in a revised classification of distal arthrogryposis
3. The embryonic myosin R672C mutation that underlies Freeman-Sheldon syndrome (distal arthrogryposis syndrome 2A) (DA2A) impairs crossbridge detachment and cycling in adult skeletal muscle (Racca et al. 2015)

2. Primary brain anomalies suggested to explain many manifestations of the syndrome
3. Also considered possibly a nonprogressive or slowly progressive myopathy (Vaněk et al. 1986)

4. Overlap of clinical characteristics of FSS with other DA syndromes suggests a shared etiology and/or pathogenesis (Stevenson et al. 2006)
   1. Several DAs can be caused by mutations in four genes that encode proteins of the troponin-tropomyosin complex of fast-twitch myofibers.
   2. Specifically, mutations in *TPM2*, *TNNT2* or *TNNT3*, and *MYH8* cause DA1, SHS, and trismus-pseudocamptodactyly (i.e., DA7), respectively.

Clinical Features

1. Variable clinical severity and phenotypic abnormalities (Weinstein and Gorlin 1969)
2. Normal intelligence
3. "Whistling face" appearance (Burzynski et al. 1975)
   1. Long philtrum
   2. Microstomia (Gurjar et al. 2013)
   3. Puckered mouth
   4. Pursed lips
   5. H-shaped cutaneous dimpling on the chin
4. Musculoskeletal anomalies
   1. Multiple joint contractures
   2. Camptodactyly
   3. Ulnar deviation of fingers
   4. Windmill vane hand (bilateral ulnar deviation and contracture of fingers two to five at the metacarpophalangeal joints with adduction of thumbs)
   5. Normal hands in a few reports
   6. Bilateral talipes equinovarus
   7. Kyphoscoliosis
5. Growth retardation
6. Other craniofacial features
   1. Masklike rigid face
   2. Flat midface
   3. Deep-sunken eyes with hypertelorism
   4. Antimongoloid slant of the palpebral fissures
   5. Blepharophimosis
   6. Convergent strabismus
   7. Full cheeks
   8. Small nose
   9. Coloboma alae of the nose
   10. Micrognathia
   11. Cleft palate or high-arched palate
   12. Choanal atresia
   13. Low-set and malformed ears
   14. Hearing loss (Zampino et al. 1996)
7. Other features
   1. Nasal speech
   2. Short neck
   3. Inguinal hernia
   4. Cryptorchidism
   5. Spina bifida occulta
8. Complications
   1. Difficulty in swallowing attributed to the mouth deformity
   2. Pulmonary problems due to decreased thoracic expansion
9. Diagnostic criteria of Freeman-Sheldon syndrome (Stevenson et al. 2006)
   1. Presence of ≥ 2 of the major clinical manifestations of distal arthrogryposis (DA) plus the presence of a small pinched

mouth, prominent nasolabial folds, and H-shaped dimpling of the chin
2. Major manifestations of DA of the upper limbs
    1. Ulnar deviation of the wrists and fingers
    2. Camptodactyly
    3. Hypoplastic, and/or absent flexion creases, and/or overriding fingers at birth
3. Major manifestations of DA of the lower limbs
    1. Talipes equinovarus
    2. Calcaneovalgus deformities
    3. A vertical talus
    4. Metatarsus varus

10. Genotype-phenotype correlation: phenotype severity varies significantly by genotype (Beck et al. 2014)
    1. Individuals with p.T178I were the most severely affected with both facial contractures and congenital scoliosis.
    2. Classification of individuals with DA2A into phenotypic groups of varying severity should facilitate providing families with more accurate information about natural history and suggests that individuals might benefit from personalized medical management motivated by *MYH3* genotype.
11. Differential diagnosis of Sheldon-Hall syndrome (SHS) (Stevenson et al. 2006); diagnostic criteria of SHS include:
    1. $\geq$2 of the major clinical manifestations of DA
    2. Deep nasolabial folds
    3. A small oral opening (but a larger oral opening than that of FSS)
    4. A small but protuberant chin (but lack an H-shaped dimpling of the chin)
    5. Webbing of the neck

Diagnostic Investigations

1. Radiography (O'Connell and Hall 1977)
    1. Skull
        1. Shallow anterior cranial fossa
        2. Hypoplastic mandible
        3. Small malar bones
    2. Ulnar deviation and flexion contractures of the fingers
    3. Talipes equinovarus
    4. Kyphoscoliosis
2. Polysomnography for sleep-disordered breathing
3. Muscle biopsy findings: structural changes predominantly involving type I fibers suggesting that the muscle lesion is a form of congenital fiber type disproportion (Duggar et al. 1989)
4. Biopsies of the affected facial muscles (orbicularis, masseter, buccinators, and risorius): reported to show atrophy of the muscular fibers with abundant infiltration of adipose tissue, fibrosis, central migration of the nucleus, and variation in diameter of the muscular fibers (Ferrari et al. 2008).
5. Molecular genetic testing of *MHY3* mutations

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Autosomal dominant inheritance: low unless a parent is affected
        2. Autosomal recessive inheritance: 25%
        3. Empirical risks for sibs of sporadic cases: 7%
    2. Patient's offspring
        1. Autosomal dominant inheritance: 50%
        2. Autosomal recessive inheritance: low unless the spouse is affected
        3. Empirical risk for children of sporadic case: 37%
    3. Parental gonadal mosaicism (molecularly proven somatic mosaicism in phenotypically normal parent after having an affected child) (Hague et al. 2016)
        1. A significantly increased recurrence.
        2. Parental testing is thus essential for accurate risk assessment for future pregnancies, and the use of new technologies with next generation sequencing may improve the detection rate of mosaicism.

2. Prenatal diagnosis
    1. Ultrasonography at 20 weeks of gestation in a fetus with a positive family history (Robbins-Furman et al. 1995).
        1. Bilateral equinovarus and abnormally positioned toes
        2. Clenched hands with overlapping thumbs
        3. An abnormally appearing mouth with pursing of the lips
    2. Molecular genetic diagnosis: if the family history is positive and the mutation is known in the family, prenatal molecular genetic diagnosis is possible by direct molecular testing of fetal DNA sample obtained from chorionic villus or amniotic fluid.
3. Management
    1. Tracheostomy required for severe upper airway narrowing (Robinson 1997)
    2. Management of anesthetic risks (Duggar et al. 1989; Fisher et al. 2016)
        1. Risks primarily related to severe microstomia
        2. Problems encountered: difficult intravenous access, failure to identify the subarachnoid space, and patient discomfort during surgery
        3. Combinations of myopathic and skeletal abnormalities predisposing affected patients to significant postoperative respiratory difficulty
        4. Awake endotracheal intubation or fiberoptic nasotracheal intubation in infants before induction of general anesthesia
        5. A combined spinal-epidural anesthetic approach
    3. Distraction osteogenesis for severe obstructive sleep apnea syndrome secondary to DA 2A (Toranto et al. 2014)
    4. Functional and cosmetic correction of microstomia (Neumann and Coetzee 2009)
    5. Combined surgical and non-surgical approach to extensive microstomia: bilateral commissuroplasty increases maximum mouth opening when combined with the use of a customized dynamic oral commissure retractor and was effective in the management of microstomia (Sadrimanesh et al. 2013)
    6. Functional hand reconstruction for hand deformities
    7. Orthopedic correction of clubfeet and scoliosis

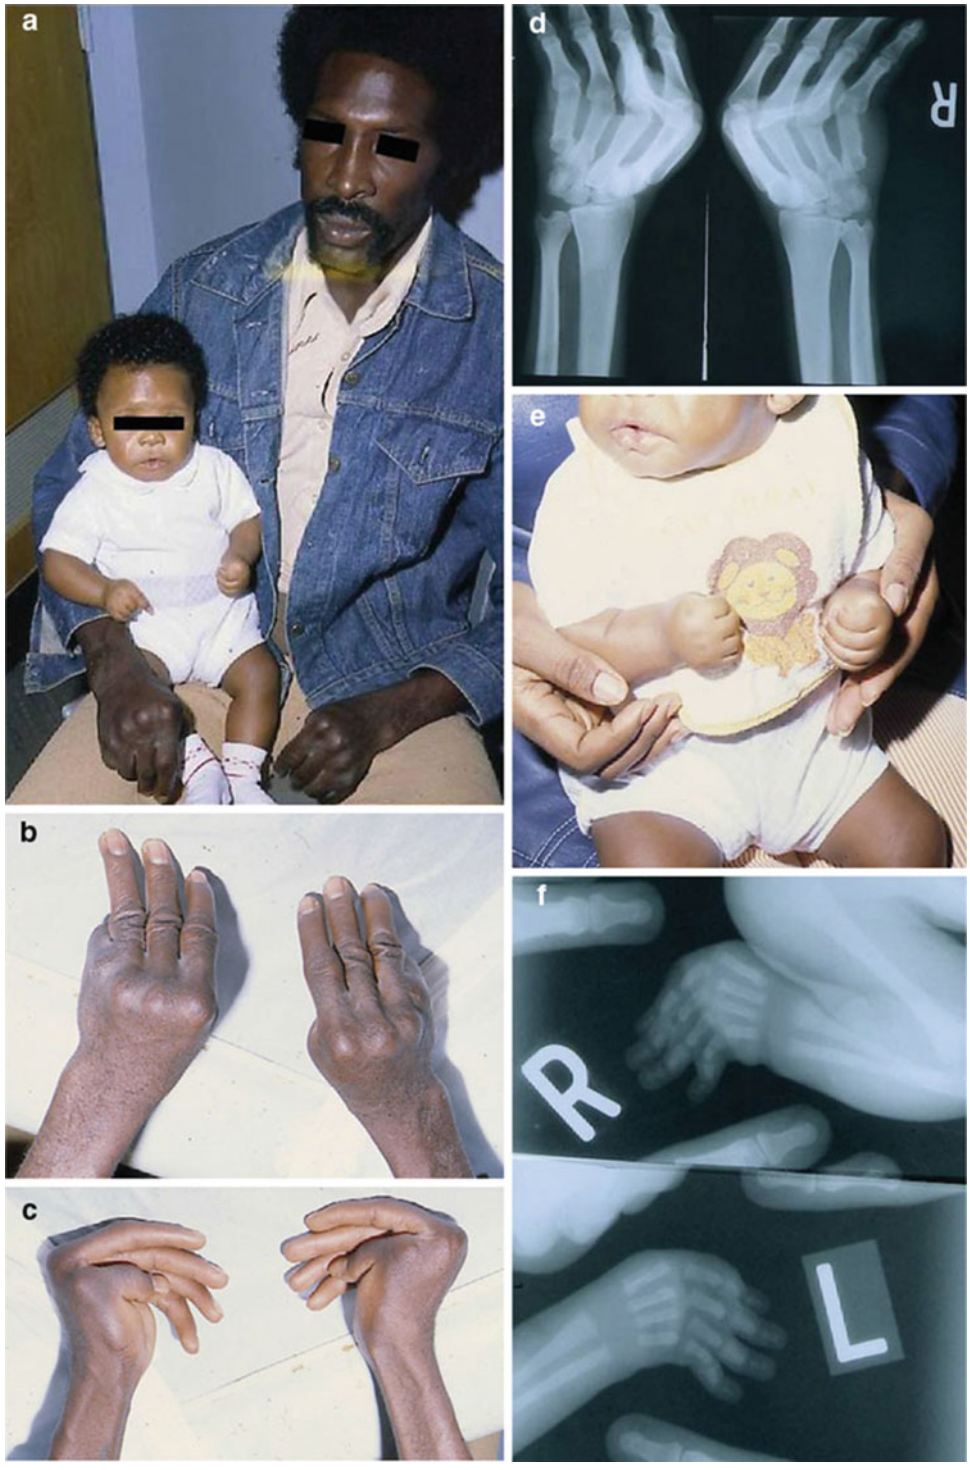

Fig. 1 (**a**–**f**) Freeman-Sheldon syndrome in a father (**a-c**) and son (**a**, **d**) showing whistling face appearance and ulnar deviation of fingers and fixed position of the thumbs. X rays of both hands and wrist AP views X-ray of the father (**d**) and the son (**a**, **e**) showed arthrogryposis, camptodactyly, and ulnar deviation of the hands and fingers

Fig. 2 (**a**, **b**) Freeman-Sheldon syndrome in a neonate showing characteristic "whistling face," ulnar deviation of the fingers with contractures, and talipes equinovarus

Fig. 3 (**a**, **b**) Another neonate showing characteristic "whistling face" with H-shaped cutaneous dimpling on the chin (**a**) and ulnar deviation and contractures of the fingers (**b**)

Fig. 4 A newborn with Freeman-Sheldon syndrome showing whistling appearance of the face, tight mouth opening, hypoplastic nasal alae, arthrogryposis of the hands and fingers with contractures and ulnar deviation of the wrists, and metatarsus adductus. Intrauterine growth retardation and Dandy-Walker malformation were detected prenatally by ultrasound

Friedreich Ataxia

Contents

During the period 1863–1877, Friedreich described the condition, now called Friedreich ataxia (FRDA), in nine members of three families. His initial report noted the following characteristics: age of onset around puberty and ataxia, dysarthria, sensory loss, muscle weakness, scoliosis, foot deformity, and cardiac symptoms.

FRDA is the commonest inherited ataxia (Harding 1984). Recent study based on molecular data suggests a carrier rate of 1 in 85 with a disease prevalence of 1 in 29,000 (Cossee et al. 1997).

Genetics/Basic Defects

1. Pathogenesis and molecular basis (Bidichandani and Delatycki 2014; Chawla 2015; Abrahão et al. 2015)
    1. An autosomal recessive disorder.
    2. The gene mutated in FRDA (frataxin) (FXN), mapped to 9q13-21.1, was initially called *X25* and later changed to *FRDA*.
3. *FXN* gene:
    1. Encodes a 210-amino acid mitochondrial protein called frataxin, whose biological function remains partially known.
    2. Both homozygous and heterozygous mutation mechanisms lead to a reduction of frataxin mRNA transcription and frataxin protein levels in different tissues, such as the heart, pancreas, peripheral blood cells, cerebellum, and dorsal root ganglia (Koeppen 2011).
4. The disease pathogenesis (Muthuswamy and Agarwal 2015):
    1. Fundamentally due to a lack of frataxin, which is claimed to play a role in iron-sulfur cluster synthesis.
    2. Oxidative stress builds up as a result of Fe accumulation in the mitochondria, causing degeneration of the cells (Delatycki et al. 2000), which primarily occurs in the neurons and later in the cardiac tissues, and to some extent in the pancreas.
5. Carriers of GAA expansion in one allele express near to 50% of FXN mRNA and are asymptomatic.
6. FRDA:
    1. Unique among trinucleotide repeat disorders in that it is autosomal recessive.
    2. The repeat is intronic (Campuzano et al. 1996).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_99

3. It is the only disease known to be the result of expansion of a GAA trinucleotide repeat.

7. GAA triplet repeat expansion in intron 1 of the *FXN* gene with four classes of alleles:
   1. Healthy individuals have GAA repeats between 10 and 66.
   2. Premutation (mutable normal) alleles: numbers between 35 and 66 GAA repeats.
      1. Not associated with FRDA but may expand during parental transmission, resulting in disease-causing alleles.
      2. Expansion of premutation alleles, sometimes more than tenfold the original size, has been observed in both paternal and maternal transmission.
   3. Disease-causing expanded (full penetrance) alleles (homozygous): 66–1,700 GAA repeats (Sharma et al. 2004).
   4. Borderline alleles: 44–66 uninterrupted GAA repeats.

2. Intergenerational instability, premutations, and origin of mutations
   1. GAA repeat underlying FRDA: unstable in its transmission from parent to offspring as in other trinucleotide repeat disorders (Timchenko and Caskey 1996).
   2. Maternal transmission may result in a larger or smaller allele in offspring, while paternal transmission always results in smaller allele (Monros et al. 1997; Pianese et al. 1997; Delatycki et al. 1998; De Michele et al. 1998). The size of the triplet repeat influences the direction of instability with smaller alleles more prone to increase in size and larger ones to decrease.
   3. Premutation alleles are prone to large expansion in one generation.
   4. Normal-sized alleles have a bimodal distribution:
      1. Small normal alleles (about 83%): between 6 and 12 repeats
      2. Large normal alleles (about 17%): between 14 and 34 repeats

3. Genotype-phenotype correlation: not possible to predict the specific clinical outcome in any individual based on genotype (Bidichandani and Delatycki 2014)
   1. Variability in individuals with FRDA may be caused by:
      1. Genetic background (e.g., Acadian individuals)
      2. Somatic heterogeneity of the GAA expansion
      3. Other unidentified factors
   2. GAA repeat size in homozygotes for pathogenic GAA repeat expansions:
      1. Statistically significant correlations with:
         1. Age of onset
         2. Presence of leg muscle weakness and/or wasting
         3. Duration until wheelchair use
         4. Prevalence of cardiomyopathy, pes cavus, and scoliosis
      2. Individuals with late-onset FRDA (LOFA): frequently exhibit fewer than 500 GAA repeats in at least one of the expanded alleles
      3. Individuals with very late-onset FRDA (VLOFA): usually have fewer than 300 GAA repeats in at least one of the expanded alleles
      4. Cardiomyopathy: more frequently seen with longer GAA repeat alleles
      5. Diabetes mellitus or abnormal glucose tolerance: does not show a clear-cut correlation with the size of the GAA expansion
   3. Spastic paraparesis without ataxia: may be seen in those with smaller expanded alleles or in association with the G130V missense mutation
   4. Compound heterozygotes for an expansion and a point mutation:
      1. Most compound heterozygotes are clinically indistinguishable from typical individuals with FRDA with homozygous GAA expansions.
      2. Compound heterozygotes for an expansion and a borderline “mutable” allele. Individuals with somatically unstable borderline alleles present with LOFA/

VLOFA, mild and gradually progressive disease, and normal reflexes/hyperreflexia.

4. Pathophysiology (Chawla 2015)
   1. Major pathophysiologic finding: "dying back phenomena" of axons, beginning in the periphery with ultimate loss of neurons and a secondary gliosis.
   2. Primary sites of changes in spinal cord and spinal roots resulting in loss of large myelinated axons in peripheral nerves, which increases with age and disease duration.
   3. Unmyelinated fibers in sensory roots and peripheral sensory nerves are spared.
5. Neuropathology of FRDA (Pandolfo 2009)
   1. Specific to this disorder (Koeppen 2002)
   2. Sensory neuronopathy in the dorsal root ganglia, accompanied by the loss of peripheral sensory nerve fibers and the degeneration of posterior columns of the spinal cord: a hallmark of the disease
6. Pathogenesis of cardiomyopathy (Koeppen et al. 2015)
   1. Cardiomyocyte hypertrophy
   2. Extensive endomysial fibrosis

Clinical Features

1. Diagnostic criteria for FRDA (Geoffroy et al. 1976)
   1. Primary (essential for diagnosis)
      1. Onset before the end of puberty (never after the age of 20 years)
      2. Progressive ataxia of gait
      3. Dysarthria
      4. Loss of joint position or vibration sense
      5. Absent tendon reflexes in the legs
      6. Muscle weakness
   2. Secondary
      1. Extensor plantar responses
      2. Pes cavus
      3. Scoliosis
      4. Cardiomyopathy
2. Diagnostic criteria for FRDA (Harding 1981)
   1. Primary (essential for diagnosis)
      1. Age of onset of symptoms before the age of 25 years
      2. Progressive unremitting ataxia of limbs and of gait
      3. Absence of knee and ankle jerks
   2. Secondary
      1. Dysarthria
      2. Extensor plantar responses
   3. Additional: if secondary criteria are absent, the following have to be present:
      1. An affected sib fulfilling primary and secondary criteria
      2. Median motor nerve conduction velocities of greater than 40 m/s, thus excluding cases of type I hereditary motor and sensory neuropathy
3. Typical and atypical FRDA (Harding 1981)
   1. Typical: cases meeting above criteria
   2. Atypical: cases not meeting above criteria
4. Main clinical features of FRDA patients (Abrahão et al. 2015)
   1. Neurological features in the classical phenotype of FRDA
      1. Ataxia (sensory and cerebellar)
      2. Areflexia
      3. Sensory loss
      4. Lower limb weakness
      5. Dysarthria/dysphagia
      6. Bilateral Babinski's sign
      7. Eye movements (involuntary saccades and square wave jerks)
      8. Optic neuropathy (uncommon)
      9. Auditory neuropathy (uncommon)
   2. Non-neurological features
      1. Cardiomyopathy (common)
      2. Diabetes mellitus (common)
      3. Skeletal abnormalities – pes cavus and scoliosis (common)
   3. Atypical phenotypes (Lecocq et al. 2016)
      1. Spastic ataxia, retained reflexes, lack of dysarthria, and lack of extra neurological signs
      2. Late-onset Friedreich ataxia (LOFA)
      3. Very late-onset Friedreich ataxia (VLOFA)

4. Friedreich ataxia with retained reflexes (FARR)
5. Early-onset FRDA

5. Differential diagnosis for FRDA and autosomal recessive ataxias (Jayadev and Bird 2013; Parkinson et al. 2013)
   1. Ataxia with vitamin E deficiency
   2. Ataxia with oculomotor apraxia types 1 and 2
   3. Ataxia telangiectasia (please see the chapter "► Ataxia-Telangiectasia")
   4. Charcot-Marie-Tooth disease (please see the chapter "► Charcot-Marie-Tooth Disease")
   5. Hereditary spastic paraplegia (please see the chapter "► Hereditary Spastic Paraplegia")
   6. Marinesco-Sjögren syndrome
   7. Refsum disease
   8. Autosomal recessive spastic ataxia of Charlevoix-Saguenay
   9. Hexosaminidase deficiency
   10. CoQ10 deficiency
   11. Mitochondrial mutations (mitochondrial recessive ataxia syndrome)
   12. Sensory ataxia, neuropathy, dysarthria, and ophthalmoplegia
   13. Cerebrotendinous xanthomatosis

Diagnostic Investigations

1. Molecular genetic testing for confirmation of the disease (Muthuswamy and Agarwal 2015)
   1. Confirmatory tests for cases that are clinically unidentifiable and undifferentiable between FRDA and spinocerebellar ataxia.
   2. A triplet repeat primed polymerase chain reaction (TP PCR) for FRDA diagnosis (Ciotti et al. 2004).
      1. Validated the results with other methods such as Southern blotting, short PCR, and long PCR. However, it has its disadvantages such as the inability to discriminate between homozygosity/heterozygosity and to determine the number of GAA repeats.
      2. Further, short PCR, fluorescent PCR, and long PCR can be used to tell apart homozygosity/heterozygosity for GAA repeat expansion. Short PCR preferentially amplifies the normal allele, whereas long PCR possesses the ability to amplify expanded alleles. Thus, long and short PCR can be combined to discriminate homozygosity or heterozygosity of expansion.
   3. Southern blotting was initially used for the sizing of GAA repeats, and it is still a gold standard method for the sizing of repeats.
      1. The enzyme Eco RI was used 11 initially, and it was replaced by BsiHKA1 because of its higher resolution.
      2. Treatment of DNA with enzymes produces a 2.4-kb fragment, which is normal, and the presence of fragments above this size is considered to be positive for GAA repeat expansion.
   4. At present, long PCR is the most commonly used technique for diagnosis, followed by TP-PCR, which is being exploited for diagnostic purposes. However, accurate sizing is still possible only by Southern blot.
2. Clinical molecular laboratory testing
   1. Targeted mutation analysis
      1. Homozygous GAA expansion in *FXN* (96%)
      2. Heterozygous GAA expansion in *FXN*
   2. Sequence analysis: heterozygous point mutation in *FXN*
      1. Approximately 4% of patients are compound heterozygotes for a GAA expansion in the disease-causing range in one *FXN* allele and another inactivating *FXN* gene mutation in the other allele.
      2. No affected individuals with inactivating point mutations in both *FXN* alleles reported to date.
3. Echocardiography: reveals symmetric, concentric ventricular hypertrophy, although asymmetric septal hypertrophy may be present
4. Brainstem auditory evoked responses: typically displaying absent waves III and IV with preservation of wave I, suggestive of involvement of central auditory pathways

5. Visual evoked potentials: absent or delayed latency and reduced amplitude of the p100 wave in two thirds of patients
6. Somatosensory evoked potentials
    1. Delayed central conduction time (N13a/N20, N13b/N20)
    2. Dispersed potentials at the sensory cortex
    3. Abnormal central motor conduction
7. Magnetic resonance imaging of the brain and spinal cord: consistently shows atrophy of the cervical spinal cord and medulla with minimal evidence of cerebellar atrophy (Collins 2013)
8. Nerve conduction studies
    1. Absent sensory nerve action potentials
    2. Absent spinal somatosensory evoked potentials, although these may be reduced or even normal early in the disease course (Harding 1984)
    3. Motor nerve conduction velocities are reduced to a lesser extent than sensory nerve action potentials.
9. Histological studies
    1. Loss of myelinated fibers of the dorsal columns and the corticospinal tracts in lower cervical cord (Weil stain)
    2. Milder involvement of spinocerebellar tracts
    3. Compact fibrillary gliosis in the affected tract on hematoxylin and eosin (H&E) stain but no breakdown products or macrophages, reflecting the very slow rate of degeneration and death of fibers
    4. Shrinkage and eventual disappearance of neurons associated with proliferation of capsular cells in the dorsal spinal ganglia (H&E)
    5. Nearly devoid of large myelinated fibers in the posterior roots
    6. Degeneration and loss of cells of the Clarke column within the thoracic spinal cord

Genetic Counseling

1. Ability to diagnose FRDA by molecular means with a high sensitivity and specificity
    1. Clinically typical patients
        1. A specific and rapid diagnosis can be made in most patients and in the 4% compound heterozygous for a point mutation.
        2. The presence of one expanded allele indicates that the diagnosis is likely.
    2. Clinically atypical patients can be diagnosed to have or not to have FRDA by:
        1. GAA repeat study
        2. Mutation analysis for point mutations
    3. Carrier testing
        1. Available for relatives of affected and their partners.
        2. There is a small possibility that a point mutation may be present.
    4. For a subject with FRDA who has a carrier partner, there is a 1:2 risk of having an affected child. The a priori risk for a person with FRDA having a child with the condition is approximately 1:200 unless there is consanguinity.
    5. If the partner of a carrier does not have an expanded allele, the chance that they carry a point mutation is about 1:5,000 (taking a FRDA carrier rate of 1:100 and that 2% of mutations are point mutations). Therefore, the risk of this couple having a child with FRDA is about 1:20,000 which is only about twice the background risk of the general population.
2. Recurrence risk (Bidichandani and Delatycki 2014)
    1. Patient's sib
        1. Both parents carry a full penetrance allele, or one parent carries a full penetrance allele, and the other parent carries another deleterious *FXN* gene mutation.
            1. At conception: each sib of an affected individual has a 25% chance of being affected, a 50% chance of being an asymptomatic carrier, and a 25% chance of being unaffected and not a carrier.
            2. Once an at-risk sib is known to be clinically unaffected, the risk of his/her being a carrier is 2/3.

3. The wide range in age of onset and variable intergenerational instability of the GAA expansion dictate the use of caution in diagnosing an at-risk sib as unaffected.

2. One parent carries a full penetrance allele or another deleterious *FXN* gene mutation, and the other parent carries a mutable normal (premutation) allele.
   1. At conception: each sib of a proband whose parent is a carrier of a mutable normal (premutation) allele has a 25% chance of inheriting both parental mutations.
   2. Since the mutable normal (premutation) allele may remain unchanged or undergo minimal change (i.e., not expand to produce a full penetrance allele), the sibs have less than 25% chance of being affected.
   3. Each sib also has a 50% chance of being an asymptomatic carrier of one of the parental alleles and a 25% chance of being unaffected and having two normal alleles.

2. Patient's offspring
   1. All offspring inherit one mutant allele from the affected parent.
   2. Offspring have a 50% chance of being affected only if the reproductive partner of the proband is a carrier of a full penetrance allele or another deleterious *FXN* gene mutation.
   3. If the reproductive partner of the proband carries a mutable normal (premutation) allele, the risk to each offspring of developing FRDA is less than 50%.

3. Prenatal diagnosis (Bidichandani and Delatycki 2014)
   1. Possible for pregnancies at 25% risk provided both disease-causing alleles of an affected family member must be identified before prenatal testing can be performed
      1. Amniocentesis
      2. Chorionic villus sampling
   2. Request for prenatal diagnosis of FRDA (Pandolfo and Montermini 1998)
      1. Usually prompted by a previous affected child.
      2. Most often both parents are carriers of a GAA expansion, so affected offspring have two expanded alleles.
      3. Alternatively, one of the parents carries a frataxin point mutation and the other has a GAA expansion. Affected offspring are compound heterozygotes.
      4. When the causative point mutation is known, prenatal diagnosis requires a test for this mutation along with expansion detection.
   3. Preimplantation genetic diagnosis: available for families in which the disease-causing mutations have been identified in an affected family member

4. Management
   1. Supporting measures (Bidichandani and Delatycki 2014; Collins 2013; Jayadev and Bird 2013):
      1. Prostheses, walking aids, and wheelchairs for mobility.
      2. Orthopedic interventions for scoliosis and foot deformities.
      3. Speech, occupational, and physical therapy.
      4. Hearing aids.
      5. Pharmacologic agents for spasticity.
      6. Dietary modifications and placement of a nasogastric tube or gastrostomy for dysphagia.
      7. Antiarrhythmic agents.
      8. Anticardiac failure medications.
      9. Anticoagulants and pacemaker insertion for cardiac disease.
      10. Oral hypoglycemic agents or insulin for diabetes mellitus.
      11. Antispasmodics for bladder dysfunction.
      12. Treatment for diabetes and dysphagia.
      13. Parkinsonian features may respond to L-dopa.
      14. Spasticity may respond to Baclofen or tizanidine.
      15. Psychological support.

2. Women with FRDA are capable of successful pregnancy with relatively few complications (Friedman et al. 2010).
3. Currently, no treatments have been proven to delay, prevent, or reverse the inexorable decline that occurs in this condition. However, several pharmaceutical agents are undergoing clinical assessment (Delatycki 2009; Abrahão et al. 2015).
4. Treatment with intermediate- and high-dose idebenone had beneficial effects on neurological symptoms (Schulz et al. 2009).
5. Improvement in both cardiac hypertrophy and neurological symptoms among patients with FRDA treated with a low dose of deferiprone with idebenone (Meier and Buyse 2009; Elincx-Benizri et al. 2016).

Fig. 1 This 22-year-old man was seen for progressive muscle weakness and progressive ataxia. The patient began noticing the problem while running during football practice in high school. In the last 6 months, he has had trouble swallowing, especially liquids, and trouble speaking. At present, he walks with a cane with ataxic gait. There was a significant thigh muscle mass loss. His deep tendon reflexes are absent. Friedreich ataxia DNA test showed that the patient is homozygous for the GAA repeat expansion mutation which confirms the clinical diagnosis of Friedreich ataxia type I (FRDA1) with X25 allele 1 of 400 GAA repeats and X25 allele 2 of 400 GAA repeats

Fig. 2 The patient stands with a cane and needs to support standing with hand support on the wall

Frontonasal Dysplasia

Contents

Frontonasal dysplasia is a developmental field defect of craniofacial region characterized by hypertelorism and varying degrees of median nasal clefting. In 1967, DeMeyer first described the malformation complex "median cleft face syndrome" to emphasize the key midface defects. Since then, several terms have been introduced: frontonasal dysplasia, frontonasal syndrome, frontonasal dysostosis, and craniofrontonasal dysplasia (currently recognized as a syndrome distinct from frontonasal dysplasia) (Dubey and Garap 2000).

Synonyms and Related Disorders

Frontonasal malformation; Frontorhiny; Median facial cleft syndrome

Genetics/Basic Defects

1. Inheritance
    1. Sporadic in most cases.
    2. Rare autosomal dominant inheritance with variable expression.
    3. First human autosomal dominant frontonasal dysplasia syndrome associated with *SIX2* deletion (Hufnagel et al. 2016).
    4. Recessive mutations in the homeobox gene *ALX3* cause a recurrent pattern of frontonasal malformation (Twigg et al. 2009).
    5. Rare autosomal recessive inheritance: disruption of *ALX1* causes autosomal-recessive *ALX*-related frontonasal dysplasia (Uz et al. 2010).
    6. Rare X-linked dominant inheritance.
2. Rare association with chromosome anomalies
    1. Partial trisomy 2q and partial monosomy 7q from a balanced maternal t(2;7)(q31;q36) (Chen et al. 1992)
    2. Partial 21q22.3 deletion (Guion-Almeida et al. 2012)
    3. 22q11 microdeletion (Stratton and Payne 1997)
    4. Reciprocal translocation t(15;22)(q22;q13) (Fryns et al. 1993)
    5. Complex translocation involving chromosomes 3, 7, and 11 (Stevens and Qumsiyeh 1995)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_100

6. Either autosomal dominant or X-linked dominant inheritance (Fryburg et al. 1993; Nevin et al. 1999)
3. Rare variants of frontonasal dysplasia/malformation with variable inheritance patterns
4. Embryologically classified as a developmental field defect (Sedano and Gorlin 1986)
5. Extreme variable phenotypic expression (Cohen et al. 1971; Qureshi and Naeem-uz-Zfar 1996)
6. Pathogenesis (Twigg et al. 2009)
    1. Formation of the human face is an exquisitely orchestrated developmental process involving multiple tissue swellings (the frontonasal, medial and lateral nasal, and maxillary and mandibular prominences) derived from the neural crest (Moore and Persaud 2007).
    2. During a critical period between 4 and 8 weeks of human fetal development, these processes must undergo cell proliferation and tissue fusion to form the orbital, nasal, and oral structures (Yoon et al. 2000; Moore and Persaud 2007).
    3. Disturbance to this developmental sequence causes frontonasal malformation, a very heterogeneous group of disorders characterized by combinations of hypertelorism, abnormal nasal configuration, and oral, palatal, or facial clefting, sometimes associated with facial asymmetry, skin tags, ocular or cerebral malformations, widow's peak, and anterior cranium bifidum (DeMeyer 1967; Sedano et al. 1970; Sedano and Gorlin 1986; van der Meulen and Vaandrager 1989; Guinon-Almeida et al. 1996; Tan and Mulliken 1997; Losee et al. 2004).

Clinical Features

1. Pure frontonasal dysplasia (Dubey and Garap 2000)
    1. Variable mental retardation
    2. Inheritance pattern
        1. Sporadic in majority of cases
        2. Familial transmission in few cases
    3. Cranium bifidum occultum
    4. CNS anomalies
        1. Frontal cephalocele
        2. Meningocele/meningoencephalocele
        3. Agenesis of the corpus callosum
        4. Holoprosencephaly (Roubicek et al. 1981)
        5. Hydrocephalus
    5. Nasal anomalies
        1. Mild colobomas of the nostril
        2. Flattening of the nose with widely separated nares
        3. A broad nasal root
        4. Broad nasal tip
        5. Notching or clefting of alae nasi (cleft nose) (Fox et al. 1976)
        6. Nasal tag
    6. Ocular anomalies (Kinsey and Streeten 1977)
        1. Hypertelorism (Edwards et al. 1971)
        2. Epicanthal folds
        3. Narrowing of the palpebral fissures
        4. Ocular colobomata (Temple et al. 1990)
        5. Accessory nasal eyelid tissue with secondary displacement of inferior puncta colobomas
        6. Upper eyelid colobomas
        7. Epibulbar dermoids
        8. Microphthalmia
        9. Vitreoretinal degeneration with retinal detachment
        10. Congenital cataracts
    7. Facial anomalies
        1. Widow's peak configuration of the anterior hairline in the forehead (Smith and Cohen 1973)
        2. Median cleft of upper lip
        3. Median cleft palate
        4. Preauricular tag
        5. Absent tragus
        6. Low-set ears
    8. Other anomalies
        1. Conductive deafness
        2. Hypoplastic frontal sinuses
        3. Cardiac anomalies, especially tetralogy of Fallot

4. Limb anomalies
    1. Clinodactyly
    2. Polydactyly
    3. Syndactyly
    4. Tibial hypoplasia
5. Umbilical hernia
6. Cryptorchidism

2. Autosomal-recessive frontonasal dysplasia in two distinct families (Uz et al. 2010)
    1. Bilateral extreme microphthalmia
    2. Bilateral oblique facial cleft
    3. Complete cleft palate
    4. Hypertelorism
    5. Wide nasal bridge with hypoplasia of the ala nasi
    6. Low-set, posteriorly rotated ears
3. Other syndromes associated with frontonasal dysplasia or frontonasal malformation (Martinelli et al. 2002)
    1. Autosomal dominant form of frontonasal dysplasia with vertebral anomalies
    2. Acromelic frontonasal dysplasia (Slaney et al. 1999)
        1. Autosomal recessive disorder
        2. Similar frontonasal "dysplasia"
        3. Rare agenesis of the corpus callosum
        4. Tibial hypoplasia
        5. Polydactyly (duplicated hallux)
    3. Craniofrontonasal dysplasia (Cohen 1979; Orr et al. 1997)
        1. Possible X-linked disorder
        2. Rare mental retardation
        3. Hypertelorism
        4. Craniosynostosis
        5. Facial asymmetry
        6. Broad nasal root
        7. Bifid nasal tip
        8. Syndactyly of toes and fingers
        9. Split nails
        10. Broad first toe
    4. Acrocallosal syndrome (Nelson and Thomson 1982)
        1. Autosomal dominant or autosomal recessive disorder
        2. Severe mental retardation
        3. Hypertelorism
        4. Hypoplastic or absent corpus callosum
        5. Prominent forehead
        6. Small nose
        7. Broad nasal bridge
        8. Normal nasal tip
        9. Cardiac defects
        10. Postaxial polydactyly of hands and feet
        11. Preaxial polydactyly of feet
        12. Syndactyly of toes
        13. Clinodactyly
    5. Oral-facial-digital syndrome (Toriello 1993)
        1. X-linked disorder
        2. Variable mental retardation
        3. Agenesis of the corpus callosum
        4. Median cleft lip and palate
        5. Lobated/bifid tongue
        6. Clinodactyly
        7. Syndactyly
        8. Polydactyly
    6. Oculo-auriculo-frontonasal dysplasia (Toriello et al. 1995)
        1. Frontonasal dysplasia
        2. Ocular dermoids
        3. Eyelid colobomata
        4. Preauricular tags
    7. Fronto-facio-nasal dysplasia/dysostosis (Gollop 1981)
        1. Autosomal recessive disorder
        2. Frontonasal dysplasia
        3. Ocular dermoids
        4. Preauricular tags
        5. Cerebral lipoma
    8. Acro-fronto-facio-nasal dysplasia I
        1. Autosomal recessive disorder
        2. Frontonasal dysplasia
        3. Macrostomia
        4. Broad and notched nasal tip
        5. Fibular hypoplasia
        6. Polydactyly
        7. Short stature
    9. Acro-fronto-facio-nasal dysplasia II
        1. Autosomal recessive disorder
        2. Frontonasal dysplasia
        3. Microcephaly

4. Nasal midline groove with blind dimples
5. Broad thumbs
6. Syndactyly

10. Greig acrocephalopolysyndactyly
    1. Autosomal dominant disorder
    2. Mild mental retardation
    3. Mild features of frontonasal dysplasia
    4. Macrocephaly
    5. Broad nasal root
    6. Normal nasal tip
    7. Postaxial polydactyly of hands
    8. Preaxial polysyndactyly of feet
    9. Broad thumbs and halluces
    10. Syndactyly
11. Meinecke frontonasal dysplasia-cardiac defects
    1. Frontonasal dysplasia
    2. Microcephaly
    3. Cardiac defects, especially tetralogy of Fallot

4. Prognosis depending on severity of defects
    1. Normal intelligence in most patients
    2. Mental retardation affecting 12% of cases without CNS abnormalities
    3. Up to 50% of cases with mental retardation complicated by agenesis of the corpus callosum

Diagnostic Investigations

1. Radiology of craniofacial structures (Kurlander et al. 1967)
    1. Orbital hypertelorism
    2. Cranium bifidum occultum frontalis
    3. Primary telecanthus
    4. Median cleft nose
    5. Median cleft prolabium and premaxilla
    6. Median cleft secondary palate
    7. Some patients with frontal lipomas, dermoids, or teratomas
    8. Large cranial foramina (Vegesna et al. 2014)
2. Radiography, CT, and MRI of the brain
    1. Anterior cranium bifidum
    2. Agenesis of the corpus callosum
    3. Lipoma of the corpus callosum
    4. Arhinencephaly
    5. Hydrocephalus
    6. Occipital lobe hypoplasia (Vegesna et al. 2014)
3. Chromosome analysis for chromosome etiology
4. Molecular genetic diagnosis of *ALX1* and *ALX3* mutations: not available clinically

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Autosomal dominant disorder: not increased in de novo case unless a parent is affected
        2. Autosomal recessive disorder: 25%
        3. X-linked dominant disorder: 50% when the mother is a carrier
        4. Chromosome disorder: not increased in a de novo case; risk of unbalanced segregation from a carrier parent
    2. Patient's offspring
        1. Autosomal dominant disorder: 50%
        2. Autosomal recessive disorder: not increased unless the spouse is a carrier
        3. X-linked dominant disorder: 50%
        4. Chromosome disorder: not surviving to reproductive age
2. Prenatal diagnosis
    1. Ultrasonography (Frattarelli et al. 1996; Chervenak et al. 1984; Martinelli et al. 2002)
        1. Hypertelorism
        2. Frontonasal cephalocele
        3. Agenesis of the corpus callosum
        4. Median cleft lip
    2. 3-D ultrasonography: increasingly helpful in identifying facial features (Johnstone et al. 2008)
    3. Fetal MRI: periventricular nodular heterotopias (Recio-Rodríguez et al. 2014)
    4. Amniocentesis for associated chromosome anomaly

3. Management
    1. Speech therapy
    2. Maxillofacial surgeries for functional and cosmetic improvement
        1. Cleft lip/palate
        2. Hypertelorism
        3. A primary rhinoplasty on a bifid nose, a very mild form of FND (Núñez-Villaveirá et al. 2013)
    3. Psychosocial and/or psychiatric support

Galactosemia

Contents

Classic galactosemia (G/G) is an autosomal recessive disorder of galactose metabolism, caused by a deficiency of galactose-1-phosphate uridyl transferase. The incidence is estimated to be 1 in 30,000–1 in 60,000 births, based on the results of newborn screening programs.

Synonyms and Related Disorders

Classic galactosemia; Clinical variant galactosemia; Duarte variant; Galactokinase (GALT) deficiency; Galactose-1-phosphate uridyl transferase deficiency; Uridine diphosphate (UDP) galactose 4-epimerase (GALE) deficiency

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Leslie 2003)
2. Cause: deficiency of galactose-1-phosphate uridyl transferase (GALT)
3. Galactose metabolism (Arn 2003)
    1. D-galactose.
        1. Galactose: an important sugar in human nutrition, especially during childhood.
        2. Milk: major source of galactose, which contains lactose, a disaccharide of glucose and galactose.
        3. Liver: the primary site of galactose metabolism.
        4. Individuals have the capacity to metabolize large quantities of galactose under normal circumstances.
    2. Normal individuals.
        1. Lactase (present in the small intestine): metabolizes galactose to glucose and galactose.
        2. The resulting glucose and galactose is then absorbed via the portal system to the liver.
        3. In the liver, a series of four reactions converts galactose to glucose-1-phosphate.
        4. Glucose-1-phosphate can be metabolized to glucose, CO_2, pyruvate, or glycogen depending on prevailing metabolic conditions.
        5. Inborn errors have been described in all of the enzymes of the pathway.
    3. Affected individuals: complete deficiency of the enzyme galactose-1-phosphate uridyl transferase (GALT) causes classic galactosemia.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_101

4. Galactose-1-phosphate uridyl transferase.
    1. Causes the most common and severe form of galactosemia.
    2. The gene for GALT is mapped on chromosome 9p13.
    3. GALT is the second enzyme in the Leloir pathway, catalyzing conversion of galactose-1-phosphate and UDP glucose to UDP galactose and glucose-1-phosphate.
    4. Essential in human infants who consume lactose as their primary carbohydrate source.
    5. Near total absence of GALT activity in infants with classical galactosemia.
    6. A deficiency causes elevated levels of galactose-1-phosphate and galactitol in body tissues.
5. Galactokinase (GALK) deficiency.
    1. The first enzyme in the pathway of galactose metabolism, converting galactose to galactose-1-phospphate
    2. The only consequence of GALK deficiency: development of cataracts
6. Uridine diphosphate (UDP) galactose 4-epimerase (GALE) deficiency (Sutton 2015).
    1. UDP GALE converts UDP galactose to UDP glucose.
    2. In most patients with GALE (or epimerase) deficiency, the defect is localized to red blood cells (RBCs).
    3. These individuals typically have normal growth and development, whereas patients with generalized GALE deficiency in both RBCs and all other tissues present with symptoms similar to classic galactosemia.
7. Endogenous production of galactose may be responsible for the long-term effects, such as cognitive dysfunction and gonadal dysfunction in female patients.
8. Duarte (D) allele (Elsas et al. 1994; Beutler 1991).
    1. Very common
    2. Defined biochemically by:
        1. Reduced enzyme activity
        2. An isoform distinguishable by gel electrophoresis and isoelectric focusing
    3. Heterozygous Duarte variants (D/N)
        1. Observed in about 11% of Caucasian subjects
        2. Have about 75% of normal GALT activity
    4. Infants with a galactosemia allele and a Duarte allele (D/G)
        1. Have 1 quarter (25%) of normal enzyme activity
        2. Have reduced capacity to metabolize galactose with abnormal accumulation of galactose-1-phsphate in the red cells
        3. Phenotypically normal with no ill effect
    5. Homozygotes for the Duarte variant: patients with two Duarte alleles (D/D)
        1. Have approximately one half (50%) of normal transferase activity
        2. Mimic carriers for galactosemia
9. Genotype-phenotype correlations (Ng et al. 1994; Elsas II 2010).
    1. Q188R mutations (prevalent in 70% of Caucasians): a poorer outcome in homozygous state associated with essentially no enzyme activity (Elsas et al. 1995)
    2. Duarte variant (N314D)
        1. Homozygous state (D/D or N314D/N314D) with erythrocyte GALT enzyme activity reduced by only 50%
        2. Compound heterozygotes (D/G or N314D/Q188R)
            1. Relatively benign in most infants
            2. May or may not require dietary intervention
    3. Los Angeles (LA) variant (Langley et al. 1997) with identical N314D missense mutation but has normal erythrocyte GALT activity
    4. S135L allele (Lai et al. 1996; Lai and Elsas 2001)
        1. Prevalent in Africa
        2. The most common allele in African-Americans with classic galactosemia
        3. A good prognosis if therapy is initiated in the neonatal period without neonatal hepatotoxicity and chronic problems

5. K285N allele
    1. Prevalent in Eastern Europeans (Southern Germany, Austria, and Croatia)
    2. A poor prognosis for neurological and cognitive dysfunction in either the homozygous state or compound heterozygous state with Q188R
6. Q188R allele: the most common classic galactosemia allele in Caucasian and Hispanic Americans

Clinical Features

1. Onset of symptoms
    1. May present by the end of the first week of life
    2. May die or develop cataracts, hepatomegaly, cirrhosis, and mental retardation in late-detected cases
2. Neonatal toxicity syndrome
    1. Exposure to dietary galactose in infants with classical galactosemia results in acute deterioration of multiple organ systems, including the following (Berry 2014):
        1. Liver dysfunction
            1. Jaundice
            2. Hepatomegaly
        2. Coagulopathy
        3. Poor feeding and weight loss
        4. Vomiting and diarrhea
        5. Lethargy and hypotonia
        6. Renal tubular dysfunction
        7. Cerebral edema (encephalopathy)
        8. Vitreous hemorrhage
        9. *Escherichia coli* (or other gram-negative) sepsis: consider diagnosis of galactosemia since a high frequency of neonatal death appears to be caused by *E. coli* sepsis (Levy et al. 1977)
    2. Withdrawal of dietary galactose results in reversal of neonatal toxicity syndrome and reducing mortality and morbidity in the early weeks of life.
3. Cataracts (Burke et al. 1989)
    1. Resulting from accumulation of galactitol within the lens
    2. Seen in infants with classical GALT-deficient galactosemia (and also in galactokinase deficiency)
        1. The ocular hallmark of untreated or late-detected patients
        2. Severity of lens involvement dependent on the severity of galactosemia and the age at commencement of therapy
    3. Reoccur in older patients who have poor dietary compliance
    4. May be prevented by dietary restriction of galactose
4. Premature ovarian failure
    1. Despite the high prevalence of premature ovarian failure and subsequent infertility in galactosemic women, spontaneous pregnancies occur and may not be as rare as is generally assumed (Gubbels et al. 2008)
    2. Hypergonadotropic hypogonadism occurring almost universally (>90%) in females with classical GALT deficiency
    3. The rapidity and severity of the ovarian failure vary widely among individuals
    4. Ovarian dysfunction: most likely caused in utero (Holton 1995)
    5. Clinical manifestations
        1. Delayed puberty
        2. Primary amenorrhea
        3. Secondary amenorrhea
        4. Oligomenorrhea
5. Chronic brain effects
    1. Specific deficits
        1. Developmental speech dyspraxia and tremor
        2. Globally decreased IQ and/or learning disability
    2. Uncertainty as to:
        1. Whether these deficits are initiated in early development, perhaps even prenatally, and unmasked, as more complex brain function is required
        2. Whether these deficits represent true neurodegenerative processes compounded by dietary exposure and endogenous production of "intoxicants"
        3. Longitudinal assessment of intellectual achievement in patients with classic galactosemia (Schadewaldt et al. 2010):

1. Confirms the presence of reduced cognitive ability in classical galactosemia
2. Presents evidence for an absence of substantial galactosemia-induced aggravation of this impairment with increasing age, at least in patients from 4 to 40 years of age
3. Remains to be clarified whether a reduction of cognitive function in galactosemia may be initiated by an in utero toxicity of endogenously formed galactose and which role such a process may play in the development of intellectual deficiencies that are later maintained throughout life

6. Prognosis
   1. A life-threatening disorder if untreated.
   2. Currently, affected infants are treated before becoming ill because of newborn screening in most states.
7. Differential diagnosis (Elsas II 2010; Berry 2015)
   1. Galactokinase (GALK) deficiency
      1. An autosomal recessive disorder
      2. Considered in patients with cataracts and galactosemia but otherwise healthy
      3. Cataracts
         1. The main clinical feature
         2. Due to accumulation of galactitol
      4. Pseudotumor cerebri
         1. Described in several cases
         2. Considered to be a true consequence of the disorder
      5. These features resolve when a galactose-restricted diet is introduced
      6. Diagnosis made by detection of reduced galactokinase activity
      7. Caused by mutations in the *GALK1* gene
   2. UDP-galactose 4-epimerase (GALE) deficiency
      1. An autosomal recessive disorder
      2. Considered in patients with liver disease, sensorineural deafness, failure to thrive, and elevated galactose-1-phosphate but normal GALT activity
      3. Response to the removal of galactose from their diets
      4. Diagnosis made by detection of reduced UDP-galactose 4-epimerase activity
      5. Caused by mutations in the *GALE* gene
   3. Neonatal hepatotoxicity
      1. Infectious diseases (sepsis)
      2. Obstructive biliary disease
         1. Progressive familial intrahepatic cholestasis (Byler disease)
         2. Metabolic diseases such as Niemann-Pick disease type C and Wilson disease
   4. Fructose 1-phosphate aldolase deficiency (fructose intolerance) (Roth 2015)
   5. Neonatal hemochromatosis (Bhatia 2015)

Diagnostic Investigations

1. Newborn screening programs in most states (Leslie 2003)
   1. An almost 100% detection of affected infants in states that include testing for galactosemia in their newborn screening programs
   2. Prevention of needless deaths associated with galactosemia, resulting from limiting diagnostic measures to infants who develop symptoms
   3. A positive (i.e., abnormal) screening, followed by a quantitative erythrocyte GALT analysis
2. Liver dysfunction
   1. Bilirubin determination.
      1. Initial unconjugated hyperbilirubinemia
      2. Later conjugated hyperbilirubinemia
   2. Abnormal liver function tests.
   3. Abnormal clotting.
   4. Raised plasma amino acids, particularly phenylalanine, tyrosine, and methionine. Raised phenylalanine may result in a false positive neonatal screening test for phenylketonuria.
3. Renal tubular dysfunction
   1. Metabolic acidosis
   2. Urinalysis

1. Galactosuria
    1. The presence of reducing substances or galactose in the urine is neither sensitive nor specific.
    2. Small quantities of galactose commonly found in the urine of any patient with liver disease.
2. Albuminuria
    1. Present in the initial stage
    2. Quick disappearance of albuminuria after eliminating lactose-containing formula from the diet
3. Aminoaciduria in the later stage

4. Abnormal carbohydrate metabolism
    1. Increased plasma galactose
    2. Increased red cell galactose-1-phosphate
    3. Increased urine and blood galactitol
5. Testing for hemolytic anemia
6. Study for septicemia, especially *Escherichia coli*
7. Slit lamp examination for cataract assessment
8. Computerized tomography and magnetic resonance imaging (Nelson et al. 1992)
    1. Abnormalities on brain imaging: common in classical galactosemia
    2. Patients with late neurologic disease
        1. Abnormal white matter
        2. Ventricular enlargement
        3. Diffuse cortical atrophy with basal ganglia and brainstem involvement
        4. Cerebellar atrophy
        5. Failure of normal myelination
9. Endocrine investigations for hypergonadotropic hypogonadism
    1. Raised follicle-stimulating hormone
    2. Raised luteinizing hormone
    3. Initially normal estradiol concentration with high gonadotropin levels, indicating continued follicular development, but fall as ovarian failure progresses
10. Increased urinary galactitol excretion
11. Beutler test
    1. A fluorescent spot test for galactose-1-phosphate uridyl transferase activity
    2. Now widely used for the diagnosis of galactosemia
    3. False negative resulting from recent blood transfusions (within 3 months)
    4. False positive resulting from glucose-6-phosphate dehydrogenase deficiency
12. Red blood cell galactose-1-phosphate
    1. Concentration always raised in classical galactosemia
    2. Not significantly affected by blood transfusions
13. Biochemical confirmation of the diagnosis
    1. Red blood cell galactose-1-phosphate uridyl transferase assay
        1. A quantitative assay to confirm the diagnosis (virtual absence of the enzyme activity in classical (G/G) galactosemia)
        2. Also identifies variants with residual enzyme activity
        3. False negative results due to blood transfusion within 3 months
    2. A GALT isoelectric-focusing electrophoresis test to distinguish variant forms such as the Duarte defect
14. DNA analysis: *GALT* genotyping for providing specific molecular diagnosis
    1. Classic (G/G) galactosemia
        1. Mutation analysis for the six common *GALT* galactosemia (G) mutations
            1. Q188R mutation: the most common *GALT* allele in whites
            2. S135L: the most common allele in blacks
            3. K285N
            4. L195P
            5. Y209C
            6. F171S
        2. *GALT* sequence analysis to detect private mutations under the following two conditions:
            1. Both disease-causing mutations not detected by mutation analysis
            2. Diagnosis of galactosemia confirmed by biochemical testing
    2. Mutation analysis for Duarte variant (D/G) galactosemia identified by biochemical testing of the patient and both parents
        1. Identification of Duarte allele (N314D) by mutation analysis

2. Identification of G allele by mutation analysis or sequence analysis

15. Carrier testing
    1. Measuring GALT activity: about 50% of control values in carriers
    2. Molecular genetic testing for carriers available to family members, provided *GALT* mutation(s) has/have been identified in the proband

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. A proband with G/G galactosemia
            1. Given the parents are G/N and G/N: a 25% chance of being affected with G/G galactosemia for each sib
            2. Given the parents are D/G and G/N: a 25% chance of being affected with G/G galactosemia and a 25% chance of being affected with D/G galactosemia for each sib
        2. A proband with D/G galactosemia, given the parents are D/N and G/N: a 25% chance of being affected with D/G galactosemia for each sib
    2. Patient's offspring:
        1. Patient with G/G galactosemia and the normal spouse with N/N: All offspring are carriers.
        2. Patient with G/G galactosemia and the carrier spouse for a G allele (N/G): a 50% chance of having G/G galactosemia.
        3. Patient with G/G galactosemia and the carrier spouse for a G allele (D/G): a 50% chance of having G/G galactosemia and a 50% chance of having D/G galactosemia.
2. Prenatal diagnosis possible for fetuses at a 25% risk for classical galactosemia (Jakobs et al. 1995; Elsas 2001)
    1. Galactose-1-phosphate uridyl transferase assay in cultured amniotic fluid cells or in chorionic villus biopsies.
    2. Galactitol estimation in amniotic fluid supernatant.
    3. Mutation analysis of DNA extracted from amniocytes or chorionic villus samples if the genotype of the index case has been characterized.
    4. Prenatal diagnosis of a treatable condition, such as classic galactosemia, may be controversial if the prenatal testing is being considered for the purpose of pregnancy termination rather than early diagnosis.
    5. Preimplantation genetic diagnosis: may be available for families in which the disease-causing mutations have been identified.
3. Management (Arn 2003; Elsas II 2010)
    1. Availability of the newborn screening results within the fifth day after birth would allow the prevention of acute decompensation in classic galactosemia. A systematic diagnostic work-up in all positive newborns is essential to unravel the etiology of hypergalactosemia (Porta et al. 2015).
    2. Dietary intervention.
        1. Lactose-galactose-restricted diet
            1. Restrict milk, the principal source of lactose, and products made from milk.
            2. Breast milk and cows' milk contraindicated.
        2. Milk substitutes
            1. Use a formula free of bioavailable lactose (e.g., Isomil or Prosobee)
            2. Casein hydrolysate (Alimentum, Nutramigen, and Pregestimil): not recommended because they contain small amounts of bioavailable lactose
        3. Difficult to totally eliminate galactose since it is present in a wide variety of food, such as infant foods, fruits, and vegetables
        4. Older patients tolerating lactose much better than children, but recommend restricted milk intake throughout life

5. Calcium supplements if calcium intake does not meet the recommended daily allowance
6. May prevent cataracts, hepatomegaly, liver cirrhosis, mental retardation, and other symptoms
7. Effect of dietary restrictions during pregnancy on the long-term complications of an affected fetus: unknown
8. Individuals with homozygous Duarte variant without symptoms: do not require treatment (Ficicioglu et al. 2008)
9. Management of D/G or N344D/Q188R compound heterozygotes
    1. Decision to treat should be based on the demonstration of abnormal biochemical indices.
    2. No dietary therapy is instituted if the blood galactose and/or galactose-1-phosphate do not rise above 12 mg/dL within 4 h following such ingestion, and there are no clinical signs associated with galactosemia.
    3. Dietary therapy should probably be given if there is a greater accumulation of galactose or of galactose-1-phosphate.
    4. There is possible benefit of dietary intervention to individuals with variant forms of galactosemia with residual GALT activity in the range of 5–20: for prevention of cataracts, ataxia, dyspraxic speech, and cognitive deficits.

3. Vitamin K and fresh-frozen plasma to correct clotting abnormalities.
4. Pharmacologic treatment.
    1. An appropriate intravenous antibiotic for gram-negative sepsis.
    2. Many medications, particularly tablets, contain lactose, and this should be considered when prescribing; however, the amount of galactose is often insignificant when given over a short period.
5. Treat unconjugated hyperbilirubinemia with phototherapy or exchange transfusion to infants who may be at an increased risk of kernicterus if albumin levels are particularly low secondary to liver disease.
6. Parental feeding if the infant is too sick to tolerate enteral feeding for more than 1 or 2 days, unless there is significant liver disease or thrombocytopenia.
7. Treat the following long-term problems in older children and adults with classical galactosemia, despite early and adequate therapy.
    1. Cataracts
    2. Speech defects
    3. Poor growth
    4. Poor intellectual function
    5. Neurological deficits, predominantly extrapyramidal findings with ataxia
    6. Ovarian failure
8. Physical/speech therapy.
    1. Speech therapy for speech delay or verbal dyspraxia (Nelson 1995)
    2. Regular assessment of development and cognitive function using standardized tests recommended (Walter et al. 1999)
9. Other therapies/evaluations.
    1. Monitoring of red cell galactose-1-phosphate available for assessing dietary compliance; despite dietary adherence, these levels never decline to normal.
    2. Ophthalmologic examination for cataract assessment to be made at the time of diagnosis, every 6 months until age 3 years, and then annually (Walter et al. 1999).
    3. Referral to a pediatric endocrinologist by the time a female patient is 10 years (Walter et al. 1999).
10. Emerging therapies.
    1. None with trial data.
    2. Environment, GALT genotype, and epigenetic pathway of galactose metabolism probably all contribute to outcome.

3. In the absence of new therapies emerging from pathogenetic studies, attempts to enhance GALT activities may prove of value (Holton 1996; Elsas and Lai 1998) .

Fig. 1 A 5-year-old boy with classical galactosemia. The initial clinical presentation was at 12 days of age with unconjugated hyperbilirubinemia, presence of reducing substance in the urine, and *E. coli* sepsis. The patient was found to have posterior stellate lens opacities OU. He was found to have deficient galactose-1-phosphate uridyl transferase activity of 0.3 (normal range: 17–37 UMOL/HR/G HGB). Galactokinase was within normal limits. The patient was put on galactose-free diet and has been growing well

Fig. 2 A 2-month-old girl with D/G compound heterozygote. The newborn screening revealed total blood galactose (Gal + Gal-1-phosphate) level of 33.4 mg/dL (normal, <15.0) and blood galactose (without Gal-1-phosphate) level of 3.7 mg/dL. Enzyme assay for uridyl transferase was 41.3 μm (normal, >40.0). DNA analysis showed one copy of the N314D (Duarte galactosemia) variant and one copy of the Q188R (classical galactosemia) mutation. The patient is currently on Isomil and growing well

Gastroschisis

Contents

Gastroschisis (Greek for belly cleft) is a congenital paraumbilical wall defect characterized by the protrusion of the intestines uncovered by the peritoneum. It represents one of the most common congenital malformations requiring multidisciplinary neonatal intensive care, with an incidence of approximately 1 in 3300 births that seems to be increasing (Alvarez and Burd 2007).

Synonyms and Related Disorders

Anterior abdominal wall defects (Bladder exstrophy; Cloacal exstrophy; Limb–body wall and body-wall complex; Omphalocele)

Genetics/Basic Defects

1. Precise etiology unknown
2. Inheritance
    1. Isolated occurrence in most cases (Calzolari et al. 1995)
    2. Rare autosomal dominant inheritance
3. Pathogenesis and risk factors Sharp et al. (2000); Fillingham and Rankin 2008; Lammer et al. 2008; Rasmussen and Frias 2008)
    1. Pathogenesis
        1. Most commonly quoted: Hoyme's vascular disruption theory with disruption occurring in the omphalomesenteric artery (Hoyme et al. 1983)
        2. More recent proposed pathogenesis
            1. Consequence of abnormal folding of the body wall (Feldkamp et al. 2007).
            2. Disruption of endothelial oxide synthase pathway (its relationship to vasculogenesis) by environmental exposures or by genetic variation may represent one pathogenetic model for gastroschisis (Lammer et al. 2008).
    2. Risk factors (Torfs et al. 1994)
        1. Vascular insult
            1. Association of maternal smoking and maternal cocaine use with an increased incidence of gastroschisis
            2. The association of intestinal atresia and gastroschisis (Luck et al. 1985)
        2. Premature atrophy or abnormal persistence of the right umbilical vein
        3. In utero rupture of a hernia of the umbilical cord

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_102

4. Young maternal age (<20 years of age) (Baer et al. 2015): the most striking epidemiological association with gastroschisis (20–25%)
5. Primiparous mothers
6. Socially disadvantaged mothers
7. Use of vasoactive drugs (e.g., decongestant pseudoephedrine) early in pregnancy
8. Use of aspirin and decongestants
9. Recreational (illicit) drug use (particularly the use of more than one drug)
10. Low socioeconomic status
11. Maternal nutrition
12. Living in close proximity to landfill sites
13. Other novel risk factors
    1. Prior history of gynecological infection/disease
    2. Change of paternity
    3. Paternal age

4. Rare syndrome association
   1. Omphalocele-exstrophy-imperforate anus-spinal defects (OEIS)
   2. Amniotic band syndrome
   3. Limb–body wall complex
5. Rare association with chromosome abnormalities
   1. Trisomy 21
   2. Trisomy 13

Clinical Features

1. Herniation of abdominal contents
   1. Through a small abdominal wall defect
      1. Lateral to the insertion of the umbilical cord
      2. Most often to the right side of the umbilical cord
   2. Without covering sac
   3. The herniated viscera floating freely in the amniotic cavity
   4. Rare extrusion of the liver
   5. Dilatation of bowel loops due to partial lymphatic and venous obstruction when they are mechanically compressed against the sidewall of the defect
   6. Massive dilatation of the bowel secondary to volvulus, atresia, and ischemia
2. The incidence of associated anomalies relatively infrequent except associated gastrointestinal anomalies (10–20%)
   1. Intestinal stenosis/atresia, often related to:
      1. Intrauterine volvulus
      2. Strangulation of the blood supply to the extruded segment of intestine at the extremely tight abdominal wall defect
   2. Adhesions
   3. Malabsorption
   4. Meckel diverticulum
   5. Protein-losing enteropathy
   6. Midgut volvulus
   7. Necrosis
   8. Severe short gut syndrome
   9. Hypoperistalsis
3. Prognosis and complications
   1. Oligohydramnios
      1. Associated with a high incidence of intrauterine growth retardation which occurs in up to 60% of affected fetuses
      2. Possible secondary effects of severe oligohydramnios
         1. Pulmonary hypoplasia
         2. Limb compression
         3. Cord compression
   2. Polyhydramnios probably associated with reduced bowel motility or bowel obstruction
   3. Fetal distress during labor
   4. IUGR (Fries et al. 1993)
   5. Small for gestational age (Chescheir et al. 1991)
   6. Prematurity
   7. Sepsis
   8. Bowel damage
   9. Cardiac anomalies
   10. Nongastrointestinal-associated anomalies including occasional occurrence of amyoplasia and arthrogryposis
   11. Problems with absorptive and motility functions
   12. Intraoperative complications

13. Greater than 90% survival rate (Baerg et al. 2003)
14. Higher mortality rate (50%) associated with herniation of the liver
15. Rare reports of spontaneous resolution of gastroschisis and closure of the anterior abdominal wall defect (Tawil et al. 2001)

4. Intrauterine fetal death rate: 10–15% (Brantberg et al. 2004)
5. Outcomes in neonates with gastroschisis in US children's hospitals (Lao et al. 2010)
    1. Critical comorbidities and procedures
        1. Cardiovascular defects (15%)
        2. Pulmonary conditions (5%)
        3. Intestinal atresia (11%)
        4. Intestinal resection (12.5%)
        5. Ostomy formation (8.3%)
    2. Factors associated with mortality
        1. Large bowel resection (odds ratio 8.26)
        2. Congenital circulatory disease (odds ratio 5.62)
        3. Pulmonary disease (odds ratio 8.22)
        4. Sepsis (odds ratio 3.87)
    3. Factors associated with sepsis
        1. Intestinal ostomy (odds ratio 2.94)
        2. Respiratory failure (odds ratio 2.48)
        3. Congenital circulatory anomalies (odds ratio 1.58)
        4. Necrotizing enterocolitis (odds ratio 4.38)
6. Differential diagnosis (Nichol et al. 2008)
    1. Omphalocele
        1. Characterized by its involvement of the cord insertion and surrounding membrane.
        2. The distinction is important given the higher risk for chromosomal and other anomalies in omphalocele.
        3. The rare finding of a ruptured omphalocele may be very difficult to distinguish from a gastroschisis in utero (Bair et al. 1986).
        4. Characteristics of omphalocele (Christison-Lagay et al. 2011)
            1. Sac: present
            2. Associated anomalies: common
            3. Location of defect: umbilicus
            4. Maternal age: average
            5. Mode of delivery: cesarean/vaginal
            6. Surgical management: not urgent
            7. Prognostic factors: associated anomalies
        5. Characteristics of gastroschisis (Christison-Lagay et al. 2011)
            1. Sac: absent
            2. Associated anomalies: uncommon
            3. Location of defect: right of the umbilicus
            4. Maternal age: younger
            5. Mode of delivery: vaginal
            6. Surgical management: urgent
            7. Prognostic factors: condition of the bowel
    2. Limb–body wall and body-wall complex
        1. Both may involve defects of the ventral body wall, often large and asymmetric, and often involving multiple organs including the liver.
        2. The lack of a free-floating umbilical cord and scoliosis, with or without limb defects, will suggest this diagnosis.
    3. Amniotic band syndrome
        1. Amniotic band syndrome is often difficult to distinguish from body-wall complex.
        2. Frequently, will also involve severe anomalies of the craniofacial area.
        3. Like limb–body wall complex, may involve adhesion to the placenta.
    4. Bladder exstrophy (Glasser 2015; Khan 2015)
        1. May present as an external, well-defined, solid or complex mass immediately superior to the fetal genitalia sonographically
        2. Prolonged and repeated scans fail to reveal the fetal bladder.
        3. The renal collecting system and ureters need not be dilated and unilateral or horseshoe kidneys may be found.
        4. Uterine and adnexal anomalies are relatively frequent.
        5. The pubis is abnormally wide.
        6. Umbilical cord insertion may be abnormal.

5. Cloacal exstrophy (Glasser 2015; Khan 2015)
    1. Consists of a low omphalocele, bladder or cloacal exstrophy, and, frequently, other caudal anomalies, including meningomyelocele anal atresia and lower limb anomalies
    2. A single umbilical artery in most affected fetuses
    3. Sonographic findings include a low anterior abdominal mass below the umbilical cord that is associated with an absent urinary bladder.

Diagnostic Investigations

1. Routine blood work
2. Chromosome analysis rarely indicated (incidence of chromosomal anomalies <5%)
3. Abdominal radiography
4. Abdominal ultrasound
5. Gastrointestinal investigations to rule out gastroesophageal reflux, abnormal intestinal absorption and motility, and Hirschsprung disease
6. Echocardiography

Genetic Counseling

1. Recurrence risk
    1. Patient's sib: The sibling recurrence risk is estimated to be 3.5% (familial occurrence of gastroschisis has been reported) (Torfs and Curry 1993) unless a parent is affected with an autosomal dominant disorder.
    2. Patient's offspring: The offspring recurrence risk is not increased unless the patient is affected with an autosomal dominant disorder.
2. Prenatal diagnosis
    1. Elevated maternal serum alpha-fetoprotein (MSAFP): MSAFP levels are greater in gastroschisis than in omphalocele (Palomski et al. 1988)
    2. Prenatal ultrasonography
        1. 2D ultrasonography followed by 3D ultrasonography can be useful for more-efficient counseling and postnatal therapeutic planning (Bonilla-Musoles et al. 2001)
        2. Demonstration of a mass adjacent to the anterior ventral wall representing the herniated viscera
        3. Herniation almost always exits through the right rather than the left lower quadrant.
        4. Cord vessels observed to the left of the exiting bowel
        5. Dilated bowel loops within or outside the abdomen observed when the abdominal wall defect is small
        6. Possible evisceration of stomach
        7. Possible evisceration of the urinary bladder with secondary hydronephrosis
        8. Polyhydramnios associated with bowel obstruction
        9. Gastroschisis can be prenatally diagnosed at 1st trimester (Cerekja et al. 2012)
    3. Amniocentesis
        1. Elevated amniotic fluid alpha-fetoprotein
        2. Positive acetylcholinesterase in gastroschisis but not omphalocele (Saleh et al. 1993)
        3. Chromosome analysis
3. Management (Langer et al. 1987)
    1. Counseling of parents (Hunter and Soothill 2002)
        1. Inform 5–10% incidence of fetal or neonatal death
        2. Inform long-term digestion problems associated with short gut syndrome
    2. No clear evidence indicating early cesarean section improves the outcome (Kirk and Wah 1983; Stringer et al. 1994; Segel et al. 2001)
    3. Requires multidisciplinary NICU care (Mills et al. 2010)
        1. Despite a high probability of survival (long-term survival rate over 85%) (Weber et al. 2002), gastroschisis babies and their families face a

prolonged hospitalization with the potential for significant long-term morbidity, especially that related to impaired capacity for enteral nutrition leading to cholestatic liver disease
    2. Potential need for organ transplantation
4. Endotracheal intubation for respiratory distress in neonates
5. Avoid hypothermia, hypovolemia, and sepsis
6. Fluid and electrolyte balance to prevent metabolic acidosis commonly observed as a result of poor perfusion related to hypovolemia
7. Insertion of an orogastric tube
    1. To prevent air swallowing
    2. To aspirate intestinal contents
8. Parenteral antibiotics
9. Surgical repair: primary repair versus staged repair with silastic silo
10. Total parenteral nutritional support for prolonged adynamic ileus (Baerg et al. 2003)
11. Potential need for organ transplantation (Mian et al. 2008)
12. Risks of prematurity must be weighed against the potential advantages of preterm delivery for infants with gastroschisis (Langer et al. 1993)
13. Early delivery is associated with prolonged enteral feeds/length of hospital stay, suggesting elective delivery at <37 weeks is not beneficial (Carnaghan et al. 2014).
14. Prenatal repair of gastroschisis (Luo et al. 2015)
    1. The ex utero intrapartum treatment procedure: performed to ensure fetal oxygen supply, which was likely to be compromised by the deep fetal anesthesia.
    2. The gastroschisis can be successfully repaired before the neonate is delivered.
    3. Maternal hemodynamics can be kept stable during this surgical procedure.
    4. The prenatal repair of abdominal wall defect is safe for the mother and the fetus, which could potentially improve the neonatal outcomes.

Fig. 1 A premature neonate had herniation of gastric antrum, small intestine, and colon through the gastroschisis, right of intact umbilicus. There was malrotation of the intestine

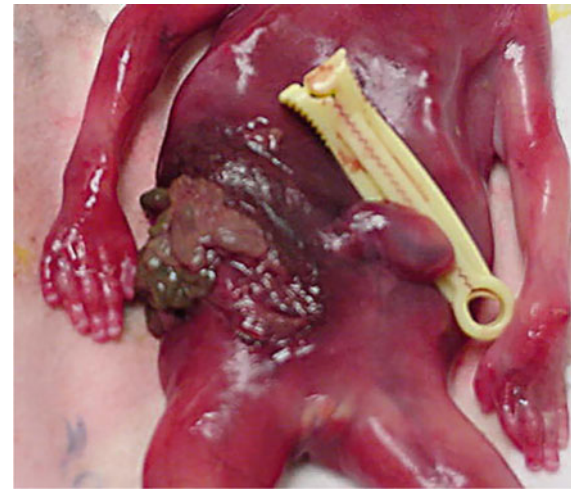

Fig. 2 A stillborn with gastroschisis showing herniation of abdominal contents

Gaucher Disease

Contents

Gaucher disease is the most common lysosomal storage disease and the most common genetic disorder among Ashkenazi Jews (Desnick 1982a, b). The disease incidence in the Ashkenazi population in Israel is 1 in 7750 to 1 in 10,000. The disease frequency in the Caucasian population is approximately 1 in 50,000 live births (Grabowski 2000).

Synonyms and Related Disorders

Acid beta-glucocerebrosidase deficiency; Gaucher disease type 1 (nonneuropathic type); Gaucher disease type 2 (acute neuropathic type); Gaucher disease type 3 (chronic neuropathic type); Gaucher disease type 4 (cardiovascular type); Glucocerebrosidase deficiency; Perinatal lethal Gaucher disease (collodion type)

Genetics/Basic Defects

1. Inheritance
   1. Autosomal recessive
   2. The gene encoding β-glucocerebrosidase (acid β-glucosidase) mapped to 1q21
2. Caused by mutation in the glucocerebrosidase (*GBA*) gene that results in deficiency of β-glucocerebrosidase activity
   1. Over 200 different mutations reported
   2. Four common mutations (N370S, L444P, 84GG, IVS2 + 1) (Grabowski 1997; Sibille et al. 1993; Charrow et al. 2000)
      1. Account for about 90% of the disease-causing alleles in the Ashkenazi Jewish population
      2. Account for 50–60% of the disease-causing alleles in the non-Jewish population
      3. Presence of the common N370S precludes neuronopathic involvement, also in combination with severe L444P.
   3. Other rare mutations and unique mutations: worldwide differences in genetic mutations.
   4. Genetic heterogeneity results in phenotypic heterogeneity: phenotypic presentation of the same mutation may vary in a wide spectrum: this difference is most possibly related with ethnicity, genetic background, and environmental and nutritional factors (Harmanci and Bayraktar 2008).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_103

5. Gaucher disease: a prototype of molecular medicine (Grabowski et al. 1996)

3. Consequences of deficient β-glucocerebrosidase activity (Charrow et al. 1998)
   1. Accumulation of glucocerebroside in the lysosomes of monocyte-derived macrophages in the reticuloendothelial system.
   2. Resulting hypersplenism produces progressive anemia and thrombocytopenia.
   3. Accumulation of glucocerebroside in bone marrow resulting in:
      1. Osteopenia
      2. Lytic bone lesions
      3. Pathologic fractures
      4. Chronic bone pain
      5. Acute episodes of excruciating "bone crisis"
      6. Bone infarct
      7. Osteonecrosis

Clinical Features

1. Notable for marked phenotypic variability/heterogeneity (Balicki and Beutler 1995; Mistry et al. 2015)
2. Type 1 (nonneuronopathic type) (GD1) (Nagral 2014; Thomas et al. 2014; Dandana et al. 2016)
   1. Absence of neurologic involvement
   2. Young adults/adults or chronic form: the most common form
   3. Representing about 85% of cases with Gaucher disease
   4. Most common in Ashkenazi Jewish population (1 in 450)
   5. 1 in 100,000 in general population
   6. Glucocerebrosidase activity: some activity but much less than normal
   7. Wide range of age of onset and rate of progression
      1. Ranging from disability in toddlers to asymptomatic disease in octogenarians
      2. The mean age at diagnosis: 21 years
   8. Skeletal involvement (Charrow et al. 1998)
      1. Clinical or radiographic evidence of bone disease in 70–100% of patients with type 1 Gaucher disease.
      2. May be the most debilitating and disabling aspect of type 1 Gaucher disease, leading to:
         1. Bone marrow infiltration by Gaucher cells
         2. Failure of remodeling
         3. Osteopenia
         4. Focal lytic or sclerotic lesions
         5. Osteonecrosis (Pastores et al. 2000)
         6. Osteomyelitis and bone crisis
         7. Chronic bone pain
         8. Pathologic fractures
   9. Hepatosplenomegaly
      1. Enlarged spleen with resultant hypersplenism associated with pancytopenia.
      2. Infarction of the spleen resulting in acute abdominal pain.
      3. Rare acute surgical emergencies because of splenic rupture.
      4. Hepatomegaly common but cirrhosis and hepatic failure rare.
   10. Pancytopenia
      1. Anemia secondary to the following cause:
         1. Hemolysis secondary to hypersplenism
         2. Hemodilution such as pregnancy
         3. Splenic sequestration
         4. Depressed erythropoiesis due to bone marrow failure from Gaucher cell infiltration or medullary infarction (in advanced cases, particularly postsplenectomy)
      2. Leukopenia
         1. Commonly noted
         2. Rarely severe enough to contribute to recurrent infections
         3. Risk of infection compounded by chemotactic defects in leukopenic patients
      3. Thrombocytopenia
         1. Resulting from hypersplenism, splenic pooling of platelets, or

marrow infiltration of Gaucher cells or infarction.
2. Associated with easy bruising or overt bleeding, particularly with trauma, surgery, or pregnancy.
3. The risk of bleeding increases when there are concomitant clotting abnormalities.

11. Pulmonary disease
    1. Interstitial lung disease
    2. Alveolar/lobar consolidation
    3. Pulmonary hypertension
    4. Hepatopulmonary syndrome
        1. Dyspnea
        2. Cyanosis with digital clubbing
        3. Liver dysfunction
12. Cholelithiasis in adult patients (32%)
13. Cardiac and renal complications rarely encountered
14. Neurological complications secondary to bone disease
    1. Severe osteopenia with vertebral compression
    2. Emboli following long bone fracture
    3. Coagulopathy secondary to hematomyelia
    4. Parkinsonian features in a few patients: uncertain cause-and-effect relationship or just a coincidence
15. Absence of primary central nervous system disease
16. Ocular signs: absent
17. Increased risk of myeloma
18. Life span with or without therapy: early childhood to late adulthood
19. Therapeutic options
    1. Respond to ERT: good
    2. Substrate reduction therapy
    3. Orthopedic interventions
    4. Consider bisphosphonates for osteopenia

3. Type 2 (acute neuronopathic type) (GD2) (Sidransky et al. 1996; Sidransky 1997; Tayebi et al. 1999; Nagral 2014; Thomas et al. 2014; Weiss et al. 2015; Dandana et al. 2016)
    1. Infantile form: the rarest and most severe form of the disease
    2. No particular ethnicity
    3. Incidence: 1 in 100,000 live births
    4. Representing about 10% of cases with Gaucher disease
    5. Glucocerebrosidase activity: very little activity
    6. Early nervous system problems
    7. Onset before age 2 years, mostly symptomatic by age 6 months
    8. Normal at birth
    9. Development of hepatosplenomegaly
    10. Regression of developmental milestones
    11. Arrest of growth
    12. Brainstem abnormalities
        1. Bulbar signs
            1. Stridor
            2. Squint
            3. Swallowing difficulty
        2. Pyramidal signs
            1. Opisthotonus
            2. Head retroflexion
            3. Spasticity
            4. Trismus
    13. Oculomotor abnormalities
        1. Oculomotor apraxia
        2. Saccadic initiation failure
        3. Opticokinetic nystagmus
        4. Strabismus
    14. Other organ involvement:
        1. Nonimmune hydrops fetalis
        2. Congenital ichthyosis
        3. Life span with or without therapy: less than 2 years
    15. Therapeutic options
        1. Response to ERT: poor, not indicated
        2. No disease-specific therapy
        3. Palliative
    16. Collodion baby phenotype (congenital ichthyosis) in some neonates (Tayebi et al. 1999; Stone et al. 2000)
    17. Perinatal lethal Gaucher disease: a subset of type 2 or a specific clinical entity (Tayebi et al. 1999; Mignot et al. 2003)
        1. Lethality of a homozygous null mutation reported (Tayebi et al. 1999;
        2. Nonneurological involvement
            1. Nonimmune hydrops fetalis
            2. Prematurity

3. Fetal demise or death usually occurring within 2 days to 3 months
4. Hepatosplenomegaly (92%)
5. Thrombocytopenia (38%) associated with purpura (22%)
6. Anemia (10%)
7. Neonatal ichthyosis/collodion baby phenotype (41%)
8. Bone marrow invasion by Gaucher cells, a constant finding at autopsy

3. Neurological involvement
   1. Neurologic signs overlapping with classical type 2 Gaucher disease.
   2. Hypokinesia (43%) with facial dysmorphology.
   3. Contractures of distal joints (club foot, camptodactyly) (30%).

18. Universally progressive and fatal, succumb to apnea or aspiration by age 2–4 years

4. Type 3 (chronic neuronopathic type) (GD3) (Nagral 2014; Thomas et al. 2014; Dandana et al. 2016)
   1. Juvenile form: presenting in childhood or early adulthood
   2. No particular ethnicity: observed primarily in a cluster of cases from Sweden (Norrbottenian type) but may occur in other ethnic groups
   3. Glucocerebrosidase activity: little activity
   4. Hepatosplenomegaly
   5. Anemia
   6. Thrombocytopenia
   7. Bony involvement
   8. Kyphosis (Gibbus)
   9. Growth retardation
   10. Pulmonary infiltrates and esophageal varices associated with liver cirrhosis
   11. Neurologic disease (later onset): neurologic manifestation less severe compared to type 2
      1. Oculomotor apraxia: frequently the only neurologic finding (Bohlega et al. 2000))
      2. Supranuclear (horizontal) gaze palsy
      3. Seizures in some patients
         1. Generalized tonic-clonic seizures
         2. Progressive myoclonic epilepsy
      4. Advanced stage
         1. Dementia
         2. Ataxia
   12. Extensive vascular and valvular involvement (calcifications): reported in type 3 Gaucher disease (Altunbas et al. 2015)
   13. Lifespan extending into the third to fourth decade
   14. Therapeutic options
      1. Response to ERT: variable
      2. Bone marrow transplantation (considered in some patients)

5. Type 4 (cardiovascular type) (GD4)
   1. Calcification of the aortic and mitral valves
   2. Mild splenomegaly
   3. Corneal opacities
   4. Supranuclear ophthalmoplegia

6. B-cell neoplasia (including multiple myeloma) and Parkinson's disease: divergent but true comorbidities of Gaucher disease (Cox et al. 2015; Huang et al. 2015)

Diagnostic Investigations

1. General clinical laboratory blood tests (Charrow et al. 1998)
   1. Hemoglobin concentration for anemia.
   2. Platelet count for thrombocytopenia.
   3. Liver enzymes for liver disease.
   4. Iron, ferritin, and total iron-binding capacity for coexistent iron deficiency or iron overload.
   5. Prothrombin time and activated partial thromboplastin time for:
      1. Clotting defects associated with liver disease
      2. Factors IX and Factor X deficiency with Gaucher disease
      3. Factor XI deficiency that may cosegregate with Gaucher disease among Ashkenazi Jewish population
   6. Alkaline phosphatase, serum calcium, phosphorous, and 24-h urinary calcium for markers of bone involvement and defects in calcium absorption and metabolism.
   7. Total and direct bilirubin, and total protein and albumin for monitoring liver function.

8. Serum protein electrophoresis and serum immunoelectrophoresis for detecting monoclonal gammopathies that may be more common in adult patients with Gaucher disease than in the general population.
9. Plasma chitotriosidase (markedly elevated in plasma).

2. Abdominal ultrasound
   1. Assessing organ volume and parenchymal abnormalities
   2. Gallstone detection
3. Brainstem auditory evoked response (BAER) for abnormal wave form in type 2 and type 3
4. Bone densitometry for quantitative assessment of osteopenia
5. Radiography (Grabowski et al. 1998; Wenstrup et al. 2002; Marcucci et al. 2014; Simpson et al. 2014; Masi and Brandi 2015)
   1. Erlenmeyer flask deformity
      1. Common but not pathognomonic finding.
      2. Deformity resulting from the impairment of remodeling of the metaphyseal region of tubular bones.
      3. Manifesting as a flaring of the distal lateral aspects of the femur and proximal tibia.
   2. Bone crises
      1. Most common in childhood and adolescence presenting as episodes of severe bone pain associated with fever and leucocytosis.
      2. The signs and symptoms are indistinguishable from osteomyelitis; however, no infection exists.
      3. The terms "pseudo-osteomyelitis" and "aseptic osteomyelitis" have been historically used to characterize this condition.
   3. Lytic bone lesions
   4. Osteosclerosis due to aberrant remodeling after bone infarction with deposition of calcium
   5. Generalized osteopenia: decreased bone density
      1. Nearly universal in children and adults with Gaucher disease
      2. Associated with increased risk of bone fractures
   6. Osteonecrosis (avascular necrosis)
      1. Believed to be secondary to chronic infarction.
      2. Affecting primarily the femoral head, proximal humerus, and vertebral bodies.
      3. Resulting in fracture and joint collapse.
   7. Cortical thinning
   8. Fractures
   9. Bone marrow infiltration
   10. Rarely acute osteomyelitis
   11. Growth retardation
6. MRI
   1. Extent of marrow involvement (Maas et al. 2002)
   2. Fibrosis and/or infarction
   3. Cerebral atrophy
7. Proton magnet resonance spectroscopy of the brain in children (Khalek et al. 2013): a noninvasive technique (Pastores 2010) that can be used to detect brain abnormalities in neuronopathic Gaucher disease (NGD), and the choline/creatine ratio can be considered a biomarker of NGD as it is well correlated with clinical types, modified severity scoring tool and genotyping
8. Bone marrow aspiration (Pastores and Hughes 2015)
   1. Presence of lipid-engorged macrophages ("Gaucher cells").
      1. Fibrillary, "crumpled silk" appearance to the cytoplasm.
      2. Eccentrically placed nucleus.
      3. Stained positively with periodic acid-Schiff (PAS) reagent.
   2. Not a mandatory test since the bone marrow findings are nonspecific changes and not reliable.
9. Assay of acid β-glucocerebrosidase enzyme activity in peripheral blood leukocytes, lymphoblasts, cultured fibroblasts, amniocytes, and chorionic villi samples (Pastores and Hughes 2015)
   1. The most efficient and confirmatory diagnostic test
   2. Affected individuals: 0–15% of normal activity

3. Individuals with type 1 Gaucher disease: 10–15% of normal activity
4. Individuals with type 2 Gaucher disease: ≤10% of normal value
5. Unreliable for carrier detection since the values overlap in carriers and noncarriers

10. Molecular diagnosis (Nagral 2014)
    1. Mutation analysis confirms the diagnosis and can prognosticate the natural course of the disease.
    2. Patients with mutations secondary to N370S substitution do not develop neurological disease15 and those with homozygosity or compound heterozygosity for L444P or D409H mutation are usually associated with neurological disease.
    3. The D409H allele is also associated with cardiovascular and corneal involvement.
11. Molecular genetic testing to identify two disease-causing alleles providing additional confirmation of the diagnosis (Pastores and Hughes 2015)
    1. Targeted mutation analysis
    2. Sequence analysis

Genetic Counseling

1. Recurrence risk (Pastores and Hughes 2015)
    1. Patient's parents
        1. Heterozygotes (carrying a single copy of a disease-causing mutation in the *GBA* gene) in most instances
        2. Asymptomatic
        3. A homozygous parent possible.
            1. High carrier frequency in certain population (approximately 1 in 18 in Ashkenazi Jews population)
            2. Variable phenotype with the N370S/N370S genotype
    2. Patient's sib
        1. 25% affected, given the parents are carriers.
        2. 50% affected when one of the parents is a homozygote and the other a heterozygote.
    3. Patient's offspring
        1. When the spouse is not a carrier: all offspring obligate heterozygotes.
        2. When the spouse is a carrier: 50% of offspring affected and 50% of offspring carriers.
    4. GD carrier screening (Falcone et al. 2012)
        1. Offered at a high rate within the scope of Jewish ancestry-based carrier screening
        2. Genetic counseling dilemma
            1. Possible difficulty of having to make a decision on whether to pursue prenatal diagnosis and possible termination for a condition with reduced penetrance, variable severity, and effective treatment
            2. Carrier screening for GD may reveal that an individual has a mild or asymptomatic form of GD.
    5. Genetic counseling (Weiss et al. 2015)
        1. Families need to be educated about risks and alternatives relevant to future family planning, including prenatal diagnosis, preimplantation diagnosis, sperm or egg donation, as well as adoption.
        2. Unusual mechanisms including uniparental disomy for chromosome 1 and germline or de novo mutations have been described in patients with GD (Saranjam et al. 2013; Benko et al. 2008). Thus, the recurrence risk is not always obvious.
2. Prenatal diagnosis
    1. Prenatal ultrasound findings in perinatal lethal Gaucher disease (Rowlands and Murray 1997; Beaujot et al. 2013)
        1. Perinatal lethal GD: phenotypic heterogeneity (Mignot et al. 2003, 2006; Plakkal et al. 2011)
        2. Nonimmune hydrops fetalis
        3. Hepatosplenomegaly
        4. Abnormal fetal movements, posture, and tone
        5. Gaucher's disease should be considered in all fetuses with hydrops and arthrogryposis (Rowlands and Murray 1997)

2. Available to pregnancies at increased risk
    1. Highly useful to predict nonneuronopathic disease with assurance.
    2. Overall difficulty in predicting disease progression adding complexity.
    3. If the disease is controlled, with proper therapy and monitoring, mothers are more likely to experience uncomplicated pregnancies and deliveries (Giannubilo et al. 2015).
3. Analysis of β-glucocerebrosidase enzymatic activity (0–15% of normal), performed on fetal cells obtained by:
    1. CVS cells
    2. Amniocytes
4. Mutation analysis of the *GBA* gene when the disease-causing *GBA* mutations have been identified in both parents or a prior affected sibling, performed on fetal cells obtained by:
    1. CVS cells
    2. Amniocytes
5. Preimplantation genetic diagnosis (PGD) (Altarescu et al. 2010)
    1. In the case of type 1 Gaucher disease, PGD might be considered because it obviates the ethical dilemma of pregnancy termination should the fetus be affected.
    2. PGD is possible for at-risk pregnancies provided the disease-causing mutations have been previously identified in the family.

3. Management (Vellodi et al. 2001; Pastores and Barnett 2003)
    1. Symptomatic care
        1. Partial or total splenectomy
            1. For patients who have massive splenomegaly with significant infarction and persistent severe thrombocytopenia with high risk of bleeding.
            2. Enzyme replacement therapy alleviates hypersplenism and eliminates the need for splenectomy.
        2. Transfusion of blood products for severe anemia and bleeding
        3. Analgesics for bone pain
        4. Joint replacement surgery to relieve bone pain and restore joint function
        5. Oral bisphosphonates suggested in patients with Gaucher disease and low bone density
    2. Therapy to reduce glucosylceramide accumulation
        1. Bone marrow transplantation
        2. Enzyme replacement therapy
        3. Substrate reduction therapy
        4. Gene therapy
    3. Bone marrow transplantation (Ringden et al. 1995)
        1. Corrects metabolic defect
        2. Improves blood counts
        3. Reduces increased liver volume
        4. Stabilizes bone disease and neurologic disease in a few patients
        5. Limited use in patients with type 1 and type 3 Gaucher disease because of the morbidity and mortality associated with the bone marrow transplantation
        6. Useful concomitant therapy for patients with chronic neurological Gaucher disease and progressive disease on enzyme replacement therapy
    4. Enzyme replacement therapy (ERT) (Barranger and O'Rourke 2001; Charrow 2009)
        1. Efficacy using alglucerase and imiglucerase (Bembi et al. 2002).
            1. For treating the visceral and hematological aspects of Gaucher disease: improvement in hematologic parameters, normalization of bone marrow fat content, and improved bone mineral content and quality of life.
            2. Treatment responses seen within months.
            3. Effective for halting or reversing the skeletal pathology of Gaucher disease.
            4. The optimal dosage and the response time of ERT for treating the skeletal system, particularly for pediatric patients, are not well defined.

2. Intravenous infusions of purified macrophage-targeted human β-glucocerebrosidase.
    1. Alglucerase (Ceredase, Genzyme Corporation), derived from human placenta
    2. Imiglucerase (Cerezyme, Genzyme Corporation), derived from recombinant DNA production methods
3. Treatment results (visceral aspects of type 1 and type 3 Gaucher disease) (Pastores et al. 1993; Weinreb et al. 2002)
    1. Breakdown of stored glucocerebroside.
    2. Reduction in liver and spleen size.
    3. Amelioration or resolution of anemia and thrombocytopenia.
    4. Decreased bone pain (Poll et al. 2002)
    5. Increased bone mineralization.
    6. Remodeling over a period of several years.
    7. Improved health-related quality of life.
    8. IgG antibodies to alglucerase reported to develop in approximately 13% of patients (Rosenberg et al. 1999). These antibodies have little clinical effect and diminish with continued therapy in most circumstances. However, the presence of antibodies could be associated with an increased risk of hypersensitivity reactions (Charrow et al. 1998).
    9. Prolonged treatment over 3 1/2 years with macrophage-targeted glucocerebrosidase produces objective reversal of disease in both the axial and appendicular skeleton in patients with type 1 Gaucher disease. Marked improvement occurs in marrow composition and bone mass in both children and adults (Rosenthal et al. 1995)
4. Four treatments available for GD1: 3 ERTs (enzyme replacement therapies) and 1 SRT (substrate reduction therapy) (Bennett and Mohan 2013)
    1. Miglustat, an SRT: approved for mild to moderate GD1
    2. ERTs are available for moderate to severe GD1 and can improve quality of life within the first year of treatment.
    3. The newest ERT, taliglucerase alfa, is plant-cell derived that can be produced on a large scale at lower cost.
    4. Eliglustat tartrate (Balwani et al. 2016; Sechi et al. 2016)
    1. A newly developed SRT for GD, which is created to specifically inhibit GCS, with the aim to reduce substrate accumulation with limited side effects
    2. Recommendations for the use of eliglustat in the treatment of adults with Gaucher disease type 1 in the United States
    5. No drugs have been approved for GD2 or GD3.
5. Management of bone disease in GD1 (Giuffrida et al. 2014)
    1. The severity of skeletal involvement in type 1 GD is variable, but associated with significant pain, disability, and reduced quality of life; thus, all patients should be monitored regularly for the onset and progression of skeletal pathology.
    2. Dual energy X-ray absorptiometry is the method of choice for measuring bone mineral density, whereas MRI is the method of choice for evaluating bone marrow infiltration.
    3. Correct performance and interpretation of these methods are paramount to obtaining clinically useful information.
6. Long-term treatment outcomes in type 1 Gaucher disease (Charrow and Scott 2015): ERT has dramatically improved the outlook for patients with Gaucher disease. The future holds promise of new therapies, which may help address as yet unmet needs. These include

pharmacologic chaperones, and the potential development of molecules able to cross the blood–brain barrier that might lead to effective treatment for neuronopathic disease.

7. Treatment in patients with type 2 Gaucher disease (Charrow et al. 1998).
    1. Enzyme therapy may slow but does not prevent the development of lethal CNS disease in Gaucher disease type 2, even when initiated presymptomatically (Bove et al. 1995)
    2. Limited and disappointing: unaltered ultimate fatal course.
    3. Therapy at birth given to an infant, identified prenatally, failed to alter the inevitable neurologic outcome.
    4. Currently not recommended to treat patients with type 2 Gaucher disease.
8. Currently, no hard data available to show the efficacy of enzyme therapy for reversing existing or rapidly progressing CNS disease in type 3 patients with Gaucher disease.
9. Effect of enzyme therapy on the cardiac, valvular, and hydrocephalic manifestations of type 4 patients remains unknown.
10. ERT is a lifelong treatment since withdrawal of therapy inevitably leads to progression of Gaucher disease and the (sometimes rapid) loss of the progress made with ERT.

5. Substrate reduction therapy
    1. Miglustat, a formulation aimed at restoring metabolic homeostasis by limiting the amount of substrate precursor synthesized to a level that can be effectively cleared by the mutant enzyme with residual hydrolytic activity.
    2. Additional controlled longitudinal studies needed to be undertaken with a larger number of patients not only to determine the biochemical but also clinical long-term outcomes of patients with type 1 Gaucher disease on miglustat therapy (Ficicioglu 2008).
6. The future of Gaucher disease therapy (Harmanci and Bayraktar 2008)
    1. Gene therapy
        1. Neither ERT nor SRT has achieved excellent results in terms of neurological and pulmonary involvement due to problems such as inability to pass through the blood–brain barrier.
        2. Possibility of administration and incorporation of a healthy genome replacing a deficient genome.
        3. In early animal models of gene therapy, the vectors responsible for "infecting" a healthy genome were viruses (adeno-associated virus, lentivirus, and retrovirus). These studies showed promising results for the future (Kim et al. 2004; Enquist et al. 2006; McEachern et al. 2006).
        4. The advantage of gene therapy: its widespread infection of specific targeted cells in the body substantially increasing the enzyme levels to a considerable level.
    2. Chaperone treatment
        1. Imino sugars: ability to increase the strength of the target enzyme (glucocerebrosidase) (Sawkar et al. 2002).
        2. These chemicals increase the half-life of the enzyme by inhibiting its degradation and by providing stabilization.
        3. Although this option currently does not seem to offer a monotherapy option, chaperones might be an option for combination treatment strategies.

Fig. 1 A 3-year-old African-American female child with Gaucher disease showing hepatosplenomegaly. She had history of "large belly" since she was 6–12 months of age, anemia (hemoglobin of 8.7 g%), and thrombocytopenia (73,000). She had an elevated total acid phosphatase of 29 U/L (2.3–5.0), a very low leukocyte beta-glucocerebrosidase of 0.01 U (0.08–0.35), and "Gaucher cells" in the bone marrow

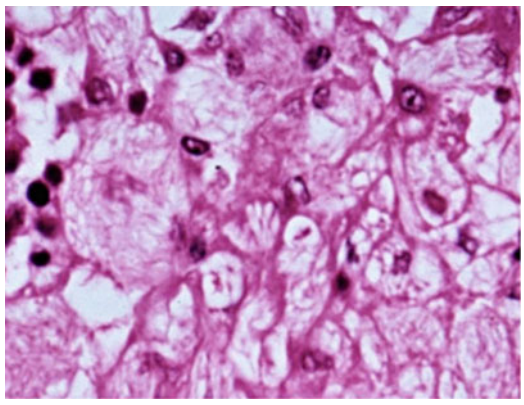

Fig. 2 Bone marrow smear from another patient with Gaucher disease showing extensive infiltration by Gaucher cells (H&E stain)

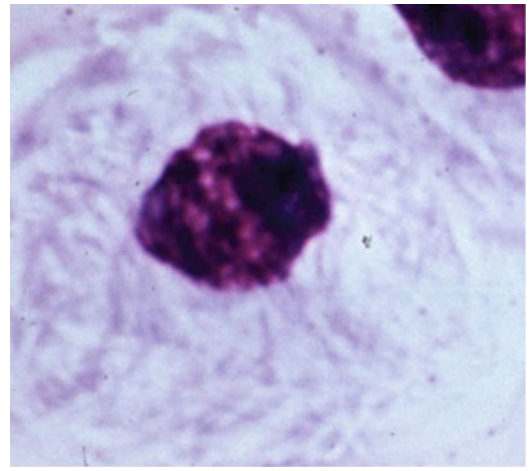

Fig. 3 Higher magnification of bone marrow smear showing a Gaucher cell (Wright-Giemsa stains)

Generalized Arterial Calcification of Infancy

Contents

General arterial calcification of infancy is a rare and usually fatal disease. The condition is also called idiopathic arterial calcification of infancy.

Synonyms and Related Disorders

Idiopathic infantile arterial calcification; Infantile occlusive arteriopathy

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Moran and Becker 1959; Stanley et al. 1988).
2. Cause (Rutsch et al. 2008).
    1. Loss-of-function mutations in *ENPP1* gene (located on chromosome 6q22-q23) that inactivate ectonucleotide pyrophosphatase/phosphodiesterase 1 (*ENPP1*).
        1. This cell-surface enzyme generates inorganic pyrophosphate, a solute that regulates cell differentiation and serves as an essential physiologic inhibitor of calcification (Rutsch et al. 2003)
        2. *ENPP1* coding region mutations are associated with generalized arterial calcification of infancy in ≈75% of subjects.
        3. This mutation was recently found to also cause autosomal-recessive hypophosphatemic rickets (Lorenz-Depiereux et al. 2010).
    2. Plasma cell membrane glycoprotein-1 (PC-1) nucleoside triphosphate pyrophosphohydrolase deficiency (Rutsch et al. 2001).
        1. Associated with human infantile arterial calcification, especially with periarticular calcification.
        2. May explain the sharing of certain phenotypic features between some infantile arterial calcification patients and PC-1-deficient mice.
3. Basic defects.
    1. Possibly a defect of elastic fiber.
        1. Occurrence of calcification particularly in the internal elastic lamina.
        2. Material with the staining properties of mucopolysaccharide accumulates around the elastic fibers.
    2. Fundamental lesions.
        1. A remarkable predilection for mineralization around the internal elastica laminae of medium- to large-sized arteries.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_104

2. Narrowing of the arterial lumen due to a marked intimal proliferation.
3. Pathogenesis.
   1. Incompletely understood.
   2. Involves calcification (calcium hydroxyapatite deposition) in the internal elastic lamina of large- and medium-sized arteries, associated with a stenosing, fibroproliferative medial smooth muscle cell-mediated process, maximal in the area of the internal elastic lamina.
   3. Relates to decreased levels of plasma and urinary inorganic pyrophosphate whose role is to inhibit hydroxyapatite crystal deposition in bone and cartilage.

Clinical Features

1. Stormy clinical course.
2. Infant usually thrive normally right after birth.
3. Thereafter, following symptoms develop rapidly.
   1. Poor feeding.
   2. Vomiting.
   3. Respiratory distress.
      1. Tachypnea.
      2. Tachycardia.
      3. Cyanosis.
   4. Hypertension (Van Dyck et al. 1989).
   5. Myocardial infarctions.
   6. Progressive congestive cardiac failure.
4. Prognosis.
   1. Death (sudden death or unexpected infant death).
      1. Usually occurring during early infancy secondary to coronary insufficiency.
      2. 85% of cases dying before 6 months of age (Byard 1996).
      3. Causes of death.
         1. Vascular occlusion due to extensive calcification of the arterial media associated with intimal proliferation.
         2. Other complications of obstructive arteriopathy including renal artery stenosis (Thiaville et al. 1994).
         3. Ischemic myocardial ischemia/cardiomyopathy resulting in refractory heart failure.
   2. Rare regression of calcification and prolonged survival (Marrott et al. 1984; Thomas et al. 1990; Ciana et al. 2006): Once the severe circulatory problems of infancy are overcome, disease prognosis may be better than previously thought.

Diagnostic Investigations

1. Blood workup.
   1. Normal calcium levels.
   2. Normal phosphate levels.
   3. Relative deficiency of plasma pyrophosphate (Stuart et al. 1990)
2. Urinalysis: Low levels of urinary inorganic pyrophosphate indicating systemic pyrophosphate deficiency (Rutsch et al. 2000)
3. Radiography Calcifications of major arteries and particularly ligaments are pathognomonic radiologic signs of this disorder (Meradji et al. 1978; Chen et al. 1982; Maayan et al. 1984)
   1. Demonstration of the calcified arteries, leading to possible diagnosis of the condition during life.
   2. Extensive vascular calcification.
      1. Upper and lower limbs.
      2. Neck.
      3. Subclavicular fossae.
      4. Axillae.
   3. Periarticular calcification and stippled calcification of the epiphyseal cartilage.
   4. Cardiac enlargement.
4. ECG changes suggesting.
   1. Coronary occlusion.
   2. Myocardial infarct.
5. Ultrasonography (Whitehall et al. 2003):
   1. Marked calcification in the aorta/arteries.
   2. Calcified plaques in the lumen of the aorta.
   3. Dropper studies: reduced arterial blood flow.

6. Echocardiography to demonstrate coronary calcification.
7. Aortogram showing striking obliterations of the peripheral vessels.
8. Biopsies of peripheral arteries showing extensive intimal mineralization.
9. Postmortem gross pathological findings usually limited to the cardiovascular system
    1. An enlarged heart.
    2. Focal calcifications of coronary arteries and other peripheral arteries.
    3. Pale or mottled areas of the myocardium or other viscera indicative of infarction.
10. Histopathology (Bird 1974; Moran 1975; Anderson et al. 1985)
    1. Extensive mineralization (calcium hydroxyapatite deposition) of arteries.
        1. Usually noted around the internal elastic lamina of the medium-sized arteries.
        2. Often accompanied by a marked intimal hyperplasia causing luminal narrowing.
        3. Tends to be most severe in the coronary arteries.
            1. Resulting in myocardial ischemia and infarction.
            2. Death usually attributable to myocardial infarction or heart failure.
    2. Involvement of a variety of arteries.
        1. Aorta.
        2. Pulmonary arteries.
        3. Carotid arteries.
        4. Iliac arteries.
        5. Femoral arteries.
        6. Visceral arteries.
        7. Limb arteries.
        8. Vessels of the brain usually not affected.
    3. Cardiac abnormalities.
        1. Left or biventricular hypertrophy.
        2. Fibrointimal thickening.
        3. Calcification of the coronary arteries.
        4. Endocardial fibroelastosis (Sholler et al. 1984)
        5. Widespread ischemic myocardial damage.
        6. Coronary artery occlusion (Lussier-Lazaroff and Fletcher 1973)
    4. Generalized arterial calcification of infancy generally indistinguishable from the following conditions.
        1. Metastatic calcification of arteries secondary to advanced renal disease.
        2. Arterial lesions in hypervitaminosis D or secondary to other toxic agents.
        3. Hyperparathyroidism of pregnancy.
11. Molecular genetic diagnosis: not yet available clinically (only available in a few research laboratories) (Cheng et al. 2005; Dlamini et al. 2009).

Genetic Counseling

1. Recurrence risk.
    1. Patient's sib: 25%.
    2. Patient's offspring.
        1. Not surviving to reproductive age in majority of patients.
        2. Low recurrence risk for those who survive.
2. Prenatal diagnosis.
    1. Fetal ultrasonography and radiography to detect calcium hydroxyapatite deposits (echogenic walls of arterial vessels).
        1. Presence of mitralic echogenic foci in the 14th week of gestation (Ciana et al. 2006).
        2. Echogenic great arteries at 29 weeks of gestation (Reitter et al. 2009).
    2. Fetal echocardiography (Nagar et al. 2003).
        1. Fetal nonimmune hydrops.
        2. Increased echo (calcific type) density of walls of the fetal aorta, pulmonary arteries, coronary arteries, within the lumen of the heart, and other arterial walls.
        3. Poor focal contraction of the heart, as a result of the expected accompanying cardiac ischemia due to coronary artery narrowing.
        4. Dilated cardiac chambers.
        5. Pericardial effusion.
        6. Hypertrophic cardiomyopathy.

3. Fetal ultrasonography, radiography, and CT scan (Spear et al. 1990)
    1. Ultrasonography: hyperechogenic artery walls
    2. Radiography: calcified aorta, celiac axis and superior mesenteric artery
    3. CT: calcified aorta, fetal ascites and maternal hydramnios
    4. Prenatal diagnosis.
        1. Reference ranges for the disease-related enzymes in amniocytes or fibroblast cultures from CVS have not been established.
        2. Molecular genetic diagnosis: Prenatal diagnosis may be possible in at-risk families, provided disease-causing mutations have been identified previously.
3. Management (Stuart 1993).
    1. Therapy with diphosphonates (nonhydrolyzable analogs of inorganic pyrophosphate) (Van Dyck et al. 1989).
        1. Function of diphosphonates.
            1. Simple chemical compounds containing phosphate-carbon-phosphate bonds.
            2. Inhibit the precipitation of several calcium salts in vitro.
            3. Block the conversion of amorphous calcium phosphate into crystalline hydroxyapatite.
            4. Partially converting apatite crystals into a colloidal state with treatment of large amounts of certain diphosphonates.
        2. Effective in some patients.
            1. Some apparent reduction of calcification.
            2. Usually with persistence of ischemic effects of intimal fibroproliferation.
            3. Except for the p.P305T mutation, which was universally lethal when present on both alleles, the identified *ENPP1* mutations per se have no discernable effect on survival. However, survival seems to be associated with hypophosphatemia linked with hyperphosphaturia and also with bisphosphonate treatment (Rutsch et al. 2008).
            4. Case report by Ramjan et al. 2009: Low-dose disodium pamidronate (0.1 mg/kg per week for 4 weeks), which commenced on the seventh day after birth and was changed to oral risedronate sodium (1 mg/kg per week as a single dose) at 4 weeks of age. Complete resolution of arterial calcification was seen by 3 months of age. Treatment with bisphosphonates is ongoing but is planned to be discontinued at 3 years of age. The child has remained healthy and developmentally normal.
    2. Management of arterial hypertension.
        1. May be refractory to conventional medical therapy.
        2. Prostaglandin E_1 infusion.
    3. Management of myocardial infarctions.
    4. Treatment with bisphosphonates (Ranjan et al. 2009).
    5. In utero diphosphonate etidronate therapy (Stuart et al. 1990; Bellah et al. 1992).
        1. Apparent radiographic and ultrasonographic improvement in the degree of vascular calcification.
        2. Unable to prevent the lethal progression of intimal vascular occlusive disease.

Fig. 1 Postmortem picture of a neonate (twin B) with generalized arterial calcification showing ischemic changes of the right arm. The pregnancy was complicated by polyhydramnios. At 2 weeks of age, he was noted to have intercostal retraction and tachypnea with distended abdomen and hepatomegaly

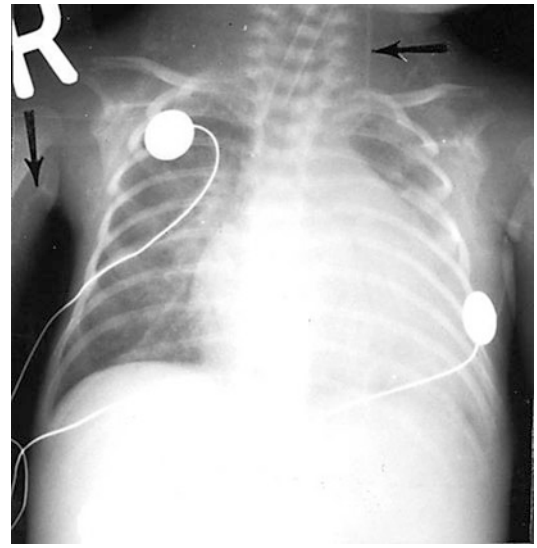

Fig. 2 Radiograph examinations showed extensive vascular calcification extending down the upper and lower limbs, neck, supraclavicular fossae, and axillae. Radiograph here shows an enlarged heart and linear calcification (*arrows*) of the carotid and brachial arteries

Fig. 3 Gross view of vessels, especially the renal arteries, intercostalis, and iliacs, which were hard with mineralization of vessel walls

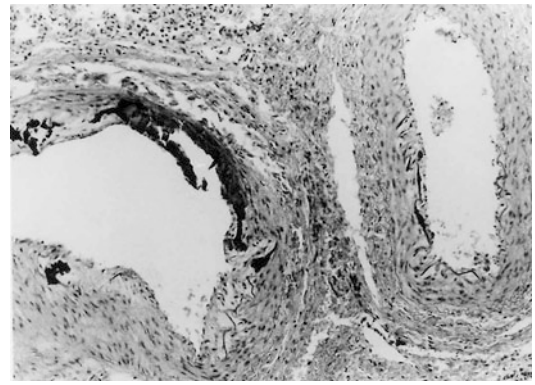

Fig. 4 Artery on the right shows the earliest type of lesion with mild intimal hyperplasia, mild fragmentation, and early mineralization of internal elastic lamina. Artery on the left shows a more advanced lesion with moderate intimal proliferation, moderate fragmentation of internal elastica lamina, and heavy mineralization in and around elastic fibers

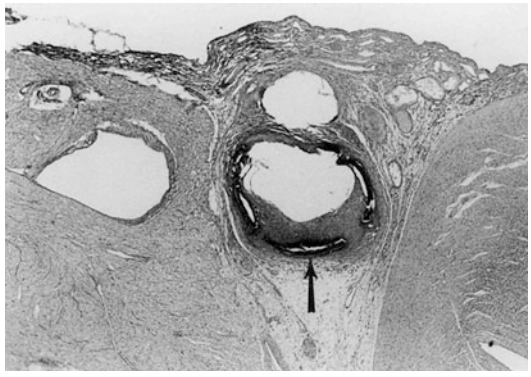

Fig. 5 Advanced mineralization in and around internal elastica lamina (coronary artery)

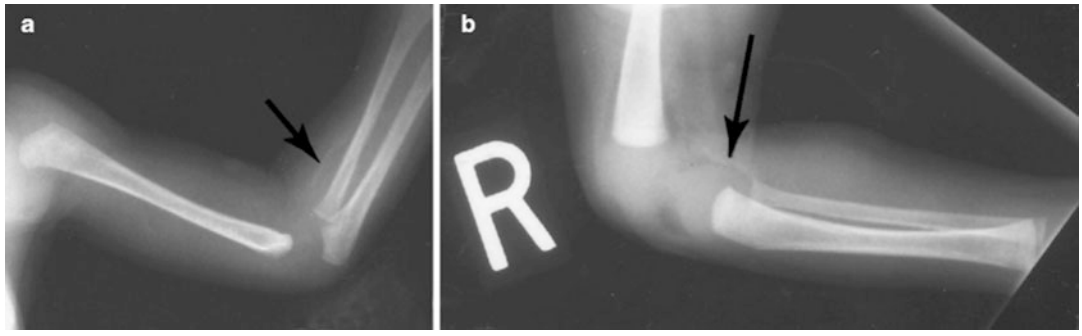

Fig. 6 (**a,b**) Radiographs of twin B show linear calcification (*arrow*) of the radial artery (*upper*) and popliteal artery (*lower*). At 35 days of age, the twin suffered a cardiac arrest and expired shortly thereafter. No autopsy was performed

Genitopatellar Syndrome

Contents

In 1988, Goldblatt et al. (1988) first reported a 4-year-old boy with hypoplastic patellae, mental retardation, scrotal hypoplasia, skeletal deformities, renal anomalies, flattened nasal bridge, and short stature. Later in 2000, Cormier-Daire et al. (2000) reported seven patients with genital anomalies (scrotal hypoplasia and cryptorchidism in the boys and clitoral hypertrophy in the girls), facial dysmorphism, renal anomalies, absent patella, and severe mental retardation in the two survivors. The condition is now known as genitopatellar syndrome (GPS).

Synonyms and Related Disorders

Absent patellar, facial dysmorphism, mental retardation, renal anomalies, and scrotal hypoplasia; Ohdo syndrome; Say-Barber-Biesecker variant of Ohdo syndrome; Say-Barber-Biesecker/Young-Simpson syndrome (SBBYSS)

Genetics/Basic Defects

1. An autosomal recessive inheritance of this condition was proposed (Cormier-Daire et al. 2000; Reardon 2002).
2. KAT6B-related disorders are inherited in an autosomal dominant manner (Campeau and Lee 2013).
3. Normal karyotypes and normal array-based comparative genome hybridization (aCGH) in all except one case of ovotestes and XY sex reversal in a female with an interstitial 9q33.3-q34.1 deletion encompassing *NR5A1* and *LMX1B* causing features of genitopatellar syndrome (Schlaubitz et al. 2007).
4. Mutations of *LMX1B*, *TBX4*, *WNT4*, and *WNT7A* genes, consistent with nail-patella syndrome, small patella syndrome, and defects in Müllerian ducts and limb development, respectively, were excluded (Abdul-Rahman et al. 2006; Schlaubitz et al. 2007).
5. GPS (Campeau et al. 2012; Gannon et al. 2015).
    1. Recently been shown to be caused by distinct mutations in the histone acetyltransferase *KAT6B* (Simpson et al. 2012).
    2. All variants are de novo dominant mutations that lead to protein truncation.
    3. Mutations leading to GPS occur in the proximal portion of the last exon and lead to the expression of a protein without an activation domain.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_105

4. Report of a deletion of the *KAT6B* gene to further delineate the haploinsufficiency phenotype
6. SBBYSS (Campeau et al. 2012; Gannon et al. 2015)
   1. Features: present only in SBBYSS including long thumbs and long great toes and lacrimal duct abnormalities
   2. Typically, patients have a distinctive mask-like face with severe blepharophimosis and ptosis, a broad nasal bridge, bulbous nasal tip, small mouth, thin upper lip, and small, low set ears.
   3. Also recently been shown to be caused by distinct mutations in the *KAT6B*
   4. Mutations leading to SBBYSS occur either throughout the gene, leading to nonsense-mediated decay, or more distally in the last exon.
   5. Synonymous variant c.3147G > A as a splice site mutation and a mutational hot spot in Say-Barber-Biesecker/Young-Simpson (SBBYS) type of blepharophimosis, "mental retardation" syndromes and the more severe genitopatellar syndrome (Yilmaz et al. 2015).

Clinical Features

1. Genital anomalies
   1. Males (Sankararaman et al. 2012)
      1. Scrotal hypoplasia
      2. Cryptorchidism
      3. Small penis
   2. Females (Lammer and Abrams 2002)
      1. Prominent clitoris and labia minora
      2. Hypoplastic clitoris and labia minora
2. Absent/hypoplastic patella (Armstrong and Clarke 2002)
3. Arthrogryposis
   1. Knees
      1. Flexion contractures
      2. Skin dimples at the knee
   2. Flexion contractures or dislocation/subluxation of the hips
4. Other skeletal anomalies
   1. Brachydactyly of the upper limbs
   2. Clubfeet
   3. Hypoplasia of pelvic bones
5. Distinctive craniofacial features
   1. Microcephaly
   2. Abnormal skull shape
   3. Hypertelorism
   4. Midfacial hypoplasia
   5. A large, broad nose with a high nasal bridge
   6. Micrognathia
6. CNS anomalies
   1. Severe psychomotor retardation
   2. Hypotonia
   3. Swallowing and feeding difficulties during neonatal period
   4. Absence of corpus callosum
   5. Colpocephaly
7. Congenital heart defects (Lifchez et al. 2003)
   1. VSD
   2. ASD
   3. PDA
   4. PFO
   5. Abnormal aortic arch
8. Renal anomalies
   1. Multicystic kidneys
   2. Hydronephrosis
   3. Large fused kidney
   4. Vesicoureteral reflux
9. Anal atresia or ventral displacement of the anus (Penttinen et al. 2009)
10. Mild manifestations of ectodermal dysplasia
    1. Sparse scalp hair
    2. Delayed tooth eruption
11. Severe respiratory problems
    1. Apnea
    2. Pulmonary hypoplasia
12. Hearing loss (Bergman et al. 2011)
13. Differential diagnosis (Bongers et al. 2005; Lam et al. 2009)
    1. Nail-patella syndrome
       1. Caused by *LMX1B* mutations
       2. Nail dysplasia
       3. Absent/hypoplastic patella
       4. Elbow synostosis
       5. Presence of iliac horns
       6. Nephropathy (glomerular basement membrane)
       7. Open-angle glaucoma

2. Small patella syndrome
    1. Caused by *TBX4* gene mutations
    2. Absent/hypoplastic patella
    3. Knee contractures
3. Isolated patella aplasia/hypoplasia
    1. A rare autosomal dominant disorder
    2. Congenital aplasia or hypoplasia of the patellae: the only clinical and radiographic feature
4. Meier-Gorlin syndrome (ear-patella-short stature syndrome)
    1. An autosomal recessive pleiotropic condition
    2. Classical triad: bilateral microtia, patellar aplasia or hypoplasia, and severe pre- and postnatal growth retardation
5. RAPADILINO syndrome (Kääriäinen et al. 1989)
    1. Autosomal recessive disorder in which patellar malformations are accompanied by short stature and external ear malformations
    2. The acronym RAPADILINO stands for the characteristic main features: RA dial and PAtellar aplasia or hypoplasia, cleft or highly arched PAlate, infantile DIarrhea and DIslocated joints, LIttle size and LImb malformation, and long slender NOse and NOrmal intelligence (Kääriäinen et al. 1989)
    3. Additional frequent findings comprise absent thumbs, micrognathia, dysmorphic auricles including dysmorphic ear lobes and partial unfolded ear helices, a high-pitched voice, and metatarsus varus.
6. Subtelomeric 1q deletion syndrome causing patellar hypoplasia and limb deformities, features overlapping with genitopatellar syndrome.

Diagnostic Investigations

1. Cranial ultrasound and MRI to detect CNS malformations
2. Radiography for skeletal anomalies and absent patella (for older child)
3. Renal ultrasound for renal anomalies
4. MRI of the patella to ascertain absence of the patella (Sankararaman et al. 2012)

Genetic Counseling

1. Recurrence risk (Campeau and Lee 2013)
    1. Patient's sib
        1. The risk to the sibs of the proband depends on the genetic status of the proband's parents.
        2. If the pathogenic variant found in the proband cannot be detected in the leukocyte DNA of either parent, the risk to sibs is low but greater than that of the general population because of the possibility of germline mosaicism.
        3. If a parent of the proband has germline mosaicism for a *KAT6B* pathogenic variant, the risk to the sibs of inheriting the pathogenic variant may be as high as 50%.
    2. Patient's offspring: To date, individuals with *KAT6B*-related disorders rarely reproduce.
2. Prenatal diagnosis/preimplantation genetic diagnosis: Possible for families in which the pathogenic variant has been identified (Campeau and Lee 2013)
3. Management: supportive

Fig. 1 The neonate was a twin A of dizygotic twins, delivered at 29 weeks via emergency C section secondary to suspected chorioamnionitis. The baby was noted to have no scrotal sac with nonpalpable testes. He was noted to have abnormal positioning of the legs with contractures of the hips and the knees and clubfeet. He was also noted to have an imperforate anus with intestinal malrotation which were repaired. Renal ultrasound showed bilateral hydronephrosis (Sankararaman et al. 2012)

Fig. 2 Craniofacial features were characterized by coarse face, flat occiput, bitemporal narrowing, and a deep crease across the nasal bridge. The neck was short. There were proximal interphalangeal contractures of the digits two to four on both hands, a single flexion crease on the fifth digit. Transverse palmar creases were present bilaterally. MRI of the brain showed absence of the corpus callosum with delayed myelination, prominent DSF spaces in the frontal region, and mega cisterna magna. Chromosome analysis and microarray analysis were normal

Fig. 3 Showed knee dimples with flexion contractures, popliteal webbing, and talipes equinovarus

Fig. 4 Dimples on both knees shown by *black arrows*

Fig. 6 This photo showed scrotal hypoplasia and imperforate anus

Fig. 5 External genitalia showed scrotal hypoplasia and bilateral cryptorchidism

Fig. 7 MRI of the knee showed absence of the patella

Giant Congenital Melanocytic Nevi

Contents

Giant congenital melanocytic nevi (GCMN) or giant congenital nevi are rare, congenital, disfiguring lesions present at birth with a risk of degeneration to malignant melanoma (Watt et al. 2004) and may be associated with neurocutaneous melanosis (NCM) (Hale et al. 2005; Ka et al. 2005). The incidence of giant-sized congenital melanocytic nevi greater than 20 cm in diameter was estimated at approximately one in 20,000 live births. The larger bathing trunk variety occurs approximately one in 500,000 live births (Castilla et al. 1981).

Synonyms and Related Disorders

Congenital melanocytic nevi (CMN); Garment or bathing trunk nevi; Giant congenital nevi

Genetics/Basic Defects

1. GCMN generally occurs in isolation, but rare familial occurrence (Voigtländer and Jung 1974; Hecht et al. 1981; De Wijn et al. 2009) points to a genetic background.
2. Genetic basis of giant nevi:
    1. Concept of paradominant inheritance (Danarti et al. 2003):
        1. Heterozygous individuals carrying the mutation are phenotypically normal, and the trait would only manifest itself when heterozygosity was lost at an early developmental stage.
        2. Would explain why lesions occur in a mosaic pattern, occur sporadically, and do not show any consistent pattern of Mendelian inheritance.
        3. Discordance for giant pigmented nevi in monozygotic twins was reported (Cantu et al. 1972).
    2. Nevi harboring the BRAFE600 mutation undergo cell cycle arrest and senescence, thus preventing the development of malignancy in these lesions (Michaloglou et al. 2005).
    3. Using single-strand conformational polymorphism and sequencing analysis, BRAF

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_106

and N-ras oncogene mutations were found to be extremely common in individuals with congenital nevi, which could explain the higher risk of developing cutaneous melanoma (Papp et al. 2005).

4. Reports on chromosome abnormalities in GCMNs – infrequent:
   1. Two balanced translocations involving the BRAF gene and one deletion of the long arm of chromosome 6 out of 27 GCMNs (Dessars et al. 2008).
   2. 22% of mitoses with polyploid and 4% with chromosome rearrangements involving 1p, 12q, and 19p from a single GCMN (Heimann et al. 1993).
5. *NRAS* mutation – the sole recurrent somatic event found in large congenital melanocytic nevi (Charbel et al. 2014):
   1. The genetic profile of small–medium CMNs: significantly different, with 70% of cases bearing NRAS mutations and 30% showing BRAF mutations.
   2. These findings strongly suggest that NRAS mutations are sufficient to drive melanocytic benign proliferations in utero.
6. Clinical variability in large CMN may be due to the many potential modifiers of a mosaic *NRAS* or *BRAF* gain-of-function genotype (Etchevers 2014).
7. *BRAF* mutations are also associated with neurocutaneous melanocytosis and large/giant congenital melanocytic nevi (Salgada et al. 2015).
8. The pattern of inheritance (De Wijn et al. 2009):
   1. Likely not Mendelian.
   2. Discordance in identical twins (Morganroth et al. 1991) and the segmental distribution of lesions suggest a postzygotic mutation.
   3. A polygenic paradominant inheritance best explains the clinically observed transmission pattern.
   4. Candidate genes include those influencing neural crest development and melanocyte proliferation.
3. Embryological origin of congenital melanocytic nevus:
   1. Not well understood
   2. Hypothesis:
      1. Giant congenital nevi develop between the 5th and 25th weeks of gestation.
      2. Dysregulated growth of melanoblasts occurs secondary to morphogenic errors in neuroectodermal development, resulting in dysregulated migration of melanoblasts from the neural crest to the skin and leptomeninges.

Clinical Features

1. Congenital melanocytic nevi (Zaal et al. 2004; Tannous et al. 2005):
   1. Definition: benign proliferation of cutaneous melanocytes, clinically apparent at birth or becoming so within the first postnatal weeks
   2. Incidence: affects approximately 1% of all newborns
   3. Characteristics: vary in size, macroscopic appearance, and histology as a group
   4. Classification of congenital melanocytic nevi based on final size of the nevi:
      1. Small: less than 1.5 cm in diameter
      2. Intermediate: 1.5–20 cm in diameter
      3. Giant or large (also called garment or bathing trunk nevi: measuring more than 20 cm in diameter) (Ruiz-Maldonado et al. 1992; West et al. 2007)
2. Giant congenital nevi: classified based on the percentage of body area affected (a congenital nevi covering 1% of body surface area in the face and neck and 2% elsewhere on the body)
3. Clinical manifestations of giant congenital nevi:
   1. Onset: flat, brown, or brownish-black patches but with increasing age may become elevated and develop a mottled appearance and nodular surface.
   2. Appear darker at birth than a few weeks later.

3. Found most commonly on the trunk, followed by the limbs and the head (Madaree et al. 1997).
4. Giant nevi: almost always confined to the skin but, rarely, invade the underlying fascia and muscle.
5. Most giant CMN involves the trunk and has a predominant bathing suit distribution.
6. Innumerable nevi with giant congenital melanocytic nevus clinically mimicking neurofibromatosis: a diagnostic challenge (Boyers et al. 2015).
7. Associated abnormalities (De Wijn et al. 2009):
    1. Neurocutaneous melanosis (Arneja and Gosain 2005; Araújo et al. 2015):
        1. Incidence of NCM in children with GCMN: 29.2% (Bekiesinska-Figatowska et al. 2014).
        2. Characterized by the presence of benign or malignant melanocytic proliferations in the CNS in association with a giant CMN or three or more smaller melanocytic nevi (Kadonaga and Frieden 1991).
        3. Signs and symptoms of symptomatic neurocutaneous melanosis (hydrocephalus, seizures, developmental delay, cranial nerve palsies, or a tethered spinal cord) (Foster et al. 2001).
        4. Almost all children with neurocutaneous melanosis have giant nevi on the head, neck, or dorsal spine.
    2. Structural brain abnormalities:
        1. Dandy–Walker malformation
        2. Hemimegalencephalopathy
        3. Meningohydroencephalocele
        4. Lissencephaly
        5. Microcephaly
        6. Spina bifida occulta
    3. Polydactyly
    4. Linear epidermal nevus syndrome
    5. Segmental neurofibromatosis
    6. Encephalocraniocutaneous lipomatosis
    7. General lipomatosis
    8. Placental nevomelanocytosis
    9. Hirschsprung disease
    10. Hypotrophy of the underlying bone or subcutaneous fat (limb hypoplasia)
    11. Ear deformities
    12. Angiomas
    13. Malignant melanoma (Marghoob et al. 1996; DeDavid et al. 1997)
4. Prognosis
    1. Usually disfiguring.
    2. The lifetime risk for the development of malignant melanoma in giant congenital nevi: approximately 4–42% (about a 14-fold increased risk of developing cutaneous and extracutaneous melanoma) (Trozak et al. 1975; Baader et al. 1992).
    3. Giant nevi on the scalp in a posterior axial location and those with surrounding satellite nevi are at greatest risk of malignant transformation.
5. The most frequently encountered clinically important vascular and pigmented birthmarks (Dohil et al. 2000): congenital nevi, hypopigmented lesions, vascular malformations and hemangiomas
6. Neonatal malignant melanoma (Dargeon et al. 1950; Leech et al. 2004)
    1. Extremely rare
    2. Develops within a giant congenital nevus or preexisting nevus
    3. Can occur de novo on apparently normal skin
    4. Arises from maternal malignant melanoma via placental metastases (Holland 1949; Brodsky et al. 1965)
    5. May metastasize or spread locally
    6. Notoriously difficult to diagnose in children, especially neonates:
        1. Clinical indicators such as changes in color, size, shape, rapid growth rate, nodularity, and even ulceration may occur in benignly evolving GCNs.
        2. Histologic features accepted as evidence of malignancy in an adult, such as mitotic activity, nuclear pleomorphism, and pagetoid melanocytic proliferation, may also be present in benign lesions in infants.

3. Morphologic findings of melanocytic lesions from frozen tissue specimen cannot be confidently interpreted.

Diagnostic Investigations

1. Twenty-four-hour urine: high concentration in children with giant melanocytic nevi, especially in those with neurocutaneous melanosis, helps in predicting patients with more serious neurological course of the disease (Sawicka et al. 2015).
2. Biopsies:
   1. Probably only useful in clarifying the nature of pathological changes that occur in discrete areas of these nevi
   2. Sampling of multiple areas required when there is a question of malignant change
3. Magnetic resonance imaging (MRI) (Kinsler et al. 2001):
   1. Highly sensitive in detecting melanin, which produces short T1 (Frieden et al. 1994) and T2 relaxation times due to interactions of unpaired electrons in the stable free radicals of melanin with the protons of free water.
   2. Can delineate the extent of underlying soft tissue involvement and assist in preoperative planning.
   3. Neither the location nor the size of the nevus appears to correlate completely with the presence or absence of MRI abnormalities suggestive of CNS melanosis.
   4. Foci of melanosis generally became more difficult to detect on follow-up images, which may be related to changes in the signal intensity of the brain that accompany myelination.
   5. Recommend MR imaging in addition to ongoing developmental and neurological evaluations to help identify individuals who are at greater risk for CNS disease, as well as encourage MR imaging for those with giant nevi in the lumbosacral region.
   6. MR findings in asymptomatic GCMN group were similar to the ones of parenchymal NCM. T1 shortening in parenchymal NCM does not cause a significant clinical significance, unless there is subsequent occurrence of leptomeningeal involvement (Kim et al. 2014).
   7. MRI of the brain is necessary in each child with giant congenital melanocytic nevi to confirm or rule out neurocutaneous melanosis, especially its most severe and lethal form, with leptomeningeal contrast enhancement (Sawicka et al. 2015).
4. Positron emission tomography (Makosz et al. 2004):
   1. To detect occult primary melanoma as well as melanoma metastases within the nevi
   2. May play an important role in long-term monitoring and management of these patients
5. Dermoscopy (episcopy, dermatoscopy, skin surface microscopy, epiluminescence microscopy): allows in vivo visualization of anatomical pigmented structures in the epidermis, dermoepidermal junction, and superficial papillary dermis not usually seen by the naked eye (Lodha et al. 2003).
6. Whole-exome sequencing for somatic mutation detection (*NRAS*, *BRAF*) (Charbel et al. 2014).

Genetic Counseling

1. Recurrence risk:
   1. Patient's sib: increased but exact risk not known
   2. Patient's offspring: increased but exact risk not known
2. Prenatal diagnosis: not reported but possible by fetoscopy (an invasive procedure)
3. Management
   1. Early and complete surgical excision is recommended because of an increased lifetime risk of malignancy (4–10%) (Warner et al. 2008).
   2. The surgical and reconstructive options for congenital melanocytic nevus are varied depending on the size and location of the nevus (Pearson et al. 2005):

1. Laser treatment: the results for congenital nevus have been unsuccessful because the deeper portions of the nevi are unaffected by the laser.
2. Dermabrasion:
    1. Plagued by recurrence if performed too superficially and hypertrophic scar if performed too deep.
    2. Produces uneven changes in the pigmentation of the skin because the melanocytic cells are found at varying depths in the dermis; dermabrasion produces uneven changes in the pigmentation of the skin.
    3. Dermabrasion has been abandoned for the treatment of nevi.
3. Curettage (Rasmussen et al. 2015):
    1. A gentle/less-invasive alternative with a lower complication rate, fewer operations needed, and good cosmetic outcome.
    2. Moreover, it is suitable for larger nevi and nevi in difficult locations.
    3. In case of repigmentation or severe morbidity after curettage, excision can always be performed at a later stage.
4. Excision:
    1. Excision followed by primary closure: a frequently used technique.
    2. Caution not to distort important structures such as oral commissure, eyelids, and eyebrows.
    3. Early excision with detailed histological examination of excised parts can speed up diagnosis of melanoma (Sawicka et al. 2015).
5. Stage excision:
    1. Consider when the resultant wound is too large to close or places excessive tension along the closure, increasing the risk of wound dehiscence
    2. An outpatient procedure involving less postoperative care and expense
6. Serial excision (Hassanein et al. 2015):
    1. CMN amenable to serial excision can be removed effectively and safely.
    2. Children are left with a single linear scar, do not have donor or recipient site morbidity from skin grafting, and are not subjected to potential tissue expander complications and injections required for expansion.
7. Skin grafting.
    1. A useful tool in the management of medium to large congenital nevi.
    2. Avoid split-thickness skin grafting because of the potential for an unsightly donor site and a greater need for inpatient care or a more complicated outpatient experience.
    3. Consider full-thickness grafts to allow for an acceptable donor site and less postoperative care.
    4. Considered in areas of the body of lesser esthetic importance.
8. Tissue expansion:
    1. Commonly used when a nevus is too large for primary closure: serial excision will produce residual deformity on the adjacent structures, or skin grafting will produce an undesirable esthetic result.
    2. The ability to replace tissue with like tissue, such as hair-bearing scalp with hair-bearing scalp, typically allows an acceptable esthetic result.
    3. The drawbacks include multiple operations (placement followed by removal and advancement), difficulty in expanding axial portions of the body, the weekly clinical visits for expansion, discomfort for the child during the expansion process, and the esthetic deformity produced during the expansion process.
9. Cultured epithelial autograft:
    1. Represents another reconstructive option
    2. Requires a tissue sample from the patient, several weeks for cellular production, and final placement
    3. Cultured epithelia autograft's application to giant congenital nevi:

natural as in the burn treatment of large total body surface area burn
4. Can be used for giant nevi that preclude the use of tissue expansion or skin grafting secondary to lack of donor site availability
5. Definite shortcomings: including expense, time required for manufacturing of the graft (less of a limiting factor in children with nevi), and durability
6. Preferred procedure to split-thickness skin grafting because no donor site morbidity exists, decreased blood loss occurs, a greater area of excision with resultant faster removal of a nevus can be accomplished, and the durability of the cultured epithelia autograft compares favorably with a split-thickness graft

10. Enzymatically separated epidermal grafting (Kishi et al. 2009):
    1. A useful method for the treatment of GCMN
    2. Easy to perform
    3. Cosmetically satisfactory results
11. A successful surgical approach to the immense surface area of lesions encountered in adulthood GCMN (Su et al. 2015):
    1. Massive en bloc excision of GCMN.
    2. Staged reconstructive process involved the use of Integra (covering the skin defect with Integra dermal regeneration template (Tønseth et al. 2015)) followed by split-thickness skin grafting.
    3. This case provides a scenario in which early treatment may have reduced the need for a more morbid operation including partial resection of muscles with localized spread even without malignant transformation. Early surgical excision should be considered not only for presence of high-risk phenotypical features concerning for development of malignant transformation but also for likelihood of improved outcomes including morbidity of delayed excision, improved cosmetic result, and quality of life.
12. Psychosocial ramifications of congenital melanocytic nevi in children (Schaffer 2015):
    1. Especially in patients with larger nevi and those located in visible sites such as the face.
    2. Children with large or giant CMN are more likely to suffer from anxiety, depression, and social problems.
    3. Patients and families facing psychological and medical issues related to congenital melanocytic nevi may benefit from counseling and internet support groups such as Nevus Network (www.nevusnetwork.org) and Nevus Outreach, Inc. (www.nevus.org).

Gilbert Syndrome

Contents

Gilbert syndrome is a benign hereditary condition of mildly (about 40–60%) impaired bilirubin glucuronidation, characterized by intermittent unconjugated hyperbilirubinemia in the absence of hepatocellular disease or hemolysis (Fretzayas et al. 2012). It is the most common inherited disorder of bilirubin glucuronidation.

Synonyms and Related Disorders

Constitutional hepatic dysfunction; Familial nonhemolytic jaundice; Hyperbilirubinemia I; Hyperbilirubinemia, Gilbert type; Meulengracht disease

Genetics/Basic Defects

1. Generally considered as an autosomal recessive disorder (Chowdhury et al. 2001).
2. Earlier reports suggested autosomal dominant inheritance (Foulk et al. 1959; Powell et al. 1967; Sleisenger et al. 1967).
3. The number of TA repeats within the promoter region of the *UGT1A1* (uridine diphosphoglucuronate-glucuronosyltransferase 1A1) gene (located at 2q37.1) ultimately influences the serum unconjugated bilirubin concentration, by reducing inducibility of the *UGT1A1* gene and therefore hepatic bilirubin conjugation and excretion (Bulmer et al. 2013).
4. Individuals with an increased number of TA repeats in the gene promoter for *UGT1A1* (usually >7 in both alleles) are often diagnosed with Gilbert's syndrome, which is defined by an individual having an unconjugated bilirubin concentration >1 mg/dL (>17.1 μM) (Strassburg 2008).
5. A number of polymorphisms in the promoter region of *UGT1A1* exist, including the UGT1A1⁄28 (7/7 TA repeats in each allele) that clearly elevate unconjugated bilirubin concentrations (Bosma et al. 1995).
6. The majority of studies confirm lowered circulating lipid concentrations in persons with higher bilirubin concentrations (Bulmer et al. 2013).

Clinical Features

1. Typically present during adolescence and more commonly diagnosed in males (Muraca and Fevery 1984).
2. Characterized by intermittent episodes of jaundice: may be triggered by dehydration, fasting,

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_273

intercurrent febrile illnesses, menstruation, physical exertion, stress, and overexertion (Fretzayas et al. 2012).
3. Hyperbilirubinemia: predominantly unconjugated.
4. Other than jaundice, most patients are typically asymptomatic.
5. Normal physical examination findings.
6. Differential diagnosis.
    1. Crigler-Najjar syndrome type I: total bilirubin levels from 20 to 45 mg/dL
    2. Crigler-Najjar syndrome type II: total bilirubin levels from 1 to 6 mg/dL

Diagnostic Investigations

1. Laboratory tests (Roy-Chowdhury et al. 2014)
    1. Unconjugated hyperbilirubinemia: total bilirubin levels usually <3 mg/dL
        1. Higher bilirubin concentration: triggering factors (fasting, hemolysis, intercurrent febrile illnesses, physical exertion, stress, and menses)
        2. Reduced bilirubin concentration (Ohkubo et al. 1981; Black and Sherlock 1970; Kutz et al. 1984)
            1. Administration of corticosteroids
            2. Administration of hepatic enzyme inducers such as phenobarbital and clofibrate
    2. A normal complete blood count, blood smear, and reticulocyte count
    3. Normal plasma aminotransferases and alkaline phosphatase concentrations
2. Molecular genetic analysis: demonstration of mutation in the *UGT1A1* gene

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Autosomal recessive: 25% risk
        2. Autosomal dominant: 50% risk if one parent is affected
    2. Patient's offspring
        1. Autosomal recessive: not increased unless the spouse is a carrier
        2. Autosomal dominant: 50% risk
2. Management
    1. No specific therapy required
    2. Most important aspect of the care of patients: recognition of the disorder and its benign nature

Fig. 1 The patient was evaluated for elevated unconjugated bilirubin levels and developmental delay. He had a history of neonatal jaundice which was getting worse. He was found to be homozygous for the A $(TA)_7TAA$ allele of *UGT1A1* gene and has the genotype known to be associated with Gilbert syndrome. The presence of elevated unconjugated bilirubin levels with this genotype in this patient suggests the diagnosis of Gilbert syndrome (Courtesy of Dr. Susanne Ursin)

Glucose-6-Phosphate Dehydrogenase Deficiency

Contents

Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common human enzyme defect, affecting more than 400 million people worldwide, especially in tropical Africa, the Middle East, tropical and subtropical Asia, some areas of the Mediterranean, and Papua New Guinea. The gene frequencies are estimated to be as high as 5–25% in these areas (Luzzatto et al. 2001).

Genetics/Basic Defects

1. Caused by mutations in the G6PD gene (mapped to Xq28 region) (Pai et al. 1980; Luzzatto 2006):
    1. About 140 mutations have been described.
    2. Most mutations are single missense point mutations, entailing single amino acid replacements in the G6PD protein.
    3. Few exceptions:
        1. Small deletions (of one to eight amino acids)
        2. Presence of two mutations (rather than one)
2. Inheritance:
    1. X-linked recessive in terms of clinical expression:
        1. Not truly recessive since heterozygous females can even develop severe hemolytic attacks
        2. Coexistence in female heterozygotes of two-cell populations, G6PD(+) and G6PD(−), secondary to X-chromosome inactivation (Davidson et al. 1963)
        3. Homozygous females not rare in many populations with high frequency of G6PD deficiency
    2. Codominant in terms of biochemical characteristics of electrophoretic variants segregating in a pedigree
3. Genetic heterogeneity (Beutler et al. 1991; Calabro et al. 1993; Luzzatto et al. 2001):
    1. Diverse biochemical characteristics:
        1. Presence of over 400 genetically distinct variants of G6PD
        2. Many allelic mutations in the G6PD gene causing these variants
        3. Presence of several structural mutants without enzyme deficiency
    2. Heterogeneous molecular characteristics (Beutler 1990, 1993):
        1. Some variants with different names proved to be identical.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_107

2. Some variants thought to be homogeneous proved to be heterogeneous.
3. Different mutations responsible for:
   1. Chronic hemolytic anemia: less common
   2. Episodic hemolysis: more frequently seen
4. Diverse clinical manifestations, to a large extent, explainable by the genetic heterogeneity (Beutler 1991).
5. Variants that are associated with nonspherocytic anemia are located either near the glucose-6-phosphate or the nicotinamide adenine dinucleotide phosphate (NADP) binding sites. Variants more distant from these sites are not associated with chronic hemolysis (Beutler et al. 1992).

4. Pathogenesis:
   1. G6PD:
      1. A central enzyme in the pentose phosphate shunt of glucose metabolism
      2. Catalyzes glucose-6-phosphate (G6P) to 6-phosphogluconic acid (6PG)
      3. Reduces nicotinamide adenine dinucleotide phosphate (NADP) to the reduced form of NADP (NADPH)
   2. NADPH: converts glutathione disulfide (GSSG) to reduced glutathione (GSH)
   3. Reduced glutathione GSH
      1. Inactivates hydrogen peroxides (H_2O_2)
      2. Protects protein sulfhydryl groups from oxidation
      3. Neutralizes agents that threaten to oxidize either hemoglobin or components of the red cell membrane
   4. In the absence of G6PD:
      1. Red cell membrane and hemoglobin damaged by oxidant exposure
      2. Leading to rapid hemolysis
5. Hemolysis secondary to inability of G6PD-deficient red cells to withstand the oxidative damage produced, directly or indirectly, by the triggering agents (Beutler 1991, 1994; Luzzatto et al. 2001):
   1. Drugs
   2. Infections
   3. Ingestion of fava beans with life-threatening manifestations especially favism in children (Luisada 1941; Kattamis et al. 1969)
6. G6PD deficiency conferring resistance against *Plasmodium falciparum* malaria based on (Luzzatto et al. 2001):
   1. Prevalence of G6PD deficiency and the past and present endemicity of *Plasmodium falciparum* malaria
   2. The high prevalence in malaria-endemic areas of G6PD mutants
   3. Heterozygote advantage

Clinical Features

1. History:
   1. Asymptomatic in the vast majority of G6PD-deficient individuals without being aware of their genetic abnormality
   2. No positive history of acute intravascular hemolytic crises without exposure to oxidant stress
   3. Neonatal jaundice/hyperbilirubinemia (Lopez and Cooperman 1971; Valaes 1994; Kaplan and Hammerman 1998; Kaplan et al. 1999)
   4. Chronic hemolytic anemia:
      1. An insidious decrease in hemoglobin
      2. Observed in certain variant enzymes
   5. Required a careful investigation to establish the history of exposure to inciting agents
2. Common clinical manifestations (Luzzatto et al. 2016):
   1. Neonatal jaundice: may cause permanent neurologic damage or death in some severe cases
   2. Episodes of acute hemolytic anemia:
      1. Drug-induced hemolysis
      2. Infection-induced hemolysis
      3. Favism: occurrence of acute hemolysis after ingestion of broad beans (*Vicia faba*)
      4. Chronic nonspherocytic hemolytic anemia

5. Associated with hemoglobinuria since red cell destruction in these acute hemolytic events is largely intravascular
6. Kernicterus (Carpentieri et al. 1974; Washington et al. 1995; De Gurrola et al. 2008)
7. Concomitance with a variety of clinical situations, including diabetic ketoacidosis, hypoglycemia, myocardial infarction with pericardial tamponade, and strenuous exercise

3. Symptoms and signs of acute hemolytic crisis:
   1. Headache
   2. Lethargy
   3. Pallor
   4. Jaundice
   5. Red, clear urine

3. Symptoms and signs of chronic hemolytic crisis:
   1. Pallor
   2. Jaundice
   3. Severe chronic hemolysis observed in a rare subset of G6PD-deficient patients

4. Drugs to be avoided by G6PD-deficient patients (Beutler 1996, 2008; Cappellini and Fiorelli 2008; Youngster et al. 2010; Luzzatto and Seneca 2014; Bubp et al. 2015):
   1. Diaminodiphenyl sulfone (dapsone)
   2. Flutamide (Eulexin)
   3. Furazolidone (Furoxone)
   4. Isobutyl nitrite
   5. Methylene blue
   6. Niridazole (Ambilhar)
   7. Nitrofurantoin (Furadantin)
   8. Phenazopyridine (Pyridium)
   9. Primaquine
   10. Rasburicase (Elitek)
   11. Sulfacetamide
   12. Sulfanilamide
   13. Sulfapyridine

5. Drugs to be used with caution in therapeutic doses for patients with G6PD deficiency (without nonspherocytic hemolytic anemia) (Beutler 1996, 2008; Cappellini and Fiorelli 2008; Youngster et al. 2010; Luzzatto and Seneca 2014; Bubp et al. 2015):
   1. Acetaminophen (Tylenol)
   2. Acetylsalicylic acid (aspirin)
   3. Antazoline (Antistine)
   4. Antipyrine
   5. Ascorbic acid (vitamin C): intravenous doses only reported
   6. Benzhexol (Artane)
   7. Chloramphenicol
   8. Chlorguanidine (proguanil, Paludrine)
   9. Chloroquine
   10. Colchicine
   11. Diphenhydramine (Benadryl)
   12. Glyburide (glibenclamide, DiaBeta, Glynase)
   13. Isoniazid
   14. L-Dopa
   15. Quinine
   16. Streptomycin
   17. Sulfacytine
   18. Sulfadiazine
   19. Sulfaguanidine
   20. Sulfamethoxazole (Gantanol)
   21. Sulfisoxazole (Gantrisin)
   22. Trimethoprim
   23. Tripelennamine (Pyribenzamine)
   24. Vitamin K

6. Types of G6PD deficiency (Segel et al. 2002):
   1. X-minus variety:
      1. Most common type seen in the USA
      2. An X-linked condition primarily affecting African-American males
      3. Females affected if homozygous for G6PD deficiency or if there's unfavorable random X-chromosome inactivation resulting in a large proportion of deficient red cells
   2. Mediterranean variety:
      1. Develops severe hemolysis when exposed to oxidant drugs
      2. Characterized by enzyme deficiency in red cells of all ages, including reticulocytes, and shows no evidence of spontaneous recovery
   3. Other varieties:
      1. Develops chronic hemolytic anemia without external oxidant exposure

2. Susceptible to develop cholelithiasis because of heightened bilirubin turnover
3. Complaints of abdominal pain or fatty food intolerance

Diagnostic Investigations

1. Newborn screening (Bernardo and Nock 2014):
   1. Useful to providers in providing excellent care for newborns.
   2. Dangerous complications of neonatal hyperbilirubinemia are preventable, and evidence supports the use of newborn G6PD screening programs in reducing such complications as hospital readmissions and kernicterus.
2. Acute hemolysis (Segel et al. 2002):
   1. Precipitous anemia:
      1. A fall in hemoglobin
      2. A fall in hematocrit
      3. Subsequent rise in reticulocyte percentage
   2. Elevated bilirubin, particularly the indirect fraction
   3. Reduced haptoglobin as it binds free hemoglobin and is removed from the circulation
   4. Hemoglobinemia +/− hemoglobinuria
3. Diagnosis of G6PD deficiency (Frank 2005; Kaplan and Hammerman 2010):
   1. Rapid fluorescent screening spot test detecting the generation of NADPH (reduced NADP) from NADP:
      1. The test is positive if the blood spot fails to fluoresce under ultraviolet light (NADPH fluoresces intensely when activated by long-wave UV light; fluorescence under UV light source is normal and indicates G6PD activity).
      2. Useful in identifying totally deficient individuals with <20% residual activity.
      3. Could erroneously classify as normal males and females with partial deficiency (20–60% residual enzyme activity).
      4. Not helpful in identifying most heterozygotes with intermediate levels of G6PD activity.
   2. Quantitative analysis of G6PD activity by assessing NADPH formation spectrophotometrically:
      1. G6PD-deficient male hemizygotes and female homozygotes: usually <50% normal activity, frequently <20%, and often undetectable (Luzzatto 2006).
      2. Heterozygous females may have intermediate activity, but this may range from normal to deficient, and many female heterozygotes with partial enzyme activity will not be detected.
      3. Falsely obtaining normal test results during or immediately after an acute hemolytic event.
   3. In field research, where quick screening of a large number of patients is needed, other tests have been used; however, they require definitive testing to confirm an abnormal result (Iwai et al. 2003; Jalloh et al. 2004).
   4. Tests based on polymerase chain reaction detect specific mutations and are used for:
      1. Population screening
      2. Family studies
      3. Prenatal diagnosis
4. Direct DNA analysis
   1. Sequence analysis (analysis of the entire coding region)
   2. Targeted mutation analysis

Genetic Counseling

1. Recurrence risk:
   1. Patient's sib (if the mother is a carrier)
      1. 50% of male siblings affected
      2. 50% of female siblings carriers (some female heterozygotes may be affected)
   2. Patient's offspring
      1. 100% of female offspring carriers (some female heterozygotes may be affected)
      2. 50% of female offspring affected (homozygotes) if the spouse is a carrier
      3. Male offspring not affected unless the spouse is a carrier

2. Prenatal diagnosis: may be possible in at-risk families, provided disease-causing mutations have been identified previously
3. Management (Luzzatto et al. 2016):
    1. Prevent or remove precipitating agents.
    2. Control infection.
    3. Phototherapy for neonatal hyperbilirubinemia.
    4. Supportive transfusion.
    5. Exchange transfusion to prevent kernicterus.
    6. Hemodialysis may be necessary if there is acute renal failure.
    7. In adults, the most important measure is to provide fluids to prevent hemodynamic shock that entails the threat of acute renal failure.
    8. In children, more often than in adults, blood transfusion may be indicated; in a child with favism, it may be lifesaving.
    9. Fortunately, once acute hemolytic anemia is overcome, full recovery without sequelae is the rule rather than the exception.

Glycogen Storage Disease, Type 2

Contents

Type II glycogen storage disease (GSD), also known as Pompe disease, is an autosomal recessive disorder caused by deficiency of the lysosomal enzyme acid α-glucosidase (acid maltase). Incidence is estimated at 1 in 50,000 in most populations, implying a carrier frequency of 1 in 100 (Kleijer et al. 1995).

Synonyms and Related Disorders

Acid maltase deficiency; Glycogenosis type II; Pompe disease

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Kleijer et al. 1995)
2. Caused by deficiency of acid maltase (acid α-glucosidase), leading to the pathological accumulation of glycogen in lysosomes, predominantly in the skeletal muscle, heart, and liver
    1. Virtual absence of α-glucosidase activity in infantile form (Pompe disease)
    2. Considerable residual enzyme activity in the great majority of patients with the adolescent or adult form (Mehler and DiMauro 1977)
3. Identification of various mutations in the α-glucosidase (*GAA*) gene (mapped on 17q23-25), leading to the disease
    1. Types of mutations
        1. Point mutations
        2. Deletions
        3. Insertions
    2. Compound heterozygotes in most patients
    3. Relatively common mutations among European patients
        1. The single base pair deletion ΔT525 causing premature termination at nucleotide 658–660
        2. Deletion of exon 18
4. Genotype-phenotype correlation
    1. The nature of the mutation is generally considered a good predictor of a clinical phenotype.
    2. Homozygosity for either exon 18 or ΔT525 mutation or compound heterozygosity for these two mutations results in a severe infantile form of GSDII (Ausems et al. 1996)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_108

3. Combination of either of these mutations with leaky IVS1t-13 g mutation results in the majority of cases in the adult phenotype
4. A splicing defect (IVS6 t-22 g) results in a removal of exon 6, and insertion of 21 nucleotides of the intronic sequence defined the juvenile phenotype in a compound heterozygote patient who carries a silent second allele. Homozygosity for the same splicing defect resulted in a milder adult phenotype
5. Growing number of cases in recent years where the genotype does not match the phenotype (Laforêt et al. 2000)

5. Pathophysiology (American Association of Neuromuscular and Electrodiagnostic Medicine 2009)
   1. Mutations in both copies of the GAA gene lead to varying degrees of GAA deficiency (Kishnani and Howell 2004)
      1. Infantile-onset form: either totally or virtually absent acid α-glucosidase enzyme activity in skin fibroblasts
      2. Late-onset form: some residual enzyme activity (1 ~ 40%) in skin fibroblasts in most affected children and adults
   2. Primary defect
      1. Progressive intralysosomal storage of glycogen
      2. Recognition of the role of dysfunctional autophagy in the disease process

Clinical Features

1. Infantile form (Slonim et al. 2000; Raben et al. 2002).
   1. Classical infantile form
      1. Onset within first weeks or months of life or even at birth
      2. Characterized by complete or near complete deficiency of α-glucosidase
      3. Poor feeding (difficulty sucking and swallowing) and failure to thrive, early complaints
      4. Cyanosis and attacks of dyspnea beginning early
      5. Frequent respiratory infections
      6. Delayed motor milestones
      7. Cardiomyopathy (hypertrophic) (~95%): the important finding suggesting diagnosis (Noori et al. 2002)
         1. Marked cardiomegaly
         2. Congestive heart failure
      8. Striking hypotonia
         1. Increasing generalized weakness
         2. Affecting bulbar musculature
         3. Without muscle atrophy
      9. Macroglossia (~62%)
      10. Moderate hepatomegaly (~82%)
      11. Calf hypertrophy
      12. Depressed or absent reflexes due to glycogen accumulation in spinal motor neurons
      13. Impaired alertness
      14. Accumulation of glycogen in the lysosomes rapidly disrupts cellular function in the most severe form
          1. Rapidly disrupts cellular function
          2. Leading to intractable cardiorespiratory failure
          3. Most patients die by 1 year of age
   2. Nonclassical infantile form
      1. Onset in infancy
      2. Slower progression
      3. Involving primarily skeletal muscle with minimal or no cardiac involvement (without cardiomegaly)
      4. May present with delayed motor milestones if onset is in early preschool age
      5. May present with a decrease in motor skills if onset is later in childhood
      6. Usually demonstrates progressive proximal weakness with different degrees of respiratory muscle involvement
      7. Presence of respiratory complications often contributing to early death
2. Juvenile form
   1. Juvenile onset (first decade)
   2. Characterized by presence of reduced but residual α-glucosidase activity
   3. Clinical boundaries between juvenile and adult forms not precisely defined
   4. Clinical manifestations

1. Predominantly skeletal muscle weakness with respiratory muscle involvement and mild hepatomegaly
2. Cardiac involvement: absent or mild
    1. Arrhythmia
    2. Mild ventricular dysfunction
3. Death results from respiratory failure after a course lasting several years

3. Adult form
    1. Onset: second to sixth decades
    2. Characterized by higher levels of residual α-glucosidase activity
    3. Slower progression of the skeletal muscle weakness
        1. Upper arms
        2. Pectoral muscles
        3. Asymmetry of affected muscle groups
        4. Limb-girdle weakness, a prominent finding
        5. Respiratory muscle involvement (weakness of the diaphragm) (about 33%): a hallmark of the disease
        6. Little or no cardiac abnormality
    4. Acute respiratory failure
4. Differential diagnosis of infantile-onset Pompe disease (with respect to shared signs and symptoms) (ACMG Work Group on Management of Pompe Disease et al. 2006; Kishnani et al. 2006)
    1. Acute Werdnig-Hoffman disease (spinal muscular atrophy I)
        1. Hypotonia
        2. Progressive proximal myopathy
        3. Absent reflexes
    2. Hypothyroidism
        1. Hypotonia
        2. Macroglossia
    3. Endocardial fibroelastosis
        1. Breathlessness
        2. Feeding difficulties
        3. Cardiomegaly
        4. Heart failure
    4. Myocarditis: cardiomegaly
    5. Congenital muscular dystrophy
        1. Severe hypotonia
        2. Severe muscle weakness
    6. Glycogen storage diseases: IIIa (Debrancher deficiency/Cori or Forbes disease) and IV (branching enzyme deficiency/Anderson disease)
        1. Cardiomegaly
        2. Myopathy
        3. Elevated creatine kinase (CK)
    7. Mitochondrial/respiratory chain disorders
        1. Hepatomegaly
        2. Muscle weakness
        3. Cardiomegaly
        4. Elevated creatine kinase (CK)
    8. Danon disease
        1. Cardiomegaly
        2. Cardiomyopathy
        3. Myopathy
        4. Vacuolar glycogen storage
    9. Idiopathic hypertrophic cardiomyopathy: biventricular hypertrophy
    10. Peroxisomal disorders
        1. Hypotonia
        2. Hepatomegaly
5. Differential diagnosis of late-onset Pompe disease (ACMG Work Group on Management of Pompe Disease et al. 2006; Kishnani et al. 2006; Katzin and Amato 2008; American Association of Neuromuscular and Electrodiagnostic Medicine (AANEM) 2009; Dubrovsky et al. 2013): Heterogeneity of presentation can mimic other neuromuscular disorders, and the differential diagnosis includes a broad range of myopathies as well as motor neuron and neuromuscular junction disorders
    1. Dystrophies
        1. Limb-girdle muscular dystrophy: progressive muscle weakness in the pelvis, legs, and shoulders (shared signs and symptoms)
        2. Dystrophinopathies (Duchenne and Becker muscular dystrophy): progressive proximal muscle weakness, respiratory impairment, difficulty walking, and elevated creatine kinase (CK) (shared signs and symptoms)
        3. Myofibrillar myopathy
        4. Myotonic dystrophy type 2
        5. Scapuloperoneal syndromes: progressive muscle weakness behind the knees and around the shoulder blades (shared signs and symptoms)

6. Danon disease: hypertrophic cardiomyopathy, skeletal muscle myopathy, and vacuolar glycogen storage (shared signs and symptoms)
7. X-linked myopathy with excessive autophagy
8. Facioscapulohumeral muscular dystrophy
9. Rigid spine syndrome: spinal rigidity and lower back pain (shared signs and symptoms)

2. Inflammatory myopathies
   1. Polymyositis: unexplained muscle weakness (shared signs and symptoms)
   2. Inclusion body myositis
3. Congenital myopathies
   1. Nemaline rod myopathy
   2. Central core and multiminicore myopathy
   3. Centronuclear myopathy
   4. Hyaline body myopathy
   5. Other congenital myopathies
4. Other metabolic myopathies
   1. Glycogen storage diseases (debranching enzyme deficiency (IIIa), branching enzyme deficiency (IV), McArdle disease (V), and muscle phosphofructokinase deficiency (VII)): hypotonia, hepatomegaly, muscle weakness, and elevated creatine kinase (CK)
   2. Mitochondrial myopathy: hypotonia, hyperreflexia, hepatomegaly, and some forms with hypertrophic cardiomyopathy, muscle weakness, and elevated creatine kinase (CK)
   3. Lipid disorder myopathies
5. Motor neuron disorders
   1. Spinal muscular atrophy types II and III: asymmetrical muscle weakness and atrophy of voluntary muscles (shared signs and symptoms)
   2. Kennedy disease
   3. Amyotrophic lateral sclerosis
6. Neuromuscular junction disorders
   1. Myasthenia gravis: generalized muscle weakness (shared signs and symptoms)
   2. Congenital myasthenic syndromes
   3. Lambert-Eaton syndrome
7. Peripheral neuropathy
   1. Hereditary neuropathies
   2. Chronic inflammatory demyelinating polyneuropathy
   3. Amyloid neuropathy
8. Rheumatoid arthritis: stiffness/pain upon exertion (shared signs and symptoms)

Diagnostic Investigations

1. Elevated serum creatine kinase in most patients (Ausems et al. 1999)
2. Elevated serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactic dehydrogenase (LDH)
3. Radiography: tremendous cardiomegaly
4. EKG: can readily observe the signs of cardiac glycogenosis (indicators of relative myocardial ischemia)
   1. Very large QRS complex in all leads
   2. Short P-R interval: pathognomonic of infantile Pompe disease
   3. Left axis deviation or absence of the normal right axis deviation (presence of biventricular hypertrophy)
   4. Inverted T wave
   5. ST segment depression
5. Echocardiography (De Dominicis et al. 1991): biventricular hypertrophy without outflow obstruction
6. EMG
   1. Infantile form: nonspecific myopathic changes or normal finding
   2. Adult form
      1. Pseudomyotonia
      2. High-frequency discharges
      3. Fibrillations
7. Muscle biopsy
   1. Presence of vacuoles that stain positive for glycogen (PAS) as well as for the lysosomal enzyme acid phosphatase
   2. A typical lacework appearance of histologic sections from the myocardium resulting from deposition of stored material in the cardiac fibrils
   3. Electron microscopy

1. Membrane-bound glycogen
2. Glycogen accumulation within the lysosome

4. The muscle biopsy, in spite of its shortcomings, allowed us to recognize an underreported, ERT-resistant pathology in late-onset Pompe disease (LOPD). Numerous lysosomes and autolysosomes loaded with lipofuscin appear to be a hallmark of LOPD skeletal muscle. Lipofuscin accumulation – a result of inefficient lysosomal degradation – may in turn exacerbate both lysosomal and autophagic abnormalities (Feeney et al. 2014)

8. Histology: glycogen accumulation
   1. Infantile form
      1. Muscle
      2. Liver
      3. Motor nuclei in the brain stem
      4. Anterior horn cells of the spinal cord
      5. Placenta (Bendon and Hug 1985)
         1. Amniotic storage cells identified and shown histochemically to contain glycogen
         2. Pathognomonic accumulation of lysosomal glycogen in the placenta by electron microscopy in the second trimester
         3. Confirmation of the prenatal diagnosis made by enzyme assay
      6. Other tissues
         1. Endothelial cells
         2. Kidneys
         3. Skin
   2. Adult form: not seen in the heart, liver, or brain
9. Lung MRI (Wens et al. 2015)
   1. An innovative tool to visualize diaphragmatic dynamics in Pompe patients and to study chest wall and diaphragmatic movements
   2. Diaphragmatic displacement may be severely disturbed in patients with Pompe disease
10. Cardiac MR imaging: hypertrophy of right and left ventricles and the interventricular septum with an irregular inhomogeneous appearance of the myocardium (Boxer et al. 1986)
11. Brain MR imaging
    1. T1-weighted MR images of the brain revealed multifocal dural thickening that enhanced after intravenous gadolinium administration. Open opercula and focal pachygyria over bilateral perisylvian regions also were noted (Lee et al. 1996)
    2. Bright tongue sign (Karam 2016)
       1. Abnormal diffuse T1 hyperintensity of the tongue musculature in an adult patient with Pompe disease
       2. Bright tongue sign is well known in patients with bulbar amyotrophic lateral sclerosis but also can be seen in other neuropathies or myopathies that can affect the tongue muscle
12. A CT angiography or an MR angiography: recommended, in late-onset Pompe disease patients, for early detection of cerebrovascular malformations as they could lead to life-threatening events such as subarachnoid hemorrhage or brainstem compression (Montagnese et al. 2016)
13. Diagnostic enzymatic test: deficient acid maltase in leukocytes, muscle, and skin fibroblasts
14. DNA analysis by targeted mutation analysis
15. Newborn screening by determining the total α-glucosidase in plasma or dried blood spots (Umapathysivam et al. 2001; Chien et al. 2009)
16. Heterozygote detection
    1. Reduced α-glucosidase activity: not reliable
    2. DNA-based detection more appropriate and definitive within families
17. Western blot analysis of cultured skin fibroblast (Bali et al. 2015)
    1. Gold standard for determining cross-reactive immunological material (CRIM) status
    2. CRIM status: an important prognostic factor in patients with infantile Pompe disease (IPD) being treated with enzyme replacement therapy

18. Next-generation sequencing: used as a first-tier test in patients with suspected muscle disorders of undetermined etiology, which could further increase overall diagnosis of muscle conditions and potentially reduce diagnostic delay (Lévesque et al. 2016)
19. Recommendations for diagnostic tests in Pompe disease in adults (Pompe Disease Diagnostic Working Group et al. 2008; Llerena Junior et al. 2016)
    1. Screening test: DBS ("dried blood spot") on filter paper to perform enzymatic activity analysis of acid α-glucosidase (GAA)
    2. "Gold standard" diagnostic test: in fibroblasts or muscle tissue for acid α-glucosidase (GAA) enzymatic assay
    3. Diagnostic test: molecular analysis of the *GAA* gene
    4. Diagnostic test in DBS: GAA activity in lymphocytes and/or leucocytes

Genetic Counseling

1. Recurrence risk (Llerena Junior et al. 2016)
    1. Parents of individuals with Pompe disease (PD): healthy obligatory heterozygotes
    2. The diagnosis of an individual with PD justifies the active search of the disease among his/her siblings. Asymptomatic or mildly symptomatic cases are often identified due to the intrafamilial clinical variability observed between two siblings with PD
    3. Patient's sib: 25%
    4. Patient's offspring: not increased unless the spouse is a carrier in which cases 50% of offspring will be affected and 50% will be carriers
2. Prenatal diagnosis (Phupong et al. 2005)
    1. Rapid prenatal diagnosis by electron microscopy of uncultured amniocytes (Hug et al. 1984)
    2. Deficient activity of lysosomal acid α-glucosidase in cultured amniocytes or CVS
    3. Electron microscopic study of chorionic villus biopsies for the pregnancy at risk: fibrocytes with typical vacuoles filled with glycogen
    4. Mutation analysis on amniocytes or CVS: 100% reliable prediction of the genetic status of the fetus, including heterozygosity (Kleijer et al. 1995)
3. Management
    1. Supportive therapy to manage symptoms and minimize complications whenever possible
        1. Respiratory therapy
        2. Physical therapy (Case and Kishnani 2006)
        3. Dietary therapy: L-alanine supplementation (Bodamer et al. 2000, 2002)
        4. Infection prevention
        5. A high-protein diet to improve muscle function
        6. Ventilator support
    2. Administration of purified α-glucosidase not effective
    3. Bone marrow transplantation (Hug 1986; Watson et al. 1986) presumably to provide enzyme secreted by the normal cells continuously
        1. Results not promising
        2. Transitory engraftment of the haploidentical transplant
        3. No enzyme detected in muscle cells
        4. Patient died of complications of the transplant
    4. Enzyme replacement therapy (Kikuchi et al. 1998; Amalfitano et al. 1999; Chen and Amalfitano 2000)
        1. ERT with recombinant human α-glucosidase from rabbit milk in Pompe patients (Van den Hout et al. 2000, 2001)
            1. Intended to directly address the underlying metabolic defect via intravenous infusions of rhGAA enzyme
            2. The enzyme generally well tolerated
            3. Normalization of muscle α-glucosidase activity
            4. Improved tissue morphology and motor and cardiac function
            5. Significantly decreased left ventricular mass index

6. Recommend early treatment (before irreversible damage) and follow-up of long-term effects
7. Anti-rhGAA antibody may limit the efficacy of the treatment
8. Extensive muscle damage may be unrefractive to therapy

2. Infantile-onset Pompe disease (Amalfitano et al. 2001; Klinge et al. 2005; Kishnani et al. 2006, 2007)
   1. Significantly prolongs survival, decreases cardiomegaly, and improves cardiac and skeletal muscle function
   2. An emerging phenotype characterized by progressive weakness and decreased motor function has been identified in patients with infantile-onset Pompe disease that initially responded well to enzyme replacement therapy with alglucosidase alfa (Case et al. 2012, 2015; Prater et al. 2012)
   3. Long-term prognosis of patients with infantile-onset Pompe disease diagnosed by newborn screening and treated with rhGAA since birth (Chien et al. 2015): experienced long-term survival without requiring ventilation and nearly normal development but presented with residual myopathy and other manifestations such as ptosis and speech disorders
3. Late-onset Pompe disease (Bernstein et al. 2010): Gastrointestinal symptoms resolved within the first 6 months of ERT with rhGAA. Patients gained weight and remain symptom free, two for over 4 years

5. Gene therapy aiming at providing a permanent endogenous source of enzyme for the affected tissues: not available currently (Poenaru 2000)

Fig. 1 An infant with massive cardiomegaly and hypotonia. Diagnosis of Pompe disease was confirmed by deficient acid maltase in the leukocytes

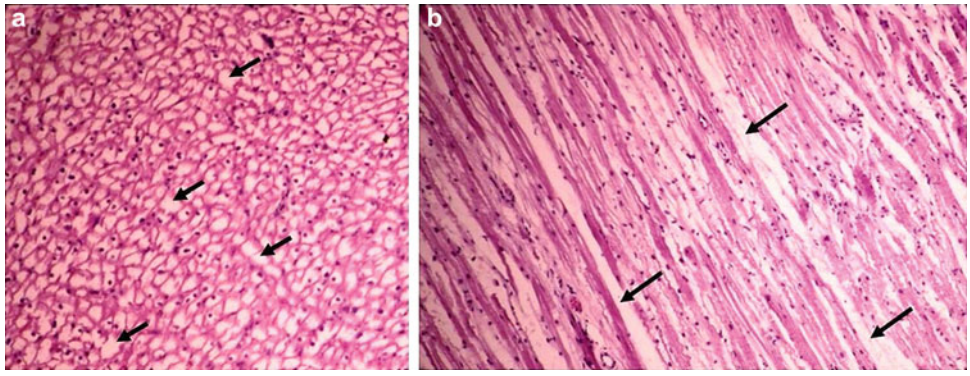

Fig. 2 (**a**, **b**) Different patient with Pompe disease. (**a**) Myocardium. Note numerous vacuolated fibers (*arrows*) due to glycogen accumulation. HE, ×40. (**b**) Smooth muscle from GI tract. Note clear areas represent glycogen deposition (*arrows*)

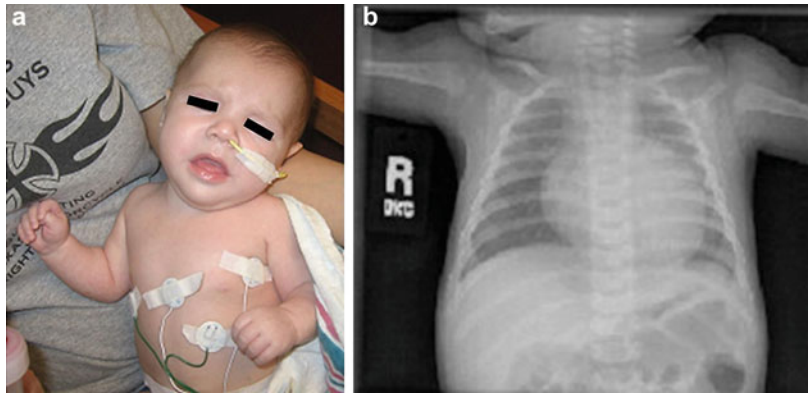

Fig. 3 (**a**, **b**) A 23-month-old boy (**a**) was seen because of respiratory distress and heart failure. A chest X-ray (**b**) showed a large globular-shaped heart. An echocardiogram showed a hypertrophic cardiomyopathy. He was noted to be hypotonic and had an enlarged liver. Muscle biopsy showed excessive glycogen storage with glycogen content 5.6 % (control: 0.94 ± 0.55 % wet weight). Muscle α-glucosidase was deficient (0.01; control: 0.42 ± 0.2 micromol/min/g of tissue). Muscle neutral α-glucosidase was 0.05 (control: 0.12 ± 0.6 micromol/min/g of tissue). Blood acid α-glucosidase was 1.3 (control: 10.0–49.0 pmol/punch/h). Blood neutral α-glucosidase was 52.3 (control: 23.8–132.6 pmol/punch/h). Urine Hex4 was 34.1 (control for <6 month: <19 nmol/mol creatinine). Mutation analysis revealed c.1846 G > A (exon 13) and c.2608 C > A (exon 18). The c.2608CA mutation is a nonsense mutation that results in a premature termination codon, a reported disease causing mutation. The c.1846 G > A mutation has not been previously reported as a mutation causing Pompe disease or a known polymorphism but has been seen once in the Duke University laboratory, in the homozygous state as the only mutation in a patient with Pompe disease. This patient received one dose of enzyme replacement therapy and tolerated his first dose of Myozyme well

Goldenhar Syndrome

Contents

In 1952, Goldenhar (1952) described a pair of monozygotic twins discordant for hemifacial microsomia, mandibular hypoplasia, auricular malformations, and epibulbar dermoids. Gorlin et al. (1963) later in 1963 coined the term "oculoauriculovertebral dysplasia" to describe patients with mandibular hypoplasia, microtia, epibulbar dermoids, and vertebral anomalies. The presence of vertebral anomalies and epibulbar dermoids delineates the so-called Goldenhar syndrome. Oculoauriculovertebral spectrum (OAVS) is a relatively common disorder affecting approximately 1 in 5,600 live births.

Synonyms and Related Disorders

Hemifacial microsomia; Oculoauriculovertebral dysplasia/spectrum

Genetics/Basic Defects

1. The term, "oculoauriculovertebral dysplasia spectrum," suggested to represent an etiologically diverse spectrum of congenital anomalies
    1. Oculoauriculovertebral dysplasia
    2. Facioauriculovertebral syndrome (Goldenhar-Gorlin syndrome)
    3. Hemifacial microsomia (second most common facial anomaly, second only to cleft lip and palate) (Sze et al. 2002)
    4. Hemifacial microtia
    5. Otomandibular dysostosis
    6. Original Goldenhar syndrome
    7. Goldenhar-Gorlin syndrome
    8. Anomalies of the first and second branchial arches (Converse et al. 1973)
2. Congenital anomalies
    1. Usually unilateral
    2. Primarily right sided
    3. More common in monozygous twins usually with one affected (Boles et al. 1987)
3. Causes: unknown but likely heterogeneous (Setzer et al. 1981; Burck 1983; Cohen et al. 1989; Kelberman et al. 2001)
    1. Usually sporadic occurrence
    2. Maternal teratogenic exposures
        1. Retinoic acid
        2. Thalidomide
        3. Primidone (Gastavson and Chen 1985)
        4. Cocaine (Lessick et al. 1991)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_109

3. Maternal diabetes (Ewart-Toland et al. 2000)
4. Discordant occurrence in monozygotic twins: arising from a disturbance of blastogenesis leading to malformations
5. Autosomal dominant inheritance (Guizar-Vazquez et al. 1978; Zankl and Zang 1979; Godel et al. 1982; Regenbogen et al. 1982; Sanchez-Corona et al. 1982; Taysi et al. 1983; Robinow et al. 1986; Oliveira et al. 1989; Orstavik et al. 1990; Stoll et al. 1998; Gupta and Patton 1995; Tasse et al. 2007; Vendramini-Pittoli and Kokitsu-Nakata 2009)
    1. A report of a family with clinical diagnosis of OAVS, autosomal dominant inheritance pattern, and detection of a 14q23.1 duplication of 1.34 Mb in size which segregates with the phenotype (Ballesta-Martínez et al. 2013)
    2. This region contains *OTX2*, which is involved in the development of the forebrain, eyes, and ears, and appears to be a good candidate gene for OAVS
    3. *OTX2* duplication: implicated in hemifacial microsomia (Zielinski et al. 2014)
6. Autosomal recessive inheritance (Ellwood et al. 1968; Konigsmark et al. 1972; Schmid et al. 1985; Strisciuglio et al. 1986)
7. Associated chromosome abnormalities (Beleza-Meireles et al. 2014)

    23. Dup(22)(q11.1q11.21), Del(22)(q11.21q11.22)
    24. Dup(Yp–q11.221), Del(Y)(q11.222–q12)

25. Amplification Xp22.33
26. Trisomy X

4. Pathogenesis: unknown but likely heterogeneous
   1. Interference with vascular supply and focal hemorrhage in the developing first and second branchial arch region
   2. Impaired interaction of cranial neural crest cells with branchial arch mesenchyme
   3. A disorder of blastogenesis
5. Hypothesis: candidate genes for OAVS, particularly in familial cases (Forest-Potts and Sadler 1997)
   1. Homeobox genes, especially of the MSX class
      1. *Msx* critical for the differentiation of first branchial arch ectoderm-mesenchyme leading to various craniofacial structures
      2. Strongly expressed in cephalic neural crest cells prior to migration of the cells that contribute extensively to craniofacial development
   2. Encompasses previous partial pathogenetic explanations for OAVS, including neurocristopathy and developmental field defects, and represents a unifying concept regarding the wide spectrum of involvement in OAVS
   3. Mutations that result in partial loss of function of these genes could explain incomplete penetrance and clinical variability occurring in individuals with different genetic backgrounds.

Clinical Features

1. Broad phenotypic spectrum (Rollnick and Kaye 1983)
2. Major clinical features (Alfi et al. 2014)
   1. Ocular manifestations (Baum and Feingold 1973; Mansour et al. 1985)
      1. Epibulbar dermoids or lipodermoid (Goldenhar syndrome)
      2. Unilateral microphthalmia
      3. Upper eyelid coloboma
      4. Strabismus
      5. Diminished visual acuity
      6. Tilted optic disk
      7. Optic nerve hypoplasia (Margolis et al. 1984)
      8. Tortuous retinal vessels
      9. Macular hypoplasia and heterotropia
      10. Microphthalmia
      11. Anophthalmia
   2. Ear anomalies (Phelps et al. 1983; Rollnick et al. 1987)
      1. Microtia or absent external ear (Bennum et al. 1985)
      2. Preauricular tags and/or pits
      3. Middle ear anomaly
      4. Inner ear defects
      5. Variable deafness (Scholtz et al. 2001)
   3. Nasal features
      1. Prominent nasal dorsum
      2. Choanal atresia or stenosis
   4. Oral features
      1. Macrostomia: clefting of the oral commissure
      2. Cleft palate ± lip
      3. Malocclusion: cross bite, open bite, asymmetry, occlusal plane with ipsilateral shortening
   5. Vertebral defects
      1. Hemivertebrae
      2. Hypoplasia of vertebrae, usually cervical (Gosain et al. 1994; Healey et al. 2002)
      3. Abnormal ribs
   6. Hemifacial microsomia (Thomas 1980)
      1. Unilateral microtia
      2. Ipsilateral hypoplasia of malar, maxillary, and mandibular region, especially temporomandibular joint
      3. Ipsilateral macrostomia
      4. Ipsilateral hypoplasia of the facial musculature
      5. A wide variety of facial nerve presentations ranging from mild weakness of a single branch of the facial nerve to full paralysis of all facial nerve branches (Cline et al. 2014)
3. Other associated features
   1. Craniofacial features
      1. Cranial nerve (VII) palsy
      2. Orbital hypoplasia
      3. Malfunction of soft palate

4. Decreased parotid secretion
5. Anomalies in function or structure of the tongue
6. Low scalp hairline
7. Branchial cleft remnants in anterior-lateral neck
8. Mandibular hypoplasia (Rollnick et al. 1987)
9. Muscular hypoplasia of muscles of mastication
10. Absent, hypoplastic, or deformed temporomandibular joint

2. CNS anomalies (Wilson 1983; Schrander-Stumpel et al. 1992)
   1. Hydrocephaly (Kumar et al. 2000)
   2. Microcephaly
   3. Plagiocephaly
   4. Frontal/occipital encephalocele
   5. Cranial bifidum
   6. Lipoma
   7. Dermoid cyst
   8. Arnold-Chiari malformation
   9. Lissencephaly
   10. Holoprosencephaly/arhinencephaly
   11. Arachnoid cyst
3. Congenital heart diseases (5–58% depending on ascertainment of cases) (Friedman and Caracal 1974; Pierpont et al. 1982; Morrison et al. 1992; Kumar et al. 1993; Nakajima et al. 1998)
   1. Tetralogy of Fallot (with or without right aortic arch) and VSD (account for over half of the cases with congenital heart diseases)
   2. Pulmonary stenosis
   3. Patent ductus arteriosus
   4. Coarctation of aorta
   5. Total atrioventricular canal defect
   6. ASD
   7. Transposition of great vessel
   8. Rare isolation of the left innominate artery infradiaphragmatic total anomalous pulmonary venous connection
   9. Wolf-Parkinson-White syndrome
4. Respiratory tract anomalies (McCarthy et al. 2001)
   1. Tracheolaryngeal anomaly (Andrews and Shott 1992; Sutphen et al. 1995)
   2. Incomplete lobulation of the lung
   3. Pulmonary hypoplasia to aplasia
   4. Sequestration
   5. Focal tracheomalacia due to extrinsic vascular compression
   6. Obstructive sleep apnea
5. Gastrointestinal anomalies (Mandelberg et al. 1985)
   1. Esophageal atresia
   2. Tracheoesophageal fistula
   3. Diaphragmatic hernia
   4. Imperforate anus
6. Renal anomalies
   1. Renal agenesis
   2. Hydronephrosis
   3. Ectopic kidney
   4. Double ureter
   5. Hydroureter
7. Prenatal growth deficiency
8. Normal intelligence in most cases

4. Differential diagnosis (Beleza-Meireles et al. 2014)
   1. VATER (VACTERL) association (please see chapter "▶ VATER (VACTERL) Association")
   2. Nager syndrome (please see chapter "▶ Nager Acrofacial Dysostosis")
   3. Treacher Collins syndrome (please see chapter "▶ Treacher-Collins Syndrome")
   4. Townes–Brocks syndrome
      1. Imperforate anus
      2. Dysplastic ears (overfolded superior helices and preauricular tags) frequently associated with sensorineural and/or conductive hearing impairment
      3. Thumb malformations: triphalangeal thumbs, duplication of the thumb, preaxial polydactyly or hypoplasia of the thumbs
      4. Renal impairment with or without structural abnormalities
   5. CHARGE syndrome (please see chapter "▶ CHARGE Syndrome")
   6. Branchio-oto-renal spectrum disorders (branchio-oto-renal and branchio-otic syndromes)
      1. Malformations of the outer, middle, and inner ear

2. Conductive, sensorineural, or mixed hearing impairment
3. Branchial fistulae and cysts
4. Renal malformations ranging from mild renal hypoplasia to bilateral renal agenesis
5. Branchio-otic syndrome has the same features as branchio-oto-renal syndrome but without renal involvement.

7. Mandibulofacial dysostosis, Guion-Almeida type
   1. Oto-facial abnormalities (acrofacial dysostosis)
   2. Esophageal atresia
   3. Thumb anomalies
   4. Intellectual disability
   5. Zygomatic anomalies
   6. Microcephaly

Diagnostic Investigations

1. Radiography (Rees et al. 1972)
   1. Platybasia/occipitalization of atlas
   2. Hypoplasia of the mandibular-maxillary bones
   3. Fused vertebrae, especially cervical
   4. Segmentation anomaly of the vertebra
   5. Hemivertebrae
   6. Klippel-Feil anomaly
   7. Rib anomalies
   8. Aplasia of radius/thumb
   9. Spina bifida
2. Neuroradiological study (Marano et al. 2015): show striking common involvement of cranial nerves among patients with oculo-auriculo-vertebral spectrum, especially among those presenting with the more severe phenotype (Goldenhar syndrome)
   1. MR imaging: abnormal cranial nerves ranging from hypoplasia/aplasia to protean morphologic abnormalities
   2. CT imaging: isolated hypoplasia of the foramen ovale and/or of the inferior alveolar nerve bone canal, consistent with trigeminal branch hypo-/aplasia, thus disclosing also a possible distal cranial nerve involvement
3. Echocardiography: variable and nonspecific findings because cardiovascular abnormalities are complex in most cases
4. Array comparative genomic hybridization (aCGH) screening of OAVS patients (Beleza-Meireles et al. 2015)
   1. Copy number variations (CNVs) on 22q11.21: identified dosage anomalies in 12 out of 22 OAVS patients tested (54.5%)
   2. 22q11 locus may harbor genes that are important in aspects of the regulation of craniofacial symmetry and 1st and 2nd branchial arch development
5. Genome-wide exome or whole genome sequencing approach: may identify other genetic loci involved in OAVS (Beleza-Meireles et al. 2015)

Genetic Counseling

1. Recurrence risk: depending on the etiology and the mode of inheritance
   1. Patient's sib
      1. Isolated: empiric recurrence risk of 2%
      2. Autosomal dominant inheritance: recurrence risk not increased unless a parent is affected, in which case the recurrence risk is 50%
      3. Autosomal recessive inheritance: 25% of siblings affected, 50% of siblings carriers, and 25% of siblings normal
   2. Patient's offspring
      1. Isolated: unknown
      2. Autosomal dominant inheritance: 50%
      3. Autosomal recessive inheritance: recurrence risk not increased unless the spouse is also a carrier, in which case the recurrence risk is 50%
2. Prenatal diagnosis by ultrasonography (Tamas et al. 1986; Benacerraf and Frigoletto 1988; De Catte et al. 1996)
   1. Hemifacial microsomia
   2. Microphthalmia or anophthalmia
   3. Facial clefting as part of the oculo-auriculo-vertebral spectrum (Witters et al. 2001)

4. Cleft lip/palate
5. Unilateral facial cleft with macrostomia
6. Unilateral ear hypoplasia
7. Unilateral preauricular tag
8. Hemiatrophy of the nose
9. Hyposegmentation of the unilateral lung
10. Single umbilical artery
11. Imperforate anus
12. Polyhydramnios

3. Management
    1. Surgical removal of epibulbar dermoids, if needed.
    2. Manage associated conductive hearing loss.
    3. Airway management (Stehling 1978).
    4. Cleft lip/palate repair.
    5. Combined surgical-orthodontic approach for dental occlusion.
    6. Traditional osteotomies, followed by acute orthopedic movement and osseous fixation for adult patients with maxillomandibular hypoplasia, facial asymmetry, congenital micrognathia, and hemifacial microsomia.
    7. Alternative procedure: distraction osteogenesis.
    8. Assess cervical spine for instability before undergoing any general surgery. C1–C2 fusion or occipitocervical fusion may be needed (Kaymak et al. 2002)
    9. Multistage and multidisciplinary approach (many surgeries including ophthalmic, plastic, and maxillofacial) leading to a good, satisfactory aesthetic and functional outcome (Bogusiak et al. 2014). Good orthodontic preparation of the patient largely contributed to the final therapeutic success.
    10. Anesthesia (Madan et al. 1990): anticipate airway obstruction and difficulty in tracheal incubation, resulting from a combination of micrognathia, unilateral mandibular hypoplasia, and vertebral anomalies including vertebral fusion and odontoid elongation.

Gorlin Syndrome

Contents

Nevoid basal cell carcinoma syndrome (NBCCS), also known as Gorlin syndrome, was first reported by Jarisch and White in 1894 who described a patient with multiple basal cell carcinomas, scoliosis, and learning disability. Howell and Caro in 1959 were the first to associate the basal cell nevus with other multiple cutaneous cancers and associated developmental anomalies. The spectrum of disease associated with this syndrome, comprising the principal triad of multiple basal cell nevi, jaw keratocysts, and skeletal anomalies, was described in detail by Gorlin and Goltz in 1960. A spectrum of other neurological, ophthalmic, endocrine, and genital manifestations are now known to be variably associated with this triad (Manfredi et al. 2004). The prevalence is estimated to be 1 in 60,000 persons (Cohen 1999).

Synonyms and Related Disorders

Basal cell nevus syndrome; Fifth phacomatosis; Gorlin-Goltz syndrome; Multiple basal cell nevi; Nevoid basal cell carcinoma syndrome; Odontogenic keratocysts and skeletal anomalies

Genetics/Basic Defects

1. An autosomal dominant disorder with complete penetrance and variable expressivity (Bare et al. 1992; Bonifas et al. 1994; Gorlin 2004).
2. The gene responsible has been localized to chromosome 9q22.1-q31 (Farndon et al. 1992; Compton et al. 1994).
3. Causes:
    1. Between 50% and 85% of patients with Gorlin syndrome harbor germ-line mutations in the only susceptibility gene identified to date, *PTCH1*, a key component in the sonic hedgehog (*SHH*) signaling pathway (Bale and Yu 2001; de Melo Pino et al. 2015):
        1. Caused by mutations in the human homologue of the Drosophila patched gene, *PTCH* (Hahn et al. 1996; Johnson et al. 1996).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_110

2. *PTCH*: a tumor suppressor gene, encoding a transmembrane glycoprotein that acts as an antagonist in the hedgehog signaling pathway (Bak et al. 2003; Ragge et al. 2005).
3. *PTCH* inhibits signaling by the membrane protein Smoothened (Smo), and this inhibition is relieved by binding sonic hedgehog (*SHH*) to *PTCH*.
4. A gain of function mutation in Smoothened: demonstrated in type 1 mosaic form of basal cell nevus syndrome (Khamaysi et al. 2016).

2. A microdeletion at 9q22.3 involving a deletion of *PTCH* gene in a few cases (Shimkets et al. 1996; Sasaki et al. 2000; Olivieri et al. 2003; Midro et al. 2004; Boonen et al. 2005; Chen et al. 2006; Yamamoto et al. 2009).
3. Human patched 2 (*PTCH2*): a putative tumor suppressor gene in basal cell carcinoma and medulloblastoma on chromosome 1p32 (Smyth et al. 1999).
4. SUFU, another component in this pathway, is known to be involved in susceptibility to medulloblastoma but has never been reported in Gorlin syndrome patients to date. A *SUFU* germ-line splicing mutation (c.1022þ1G>A) has been identified for the first time in a family that was *PTCH1*-negative and who had signs and symptoms of Gorlin syndrome, including medulloblastoma (Pastorino et al. 2009).
5. Most germ-line mutations in the nevoid basal cell carcinoma syndrome lead to a premature termination of the PATCHED protein, and no genotype-phenotype correlations are evident (Wicking et al. 1997).
6. Type I mosaicism: some reported cases of segmentally arranged lesions of Gorlin syndrome can be taken as examples of type 1 mosaicism (Shelley et al. 1969; Camisa et al. 1985).
7. Type 2 mosaicism: the presence of a germline mutation in exon 18 of *PTCH1* inherited from her father, and a second *PTCH1* mutation involving exon 3 that was found in the affected skin but not in her contralateral, clinically normal skin or in her blood, thus providing evidence of the concept of superimposed mosaicism (Torrelo et al. 2013).

4. Odontogenic keratocysts (Agaram et al. 2004).
   1. A distinctive odontogenic cyst with a potential for aggressive behavior, local recurrence, and an association with nevoid basal cell carcinoma syndrome.
   2. A significant number of odontogenic keratocysts show clonal loss of heterozygosity of common tumor suppressor genes.
   3. The presence of clonal deletion mutations of genomic DNA in these cysts supports the hypothesis that they are neoplastic rather than developmental in origin.

Clinical Features

1. Clinical features (Bitar et al. 2002; Ahn et al. 2004; Gorlin 2004; Lo Muzio 2008):
   1. An increasing number of basal cell nevi:
      1. Mostly appearing from the age of puberty onward
      2. Having tendency to develop into basal cell carcinomas of the skin
      3. Most commonly in sun-exposed areas
   2. Dermal pits of the palms and soles:
      1. Particularly useful in diagnosis
      2. Pits more pronounced when the hands and feet are soaked in warm water for up to 10 min, appearing as white "punched-out" or pink "pinpricked" lesions
   3. Keratocysts of the jaws
   4. Skeletal anomalies:
      1. Spine and rib anomalies:
         1. Bifid ribs
         2. Thoracic and cervical vertebral anomalies (Ratcliffe et al. 1995)
         3. Scoliosis
         4. Spina bifida
         5. Osteoporosis
         6. Short fourth metacarpals
      2. Abnormal craniofacial configurations:
         1. Macrocephaly

2. Frontal, parietal, and temporal bossing
3. Hypertelorism
4. Broad nasal bridge
5. Maxillary retrognathia
6. Mandibular prognathism
7. Increased gonion angle
8. Increased facial height

5. Intracranial calcifications (Dahl et al. 1976; Donatsky et al. 1976; Kimonis et al. 1997; Evans et al. 1993):
   1. Falx cerebri
   2. Falx cerebelli
   3. Petroclinoid ligament
   4. Dura
   5. Pia
   6. Choroid plexus
6. Other features (Shanley et al. 1994):
   1. Sensitive to ultraviolet and ionizing radiation
   2. Occasional abnormalities (Evans et al. 1993; Kimonis et al. 1997):
      1. Dental agenesis
      2. Cleft palate and lip
      3. Mental deficiency
      4. Agenesis of corpus callosum
      5. Vermian dysgenesis
      6. Anosmia
      7. Hydrocephalus
      8. Cataract
      9. Coloboma of iris
      10. Retinal atrophy
      11. Glaucoma
      12. Strabismus
      13. Mandibular coronoid process hyperplasia
      14. Arachnodactyly
      15. Polydactyly
      16. Renal anomalies
      17. Other neoplasms such as medulloblastoma, meningioma, fibroma, lipomata, melanoma, neurofibromata of skin, cardiac fibromas, eyelid carcinomas, breast cancer, lung cancer, lymphoid leukemia, non-Hodgkin's lymphoma, ovarian dermoid, lymphomesenteric cysts, and hepatic mesenchymal tumors

2. Diagnostic criteria for nevoid basal cell carcinoma syndrome (Evans et al. 1993; Kimonis et al. 1997, 2004; Veenstra-Knol et al. 2005; Evans and Farndon 2010; Bree et al. 2011; Bresler et al. 2016). A diagnosis can be made when two major or one major and two minor criteria are fulfilled:
   1. Major criteria:
      1. Multiple (>2) basal cell carcinomas (BCC) or one BCC under the age of 20 years or >10 basal cell nevi
      2. Any odontogenic keratocyst histologically or observed on orthopantogram as an area of translucency or polyostotic bone cyst
      3. Palmar or plantar pits (three or more)
      4. Ectopic calcification: lamellar (sheet like) falx calcification or evidence of early calcification in an individual younger than 20 years
      5. Medulloblastoma, typically desmoplastic
      6. First-degree relatives with NBCCS
   2. Minor criteria:
      1. Congenital skeletal anomaly: bifid, fused, splayed, or missing ribs or bifid, wedged, or fused vertebra
      2. Occipital-frontal circumference >97 percentile (macrocephaly), with frontal bossing
      3. Macrocephaly
      4. Cardiac or ovarian fibromas
      5. Childhood medulloblastoma (primitive neuroectodermal tumor)
      6. Lymphomesenteric or pleural cysts
      7. Congenital malformation: cleft lip and/or palate, polydactyly, eye anomaly (hypertelorism, strabismus, cataract, glaucoma, coloboma, microphthalmia)

Diagnostic Investigations

1. Family history:
   1. Brain tumors (Evans et al. 1991a)
   2. Female organ tumors
2. Medical and dental history:
   1. Removal of jaw cysts
   2. Abscesses
   3. Skin lesions

3. Physical examination:
    1. Mandibular and maxillary swelling
    2. Head circumference
    3. Head shape
    4. Skin basal cell nevi
    5. Pits on the palms and soles
4. Radiographic studies (Bitar et al. 2002):
    1. Skull radiography for detection of calcified cerebral falx
    2. Jaw radiography for detection of maxillary and mandibular cystic lesions
    3. Chest radiography for rib and vertebral anomalies
5. Dermoscopy (Moreira et al. 2015):
    1. Palmar pitting: flesh-colored, irregular-shaped and slightly depressed lesions, some with red globules
    2. Early detection of basal cell carcinomas: arborizing vessels, ulceration, blue-gray globules, and spoke-wheel areas
6. CT scan: multiple bilateral unilocular cysts in the mandible and maxilla, along with calcification of anterior part of the falx cerebri (Hajalioghli et al. 2015)
7. MRI of the brain to detect meningiomas or medulloblastomas at an early age.
8. Ovarian ultrasonography for detection of ovarian cysts or fibromas.
9. MRI: calcified bilateral adnexal lesions with low signal intensity on T2-weighted MR sequences (Singh et al. 2014).
10. Echocardiograms to evaluate cardiac fibromas.
11. Cytogenetic analysis to detect rare interstitial 9q deletion associated with clinical features of NBCCS and additional features such as severe developmental delay or short stature (Chen et al. 2006).
12. Molecular genetic testing (Evans and Farndon 2010):
    1. Sequence analysis of exons 2–23 with intron-exon junctions and one of the splice forms of exon 1 to detect *PTCH1* gene mutation (Marsh et al. 2005; Klein et al. 2005)
    2. Deletion testing to detect exonic and whole *PTCH1* gene deletions
13. The high detection rate of *PTCH1* mutations in NBCCS patients enables molecular diagnostics to become a valuable tool for establishing an early diagnosis, especially in the case of atypical phenotype and for yet unaffected family members (Škodrić-Trifunović et al. 2015). Moreover, family members of the patients with the Gorlin syndrome should be examined to decrease the risk for developing skin tumors, like basal cell carcinoma, which could be prevented by decreased sun exposure and avoidance of x-ray imaging.

Genetic Counseling

1. Recurrence risk:
    1. Patient's sib:
        1. An affected parent: a 50% risk
        2. Unaffected parents: a low risk
    2. Patient's offspring: a 50% risk
2. Prenatal diagnosis:
    1. Ultrasonography:
        1. Hydrocephalus
        2. Macrocephaly
        3. Cleft lip and palate
        4. Intracardiac tumor
        5. Fetal hydrops
        6. Fetal chylothorax
    2. Molecular genetic testing available, provided the disease-causing allele of an affected family member has been identified, by analyzing DNA extracted from fetal cells obtained by (Lo Muzio 2008):
        1. CVS
        2. Amniocentesis
3. Management (Van der Geer et al. 2009; Bresler et al. 2016):
    1. Frequent dermatologic surveillance: necessary
    2. Surgical excision of keratocysts identified early in life
    3. Basal cell carcinomas:
        1. Complete eradication of aggressive BCCs, surgical excision supplemented by cryotherapy, laser treatment for early lesion, and photodynamic therapy (Itkin and Gilchrest 2004; Oseroff et al. 2005).
        2. Preserve normal tissue to prevent disfigurement.

3. Tropical 5% imiquimod (Kagy and Amonette 2000; Marks et al. 2001; Stockfleth et al. 2002).
4. Cyclopamine: specifically inhibits smoothened activity and appears to be a promising agent in the treatment of medulloblastomas, BCCs, and breast and prostate cancer (Debeer and Devriendt 2005).
5. Radiotherapy: contraindicated.

4. Surgical excision of ovarian fibromas

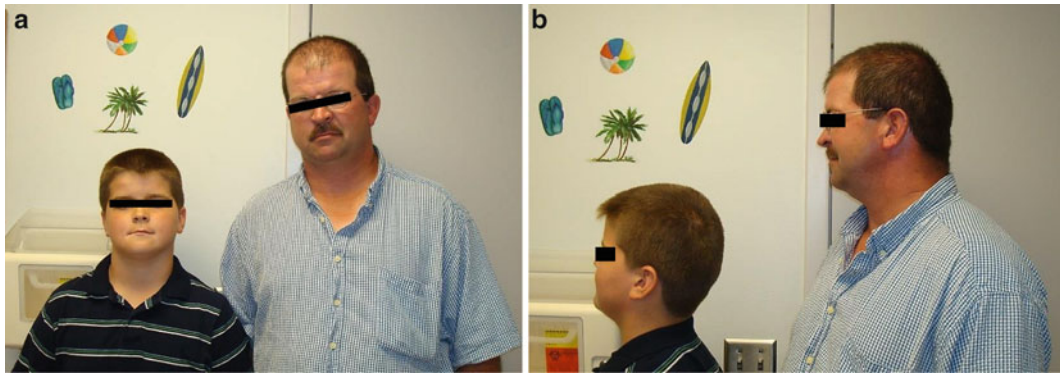

Fig. 1 (**a**, **b**) An 11-year-old boy and his father both have Gorlin syndrome. The boy had multiple odontogenic cysts removed from his jaw. Craniofacial CT scan showed extensive dural and choroid plexus calcifications and abnormal enlargement of subarachnoid space in the left frontal and anterior temporal regions. He was noted to have macrocephaly, forehead bossing, and plantar pits. His father had his multiple odontogenic cysts removed at 16 years of age. In addition, he has several soft subcutaneous tissue masses in his fingers and his right foot. The patient is heterozygous for a duplication of a single "A" nucleotide in exon 2 of the *PTCH* gene. The normal sequence with the base that is duplicated in braces is "TTGTT(A)CATTCA." This mutation is denoted c.278dupA at the cDNA level or p Tyr93Stop (Y93X). The c.278DupA mutation results in the replacement of a tyrosine codon with a Stop codon at position 93

Fig. 2 Panoramic radiograph of jaw shows multiple odontogenic cysts

Fig. 3 A small subcutaneous nodule seen in the index fingers of the father

Fig. 4 A small subcutaneous nodule seen in the dorsal aspect of the foot of the father

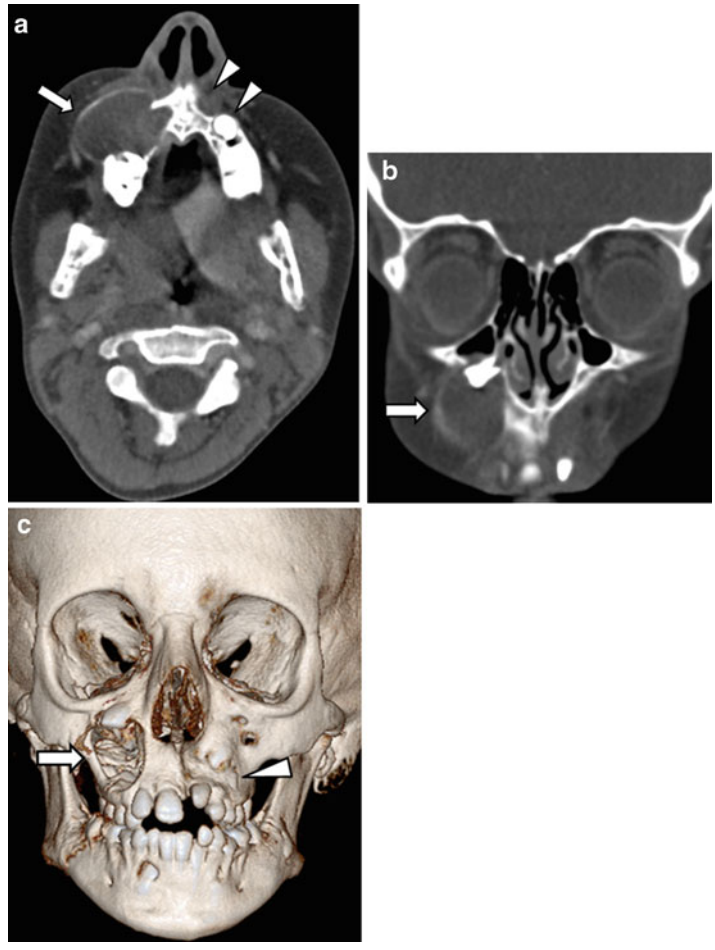

Fig. 5 (**a–c**) An 8-year-old female with a history of macrocephaly, developmental delay, pyloric stenosis, and multiple odontogenic keratocysts. A *PTCH1* p.Leu106Arg mutation confirmed the diagnosis of Gorlin syndrome. The mother was affected with Gorlin syndrome and had a history of skin cancer removal. CT images (**a–c**) demonstrate an expansile 3.5 cm fluid attenuating lesion in the right maxilla (*arrows*) causing destruction of the inferior wall of the maxillary sinus with extension into the right maxillary sinus. Three-dimensional reconstruction CT image shows a displaced tooth within the right maxillary sinus about the superior aspect of this lesion (**c**). The findings are compatible with an odontogenic keratocyst. Deformed left anterior maxilla (*arrow heads*) is seen secondary to postoperative changes for an odontogenic keratocyst removal 2 years previously (Courtesy of Dr. Grace Guo)

Greig Cephalopolysyndactyly Syndrome

Contents

Greig cephalopolysyndactyly (GCPS) syndrome is named after David Middleton Greig for his 1926 description of a patient with unusual head shape, hypertelorism, and limb anomalies. It is a rare, pleiotropic, multiple congenital anomaly syndrome characterized by the primary clinical triad of polysyndactyly, macrocephaly, and hypertelorism.

Synonyms and Related Disorders

Cephalopolysyndactyly; *GLI3* mutation; Pallister-Hall syndrome; Polysyndactyly with peculiar skull shape

Genetics/Basic Defects

1. Inheritance: autosomal dominant with high penetrance in majority of cases (Patel et al. 2014).
2. Caused by mutations in the transcription factor *GLI3* on chromosome 7p13 resulting in functional haploinsufficiency of *GLI3* (Pettigrew et al. 1991; Hurst et al. 2011). The mutations include the following:
    1. Point mutations (Wild et al. 1997; Kalff-Suske et al. 1999)
    2. Translocation mutations
    3. Deletion mutations
    4. Intragenic mutations
    5. Truncation mutations (frameshift and nonsense mutations) (Patel et al. 2014)
    6. Insertion mutations
3. Allelic to the Pallister-Hall syndrome (PHS) (Démurger et al. 2015) and one form of the acrocallosal syndrome:
    1. Severe GCPS phenotype is likely caused by deletion of contiguous genes and substantially overlaps with the mild end of the acrocallosal syndrome (an autosomal recessive disorder characterized by pre- or postaxial polydactyly, syndactyly, agenesis corpus callosum, ocular hypertelorism, macrocephaly, moderate to severe mental retardation, intracerebral cysts, seizures, and umbilical and inguinal hernias).
    2. *GLI3* mutations can also cause PHS, postaxial polydactyly type A, and other *GLI3* morphopathies. GCPS and PHS are likely allelic with distinct modes of pathogenesis.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_111

4. Phenotypes caused by mutations in GLI3 are diverse, discrete, variable, and pleiotropic. The mutations in GLI3 that cause PHS and GCPS correlate with the phenotypes on two levels:
   1. Many types of inactivating mutations cause GCPS.
   2. Whereas PHS is caused almost exclusively by truncation mutations in the middle third of the gene.
5. Mutations in genes other than *GLI*: possible in some patients with a GCPS phenotype.
6. Update of human polydactyly entities by phenotype and mutated gene (Biesecker 2011):
   1. Phenotypes with overlapping manifestations, genetic heterogeneity, and distinct phenotypes generated from mutations in single genes.
   2. Among 310 clinical entities, 80 are associated with mutations in 99 genes.

Clinical Features

1. Variable clinical manifestations (Duncan et al. 1979; Kroisel et al. 2001; Debeer et al. 2003; Balk and Biesecker 2008; Curran and Cronin 2015; Démurger et al. 2015)
2. The primary clinical triad:
   1. Macrocephaly
   2. Hypertelorism
   3. Polysyndactyly
3. Developmental history:
   1. Feeding problems/failure to thrive
   2. Developmental delay, seizures, and psychomotor retardation: more likely in a child with rare CNS malformations or uncommon hydrocephalus and more common in individuals with large (>300 kb) deletions that encompass *GLI3*
4. Craniofacial features – highly variable:
   1. Significant hypertelorism (increased interpupillary distance) with or without telecanthus (increased inner canthal distance) in some patients
   2. Macrocephaly, not typically associated with CNS anomalies, such as hydrocephalus and seizures
5. Digital anomalies (Curran and Cronin 2015):
   1. Polydactyly:
      1. Classically described as preaxial.
      2. May occur in any limb.
      3. Postaxial may be more common than preaxial.
      4. Most common finding: postaxial polydactyly of the hands and preaxial polydactyly of the feet.
      5. Broad thumbs and broad great hallux
      6. Severity varies widely among individuals and among limbs in the same individual. This can vary from an apparently normal extremity, through subtle broadening of the thumb or hallux, tiny postaxial nubbins, to partially bifid digits, hypoplastic supernumerary digits, fully formed supernumerary digits, and higher order polydactyly.
   2. Cutaneous syndactyly – highly variable:
      1. Absent in many patients.
      2. Mild partial cutaneous syndactyly of a few digits in some patients.
      3. The spectrum continues through to complete cutaneous syndactyly of all digits, not unlike that seen in patients with Apert syndrome.
6. Less common anomalies:
   1. Craniosynostosis: metopic and sagittal synostosis (Hurst et al. 2011)
   2. Mental retardation: not common
   3. Agenesis of the corpus callosum
   4. Ventricular dilatation
   5. Umbilical and diaphragmatic hernias
   6. Risk of cognitive impairment appears to be associated with the GCPS-contiguous gene syndrome
7. Diagnostic criteria (Johnston et al. 2005):
   1. Presumptive diagnosis: a proband with:
      1. Preaxial polydactyly
      2. Syndactyly of toes 1–3 or fingers 3–4
      3. Ocular hypertelorism
      4. Macrocephaly
   2. Firm diagnosis:
      1. The presence of an affected first-degree relative whom the diagnosis has been independently established

2. A proband who has features of GCPS and a mutation in *GLI3*
3. Cautions in applying above diagnostic criteria:
   1. Clinical criteria: useful but not sufficiently specific to warrant a "firm" diagnosis on clinical grounds alone.
   2. A small but significant fraction of individuals with features of GCPS do not have mutations in *GLI3*.
   3. Features of GCPS are seen in many other syndromes.
8. Diagnostic criteria (combined clinical-molecular definition for the syndrome) (Biesecker 2008):
   1. A presumptive diagnosis with the classic triad:
      1. Preaxial polydactyly with cutaneous syndactyly of at least one limb
      2. Hypertelorism
      3. Macrocephaly
   2. Definitive diagnosis:
      1. A phenotype consistent with GCPS but which may not manifest all three attributes listed above
      2. The presence of a *GLI3* mutation
9. Additional definitive diagnostic criteria: persons with a GCPS-consistent phenotype who are related to a definitively diagnosed family member in a pattern consistent with autosomal dominant inheritance
10. Prognosis:
    1. A mild form: excellent general health and normal longevity reported in several large families
    2. Slight increase in the incidence of developmental delay or cognitive impairment
    3. Worse prognosis in patients with large deletions that include *GLI3*
11. Differential diagnosis (Biesecker 2006):
    1. Preaxial polydactyly type IV/postaxial polydactyly type A/B (Radhakrishna et al. 1999)
    2. GCPS-contiguous gene syndrome (Johnston et al. 2003)
    3. Acrocallosal syndrome (ACLS):
       1. Inherited in an autosomal recessive manner.
       2. Preaxial polydactyly type IV (Baraitser et al. 1983) or postaxial polydactyly.
       3. Syndactyly.
       4. Agenesis of the corpus callosum (rare in GCPS).
       5. Ocular hypertelorism.
       6. Macrocephaly.
       7. Moderate to severe mental retardation.
       8. Intracerebral cysts.
       9. Seizures.
       10. Umbilical and inguinal hernias.
       11. The milder end of the ACLS phenotype can overlap with the severe end of the GCPS phenotype caused by interstitial deletions of 7p13 that delete *GLI3* and additional neighboring genes.
       12. Frequency of consanguinity, sibling recurrences with unaffected parents, and preliminary mapping data suggest that ACLS can be a disorder distinct from severe GCPS.
    4. Gorlin syndrome (please see chapter "▶ Gorlin Syndrome")
    5. Carpenter syndrome (please see chapter "▶ Carpenter Syndrome")
    6. Teebi syndrome
    7. Pallister-Hall syndrome

Diagnostic Investigations

1. Radiographic studies of digital anomalies (Debeer et al. 2003)
2. CNS imaging studies:
   1. For individuals showing signs of increased intracranial pressure, developmental delay, loss of milestones, or seizures
   2. To evaluate hydrocephalus or other CNS abnormalities
3. Chromosome analysis (Williams et al. 1997): performed either as a first test or in all patients who have GCPS but no mutation was found by sequencing:
   1. Detection of visible pure chromosomal deletions involving 7p13 or a deletion combined with a translocation

2. Detection of familial translocation: a risk for offspring with unbalanced translocations in addition to their risk of having a child with GCPS

4. Molecular genetic testing:
   1. Indications:
      1. Confirmatory diagnostic testing
      2. Prenatal diagnosis
   2. FISH analysis: Using hybridization of the labeled BAC clone to metaphase spreads detects deletions in the estimated 5–10% of individuals with large deletions.
   3. Comparative genomic hybridization (CGH):
      1. An array of *GLI3* is available on a limited clinical basis.
      2. CGH array would be expected to detect a deletion that encompasses more than one target on the array (Johnston et al. 2007).
   4. Other methodologies:
      1. Loss-of-heterozygosity (LOH) analysis to detect large deletions
      2. Sequencing of the *GLI3* coding exons or scanning with denaturing high-performance liquid chromatography (DHPLC), single-strand conformation polymorphism (SSCP), or other conformation detection methods: an appropriate first screen for patients with typical GCPS
      3. Quantitative PCR

Genetic Counseling

1. Recurrence risk (Biesecker 2014)
   1. Patient's sib:
      1. De novo cases: recurrence risk low.
      2. Fifty percent of siblings are affected if one of the parents is affected.
      3. No instances of germline mosaicism reported, but it remains a possibility.
      4. Proband with an unbalanced structural chromosome constitution:
         1. Neither parents with a structural chromosome rearrangement: risk to sibs negligible.
         2. A parent with a balanced structural chromosome rearrangement: risk to sibs increases and depends upon the specific chromosome rearrangement.
   2. Patient's offspring:
      1. Fifty percent risk of inheriting the mutation and having an affected offspring: since intrafamilial variability is generally low, affected offspring are expected to have clinical findings similar to those of the parent.
      2. Offspring of an individual with a balanced or unbalanced chromosomal rearrangement: at risk of having a similar or related rearrangement.
2. Prenatal diagnosis (Biesecker 2014; Raposo et al. 2015)
   1. Ultrasound studies in pregnancies at 50% risk may detect the following findings:
      1. Polydactyly
      2. Syndactyly
      3. Broad halluces on both feet
      4. CNS malformations such as hydrocephalus
   2. Chromosome analysis of fetal cells in at-risk families with a parent having a cytogenetically visible 7p13 deletion or a balanced chromosomal rearrangement.
   3. Molecular genetic testing for GLI3 gene: antenatal molecular diagnosis is technically straightforward to perform.
   4. Preimplantation genetic diagnosis (PGD): may be available for families in which the disease-causing mutation or chromosome abnormality has been identified in an affected family.
3. Management:
   1. Symptomatic treatment with plastic or orthopedic surgery indicated for significant limb malformations
   2. Surgical repair:
      1. Preaxial polydactyly of the thumbs: a higher priority for surgical correction than postaxial polydactyly of the hand or polydactyly of the foot because of the importance of the thumbs for prehensile grasp

2. Severe syndactyly of the fingers
3. Surgical correction of the feet for orthopedic complications, cosmetic benefits, and easier fitting of shoes

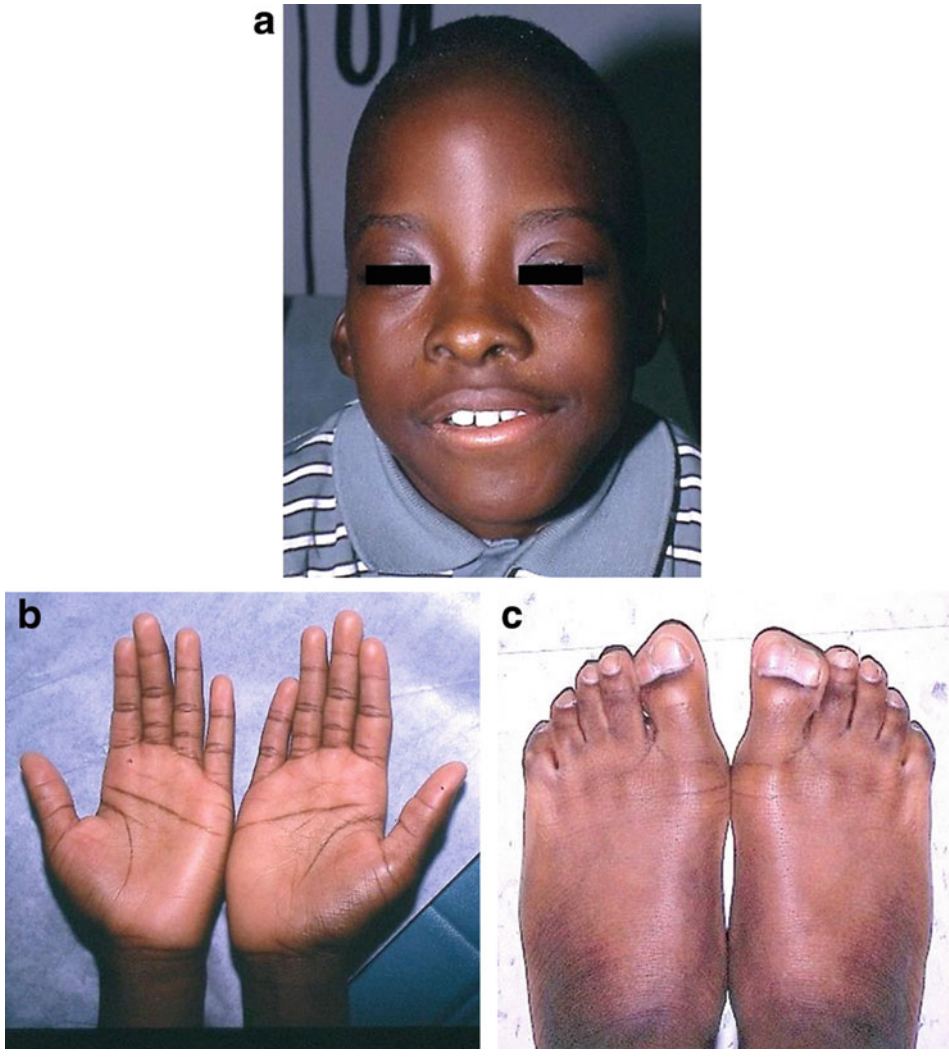

Fig. 3 (**a**–**c**) Another patient (**a**) with macrocephaly, ocular hypertelorism, transverse palmar creases (**b**), and a partially duplicated great hallux (**c**)

Hallermann-Streiff Syndrome

Contents

Hallermann-Streiff syndrome was independently described by Hallermann in 1948 and Streiff in 1950. The syndrome is characterized by proportionate short stature and craniofacial dysostoses consisting of skeletal, ophthalmologic, and cutaneous defects.

Synonyms and Related Disorders

Francois dyscephalic syndrome (François 1982)

Genetics/Basic Defects

1. Sporadic in virtually all cases
2. Inheritance pattern unknown

Clinical Features

1. Characteristic craniofacial features
    1. Dyscephaly (malformation of the cranium and bones of the face) (89–90%)
        1. Calvarium
            1. Brachycephaly
            2. Thin calvarium
            3. Delayed closure of fontanelles
            4. Wide cranial sutures
        2. Cranial base
            1. Platybasia
            2. Depressed sella
            3. Elevated anterior cranial fossa
        3. Parrot-like face
            1. A beaked nose
            2. Hypoplastic mandible
    2. Hypotrichosis (80–82%)
        1. Alopecia
            1. Characteristic sutural alopecia (hair loss following the lines of the cranial sutures)
            2. Frontal alopecia
            3. Alopecia at the scalp margins
        2. Hypotrichosis involving the eyebrows and eyelashes
        3. Brittle and sparse scalp hair
    3. Cutaneous atrophy (68–70%)
        1. Face (nose)
        2. Scalp
        3. Cutaneous atrophy with telangiectasia (François and Victoria-Troncoso 1981; Singh et al. 2013)
    4. Ocular abnormalities (Cohen 1991; David et al. 1999)
        1. Congenital cataracts (81–90%)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_112

2. Microphthalmos (78–83%)
3. Nystagmus
4. Strabismus
5. Glaucoma (Aracena and Sangueza 1977)
6. Blue sclera
7. Fundal anomalies
8. Conjunctival defects
9. Corneal abnormalities
10. Down-slanting palpebral fissures
11. Intraocular hypertension
12. Lower lid coloboma
13. Iris atrophy
14. Persistent pupillary membrane
15. Enophthalmos
16. Bilateral retinal detachments (Haque et al. 2009)
17. Epicanthal folds

5. Mouth (Hutchinson 1971; Ohishi et al. 1986)
   1. Microstomia
   2. Narrow/high-arched palate
   3. Dental/alveolar abnormalities (80–85%) (Slootweg and Huber 1984)
      1. Natal teeth
      2. Partial anodontia/hypoplasia
      3. Persistent deciduous teeth
      4. Irregular implantation of the teeth
      5. Anterior open bite
   4. Generalized odontodysplasia (Damasceno et al. 2014)

2. Musculoskeletal abnormalities
   1. Proportionate short stature (45–69%)
   2. Syndactyly
   3. Lordosis
   4. Scoliosis
   5. Spina bifida
   6. Winged scapulae
   7. Hyperextensible joints including temporomandibular joints
   8. Hip dislocation
   9. Periodic osteoporosis
3. Other abnormalities
   1. Mild to severe mental retardation (15%)
   2. Calcified falx cerebri
   3. Neurologic abnormalities
      1. Neurofibromatosis
      2. Epilepsy
   4. Genital anomalies (10–12%)
      1. Hypogenitalism
      2. Cryptorchidism
      3. Hypospadias
      4. Subseptate uterus
      5. Clitoral hypertrophy
   5. Cardiac defects (2–9%) (Dinwiddie et al. 1978)
      1. Pulmonic stenosis
      2. Atrial septal defect
      3. Ventricular septal defect
      4. Patent ductus arteriosus
      5. Tetralogy of Fallot
   6. Endocrinological abnormalities
      1. Immune deficiency
      2. Hypoparathyroidism
      3. Hypothyroidism
      4. Hypopituitarism
   7. Ear anomalies (9%)
   8. Hematopoietic abnormalities (7%)
   9. Pulmonary anomalies (3%)
      1. Obstructive sleep apnea
      2. Tracheomalacia (Salbert et al. 1991)
      3. Recurrent pulmonary infections
      4. Cor pulmonale
   10. Gastrointestinal abnormalities (3%)
   11. Muscular hypotrophy (3%)
   12. Hepatic anomalies (2%)
   13. Renal anomalies (1–2%): bilateral duplication of renal collecting system
4. Prognosis (Steele and Bass 1970)
   1. Some patients succumb in infancy to respiratory infections and pulmonary insufficiency, possibly related to airway obstruction and abnormal compliance.
   2. Majority of patients with a normal life span.
5. Diagnostic criteria
   1. Major features
      1. Dyscephaly with beak nose and mandibular hypoplasia
      2. Dental abnormalities
      3. Proportional short stature
      4. Hypotrichosis
      5. Cutaneous atrophy
      6. Microphthalmia
      7. Congenital cataracts
   2. Minor features
      1. Narrow/high-arched palate

2. Ocular features
    1. Blue sclera
    2. Antimongoloid palpebral fissures
    3. Synechiae irides
    4. Choroid atrophy
3. Hypoplastic genitalia
4. Musculoskeletal features
    1. Elevated scapulae
    2. Scoliosis
    3. Lordosis
    4. Hyperextensible joints
5. Mental retardation

Diagnostic Investigations

1. Radiography (Christian et al. 1991; Cohen 1991)
    1. Skull
        1. A large, poorly ossified skull
        2. Delayed closure of fontanelles with persistent wide sutures
        3. The presence of Wormian bones
        4. Brachycephaly
        5. Platybasia
        6. Depressed sella turcica
        7. Frontal or parietal bossing
        8. Small orbits
        9. Disproportion between the large cranial vault and the small facial skeleton
        10. Midfacial hypoplasia
            1. Hypoplastic mandibular ramus
            2. Possible absent condyles
            3. Anteriorly displaced temporomandibular joint
            4. Hypoplastic malar bones
        11. A birdlike nose
        12. Micrognathia
        13. Dental anomalies
            1. The presence of natal teeth
            2. Retained decidual teeth
            3. Partial anodontia
            4. Supernumerary and hypoplastic teeth
            5. Anterior open-bite malocclusion
        14. Odontodysplasia
            1. All teeth showing wide pulp chambers and roots with thin dentinal walls and open apices, resembling ghost teeth and indicating a diagnosis of odontodysplasia (Damasceno et al. 2014)
            2. Developmental malformations in the hard structures of the deciduous and permanent teeth (especially in dentin), causing a "ghost teeth" appearance (Gungor et al. 2015)
    2. Long bones
        1. Thin/gracile
        2. Retarded bone age
    3. Other skeletal anomalies
        1. Scaphocephaly
        2. Cervical vertebral anomalies
        3. Mild platyspondyly
        4. Scoliosis
        5. Lordosis
        6. Elevated scapulae
        7. Hip dislocation
        8. Spina bifida
        9. Syndactyly
2. Overnight polysomnography to confirm obstructive sleep apnea
3. Endocrine evaluation for hypothyroidism, hypoparathyroidism, or hypopituitarism
4. Chromosome study: no diagnostic cytogenetic characteristics

Genetic Counseling

1. Recurrence risk
    1. Patient's sib: not increased
    2. Patient's offspring: not increased
2. Prenatal diagnosis: not been reported
3. Management
    1. Surgery
        1. Repair of cardiovascular defect
        2. Ophthalmological procedure (cataract removal)
        3. Rhinoplasty
        4. Facial augmentation
        5. Dental surgery (Patterson et al. 1982)
            1. General restorative dentistry
            2. Orthodontic palatal expansion
            3. Realignment of the dental arches

6. Mandibular advancement
7. Nasal lipofilling to treat the atrophy of the nasal skin (Bénateau et al. 2015)

2. General anesthesia and airway management (Sataloff and Roberts 1984; Malde et al. 1994)
   1. Difficult laryngoscopy and endotracheal intubation secondary to micrognathia, microstomia, and serious upper airway compromise
   2. Brittle and easily broken natal teeth during laryngoscopy
   3. Orotracheal intubation precluded by the anterior placement or absence of the temporomandibular joints
   4. Difficult nasotracheal intubation secondary to hypoplastic nose and deviated nasal septum
   5. Consider preoperative tracheotomy or prepare for emergency tracheotomy
3. Long-term nasal continuous positive airway pressure therapy for obstructive sleep apnea (Ryan et al. 1990)
4. Management for endocrine problem if present

Harlequin Ichthyosis

Contents

Harlequin ichthyosis is a rare severe scaling disorder and the most devastating congenital ichthyosis, which manifests in utero and is often fatal early in life.

Synonyms and Related Disorders

Autosomal recessive congenital ichthyosis; Collodion baby; Congenital ichthyosis erythroderma; Congenital ichthyosis of harlequin type; Harlequin fetus; Lamellar ichthyosis

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. *ABCA12* gene
    1. Located on chromosome 2q34
    2. Consists of 53 exons and codes a 2595–amino acid protein member of the adenosine triphosphate (ATP)-binding cassette transporter family (Lefévre et al. 2003; Akiyama et al. 2005; Kelsell et al. 2005)
3. Caused by loss-of-function mutations in *ABCA12* (Akiyama and Shimizu 2008; Akiyama 2010)
    1. Truncation mutations: most mutations
        1. Nonsense mutations
        2. Frameshift mutations (deletion/insertion mutations)
        3. Splice site mutations
    2. Missense mutations
    3. Exon deletion
    4. Single amino acid deletions
4. Novel homozygous mutation p.R287X resulted from complete paternal isodisomy (Castiglia et al. 2009)
    1. Nonmosaic chromosome 2 trisomy from chorionic villus karyotyping while postnatal peripheral blood karyotype was normal female.
    2. These findings indicate that trisomic rescue is one step of the mutational cascade leading to reduction to homozygosity for the *ABCA12* mutation in the embryo.
5. Pathomechanisms of ichthyosis involving *ABCA12* mutations (Akiyama 2006, 2010): several morphological abnormalities including abnormal lamellar granules in the keratinocyte granular layer and a lack of extracellular lipid lamellae within the stratum corneum observed in harlequin ichthyosis (Akiyama et al. 2005)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_113

1. Lack of *ABCA12* function subsequently leads to disruption of lamellar granule lipid transport in the upper keratinizing epidermal cells resulting in malformation of the intercellular lipid layers of the stratum corneum.
2. Cultured epidermal keratinocytes from a harlequin ichthyosis patient carrying *ABCA12* mutations demonstrated defective glucosylceramide transport, and this phenotype was recoverable by in vitro *ABCA12* corrective gene transfer.
3. To date, intracytoplasmic glucosylceramide transport has been studied using cultured keratinocytes from a total of three patients harboring *ABCA12* mutations (Akiyama et al. 2005, 2006, 2007).
    1. One patient was a homozygote for a splice site mutation c.3295-2A > G.
    2. Another patient was a compound heterozygote for p.Ser387Asn and p.Thr1387del.
    3. Only one heterozygous mutation p.Ile1494Thr was identified in the other patient.
    4. Cultured keratinocytes from all the three patients showed apparently disturbed glucosylceramide transport, although this assay is not quantitative.
6. More than 93% of patients with harlequin ichthyosis have been reported to have mutations in the *ABCA12* gene (Richard and Bale 2014; Rajpopat et al. 2011).
7. At least 60% of lamellar ichthyosis and congenital ichthyosis erythroderma cases originate from mutations in the *TGM1*, *NIPAL4,* and *ALOX12B* genes (Oji et al. 2010). TGM1 mutations cause > 50% of autosomal recessive congenital ichthyosis cases in the USA (Farasat et al. 2009). The *TGM1* gene encodes the transglutaminase (TGase)-1 protein, a critical enzyme implicated in cornified cell envelope synthesis (Nemes et al. 1999; Eckert et al. 2005). More than 135 *TGM1* etiological sequence variants have been reported to date, most of which consist of missense and nonsense mutations (Farasat et al. 2009; Herman et al. 2009; Oji et al. 2010).
8. Report of a male with harlequin ichthyosis with a de novo deletion of the long arm of chromosome 18 [46,XY,del(18)(q21.3)] suggesting the possible gene localization within the deleted region (Stewart et al. 2001).

Clinical Features

1. Major clinical features
    1. Large, thick, and yellowish armor-like plaques (plate-like scales) with reddish, moist, oozing fissures and cracks, covering the whole body
    2. Severe ectropion (complete eversion of the nonkeratinizing mucosa of the eyelids with occlusion of the eyes)
    3. Eclabium (eversion of the nonkeratinizing mucosa of the lips)
    4. "Frog-like" grotesque appearance of the face
    5. Crumpled and flattened ears
    6. Flattened nasal tip with anteversion of the nares (nasal hypoplasia)
    7. Permanently opened mouth unable to suck properly
    8. Swollen extremities secondary to tight sausage-like encasement by the thickened stratum corneum
    9. Semiflexed rigid extremities (allowing little limb movement) with hypoplastic fingers
2. Minor clinical features
    1. Absent eyebrows and eyelashes
    2. Absent scalp hair
3. Associate anomalies
    1. Renal tubular defects
    2. Altered thymic structures
    3. Pulmonary hypoplasia
4. Natural history
    1. Restricted fetal movement caused by dense masses of hyperkeratotic scale
    2. Prematurity in most cases
    3. Perinatal death (usually in the first few weeks) secondary to
        1. Respiratory compromise due to mechanical limitation of rib cage excursion
        2. Sepsis
        3. Hypothermia

4. Dehydration
5. Malnutrition
6. Severe anemia
7. Renal failure

4. The phenotype at birth is a collodion baby, where the neonate is covered with a taut, shiny, membrane-like skin or a severe phenotype called harlequin ichthyosis subsequently evolve into phenotypes of varying severity, like lamellar ichthyosis and congenital ichthyosiform erythroderma (Richard and Bale 2014; Oji et al. 2010)
5. Rare survivals
   1. Variable neurological impairment
   2. Short stature
   3. Failure to thrive
   4. At risk for severe keratitis due to ectropion of all eyelids

5. Genotype-phenotype correlations (Richard and Bale 2014; Rajpopat et al. 2011; Aggarwal et al. 2015)
   1. Severe *ABCA12* mutations leading to complete destruction of function or loss of production of *ABCA12* protein cause harlequin ichthyosis phenotype.
   2. Milder mutations lead to lamellar ichthyosis phenotype.

Diagnostic Investigations

1. Light microscopy findings.
   1. Extraordinary compact orthohyperkeratosis (thickened orthokeratotic stratum corneum)
   2. Keratin plugs in hair follicles and sweat ducts
   3. Absent lamellar bodies and abundant vesicles in both the stratum granulosum and stratum corneum
   4. Abnormal lipid droplets and vacuoles in the cytoplasm of keratinized cells in the thick stratum corneum
2. Ultrastructural findings (Akiyama et al. 1998).
   1. Abnormal lipid droplets and vacuoles in the cytoplasm of keratinized cells in the thick stratum corneum
   2. Absent normal lamellar granules in the cytoplasm of granular layer keratinocytes
   3. Lack of lamellar structure in the extracellular space between the first cornified cell and the granular cell
3. Biochemical analysis of skin samples: a defect of conversion from profilaggrin to filaggrin.
4. Family history for evidence of consanguinity.
5. Sequence analysis *ABCA12*, *TGM1*, *ALOX12B*, *ALOXE3*, *NIPAL4*, *CYP4F22*, and *PNPLA1* genes and sequence analysis of *NIPN* and *CERS3* genes can help patients and their families to understand their disease (Richard and Bale 2014; Ortega-Recalde et al. 2015).

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: 25%
   2. Patient's offspring: patient not surviving to reproductive age
2. Prenatal diagnosis possible in families at risk
   1. Ultrasonography (2D, 3D, and 4D) at 18–24 weeks (Bongain et al. 2002; Kudla and Timmerman 2010).
      1. Minimal fetal movement with stiff limbs in a semiflexed position
      2. Swollen limbs with hypoplastic fingers and toes and short phalanges
      3. Shriveled hands that do not open
      4. Characteristic facial features
         1. Flat face profile
         2. Open eyes
         3. Ectropion
         4. Cataracts
         5. Flat nose
         6. Thick lips
         7. Eclabium
         8. Absence of typical ear morphology (hypoplasia of the ears)
         9. Large open mouth
         10. Micrognathia
         11. Partitioned cystic formations in front of the eyes
      5. Short neck
      6. Thick skin
      7. Choroid plexus cysts

8. Short umbilical cord
9. Hyperechogenic amniotic fluid
10. Absence of associated visceral anomalies

2. Amniocentesis (Akiyama 1998; Akiyama et al. 1999): demonstration of clumping of keratinocyte cells in the amniotic fluid containing lipid droplets and amorphous electron-dense material.
3. Electron microscopy of the fetal skin biopsy specimen from fetoscopy at 20–22 weeks.
   1. Abnormal vacuoles in keratinized cells
   2. Abnormal lamellar granules in the hair canal
4. Molecular genetic testing: After identification of ABCA12 as the causative gene for harlequin ichthyosis, it is feasible to perform DNA-based prenatal diagnosis for harlequin ichthyosis by chorionic villus or amniotic fluid sampling (Akiyama et al. 2007; Yanagi et al. 2008) or preimplantation genetic diagnosis (Bale and Richard 2009). Both disease-causing alleles of an affected family member must be identified before prenatal testing can be performed.

3. Management (Prasad et al. 1994)
   1. Temperature control.
   2. Electrolyte and fluid balance.
   3. Adequate caloric intake.
   4. Prevention of infection with antibiotics.
   5. Topical steroids to reduce secondary inflammation.
   6. Tretinoin creams or ointments or oral retinoid treatment to reduce the amount of scale (Singh et al. 2001). Early use of systemic retinoids promotes accelerated shedding of the hyperkeratotic plates, whereas continued use reduces scale and improves ectropion and eclabium (Harvey et al. 2010).
   7. Pain management with anti-inflammatory drugs and morphine sulfate if necessary.
   8. Ocular management.
      1. Intensive topical eye ointment
      2. Treat keratitis promptly
      3. Surgical management of the ectropion by skin release surgery with autologous skin grafting in patients with severe exposure keratitis or cosmetically unacceptable ectropion
   9. Careful handling to avoid hard friction and physical contract for prevention of blistering.
   10. Most neonates don't survive. With aggressive neonatal care, survival and evolutions into a milder ichthyosis have been reported (Rajpopat et al. 2011).

Fig. 1 (**a**–**d**) A newborn with harlequin ichthyosis, covered with yellowish plaques (severe hyperkeratosis) with moist fissures and cracks and grotesque appearance of face with ectropion, eclabium, a flat nose, crumpled/flat ears, and swollen/semiflexed rigid limbs

Fig. 2 (**a**–**e**) The baby was born to a 19-year-old primigravida mother of Yemeni origin via normal spontaneous vaginal delivery. The APGARs were 7 and 9 at 1 and 5 min respectively. The weight was 2,065 g, crown-heel length 47.4 cm, and crown to rump 32.5 cm. The newborn showed severe ectropion, flattened nose, eclabium of lips, "fish mouth" deformity, crumped and flattened ears, alopecia with absent eyebrows and eyelashes, and ambiguous genitalia with non-notable penis or scrotum (**a**, **b**). Skin (**a**–**c**) showed diffuse hyperkeratotic plates with deep erythematous creases. Erythema was noted diffusely on parts of the skin, especially in cracked regions. The upper and lower extremities had flexion contractures. The hands and feet were clubbed and swollen with flexion contractures of the fingers with hypoplastic fingers and nails (**d**, **e**). An apparently homozygous K1086X nonsense mutation was identified in the *ABCA12* gene in the skin punch specimen. An A > T nucleotide substitution in exon 23 results in the replacement of a Lysine codon with a stop codon (AAA) at amino acid position 1086. This mutation is denoted c.3256 A > T at the cDNA level or p.Lys1086Stop (K1086X) at the protein level. The K1086X nonsense mutation in the *ABCA12* gene is predicted to cause loss of normal protein function whether through protein truncation or nonsense-mediated mRNA delay. Although this mutation has not been reported previously, its presence is consistent with the diagnosis of Harlequin ichthyosis in this individual. Target carrier testing of both parents has not been carried out (Courtesy of Dr. Shabnum Chaudhery)

Fig. 3 Microscopic examination of the skin punch specimen showed massive hyperkeratosis with normal to decreased granular cell layer and papillomatosis of the epithelium. The dilated spaces in the stratum corneum represent dilated ostial or eccrine ducts (A12-250) The figure shows massively thickened and compact orthokeratotic stratum corneum with normal granular layer. The dilated spaces in the stratum corneum represnt dilated ostia of eccrine ducts (*short arrow*). Hair follicles show marked concentric accumulation of keratotic material around hair shafts (*long arrow*) (Courtesy of Dr. Shabnum Chaudhery)

Hemangiomas of Infancy

Contents

Hemangiomas of infancy (infantile hemangiomas) are the most common benign pediatric tumors, characterized by an initial phase of rapid proliferation followed by slow involution and often leading to complete regression (Bruckner and Frieden 2003). The incidence of infantile hemangiomas in Caucasian infants is 3–10% (Margileth and Museles 1965). Multiple lesions are found in 15–30% of patients with infantile hemangiomas (Kilcline and Frieden 2008). Most infantile hemangiomas are sporadic, although families with multiple affected individuals have been reported (Blei et al. 1998; Walter et al. 1999).

In addition to common infantile hemangiomas, there are other rare vascular tumors that present fully grown at birth and behave quite differently, as designated by the acronyms: rapidly involuting congenital hemangioma (RICH) and noninvoluting congenital hemangioma (NICH) (Mulliken and Enjolras 2004). Some hemangiomas may be life or function threatening or have associated structural congenital anomalies.

Synonyms and Related Disorders

Diffuse neonatal hemangiomatosis; Infantile hemangiomas; Multifocal infantile hemangiomas; Noninvoluting congenital hemangiomas (NICH); PHACE syndrome; Rapidly involuting congenital hemangiomas (RICH); Vascular malformations

Genetics/Basic Defects

1. Infantile hemangiomas (Kwon et al. 2013)
    1. Current theories on the origin of hemangiomas (Bauland et al. 2006)
        1. Nonendothelial cells in hemangioma formation
        2. Angioblast theory
        3. Manifestation of a developmental field defect
        4. Placental origin
        5. Derangement of angiogenesis
        6. Mutation in cytokine regulatory pathway
    2. The origin of infantile hemangiomas: likely heterogeneous and multifactorial (Grimmer et al. 2011)
    3. In one study, 12% of 1,058 children with infantile hemangiomas were reported to have a first-degree relative with hemangiomas (Haggstrom et al. 2007).
    4. Somatic mutation(s) in a single, endothelial cell progenitor with ensuing clonal

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_260

expansion causes hemangioma of infancy (Boye et al. 2001; Walter et al. 2002).
5. An autosomal dominant inheritance has been described (Blei et al. 1998).
6. A follow-up family linkage study demonstrated linkage to chromosome 5q31-33 (Walter et al. 1999).
7. Infantile hemangiomas: the only lesions positive for a marker called GLUT1, independent of the stage (North et al. 2000; Mulliken and Enjolras 2004)
8. Subsequent sequencing of candidate genes in the region (Walter et al. 2002)
    1. Somatic mutations in genes encoding vascular endothelial growth factor receptors, VEGFR-2 (FLK/KDR) and VEGFR-3 (FLT4), in DNA isolated from two infantile hemangioma tissue specimens (Walter et al. 2002).
    2. Further evidence in support of a genetic component is provided by missense mutations found in genes encoding VEGFR-2 and the integrin-like receptor, tumor endothelial marker 8 (TEM8) (ANTXR1) (Jinnin et al. 2008).

2. Congenital vascular tumors (RICH and NICH): Different mutations possibly account for the behavioral divergence, either rapid involution or noninvolution, and the absence of immunoreactivity in the congenital vascular tumors (Mulliken and Enjolras 2004).
3. Vascular malformations (Vikkula et al. 2001)
    1. Localized errors of angiogenic development
    2. Most cases are cutaneous (also called vascular "birthmarks").
    3. Usually obvious in the newborn, grow commensurately with the child, and gradually expand in adulthood (Mulliken and Glowacki 1982)
    4. Can occur in visceral organs, such as the respiratory and gastrointestinal tract, but are more common in the brain (Mulliken and Young 1988)
    5. Composed of tortuous vascular channels of varying sizes and shapes, lined by a continuous endothelium, and surrounded by abnormal complement of mural cells
    6. Can be life threatening due to obstruction, bleeding, or congestive heart failure
    7. Most anomalies occur sporadically.
    8. There are families exhibiting autosomal dominant inheritance.
    9. Genetic studies of such families have resulted in the identification of mutated genes, directly giving proof of their important role in the regulation of angiogenesis: a mutation in the gene encoding the endothelial-specific receptor tyrosine kinase TIE2, the angiopoietin receptor (Vikkula et al. 1996).

Clinical Features

1. Natural history of growth and regression of infantile hemangioma (Bruckner and Frieden 2003; Restrepo et al. 2011; Kwon et al. 2013) (Figs. 1 and 2)
    1. Nascent phase
        1. A premonitory mark evident at birth or during the first few weeks of life in approximately 50% of neonates (Finn et al. 1983; Mulliken et al. 2000)
        2. The nascent lesions may appear as a telangiectatic macule surrounded by a pale halo, a pale macule, an erythematous macule, or less commonly as a bruise or scratch (Hidano and Nakajima 1972).
    2. Proliferating phase
        1. Most hemangiomas begin growth phase in the first few weeks of life.
        2. Occasionally deeper hemangiomas are not noticed until a few months of age.
        3. Rapid growth usually most pronounced during the first 3–6 months of life and reaching maximum size by 9–12 months of age
    3. Involuting phase
        1. Time of onset unpredictable
        2. Some begin at a few months.
        3. Most by 12–18 months
    4. Involuted phase
        1. Completed involution occurs at an estimated rate of 10% per year (Bowers et al. 1960).

2. Approximately 50% of patients followed up had "no trace" of hemangiomas on its resolution (Lister 1938).
3. Cutaneous changes
    1. Mild residual changes: telangiectasia, atrophic wrinkling, or yellowish discoloration
    2. Redundant skin with underlying fibrofatty residua or scarring if ulceration occurred
    3. Alopecia

2. Three clinical morphologies (Drolet et al. 1999; Chiller et al. 2002; Haggstrom et al. 2007)
    1. Superficial hemangiomas: present with a bright red color and are located at the superficial dermis
    2. Deep hemangiomas: involve the deep dermis and subcutis and appear as blue or skin-colored nodules
    3. Mixed hemangiomas: have components of both superficial and deep infantile hemangiomas
3. Another subclassification of infantile hemangiomas (Chiller et al. 2002; Haggstrom et al. 2006)
    1. Localized/focal hemangioma: discrete and oval/round, red, and raised
    2. Segmental hemangioma:
        1. Extend across a large anatomic region and have a geographic shape and typically at high risk for complications
        2. Larger, plaquelike, and geographical in a segmental distribution
    3. Indeterminate hemangioma: mixed features of both focal and segmental hemangiomas
4. Sites of involvement of infantile hemangiomas
    1. A large series (Finn et al. 1983)
        1. Head and neck (60%)
        2. Trunk (25%)
        3. Extremities (15%)
    2. Facial hemangiomas of infancy (Waner et al. 2003)
        1. Nonrandomly distributed
        2. Majority: Focal tumorlike lesions tend to occur near lines of embryonic fusion.
        3. Less commonly: involve a region of skin corresponding to a derivation from the embryologic mesenchymal prominences and tend to be more plaquelike in character
    3. So-called segmental hemangiomas of infancy: more likely to be associated with complications, structural anomalies, or extracutaneous hemangiomas of infancy (Chiller et al. 2002)
5. Location and morphology of infantile hemangiomas and associated risks (Bruckner and Frieden 2003)
    1. Large segmental facial: PHACE syndrome (*P*osterior fossa malformations, *H*emangioma, *A*rterial anomalies, *C*oarctation of the aorta and cardiac defects, *E*ye abnormalities, and occasionally sternal defects) (Frieden et al. 1996)
    2. Nasal tip, ear, large facial (especially with prominent dermal component): permanent scarring and disfigurement
    3. Periorbital and retrobulbar: ocular axis occlusion, astigmatism, amblyopia, and tear duct occlusion
    4. Segmental "beard area" and central neck: airway hemangioma
    5. Perioral, lips: ulceration, disfigurement
    6. Lumbosacral spine: tethered spinal cord and genitourinary anomalies
    7. Perineal, axilla, neck, and perioral: ulceration
    8. Multiple hemangiomas: visceral involvement (especially liver, gastrointestinal tract) with high risk of congestive heart failure
6. Complications (Chamlin et al. 2007; Kwon et al. 2013)
    1. Ulcerations: most common
        1. Pain
        2. Irritability
        3. Difficulty in feeding and sleeping
        4. Infection
        5. Bleeding: most often mild or moderate (most ulcerations are superficial), only rarely requiring transfusion
        6. Disfigurement
        7. Permanent scaring
        8. A subset of hemangiomas at greatest risk
            1. Proliferative phase
            2. Mixed (superficial deep) subtype, with segmental pattern, occurring in

certain anatomic sites, namely, the lower lip, neck, and anogenital region
3. Localized lesions, which are far more common, also develop ulceration.

2. Periorbital infantile hemangiomas: at risk for visual compromise (Ceisler et al. 2004)
1. Astigmatism due to pressure from the infantile hemangioma on the cornea
2. Amblyopia
3. Exophthalmos or displacement of the globe
4. Other possible complications include strabismus, exposure keratopathy, and optic neuropathy.

3. Airway infantile hemangiomas
1. Location: beard distribution, central neck
2. Difficulty breathing with cough, stridor, hoarse cry, and/or cyanosis
3. Subsequent respiratory failure

4. Visceral infantile hemangiomas
1. Occur most often in the gastrointestinal tract, liver, pancreas, spleen, and CNS
2. Commonly asymptomatic
3. Complications depending on the particular site of involvement
1. Gastrointestinal bleeding
2. High-output cardiac failure due to a large liver
3. Obstructive jaundice
4. CNS injuries
4. Presence of multifocal cutaneous hemangiomas: a strong predictor for visceral involvement although visceral infantile hemangioma can occur in the absence of cutaneous infantile hemangiomas

5. Associated anomalies and syndromes
1. PHACE syndrome
1. Diagnosis: based on a defined set of major and minor criteria (Metry et al. 2009a, b)
2. Pathogenesis: likely due to a disruption in early embryonic development
3. Typically present with large, segmental, facial hemangiomas
4. Cerebrovascular abnormalities common: increased risk of stroke (Siegel et al. 2012)
5. Developmental delay due to structural brain anomalies
2. Lumbosacral infantile hemangiomas: at risk of underlying developmental anomalies, such as anorectal and urinary tract defects

7. GLUT1 positive (independent of stage), also positive for Lewis Y antigen and Fc gamma receptor II

8. Congenital hemangiomas (Nasseri et al. 2014)
1. Rare lesions
2. Arise and proliferate in utero (Bronshtein et al. 1992; Marler et al. 2002)
3. Sometimes diagnosed prenatally
4. Fully developed at birth
5. GLUT1 negative
6. Denotes a vascular tumor that had grown to its maximum size at birth and does not exhibit accelerated postnatal growth (Boon et al. 1996)
7. Two major subtypes
1. Involuting congenital hemangioma (RICH): involutes completely within the first 6–14 months of life (Boon et al. 1996)
2. Noninvoluting congenital hemangioma (NICH): grows proportionally with the child and does not regress (Enjolras et al. 2001)
8. Congenital vascular tumor (NICH or RICH) can coexist with infantile hemangioma.
9. RICH may transform into NICH (Mulliken and Enjolras 2004).

9. Diffuse neonatal hemangiomatosis
1. Characterized by multiple cutaneous and visceral hemangiomas
2. Associated with a 60–90% mortality rate in the first few months of life, usually as a result of high output cardiac failure caused by arteriovenous shunting (Haik et al. 1983; Golitz et al. 1986; Stratte et al. 1996; Dotan and Lorber 2013)
3. Familial cases have been described (Ronan and Solomon 1984), including a case of diffuse neonatal hemangiomatosis with eyelid, conjunctiva, and iris hemangiomas (Chang et al. 1998).

10. Classification by the International Society for the Study of Vascular anomalies (Mulliken and Glowacki 1982) classifying vascular anomalies according to natural history and endothelial cell features
    1. Vascular (or vasoproliferative) neoplasms
        1. Infantile hemangiomas
        2. Congenital hemangiomas
            1. Rapidly involuting congenital hemangioma (RICH)
            2. Noninvoluting congenital hemangioma (NICH)
        3. Kaposiform hemangioendothelioma and tufted angiomas (with or without Kasabach-Merritt syndrome)
        4. Spindle cell hemangioendothelioma
        5. Epithelioid hemangioendotheliomas
        6. Other rare hemangioendotheliomas (composite, retiform, and others)
        7. Angiosarcoma
        8. Dermatologic acquired vascular tumors (i.e., pyogenic granuloma)
    2. Vascular malformations
        1. Slow-flow vascular malformations
            1. Capillary malformation
            2. Venous malformation
            3. Lymphatic malformation
        2. Fast-flow vascular malformations
            1. Arterial malformation
            2. Arteriovenous malformation
            3. Arteriovenous fistula
        3. Combined vascular malformations (various combinations of the above)
11. Differential diagnosis of multifocal vascular tumors, vascular malformations, and arteriovenous malformations (Elsayes et al. 2007; Glick et al. 2012)
    1. Infantile hemangioma: most common vascular tumor of infancy
    2. Multifocal lymphangioendotheliomatosis with thrombocytopenia
    3. Pyogenic granuloma
    4. Tufted angioma
    5. Kaposiform hemangioendothelioma
    6. Glomuvenous malformation
    7. Blue rubber bleb nevus syndrome
    1. A rare disorder characterized by multiple distinctive cutaneous and gastrointestinal venous malformations
    2. The name of syndrome: derived from the bluish color of the associated cutaneous lesions and their rubbery consistency at palpation (Bean 1958)
    3. Usually sporadic and generally presents at birth or in early childhood (Kassarjian et al. 2003)
    4. Cutaneous lesions may number from a few to more than 1,000.
    5. Preferentially involve the trunk and upper extremities
    6. Painful lesions
    7. Size: range from a few millimeters to several centimeters in diameter
    8. May be associated with vascular malformations of the gastrointestinal tract (Crosher et al. 1988; Gallo and McClave 1992)
        1. Manifestations: hematemesis, melena, or hematochezia
        2. Risk of life-threatening gastrointestinal hemorrhage
        3. Consumptive coagulopathy and iron deficiency anemia secondary to occult bleeding episodes
    9. May be associated with development of certain tumors, including medulloblastoma, chronic lymphocytic leukemia, renal cell carcinoma, and squamous cell carcinoma (Kassarjian et al. 2003)
8. Proteus syndrome: associated soft tissue abnormalities include vascular malformations, lipomas and fatty hypertrophy, regional fatty atrophy, hyperpigmentation, and nevi (Elsayes et al. 2007).
9. "► Klippel-Trenaunay Syndrome" (please see the chapter) and Parkes Weber syndrome
    1. The port-wine stain (a cutaneous capillary vascular malformation): present in 98% of patients and is the most common manifestation (Jacob et al. 1998)

2. Typically does not markedly progress or regress with time (unlike a hemangiomas)
3. May involve gastrointestinal tract in about 20% of patients (Baskerville et al. 1985; Schmitt et al. 1986; Wilson et al. 2001)
4. Cavernous hemangiomas can occur within abdominal solid organs and the mediastinum and retroperitoneum (Kuo et al. 2003).
5. Complication most often related to the vascular system
    1. Stasis dermatitis
    2. Thrombophlebitis
    3. Cellulitis
    4. Deep venous thrombosis
    5. Pulmonary embolism
    6. Coagulopathy
    7. Congestive heart failure (in patients with associated arteriovenous malformations)

10. "► Kasabach–Merritt Syndrome" (please see the chapter)
    1. Can result in severe disturbances of blood coagulation, such as disseminated intravascular coagulation
    2. In diffuse neonatal hemangiomatosis
        1. Widespread hemangiomas of the skin and viscera
        2. Can be complicated by Kasabach-Merritt syndrome, congestive heart failure, and gastrointestinal bleeding
    3. Other vascular lesions
        1. Angiosarcoma
        2. Arteriovenous malformations

Diagnostic Investigations

1. Histopathologic diagnosis (Kwon et al. 2013; Lowe et al. 2012)
    1. Currently gold standard
    2. Features vary depending on the stage of the life of infantile hemangiomas.
        1. Early stage: presence of rapidly proliferating, plump, endothelial-like cells and pericytes
        2. Later stage during the proliferating phase: fibrous septae containing large vessels separate lobules of plump endothelial-like cells and the presence of mitotic figures, apoptotic bodies, and mast cells within the infantile hemangiomas.
        3. Final involutional phase: presence of flattening of the endothelial-like cells, reduction in mitotic figures, decrease in vessels, and appearance of fibrofatty tissue
2. Immunohistochemical diagnosis (North et al. 2000)
    1. Positive staining of endothelial cells in infantile hemangioma tumor specimens with GLUT1, present at all stages: can differentiate infantile hemangiomas from other vascular tumors and malformations
    2. The immunodiagnostic marker (GLUT1): useful in differentiating infantile hemangiomas from other vascular anomalies such as congenital hemangiomas, which are present at birth and will not stain with GLUT1
3. Vasoproliferative neoplasms (infantile hemangioma) (Burrows et al. 1998)
    1. Grayscale ultrasound
        1. Well defined
        2. Solid
        3. Homogenous
        4. Variable echogenicity
    2. Doppler ultrasound
        1. Hypervascular
        2. Arterial and venous waveforms
        3. High vessel density (>5 vessels/cm^2)
        4. High Doppler shift (>2 kHz)
    3. MRI (Fig. 3)
        1. Iso-to-intermediate signal on T1 weighted
        2. Bright signal on T2 weighted
        3. High-intensity flow enhancement on gradient echo
        4. Internal flow voids
        5. Vigorous enhancement after contrast administration

4. Slow-flow vascular malformations (Burrows et al. 1998)
    1. Venous
        1. Grayscale ultrasound: solid echogenic mass with phleboliths, often multispacial and compressible
        2. Dropper ultrasound: monophasia (venous) or no flow pattern
        3. MRI: T1-weighted heterogeneous intermediate signal, no flow voids, T2 fast spin-echo fat-saturated or short T1 inversion recovery high-signal intensity, T1-weighted SE postgadolinium: enhancement
    2. Lymphatic
        1. Grayscale ultrasound: variable multicystic, multispacial masses, with or without fluid and/or debris levels
        2. Dropper ultrasound: multispacial, macrocystic mass with no flow except in septa
        3. MRI: T1-weighted low-intermediate signal intensity; T2-weight high-signal intensity; T1-weighted postgadolinium: no enhancement, except within septa
    3. Venolymphatic: combined venous and lymphatic components above
5. Fast-flow vascular malformations (arteriovenous malformations and fistulas) (Burrows et al. 1998)
    1. Grayscale ultrasound: cluster of vessels with no intervening well-defined mass
    2. Dropper ultrasound: arterial and venous signals from vessels in the lesions with arterialization of venous structures
    3. MRI: T1-weighted and T2-weight sequences show serpiginous signal voids without a focal mass

Genetic Counseling

1. Recurrence risk
    1. Patient's sib: a twofold increased risk according to multifactorial inheritance (Grimmer et al. 2011)
    2. Patient's offspring:
        1. Isolated: unknown but can be a twofold increase
        2. Autosomal dominant inheritance: 50%
2. Prenatal diagnosis and management
    1. Ultrasonography: Vascular anomalies (congenital hemangiomas) are diagnosed prenatally with increasing frequency (Marler et al. 2002).
        1. Overall diagnostic accuracy of 59%
        2. Capillary-lymphatic-venous malformation correctly diagnosed most often (67%), followed by lymphatic malformation (62 and hemangioma (59%)
        3. Most diagnoses : made during the mid- to late second trimester and third trimester
        4. Can be detected as early as the end of the first trimester (Boon et al. 1996; Berenguer et al. 2003)
    2. MRI: further define the characteristics of the lesion and monitor growth (Ozcan 2010)
    3. Maternal steroids: administered for a fetus with an intrahepatic hemangioma and deteriorating cardiac function, with subsequent stabilization and successful delivery of a healthy neonate (Sheu et al. 1994; Morris et al. 1999)
    4. Maternal interferon (Chuileannain et al. 1999)
    5. Cesarean section to prevent trauma associated with passage through the birth canal and massive hemorrhage (Nolan et al. 2012)
3. Management (Donnelly et al. 2000; Bruckner and Frieden 2003; Kwon et al. 2013)
    1. Major goals of management (Frieden et al. 1997)
        1. Preventing or reversing life- or function-threatening complications
        2. Preventing permanent disfigurement
        3. Minimizing psychosocial stress for the patient and family
        4. Avoiding aggressive and potentially scarring procedures

5. Preventing or adequately treating ulceration to minimize scarring, infection, and pain
2. Management of ulceration
   1. Local wound care
      1. Compresses
      2. Tropical antibiotics
      3. Occlusive dressings
      4. Systemic antibiotics in infected ulcerated hemangiomas
   2. Vascular-specific pulsed dye laser
   3. Pain management
3. Active nonintervention: a valuable approach for children with small, innocuous hemangiomas
4. Propranolol (a nonselective beta blocker)
   1. Induces apoptosis of endothelial cells in the capillaries
   2. Lowers intravascular pressure of the lesions
   3. Blocks vascular growth factors, mainly vascular endothelial growth factor and basic fibroblast growth factor
   4. Topical therapy with 1% propranolol ointment: safe and effective method of treating superficial infantile hemangiomas (Xu et al. 2012)
   5. Used for shrinking severe hemangiomas of infancy with excellent results (Léauté-Labrèze et al. 2008)
5. Systemic corticosteroids:
   1. Used as mainline therapy for hemangiomas since the 1960s (Zarem and Edgerton 1967; Fost and Esterly 1968)
   2. Used particularly for large and/or aggressive hemangiomas that are causing or threatening to cause functional impairment or severe disfigurement
6. Intralesional and topical corticosteroids:
   1. To avoid side effects associated with systemic corticosteroids
   2. Primarily in treating periorbital hemangiomas (Kushner 1979)
7. Interferon-α
   1. Reserve for infants with life-threatening or severely function-threatening hemangiomas who have failed to respond to steroid therapy
   2. Severely limited its use in infantile hemangiomas due to its neurotoxicity
8. Other systemic agents
   1. Vincristine: effective in treating vascular tumors associated with Kasabach-Merritt phenomenon (Haisley-Royster et al. 2002) and large, endangering hemangiomas (Boehm and Kobrinsky 1993; Moore et al. 2001)
   2. Cyclophosphamide (Vlahovic et al. 2009)
9. Pulse dye laser treatment: remains controversial for the treatment of proliferating infantile hemangioma as adverse outcomes including ulceration and scarring have been described (Witman et al. 2006), although successfully used for vascular birthmarks, namely, capillary malformations or "port-wine stains" for years
10. Embolization
11. Surgical excision (Holland and Drolet 2010)
    1. An option for function- or life-threatening hemangiomas when medical therapy fails or is not tolerated
    2. For removal of residual fibrofatty tissue or correction of scarring after involution
    3. May be pursued at an earlier age if it is clear that the child will ultimately need a procedure for the residual effects
12. Other treatments
    1. Intermittent pneumatic and continuous compression: used to treat lesions on the extremities and symptomatic hemangiomas (Stringel 1987; Kaplan and Paller 1995)
    2. A contact probe cooled by liquid nitrogen to treat isolated, raised lesions
    3. Radiation therapy as a last resort for infants with life- or function-threatening hemangiomas that have not responded to other therapeutic modalities (Ogino et al. 2001)

Fig. 1 (**a**, **b**, **c**) This infant was noted to have hemangiomas, a preauricular skin tag on his left ear, and a limbal dermoid on the left lower conjunctiva. There were multiple hemangiomas, located on the back of the head, chest, right shoulder, and the right side of his back. Chromosomes were normal 46,XY

Fig. 2 (**a**, **b**) This 9-month-old female infant was evaluated for multiple raised strawberry-like hemangiomas throughout the body, especially several large ones (>1–1.5 cm) at the shoulders, abdomen, and the chest

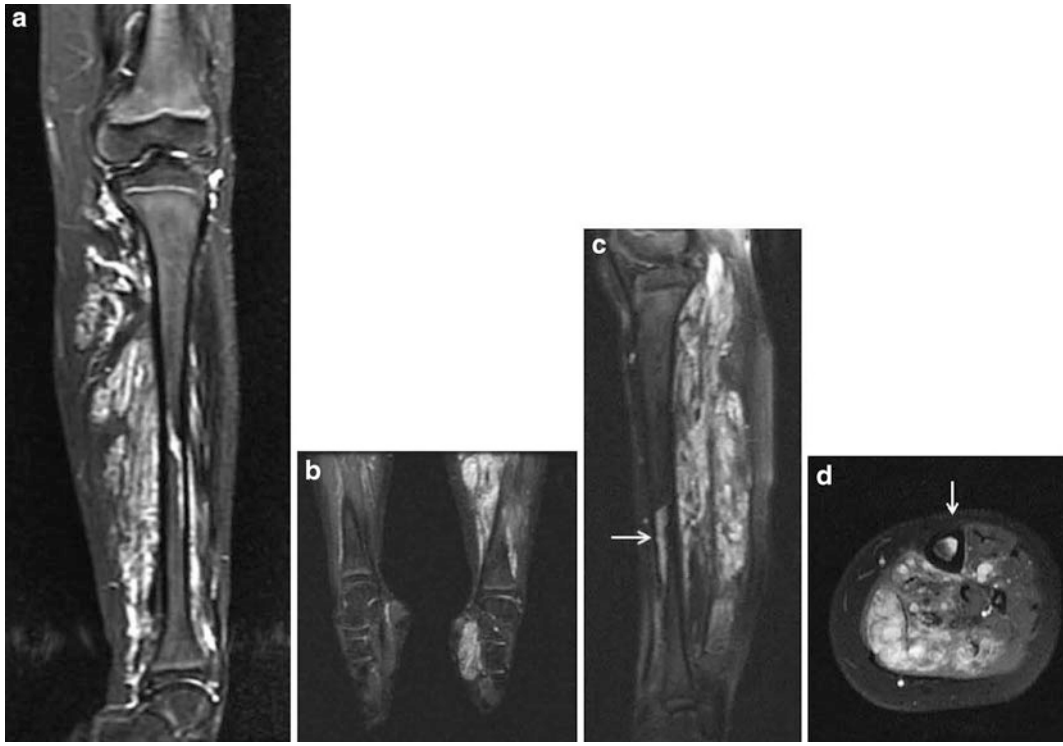

Fig. 3 (**a**–**d**) This 6-year-old female was seen for her enlarged left calf associated with limp and occasional pain. These symptoms seemed to be gradually worsening over the year. She had a hemangioma excised from the left foot at 18 months of age. Family history showed presence of some type of vascular malformation in many female relatives. On examination, there was soft tissue fullness and mild ecchymotic discoloration on the left side of the mons pubis, consistent with a hemangioma. The girth of the left calf was wider than the girth of the right. She had minimal tenderness to palpation of the left calf, but no tenderness to palpation over the left thigh or right calf. MRI showed a large, predominantly intramuscular infiltrating, enhanced hemangioma in the left lower extremity extending from the upper thigh to the foot (**a**, **b**). Infiltrative lesion was also seen in the left pelvis (not shown). There was an intraosseous extension in the mid- to lower tibial shaft (*arrows*) (**c**, **d**) (Courtesy of Dr. Grace Guo)

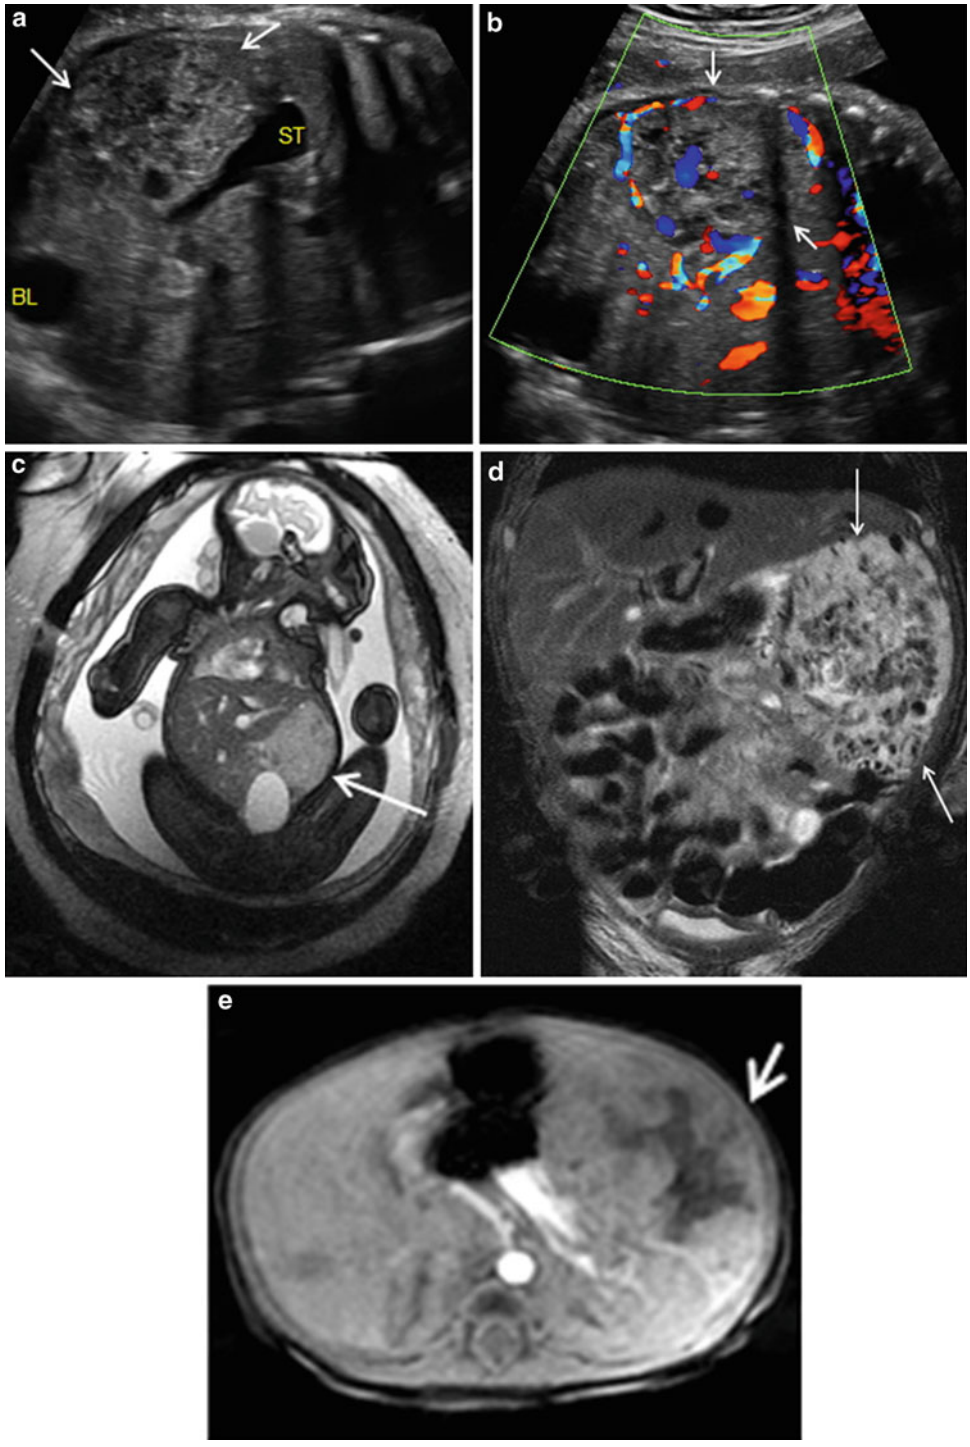

Fig. 4 (**a**–**e**) A 2-day-old female was seen with a history of prenatal diagnosis of intraabdominal mass. At 34 weeks' gestational age, fetal US showed a large, well-defined mass in the left upper abdomen with mixed echogenicity (*arrows*) (**a**) and prominent vascularity (*arrow*) (**b**). Fetal MRI showed a mass located just inferior and lateral aspect of the left lobe of the liver (*arrow*) (**c**). Postnatal MRI showed the mass with predominantly T2 hyperintense and multiple vascular flow voids (*arrows*) (**d**). There was minimal enhancement on initial postcontrast imaging and

Fig. 4 (continued) nodular peripheral enhancement seen on 5-min delayed postcontrast imaging (*arrow*) (**e**). The lesion was most consistent with a giant pedunculated congenital hepatic hemangioma. After birth, the patient has high output cardiac failure secondary to mitral valve regurgitation and shunting with large hemangioma. At 3 months of age, surgical excision of the left liver mass was performed. Pathologic examination confirmed the diagnosis of congenital hepatic hemangioma (GLUT1 negative) with central infarction and calcification (Courtesy of Dr. Grace Guo)

Hemophilia A

Contents

Hemophilia A is a congenital X chromosome-linked coagulation disorder characterized by deficiency in factor VIII clotting activity that results in prolonged oozing after injuries, tooth extractions, or surgery and delayed or recurrent bleeding prior to complete wound healing. It affects approximately 1 in 5,000 to 1 in 10,000 male births.

Synonyms and Related Disorders

Classic hemophilia; Factor VIII deficiency; Hemophilia B; von Willebrand disease

Genetics/Basic Defects

1. Inheritance (Hedner et al. 2000)
    1. An X-linked recessive disorder
    2. New mutations in approximately one third of patients
    3. Hemophilia A in females
        1. Rarely reported
        2. Possible explanation
            1. Extreme skewing of X chromosome inactivation resulting in unusually low factor VIII levels in female hemophilia A carriers
            2. Rare individuals carrying a hemophilia A mutation associated with an X chromosome-autosome translocation or other cytogenetic abnormality, which may result in exclusive inactivation of the normal X chromosome
            3. Rare individuals carrying a hemophilia A mutation in the rearranged X chromosome
2. Molecular genetics (Hedner et al. 2000)
    1. Caused by absent or decreased factor VIII (FVIII) procoagulant function, resulting from mutations in FVIII (*F8*) gene, mapped on chromosome Xq28.
    2. A unique rearrangement within the FVIII gene (intron 22 gene inversion), recently identified as a common, recurrent mechanism for hemophilia A.
        1. Accounting for approximately 45% of all severe hemophilia A patients.
        2. The mutation almost always arises during a male meiosis.
        3. The mother of an apparently new mutation patient with an identified gene inversion can generally be assumed to be a carrier, with the recombination event

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_114

often identified in the maternal grandfather's allele.
3. The remaining 55% of severe hemophilia patients are shown to have a more conventional molecular defect in the FVIII gene.
    1. Approximately 50% of patients with specific point mutations in exons or at splice junctions within the FVIII gene
    2. Approximately 5% of patients with deletions which remove varying-sized segments of the FVIII gene
    3. Rare small insertions and deletions
4. Nearly all patients with mild or moderately severe hemophilia A have some residual level of FVIII activity, shown to have a point mutation within the FVIII coding sequence, resulting in a single amino acid substitution.
5. Clinical severity of the hemophilia A phenotype correlates very closely with the amount of residual factor VIII activity.

Clinical Features

1. Clinical features suspecting a coagulation disorder (Hedner et al. 2000)
    1. Hemophilic arthropathy (Wyseure et al. 2016)
        1. Arthropathy is a form of joint disease that develops secondary to joint bleeding.
        2. Presents with synovial hypertrophy, cartilage, and bony destruction.
        3. The arthropathy can develop despite clotting factor replacement.
        4. Especially disabling in the aging population.
    2. Deep muscle hematomas
    3. Intracranial bleeding in the absence of major trauma
    4. Cephalohematoma or intracranial bleeding at birth
    5. Prolonged oozing or renewed bleeding after initial bleeding stops following tooth extractions, mouth injury, or circumcision
    6. Prolonged bleeding or renewed bleeding following surgery or trauma
    7. Unexplained gastrointestinal bleeding or hematuria
    8. Menorrhagia, especially at menarche
    9. Prolonged nosebleeds, especially recurrent and bilateral
    10. Excessive bruising, especially with firm, subcutaneous hematomas
2. Severe hemophilia A (43% of hemophiliacs)
    1. Spontaneous bleeding
        1. Joints: the most frequent symptom
        2. Other sites
            1. Kidneys
            2. Gastrointestinal tract
            3. Brain
    2. Without treatment
        1. Bleeding from minor mouth injuries and large "goose eggs" from minor head bumps during the toddler period
        2. Rare intracranial bleeding resulting from head injuries
        3. Almost always with subcutaneous hematomas
        4. Frequency of bleeding
            1. Relating to the FVIII clotting activity
            2. Varying from two to five spontaneous bleeding episodes each month
            3. Bleeding episodes more frequent in childhood and adolescence than in adulthood
    3. Age of diagnosis
        1. Usually diagnosed during the first year of life
        2. Relating to the FVIII clotting activity
3. Moderately severe hemophilia A (26% of hemophiliacs)
    1. Seldom with spontaneous bleeding
    2. Without treatment
        1. Prolonged or delayed oozing after relatively minor trauma
        2. Frequency of bleeding
            1. Varying from once a month to once a year
            2. Bleeding episodes more frequent in childhood and adolescence than in adulthood

3. Usually diagnosed before the age of 5–6 years
4. Mild hemophilia A (31% of hemophiliacs)
   1. Absent spontaneous bleeding
   2. Without treatment
      1. Occurrence of abnormal bleeding with surgery, tooth extraction, and major injuries
      2. Frequency of bleeding
         1. Varying from once a year to once every 10 years
         2. Bleeding episodes more frequent in childhood and adolescence than in adulthood
   3. Often not diagnosed until later in life
5. Carrier females (Graham et al. 1986)
   1. Risk of bleeding in approximately 10% of carrier females
   2. Mild symptoms
6. Complications of untreated bleeding
   1. Intracranial hemorrhage: the leading cause of death
   2. Chronic joint disease: the major cause of disability
7. Life expectancy: 60–70 years
8. Differential diagnosis (Brower and Thompson 2008; Konkle et al. 2014)
   1. Inherited bleeding disorders associated with a low factor VIII clotting activity
      1. Type 1 vWD (mild von Willebrand disease)
         1. An autosomal dominant disorder
         2. Predominant feature: mucous membrane bleeding
         3. Quantitative deficiency of von Willebrand factor (low vWF antigen, factor VIII clotting activity, and ristocetin cofactor activity) in 80% of patients
      2. Type 2 vWD
         1. Quantitative deficiency of vWF with a decrease of the high-molecular-weight multimers
         2. Low normal to mildly decreased vWF antigen and factor VIII clotting activity
         3. Low functional vWF level in a ristocetin cofactor assay
      3. Type 2 N (Normandy) vWD
         1. An uncommon variant due to several missense mutations in the amino terminus of the vWF protein, resulting in defective binding of factor VIII to vWF
         2. Low factor VIII clotting activity usually showing autosomal recessive inheritance
         3. Indistinguishable clinically from mild hemophilia A, which can be differentiated with molecular genetic testing of the FVIII gene, molecular genetic testing of the vWF gene, or measuring binding of factor VIII to vWF using ELISA or column chromatography
      4. Type 3 vWD (severe von Willebrand disease)
         1. An autosomal recessive disorder
         2. Frequent episodes of mucous membrane bleeding and joint and muscle bleeding similar to hemophilia A
         3. $<1\%$ vWF level
         4. Two to eight FVIII clotting activity
      5. Mild combined factor V and factor VIII deficiencies
         1. A rare autosomal recessive disorder
         2. Deficiency of a chaperone protein (ERGIC-53)
   2. Acquired hemophilia A (Collins et al. 2010)
      1. A bleeding disorder caused by an autoantibody to factor VIII.
      2. Estimated incidence: 1.5/million/year.
      3. Predominantly affects older patients.
      4. Acute onset of severe and life-threatening bleeding or widespread subcutaneous bleeds.
      5. Bleeding sites atypical of congenital hemophilia.
      6. Presence of underlying diseases and conditions.
      7. No personal or family history of bleeding.
      8. High mortality with both early and late deaths: estimated at between 9% and 22%.

9. Prolonged aPTT (activated partial thromboplastin time) with a normal prothrombin time (PT).
10. Mixing test: failure of normal plasma to correct the aPTT by more than 50% is usually taken as evidence that an inhibitor is present (Kasper 1991).

3. Other bleeding disorders with normal factor VIII clotting activity
    1. Hemophilia B
        1. An X-linked recessive disorder caused by mutations in the factor IX (FIX) gene
        2. Clinically indistinguishable from hemophilia A
        3. Diagnosis based on factor IX clotting activity of <40%
    2. Factor XI deficiency
        1. An autosomal recessive disorder
        2. Homozygotes with factor XI coagulant activity of <1–15%
        3. Heterozygotes with factor XI coagulant activity of 25–75%
    3. Factor XII, prekallikrein, or high-molecular-weight kininogen deficiencies
        1. Do not cause clinical bleeding
        2. A prolonged activated partial thromboplastin time (aPTT)
    4. Prothrombin (factor II) or factor V, X, or VII deficiencies
        1. Autosomal recessive disorders
        2. Clinical features: easy bruising and hematoma formation, epistaxis, menorrhagia, and bleeding after trauma and surgery
        3. Diagnosis established by specific coagulation factor assays
    5. Fibrinogen disorders
        1. Congenital afibrinogenemia: an autosomal recessive disorder characterized by prolonged bleeding from minor cuts due to the lack of fibrinogen to support platelet aggregation
        2. Hypofibrinogenemia: inherited either in an autosomal dominant or recessive fashion with mild to moderate bleeding symptoms or may be asymptomatic
        3. Dysfibrinogenemia: an autosomal dominant disorder with symptoms similar to hypofibrinogenemia
    6. Factor XIII deficiency
        1. An autosomal recessive disorder
        2. Occurrence of umbilical stump bleeding in >80% of cases
        3. Intracranial bleeding occurring spontaneously or following minor trauma in 30% of cases
        4. Subcutaneous hematomas
        5. Muscle hematomas
        6. Defective wound healing
        7. Recurrent spontaneous abortion
        8. Rare joint bleeding
    7. Platelet function disorders
        1. General features: bleeding problems similar to thrombocytopenia (skin and mucous membrane bleeding, recurring epistaxis, gastrointestinal bleeding, menorrhagia, excessive bleeding during or immediately after trauma and surgery)
        2. Bernard-Soulier syndrome: an autosomal recessive disorder involving the vWF receptor and platelet GPIb characterized by thrombocytopenia and large platelets
        3. Glanzmann thrombasthenia: an autosomal recessive disorder involving the GPIIb-IIIa receptor necessary for platelet aggregation

Diagnostic Investigations

1. Coagulation screening test
    1. Prolonged partial thromboplastin time (PTT) in severe and moderately severe hemophilia A
    2. PTT often normal in mild hemophilia A
2. Coagulation factor assay for factor VIII clotting activity
    1. Normal range: 50–150%
    2. Low to low normal: above 35%
        1. Usually do not have bleeding.

2. Bleeding can occur in association with mild von Willebrand disease.
3. Factor VIII clotting activity unreliable in the detection of carriers
4. Diagnosis of hemophilia A established in patients with low FVIII clotting activity (<35%) in the presence of a normal von Willebrand factor (vWF) level
    1. Activity <1%: severe hemophilia A
    2. Activity 1–5%: moderately severe hemophilia A
    3. Activity 5–35%: mild hemophilia A

3. Hemophilia imaging (Maclachlan et al. 2009)
    1. Hemophilia arthropathies: radiography, ultrasound, MRI (Cross et al. 2013)
    2. Intramuscular hemorrhage: MRI
    3. Soft tissue hemorrhage (pseudotumors): CT/MRI
    4. Intracranial hemorrhage: CT/MRI
    5. Complications secondary to administration of blood products (liver cirrhosis, liver failure, hepatocellular carcinoma): CT/MRI
4. Molecular genetic diagnosis (Brower and Thompson 2008)
    1. Severely affected and isolated hemophiliac: in ~90% of those patients, the pathogenic gene defect could be identified (Becker et al. 1996).
    2. Targeted mutation analysis
        1. An *F8* intron 22-A gene inversion: accounts for nearly half of families with severe hemophilia A (Kaufman et al. 2006)
        2. An F8 intron 1 gene inversion: accounts for 2–3% of severe hemophilia A (Bagnall et al. 2002)
    3. Mutation scanning or sequence
        1. Seventy-five to ninety-eight percent mutation detection rate in individuals with hemophilia A who do not have one of the two common inversions
        2. Gross gene alterations (including large deletions or insertions, frame shift and splice junction changes, and nonsense and missense mutations) of F8: account for approximately 50% of mutations detected in severe hemophilia A (Kemball-Cook et al. 1998; El-Maarri et al. 2005; Kaufman et al. 2006)
        3. Missense mutations within the exons coding for the three A domains or the two C domains: account for most of the mutations detected in mild to moderately severe hemophilia A (Kemball-Cook et al. 1998; Kaufman et al. 2006)
    4. Deletion analysis
        1. Available clinically to detect exonic, multiexonic, or larger deletions in affected males
        2. Also available for direct diagnosis in potential carrier females
    5. Indirect genetic linkage analysis (Ljung and Tedgård 2003)
        1. Using linked polymorphic markers (restriction fragment length polymorphisms, RFLP) to trace the inheritance of the hemophilia gene within a pedigree if mutation is not found
        2. Limitation of linkage analysis
            1. Uninformative patterns of polymorphic markers
            2. Ethnic variation
            3. Linkage disequilibrium
            4. Need for participation of family members
            5. Not useful in sporadic families which constitute more than half of the hemophilia families

Genetic Counseling

1. Recurrence risk
    1. Obligatory carrier (Ljung and Tedgård 2003).
        1. A woman whose father has hemophilia
        2. A woman who has given birth to two boys with hemophilia, excluding identical twins
        3. A woman who has given birth to one son with hemophilia and a daughter who has a son with hemophilia

2. Establish the genetic probability for carriership for women in a pedigree who are not genetic obligatory carriers based on:
    1. Pedigree data
    2. Clotting factor (FVIII:C) analysis
3. Patient's sib (sib of a male proband): risk to the sibs depending on the carrier status of the mother.
    1. Mother is a carrier: a 50% risk of having a male sib with hemophilia A and a 50% risk of having a carrier female sib
    2. Possibility of maternal germline mosaicism: a low recurrence risk of having a male sib with hemophilia A if the mother has a normal factor VIII clotting activity and no evidence of her carrying her son's FVIII disease-causing mutation in her leukocytes, unless she has germline mosaicism
4. Patient's offspring.
    1. No sons will inherit the mutant allele and therefore will not be affected with hemophilia A.
    2. All daughters will be carriers for hemophilia A.
5. Somatic mosaicisms were detected in 18.8% of the de novo mutations in the patients' mothers, indicating that this phenomenon should be considered in genetic counseling (Becker et al. 1996).
6. Risk assessment in genetic counseling should include consideration of the possibility of somatic mosaicism in families with apparently de novo mutations, especially families with the subtype of point mutations (Leuer et al. 2001).

2. Prenatal diagnosis available to pregnancies of carrier women with hemophilia A (Konkle et al. 2014)
    1. Fetal karyotyping to determine male fetus (46,XY) (Graham 1977).
    2. DNA extracted from fetal cells by amniocentesis or CVS analyzed for:
        1. The known FVIII disease-causing mutation: A case of hemophilia A was prenatally suspected because PCR CVS revealed an inversion within intron 1 in part for hemophilia A (Jovandaric and Jesic 2015).
        2. The informative linked polymorphic markers (Chowdhury et al. 2003).
    3. Fetal blood sample obtained by percutaneous umbilical blood sampling (PUBS) for assay of factor VIII clotting activity if the disease-causing FVIII mutation is not known and if linkage testing is not informative.
    4. Preconception genetic counseling is required to inform patients of the available options and the complex and time-consuming nature of F8 testing (Kessler et al. 2014).
    5. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified in an affected family member.
3. Management (Aledort 1982; Mannucci 2003a, b)
    1. Prophylactic treatment using plasma-derived concentrate of coagulation factor in the past.
        1. Preventing majority of bleeding episodes
        2. Minimizing the impact of arthropathy
        3. Complications
            1. Concentrates manufactured from plasma, pooled from thousands of donors, and invariably contaminated with blood-borne viruses that caused posttransfusion hepatitis B and non-A, non-B (hepatitis C) in practically all treated hemophiliacs.
            2. Optimistic perception of hemophilia: benefits of concentrates seemed to outweigh hepatitis risks.
            3. Tragedy: 60–80% of persons with severe hemophilia became infected with the human immunodeficiency virus (HIV) with contaminated concentrates in the early 1980s.
    2. Infusion of plasma-derived or recombinant FVIII (Helixate, Kogenate, Recombinate, ReFacto) (Bhattacharyya et al. 2003; Vandendriessche et al. 2003).

1. Markedly improves both the life expectancy and the quality of life of patients suffering from hemophilia A
2. Still at risk for life-threatening bleeding episodes and chronic joint damage
3. Side effect of clotting factor substitution therapy: develop neutralizing antibodies against FVIII, rendering further substitution ineffective (10–40% of cases)

3. Promising new recombinant factor VIII products are in advanced stages of clinical trials, and studies are underway to address how to optimally use current resources to improve quality of life for individuals with severe hemophilia A (Powell 2009).
4. Factor VIII/factor IX prophylaxis for severe hemophilia (Carcao and Srivastava 2016).
    1. With the development of new bioengineered clotting factor concentrates (CFCs) with extended half-life (EHL), prophylaxis regimens are likely to change.
    2. EHL CFCs (particularly EHL factor IX) may make prophylaxis more convenient, may allow for more individualization of prophylaxis, may improve adherence to prophylaxis, may expand prophylaxis to patients with less severe forms of hemophilia, and may allow patients to achieve an early normal life.
5. Orthopedic management (Rodriguez-Merchan 2008).
    1. Hemarthrosis: arthrocentesis.
    2. Synovitis: synoviorthesis and synovectomy.
    3. Flexion contractures.
        1. Tendon-lengthening procedures
        2. Supracondylar osteotomy to correct a fixed-knee contracture
        3. Implantation of an external fixator
    4. Hemophilic arthropathy.
        1. Subchondral bone cysts: cheilectomy and curettage
        2. Alignment osteotomy
        3. Joint debridement
        4. Arthrodesis
        5. Joint prosthesis
        6. Total knee arthroplasty
        7. Total hip arthroplasty
    5. Intramuscular hematomas: usually reabsorb without complication when hematological treatment is adequate.
        1. Iliopsoas hematoma
        2. Compartment syndrome (fasciotomy)
        3. Pseudotumors
    6. Orthopedic surgery in patients with inhibitors: contemporary orthopedic and hematological advances such as recombinant activated factor VII (rFVIIa; NovoSeven®, Novo Nordisk, Bagsværd, Denmark) and activated prothrombin complex concentrates (aPCC; FEIBA, Baxter Corp, Deerfield, IL) enable major orthopedic operations to be performed on hemophilia patients with inhibitors, despite these patients having a higher risk of bleeding complications than patients with hemophilia who do not have inhibitors (Rodriguez-Merchan et al. 2007).
6. Obstetrical issues.
    1. Asymptomatic carrier
        1. Uncommon intracranial hemorrhage in affected male fetuses (1–2%)
        2. Cesarean section reserved for complicated deliveries
    2. Symptomatic carrier (baseline factor VIII clotting activity <35%)
        1. Somewhat protected by the natural rise of factor VIII clotting activity during pregnancy
        2. Delayed postpartum bleeding when factor VIII clotting activity returns to baseline within 48 h
7. Neonatal issues.
    1. Early determination of the genetic status of male infants at risk
        1. Assay factor VIII clotting activity from a cord blood sample obtained by venipuncture of the umbilical vein

2. Molecular genetic testing for the FVIII mutation identified in the family
2. Avoid circumcision and heel sticks in infants at risk with a family history of hemophilia A (Car and Tortella 2015), unless:
    1. Hemophilia A is excluded.
    2. Factor VIII concentrate is administered just prior and subsequent to the procedure to prevent delayed oozing and poor wound healing.
8. Analysis of patient's DNA.
    1. Permits identification of the gene lesions that cause hemophilia
    2. Allows the disease to be controlled through carrier detection and prenatal diagnosis
9. New extended half-life clotting factor products, newer agents being developed for patients with inhibitors, and new nonfactor replacement therapies for hemophilia (Car and Tortella 2015).
10. Future gene therapy (Vandendriessche et al. 2003).
    1. Providing a cure for the disease
    2. Providing constant, sustained FVIII synthesis in the patient
        1. Obviate the risk of spontaneous bleeding
        2. Obviate the need for repeated FVIII infusions
        3. Obviate the risk of viral infections associated with plasma-derived FVIII
    3. Requires the use of a gene delivery system that is efficient, safe, nonimmunogenic, and allows for long-term gene expression
    4. Must compare favorably with existing protein replacement therapies
    5. Initiation of several gene therapy phase I clinical trials in patients suffering from severe hemophilia A
        1. Fewer bleeding episodes reported in some patients
        2. Occasional detection of low levels of clotting factor activity
11. Gene therapy for hemophilia: past, present, and future (George and Fogarty 2016).
    1. Over the past several decades, great strides have been taken in the clinical development of gene therapy for hemophilia.
    2. The most advanced contemporary clinical trials, which use gene transfer and an AAV-8 vector platform, have demonstrated the ability to substantially correct the deficiency in coagulation factor activity in an enduring fashion in selected subjects.
    3. Provided that later stage trials are successful, the approach will represent a shift in the current treatment paradigm (i.e., periodic intravenous infusion to replace the missing coagulation factor) that has dominated the treatment landscape in developed countries for nearly 40 years.

Fig. 1 A boy with hemophilia A who is asymptomatic with prophylactic infusions of recombinant FVIII

Fig. 2 An infant boy with hemophilia A who was found to have low factor VIII activity. The mother and maternal grandmother had histories of nosebleeds and prolonged bleeding after small cuts and bruise easily

Fig. 3 A 30-year-old man with hemophilia B

Hereditary Hearing Loss

Contents

Hearing loss can be divided into conductive, sensorineural, mixed, and central types (Gifford et al. 2009). Conductive hearing loss (CHL) results from interference with the mechanical transmission of sound through the external and middle ear. Sensorineural hearing loss (SNHL) results from a failure to transduce vibrations to neural impulses effectively within the cochlea or transmit these impulses down the vestibulocochlear nerve. Mixed hearing loss involves a combination of CHL and SNHL, usually due to damage throughout the middle ear and the inner ear. Central hearing loss refers to defects in the brainstem or higher processing centers of the brain. Both CHL and SNHL may be caused by a wide variety of congenital/hereditary and acquired factors.

Understanding genetic basis of hearing loss is important because almost 50% of profound hearing loss (affecting almost 1 in 1,000 newborns) is caused by genetic factors and more than 120 independent genes have been identified (Bayazit and Yilmaz 2006).

Genetics/Basic Defects

1. Causes of conductive hearing loss (Bayazit and Yilmaz 2006; Gifford et al. 2009; Hilgert et al. 2009).
    1. Congenital
        1. Microtia/atresia
        2. Tympanic membrane abnormalities
        3. Ossicular malformations
    2. Acquired
        1. Infections
            1. Acute otitis media
            2. Otitis externa
            3. Ossicular erosion
        2. Otitis media with effusion
        3. Foreign body including cerumen
        4. Cholesteatoma
        5. Trauma
            1. Ossicular disruption
            2. Tympanic membrane perforation
2. Nonhereditary causes of sensorineural hearing loss (SNHL).
    1. In utero infections
        1. *Cytomegalovirus* (CMV): the most common environmental (nongenetic) cause of congenital hearing loss
        2. Measles
        3. Mumps
        4. Rubella
        5. Varicella
        6. Syphilis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_115

2. Anatomic abnormalities of the cochlea or temporal bone
3. Exposure to ototoxic drugs during pregnancy
    1. Alcohol
    2. Isotretinoin
    3. Cisplatinum
4. Hyperbilirubinemia
5. Infections
6. Trauma
    1. Physical
    2. Acoustic
7. Radiation therapy for head and neck tumors

3. Hereditary hearing loss: mutations and polymorphisms.
    1. Recessive gene mutations
        1. Homozygosity
            1. Same mutation is present in both alleles
            2. Having two identical alleles as a specific autosomal (or X chromosome in a female) gene locus
            3. Can cause hearing impairment
        2. Heterozygosity
            1. Having two different alleles as a specific autosomal (or X chromosome in a female) gene locus.
            2. "Compound heterozygote": both alleles have different disease-causing mutations and can cause hearing impairment.
            3. "Carrier": only one of the alleles has the disease-causing mutation and the other allele is normal and does not have hearing impairment.
    2. Dominant gene mutations
        1. Presence of a mutation in only one of the alleles: enough for the individual to have the disease
        2. Penetrance in the dominant gene
            1. Likelihood that a person carrying a particular mutant gene will have an altered phenotype.
            2. May differ in different individuals.
            3. Presence of a dominant mutation in the parents does not always mean that the siblings will always have hearing impairment.
        3. Expression of a disease-causing gene
            1. May cause differences in the phenotype.
            2. Expression may be one of the reasons why the same genotype or mutations are manifested by different phenotypes in genetic hearing loss.
    3. Genetic polymorphism
        1. Most polymorphisms have no detectable clinical effects.
        2. If one of the alleles is mutated and the other allele has a polymorphism, the individual will probably not have hearing impairment.
4. Genetic nonsyndromic hearing loss (NSHL) (Finsterer and Fellinger 2005): to date, there are 46 nonsyndromic deafness genes reported in the literature (Hilgert et al. 2009).
    1. Autosomal dominant NSHL.
        1. Constitutes 18% of NSHL
        2. Affects almost 50% of the siblings.
        3. Usually postlingual hearing loss except for DFNA3, DFNA6, DFNA8, DFNA12, DFNA13 (De Leenheer et al. 2001), DFNA19, and DFNA14
        4. *WFS1* gene mutations cause:
            1. Autosomal dominant low-frequency SNHL
            2. Wolfram syndrome (hearing loss, diabetes mellitus, diabetes insipidus, and optic atrophy)
        5. *KCNQ4* gene mutations.
            1. Frequent cause of autosomal dominant NSHL.
            2. Missense mutations cause hearing loss beginning at a young age and affecting all frequencies.
            3. Deletion mutations cause a milder phenotype with later onset and affecting only the high frequencies.
            4. W276S mutation in *KCNQ4*: may be a mutational "hot spot" (van Camp et al. 2002).
        6. *COCH* gene mutations.
            1. Frequent mutations: P51S in Belgium and the Netherlands
            2. Cause progressive hearing loss and vestibular impairment with late onset

7. *TECTA* gene mutations cause autosomal dominant mid-frequency HL and high-frequency HL.
8. *TBC1D24* mutation causes autosomal dominant nonsyndromic hearing loss (Azaiez et al. 2014).
9. Dominant mutations in *GJB2* cause:
    1. Autosomal dominant NSHL
    2. Syndromic hearing loss associated with diverse skin disorders (include diffused palmoplantar keratoderma-hyperkeratosis, Vohwinkel syndrome, and keratitis-ichthyosis-deafness [KID] syndrome) (Richard et al. 2002; de Zwart-Storm et al. 2008)

2. Autosomal recessive NSHL
    1. Constitutes 80% of all NSHL cases
    2. Usually prelingual and severe hearing loss except for DFNB8 in which hearing loss is postlingual and rapidly progressive
    3. Affects almost 25% of siblings
    4. DFNB1 (Kelsell et al. 1997; Denoyelle et al. 1999): caused by a mutation in the *GJB2* gene on chromosome 13q12-13 that codes for a gap junction protein called connexin 26
        1. *GJB2* mutations: the most frequent cause of autosomal recessive nonsyndromic hearing loss in most world populations, frequent in the Caucasian, Jewish, and Asian populations (Carrasquillo et al. 1997; Zelante et al. 1997; Kelley et al. 1998; Morell et al. 1998; Abe et al. 2000)
        2. 35delG mutation: most frequent in the majority of Caucasian populations and may account for up to 70% of all *GJB2* mutations (Estivill et al. 1998; Snoeckx et al. 2005)
    5. *SLC26A4* gene mutations
        1. The second most frequent cause of autosomal NSHL
        2. Associated phenotypic spectrum: ranges from Pendred syndrome at one extreme to isolated NSHL with enlarged vestibular aqueduct at the other (DFNB4 locus)
    6. *MYO15A* gene mutations
        1. Cause congenital severe-to-profound hearing loss at the DFNB3 locus.
        2. All 28 identified mutations have been found by linkage analysis in consanguineous families, most of which originate from Pakistan.
    7. *OTOF* gene mutations
        1. Cause prelingual, profound autosomal recessive NSHL
        2. Suggest as the major cause of auditory neuropathy
    8. *CDH23* gene mutations: cause both Usher syndrome type 1D and moderate-to-profound progressive autosomal recessive NSHL at the DFNB12 locus
    9. *TMC1* gene mutations
        1. One of the more frequent causes of autosomal recessive NSHL in consanguineous populations
        2. Characterized by prelingual severe-to-profound hearing loss
3. X-linked recessive NSHL
    1. Constitutes 1–3% of all NSHL cases
    2. Usually prelingual hearing loss except for DFN6
    3. Frequently affects boys
    4. DFN2 and DFN4: mostly cause severe prelingual sensorineural hearing loss
    5. *POU3F4* gene (at locus DFN3) mutations
        1. Cause X-linked mixed or purely sensorineural HL
        2. Deafness with fixation of the stapes (DFN3): the most frequent X-linked form of hearing impairment (De Kok et al. 1995)
        3. May be associated with Mondini dysplasia, cochlear hypoplasia, and/or stapes fixation
4. Mitochondrial hearing loss (Kokotas et al. 2007; Yelverton et al. 2013)
    1. Mutations in mitochondrial genes: the majority are the cause of a broad

spectrum of maternally inherited multisystem disorders.
2. At present, more than 50 mitochondrial mutations leading to syndromic or nonsyndromic deafness have been identified (Zheng et al. 2012).
3. Variants involving *MT-RNR1* and *MT-TS1*, encoding the 12S ribosomal RNA (rRNA) and transfer tRNASer$^{(UCN)}$ respectively, are the most common.

5. Genetic syndromic hearing loss.
   1. Usher syndrome
      1. The most common cause of autosomal recessive syndromic hearing loss (Smith et al. 1994)
      2. Affects almost 50% of the blind and deaf people in the USA
      3. Mutations
         1. USH1A-G
         2. USH2A-C
         3. USH3
   2. Pendred syndrome
      1. Almost 50% of families with *SLC26A4* (PDS) gene mutation on chromosome 7q21-q34
      2. The same mutation can also cause DFNB4 (Li et al. 1998)
   3. Jervell and Lange-Nielsen syndrome: mutations in the following potassium channel genes:
      1. JLNS1 locus in the *KVLQT1* gene located on chromosome 11p15.5
      2. JLNS2 locus in the *KCNE1* (*IsK*) gene located on chromosome 21q22.2
   4. Biotinidase deficiency: resulting from deficiency of an enzyme required for the normal recycling of the vitamin biotin
   5. Waardenburg syndrome (WS): has four subgroups (Van Camp and Smith 2010)
      1. Type I: *PAX3* on 2q35
      2. Type II: *MITF* on 3p14.1-p12.3; *SLUG* on 8q11
      3. Type III: *PAX3* on 2q35
      4. Type IV: *EDNRB* on 13q22; *EDN3* on 20q13.2-q13.3; *SOX10* on 22q13
   6. Branchio-oto-renal (BOR) syndrome
      1. *EYA1* gene mutation on chromosome 8q13.3 (in 50% of patients).
      2. Mutations on chromosome 1q31 may also cause this syndrome (Abdelhak et al. 1997).
   7. Stickler syndrome
      1. The STL1 locus in the *COL2A1* gene located on chromosome 12q13.11-q13.2 is responsible for type 1.
      2. The STL2 locus in the *COL11A1* gene located on chromosome 1p21 is responsible for type 2.
      3. The STL3 locus in the *COL11A2* gene located on chromosome 6p21.3 is responsible for type 3.
   8. Treacher Collins syndrome (TCOF): caused by *TCOF1* gene mutation on chromosome 5q32-q33.1
   9. Alport syndrome
      1. X-linked (85%): *COL4A5* gene (Xq22) mutation is responsible.
      2. *COL4A3* and *COL4A4* (on 2q36-q37) mutation: responsive for the autosomal recessive and autosomal dominant types.
         1. Autosomal recessive (15%)
         2. Autosomal dominant (rare)
   10. Norrie disease
      1. Caused by *Norrin* gene mutation on Xp11.3.
      2. *Norrin* gene is considered to control vascularization in the cochlea and retina.
6. Mitochondrial hearing loss.
   1. Constitutes <1% of all HHL cases.
   2. Only maternal DNA is transmitted to the child while paternal DNA is not.
   3. All children are at risk of having hearing impairment when the mitochondrion of the mother possesses a disease-causing mutation.
7. Heterogeneity of genetic hearing loss.
   1. Genetic hearing loss: a heterogeneous condition although it is mostly caused by a mutation in a single gene (Hardisty et al. 1999).

2. Syndromic, nonsyndromic, recessive, or dominant hearing loss may be caused by the same mutation in a single gene.
3. Recessive or dominant NSHL can be caused by connexin 26, connexin 31, and *MYO7A* mutations.
4. *COL11A2*, PDS, *MYO7A*, and connexin 26 mutations can cause syndromic or nonsyndromic hearing loss (De Leenheer et al. 2001; Tamagawa et al. 2002).

Clinical Features

1. Classification of hearing impairment (HI) (Ječmenica et al. 2015): for partition of the threshold of hearing for tone on important speech frequencies includes mild, moderate, moderately severe, severe, and profound HI.
    1. Mild, moderate, moderately severe, severe, and profound HI: for partition of the threshold of hearing for tone on important speech frequencies
    2. Conductive HI: the result of insufficient functioning of the conduction part, outer and middle ear
    3. Sensorineural hearing impairment (SNHI): the result of damaged membranous labyrinth, the organ of Corti, or some of the structures involved in the transmission of sound to the temporal cortex
    4. Mixed HI: involves dysfunction of both parts of the hearing organ, conductive and perceptive
    5. Transient or permanent HI (with regard to duration)
    6. Progressive or nonprogressive (in relation to behavior)
    7. Unilateral or bilateral (in relation to the side on which the lesion is present)
    8. Genetic (hereditary) and acquired (according to the origin)
    9. Prenatal, perinatal, congenital, and postnatal (depending on the time of onset)
    10. Prelingual and lingual (depending on the time of HI manifestation)
2. Usher syndrome (Bayazit and Yilmaz 2006)
    1. The most common cause of autosomal recessive syndromic hearing loss (Smith et al. 1994).
    2. Almost 50% of the blind and deaf people in the USA have this syndrome.
    3. Type 1
        1. Severe hearing loss and vestibular dysfunction
        2. Retinitis pigmentosa (a progressive degeneration of the retina leading to loss of night vision, restriction of the visual fields, and blindness) starting in childhood
    4. Type 2
        1. Mild to moderate hearing loss
        2. Normal vestibular function
        3. Retinitis pigmentosa occurring after childhood
    5. Type 3
        1. Progressive hearing loss and vestibular dysfunction
        2. Retinitis pigmentosa occurring any time in life
3. Pendred syndrome (Reardon et al. 1997)
    1. Severe congenital sensorineural hearing loss.
    2. Euthyroid goiter
        1. Due to a specific defect in the organification of iodine
        2. Can be demonstrated by the perchlorate test
    3. Labyrinthine bone abnormality like Mondini dysplasia seen in 86% of cases.
    4. Vestibular dysfunction can occur.
    5. Onset may be delayed and clinically unapparent.
    6. Rarely associated with hypothyroidism.
4. Jervell and Lange-Nielsen syndrome (Splawski et al. 1997)
    1. Congenital hearing loss
    2. Elongation of the QT interval on electrocochleography (QT $>$ 440 ms)
    3. Syncope and sudden death due to a cardiac problem

5. Biotinidase deficiency: clinical manifestations within the first few months of life if untreated
    1. Skin rashes.
    2. Seizures.
    3. Hair loss.
    4. Hypotonia.
    5. Vomiting.
    6. Acidosis.
    7. Seventy five percent of the affected infants develop hearing loss if untreated.
    8. Biotinidase deficiency is a completely preventable form of genetic deafness with supplementation of biotin.
6. Waardenburg syndrome
    1. Sensorineural hearing loss
        1. Accounts for 1–2% of individuals with profound hearing loss
        2. Can be bilateral or unilateral of varying severity
    2. Pigmentation abnormality in the skin and hair
    3. White forelock
    4. Dystrophia canthorum (lateral displacement of the inner canthi of the eyes)
    5. Pinched nose
    6. Heterochromia iridis (different iris colors)
    7. Gastrointestinal features
        1. Constipation
        2. Hirschsprung disease
    8. Neural tube and limb defects
7. Branchio-oto-renal (BOR) syndrome
    1. Conductive, sensorineural, or mixed hearing loss
        1. Some degree of hearing loss in almost 80% of gene carriers
        2. Can be delayed in onset
    2. Branchial cleft cyst
    3. Auricle or external auditory canal abnormality
    4. Preauricular pits
    5. Renal abnormalities
        1. Renal dysplasia
        2. Polycystic kidney
        3. Malformation of the calyces
    6. Inner ear abnormalities
        1. Mondini dysplasia
        2. Stapes fixation
8. Stickler syndrome
    1. Progressive sensorineural hearing loss
    2. Cleft palate
    3. Abnormal development of the epiphysis
    4. Vertebral abnormalities
    5. Osteoarthritis
9. Treacher Collins syndrome
    1. Hearing loss
        1. Conductive in 55% of cases
        2. Sensorineural hearing loss usually occurs at high frequencies
    2. Symmetric and hypoplastic zygoma
    3. Lower palpebral fissure
    4. Malformed and small ear
    5. Auditory pit
10. Alport syndrome
    1. Progressive bilateral hearing loss
        1. In almost 50% of cases
        2. Usually begins in the second decade
        3. Initially involves high-frequency hearing loss
    2. Renal disorder
        1. Glomerulonephritis
        2. Hematuria
        3. Renal failure
    3. Ocular abnormalities
        1. Cataract
        2. Spherophakia
        3. Retinal flecks
        4. Anterior lenticonus
11. Norrie disease
    1. Progressive sensorineural hearing loss
    2. Eye disorders
        1. Pseudotumor
        2. Retinal lesions
            1. Hyperplasia
            2. Hypoplasia
            3. Necrosis
        3. Cataract
    3. Mental retardation
12. Mitochondrial mutations causing syndromic hearing loss that may be associated with:
    1. Diabetes mellitus
    2. Neurologic disorder
    3. Progressive myoclonic epilepsy
    4. Ataxia
    5. External ophthalmoplegia

6. Retinopathy
7. Arrhythmia

13. Mitochondrial mutations causing nonsyndromic hearing loss that may be associated with:
    1. Palmoplantar keratoderma
    2. Neurologic disorder

Diagnostic Investigations

1. Obtain family history (ACMG Statement 2002; Smith et al. 2010; Gifford et al. 2009).
    1. Pedigree
        1. Consanguinity
        2. Paternity
        3. Hearing status of the parents and siblings
    2. Ethnicity and country of origin
    3. Inheritance pattern of hearing loss
        1. Autosomal dominant
        2. Autosomal recessive
        3. X-linked
        4. Mitochondrial
    4. Audiometric characteristics in any deaf and hearing-impaired family members
        1. Age of onset
        2. Progression
        3. Conductive hearing loss
        4. Nonsyndromic hearing loss
        5. Auditory neuropathy
    5. Evidence of vestibular dysfunction
    6. Syndromic versus nonsyndromic features
2. Evaluate and inquire the following conditions in the patient and/or relatives:
    1. Visual anomalies
        1. Heterochromia iridis
        2. Retinitis pigmentosa
        3. Myopia
        4. Retinal detachment
        5. Early cataracts
    2. Facial/cervical dysmorphology
        1. Synophrys
        2. Dystopia canthorum
        3. Preauricular pits
        4. Aural atresia
        5. Branchial cysts
        6. Cleft palate
        7. Dental anomalies
    3. Endocrine abnormalities
        1. Thyromegaly
        2. Diabetes
    4. Cardiac signs and symptoms
        1. Syncope
        2. Sudden death
        3. Arrhythmia
        4. Prolonged QT interval
        5. Fainting spells
        6. Congenital heart defect
    5. Renal abnormalities
        1. Hematuria
        2. Proteinuria
        3. Structural defects
    6. Integumentary changes
        1. Premature graying
        2. White forelock
        3. Abnormal pigmentation
        4. Dry skin/keratoderma
3. Obtain patient history with respect to specific risk factors.
    1. Intrauterine infections such as:
        1. Toxoplasmosis
        2. Rubella
        3. CMV
        4. Herpes simplex
    2. Meningitis
    3. Extracorporeal membrane oxygenation (ECMO)
    4. History of hypoxia
    5. Prenatal alcohol exposure
    6. Exposure to ototoxic drugs
4. Perform physical examination
    1. Otologic examination
    2. Airway examination
    3. Documentation of dysmorphisms
    4. Neurologic evaluation including assessment of vestibular function in older patients
5. Laboratory tests/imagings (Grundfast et al. 2000; Parving 2007; Martini et al. 2009)
    1. Viral antibodies
        1. Rubella
        2. CMV
        3. HIV
        4. Others
    2. Bacterial antibodies
        1. Syphilis

2. Toxoplasmosis
3. Others

3. Thyroid studies for suspected Pendred syndrome
    1. TSH (Thyroid stimulating hormone)
    2. T3
    3. T4
    4. Perchlorate test
4. Urine analysis
    1. A positive proteinuria or hematuria can reflect Alport syndrome
    2. Viral cultural isolation
    3. Measurement of electrolyte levels
5. Electrocardiogram for suspected Jervell and Lange-Nielsen syndrome
6. Ophthalmologic examination including electroretinography and slit lamp examination
7. Renal and cardiac ultrasonography
8. Radiographic testing
    1. Bilateral acoustic neuromas: frequently detected radiographically in NF2
    2. Temporal Bone CT scan
        1. Can help visualize cochlear abnormalities such as the Mondini deformity in Pendred (enlarged vestibular aqueduct) and Waardenburg syndrome
        2. Can detect internal auditory canal aberrations associated with X-linked mixed hearing loss with stapes gusher and might reveal cochlear dysplasia
    3. MR imaging
        1. With gadolinium enhancement: the study of choice in patients with a family history of NF2
        2. Used when the hearing loss is progressive but the CT scan is normal
9. Cytogenetic testing: FISH for velocardiofacial/DiGeorge syndrome
10. Array CGH
11. Mutation analysis
    1. Connexins
        1. *GBJ2*
        2. *GBJ6*
    2. Other relevant genes such as:
        1. *WFS1*
        2. *SLC26A4*
12. Effective use of next-generation sequencing technique to detect pathogenic mutations in affected individuals who were not candidates for classical genetic studies (Qing et al. 2014)
13. Next-generation sequencing: allows for development of comprehensive genetic panels, which test for up to 129 genes while improving the accuracy and efficiency of testing (Jasper et al. 2015)

6. Universal newborn hearing screening
    1. Evoked otoacoustic emission (OAE) testing: detects the evoked sound from the cochlea in response to clicks or tones
    2. Auditory brain stem response (ABR, also known as BAER or BSER)
        1. Measures the electroencephalographic waveform response from the vestibulocochlear nerve
        2. Has potential of detecting the following hearing losses:
            1. Hearing loss due to auditory neuropathy, a condition to which the newborn intensive care unit population is particularly prone
            2. Hearing loss resulting from middle and inner ear disorders
    3. Combination of OAE and ABR
7. Other hearing tests to diagnosis and characterization of hearing loss
    1. Tympanometry
        1. External ear canal of individuals (except newborn) is sealed with probe tip.
        2. Measure sound reflection by tympanic membrane while ear canal pressure is varied.
        3. An effective assessment of middle ear pressure and function.
    2. Audiometry
        1. Behavioral observation audiometry.
            1. Infant in a soundproof room is presented with warbled pure tones, speech, or white and narrowband noise through loudspeakers.
            2. Observe responses such as the auropalpebral reflex, startle responses, and head turning

2. Visual reinforcement audiometry: child is seated between two speakers and conditioned to look toward the active speaker.
3. Play audiometry.
    1. Tones of varying frequencies are delivered through headphones or a bone vibrator.
    2. Child is conditioned to perform play activities, such as dropping a block or placing a peg in a board.
4. Conventional audiometry.
    1. Tones of varying frequencies are delivered through headphones or a bone vibrator.
    2. Child is instructed to raise a hand or push a button when a tone is heard.
5. Pure tone audiometry (air and bone conduction): involves determination of the lowest intensity at which an individual "hears" a pure tone.
6. Air conduction audiometry.
    1. Presents sounds through earphones.
    2. Threshold depends on the condition of the external ear canal, middle ear, and inner ear.
7. Bone conduction audiometry.
    1. Presents sounds through a vibrator placed on the mastoid bone or forehead, thus bypassing the external and middle ears.
    2. Thresholds depend on the condition of the inner ear.
8. Conditioned play audiometry.
    1. Used to test children from age 2.5–5 years.
    2. A complete frequency-specific audiogram for each ear can be obtained from a cooperative child.
9. Audioprofile
    1. Recording of several audiograms on a single graph.
    2. These audiograms may be from one individual at different times, but more frequently they are from different members of the same family segregating deafness usually in an autosomal dominant fashion.
    3. By plotting numerous audiograms with age on the same graph, the age-related progression of hearing loss can be appreciated within these families.
    4. Often the composite picture is a characteristic of specific genetic causes of autosomal dominant nonsyndromic hearing loss.
    5. One of the most characteristic audioprofiles is associated with DFNA6/14/38 hearing loss caused by mutations in *WFS1*.
8. Degree and effects of hearing loss (Bachmann and Arvedson 1998; Gifford et al. 2009)
    1. Normal hearing (no hearing loss) (0–15 dB loss): can detect all aspects of speech
    2. Minimal hearing loss (16–25 dB loss)
        1. May miss up to 10% of speech
        2. May respond inappropriately
    3. Mild hearing loss (26–40 dB loss)
        1. May miss up to 50% of speech
        2. May be labeled as "behavior problem" and "poor listener"
    4. Moderate hearing loss (41–55 dB loss)
        1. May miss 50–100% of speech
        2. Speech quality likely to be poor
        3. Limited vocabulary
        4. Low self-esteem possible
    5. Moderate to severe hearing loss (56–70 dB loss)
        1. 100% of normal volume speech lost
        2. Delayed speech and poor intelligibility
        3. Social isolation likely
    6. Severe hearing loss (71–90 dB loss)
        1. Loud voices only heard within 12 in. of ear
        2. Delayed speech and language if loss is prelingual
        3. Declining speech abilities and atonal voice if loss is postlingual
    7. Profound hearing loss (>90 dB loss)
        1. Sound vibrations felt rather than heard
        2. Visual cues primary for communication
        3. Peer group of hearing-impaired children preferred
9. Triage/testing and triage paradigm (ACMG Statement 2002)

1. If a form of syndromic deafness is suspected: perform gene-specific mutation screening.
2. If nonsyndromic deafness is suspected and the patient is a simplex case:
    1. CMV testing should be performed.
        1. A negative test for CMV antibodies in early infancy may exclude CMV-related hearing loss.
        2. A positive result must be interpreted with caution.
    2. *GJB2* (connexin 26) mutation screening by sequence analysis.
        1. A negative test result does not exclude a genetic etiology.
        2. A positive test result may make it possible to avoid other expensive and potentially invasive tests.
3. If nonsyndromic deafness is suspected and the patient is a multiplex case with other hearing-impaired first-degree relatives: proceed directly to connexin 26 testing.
4. If nonsyndromic deafness is suspected and the pedigree suggests dominant inheritance: connexin-related deafness is not excluded and gene-specific mutation screening for other loci may be available.
5. If nonsyndromic deafness is suspected and the pedigree suggests mitochondrial DNA inheritance: testing for the A1555G mutation (associated with aminoglycoside-induced hearing loss) and the A7445G mutation, both of which are associated with some rare familial cases of hearing loss, may be appropriate after common *GJB2* mutations are excluded.
6. If nonsyndromic deafness is suspected and both parents are deaf:
    1. Connexin-related deafness will be strongly suspected (since mutations in *GJB2* are the most common cause of deafness in the United States and the vast majority of marriages between deaf individuals who produce deaf offspring are between individuals with *GJB2* mutations).
    2. Possible to ascribe a genetic etiology to the hearing loss in many persons after triage/testing:
        1. For example, a child may be diagnosed with *GJB2*-related deafness.
        2. If two clearly pathologic alleles are found, the cause of that child's deafness will be known with virtual certainty and can accurately predict the chance of recurrence in a subsequent child.
    3. Alternatively, mutation screening may be negative:
        1. A negative mutation screen must not be taken to mean that the deafness is not genetic: important to be conveyed to parents of deaf children who undergo genetic testing (Brunger et al. 2000).
        2. The probability that the deafness is genetic in patients with an unremarkable family history of deafness and a negative test result for connexin 26 will vary based on the number of hearing siblings. The proportional distribution of the different mutations in the connexin 26 locus also varies in different ethnic groups (Kenneson et al. 2002).

Genetic Counseling

1. Recurrence risk (Smith et al. 2010)
    1. Patient's sib
        1. Autosomal dominant hereditary hearing loss
            1. A 50% risk of inheriting the mutant allele if one of the proband's parents has a mutant allele.
            2. Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable.

2. Autosomal recessive hereditary hearing loss
    1. A 25% risk of being deaf.
    2. A 50% risk of having normal hearing and being a carrier.
    3. A 25% risk of having normal hearing and not being a carrier.
    4. Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable.
    5. For siblings with the identical *GJB2* genotype as the probands with severe-to-profound deafness: a 91% risk of having severe-to-profound deafness and a 9% risk of having mild-to-moderate deafness.
    6. For siblings with the identical *GJB2* genotype as the proband with mild-to-moderate deafness: a 66% risk of having mild-to-moderate deafness and a 34% risk of having severe-to-profound deafness.
3. X-linked hereditary hearing loss
    1. A carrier mother has a 50% risk of transmitting the deafness-causing mutation with each pregnancy: sons who inherit the mutation will be deaf; daughters who inherit the mutation are carriers and likely to have normal hearing.
    2. A non-carrier mother: the risk to sibs is low but greater than that of the general population because of the possibility of germline mosaicism.
    3. Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable.
4. Mitochondrial disorders with hearing loss as a possible feature
    1. The risk to the sibs depends on the genetic status of the mother: the mother of a proband usually has the mitochondrial mutation and may or may not have symptoms (note that the father is not at risk of having the disease-causing mtDNA mutation).
    2. If the mother has the mitochondrial mutation, all sibs are at risk of inheriting it.

2. Patient's offspring
    1. Autosomal dominant hereditary hearing loss.
        1. A 50% risk of transmitting the mutant allele to each child.
        2. In case of an apparent de novo mutation in the proband (neither parent of a proband with an autosomal dominant condition has the deafness-causing mutation or clinical evidence of the disorder), explore possible nonmedical explanations (alternate paternity or maternity such as with assisted reproduction or undisclosed adoption).
        3. Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable.
    2. Autosomal recessive hereditary hearing loss: all of the offspring are obligate carriers.
    3. X-linked hereditary hearing loss: males with X-linked hereditary hearing loss will pass the deafness-causing mutation to all of their daughters and none of their sons.
    4. Mitochondrial disorders with hearing loss as a possible feature.
        1. All offspring of females with an mtDNA mutation are at risk of inheriting the mutation.
        2. Offspring of males with a mtDNA mutation are not at risk.

2. Prenatal diagnosis
    1. Prenatal diagnosis for some forms of hereditary hearing loss is technically possible by analysis of DNA extracted from fetal cells obtained by:

    1. Amniocentesis usually performed at approximately 15–18 weeks' gestation
    2. Chorionic villus sampling (CVS) at approximately 10–12 weeks' gestation
  2. The deafness-causing allele(s) of a deaf family member must be identified before prenatal testing can be performed.
  3. Preimplantation genetic diagnosis (PGD): may be available for families in which the deafness-causing mutation(s) have been identified.
3. Management
  1. Multidisciplinary team consisting of:
    1. An otolaryngologist
    2. An audiologist
    3. A clinical geneticist
    4. A pediatrician
    5. An educator of the deaf
    6. A neurologist
    7. A pediatric ophthalmologist
  2. Treatment
    1. Determine the appropriate habilitation option such as:
      1. Hearing aids
      2. Vibrotactile devices
    2. Cochlear implantation: considered in children over age 12 months with severe-to-profound hearing loss.
    3. Early auditory intervention through amplification, otologic surgery, or cochlear implantation is essential for optimal cognitive development in children with prelingual deafness.
  3. On the basis of genetic testing for the couple with hearing loss, human assisted reproductive technology is a viable option to avoid the birth of infant with hereditary deafness (Liu et al. 2015).

Hereditary Hemochromatosis

Contents

Hereditary hemochromatosis (HHC; *HFE* 1) is a common hereditary disorder of iron metabolism and the most common inherited autosomal recessive disorder in Caucasians with a prevalence of 1 in 300 to 1 in 500 individuals. It is characterized by inappropriately high iron absorption resulting in progressive iron overload.

Synonyms and Related Disorders

Hemochromatosis; Neonatal hemochromatosis

Genetics/Basic Defects

1. The human leukocyte antigen (HLA)-linked iron-loading (*HFE*) gene associated with the autosomal recessive disorder known as hereditary hemochromatosis occurs in about 10% of subjects of European descent, most of whom are unaffected heterozygotes. In contrast, the 3–5 per 1,000 who are homozygotes are at risk of developing severe and potentially lethal iron overload, with damage to a number of organs, including the liver, pancreas, heart, joints, and endocrine glands (Bothwell and MacPhail 1998).
2. Cause: result of a single faulty *HFE* gene on chromosome 6p21.3 near the *HLA* complex that codes for a glycoprotein called HFE, which binds to the transferrin receptor and reduces its affinity for iron-bound transferrin, allowing cellular uptake of iron-based transferrin. Other genes, including a second transferrin receptor and the circulating peptide hepcidin, participate in a shared pathway with *HFE* in regulation of iron absorption (Fleming and Sly 2002).
3. Two common mutations (missense):
    1. C282Y:
        1. Accounts for most cases of HHC (Feder et al. 1996).
        2. Homozygotes for C282Y (p.Cys282Tyr) mutation (>80% cases worldwide) are at high risk for HHC.
        3. Heterozygote for C282Y mutation:
            1. Have increased levels of transferrin saturation
            2. Rarely have organ damage
    2. H63D: Homozygotes for H63D (often has a potentiator, such as hepatitis C infection, β-thalassemia trait) are unlikely to develop HHC.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_116

3. C282Y/H63D (11% present phenotypically): Compound heterozygotes for C282Y/H63D have a milder form of HHC than C282Y homozygotes.
4. Other *HFE* mutations:
   1. Missense mutations:
      1. S65C: the third most common mutation
      2. G93R
      3. I105T
      4. Q127H
      5. R330M
   2. Frameshift mutations:
      1. P160ΔC
      2. V68ΔT
   3. Nonsense mutations
   4. Spice site mutation
5. Clinical expression of the disease:
   1. Homozygotes: affected clinically
   2. Heterozygotes:
      1. Can have minor abnormalities of the parameters that reflect body iron status
      2. Can develop significant iron overload only when other diseases that affect iron metabolism coexist, such as:
         1. Heterozygous β-thalassemia
         2. Hereditary spherocytosis
         3. Sporadic porphyria cutanea tarda
6. Hereditary hemochromatosis not attributable to mutations in *HFE*:
   1. A subgroup of hereditary hemochromatosis indistinguishable from *HFE*-associated HHC.
   2. Does not have mutations in *HFE*.
   3. The disease does not appear to be linked to the HLA complex.
   4. The genetic basis has not been defined.
7. Pathophysiology (Whittington and Kowdley 2002):
   1. Inappropriately high intestinal iron absorption: the most important pathophysiological step in body iron loading
   2. Effects of mutations on iron absorption: central to the understanding of the pathological basis of hereditary hemochromatosis
8. Neonatal hemochromatosis (Feldman and Whitington 2013):
   1. A clinical condition in which severe liver disease in the newborn is accompanied by extrahepatic siderosis.
   2. Gestational alloimmune liver disease (GALD) has been established as the cause of fetal liver injury resulting in nearly all cases of neonatal hemochromatosis.
   3. In GALD, a women is exposed to a fetal antigen that she does not recognize as "self" and subsequently begins to produce IgG antibodies that are directed against fetal hepatocytes.
   4. These antibodies bind to fetal liver antigen and activate the terminal complement cascade resulting in hepatocyte injury and death.
   5. GALD can cause congenital cirrhosis or acute liver failure with and without iron overload and siderosis.
   6. Practitioners should consider GALD in cases of fetal demise, stillbirth, and neonatal acute liver failure.
   7. Identification of infants with GALD is important as treatment is available and effective for subsequent pregnancies.

Clinical Features

1. Variable clinical presentation.
2. Median age at presentation of symptoms:
   1. Fifty-one years in males
   2. Female homozygotes:
      1. Less likely to develop symptomatic disease
      2. Median age: age 50
3. Asymptomatic: abnormal serum iron studies on routine screening.
4. A clinical triad (Andrews 1999):
   1. Glycosuria
   2. Cirrhosis
   3. Hyperpigmentation of the skin
5. Early manifestations:
   1. Often subtle
   2. Vague arthralgias
   3. Fatigue
   4. Lethargy

5. Apathy
6. Weight loss

6. Later manifestations as tissue iron progressively accumulates:
    1. Discoloration of the skin
    2. Hemochromatosis arthropathy (Husar-Memmer et al. 2014):
        1. A common feature of HH.
        2. Due to iron accumulation in joint tissues.
        3. Arthritis with joint swelling most commonly involves:
            1. Metacarpophalangeal (MCP) joints
            2. Proximal interphalangeal joints
            3. Knees
            4. Feet
            5. Wrists
            6. Back
            7. Hips
            8. Neck
        4. Chondrocalcinosis:
            1. Involves the knees and wrists
            2. May be asymptomatic
        5. Symptoms usually do not respond to iron removal.
    3. Liver involvement
        1. Abdominal pain associated with hepatomegaly
        2. Hepatomegaly, the most common physical abnormality
        3. Splenomegaly
        4. Cirrhosis
        5. Portal hypertension:
            1. Ascites
            2. Encephalopathy
        6. Hepatocellular carcinoma in about 30% of cases
    4. Cardiac involvement:
        1. Dilated cardiomyopathy
        2. Arrhythmias
        3. Cardiac failure
    5. Endocrine dysfunction in hereditary hemochromatosis (Pelusi et al. 2016):
        1. Diabetes mellitus
        2. Pituitary hypogonadism:
            1. Decreased libido and impotence (testicular atrophy) in men
            2. Amenorrhea in women
        3. Hypopituitarism or other tropin defects
        4. Thyroid dysfunction
        5. Adrenal dysfunction
        6. Parathyroid defects and osteoporosis

7. Suspect diagnosis from characteristic clinical manifestations:
    1. Classical clinical triad of "bronzed cirrhosis with diabetes" in a middle-aged man:
        1. Diffuse hyperpigmentation (melanoderma), often with a metallic gray or "bronze" rather than a brown discoloration
        2. Hepatomegaly, with the liver markedly enlarged, firm, and sharp to palpation but without signs of hepatocellular insufficiency (no palmar erythema, no spider nevi, no bruises, normal prothrombin time) or of portal hypertension
        3. Diabetes mellitus, often requiring insulin
    2. Presence of cardiomyopathy
    3. Diagnosis at this late stage: considered a diagnostic failure
8. Suspect diagnosis from earlier signs and symptoms:
    1. Sex and age: Both young adults and older women are at risk.
    2. "Rule of three A's":
        1. Asthenia: unexplained chronic fatigue
        2. Arthralgia:
            1. A "painful" handshake: resulting from chronic arthritis of the second and third MCP joints.
            2. Other joints affected especially the knees and wrists.
            3. Can also suffer from pseudogout (pyrophosphate arthropathy).
            4. Arthritis greatly diminishes the quality of life.
        3. Aminotransferase (transaminases) elevation
9. Prognosis of hemochromatosis and most of its complications, including liver cancer, depend on the amount and duration of iron excess (Phatak and Cappuccio 1994; Niederau et al. 1996). Early diagnosis and

therapy largely prevent the adverse consequences of iron overload.

10. Cause of death (Niederau et al. 1985):
    1. Liver failure
    2. Cancer
    3. Congestive heart failure
    4. Arrhythmia
11. Different types of hereditary hemochromatosis (Camaschella and Piperno 1997; Harrison and Bacon 2003; Pietrangelo 2006, 2010; Barton 2013; Bardou-Jacquet and Brissot 2014; Ekanayake et al. 2015; Yun and Vincelette 2015):
    1. Type 1 (*HFE*-related) hereditary hemochromatosis: classic form of hereditary hemochromatosis:
        1. An autosomal recessive disorder with 2–28% penetrance
        2. Common loci:
            1. Caucasian: C282Y, S65C
            2. Worldwide: H63D, IVS5 + 1, G > A
        3. Prevalence:
            1. Most common form worldwide
            2. Varies by race
    2. Type 2 (*HJV*- and *HAMP*- related) hemochromatosis:
        1. An autosomal recessive disease
        2. Type 2A hemochromatosis: caused by mutations of hemojuvelin (*HJV* on 1q21) gene
        3. Type 2B hemochromatosis: caused by mutations of the hepcidin (*HAMP*, on 19q13) gene
        4. Ethnicity: Caucasian or non-Caucasian
        5. Sex: male or female
        6. Onset: 15–20 years
        7. Clinical pictures:
            1. Cardiomegaly.
            2. Central endocrine involvement (hypogonadotropic hypogonadism): impotence, amenorrhea.
            3. Massive iron overload.
            4. Although liver fibrosis is frequent, cardiac and endocrine manifestations are predominant.
    3. Type 3 (*TFR2*-related) hemochromatosis
        1. An autosomal recessive disorder
        2. Caused by mutations in the transferrin receptor 2 (*TFR2*, on 7q22) gene (Joshi et al. 2015)
        3. Ethnicity: Caucasian or non-Caucasian
        4. Sex: male or female
        5. Onset: 30–40 years
        6. Clinical picture:
            1. Cardiomyopathy
            2. Endocrinopathy
            3. Liver disease
            4. Arthropathy: not uncommon
            5. Massive iron overload
            6. Elevated transferrin saturation (TS) and serum ferritin (SF)
    4. Type 4 hemochromatosis (ferroportin disease)
        1. An autosomal dominant disease
        2. Caused by mutations of the ferroportin (*SLC40A1*, on 2q32) gene
        3. More frequent than type 2 or type 3
        4. Type 4A ferroportin disease: caused by loss of the iron export function
        5. Type 4B ferroportin disease (rarer): caused by resistance of ferroportin to hepcidin activity, resulting in an unregulated cellular iron egress
        6. Ethnicity: Caucasian or non-Caucasian
        7. Sex: male or female
        8. Onset: 10–80 years
        9. One patient with unexplained hyperferritinemia
        10. Unexplained elevation of SF and normal TS
12. Other rare iron overload diseases:
    1. Iron-loading anemias (ineffective erythropoiesis, increased iron absorption, blood transfusions):
        1. β-Thalassemia
        2. Congenital dyserythropoietic anemias
        3. Sideroblastic anemia
        4. Pyridoxine-responsive anemia

2. Hypoplastic anemias (blood transfusions):
   1. Aplastic anemia
   2. Myelodysplastic syndromes
   3. Pure red cell aplasia
3. Chronic hemolytic anemias (increased iron absorption):
   1. Spherocytosis
   2. Sickle cell anemia
   3. Pyruvate kinase deficiency
4. Parental iron overload:
   1. Red blood cell transfusion
   2. Iron dextran injections
   3. Long-term hemolysis
5. Ceruloplasmin deficiency (aceruloplasminemia) (decreased ferroxidase activity)
6. A(hypo)transferrinemia: transferrin (Tf/3q21)
7. Sub-Saharan iron overload (increased dietary iron, increased iron absorption)
8. Porphyria cutanea tarda (increased iron absorption)
9. Hepatic disorders:
   1. Chronic viral hepatitis
   2. Alcoholic cirrhosis
   3. Portacaval shunts (increased iron absorption)

Diagnostic Investigations

1. Biochemical testing (Ramrakhiani and Bacon 1998):
   1. The first step in the diagnostic evaluation for hereditary hemochromatosis (HH): involves measurement of fasting transferrin saturation (TS) and serum ferritin levels. These studies are abnormal (high serum ferritin levels) in symptomatic patients.
   2. If the patient being evaluated is young, the iron studies may be normal, even in those who are homozygous for the genetic defect. This relates to the amount of time it takes for patients with the genetic defect and associated increased intestinal iron absorption to develop significant degrees of iron loading.
   3. Thus, as many as 30% of women with HH younger than 30 years of age may not have an elevated TS (Edwards et al. 1988).
   4. Alternatively, serum iron studies (predominantly ferritin) can be abnormal in about 40–50% of patients with chronic viral hepatitis, nonalcoholic steatohepatitis, and alcoholic liver disease, in the absence of HH (Bacon 1997).
   5. Additionally, other inflammatory disorders (e.g., rheumatoid arthritis) and various neoplastic disorders can cause elevated serum ferritin levels. Therefore, TS and serum ferritin levels by themselves cannot be relied on to make a diagnosis of HH.
2. Radiographic features of hemochromatosis arthropathy:
   1. Hook-like osteophytes (MCP joints)
   2. Joint space narrowing
   3. Subchondral cysts
   4. Marginal erosions
   5. Chondrocalcinosis (frequent, wrist, knee; rare, MCP joints, ankle joints)
   6. Femoral head necrosis (rare)
3. MRI of the liver:
   1. The most promising noninvasive technique for identification of HHC. High hepatic iron content causes:
      1. A decrease in signal intensity of the liver
      2. A marked decrease in transverse (T2) relaxation time
   2. Role of magnetic resonance imaging T2 in the evaluation of iron overload early in hereditary hemochromatosis: excessive iron stores in the liver were detected in 39% of patients, showing that iron accumulation begins in the liver (Assis et al. 2015).
4. Liver biopsy to assess histologic hepatic iron stores (Morrison et al. 2003):
   1. Usually not indicated for diagnostic purposes in HFE-HHC.

2. Recommended to C282Y homozygotes with a serum ferritin concentration of >1,000 ng/mL to determine if cirrhosis is present; those with a serum ferritin concentration <1,000 ng/mL need not undergo biopsy.
3. Useful to determine hepatic iron overload, particularly in patients with presumed hemochromatosis who lack the common *HFE* mutations associated with HFE-HHC.

5. Elevated serum iron, transferrin saturation, and ferritin suggest HH, but results can also indicate other forms of hepatocyte injury such as alcoholic or viral hepatitis, or other inflammatory disorders involving the liver (Moyer et al. 2011). In the context of elevated serum iron, transferrin saturation, and ferritin, and after ruling out secondary causes of iron overload, *HFE* gene evaluation is the preferred test to confirm the diagnosis of HH. However, 5–15% of patients with phenotypic HH do not have *HFE* gene mutations. In these cases, MRI evaluation or liver biopsy with iron quantification is indicated.
6. Hormonal and metabolic tests (Pelusi et al. 2016):
   1. Glucose metabolism: glycemia, insulin, and glycated hemoglobin
   2. Pituitary gonadal axis: LH, FSH, testosterone (male), estradiol (female)
   3. Bone metabolism: PTH, serum calcium, phosphate, creatinine, alkaline phosphatase, 25-hydroxy vitamin D plus dual-energy X-ray absorptiometry
7. Molecular genetic testing (Brittenham et al. 2000; Seckington and Powell 2015):
   1. Mutation analysis for the disease-causing alleles in the *HFE* gene (C282Y and H63D):
      1. C282Y/C282Y homozygotes (60–90%)
      2. C282Y/H63D compound heterozygotes (3–8%)
      3. H63D/H63D homozygote (1%)
      4. H63D/? (4%)
      5. C282Y/? (1%)
      6. ?/? (6%)
   2. Testing strategy for a proband:
      1. Mutation analysis warranted in adults with serum transferrin-ion saturation of >45%
      2. Individuals with homozygous C282Y/C282Y or compound heterozygous C282Y/H63D: have genetic makeup to develop HFC-HHC
      3. Individuals who are not C282Y homozygotes:
         1. Generally represent a heterogeneous group.
         2. Many have liver disease unrelated to HFE-HHC or other metabolic syndromes.
         3. Some may have primary iron overload in a pattern identical to HFE-HHC.
         4. The next diagnostic step: perform liver biopsy with assessment of histology and measurement of hepatic iron concentration.
   3. Carrier detection: identification of carriers and noncarriers in at-risk family members is possible provided both *HFE* alleles have been identified in the proband.
   4. Whole-exome sequencing offered complete coverage of target genes and is a fast, cost-effective diagnostic tool for characterization of non-HFE hemochromatosis (Farrell et al. 2015).
8. Screening for HHC (Phatak et al. 1994):
   1. HHC: a prime target for screening because of its high prevalence, morbidity, and mortality, as well as the benefits of early diagnosis and treatment.
   2. Initial screening probe for HHC diagnosis:
      1. Transferrin saturation
      2. Unsaturated iron-binding capacity
   3. Elevation of serum ferritin is common, particularly in Asians, Pacific Islanders, and Africans (Mclaren and Gordeuk 2009).
   4. Generalized population screening is not recommended (Hanson et al. 2001).
   5. The incomplete penetrance of disease means diagnosis cannot be purely based on genetic screening. As such, currently diagnosis relies on a combination of

imaging, biochemical iron, and genetic studies (Ekanayake et al. 2015).

9. Diagnostic workup of neonatal hemochromatosis (Heissat et al. 2015):
    1. In unexplained fetal death or neonatal liver failure, the diagnosis of subsets of NH requires tissue analysis (autopsy) to assess extrahepatic siderosis.
    2. In patients with NH, if mitochondrial respiratory chain disorder is ruled out, NH-GALD is likely.

Genetic Counseling

1. Recurrence risk (Seckington and Powell 2015):
    1. Patient's sib:
        1. Twenty-five percent if both parents are HFE-HHC heterozygotes
        2. Fifty percent if one parent is HFE-HHC heterozygotes and other parent HFE-HHC homozygote
    2. Patient's offspring – 5% risk to be affected due to the high carrier rate for *HFE* mutant alleles in the general population:
        1. The risk that the partner of an individual with HFE-HHC is heterozygous for the C282Y allele is 1/9.
        2. Therefore, the risk to the offspring to be a homozygote for C282Y allele is $1/2 \times 1/9 = 1/18$ (about 5%).
2. Prenatal diagnosis (Seckington and Powell 2015):
    1. Prenatal testing for pregnancies at increased risk may be available from a clinical laboratory that offers either testing of this gene or custom prenatal testing.
    2. Preimplantation genetic diagnosis (PGD) may be an option for some families in which the HFE pathogenic variants have been identified.
3. Management (Phatak and Cappuccio 1994; Tavill 2001; Seckington and Powell 2015):
    1. Early diagnosis and treatment:
        1. Can completely prevent the development of clinical complications
        2. Offer patients a normal life expectancy
    2. Treatment of iron overload:
        1. Periodic phlebotomy:
            1. Goal of therapy: to achieve and maintain a serum ferritin concentration of $\leq$50 ng/mL.
            2. Usual therapy: removal of the excess iron by weekly phlebotomy until the serum ferritin concentration is $\leq$50 ng/mL.
            3. Treatment with weekly phlebotomy frequently results in some clinical improvement in patients with established disease, and if initiated early, organ damage can be prevented and a normal life-span can be expected (Nichols and Bacon 1989).
        2. Dietary management:
            1. Avoid medicinal iron.
            2. Avoid mineral supplements.
            3. Avoid excess vitamin C which increases intestinal absorption of inorganic iron.
            4. Avoid uncooked shellfish or other seafood which can be contaminated with *V. vulnificus* causing sepsis in patients with HHC.
            5. Avoid alcohol consumption for patients with liver involvement.
        3. Iron chelation therapy: not recommended unless the patient has an elevated serum ferritin concentration and concomitant anemia that makes therapeutic phlebotomy impossible
    3. Postnatal treatment, previously based on the use of antioxidants and chelation therapy, has now successfully been replaced by exchange transfusions and intravenous immunoglobulin substitution (Lopriore et al. 2013).
    4. Conventional therapies for diabetes, hepatic failure, and cardiac failure.
    5. Cirrhosis: screen for hepatocellular cancer:
        1. Biannual abdominal ultrasound
        2. Annual serum alpha-fetoprotein testing

6. Orthotopic liver transplantation for end-stage liver disease from decompensated cirrhosis (Salgia and Brown 2015).
7. Surveillance of at-risk asymptomatic adults with C282Y homozygotes:
   1. Monitor serum ferritin concentrations yearly starting in early adulthood.
   2. Initiate therapeutic phlebotomy when serum ferritin concentrations are elevated.
8. Prevention of neonatal hemochromatosis (NH) (Feldman and Whitington 2013):
   1. Once a woman has delivered an infant with NH, the probability that the next pregnancy will be lethally affected is greater than 90% (Whitington and Kelly 2008).
   2. However, recurrence of severe NH can be prevented by treatment with intravenous immunoglobulin starting at 14 weeks' gestation (Lopriore et al. 2013; Whitington and Hibbard 2004).

Fig. 1 Father (40-year-old) and son (12-year-old) both carry heterozygous C282Y mutation. H63D and S65C were not detected. The father currently receives periodic phlebotomy with fasting transferrin-iron saturation level of 56% (15–50) and ferritin level of 1,238 ng/mL (20–345). The son is currently asymptomatic. Approximately 3–5% of patients with hereditary hemochromatosis have this genotype. The molecular results do not rule out the possibility of disease-causing mutations in other regions of the *HFE* gene or in other as yet undefined genes

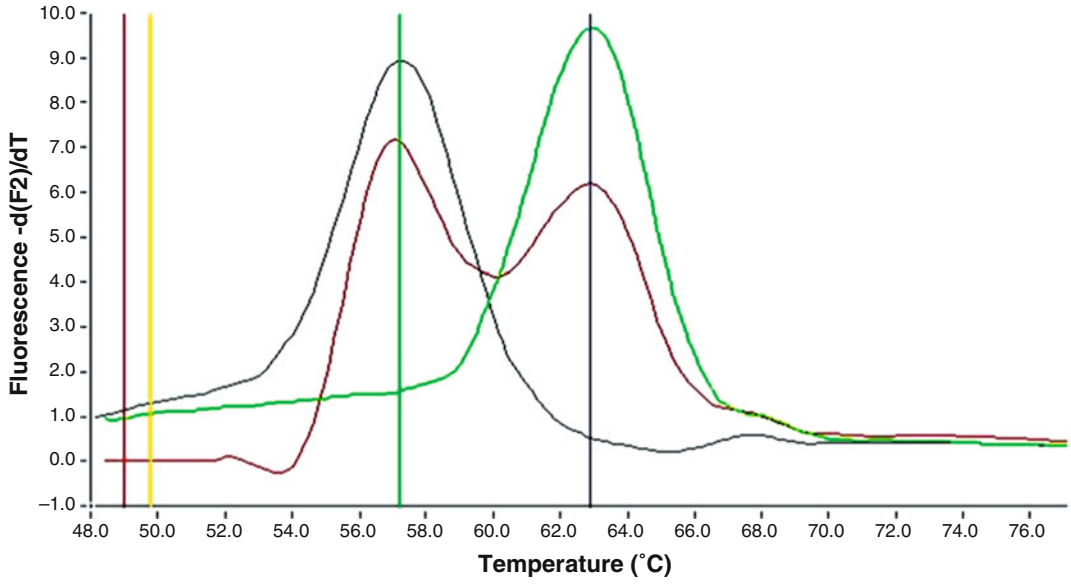

Fig. 2 Real-time PCR of HFE gene in another patient. The patient is homozygous for *C282Y* mutation, demonstrated by the *green line* (melting point (Tm) = 62.89)

Hereditary Multiple Exostoses

Contents

Hereditary multiple exostosis (HME) is a type of skeletal dysplasia characterized by osteochondral growths (osteochondromas) on the periphery of bones, comprised of the bone surrounded by a cap of the cartilage. The estimated prevalence is about 1 in 50,000 Caucasians (Schmale et al. 1994).

Synonyms and Related Disorders

Diaphysis aclasis; Hereditary multiple osteochondromas; Hereditary multiple osteochondromatosis; Multiple cartilaginous exostoses; Multiple hereditary exostoses; (Multiple hereditary) osteochondromatosis

Genetics/Basic Defects

1. Exostoses (Schmale et al. 1994):
    1. Result of dysplasia of the peripheral aspect of the growth plate.
    2. The most common type of benign bone tumors.
    3. Small exostoses may not be discovered because many do not cause symptoms.
    4. Multiple lesions develop in individuals who have a hereditary type.
2. Inheritance:
    1. Autosomal dominant with incomplete penetrance and expressivity skewing (Wicklund et al. 1995; Legeai-Mallet et al. 1997).
    2. About 90% of patients have an affected parent.
    3. About 10% of patients result from a de novo gene mutation.
3. Genetic heterogeneity (Hecht et al. 1997): linkage analysis identified the following three genes associated with hereditary multiple exostoses:
    1. *EXT1* gene:
        1. A ubiquitously expressed gene located on chromosome 8q24.1.
        2. Normal gene product: exostosin 1.
        3. Mutations in *EXT1* are responsible for about half of cases.
    2. *EXT2* gene:
        1. A ubiquitously expressed gene located on chromosome 11p11-p12.
        2. Normal gene product: exostosin 2.
        3. Mutations in *EXT2* are responsible for about one third of cases.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_117

3. *EXT3* gene:
    1. A gene located on chromosome 19p (Le Merrer et al. 1994).
    2. Mutations in *EXT3* are implicated in a minority of cases.
4. These three genotypes may result in different phenotypic expressions of HME and thus explain the variable manifestations of the disease (Carroll et al. 1999).
5. Loss of heterozygosity in the *EXT1* or *EXT2* implicated in causing osteochondromas, which are the most common bone tumors in children, characterized by cartilage-capped, bony excrescences (exostoses) arising from the metaphyseal ends of rapidly growing long bones (Bovée et al. 1996).
6. Deletion of *EXT1* gene and adjacent *TRPS1* gene (a gene located on chromosome 8 proximal to the *EXT1* gene) resulting in Langer-Giedion syndrome (trichorhinophalangeal syndrome, type II) in which multiple exostoses are distinguishing features.
7. EXT genes:
    1. Encode glycosyltransferases.
    2. Catalyze heparin sulfate polymerization.
8. Genotype-phenotype correlations (Pannier and Legeai-Mallet 2008):
    1. More severe disease in individuals with *EXT1* mutations than *EXT2* mutations on the basis of short stature, skeletal deformity (shortened forearm or bowing, knee deformity) and function (elbow, forearm, and knee range of motion) (Francannet et al. 2001; Porter et al. 2004).
    2. The risk of chondrosarcoma may also be higher in individuals with an *EXT1* mutation than in those with an *EXT2* mutation, but *EXT1* mutations are responsible for most cases of HME.

Clinical Features

1. Exostoses (cartilage-capped bony growths):
    1. Bony swellings (bumps) near the growing ends of the long bones: initially painless but later the majority of patients experience pain
    2. Onset during childhood (often asymptomatic)
    3. Sites (Hennekam 1991):
        1. Humerus
        2. Distal end of the femur
        3. Proximal end of the tibia and fibula
        4. Distal ends of the radius
        5. Ribs
        6. Scapula
        7. Ilium
    4. Types:
        1. Pedunculated with a narrow pedicle
        2. Sessile with a broad pedicle
    5. Size and number:
        1. Grow in size and gradually ossify during skeletal development
        2. Ceases with skeletal maturity (when the growth plates close at puberty) after which no new exostoses develop
2. Bowing:
    1. Often occurs without exostoses
    2. Bowing of forearms: ulnar deviation of the wrist secondary to a bowing of the radius and shortening of the ulna
    3. Bowing of lower legs
3. Genu valgum
4. Deformities observed in children (Ham 2013):
    1. Most common deformities:
        1. Disproportionate short stature (40%)
        2. Limb length discrepancies (Gross 1978)
        3. Valgus deformities of the knee and ankle
        4. Asymmetry of the pectoral and pelvic girdles
        5. Bowing of the radius with ulnar subluxation of the carpus
        6. Subluxation of the radial head
        7. Relative shortening of the metatarsals, metacarpals, and phalanges
    2. Less common deformities:
        1. Scoliosis
        2. Coxa valga (Wang et al. 2015)
        3. Acetabular dysplasia
5. Prognosis and complications (Ham 2013):
    1. Normal life span.
    2. Normal intelligence.

3. Cosmetic concern (one of the most common clinical complaints).
4. Mechanical restriction of adjacent joint movements.
5. Adventitious bursa with bursitis.
6. Compression or displacement of the adjacent nerves (22%):
    1. Pain (one of the most common clinical complaints)
    2. Sensory or motor deficits
7. Compression or displacement of the adjacent vessels (11%).
8. Spontaneous hemothorax as a result of rib exostoses (rare) (Castells et al. 1993).
9. Urinary or intestinal obstruction resulting from large pelvic exostoses (rare).
10. Compression of the spinal cord:
    1. Very rare occurrence
    2. Extremely serious complication
11. Slipping of the adjacent tendons.
12. Scapular winging.
13. Fractures at the pedicle.
14. Spinal cord compression.
15. Obstetric problems: complications can occur during delivery due to the aberrant morphology of the pelvis or the presence of osteochondromas on the interior pelvis.
16. Psychosocial problems.
17. Malignant transformation of osteochondroma to osteochondrosarcoma (0.5–5%), the most important complication:
    1. Rapid growth: rare occurrence of a giant costal chondrosarcoma (Acharya et al. 2014; Liu et al. 2013)
    2. Increasing pain
    3. A bulky cartilage cap
18. Morphological classification (based on X-ray and CT images) and malignant transformation (Fan et al. 2014):
    1. Cauliflower-like tumors: exostotic chondrosarcomas were more common in cauliflower-like tumors.
    2. Non-cauliflower-like tumor (pedunculated type, sessile type): benign exostoses were more common in non-cauliflower-like tumors.

6. Differential diagnosis (Pannier and Legeai-Mallet 2008; Kwee et al. 2016):
    1. Metachondromatosis (Kennedy 1983; Bassett and Cowell 1985; Fisher et al. 2013):
        1. An autosomal-dominant disorder, caused by loss of function of the *PTPN11* gene.
        2. Lesions typically occur in hands, feet, femora, tibiae, and the pelvis.
        3. A rare disorder exhibiting, synchronously, both multiple osteochondromas and enchondromas in children.
        4. In contrast to HME, the exostoses of metachondromatosis point toward the joints and frequently regress spontaneously.
        5. Exostoses do not result in the shortening of affected long bones or produce bowing, joint deformity, or subluxation as seen in HME.
    2. Langer-Giedion syndrome:
        1. A contiguous gene deletion syndrome involving *EXT1* and *TRPS1* genes (trichorhinophalangeal syndrome I).
        2. Affected individuals have exostoses, intellectual disability, craniofacial abnormalities (laterally protruding ears, broad nasal bridge and bulbous nose, sparse hair), and digital anomalies (cone-shaped epiphyses).
    3. 11p11.2 deletion syndrome (formerly known as Potocki-Shaffer syndrome) (Wu et al. 2000):
        1. A contiguous gene deletion syndrome involving *EXT2* and *ALX4* (homeobox) genes.
        2. Affected patients have multiple exostoses, an ossification defect of the skull (enlarged parietal foramina), craniofacial dysostosis, and intellectual disability.
    4. Enchondromatosis (Ollier disease) (please see the chapter of "► Enchondromatosis"):
        1. Enchondromas:
            1. Common benign cartilage tumors of the bone

2. Can occur as solitary lesions or as multiple lesions in enchondromatosis, often with unilateral predominance
2. Usually a nonhereditary disorder.
3. The association of hemangiomas is referred to as "Maffucci syndrome."
4. Risk of malignant transformation into chondrosarcomas (20–50%).

5. Dysplasia epiphysealis hemimelica (Trevor disease, tarso-epiphyseal aclasis) (Bovée 2008) (please see the chapter of "► Dysplasia Epiphysealis Hemimelica"):
   1. Cartilaginous overgrowth of a portion of one or more epiphyses
   2. Usually restricted to either medial (most frequent) or lateral side of the limb (hemimelic)
   3. Predominantly affects the lower extremity on one side of the body

Diagnostic Investigations

1. Radiographic features:
   1. Pedunculated or sessile exostoses pointing away from the joint.
   2. The cortex of exostoses continuous with that of the underlying bone.
   3. Exostoses originated in the metaphysis in the long bones and migrate to the diaphysis as growth continues in the epiphysis.
   4. Cartilaginous cap:
      1. Usually radiolucent
      2. The appearance of irregular zones of calcification after puberty
      3. Extensive calcification with irregularities of the cap suggesting the possibility of malignant change
   5. Exostoses prevent normal bone tabulation resulting in metaphyseal widening and growth retardation.
   6. Broad and barrel-shaped metaphyses without normal remodeling.
   7. Wrist:
      1. Shortening of the ulna
      2. Bowing of the radius with subluxations of the inferior radioulnar joint
2. CT and MRI imagings: evaluate spinal cord compression from an osteochondroma (Roach et al. 2009):
   1. The presence of a risk of having a lesion within the spinal canal
   2. Potential occurrence of serious neurologic injury
3. Multidetector CT evaluation (Kwee et al. 2016):
   1. Assessment of emergent complications of HME:
      1. Spinal cord compression
      2. Pneumothorax and hematothorax
      3. Pseudoaneurysms
      4. Fractures
   2. Assessment of non-emergent complications of HME:
      1. Growth disturbances
      2. Chondrosarcoma transformation
      3. Muscular and peripheral nerve involvement
4. MRI imaging: always be the first imaging method due to the absence of radiation and better display of the cartilaginous cap and the relation with the surrounding soft issues (Kwee et al. 2016).
5. Serial technetium bone scans: increased radionucleotide uptake suggests malignancy (Lange et al. 1984; Bouvier et al. 1986).
6. Histology of exostosis:
   1. Core: cancellous bone
   2. Surrounding: cortical bone
   3. Apex: covered with a cap of hyaline cartilage
7. DNA analysis of mutations in the *EXT1*, *EXT2*, and *EXT3* genes available clinically for *EXT1* and *EXT2*:
   1. FISH on metaphase cells.
   2. Genomic microarray analysis.
   3. Screening of the entire coding region.
   4. A combination of sequence analysis and deletion analysis of the entire coding regions of both *EXT1* and *EXT2* detects mutations in 70–95% of affected individuals (Schmale et al. 2013).

Genetic Counseling

1. Recurrence risk:
   1. Patient's sib:
      1. Usually with 50% risk of inheriting the gene alteration, since most probands (about 90%) have a parent with the altered gene and 95% risk of manifesting symptoms (penetrance)
      2. Low risk if both parents are normal
   2. Patient's offspring: 50% risk of inheriting the mutant allele
2. Prenatal diagnosis: available clinically for pregnancies at risk:
   1. Molecular genetic analysis on fetal DNA obtained from amniocentesis or CVS for *EXT1* or *EXT2* mutation, provided the disease-causing allele of an affected family member has been identified prior to prenatal diagnosis
   2. Preimplantation diagnosis using embryonic cells available to couples at 50% risk of having a child with hereditary multiple exostosis, provided the disease-causing mutation of the *EXT1* or *EXT2* gene has been identified in the affected parent
3. Management (Bovée et al. 1996):
   1. Exostoses without clinical problems required no therapy.
   2. Surgical intervention of exostoses:
      1. Indications for surgical excision of exostoses (Peterson 1989):
         1. Painful lesion without bony deformity
         2. Pain due to irritation of the skin, tendons, or nerves
         3. Slowing growth disturbance
         4. Compromise joint motion
         5. Secondary impingement of the tendon, nerve, or vessel
      2. Angular deformities
      3. Improving cosmesis
      4. Either epiphysiodesis of the longer leg or lengthening of the involved leg for leg length discrepancy greater than one inch
      5. Excision of the exostoses and corrective osteotomies for forearm deformity (pain and stiffness of the elbow and wrist are a common cause of disability) (Fogel et al. 1984; Wood et al. 1985; Arms et al. 1997)
   3. Sarcomatous degeneration:
      1. Surgical resection
      2. Adjuvant radiotherapy and chemotherapy for secondary osteosarcoma

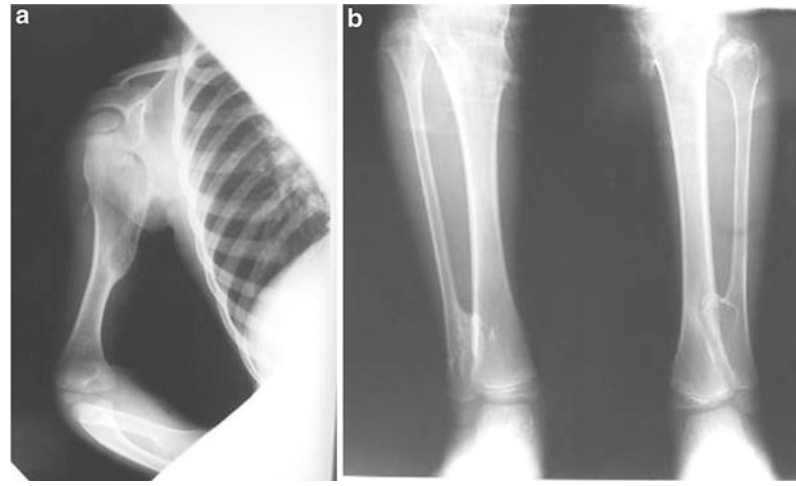

Fig. 2 (**a**, **b**) Radiographs of a 5-year-old boy with hereditary multiple exostoses showing multiple exostoses of the humerus (**a**), radius, tibia, and fibula (**b**)

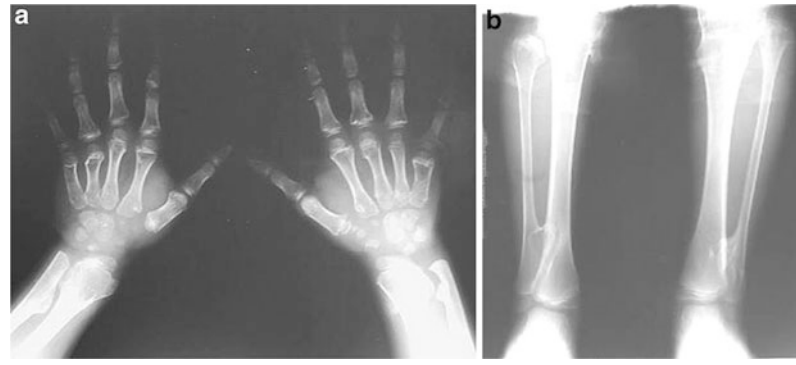

Fig. 3 (**a**, **b**) A 7-year-old boy with hereditary multiple exostoses showing more severe degree of multiple exostoses of the humerus, radius (**a**), tibia, and fibula (**b**)

Fig. 4 (**a**–**c**) A 20-year-old female (**a**) with hereditary multiple exostoses showing pedunculated exostosis on the left proximal tibia and fibula, exostosis on the shaft of the left fibula (**b**), and exostoses on the distal radius and ulna (**c**). She was discovered to have multiple exostoses since 1 year of age and has had multiple surgeries to remove multiple tumors from the right femur, left tibia, and left fibula. Currently, she has bumps on the right distal femur, right proximal fibula, right distal tibia, left distal fibula, left distal forearm, right distal phalange of the right fifth finger, and left second toe. Her father is also affected

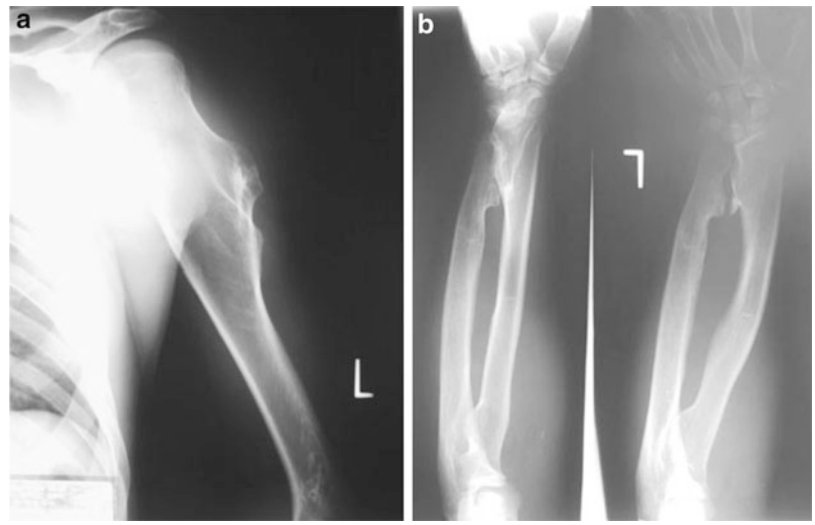

Fig. 5 (**a**, **b**) A 27-year-old male with hereditary multiple exostoses showing exostoses (**a, b**), ulnar shortening, and ulnar carpal drift (**b**)

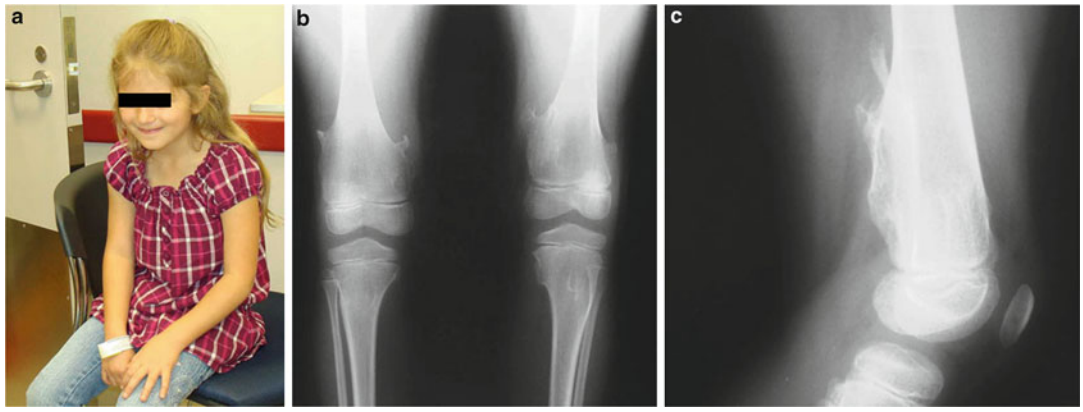

Fig. 6 (**a**–**c**) A 9-year-old girl (**a**) with hereditary multiple exostoses showing typical radiographic features of both distal femurs (**b**)

Fig. 7 (**a**, **b**) An 18-year-old male who was diagnosed to have hereditary multiple exostoses at age 3. The mother had a history of bone spur removal at age 11 from the left lower leg. The radiography (**a**) and CT images (**b**) demonstrate multiple exostoses projecting off the proximal (not shown) and distal femora, tibiae, and fibulae. Length discrepancy between the bilateral lower extremities is seen (Courtesy of Dr. Grace Guo)

Hereditary Sensory and Autonomic Neuropathies

Contents

Congenital indifference to pain has been reported since early 1930s (Dearborn 1932; Ford and Wilkins 1938; Boyd and Nie 1949; Winkelmann et al. 1962). Children with underlying peripheral neuropathies have impairment in both the sensory-discriminative and affective-motivational components of pain perception. The majority of them have a type of hereditary sensory and autonomic neuropathy (HSAN). These disorders are characterized by loss of pain sensation and other sensory or autonomic abnormalities (Dyck et al. 1983; Thomas 1993). At present, five types of HSAN have been identified (Axelrod and Hilz 2003; Nagasako et al. 2003; Butler et al. 2006).

Synonyms and Related Disorders

Congenital absence of pain; Congenital general pure analgesia; Congenital insensitivity to pain; Congenital insensitivity to pain with anhidrosis; Congenital pain insensitivity syndrome; Congenital universal indifference to pain; Congenital universal insensitiveness to pain; Hereditary sensory neuropathy type IA (HSN IA); Hereditary sensory radicular neuropathy; HSAN; Inherited autonomic neuropathies; Morvan disease; Riley-Day syndrome (familial dysautonomia)

Genetics/Basic Defects

1. HSAN type 1 (HSAN1)
   1. Inheritance pattern: autosomal dominant
   2. Genetic abnormality: Mutation in *SPTLC1* (serine palmitoyltransferase) gene at locus 9q22.1-q22.3
2. HSAN type 2 (HSAN2)
   1. Inheritance pattern: autosomal recessive
   2. Genetic abnormality: Mutation in *HSN2* (hereditary sensory neuropathy type 2) gene at locus 12p13.33
3. HSAN type 3 (HSAN3)
   1. Inheritance pattern: autosomal recessive
   2. Genetic abnormality: mutation in *IKBKAP* (inhibitor of kappa light polypeptide gene enhancer in B cells, kinase complex-associated protein) gene at locus 9q31
4. HSAN type 4 (HSAN4)
   1. Inheritance pattern: autosomal recessive
   2. Genetic abnormality: mutation in *NTRK1* (neurotrophic tyrosine kinase receptor type 1) gene at locus 1q21-q22

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_261

5. HSAN type 5 (HSAN5)
    1. Inheritance pattern: autosomal recessive
    2. Genetic abnormality: mutation in *NGFB* (nerve growth factor B) gene at locus 1p13.2-p11.2 (Capsoni 2014)
6. Unclassified

Clinical Features

1. HSAN type 1 (hereditary sensory radicular neuropathy)
    1. Late onset (second to fourth decade)
    2. Progressive distal sensory loss (pain and thermal sensation)
    3. Loss of distal reflexes/distal muscle wasting
    4. Numbness or distal pain predominantly affecting the distal lower extremities
    5. Intermittent lancinating pains occurring in some kinships
    6. Usually no autonomic dysfunction
    7. Intelligence may be mildly impaired
    8. Hearing loss (deafness)
    9. Ataxic gait
    10. Severe ulceration of extremities
    11. Painless injuries
    12. Stress fractures
    13. Osteomyelities
2. HSAN type 2 (Morvan disease)
    1. Onset in early infancy
    2. A rare disorder
    3. Nonprogressive
    4. Global distal sensory loss/minimal weakness (hypotonia)
    5. Delayed milestones
    6. Self-mutilation
    7. Usually no autonomic dysfunction
3. HSAN type 3 (Riley-Day syndrome; familial dysautonomia)
    1. Onset at birth
    2. Progressive
    3. Ashkenazi Jewish disease
    4. Earliest signs
        1. Feeding difficulties due to poor oral coordination
        2. Hypotonia
        3. Frequent gastroesophageal reflux leading to aspiration
    5. Profound autonomic dysfunction
        1. Absence of tears (alacrima) with emotional crying: one of the cardinal features of the disorder.
        2. Protracted episodes of nausea and vomiting triggered by emotional or physical stress and even arousal from sleep. These episodes, termed the "dysautonomic crisis," are usually associated with a constellation of signs including agitation, tachycardia, and hypertension.
        3. Vasomotor and cardiovascular perturbations manifest as erythematous skin blotching and hyperhydrosis with excitation or even eating.
    6. Loss of pain and thermal sensation
    7. Absent deep tendon reflexes
    8. Absent fungiform papillae on the tongue
    9. Normal sweat response
4. HSAN type 4 (congenital insensitivity to pain with anhidrosis)
    1. Onset in infancy
    2. Commonest HSAN
    3. Profound insensitivity to pain
    4. Decreased or absent thermal sensation
    5. Deep tendon reflexes usually intact
    6. Absent or markedly decreased sweating (anhidrosis): cardinal feature
    7. Episodic fever and extreme hyperpyrexia: usually the earliest sign of the disorder
    8. Severe learning disability
    9. Self-mutilation
    10. Auto-amputation
    11. Osteomyelitis
    12. Corneal scarring
5. HSAN type 5 (congenital insensitivity to pain)
    1. Onset in infancy
    2. Only a few cases described in the literature
    3. Profound insensitivity to pain
    4. Painless burns (Aguayo et al. 1971)
    5. Finger and toe mutilations (Van Epps and Kerr 1940)
    6. Tactile, vibratory, and thermal sensation usually intact
    7. Deep tendon reflexes intact

8. Usually no autonomic dysfunction
9. Intelligence may be mildly impaired
10. Hearing loss (deafness)
11. Severe ulceration of extremities
12. Joint injuries (Swanson 1963)
13. Painless injuries/fractures

Diagnostic Investigations

1. Radiological studies
   1. Radiographic features (Zhang and Haga 2014)
      1. Fractures
      2. Joint dislocations
      3. Osteomyelitis/arthritis
      4. Charcot joints
   2. Magnetic resonance imagings: useful when bone infections or necrosis are suspected (Auer-Grumbach 2008)
2. Peripheral nerve abnormality
   1. HSAN type 1
      1. Severe loss of small myelinated and unmyelinated fibers
      2. Moderate loss of large unmyelinated fibers
   2. HSAN type 2
      1. Severe loss of myelinated fibers
      2. Some loss of unmyelinated fibers
   3. HSAN type 3
      1. Total absence of large diameter myelinated neurons
      2. Severe loss of unmyelinated fibers
   4. HSAN type 4
      1. Virtual absence of unmyelinated fibers
      2. Reduction of small myelinated fibers
   5. HSAN type 5
      1. Severe reduction of unmyelinated fibers
      2. May be moderate loss of thin myelinated fibers
3. Molecular genetic studies
   1. HSAN 1
      1. Sequence analysis of *SPTLC1* for HSAN 1A
      2. Sequence analysis of *SPTLC2* for HSAN 1C
   2. HSAN 2
      1. *WNK1* (type HSAN 2A)
      2. *FAM134B* (type HSAN 2B)
      3. *KIF1A* (type HSAN 2C)
   3. HSAN 3: target mutation analysis and sequence analysis of *IKBKAP*
   4. HSAN 4: sequence analysis of *CIPA*
   5. HSAN 5: sequence analysis of *NGF*

Genetic Counseling

1. Recurrence risk.
   1. Patient's sib
      1. Autosomal recessive: 25%
      2. Autosomal dominant: not increased unless one of the parents is affected
   2. Patient's offspring:
      1. Autosomal recessive: recurrence risk not increased unless the spouse is a carrier or affected
      2. Autosomal dominant: a 50% risk
2. Prenatal diagnosis for pregnancies at increased risk is possible by analysis of DNA extracted from fetal cells obtained by amniocentesis usually performed at approximately 15–18 weeks of gestation or chorionic villus sampling at approximately 10–12 weeks of gestation. Both disease-causing alleles (autosomal recessive) must be identified in the family before prenatal testing can be performed.
3. Preimplantation genetic diagnosis may be an option for some families in which the disease-causing mutations have been identified.
4. Management.
   1. Symptomatic management for feeding problems, GE reflux, aspiration pneumonia, hypertension, orthostatic hypotension, and corneal ulcerations
   2. Treatment of self-injurious behavior (Kuhn et al. 2008)
      1. Pharmacological interventions: little evidence in support of the efficacy
         (a) Anticonvulsants
         (b) Antipsychotics
      2. Behavior intervention (a simplified habit reversal treatment)
   3. Training in the care of the sensory-impaired limb: important

1. Self-examination especially of the feet for any signs of trauma
2. Prevent callous formation in neuropathic skin
3. Cleaning and protection of wounds on neuropathic limbs in combination with antiseptic treatment to eradicate infections help prevent osteomyelitis and amputations
4. Administration of bisphosphonates and vitamin D: beneficial to painless fracture in HSAN 1 (Marik et al. 2012)

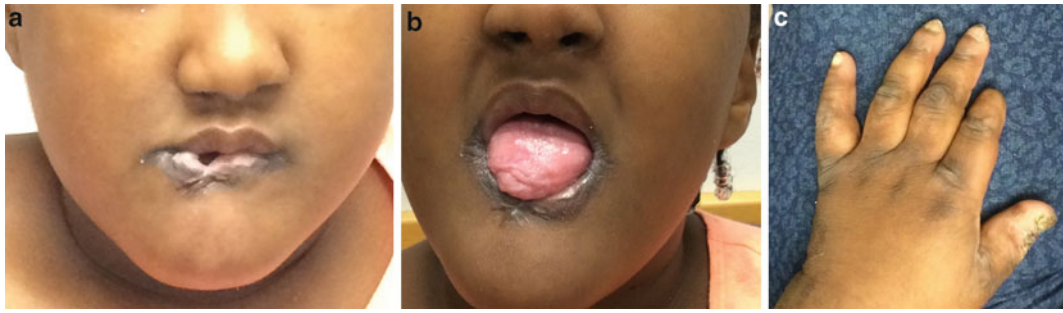

Fig. 1 (**a**–**c**) The patient is a 7-year-old African American girl who was followed for congenital insensitivity to pain, developmental delay, hypotonia, mild to moderate sensorineural hearing loss, strabismus, and myopia. She perspires. She had significant damages to her hands, feet, and face because of her insensitivity to pain. Past history showed that she did not cry when she got her immunizations. She had osteomyelitis at 1 year of age in her left heel after a bout of cellulitis. She also had a history of fracturing her tibia/fibula by jumping down. She had surgeries for strabismus, tongue injuries secondary to repeat bitings, and central corneal opacification and scarring secondary to repeat scratching of the eyes. The pictures here show bitten lower lip (**a**), tongue (**b**), and damaged finger (**c**). EMG and nerve conduction studies were normal. Oligonucleotide array CGH analysis was normal (Courtesy of Dr. Susonne Ursin)

Hereditary Spastic Paraplegia

Contents

The hereditary spastic paraplegia (HSP) are inherited disorders in which the primary neurological syndrome is bilateral, approximately symmetrical, lower-extremity spastic weakness, often accompanied by urinary urgency (Fink 2003; Figs. 1 and 2)

Synonyms and Related Disorders

Allan–Herndon–Dudley syndrome; Cerebral palsy; Crash syndrome; Familial spastic paraplegia; Gareis–Mason syndrome; Kjellin syndrome; Mast syndrome; MASA syndrome; Pelizeaus–Merzbacher disease; Silver syndrome; Spastic quadriplegia/tetraplegia; Strumpell disease; Troyer syndrome; X-linked hydrocephalus

Genetics/Basic Defects

1. Genetic types of HSP (Fink 1997, 2002, 2003, 2013; Online Mendelian Inheritance in Man (OMIM))
    1. Autosomal dominant, autosomal recessive, and X-linked HSP are each genetically heterogeneous
    2. Twenty genetic types of HSP defined by genetic linkage analysis
    3. HSP loci are designated SPG ("spastic paraplegia") 1–21 in order of their discovery
2. Autosomal dominant HSP
    1. SPG3A (OMIM 182600) (14q22.1)
        1. Caused by mutation in the atlastin gene
        2. Symptoms usually begin in early childhood, often nonprogressive (Strumpell disease)
    2. SPG4 (OMIM 182601) (2p22.3)
        1. Caused by mutation in the spastin gene
        2. Most common type of dominantly inherited HSP (45%)
        3. May be associated with dementia
    3. SPG6 (OMIM 600363) (15q11.2)
        1. Caused by mutation in the nonimprinted gene in Prader–Willi syndrome/Angelman syndrome chromosome region-1 gene (*NIPA1*)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_272

2. Prototypical late-adolescent, early-adult onset, slowly progressive uncomplicated HSP. Rarely complicated by epilepsy or variable peripheral neuropathy

4. SPG8 (OMIM 603563) (8q24.13)
   1. Caused by mutation in the KIAA0196 gene
   2. Symptoms begin in adulthood, often severe
   3. Progressive lower-limb spasticity and hyperreflexia resulting in difficulty walking
   4. Other features: upper limb spasticity, impaired vibration sense in the distal lower limbs, and urinary urgency or incontinence (de Bot et al. 2013)
5. SPG10 (OMIM 604187) (12q13.3)
   1. Caused by mutation in the kinesin-5A gene
   2. Associated with distal muscle wasting
6. SPG12 (OMIM 604805) (19q13.32)
   1. Caused by mutation in the reticulon 2 gene (*RTN2*)
   2. Lower-limb spasticity and hyperreflexia, resulting in walking difficulties, with some patients having urinary symptoms and distal sensory impairment (Montenegro et al. 2012)
7. SPG13 (OMIM 605280) (2q33.1)
   1. Caused by mutation in the mitochondrial chaperonin HSP60 gene
   2. Lower-limb spasticity/weakness, hyperreflexia, extensor plantar responses, pyramidal signs, decreased vibratory sense in the lower limbs, and urinary urgency/incontinence
8. SPG17 (OMIM 270985) (11q12.3)
   1. Caused by mutation in the BSCL gene
   2. Spastic paraplegia with amyotrophy of hands and feet (Silver syndrome) (Silver 1966)
9. SPG31 (OMIM 610250) (2p11.2)
   1. Caused by mutation in the receptor expression–enhancing protein-1 gene (*REEP1*)
   2. Onset: most in first or second decade
10. SPG33 (OMIM 610244) (10q24.2)
    1. Caused by mutation in the zinc finger FYVE domain–containing protein-27 gene (*ZFYVE27*)
    2. Lower-limb spasticity/weakness, spastic gait, hyperreflexia, extensor plantar responses, ankle clonus
11. SPG42 (OMIM 612539) (3q25.31)
    1. Caused by mutation in the solute carrier family 33 (acetyl-CoA transporter), member 1 gene (*SLC33A1*)
    2. Varied age of onset with increased lower-limb tone, hyperreflexia, lower-limb muscle weakness/atrophy, extensor plantar responses, and pes cavus in Chinese (Lin et al. 2008)
12. SPG61 (OMIM 615685) (16p12.3)
    1. Caused by mutation in the ARL6IP1 gene
    2. Spastic paraplegia with polysensory and motor neuropathy and loss of terminal digits due to acropathy (Novarino et al. 2014)

3. Autosomal recessive HSP
   1. SPG5A (OMIM 270800) (8q12.3)
      1. Caused by mutation in the cytochrome P450, family 7, subfamily b, polypeptide 1 gene (*CYP7B1*)
      2. Some patients with pure spastic paraplegia affecting gait, whereas others with complicated phenotype with additional manifestations including optic atrophy or cerebellar ataxia (Arnoldi et al. 2012)
   2. SPG7 (OMIM 607259) (16q24.3)
      1. Caused by mutation in the paraplegin gene (*PGN*)
      2. Variably associated with mitochondrial abnormalities on skeletal muscle biopsy and dysarthria, dysphagia, optic disc pallor, axonal neuropathy, and evidence of "vascular lesions," cerebellar or cerebral atrophy on cranial MRI
   3. SPG11 (OMIM 604360) (15q21.1)
      1. Caused by mutation in the spatacsin gene

2. Perhaps the most common autosomal recessive form of HSP (50%)
3. Variably associated with thin corpus callosum, mental retardation, upper extremity weakness, dysarthria, and nystagmus
4. Symptoms begin in the first or second decades

4. SPG15 (OMIM 270700) (14q24.1)
   1. Caused by mutation in the gene encoding spastizin (*ZFYVE26*)
   2. Progressive spasticity affecting the lower limbs associated with retinal degeneration, pigmental maculopathy, distal amyotrophy, dysarthria, mental retardation, and further intellectual deterioration (Kjellin syndrome) (Goizet et al. 2009)
5. SPG18 (OMIM 611225) (8p11.3)
   1. Caused by mutation in the endoplasmic reticulum lipid raft–associated protein 2 gene (*ERLIN2*)
   2. Spastic paraplegia complicated by mental retardation and thin corpus callosum. Also juvenile primary lateral sclerosis
6. SPG20 (OMIM 275900) (13q13.3)
   1. Caused by mutation in the gene encoding spartin (*SPG20*)
   2. Spastic paraplegia associated with distal muscle wasting (Troyer syndrome)
7. SPG21 (OMIM 248900) (15q22.31)
   1. Caused by mutation in the gene encoding the 33-kD acidic cluster protein (ACP33)
   2. Progressive spastic paraparesis associated in more advanced cases with cognitive decline, dementia, other neurological abnormalities, and brain imaging showing thinning of the corpus callosum (Simpson et al. 2003)
   3. Also called Mast syndrome
8. SPG26 (OMIM 609195) (12p11.1-q14)
   1. Caused by mutation in the beta-1,4-*N*-acetylgalactosaminyltransferase 1 gene (*B4GALNT1*)
   2. Onset in the first two decades of life of gait abnormalities due to lower-limb spasticity and muscle weakness with upper limb involvement in some patients
   3. Additional features: intellectual disability, peripheral neuropathy, dysarthria, cerebellar signs, extrapyramidal signs, and cortical atrophy (Boukhris et al. 2013)
9. SPG 28 (OMIM 609340) (14q22.1)
   1. Caused by mutation in the DDHD1 gene
   2. Early-onset, slowly progressive lower-limb spasticity resulting in walking difficulties, with some patients having distal sensory impairment (Tesson et al. 2012)
10. SPG 30 (OMIM 610357) (2q37.3)
    1. Caused by mutation in the kinesin family member 1A gene (*KIF1A*)
    2. Onset in the first and second decades of unsteady spastic gait and hyperreflexia of the lower limbs (Erlich et al. 2011)
11. SPG35 (OMIM 612319) (16q23.1)
    1. Caused by mutation in the gene encoding fatty acid 2-hydroxylase (*FA2H*)
    2. Childhood onset of gait difficulties due to progressive spastic paraparesis, dysarthria, and mild cognitive decline associated with leukodystrophy on brain imaging
    3. Other variable neurological features: dystonia, optic atrophy, and seizures (Dick et al. 2010)
    4. Phenotypic spectrum of disorders referred as fatty acid hydrolase–associated neurodegeneration (Kruer et al. 2010)
12. SPG39 (OMIM 612020) (19p13.2)
    1. Uncomplicated HSP
    2. Caused by mutation in the patatin-like phospholipase domain–containing protein 6 gene (*PNPLA6*)
    3. Progressive spastic paraplegia associated with distal upper- and lower-

extremity wasting (Rainier et al. 2008)

13. SPG43 (OMIM 615043) (19q12)
    1. Caused by mutation in the chromosome 19 open reading frame 12 gene (*C19ORF12*)
    2. Progressive spastic paraplegia with atrophy of intrinsic hand muscles and dysarthria
14. SPG44 (OMIM 613206) (1q42.13)
    1. Caused by mutation in the gap junction protein, gamma-2 gene (GJC2)
    2. Lower-/upper-limb spasticity, spastic gait, hyperreflexia, extensor plantar responses, dysarthria, intentional tremor, dysmetria, cerebellar ataxia, hypomyelinating leukoencephalopathy, and thin corpus callosum (Orthmann-Murphy et al. 2009)
15. SPG45 (OMIM 613162) (10q24.3-25.1)
    1. Caused by mutation in the 5-prime nucleotidase cytosolic II gene (NT5C2)
    2. Onset in the first 2 years of life with lower-limb spasticity, spastic gait, hyperreflexia, mental retardation, and brain MRI features of dysplastic/thin corpus callosum and white-matter changes (Novarino et al. 2014)
16. SPG46 (OMIM 614409) (9p13.3)
    1. Caused by mutation in the beta acid glucosidase 2 gene (*GBA2*)
    2. Onset: childhood with slowly progressive spastic paraplegia and cerebellar signs
    3. Some patients with cognitive impairment, cataracts, and cerebral, cerebellar, and corpus callosum atrophy (Boukhris et al. 2010; Martin et al. 2013)
17. SPG47 (OMIM 614066) (1p13.2)
    1. Caused by mutation in the adapter-related protein complex 4, beta-1 subunit gene (*AP4B1*)
    2. Neonatal hypotonia progressing to hypertonia and spasticity and severe mental retardation with poor or absent speech development (Abou Jamra et al. 2011)
18. SPG48 (OMIM 613647) (7p22.1)
    1. Caused by mutation in the KIAA0415 gene
    2. Progressive spastic paraplegia associated with urinary incontinence in two adult French sibs (Slabicki et al. 2010)
19. SPG49 (OMIM 615031) (14q32.31)
    1. Caused by mutation in the tectonin beta-propeller repeat-containing protein 2 gene (*TECPR2*)
    2. Onset of spastic paraplegia in the first decade associated with delayed psychomotor development, mental retardation, dysmorphic features, thin corpus callosum on MRI, and episodes of central apnea, which may be fatal (Oz-Levi et al. 2012)
20. SPG50 (OMIM 612936) (7q22.1)
    1. Caused by mutation in the adapter-related protein complex 4, MU-1 subunit gene (*AP4M1*)
    2. Neonatal hypotonia progressing to hypertonia, spastic quadriplegia, severe mental retardation with poor or absent speech development, dysmorphic features, and abnormal brain MRI (ventriculomegaly, white-matter abnormalities and variable cerebral atrophy) (Verkerk et al. 2009)
21. SPG51 (OMIM 613744) (15q21.2)
    1. Caused by mutation in the adapter-related protein complex 4, epsilon-1 subunit gene (*AP4E1*)
    2. Neonatal hypotonia progressing to hypertonia and spastic quadriplegia/tetraplegia and severe mental retardation, poor or absent speech development, dysmorphic features, and abnormal brain MRI (enlarged ventricles, cortical and cerebellar atrophy, and diffuse white-matter loss) (Moreno-De-Luca et al. 2011)

22. SPG52 (OMIM 614067) (14q12)
    1. Caused by mutation in the adapter-related protein complex 4, sigma-1 subunit (*AP4S1*)
    2. Neonatal hypotonia progressing to hypertonia, spastic quadriplegia, severe mental retardation with poor or absent speech development, dysmorphic features, shy character, and short stature (Abou Jamra et al. 2011)
23. SPG53 (OMIM 614898) (8p22)
    1. Caused by mutation in the homologue of the yeast vacuolar protein sorting 37 gene (*VPS37A*)
    2. Onset in infancy of delayed motor development progressing to upper- and lower-limb spasticity with impaired walking and mild-to-moderate cognitive impairment (Zivony-Elboum et al. 2012)
24. SPG54 (OMIM 615033) (8p11.23)
    1. Caused by mutation in the DDHD domain-containing protein 2 gene (*DDHD2*)
    2. Psychomotor delay, cognitive impairment, progressive spasticity (onset before age 2 years), thin corpus callosum, periventricular white-matter abnormalities.
    3. Additional clinical features: foot contractures, dysarthria, dysphagia, strabismus, optic hypoplasia
25. SPG55 (OMIM 615035) (12q24.31)
    1. Caused by mutation in the chromosome 12 open reading frame 65 gene (*C12ORF65*)
    2. Spastic paraplegia associated with distal muscle atrophy/weakness, predominantly affecting the lower limbs, optic atrophy, hyperreflexia, steppage gait, difficulty walking, extensor plantar responses, axonal neuropathy, distal sensory impairment, and hypoplastic corpus callosum in some patients (Shimazaki et al. 2012; Spiegel et al. 2014)
26. SPG56 (OMIM 615030) (4q25)
    1. Caused by mutation in the cytochrome P450, family 2, subfamily U, polypeptide 1 gene (*CYP2U1*)
    2. Early-onset progressive lower-limb spasticity resulting in walking difficulties and often affected upper limbs (Tesson et al. 2012)
27. SPG57 (OMIM 615658) (3q12.2)
    1. Caused by mutation in the TRK-fused gene (*TFG*)
    2. Severe spasticity affecting lower limbs with inability to walk, hyperreflexia, extensor plantar responses, muscle weakness/atrophy affecting upper and lower limbs due to an axonal demyelinating sensorimotor neuropathy, and optic atrophy (Beetz et al. 2013)
28. SPG63 (OMIM 615686) (1p13.3)
    1. Caused by mutation in the AMPD2 gene
    2. Delayed walking and a scissors gait, followed by hypertonia, hyperreflexia, and MRI showing periventricular deep white-matter changes in the corpus callosum (Novarino et al. 2014)
29. SPG64 (OMIM 615683) (10q24.1)
    1. Caused by mutation in the ENTPD1 gene
    2. Childhood onset with unsteady gait with areflexia/hyperreflexia, dysarthria, and spasticity (Novarino et al. 2014)
30. SPG72 (OMIM 615625) (5q31.2)
    1. Caused by mutation in the receptor expression–enhancing protein 2 gene (*REEP2*)
    2. Spastic paraplegia with difficulty walking and stiff legs associated with hyperreflexia and extensor plantar responses in early childhood (Esteves et al. 2014)
    3. Autosomal recessive form has been described

4. X-linked HSP
    1. SPG1 (OMIM 303350) (Xq28)

1. Caused by mutation in the gene encoding the L1 cell adhesion molecule (LICAM)
2. Mutations in this gene also cause MASA syndrome and X-linked recessive hydrocephalus (Crash syndrome) (OMIM 303350)
3. Some forms of HSP with progressive spasticity occurs in isolation
4. Others with progressive spasticity with other neurologic features including mental retardation, and variably, hydrocephalus, aphasia, and adducted/clapsed thumbs
5. Also called Gareis-Mason syndrome

2. SPG2 (OMIM 312920) (Xq22.2)
   1. Caused by mutation in the myelin proteolipid protein gene (*PLP1*)
   2. X-linked recessive inheritance
   3. Allelic to Pelizaeus-Merzbacher disease
   4. Progressive spasticity occurs in isolation or occurs with other neurologic features, variably associated with MRI evidence of CNS white matter abnormality
   5. Mutations in this gene also cause Pelizeaus-Merzbacher disease (OMIM 312080)
3. SPG22 (OMIM
   1. Caused by mutation in the monocarboxylate transporter 8 gene (*MCT8*)
   2. Also called Allan-Herndon-Dudley syndrome (X-linked dominant)
   3. Congenital onset with neck muscle hypotonia in infancy, mental retardation, dysarthria, ataxia, spastic paraplegia, abnormal facies

Clinical Features

1. Variable onset of symptoms, rate of progression and degree of disability between genetic types of HSP (Fink and Hedera 1999; Fink 2003), as well as within individual families in which all subjects have precisely the same HSP gene mutation
   1. Initial symptoms: tumbling and tripping due to lower-extremity stiffness and weakness with age of onset at any age from infancy to senescence
   2. Later symptoms
      1. Marked lower-extremity spastic weakness
      2. Requiring cane, walker, or wheelchair
2. Correlation of age of onset and progression of the disease
   1. In general, HSP symptoms beginning in early childhood may not show significant worsening even over many years.
   2. In contrast, HSP symptoms beginning after adolescence typically worsen insidiously
   3. Urinary urgency is very common, and although usually occurring after many years, it may occasionally be the presenting symptom of HSP
   4. In uncomplicated HSP
      1. Spastic weakness: confined to the lower extremities
      2. Normal strength and dexterity of the upper extremities, speech, and swallowing remain normal
3. Classification of HSP (Harding 1983)
   1. Uncomplicated HSP
      1. Neurological findings confined to the lower extremities
         1. Spastic weakness
         2. Hyperreflexia
         3. Extensor plantar responses
         4. Mildly impaired vibratory sensation in the distal lower extremities
      2. Normal strength and dexterity of the upper extremities, speech, and swallowing remain normal
   2. Complicated HSP
      1. Signs of uncomplicated HSP plus
      2. Other neurological or systemic impairments not attributed to coexisting disorders
         1. Cataracts
         2. Motor neuropathy

3. Mental retardation
4. Muscle wasting

4. Diagnosis of HSP
   1. Typical symptoms of gait disturbance often associated with urinary urgency
      1. Childhood onset, essentially non-progressive spastic diplegia
      2. Childhood-through-adulthood onset of insidiously progressive spastic weakness in the legs
   2. Neurological findings of corticospinal tract deficits
      1. Lower extremities
         1. Spasticity
         2. Weakness
         3. Hyperreflexia
         4. Extensor plantar responses
      2. Upper extremities
         1. Brisk but not pathological reflexes
         2. Normal muscle tone
   3. Family history of similar disorder
   4. Exclusion of alternate disorders such as
      1. Multiple sclerosis
      2. Leukodystrophy
      3. Structural abnormalities involving the brain and spinal cord
      4. Dopa-responsive dystonia
5. Differential diagnosis of spastic paraplegia with additional abnormalities on MRI of the brain (de Bot et al. 2010)
   1. Leukoencephalopathy
      1. Many neurometabolic and other hereditary white-matter disorders with characteristic MRI pattern like Krabbe disease, Alexander disease, X-linked adrenoleukodystrophy, vanishing white matter; inflammatory disorders like multiple sclerosis, acute disseminated encephalomyelitis, and neuromyelitis optica
      2. HSPs: SPG4 (some), SPG11, SPG15, SPG21
   2. Thin corpus callosum
      1. Thin corpus callosum + epilepsy, Andermann syndrome (agenesis of the corpus callosum with peripheral neuropathy) (OMIM 218000)
      2. HSPs: SPG1, SPG4 (some), SPG11, SPG15, SPG21, SPG32
   3. Cerebral atrophy
      1. Cerebellar ataxia
      2. HSPs: SPG7
6. Differential diagnosis of spastic paraplegia with additional clinical features (de Bot et al. 2010)
   1. Mental retardation
      1. Many neurometabolic or neurogenetic disorders; sometimes recognizable based on MRI abnormalities or further additional features
      2. HSPs: SPG1, SPG2, SPG11, SPG14, SPG15, SPG16, SPG20, SPG21, SPG23, SPG27, SPG32, SPG35
   2. Dysmorphisms
      1. Andermann syndrome, hydrocephalus due to congenital stenosis of aqueduct of Sylvius
      2. HSPs: SPG1, SPG23
   3. Optic atrophy
      1. Cobalamin C disease, biotinidase deficiency, cerebral folate deficiency, SPOAN (spastic paraplegia, optic atrophy, and neuropathy), ARSACS (autosomal recessive spastic ataxia of Charlevoix-Saguenay), type III 3-methylglutaconic aciduria
      2. HSPs: SPG7
   4. Retinopathy
      1. Cobalamin C disease, Sjögren–Larsson syndrome, homocarnosinosis, abetalipoproteinemia
      2. HSPs: SPG15
   5. Cataract
      1. Cerebrotendinous xanthomatosis, α-methyl-CoA racemase deficiency
      2. HSPs: SPG9
   6. Hearing loss/deafness
      1. Biotinidase deficiency, cerebral folate deficiency
      2. HSPs: SPG29
   7. Neuropathy/amyotrophy
      1. dHMN (distal hereditary motor neuropathy), HMSN (hereditary motor and sensory neuropathy) V,

cerebrotendinous xanthomatosis, cobalamin C disease, MTHFR (5,10-methylenetetrahydrofolate) deficiency, metachromatic leukodystrophy, Krabbe disease, adrenomyeloneuropathy, polyglucosan body disease, α-methyl-CoA racemase deficiency, biotinidase deficiency, abetalipoproteinemia (posterior column), homocysteine remethylation defects, SPOAN, ARSACS, Andermann syndrome
2. HSPs: SPG7, SPG9, SPG10, SPG11, SPG14, SPG17, SPG20, SPG27, SPG38, SPG39

8. Cerebellar ataxia
   1. Atypical Friedreich ataxia, cerebrotendinous xanthomatosis, triple H (hyperornithinemia-hyperammonemia-homocitrullinuria) syndrome, cerebral folate deficiency, metachromatic leukodystrophy, SAX (spastic ataxia) 1, SAX2, ARSACS, ARSAL (autosomal recessive spastic ataxia with leukoencephalopathy), Type III 3-methylglutaconic aciduria, Alexander disease
   2. HSPs: SPG7, SPG15, SPG20, SPG21, SPG27
9. Extrapyramidal signs/diurnal fluctuations
   1. Dopamine synthesis defects and cerebral folate deficiency (dystonia), amyotrophic dystonic paraplegia (dystonia), polyglucosan body disease, phenylketonuria and cerebrotendinous xanthomatosis (parkinsonism), dopa-responsive dystonia (diurnal fluctuations)
   2. HSPs: SPG21, SPG23 (tremor)
10. Epilepsy
    1. Dopamine synthesis defects, α-methyl-CoA racemase deficiency, triple H syndrome, metachromatic leukodystrophy, cerebrotendinous xanthomatosis, arginase deficiency, cerebral folate deficiency, thin corpus callosum + epilepsy, Alexander disease
    2. HSPs: SPG2, SPG35
11. Cutaneous signs
    1. Cerebrotendinous xanthomatosis (xanthomas), biotinidase deficiency (alopecia, dermatitis), Sjögren–Larsson (ichthyosis), adrenoleukodystrophy/adrenomyeloneuropathy (melanoderma)
    2. HSPs: SPG23 (pigmentary abnormalities)
12. Episodes of confusion, nausea/vomiting, or diarrhea
    1. Cobalamin C disease, MTHFR deficiency, triple H, arginase deficiency, cerebrotendinous xanthomatosis (chronic diarrhea), adrenal insufficiency (adrenomyeloneuropathy, adrenoleukodystrophy), abetalipoproteinemia (diarrhea), homocysteine remethylation defects (confusion)
    2. HSPs: SPG9 (gastroesophageal reflux), SPG29 (hiatus hernia, hyperbilirubinemia)

Diagnostic Investigations

1. MRI (Fink 2006)
   1. Important to exclude alternative disorders including multiple sclerosis, leukodystrophies, and structural abnormalities affecting the brain or spinal cord
   2. Uncomplicated HSP: normal in conventional brain MRI
   3. Severe forms of complicated HSP: brain MRI may reveal syndrome-specific abnormalities such as thin corpus callosum in SPG11, cerebral or cerebellar abnormalities in SPG7, and hydrocephalus in SPG1
   4. MRI of the spinal cord: may be entirely normal or show atrophy, particularly involving the thoracic spinal cord
2. Electromyography (EMG)/nerve conduction studies (NCSs) (Fink 2006)

1. Uncomplicated HSP: usually normal
2. Complicated forms of HSP (e.g., SPG10, SPG14, SPG15, and SPG26): associated with peripheral neuropathy and evidence of lower motor neuron involvement

3. Muscle biopsy in some subjects with SPG7 (due to mutations in the mitochondrial metalloprotease paraplegin) shows ragged red fibers and cytochrome oxidase C negative fibers (DeMichele et al. 1998)
4. Neuropathologic studies in uncomplicated HSP (Behan and Maia 1974)
   1. Axonal degeneration of selected motor (corticospinal tracts) and sensory (dorsal column fibers) within the spinal cord, particularly prominent in the distal aspects of these fibers
   2. Anterior horn cells are generally preserved
5. Molecular genetic analysis: uncomplicated, complicated, and full panel gene tests for HSP are clinically available at Invitae, San Francisco, CA (www.invitae.com)

Genetic Counseling

1. Recurrence risk (Fink 2006; Finsterer et al. 2012)
   1. Patient's sib
      1. Autosomal dominant inheritance
         1. Over 90% of the affected individuals have an affected parent, depending on the penetrance, proportion of de novo mutations, and germinal mosaicism
         2. Each child of an affected individual has a 50% chance of inheriting the mutation
      2. Autosomal recessive inheritance: Each sibling of an affected patient has a 25% chance of being affected, a 50% risk of being an asymptomatic carrier, and a 25% chance of being unaffected and not a carrier
      3. X-linked recessive inheritance
         1. Mother is a carrier: 50% of brothers are affected and 50% of sisters are carriers
         2. Mother is not a carrier: low recurrence risk but still exists since the risk of germline mosaicism in mothers is not known
      4. X-linked dominant inheritance
         1. A carrier mother: a 50% risk of transmitting the disease-causing mutation with each pregnancy. Sons who inherit the mutation will be affected. Daughters who inherit the mutation will be carriers and may or may not be affected
         2. A noncarrier mother: recurrence risk to sibs low but not zero since the risk of germline mosaicism in mothers is not known
   2. Patient's offspring
      1. Autosomal dominant inheritance: 50%
      2. Autosomal recessive inheritance: not increased unless the spouse is a carrier
      3. X-linked recessive inheritance
         1. No sons will inherit the mutant allele and therefore will not be affected
         2. All daughters will be carriers
      4. X-linked dominant inheritance
         1. All the daughters of an affected male inherit the mutation but may or may not have symptoms
         2. None of his sons will be affected
   3. Frequency of spontaneous mutations for dominantly inherited HSP: 12%
   4. Genetic penetrance
      1. Uncomplicated HSPs: age-dependent and high penetrance (70–85% for SPG4)
      2. Incomplete penetrance: reported in SPG4, SPG8, and SPG3A
      3. Extent of clinical variability
      4. Genetic anticipation (affected individuals in succeeding generations may be more severely affected and develop symptoms at an earlier age): reported in a minority of SPG3A
2. Prenatal diagnosis for pregnancies at risk is offered by specialized laboratories providing custom prenatal diagnosis to families in which the disease-causing mutation has been identified

3. Management: presently limited to symptomatic reduction of muscle spasticity (Fink 2003)
    1. Exercise/daily physical therapy
        1. Maintain and improve muscle flexibility and range of motion (stretching exercises)
        2. Improve muscle strength (resistance exercise)
        3. Maintain walking reflexes (walking on a slowly moving treadmill with arm supports or walking in a swimming pool)
        4. Improve cardiovascular fitness
        5. Ankle-foot orthotic devices: often useful to reduce toe dragging
    2. Medications
        1. Lioresal (oral or intrathecal)
        2. Tizanidine
        3. Dantrolene
        4. Oxybutynin (helpful in reducing urinary urgency)

Fig. 1 This 8-year-old boy was noted to have unstable gait with frequent falls, and weakness on the upper extremities. On examination, he had ankle clonuses, brisk deep tendon reflexes (DTR), weak grasp, and occasional tip-toe walking. He was receiving special education. Chromosome analysis (46, XY), Fragile X analysis, and brain MRI were normal. The 7-year-old brother had similar but milder symptoms. The father is similarly affected

Fig. 2 This 4-year-old girl was evaluated for spastic legs with onset since 3 month of age. On examination, she was noted to have brisk DTR, ankle clonuses, tight Achilles tendon, and tip toe walking. Her mother had spastic legs with brisk DTR, ankle clonuses, and some loss of sensation in her toes. The maternal grandmother had a history of leg weakness and bladder problems with onset in her 30s

Herlyn-Werner-Wunderlich Syndrome

Contents

Herlyn-Werner-Wunderlich syndrome (HWWS) (Herlyn and Werner 1971; Wunderlich 1976) is a rare Müllerian anomaly consisting of a didelphic uterus, a hemivaginal septum, and an ipsilateral renal agenesis. The diagnosis should be suspected in adolescent females with a pelvic mass and an ipsilateral renal agenesis.

Synonyms and Related Disorders

Blind hemivagina with ipsilateral renal agenesis; Obstructed hemivagina; Septate uterus; Uterus didelphys with obstructed hemivagina and ipsilateral renal agenesis

Genetics/Basic Defects

1. Anatomical defect is caused by a failure of lateral fusion of Müllerian ducts (didelphic/septate uterus and double vagina) combined with a failure of vertical fusion between the Müllerian duct and the urogenital sinus (hemivaginal septum) ipsilateral to the side of the renal agenesis.
2. Various types of uterine anomalies secondary to nondevelopment or failure of fusion of the distal segments of the Müllerian ducts (Troiano and McCarthy 2004).
    1. Hypoplasia/agenesis of the uterus
    2. Unicornuate uterus (approximately 20%)
    3. Didelphic uterus (approximately 5%)
    4. Bicornuate uterus (approximately 10%)
    5. Septate uterus: the most common Müllerian duct anomaly (approximately 55%)
    6. Arcuate uterus
3. Various types of vaginal anomalies secondary to the different embryological origins of the upper two-thirds of the vagina (originates from the Müllerian ducts of mesodermal origin) and the lower third of the vagina (originates from the urogenital sinus of endodermal origin): the anomaly may exist alone or in association with Müllerian anomalies.
    1. Hypoplasia/aplasia
    2. Duplication
    3. Septa
4. Close interrelationship between the urinary and reproductive systems during embryogenesis may explain the coexistence of urinary and reproductive tract abnormalities.
5. Specific association of a didelphic uterus, an obstructed hemivagina, and an ipsilateral renal

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_118

agenesis is a rare malformation concomitantly involving both Müllerian and Wolffian ducts.
6. Mode of inheritance: unclear but Wiersma et al. (1976) had reported mother and daughter with uterus bicornis bicollis with partial vaginal septum and unilateral hematocolpos with ipsilateral renal agenesis, suggesting a possible sex-limited autosomal dominant inheritance.

Clinical Features

1. Presenting symptoms (Vercellini et al. 2007; Rana et al. 2008; Bhoil et al. 2016): the median age of presentation is 13 years. The condition is usually discovered at puberty shortly after menarche. The diagnosis is generally made only if the suspicion of the existence of this syndrome is raised.
    1. Abdominal pelvic mass due to hemihematocolpos resulting from retained long-standing, partially clotted menstrual blood in the obstructed hemivagina.
    2. Recurrent and progressive pelvic pain.
    3. Dysmenorrhea (painful menstruation).
    4. Foul-smelling discharge.
    5. Menstrual bleeding.
    6. Menstrual irregularity.
    7. Intra-abdominal abscess.
    8. Fever and vomiting can be the presenting symptoms.
    9. If not treated, complications leading to infertility, endometriosis, pelvic adhesions, and pyosalpinx or pyocolpos may present in the late phase with a high miscarriage rate.
2. A didelphic uterus (Heinonen 1982, 2000; Zurawin et al. 2004; Vercellini et al. 2007)
    1. Characterized by two uterine bodies and two cervices
    2. The presence of a longitudinal vaginal septum in the majority of cases
3. Consequences of blood stasis and retrograde menstruation in the obstructed system
    1. Hematocolpos (a dilated hemivagina)
    2. Hematometra (a dilated uterine cavity)
    3. Hematosalpinx (bleeding/dilated fallopian tube)
4. Other vaginal anomalies
    1. Imperforate hymen variants
    2. Vaginal atresia
    3. Duplicated vagina
    4. Fused labia
5. Ipsilateral renal agenesis (Rock and Jones 1980)
6. Occasional gastrointestinal tract malformations
    1. Esophageal atresia
    2. Imperforate anus
7. Natural history if untreated
    1. Endometriosis
    2. Pelvic adhesions
    3. Pyosalpinx
    4. Pyocolpos
8. Unusual dichotomy in reproductive function
    1. Fertility not compromised with high spontaneous abortion rate (40%)
    2. No obstetric difficulties when a pregnancy is carried to term (Rana et al. 2008)

Diagnostic Investigations

1. Abdominal examination finding of a suprapubic mass with tenderness to palpation.
2. Pelvic and/or rectal examination findings of a paravaginal cystic mass.
3. Abdominal and pelvic imagings (Gholoum et al. 2006; Madureira et al. 2006; Orazi et al. 2007):
    1. Ultrasonography allows the correct diagnosis by showing uterovaginal duplication, hematocolpos, pyocolpos, or hematometrocolpos and the absence of the ipsilateral kidney.
    2. CT scan: limited due to radiation exposure and limited soft-tissue resolution.
    3. Magnetic resonance imaging provides more detailed information regarding uterine morphology, the continuity with each vaginal channel (obstructed and nonobstructed), and the bloody nature of the contents.
4. Laparoscopy:
    1. The gold standard for diagnosis
    2. Has the added benefit of performing therapeutic drainage of hematometra/

hematocolpos, vaginal septotomy, and marsupialization (Gholoum et al. 2006)

5. Unilateral renal agenesis can be diagnosed prenatally. Female fetuses or neonates with renal malformations or multidysplastic kidneys need to be screened for genital malformations and to look for an obstructed Müllerian system. The uterine anomaly can be better detected in the neonatal period because the uterus is still under maternal hormonal stimulation and is characterized by a prominent myometrium and an echogenic endometrium. It is advisable that follow-up ultrasonographic examination of these asymptomatic patients be performed until the end of puberty.

Genetic Counseling

1. Recurrence risk: possible sex-limited autosomal dominant inheritance
    1. Patient's sib: recurrence risk not increased in female sibs unless the mother is affected
    2. Patient's offspring: a 50% risk for female offspring
2. Prenatal diagnosis: Uterus didelphys with blind hemivagina and ipsilateral renal agenesis (Herlyn-Werner-Wunderlich syndrome) suspected on the presence of hydrocolpos on prenatal sonography (Han et al. 2013).
3. Management
    1. Operative management:
        1. Vaginal septectomy with marsupialization and drainage of hematocolpos/hematometrocolpos to provide relief of pain and prevent further complications: a preferred surgical approach with a good long-term outcome.
        2. Salpingectomy for pyosalpinx if needed.
        3. One-fifth of patients with HWWS were susceptible to pelvic endometriosis, and all of the ovarian endometriotic cysts were ipsilateral to the vaginal septum. Pelvic endometriosis in adolescents appeared to be related to obstructed genital abnormality.
        4. Vaginal septum resection should be the first step in treatment and surgery has an important role in the treatment of endometriosis and pelvic adhesion (Tong et al. 2014).
    2. Errors in the surgical management can occur when the diagnosis is not suspected, and laparotomy to explore and resect the intra-abdominal mass is performed.
    3. Hemihysterectomy with or without salpingo-oophorectomy is rarely indicated and should be avoided to provide the best chance for a successful reproductive outcome.
    4. Postoperative considerations:
        1. To achieve the goal of normal sexual relations and successful reproductive outcomes
        2. Vaginal adenosis in the previously obstructed vagina

Fig. 1 A 13-year-old female was evaluated for vaginal bleeding and lower abdominal pain. Abdominal ultrasonography showed a very unusual appearance of the uterus with two horns which converge to form one lower uterine segment which then go into a prominent cervix where there was a large amount of fluid (blood) within the cervix and vagina

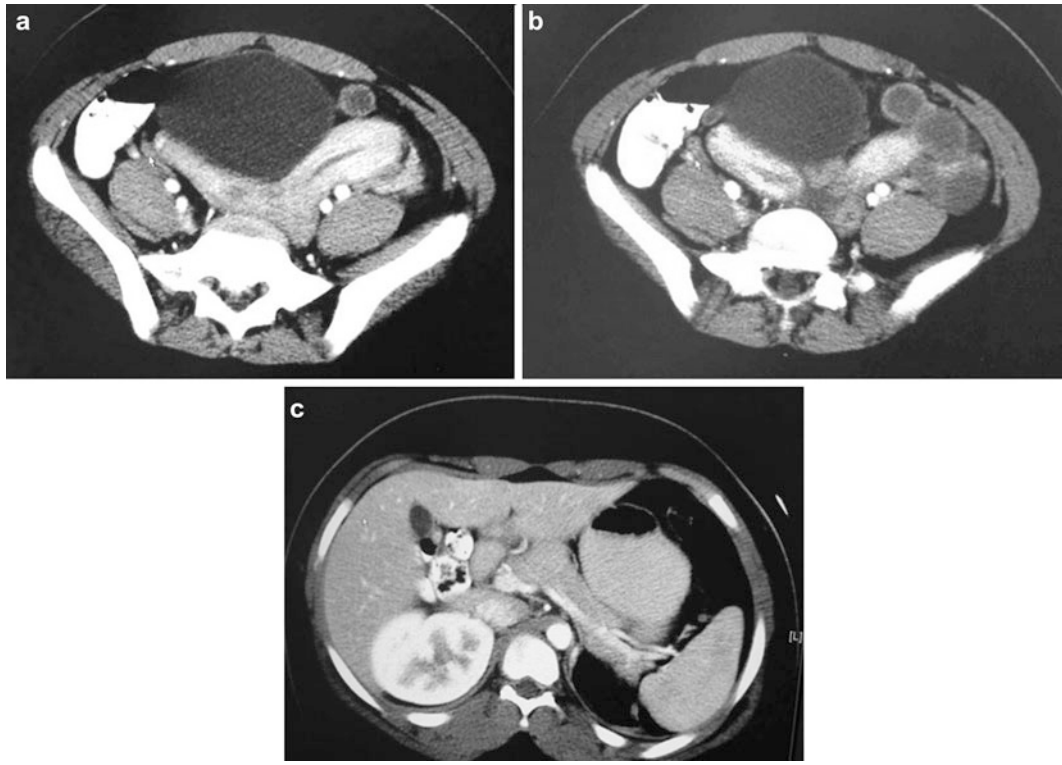

Fig. 2 (**a**–**c**) CT scan of the abdomen and pelvis showed congenital uterine anomaly likely a didelphic uterus, the absence of left kidney, and the presence of hypertrophic right kidney

Holoprosencephaly

Contents

Holoprosencephaly (HPE) is a heterogeneous entity of CNS anomalies caused by the impaired midline cleavage of the embryonic forebrain. The incidence is estimated to be 1 in 16,000 live births and observed in 1 of 250 spontaneous abortions (Roessler and Muenke 2001).

Synonyms and Related Disorders

Arhinencephaly; Cebocephaly; Ethmocephaly; Holoprosencephaly (alobar, lobar, semilobar); Holoprosencephaly facies syndrome; Premaxillary agenesis

Genetics/Basic Defects

1. Isolated and sporadic in most cases.
2. Genetically heterogeneous (Nanni et al. 2000), involving at least 12 loci on 11 chromosomes (Wallis and Muenke 2000). There are at least five putative loci for HPE:
    1. *HPE1*.
        1. Map locus: 21q22.3
        2. Familial alobar holoprosencephaly
    2. *HPE2* (*SIX3*).
        1. Map locus: 2p21 (Muenke et al. 1989)
        2. Chromosome 2 form of holoprosencephaly, including midline cleft syndrome and DeMyer sequence
        3. Caused by mutations in the homeobox-containing *SIX3* gene (Wallis et al. 1999)
    3. *HPE3* on 7q36-qter (Gurrieri et al. 1993), characterized as the locus containing the human *sonic hedgehog* gene (*SHH*).
        1. Either loss-of-function mutation or disruption of one of the *sonic hedgehog* alleles at 7q36 (haploinsufficiency) shown to cause variable phenotype of holoprosencephaly.
        2. A broad spectrum of holoprosencephaly present in patients with de novo 7q36 deletions (Frints et al. 1998) or with autosomal dominant holoprosencephaly having a linkage on 7q36.
        3. 7q deletion syndrome without typical holoprosencephaly in some patients.
        4. Interaction of partial trisomy 3p and partial monosomy 7q: invariably associated with severe forms of holoprosencephaly

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_119

and facial dysmorphism. This delineates an autosomal imbalance syndrome or a dosage effect involving distal 3p duplication/terminal 7q deletion and dysmorphogenesis of the forebrain and midface.

4. *HPE*4 (TG-interacting factor, *TGIF*) on 18p11.3. Mutations of *TGIF* have been associated with holoprosencephaly and premaxillary agenesis.
5. *HPE5* (*ZIC2*) on 13q32 (Brown et al. 1998).

3. SHH signaling pathway or the Nodal/TGF pathway (Roessler et al. 1996; Cohen 2006; Bertolacini et al. 2010):
   1. *SHH* is the major gene implicated in holoprosencephaly (12.7 % of HPE cases: 50% of overall point mutations and 38% of overall large deletions) (Dubourg et al. 2004).
   2. *ZIC2* is the second HPE gene by order of involvement (9.2 % of HPE cases: 31% of overall point mutations and 38% of overall large deletions).
   3. Point mutations and large deletions in *SIX3* represent 3% and 1% of HPE cases, respectively. They are generally found in severe phenotypes (Pasquier et al. 2005).
   4. Mutations in *TGIF* account for 1% of studied cases and large deletions for nearly 1% (Gripp et al. 1998, 2000).
4. *GLI2* mutations (Rahimov et al. 2006): nucleotide change and diverse phenotype:
   1. 451A → G (Arg151Gly): holoprosencephaly-like phenotype
   2. 3,677C → T (Pro1226Leu): lobar HPE
   3. 1,809C → T (Pro604Ser)
      1. Anophthalmos
      2. Branchial arch anomalies
      3. CNS anomalies
   4. 3,348G → A (Met1116Ile)
      1. Heminasal aplasia
      2. Orbital anomalies
5. *FAST1* (forkhead activin signal transducer 1) mutations: *FAST1* is the first human gene with mutations causing both midline defects (holoprosencephaly) and lateral defects (anomalies of cardiac looping) (Ouspenskaia et al. 2002).
6. Other known HPE-associated genes:
   1. *PTCH*.
      1. Patched mutations in humans result in haploinsufficiency.
      2. A few of such mutations cause holoprosencephaly.
      3. Common in nevoid basal cell carcinoma syndrome and in isolated basal cell carcinomas.
   2. *DHCR7*.
      1. Mutations resulting in reduced serum cholesterol and accumulation of 7-dehydrocholesterol in autosomal recessive Smith-Lemli-Opitz syndrome.
      2. Four percent of cases with Smith-Lemli-Opitz syndrome have holoprosencephaly.
   3. *DISP1*: Loss-of-function mutations may be associated with normal brain structure and development but facial features usually seen in conjunction with frank HPE (Roessler et al. 2009).
   4. *NODAL*: Mutations may result in HPE but are more commonly associated with cardiac and laterality defects (Roessler et al. 2009).
   5. *FOXH1* (part of the NODAL signaling pathway): Mutations may result in HPE or cardiac defects (Roessler et al. 2008).
   6. *FGF*8: A loss-of-function mutation has been described in three members of one family with a range of classic HPE-spectrum features (Araúz et al. 2010).
   7. *TDGF1*: *TDGF1* encodes a membrane-associated protein that serves as a coreceptor for Nodal signaling (de la Cruz et al. 2002).
   8. *NOG*: Mutations in the coding region of *NOG* are rare and play at most an uncommon role in human HPE (Srivastava et al. 2012).
   9. *STIL*: Homozygous mutation causes holoprosencephaly and microcephaly in two siblings (Mouden et al. 2015).
   10. *GAS1: GAS1* is a positive regulator of SHH; mutations may result in the full

spectrum of HPE. The functional effects of all reported variants have not been confirmed (Ribeiro et al. 2010; Pineda-Alvarez et al. 2012).

11. *DLL1*: Deletions (and a single variant) implicate the NOTCH signaling pathway in the pathogenesis of HPE (Dupé et al. 2011).
12. *CDON*: *CDON* is a SHH coreceptor; mutations may result in a small proportion of HPE (Bae et al. 2011).

7. Subtypes of holoprosencephaly and the range of possible craniofacial features (Blaas et al. 2002; Hahn and Plawner 2004):
    1. Alobar holoprosencephaly: The most severe form characterized by complete or nearly complete lack of separation of the cerebral hemispheres with a single midline forebrain ventricle (monoventricle), which often communicates with a dorsal cyst. The interhemispheric fissure and corpus callosum are completely absent.
        1. Cyclopia (a single eye or a partially divided eye in a single orbit with or without proboscis above the eye)
        2. Ethmocephaly (extreme ocular hypotelorism with proboscis located between the eyes)
        3. Cebocephaly (ocular hypotelorism with a single-nostril nose)
        4. Premaxillary agenesis (ocular hypotelorism with median cleft lip and palate)
        5. Bilateral cleft lip
        6. Ocular hypotelorism only
        7. Anophthalmia or microphthalmia
        8. Relatively normal facial appearance
    2. Semilobar holoprosencephaly: There is a failure of separation of the anterior hemispheres, whereas some portion of the posterior hemispheres manifests separation. The frontal horns of the lateral ventricle are absent, but posterior horns are present. The corpus callosum is absent anteriorly, but the splenium of the corpus callosum is present.
        1. Bilateral cleft lip with median process representing the philtrum-premaxilla anlage
        2. Flat nasal bridge
        3. Absent nasal septum
        4. Flat nasal tip
        5. Midline cleft lip and/or palate
        6. Ocular hypotelorism
        7. Flat nose
        8. Anophthalmia/microphthalmia
        9. Relatively normal facial appearance
    3. Lobar holoprosencephaly: The mildest form, the cerebral hemispheres are fairly well separated, whereas only the most rostral/ventral aspects are nonseparated. The splenium and body of the corpus callosum are present, although the genu may be poorly developed. Rudimentary formation of the frontal horns may be present.
        1. Bilateral cleft lip with median process
        2. Ocular hypotelorism
        3. Flat nose
        4. Relatively normal facial appearance
    4. Middle interhemispheric variant or syntelencephaly: In contrast to classic HPE, there is failure of separation of the posterior frontal and parietal lobes, whereas the poles of the frontal and occipital lobes are well separated (Barkovich and Quint 1993; Simon et al. 2002).
    5. Septopreoptic type: Nonseparation is restricted to the septal and/or preoptic regions and was described in small case series (Hahn et al. 2010).
8. Causes: (Cohen 1982, 1989a, b; Vance et al. 1998; Muenke et al. 2000; Bendavid et al. 2010; Solomon et al. 2013)
    1. Detectable chromosome abnormalities (24–45 %):
        1. Numerical chromosomal abnormalities:
            1. Trisomy 13 (most common)
            2. Trisomy 18
            3. Triploidy
            4. Mosaic trisomy 9
        2. Structural chromosomal abnormalities: reported in virtually all chromosomes. The most frequent ones are as follows:
            1. Involving 13q [del(13q), r(13), dup (13q)]
            2. Del(18p)
            3. Del(7)(q36) (20%)
            4. Dup(3)(p24-pter) (10%)

5. Del(2)(p21)
6. Del(21)(q22.3)
7. Del(22q11)
8. i(18q) (Bangma et al. 2011)
9. Partial monosomy 14q

2. Monogenic holoprosencephaly (18–25 %):
   1. Autosomal dominant
      1. Pallister-Hall syndrome
      2. Rubinstein-Taybi syndrome
      3. Kallmann syndrome
      4. Martin syndrome (with club foot and spinal anomalies)
      5. Steinfeld syndrome (with congenital heart disease, absent gallbladder, renal dysplasia, and radial defects)
      6. Ectrodactyly and hypertelorism
   2. Autosomal recessive
      1. Meckel-Gruber syndrome
      2. Smith-Lemli-Opitz syndrome
      3. Pseudotrisomy 13 syndrome
      4. XK aprosencephaly syndrome
      5. Heterotaxy and holoprosencephaly
      6. Genoa syndrome (with craniosynostosis)
      7. Lambotte syndrome (with microcephaly, prenatal growth retardation, and hypertelorism)
      8. Hydrolethalus syndrome (with hydrocephalus, polydactyly, and other anomalies)
      9. Facial clefts and brachial amelia
   3. X-linked recessive (holoprosencephaly with fetal hypokinesia/akinesia)
3. Agnathia-otocephaly (10%)
4. Frontonasal dysplasia (6.7 %)
5. Sirenomelia association
6. Holoprosencephaly, ectopia cordis, and embryonal neoplasms

9. Nongenetic risk factors (Muenke and Beachy 2000; Cohen and Shiotas 2002; Johnson and Rasmussen 2010):
   1. Maternal diabetes
      1. One to 2% of newborn infants of diabetic mothers develop holoprosen-cephaly.
      2. The most commonly studied with the strongest association of the risk factor.
   2. Salicylates use, respiratory and sexually transmitted infections, and use of assisted reproductive technologies: identified in epidemiologic studies as possibly associated with increased risk of HPE
   3. Quality of diet and use of multivitamin supplements: associated with a decreased risk
   4. Retinoic acid
      1. CNS anomalies, particularly hydrocephalus
      2. Holoprosencephaly
   5. Ethyl alcohol
      1. Holoprosencephaly/arhinencephaly
      2. Agnathic cyclopia
      3. Midline cerebral dysgenesis with hypothalamic-pituitary dysfunction
      4. Hydrocephalus
      5. Agenesis of the corpus callosum and anterior commissure
   6. Estrogen/progestin
   7. Anticonvulsants
   8. Low-calorie weight reduction diets
   9. Prenatal infections
      1. Cytomegalovirus
      2. Rubella
      3. Toxoplasma
   10. Poverty
   11. Previous pregnancy loss

Clinical Features

1. Variable expression, ranging from a small brain with a single cerebral ventricle and cyclopia to clinically unaffected carriers in familial holoprosencephaly.
2. Face (DeMyer et al. 1964; Cohen and Sulik 1992; Blaas et al. 2002): Holoprosencephaly is often associated with distinct facial appearance (holoprosencephaly facies syndrome). The face predicts the brain approximately 80% of the time. In decreasing order of severity:
   1. Absence of eye(s) (the most severe form)
   2. Cyclopia
      1. The most severe dysmorphism
      2. A median monophthalmia (a single midline eye)

3. Synophthalmia (fusion of two eyes in a single midline orbit)
4. Anophthalmia
5. Presence of a single median orbit (sine qua non for the diagnosis)
6. Without or with proboscis (single or double protruding from the glabella, just above the median eye)
7. Complete arhinia with no nose, no nasal bones
8. Degree of facial dysmorphism strongly correlated with the severity of brain malformation (facial and the oculo-orbital phenotype reflects the underlying central nervous system pathology)

3. Ethmocephaly
   1. Rarest type
   2. Close-set eyes (ocular hypotelorism) located in two separate orbits
   3. A median proboscis between the two eyes as a rudimentary tubelike nose
   4. Hypoplastic or absent median facial bones
4. Cebocephaly
   1. Close-set eyes (ocular hypotelorism) into separate orbits
   2. A nose with a single nostril
   3. No cleft lip
5. Premaxillary agenesis
   1. Close-set eyes (ocular hypotelorism)
   2. Median cleft lip and palate

3. Eyes.
   1. Anophthalmia
   2. Microphthalmia
   3. Cyclopia
   4. Fused eyes
   5. Coloboma
   6. Hypotelorism
   7. Bulging eyes
   8. Other eye malformations
      1. Fused lids
      2. Optic disk hypoplasia
      3. Cataract
4. Nose.
   1. Proboscis
   2. Arhinia with or without proboscis
   3. Flat nose
      1. With proboscis
      2. Absent or nonpatent nares
      3. Other malformations
5. Mouth.
   1. Median cleft lip
   2. Bilateral cleft lip
   3. Unilateral cleft lip
   4. Cleft palate alone
   5. Cleft lip with cleft palate
   6. Cleft lip alone
   7. Cleft uvula
   8. Microstomia
   9. Macrostomia
   10. Agnathia
   11. Micrognathia
6. Ear.
   1. Fused ears
   2. Other ear malformations
7. Neurodevelopmental deficits.
   1. Hoarse or "barking" voice and high-pitched crying
   2. Major feeding problems with choking spells
   3. Common growth delay
   4. Seizures
   5. Spasticity or floppy muscle tone
   6. Brainstem dysfunction with irregular breathing and heart rate and erratic body temperature control
   7. Profound developmental delay with very limited expressive language and minimal attainment of motor skills
   8. Behavioral problems
8. Endocrine disorders.
   1. Occasional diabetes insipidus with episodes of dehydration
   2. Rare panhypopituitarism
9. Presence of microforms of holoprosencephaly in relatives of patients with holoprosencephaly.
   1. Microcephaly
   2. Single central maxillary incisor (Berry et al. 1984)
   3. Ocular hypotelorism
   4. Anosmia/hyposmia secondary to absent olfactory tracts and bulbs
   5. Iris coloboma
   6. Absent superior labial frenulum
   7. Midface hypoplasia
   8. Congenital nasal pyriform aperture stenosis
   9. Developmental delay

10. Holoprosencephaly-agnathia spectrum (Kauvar et al. 2010).
    1. Holoprosencephaly, the most common developmental disorder of the human forebrain, is occasionally associated with the spectrum of agnathia or virtual absence of the mandible.
    2. This condition results in a constellation of structural cerebral and craniofacial abnormalities.
    3. The majority of these patients are female and have the most severe forms of HPE, with cyclopia present more frequently than is usually observed in cohorts of patients with HPE. Also, many patients have additional clinical findings not typical in patients with classic HPE, particularly situs abnormalities.
11. Prognosis.
    1. Infants born with cyclopia, ethmocephaly, and cebocephaly: virtually, all die within a week of birth.
    2. Infants born with premaxillary agenesis, unilateral or bilateral cleft lip, or more normal facies.
        1. Half of the patients die before 4–5 months.
        2. Twenty to 30% of the patients live to 1 year of age. Longer survival is possible to at least 11 years.
    3. Cases diagnosed in utero will have an extremely poor neurologic development after birth.
    4. Causes of death (Barr and Cohen 1999) most often due to brainstem malfunction (unable to control the respiration and heart rate) aggravated by infections and other stresses.

Diagnostic Investigations

1. Laboratory (Hahn and Plawner 2004).
    1. Electrolytes and osmolarity
    2. Cortisol, ACTH, TSH, free T4, IGF1
2. Radiographs for bony and spine abnormalities.
3. Neuroimaging assessment of holoprosencephaly (MRI/CT of the brain) (Hahn and Plawner 2004).
    1. Deep gray nuclei abnormalities (nonseparation)
        1. Thalamic nuclei (degree of nonseparation and orientation)
        2. Caudate nuclei
        3. Lentiform nuclei
        4. Hypothalamus
        5. Pituitary (normal or abnormal based on location, morphology, and signal intensity)
        6. Mesencephalon
    2. Ventricular system
        1. Presence of a monoventricle
        2. Presence of dorsal cyst
        3. Aqueductal abnormalities
        4. Hydrocephalus
    3. Cerebral cortex
        1. Gyral and sulcal abnormalities (thickness and numbers)
        2. Subcortical heterotopias
        3. Sylvian fissure abnormalities
        4. White matter maturation Delayed or appropriate
    4. White matter maturation
    5. Other malformations
        1. Dandy-Walker malformation
        2. Encephalocele
        3. Myelomeningocele
4. Electrophysiology for seizures.
5. Cytogenetic analysis (Berry et al. 1990; Bendavid et al. 2009, 2010).
    1. An essential diagnostic tool.
    2. Initially, karyotype approach led to the identification of several recurrent chromosomal anomalies predicting different HPE loci.
6. Molecular genetic diagnoses.
    1. Subsequently, several genes were isolated from these critical HPE regions, but point mutations and deletions in these genes were found only in 25% of the genetic cases.
    2. In order to identify other HPE genes, a more accurate investigation of the genome in HPE patients was necessary: If HPE is isolated and nonsyndromic, including sporadic

cases, the study of the four major genes involved in the disease should be undertaken.

3. To date, high-resolution cytogenetic techniques such as subtelomeric multiplex ligation-dependent probe amplification (MLPA) and microarray-based comparative genomic hybridization (array CGH) have enhanced chromosomal aberration analysis.
    1. A systematic search for gains or losses in the subtelomeres by MLPA
        1. Leads to identification of 4% more anomalies.
        2. Rearrangements, deletions, or duplications must be verified by FISH on the karyotype of the proband and parents, so the identification of a cryptic-balanced translocation in a parent can change the approach to genetic counseling.
    2. Array-CGH analysis
        1. A part of the molecular diagnosis algorithm to help clinicians get more disease markers for difficult HPE genetic counseling (Pineda-Alvarez et al. 2010)
        2. Indicates a high prevalence of genomic rearrangements in HPE (Bendavid et al. 2009)
        3. Detects a high frequency of submicroscopic anomalies with a yield of 25%, especially in severe forms and in fetuses
        4. Helpful in identification of unbalanced anomalies, as MLPA for subtelomeres, and leading secondarily to identification of parental cryptic-balanced translocations by FISH (Bendavid et al. 2009)
        5. Would allow identification of new HPE loci

7. Necropsy and anatomical classification (Demyer and Zeman 1963; Delezoide et al. 1990; Dubourg et al. 2007): Holoprosencephaly is generally classified into three major types and one milder subtype. The distinction among the following three types is not always clear.
    1. Alobar holoprosencephaly
        1. The most severe form
        2. Complete failure of brain tissue to develop into the normal right and left cerebral hemispheres
        3. The brain consisting of a single fused cerebral hemisphere located in the frontal region
        4. Total absence of interhemispheric fissure and falx cerebri
        5. The brain surface is smooth with sparse convolutional markings
        6. A single dilated ventricle communicating with a large dorsal cyst
        7. Absence of the third ventricle, neurohypophysis, and olfactory bulbs and tracts
        8. Absence of corpus callosum
        9. Fused thalami and basal ganglia
        10. Migrational anomalies often present
    2. Semilobar holoprosencephaly
        1. The less severe form.
        2. Rudimentary cerebral lobes. Only partial separation into two cerebral hemispheres; the hemispheres are not separated across the midline in the front part of the brain.
        3. A single ventricle.
        4. Olfactory bulbs and corpus callosum are usually absent.
        5. Partial presence of the septum pellucidum and corpus callosum pending on the severity.
    3. Lobar holoprosencephaly
        1. The least severe form
        2. Well-formed cerebral lobes that may be of normal size
        3. Virtual complete separation of the cerebral hemispheres
        4. Various degree of rostral and basilar nonseparation
        5. Absent, hypoplastic, or normal olfactory bulbs and tracts and corpus callosum
        6. Gray matter heterotopias and other associated migrational anomalies
    4. Middle interhemispheric variant or syntelencephaly
        1. Failure of separation of the posterior frontal and parietal lobes

2. Callosal genu and splenium normally formed
3. Absence of corpus callosum
4. Hypothalamus and lentiform nuclei normally separated
5. Heterotopic gray matter

Genetic Counseling

1. Based on a rigorous clinical evaluation exploring family history, environmental factors, and associated features (Mercier et al. 2010)
2. Recurrence risk: depending on the basis for the actual condition (Blaas et al. 2002)
    1. Patient's sib
        1. Empirical estimate of 20% for holoprosencephaly, 15% for a microform, and 15% for normal phenotype.
        2. Increased recurrence risk depending on the type of Mendelian inheritance (autosomal recessive and dominant conditions with holoprosencephaly). Existence of incomplete penetrance or an incomplete form or microform of holoprosencephaly makes the interpretation of familial occurrence difficult.
        3. Fifty percent recurrence risk of having affected siblings with variable clinical symptoms and severity if a parent is affected with holoprosencephaly.
        4. Germline mosaicism in which apparently unaffected parents with negative family history having more than one affected child.
        5. Sibs of a child with a numeric chromosome abnormality have a slightly increased risk of having a similar chromosome abnormality (depending on the specific abnormality and the age of the mother) with a similar or different phenotype.
        6. Increased in a case where a parent carries a chromosome translocation or other chromosome rearrangement.
    2. Patient's offspring
        1. Severe cases of prosencephaly: not surviving to reproductive age
        2. Individuals with mild form or microform holoprosencephaly (with a gene mutation for the autosomal dominant nonsyndromic holoprosencephaly): 50% recurrence risk of having an affected child
3. Prenatal diagnosis
    1. Prenatal ultrasonography (Nyberg et al. 1987; Lai et al. 2000) can detect CNS and facial abnormalities of severe HPE as early as the first trimester, but is less sensitive for the detection of milder forms of HPE, such as lobar HPE.
        1. General characteristics
            1. Polyhydramnios
            2. Ocular hypotelorism
            3. Cleft lip/palate
            4. Arhinia
            5. Cyclopia and proboscis: identifiable at the beginning of the ninth week of gestation by 2-D and 3-D ultrasonography
            6. Absence of central falx
            7. Demonstration of a single rudimentary cerebral ventricle
        2. Alobar holoprosencephaly
            1. Single ventricle
            2. Presence or absence of dorsal sac
            3. Fused thalami
            4. Absence of cavum septum pellucidum
        3. Semilobar holoprosencephaly
            1. Single ventricle with rudimentary occipital horns
            2. Presence or absence of dorsal sac
            3. Fused thalami
            4. Absence of cavum septum pellucidum
        4. Lobar holoprosencephaly (Pilu et al. 1992)
            1. Almost divided ventricles except at frontal horns of lateral ventricles
            2. Some enlargement of lateral ventricle

3. Flat roof of frontal horns in microtonal view
4. Wide communication between the frontal horns and the inferior third ventricles
5. Absence of dorsal sac
6. Divided thalami
7. Absence of cavum septum pellucidum

2. In utero helical CT 3D imaging: diagnosed agnathia-holoprosencephaly at 23 weeks of gestation (Ebina et al. 2001)
3. Fetal MRI provides better characterization of brain malformations, but only later in the third trimester of pregnancy (Hahn and Barnes 2010; Mercier et al. 2010).
4. Cytogenetic analysis from CVS or amniocytes (Chen et al. 1992, 1996, 1999, 2001).
   1. Parent with a balanced chromosomal rearrangement
   2. Fetus with multiple anomalies including holoprosencephaly from prenatal ultrasonography
5. Prenatal diagnosis by molecular analysis on fetal DNA obtained from amniocentesis or CVS for the disease-causing mutation previously identified in the proband.
   1. Sequence analysis or deletion/duplication analysis
      1. *SIX3*-related holoprosencephaly
      2. *SHH*-related holoprosencephaly
      3. *TGIF*-related holoprosencephaly (Chen et al. 2002)
      4. *ZIC2*-related holoprosencephaly
      5. *GLI2*-related holoprosencephaly
      6. *PTCH1*-related holoprosencephaly
      7. *TRAPPC10*-related holoprosencephaly
      8. *ZIC2*-related holoprosencephaly
   2. Pallister-Hall syndrome: mutation analysis for mutation panel GLI3 (2023delG and 2012delG)
   3. Rubinstein-Taybi syndrome: FISH analysis of the deletion of the *CREBBP* gene on chromosome 16 (16p13.3)
   4. Smith-Lemli-Opitz syndrome
      1. Detection of two disease-causing mutations in the *DHCR7* gene previously identified in the proband
      2. Abnormal concentration of 7-dehydrocholesterol levels
6. Preimplantation genetic diagnosis.
   1. May be available for families in which the disease-causing mutation has been identified
   2. Reported for sonic hedgehog mutation causing familial holoprosencephaly (Verlinsky et al. 2003)

4. Management
   1. Care for common medical problems (Levy et al. 2010).
      1. Hydrocephalus.
      2. Seizures.
      3. Motor impairment.
      4. Oromotor dysfunction with risk of poor nutrition and aspiration.
      5. Chronic lung disease.
      6. Gastroesophageal reflux.
      7. Constipation.
      8. Hypothalamic dysfunction with disturbed sleep-wake cycles and temperature dysregulation.
      9. Endocrine dysfunction: Diabetes insipidus in particular is found in about 70% of children with classic HPE.
   2. Treatment strategies based on the types of brain malformations and associated anomalies
      1. Lethal entity: no specific treatment available
      2. Nonlethal entity
         1. Ventriculoperitoneal shunt for hydrocephalus
         2. Cleft lip and palate repair if indicated
         3. Monitoring of fluid and electrolyte intake in patients with diabetes insipidus
         4. Hormone replacement therapy for pituitary dysfunction
   3. Supportive
      1. Multidisciplinary team approach
      2. Support and counseling of the parents
      3. Seizure management

4. Gastrostomy tube placement and fundoplication for gastroesophageal reflux and vomiting

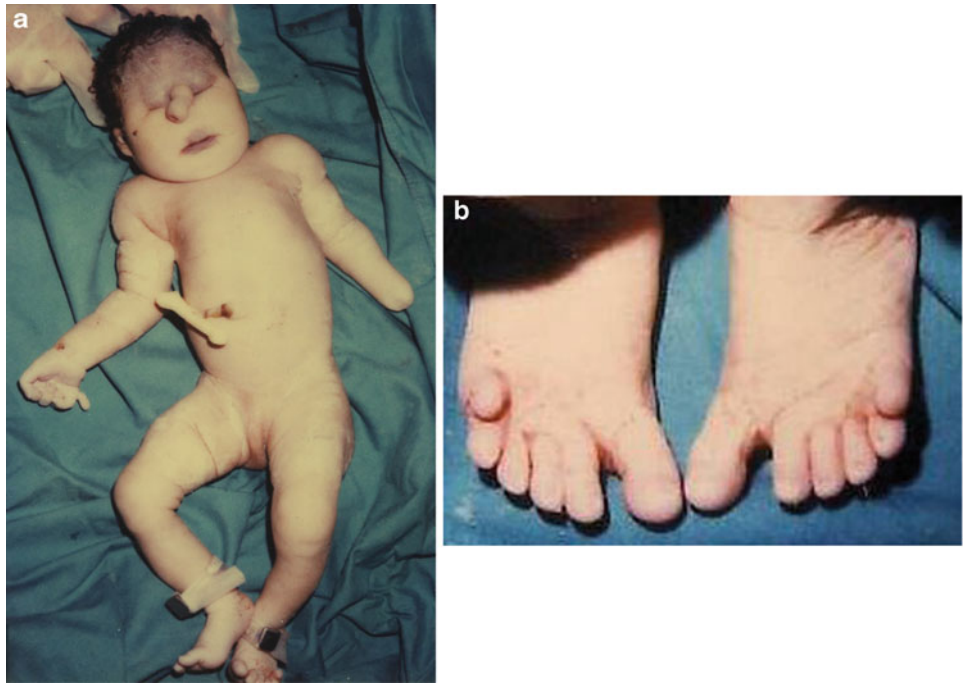

Fig. 1 (**a**, **b**) A neonate with trisomy 13 showing ethmocephaly, transverse reduction of the left forearm, and polydactyly of the right hand and both feet

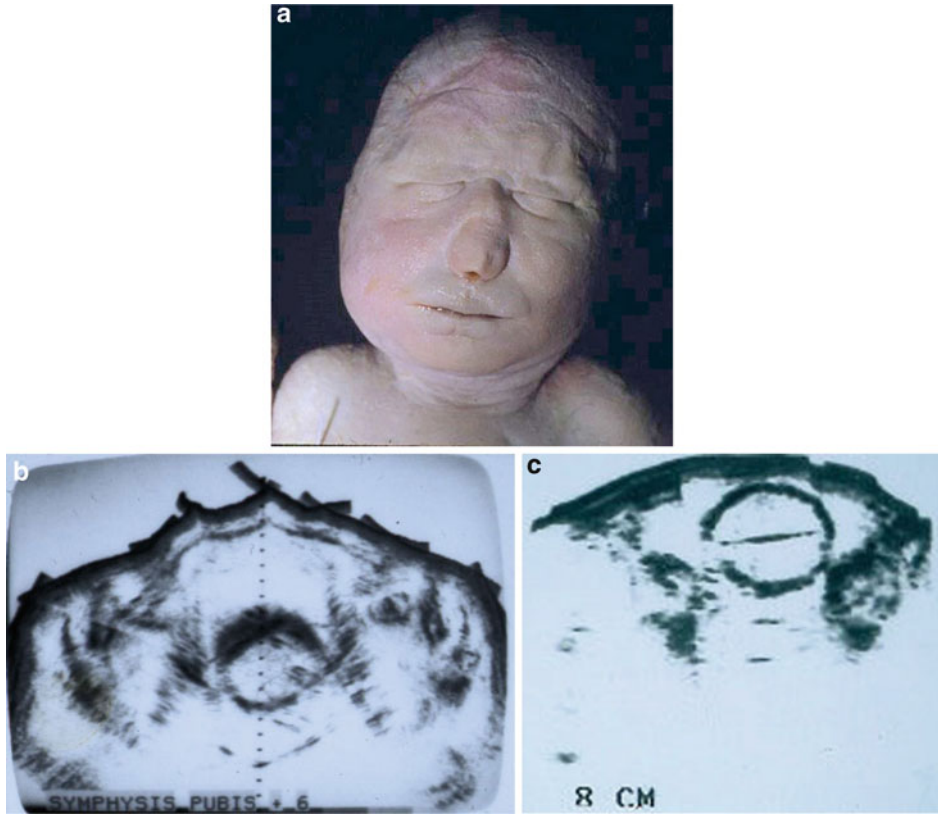

Fig. 2 (**a**–**c**) A neonate with trisomy 18 showing cebocephaly. The prenatal ultrasound showed fetal scalp edema, microcephaly, and holoprosencephaly (a normal brain ultrasound at the same gestation is illustrated here)

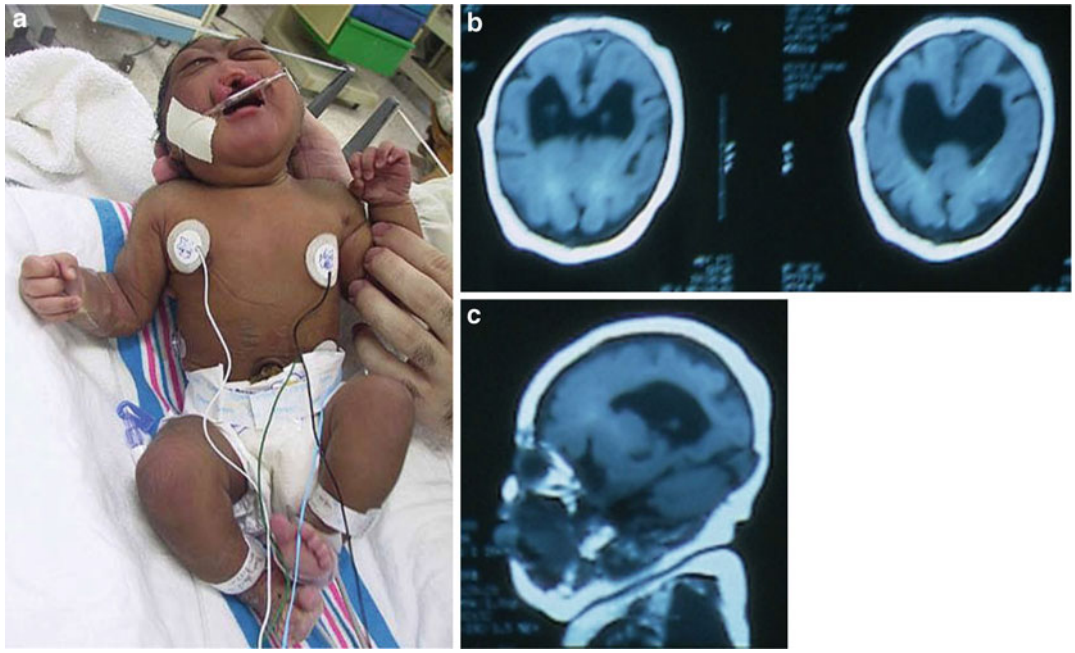

Fig. 3 (**a**–**c**) A neonate with semilobar holoprosencephaly illustrated by MRI of the brain

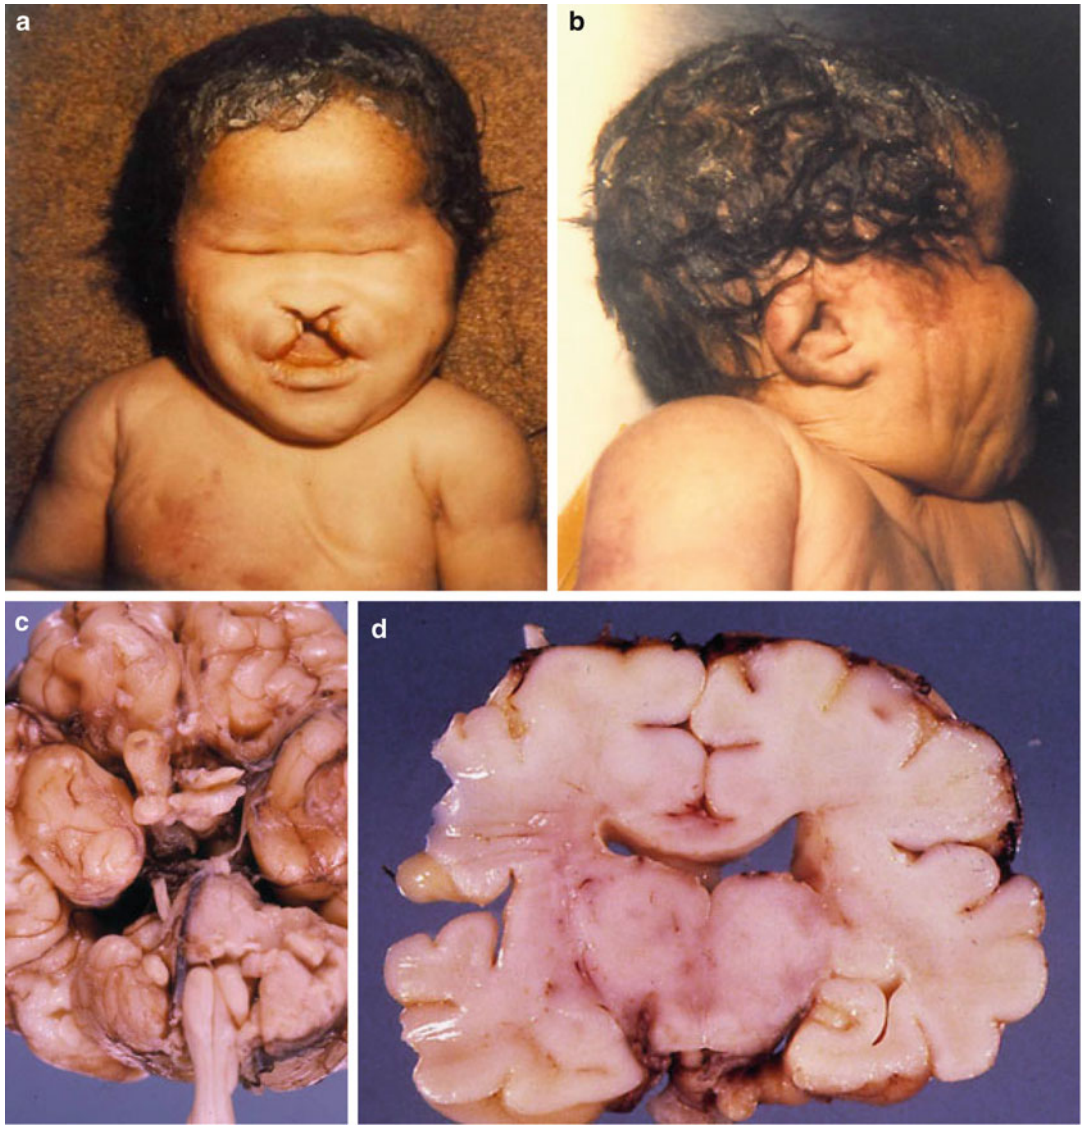

Fig. 4 (**a**–**d**) Front and lateral views of an infant with arhinencephaly. The postmortem brain showed absence of olfactory tract and sulci and septum pellucidum and fused thalami

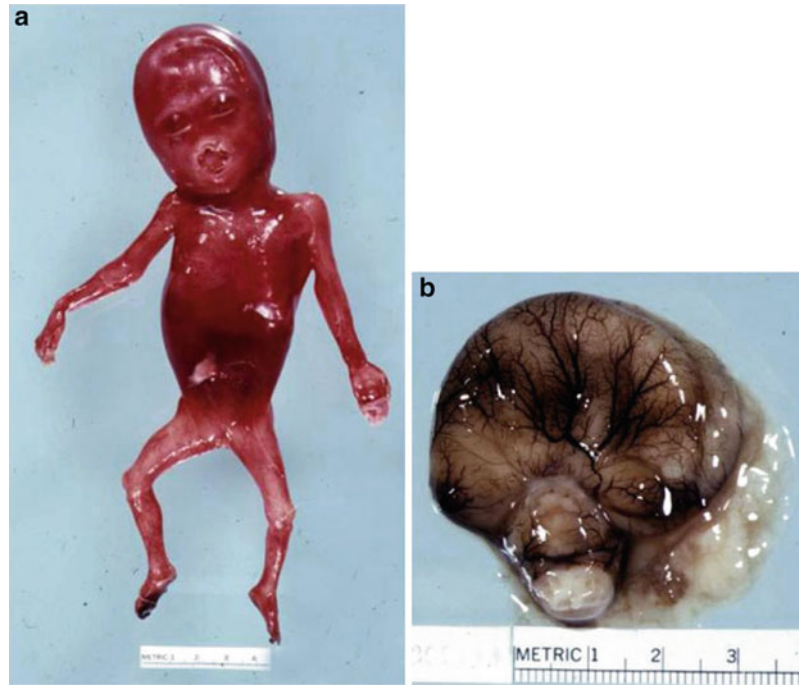

Fig. 5 (**a**, **b**) A fetus with premaxillary agenesis showing facial dysmorphism, including hypotelorism, absence of nose, median cleft lip and palate, and low-set ears. In addition, the fetus had 13 pairs of ribs and absence of uterus and left kidney. The pregnancy was terminated at 17 weeks of gestation because of alobar holoprosencephaly detected by ultrasonography. The postmortem brain showed alobar prosencephaly with a cerebral vesicle. Gyri were not developed

Fig. 6 A newborn with sirenomelia associated with holoprosencephaly

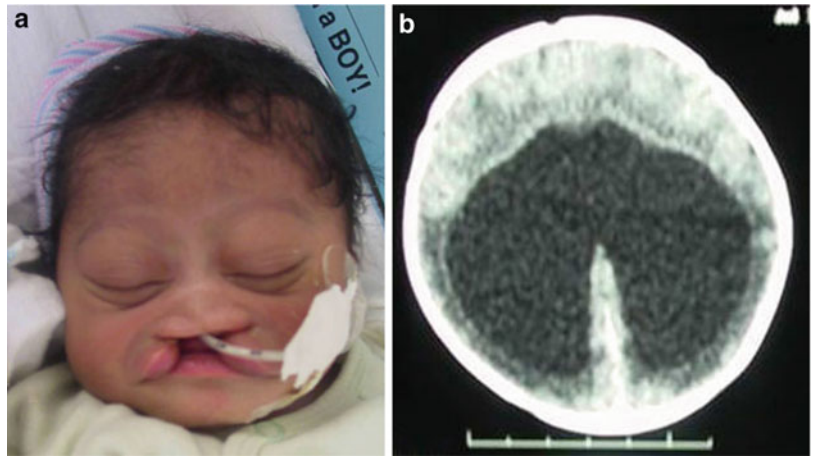

Fig. 7 (**a**, **b**) A neonate with premaxillary agenesis and holoprosencephaly illustrated by MRI of the brain

Fig. 8 (**a**–**c**) A child with premaxillary agenesis and upper limb defects

Fig. 9 (**a**–**d**) Four infants with premaxillary agenesis

Fig. 10 (**a**, **b**) An infant with hypotelorism and duplicated nose

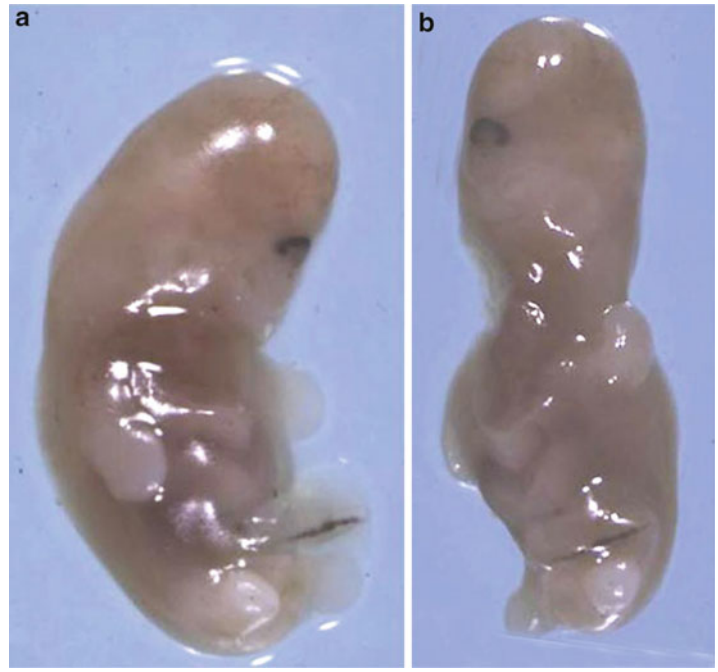

Fig. 11 (**a**, **b**) An aborted embryo with cyclopia

Fig. 12 (**a**, **b**) A girl with mild hypotelorism, antimongoloid slant, and a central incisor

Fig. 13 A neonate with cyclopia. The infant had holoprosencephaly (arhinencephaly), agenesis of olfactory and optic nerves, agenesis of pituitary, cor biloculare, left diaphragmatic hernia, bilobar spleen, agenesis of adrenal glands, and absence of right umbilical artery

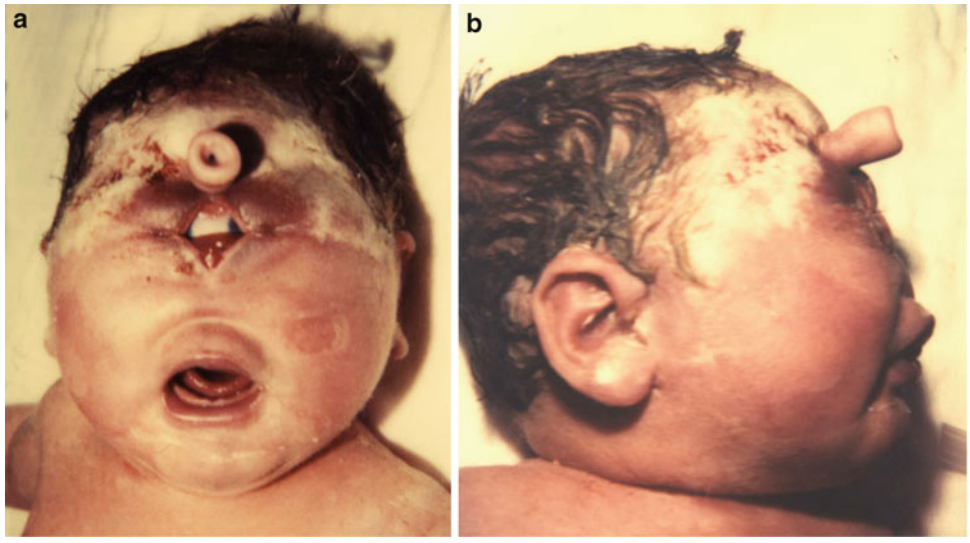

Fig. 14 (**a**, **b**) Another neonate with cyclopia

Fig. 15 An infant with ethmocephaly

Fig. 16 Postmortem brain with holoprosencephaly (dorsal view) showing a dilated single ventricle. The large dorsal cyst was ruptured during dissection, and the remnants of the membranous cyst wall are vaguely visible at the margins of the ventricle, especially on the right side

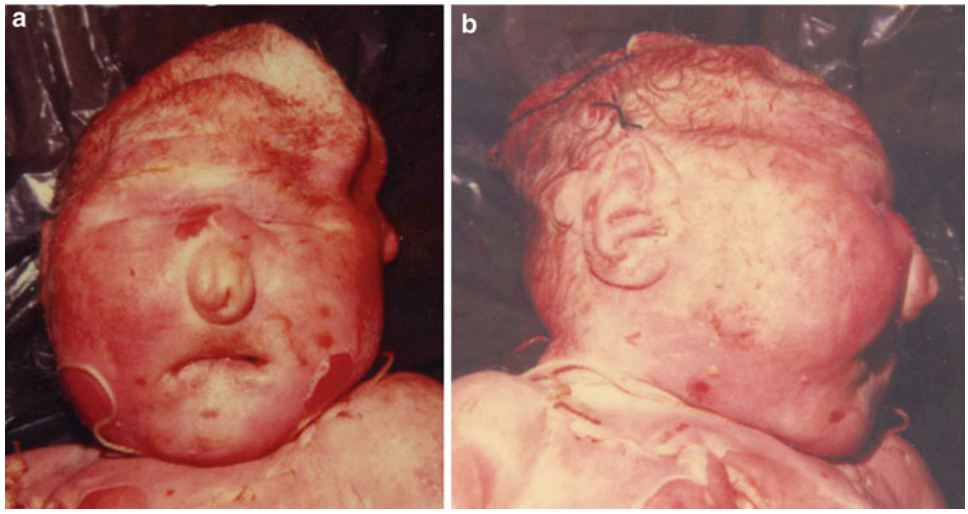

Fig. 17 (**a**, **b**) A neonate with cebocephaly

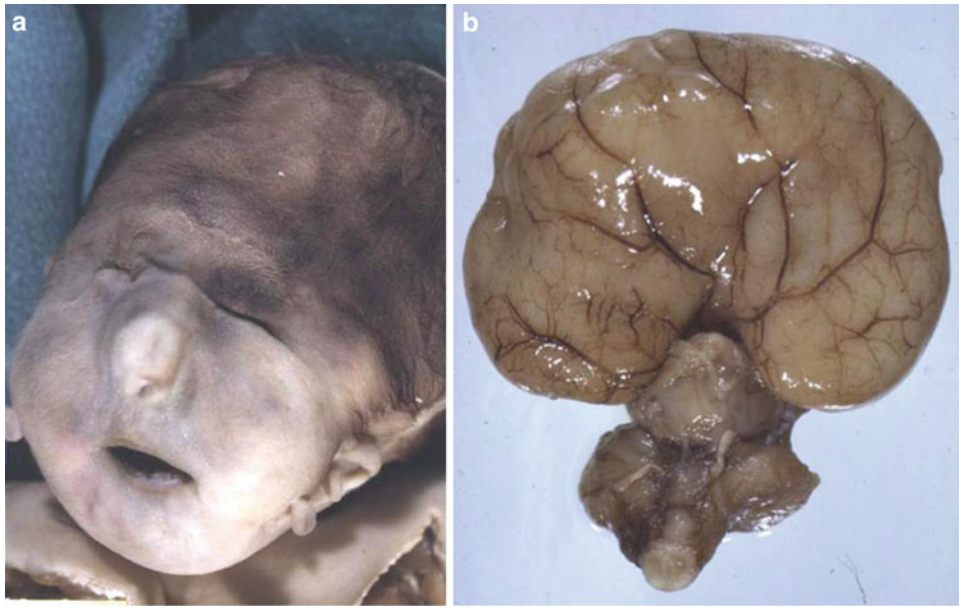

Fig. 18 (**a**, **b**) A premature neonate with cebocephaly. The infant had anophthalmia; bilateral nasal atresia; alobar holoprosencephaly (*ventral view*) with a 4.5 × 5.5 × 6.0 cm dorsal cyst (not shown), atresia of left external auditory canal with hypoplastic malformed auricle; agenesis of left lung; left kidney and left ureter; hypoplasia of left posterior cranial fossa and left cerebellum; multiple skin tags; hemivertebrae; and absence of right umbilical artery

Fig. 19 A neonate with cebocephaly and 48, XXY, +13

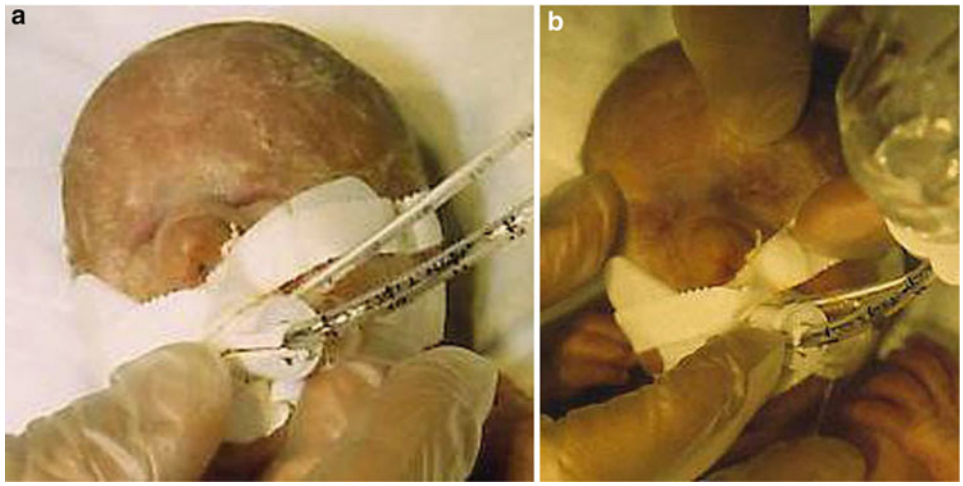

Fig. 20 (**a**, **b**) A newborn with trisomy 13 showing ocular hypotelorism and extreme microphthalmia

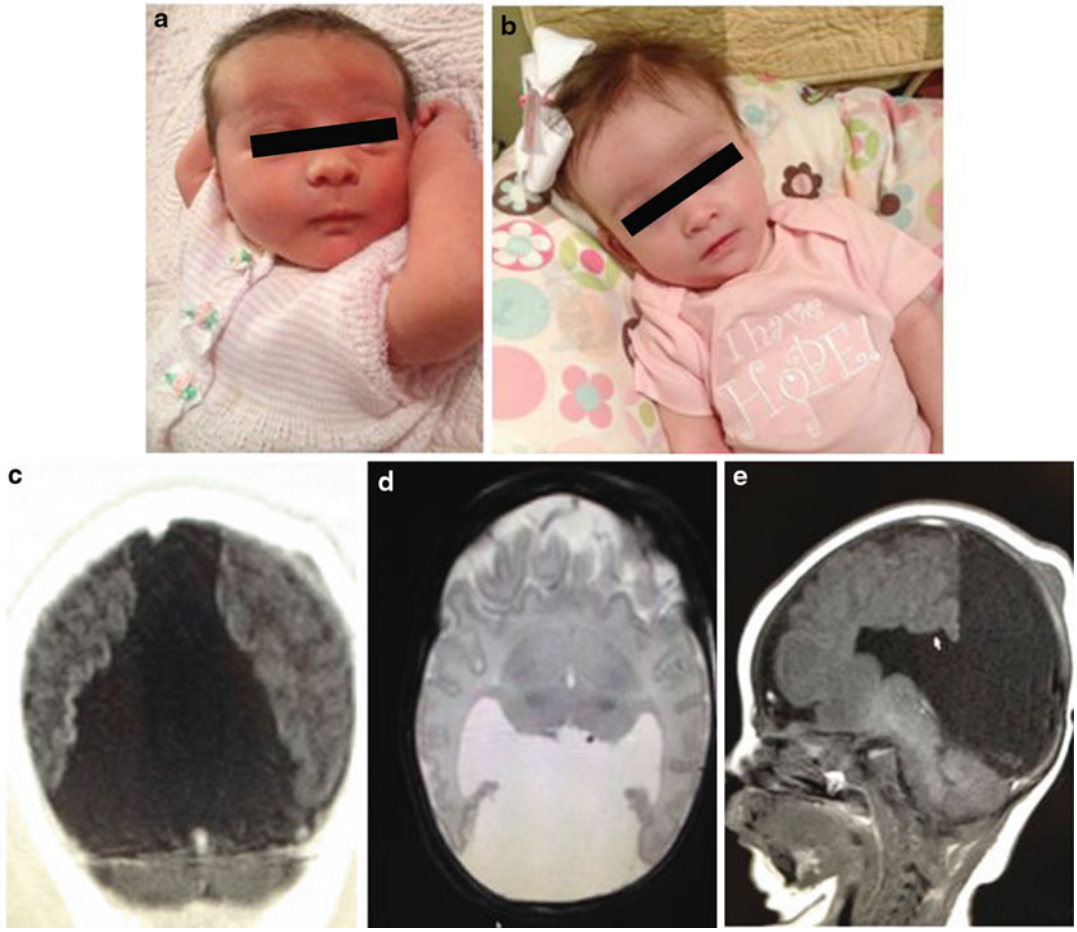

Fig. 21 (**a**–**e**) This female infant was evaluated at 4 weeks of age (**a**) and 18 months of age (**b**) for holoprosencephaly. Prenatal ultrasound examination at 17 weeks of gestation showed significant cerebral fluid accumulation in the fetal brain, a single ventricle of the brain, and a normal midface. A repeat ultrasound examination at 20 weeks of gestation showed a small head, abnormal intracerebral architecture, fused thalami, a large ventricle, and evidence of significant hydrocephalus. The baby was born at 36 weeks of gestation. The baby surprisingly looked normal despite the prenatal ultrasound findings of holoprosencephaly. The MRI of the brain (**c**–**e**) at birth showed dysgenesis of the corpus callosum, fusion of the posterior ventricle with absence of the septum pellucidum, interhemispheric fusion of the frontal lobe, enlarged cystic area over the posterior parieto-occipital region, partial formation of the frontal falx but bilateral Sylvian fissures communicated at the vertex, and severe hypoplasia of frontal lobe. These MRI findings are compatible with the diagnosis of semilobar holoprosencephaly. Molecular study (GeneDx) identified that the newborn was heterozygous for the C > A nucleotide substitution in exon 1 of the *ZIC2* gene, resulting in the replacement of a histidine codon (CAC) with a glutamine codon (CAA) at amino acid position 286 (c.858C > A or p.His286Gln)(H286Q). The presence of H286Q is considered a disease-causing mutation, and its presence is consistent with the diagnosis in this patient. No mutations were identified in the *SHH*, *SIX3*, or *TGIF* genes by sequencing

Fig. 22 **(a–h)** This baby girl was delivered at 36 6/7 weeks of gestation via cesarean section. Holoprosencephaly was diagnosed by prenatal ultrasound. Prenatal laboratories were unremarkable. Chromosome analysis of amniotic fluid revealed normal 46, XX. The chromosome microarray analysis was normal. At birth, the

Fig. 22 (continued) baby was noted to have ocular hypotelorism, depressed nasal bridge, and median cleft lip and palate (**a**, **b**). CT of the facial bones (**c**, **d**) revealed absence of the soft palate with a single cavity for the mouth and nasopharynx. There was essentially absence of the anterior maxilla and absence of the soft palate with a unicavity of the mouth and nasopharynx. CT of the brain (**e**, **f**) revealed a single ventricle with a large dorsal cyst and a pancaking of the residual cortex anteriorly. The basal ganglia regions were fused as are the thalami. The falx and the corpus callosum were absent. Multiplanar/multipulse sequence MRI of the brain (**g**, **h**) showed absence of anterior and posterior falx, a monoventricle along with fusion of both thalami, and absence of the corpus callosum. Hypogenesis/agenesis of the nasal cavity and nasal bones with cleft palate was present. The CT and MRI findings are consistent with alobar holoprosencephaly (Courtesy of Dr. Lea Bonifacio)

Holt-Oram Syndrome

Contents

In 1960, Holt and Oram (1960) described a family in which nine members in four generations were affected by skeletal abnormalities of the upper limbs, cardiac malformations, and arrhythmias. The prevalence is about 1 in 100,000 live births. About 40–85% of cases are due to fresh mutation.

Synonyms and Related Disorders

Atrial digital dysplasia; Heart-hand syndrome

Genetics/Basic Defects

1. An autosomal dominant disorder (Holmes 1965; Massumi and Nutter 1966):
   1. Complete penetrance (Gladstone and Sybert 1982)
   2. Widely variable expression (Gall et al. 1966; Kaufman et al. 1974; Letts et al. 1976; Smith et al. 1979)
2. Holt-Oram syndrome frequently linked to the gene *TBX5*, which is mapped to 12q24.1 (Terrett et al. 1994).
3. TBX5: essential for heart development (Horb and Thomsen 1999).
4. Caused by mutations in the *TBX5* gene, a member of the T-box family that encodes a transcription factor (Basson et al. 1997; Li et al. 1997; Akrami et al. 2001; Huang 2002; Fan et al. 2003):
   1. Mutations predicted to create null alleles cause substantial abnormalities in both the limb and heart.
   2. Nonsense mutations of *TBX5* produce distinct phenotypes (Basson et al. 1999):
      1. One class of missense mutations: causes significant cardiac malformations but only minor skeletal abnormalities.
      2. Other class of nonsense mutations: causes extensive upper limb malformations but few significant cardiac abnormalities.
      3. Several novel missense mutations in *TBX5* lead to functional haploinsufficiency and result in a reduced transcriptional activation of target genes, which is likely central to the pathogenesis of Holt-Oram syndrome (Boogerd et al. 2010).
5. Chamber-specific cardiac expression of Tbx5 and heart defects in Holt-Oram syndrome: provides an embryologic basis for the prevalence

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_120

of atrial septal defects (ostium primum and secundum), ventricular muscular septal defects, and left-sided malformations (endocardial cushion defects, hypoplastic left heart, and aberrant trabeculation), observed in patients with Holt-Oram syndrome (Bruneau et al. 1999).

6. Intrafamilial variations of the malformations: suggest that genetic background or modifier genes play an important role in the phenotypic expression of Holt-Oram syndrome (Huang 2002).
7. Sporadic cases may represent a de novo germline mutation in *TBX5* (Basson 2014).
8. T-box genes in human disorders (Packham and Brook 2003):
    1. Holt-Oram syndrome/TBX5
    2. Ulnar-mammary syndrome/TBX3
    3. DiGeorge syndrome/TBX1
    4. ACTH deficiency/TBX19
    5. Cleft palate with ankyloglossia/TBX22
9. Hand-heart syndromes (syndromes with frequent association of congenital cardiac and upper limb malformations): genetically heterogeneous (Basson et al. 1995):
    1. Holt-Oram syndrome: the most common form
    2. Heart-hand syndrome type II (Tabatznik syndrome)
        1. Hypoplastic deltoids
        2. Skeletal anomalies in the humeri, radii, ulnae, and thenar bones
        3. Brachydactyly type D
        4. Congenital cardiac arrhythmias (junctional rhythms and atrial fibrillation)
    3. Heart-hand syndrome type III
        1. Cardiac conduction defects (intraventricular delays and sick sinus syndrome)
        2. Skeletal malformations limited to the hands and feet (brachydactyly type C)
    4. Autosomal dominant "partial phenocopy" conditions
        1. Familial atrial septal defects with conduction disease occurring without limb deformities
        2. Familial limb malformations occurring without cardiac defects

Clinical Features

1. Preaxial radial ray abnormalities of the upper limb(s) (Ashby et al. 1969; Hurst et al. 1991; Basson et al. 1994; Newbury-Ecob et al. 1996; Venugopalan 2015)
    1. Almost always present
    2. Unilateral or bilateral
    3. Symmetric or asymmetric (left side more affected than the right side)
    4. Severe (phocomelia) to mild phenotype due to aplasia, hypoplasia, fusion, or anomalous development of involved bones
    5. Thumbs
        1. Aplasia
        2. Hypoplasia
        3. Triphalangeal
        4. Syndactyly
        5. Long
        6. Normal
    6. Fingers
        1. Clinodactyly
        2. Brachydactyly
        3. Hypoplasia
        4. Absent
        5. Syndactyly
        6. Normal
    7. Radial bones
        1. Hypoplasia
        2. Aplasia
    8. Ulnar
        1. Hypoplasia
        2. Aplasia
    9. Carpal bones
        1. Deformed
        2. Extra
    10. Thenar bones: hypoplastic thenar eminence
    11. Humerus
        1. Hypoplasia
        2. Abnormal head
        3. Aplasia
        4. Normal
    12. Clavicles
        1. Hypoplasia
        2. Prominent acromioclavicular joint
        3. Normal

13. Thorax
    1. Pectus excavatum
    2. Hypoplasia pectoralis major
14. Limited supination
15. Limited extension of the elbow

2. Cardiac anomaly (75% of cases) (Ashby et al. 1969; Sletten and Pierpont 1996; Basson 2014)
    1. Structural defects
        1. Atrial septal defect (most common type, usually of secundum variety)
        2. Ventricular septal defect
        3. Pulmonary stenosis (including peripheral arterial)
        4. Mitral valve prolapse
        5. Complex cardiac malformations (tetralogy of Fallot, hypoplastic left heart, endocardial cushion defects, truncus arteriosus)
    2. Cardiac conduction defects
        1. Paroxysmal tachycardia
        2. Prolonged PR interval (ECG)
        3. Wandering atrial pacemaker
        4. Atrial ectopics
        5. Sinus bradycardia
        6. Syncope
        7. Sinus arrest
        8. Atrioventricular block
        9. Atrial fibrillation
3. Mild to no symptoms in children and young adult
    1. Recurrent respiratory infections
    2. Failure to thrive
4. Older adults
    1. Congestive heart failure
    2. Supraventricular arrhythmia, especially atrial fibrillation
5. Differential diagnosis (Huang 2002)
    1. Fanconi anemia syndrome
        1. Multiple congenital anomalies consisting of malformations of the thumbs, forearms, and heart
        2. Progressive bone marrow failure with pancytopenia, typically in the first decade
        3. An increased risk for myelodysplasia or acute myelogenous leukemia
        4. Diagnosis based on detection of chromosomal breakage or rearrangement in the presence of diepoxybutane or mitomycin C
    2. Thrombocytopenia-absent radius
        1. Both radii always absent.
        2. Thumbs always present.
        3. Occasional phocomelia.
        4. Possible involvement of lower limbs:
            1. Club foot
            2. Knee instability
        5. Thrombocytopenia:
            1. Present in infancy
            2. Generally improves with time
        6. Heart defect can be present.
    3. Heart-hand syndrome II (Tabatznik) (Silengo et al. 1990)
        1. Type D brachydactyly (shortening of the distal phalanx of the thumb with or without shortening of the fourth and fifth metacarpals)
        2. Sloping shoulders
        3. Short upper limbs
        4. Bowing of the distal radii
        5. Absence of the styloid process of the ulna
        6. Supraventricular tachycardia
        7. Possible mild mental retardation and mild facial dysmorphism
    4. Heart-hand syndrome III
        1. Type C brachydactyly (shortening of the middle phalanges)
        2. An accessory wedged-shaped ossicles on the proximal phalanx of the index fingers
        3. Sick sinus syndrome
    5. Okihiro syndrome
        1. Duane syndrome
            1. A congenital eye movement disorder resulting from abnormal development of cranial nerve VI
            2. Absence of abduction of the globe
            3. Narrowing of the palpebral fissure on adduction of the globe
        2. Upper extremity reduction defects
        3. Cardiac malformations
    6. Long-thumb brachydactyly syndrome
        1. Elongation of the thumb distal to the proximal interphalangeal joint
        2. Often associated with index finger brachydactyly and clinodactyly

3. Narrow shoulders
4. Secondary short clavicles
5. Pectus excavatum
6. Occasional rhizomelic limb shortening
7. Frequent with cardiac conductive defect

7. VACTERL association
   1. Radial defect usually unilateral
   2. Accompanied by other malformations such as imperforate anus and tracheoesophageal fistula and congenital heart defect

Diagnostic Investigations

1. Radiography (Poznanski et al. 1970)
   1. Phocomelia of the upper limbs
   2. Shortened humeri
   3. Shortened forearms
      1. Aplasia/hypoplasia of the radius
      2. Hypoplastic ulna
      3. Radioulnar synostosis
      4. Humeral-ulnar synostosis
   4. Thumbs
      1. Absent thumbs
      2. Triphalangeal thumbs
      3. Clinodactyly
      4. Syndactyly
      5. Absent first metacarpals
      6. Hypoplastic thenar eminences
   5. First metacarpals
      1. Absent
      2. Hypoplastic
   6. Fifth fingers
      1. Short middle phalanx
      2. Clinodactyly
   7. Carpal bones
      1. Deformed
      2. Extra carpals
      3. Fused
      4. Irregular
      5. Delayed formation
   8. Shoulders
      1. Deformed scapula and/or clavicle
      2. Deformed head of the humerus
      3. Accessory bones
   9. Deformed sternum
2. Echocardiography for structural cardiac defects
3. Electrocardiography for cardiac conduction defects (Bossert et al. 2002)
   1. Sinus arrest
   2. Various degrees of atrioventricular block
   3. Right bundle branch block
   4. Sinus node dysfunction
   5. Wandering pacemaker
   6. Bradycardia
   7. Atrial fibrillation/flutter
   8. Supraventricular tachycardia and WPW syndrome
   9. Premature ventricular complexes
4. Karyotyping: helps map the breakpoints within the critical area of 12q (Venugopalan 2015)
5. Molecular genetic testing of *TBX5* by sequencing of entire coding region or mutation scanning

Genetic Counseling

1. Recurrence risk
   1. Probands
      1. Sixty to seventy percent have an affected parent
      2. Thirty to forty percent have a de novo mutation
   2. Patient's sib: not increased unless a parent is affected in which case, there is 50% recurrence risk
   3. Patient's offspring: 50%
2. Prenatal diagnosis
   1. Ultrasonography of Holt-Oram syndrome (Brons et al. 1988; Tongsong and Chanprapaph 2000) for fetuses at risk involving severe anomalies by demonstrating cardiac defect associated with upper limb defects, especially the radial ray defects
   2. Molecular genetic testing of *TBX5* of fetal DNA obtained from amniocentesis or CVS, provided the disease-causing mutation has been identified in the family
   3. Preimplantation genetic diagnosis
      1. May be available for families in which the disease-causing mutation has been identified

   2. Reported for Glu69ter *TBX5* mutation causing Holt-Oram syndrome (McDermott et al. 2005)
3. Management
   1. A permanent pacemaker for advanced heart block
   2. Surgery for severe cardiac defect
   3. Prostheses for children with severe limb shortening
   4. Orthopedic management of severe limb defects

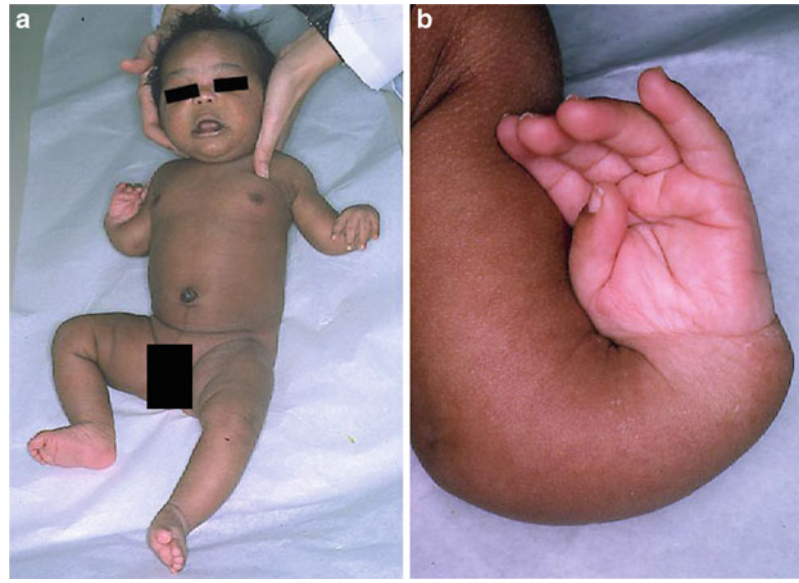

Fig. 1 (**a**, **b**) An infant with Holt-Oram syndrome showing club hands and fingerlike thumbs

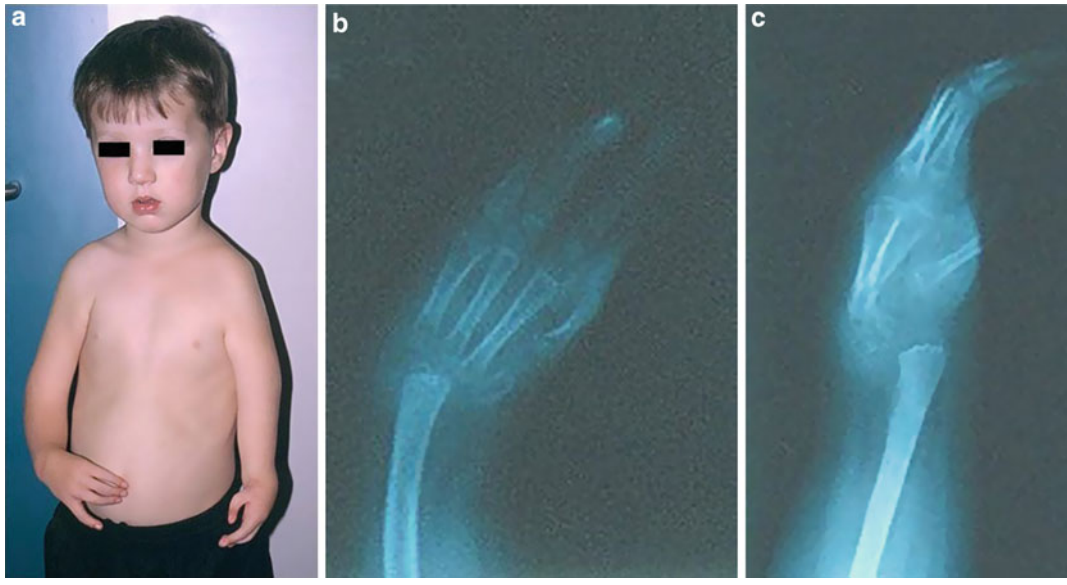

Fig. 2 (**a**–**c**) A child with Holt-Oram syndrome showing bilateral club hands, absent radius, and absent thumbs, demonstrated by radiographs

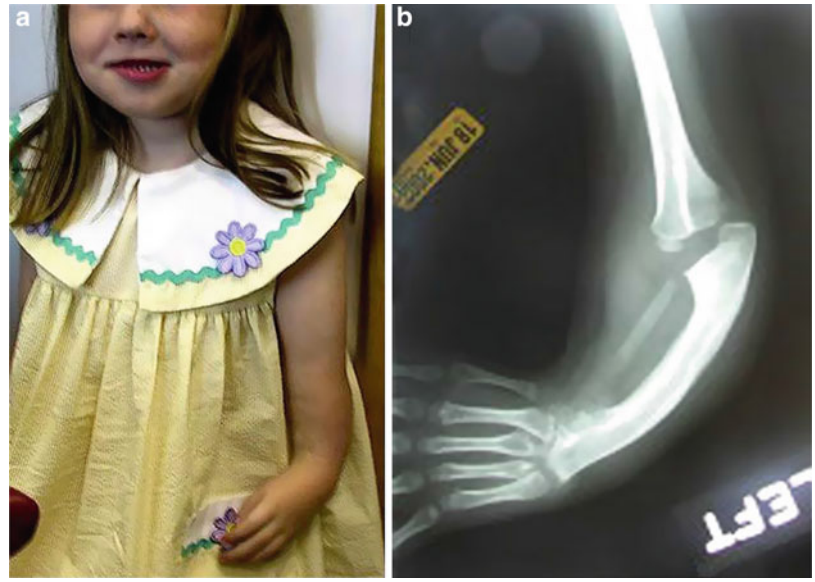

Fig. 3 (**a**, **b**) A child with Holt-Oram syndrome showing left club hand and hypoplastic radius, illustrated by radiography

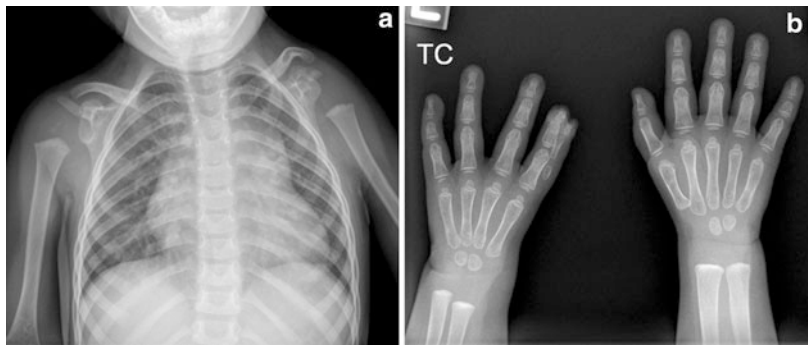

Fig. 4 (**a**, **b**) This 2-year-old girl with a history of Holt-Oram syndrome was evaluated. Chest X-ray (**a**) demonstrates dysplastic left glenoid with dysplastic appearance of the far lateral aspect of the left clavicle. Cardiac silhouette is mildly enlarged with prominent pulmonary vascularity and the normal left aortic arch is not seen. Findings are suggestive of cardiovascular anomaly. The X-ray of bilateral hands (**b**) demonstrates an abnormal left hand with findings suggestive of absence of the thumb, although with supernumerary bony and soft tissue along the margins of the second digit involving the phalanges. No accessory metacarpal was identified (Courtesy of Dr. Grace Guo)

Huntington Disease

Contents

Huntington disease (HD) is an autosomal dominant, progressive neurodegenerative disorder, typically characterized by a movement disorder, affecting middle-aged adults. It is the most frequent cause of genetic chorea with reported prevalence rates in North America and Europe ranging from 3 to 7 per 100,000 (Cardoso et al. 2006).

Synonyms and Related Disorders

Huntington chorea

Genetics/Basic Defects

1. Caused by a mutation in the *IT15* gene, which is a 210-kb gene located near the tip of the short arm of chromosome 4 (4p16.3), resulting in the N-terminal region of huntingtin protein (Htt) (The Huntington's Disease Collaborative Research Group 1993; Cardoso 2009; Harris et al. 2009).
2. "Biallelic mutations" or "compound heterozygosity" are more accurate descriptive terms than "homozygosity" when there are two nonidentical expanded huntingtin (HTT) alleles (Uhlmann et al. 2015).
3. Patients with Huntington disease have an expanded and unstable trinucleotide CAG (cytosine-adenine-guanine) repeat in the *IT15* gene within exon 1 (Rubinsztein et al. 1996). Huntington disease is, therefore, considered one of the trinucleotide repeat disorders (Myers 2004).
    1. Normal CAG repeat length in the *HD* gene: 26 or lower.
    2. Expansions of 40 or more cause HD with complete penetrance.
    3. Individuals with 36–39 repeats may also develop HD but penetrance is incomplete (Rubinsztein et al. 1996).
    4. A CAG repeat range between 27 and 35: considered normal allele with particular risk for expansion into the HD range in the paternal germline (Ranen et al. 1995; Laccone et al. 1999)
    5. The number of CAG repeats
        1. Has significant implications for age at onset, disease severity, and stability of the gene between generations.
        2. Presence of a robust inverse correlation between the number of polyglutamine repeats and the age at disease onset so

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_121

that longer repeat lengths are associated with earlier onset of Huntington disease (Shelbourne et al. 2007).
3. The number of CAG repeats, however, is not an absolute prediction of disease onset.

4. The nature of the genetic defect in the *HD* gene (Myers et al. 1998) explains many of the genetic features of the disorder, including:
1. The variability in age at onset
2. The tendency for juvenile disease to be inherited from fathers
1. Merritt et al. (1969) first observed that a disproportionate number of cases with onset before the age of 21 had inherited the *HD* gene from affected fathers.
2. The observation of earlier ages at onset in successive generations, termed "anticipation," is seen in several of the trinucleotide repeat disorders including HD.
3. Meiotic instability of the *HD* repeat in paternal transmission explains the observation of anticipation in HD.
3. The sporadic appearance of new mutations to HD

5. Pathophysiology (Roze et al. 2008)
1. The expanded polyglutamine repeat alters the normal functions of Htt.
2. The mutated protein, Exp-Htt, is itself toxic.
3. Htt interacts with an array of proteins in neuronal cells.
4. One important characteristic of Huntington disease is the particular vulnerability of a particular brain region, the caudate-putamen, despite similar expression of the mutated protein in other brain areas.

6. Potential pathways for pathogenesis of Huntington's disease (Frank 2014)
1. Neuronal aggregates
1. Neuronal intracytoplasmic and intranuclear inclusions containing mutant huntingtin, truncated N-terminal mutant and wild-type fragment, and chaperones and components of the proteolytic pathway are characteristic of HD neuropathology.
2. Accumulation of mutant protein aggregates may be a result of impairment of the ubiquitin–proteosome pathway.
3. Autophagic mechanisms are implicated in the clearance of protein aggregates.
2. Transcriptional dysregulation
1. Aberrant nuclear localization of mutant toxic huntingtin fragments and their association with transcription factors.
2. Dysregulation related to entrapment of transcriptional factors in protein aggregates.
3. Excitotoxicity: Excitotoxic neuron death in HD could result from a combination of increased glutamate and glutamate agonist release from cortical afferents.
4. Mitochondrial dysfunction and altered energy metabolism.
1. Selective inhibitors of complex II of the mitochondrial electron transport chain, 3-nitropropionic acid, and malonate cause selective striatal neuronal loss similar to that seen in patients with HD.
2. Multitude of bioenergetic defects has been reported in patients with HD.
5. Changes in axonal transport and synaptic dysfunction.
6. Normal huntingtin plays a role in axonal trafficking.
7. Disruption of axonal transport contributes to pathologic process in HD.

Clinical Features

1. A triad of HD (Cardoso 2009; Harris et al. 2009; Bordelon 2013)
1. Movement disorder (Leigh et al. 1983; Carella et al. 1993; Jankovic and Ashizawa 1995; Reuter et al. 2000; Tan et al. 2000)
1. Full spectrum of motor impairment
1. Eye movement abnormalities
2. Parkinsonian features
3. Dystonia (particularly in juvenile HD)
4. Myoclonus

5. Tics
6. Ataxia
7. Dysarthria
8. Dysphagia
9. Spasticity with hyperreflexia and extensor plantar responses

2. Chorea: often superseded by dystonia or akineto-rigid parkinsonian features with progressing illness
3. Dystonia: found in more than 90% of patients with HD in one study (Louis et al. 1999) although rarely it becomes as prominent as in idiopathic dystonias
4. Rigidity
5. Bradykinesia (slowness of movement)

2. Cognitive decline
   1. Universally go through cognitive decline, mental slowing, impaired problem-solving abilities, and other signs of a frontal dysexecutive syndrome, and they eventually become demented. These patients present with the prototype of so-called subcortical dementia (Lawrence et al. 1996; Kirkwood et al. 2001; Ho et al. 2003).
   2. Cognitive decline also heralds the juvenile onset of HD (Ribai et al. 2007).
   3. Asymptomatic carriers of the HD gene have decreased phonemic fluency (Larsson et al. 2008).
3. Behavioral changes
   1. Universal and may occasionally antedate motor manifestations
   2. Major depression is common, diagnosed in more than 40% of subjects, and responsible for increased suicide rates in HD
   3. Broad spectrum of behavioral abnormalities (Caine and Shoulson 1983; Mendez 1994; Schoenfeld et al. 1984; Shiwach 1994; Rosenblatt and Leroi 2000; Rosenblatt et al. 2003; Guttman et al. 2003)
      1. Depression.
      2. Anxiety or panic attacks.
      3. Obsessive-compulsive symptoms.
      4. Manic features.
      5. Psychosis.
      6. Irritability and aggressive behavior.
      7. Sexual disinhibition.
      8. Apathy.
      9. In presymptomatic HD, significantly more psychiatric symptoms (specially depression, anxiety, and obsessive-compulsiveness) were reported than for the controls (Duffin et al. 2007).
      10. Similarly, psychiatric difficulties are indicators of juvenile HD onset (Ribai et al. 2007).

2. End-stage HD
   1. Relentlessly progressive course with death occurring 15–20 years after symptom onset with particularly rapid progression in the juvenile Westphal variant.
   2. Typically rigid and akinetic, demented, and mute.
   3. Immobility and dysphagia often lead to aspiration pneumonia, the most common cause of death in these patients (Marshall 2004; Sorensen and Fenger 1992; Lanska et al. 1988).
3. Differential diagnosis
   1. Choreoacanthocytosis: the most likely disorder to be confused
      1. Dementia
      2. Involuntary movements
      3. Caudate atrophy
      4. Abnormal red blood cell morphology
      5. Neuropathy
      6. Seizures
      7. Myopathy
      8. Elevated creatine phosphokinase
      9. Self-mutilation
      10. An unusual eating dystonia
   2. Different causes of chorea
      1. Genetic causes of chorea syndromes (Gövert and Schneider 2013)
         1. Huntington disease
         2. Huntington disease-like (HDL) illnesses (HDL1, HDL2, HDL4)
         3. Chorea-acanthocytosis (Levine-Critchley syndrome)
         4. McLeod syndrome

5. Wilson disease (Hepatolenticular degeneration)
6. Benign hereditary chorea (Thyroid-lung syndrome)
7. Spinocerebellar atrophy types 2, 3, 17
8. Dentatorubropallidoluysian degeneration (DRPLA)
9. Ataxia-telangiectasia
10. Ataxia associated with oculomotor apraxia
11. Neuroferritinopathy (Haw River syndrome, Naito-Oyanagi disease)
12. Pantothenate kinase-associated degeneration
13. Leigh disease and other mitochondriopathy
14. Lesch-Nyhan disease
15. Creutzfeldt-Jakob disease
16. Neuronal ceroid lipofuscinosis
17. Glutaric aciduria
18. Polycythemia vera
19. Celiac disease

2. Immunologic causes
   1. Sydenham chorea
   2. Systemic lupus erythematosus
   3. Antiphospholipid antibody syndrome
3. Drug-induced chorea
   1. Amantadine
   2. CNS stimulants (amphetamines, methylphenidate, cyproheptadine)
   3. Anticholinergics
   4. Anticonvulsants (carbamazepine, phenytoin)
   5. Carbon monoxide
   6. Cocaine
   7. Dopamine agonists
   8. Dopamine-receptor blockers
   9. Estrogens
   10. Ethanol
   11. Levodopa
   12. Levofloxacin
   13. Lithium
   14. Sympathomimetics
   15. Theophylline
   16. Tricyclic antidepressants
   17. Carbamazepine
   18. Drugs that cause tardive dyskinesia
   19. Withdrawal emergent syndrome
4. Infections
   1. AIDS-related (toxoplasmosis, progressive multifocal leukoencephalopathy, HIV encephalitis)
   2. Bacteria (diphtheria, scarlet fever, whooping cough)
   3. Encephalitis (B19 parvovirus, Japanese encephalitis, measles, mumps, West Nile river encephalitis, others)
   4. Parasites (neurocysticercosis)
   5. Protozoan (malaria, syphilis)
5. Endocrine-metabolic dysfunction
   1. Adrenal insufficiency
   2. Hyper/hypocalcemia
   3. Hyper/hypoglycemia
   4. Hypomagnesemia
   5. Hypernatremia
   6. Liver failure
6. Vascular
   1. Postpump chorea (cardiac surgery)
   2. Stroke
   3. Subdural hematoma
7. Miscellaneous
   1. Anoxic encephalopathy
   2. Cerebral palsy
   3. Kernicterus
   4. Multiple sclerosis
   5. Normal maturation (less than 12 months old)
   6. Nutritional (e.g., B12 deficiency)
   7. Posttraumatic (brain injury)
   8. Chorea gravidarum hyperthyroidism
   9. External pallidal atrophy
   10. Pick disease
   11. Paraneoplastic syndromes
   12. Acute disseminated encephalomyelopathy
   13. Multiple system atrophy

Diagnostic Investigations

1. A confirmed family history of Huntington disease combined with clinical manifestations: sufficient for diagnosis (Harris et al. 2009)

2. Neuroimaging (MRI and CT)
    1. Severe atrophy of the caudate nucleus in moderately disabled patients
    2. May be relatively normal in patients in the early stages
3. Pet scan: Atrophy of the caudate nucleus can be detected in a presymptomatic state by the finding of head of caudate hypometabolism
4. Neuropathological features
    1. Neuronal loss and gliosis in the cortex and striatum, particularly the caudate nucleus: the most prominent neuropathologic features (Roth et al. 2005).
    2. Neuronal injury occurs initially in the caudate tail, in the medial paraventricular caudate, and in the dorsal part of the putamen.
    3. Further neuronal loss and an increase in astrocytes can be observed in widespread cortical and subcortical regions as the neurodegenerative process progresses.
    4. Pathologic observation of affected striatum shows loss of GABAergic spiny projection neurons with preservation of the aspiny interneurons and large aspiny acetylcholinesterase-positive neurons.
    5. A decrease of important neurotransmitters and neuropeptides, such as γ-aminobutyric acid (GABA), calbindin, enkephalin, and substance P, as a result of selective loss of the medium spiny neurons
5. Three main types of genetic testing of HD
    1. To confirm or rule out disease
    2. Presymptomatic testing to determine the carrier status of an individual at genetic risk for inheriting the disease
        1. To assist in making decisions about marriage, procreation, or career.
        2. The emotional impact of the result can be difficult to anticipate and can evoke substantial adverse emotional reactions (Taylor and Myers 1997; Almqvist et al. 1999).
        3. Appropriate pretest counseling is important to assist the at-risk individual in considering the risks and benefits of genetic testing for diseases such as HD for which available treatment does not justify testing.
    3. Prenatal testing to determine the carrier status of a fetus
6. Other laboratory testings (Singer 2012)
    1. Complete blood count
    2. Creatine phosphokinase
    3. Peripheral smear for acanthocytes
    4. Comprehensive metabolic panel
    5. Ceruloplasmin level
    6. Measurement of thyroxine (T4) and triiodothyronine (T3)
    7. B12 tests
    8. Antinuclear antibody sedimentation rate
    9. Lupus anticoagulant-anticardiolipin antibodies
    10. Antistreptolysin O (ASO) titer
    11. Anti-DNase-B titer

Genetic Counseling

1. Recurrence risk (Warby et al. 2014)
    1. Patient's sib
        1. A 50% risk if a parent is affected or has a CAG size of 40 or greater.
        2. An estimated risk as high as 5% (50 × 10%) of inheriting a mutant allele (≥36 CAG repeats) if the father has an intermediated allele (Chong et al. 1997).
        3. A sib who inherits an *HD* allele with reduced penetrance may or may not develop symptoms of HD.
    2. Patient's offspring
        1. A 50% risk of inheriting the disease-causing mutation from a parent with heterozygosity for the *HD* allele
        2. A 100% risk of inheriting the disease-causing allele from a parent with homozygosity for CAG repeat expansion in the *HD* gene
    3. A new mutation for Huntington disease following maternal transmission of an intermediate allele: While the likelihood remains exceedingly low, the possibility that intermediate alleles may unexpectedly undergo large expansions and produce a

new mutation following maternal transmission is important information to share when providing genetic counseling to families (Semaka et al. 2015)

2. Prenatal diagnosis (Warby et al. 2014)
    1. Prenatal diagnosis is possible for pregnancies at 50% risk by analyzing DNA extracted from fetal cells obtained by amniocentesis or CVS, provided the disease-causing allele in the affected parent or in an affected relative has been confirmed.
    2. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified in an affected family member.
3. Management (Harris et al. 2009)
    1. No definitive cure
    2. Limited therapeutic options currently
    3. Multidisciplinary team approach
        1. Medical
        2. Social work
        3. Physical therapy
    4. Selective serotonin reuptake inhibitors – effective in treating depression symptoms:
        1. Depression
        2. Mania
        3. Delusions
        4. Paranoia
        5. Chorea
        6. Other symptoms related to depression
            1. Rumination
            2. Perseveration
            3. Obsessive-compulsive disorder
            4. Suicide
        7. Mood stabilizers (valproate, carbamazepine, lamotrigine, or lithium) for bipolar disorders
    5. Neuroleptic for delusions and paranoia symptoms as well as chorea
    6. Atypical antipsychotics (risperidone, clozapine, olanzapine, and quetiapine) provide sufficient control of psychotic symptoms with a lower risk for extrapyramidal adverse effects and tardive dyskinesia.
    7. Nutritional management (Żukiewicz-Sobczak et al. 2014)
        1. In the early stages of HD, small amounts of blenderized foods given orally are recommended.
        2. In more advanced stages, enteral nutrition is essential using gastric, or jejunal tubes for short term.
        3. Most severe cases require gastrostomy or gastrojejunostomy.
    8. Palliative care in managing the latter stage of the disease
        1. Bedridden
        2. Mute
        3. Rigid
        4. Dysphagia
        5. Aspiration
4. Frequently used interventions, both pharmacologic and nonpharmacologic, in the management of the commonest HD symptoms and complications (Dayalu and Albin 2015)
    1. Chorea
        1. Dopamine depletion (tetrabenazine)
        2. Dopamine-receptor blockers
        3. Amantadine
    2. Parkinsonism and rigidity: Levodopa (juvenile HD)
    3. Dysarthria: speech therapy
    4. Dysphagia
        1. Speech and swallow therapy
        2. Dietary modification
    5. Gait impairment and falls
        1. Physical therapy
        2. Assistive devices
        3. Home modification
    6. Depression
        1. Selective serotonin reuptake inhibitors (SSRIs)
        2. Other antidepressants
    7. Anxiety
        1. SSRIs
        2. Buspirone
    8. Obsessive-compulsive behaviors: SSRIs
    9. Outbursts and impulsivity
        1. Antipsychotics
        2. Mood-stabilizing anticonvulsants
    10. Delusions and hallucinations: antipsychotics
    11. Apathy: structured routine and cues

12. Cognitive dysfunction and dementia: structured routine and cues
13. Weight loss
    1. High-calorie supplements
    2. Dietary consultation
14. Caregiver burden and family stress
    1. Social work services
    2. Individual and family therapy
    3. Respite care

5. Treatment advances in HD: A number of promising agents are in various phases of clinical investigation (Shannon and Fraint 2015)
    1. Deuterated tetrabenazine, pridopidine, cysteamine, resveratrol, the PDE10A inhibitor PF-02545920, laquinimod, green tea polyphenol, and an experimental lipid peroxidation inhibitor are currently ongoing, and others are planned.
    2. These represent a great hope for the HD community that real treatments are on the horizon for this devastating disease.

Fig. 1 The patient, a 42-year-old lady, was evaluated for increasing weakness of her legs over the past 1 year, dropping things out of her hands and increased balance difficulties. She was ambulatory but had difficulty going upstairs and on uneven surfaces. She later developed typical movement disorders, chorea, dystonia, cognitive decline, and behavioral changes. The family history was significant for affected family members (mother and two brothers). The diagnosis of Huntington disease was confirmed by the presence of over 40 CAG repeats

Hydranencephaly

Contents

Hydranencephaly is a severe central nervous system disorder, characterized by complete or almost complete absence of cerebral cortex with preservation of meninges, basal ganglia, pons, medulla, cerebellum, and falx. Cerebral hemispheres are completely or partially destroyed and transformed into membranous sacs containing cerebrospinal fluid (Greco et al. 2001). Hemihydranencephaly is an extremely rare brain condition in which the vascular occlusion is presumed to be unilateral. Hydranencephaly occurs in less than 1 in 10,000 births (To and Tang 1999).

Synonyms and Related Disorders

Fowler syndrome; Hemihydranencephaly

Genetics/Basic Defects

1. Maternal risk factors
    1. Intercurrent infections
        (i) Toxoplasmosis
        (ii) Rubella

        (iv) Herpes simplex
    2. Exposure to irradiation
    3. Exposure to teratogenic agents
        (i) Warfarin
        (ii) Estrogens
        (iii) Valproic acid
        (iv) Drug abuse: cocaine
    4. Twin-twin transfusion
    5. Intrauterine death of a monozygotic co-twin leading to vascular disruption of cerebral tissue
    6. Alloimmune and idiopathic thrombocytopenia
    7. Von Willebrand disease
    8. Congenital factor X and factor V deficiencies leading to hemorrhage into various congenital tumors
2. Presumably resulting from intrauterine bilateral internal carotid artery occlusion
    1. The structural defects occurring during the 4th and 6th months of gestation, after neuronal migration (Greco et al. 2001)
    2. Occurring between the 8th and 12th weeks, based on fetal ultrasound data, histopathologic findings, embryogenic vascular development, and postnatal CT and MRI findings (Cecchetto et al. 2013)
3. May be associated with porencephaly and congenital hydrocephalus

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_262

4. Fowler (proliferative vasculopathy and hydranencephaly-hydrocephaly) syndrome (Fowler et al. 1972; Meyer et al. 2010):
    1. An autosomal recessively inherited prenatal lethal disorder characterized by hydranencephaly
    2. Brain stem, basal ganglia, and spinal cord diffuse clastic ischemic lesions with calcifications
    3. Glomeruloid vasculopathy of the central nervous system and retinal vessel
    4. A fetal akinesia deformation sequence with muscular neurogenic atrophy
    5. Associated with mutations in *FLVCR2* (feline leukemia virus subgroup C receptor 2)

Clinical Features

1. Markedly reduced life expectancy
    1. Stillborn
    2. Dying within a few weeks or months after birth
    3. Rare reports of prolonged survival (McAbee et al. 2000; Bae et al. 2008)
2. First year of life
    1. Typically marked by medical emergencies (Merker 2008)
        1. Uncontrolled epileptic seizures
        2. Pulmonary sequels to reflux and aspiration
        3. Unregulated intracranial pressure (hydrocephalus)
        4. Problems with temperature regulation
    2. Other features
        1. Macrocephaly
        2. Hyperirritability
        3. Retardation
        4. Transillumination
3. Survivors after first year of life
    1. The previously mentioned problems brought under control by medication, shunting, and other interventions
    2. Cases reported with diagnosis of developmental or persistent vegetative state (The Multi-society Task Force on the Persistent Vegetative State 1994)
    3. Cases reported exhibiting a responsiveness to surroundings incompatible with the classification vegetative state (Shewmon et al. 1999)
    4. Merker (2007) provided a detailed examination of functional reasons for expecting individuals with early and drastic (even complete) loss of cortical tissue to display forms of coherent responsiveness to their surroundings incompatible with a diagnosis of vegetative state.

Diagnostic Investigations

1. Transillumination of the skull (Alexander et al. 1956; Levin 1957; Barozzino and Sgro 2002)
    1. Used as a screening procedure for infants with macrocephaly and those suspected of having the following:
        1. Hydranencephaly
        2. Subdural effusion
        3. Subdural hematoma
        4. Hydrocephalus
        5. Porencephaly
        6. Increased intracranial pressure
        7. Skull fracture
        8. Nutritional deficiencies
    2. Has become a somewhat forgotten tool with advancements in and increased availability of neuroimaging techniques, but sometimes even a simple otoscope placed in the appropriate position can provide clinical "enlightenment."
2. CAT angiography (Jordan et al. 2004): A fast and safe way to assess the vascular anatomy of newborn babies with significant cerebral anomalies
3. MRI of the brain: better delineation of detail anatomy of the brain
    1. Absence of cerebral mantle (temporal and occipital lobe remnants commonly present)
    2. Falx cerebri partially or completely intact
    3. Thalamus and hypothalamic mesencephalic structures usually preserved
    4. Brainstem usually atrophic
    5. Cerebellum always intact

4. EEG for seizures
5. Comprehensive molecular test for Fowler syndrome (Sanger sequencing and HDT array deletion duplication) for FL/VCR2 mutation is available clinically

Genetic Counseling

1. Recurrence risk
   1. Sporadic occurrence
      1. Patient's sib: not increased
      2. Patient's offspring: not reported due to reduced life expectancy
   2. Autosomal recessive inheritance (Fowler syndrome)
      1. Patient's sib: 25%
      2. Patient's offspring: low unless the spouse is affected
2. Prenatal diagnosis (Lam and Tang 2000)
   1. Ultrasonography
      1. Hydranencephaly is suspected when there is a large fluid collection in the head with no recognizable cerebral cortex.
      2. During the early stages of disease, hydranencephaly is characterized by the presence of a large intracranial saclike structure containing homogeneous echogenic material, representing blood and necrotic debris secondary to massive liquefaction of the developing cerebral hemispheres (Sepulveda et al. 2012).
      3. Differentiated sonographically from holoprosencephaly by identifying the presence of dural attachments and distinctly separate thalami (McGahan et al. 1988)
      4. In severe hydrocephalus, a rim of cerebral cortex around the cystic cavity and enlargement of the 3rd ventricle may be visualized.
   2. Fetal MR imaging (Ghosh et al. 2013) shows normal-appearing brain stem, cerebellum, portions of the occipital and temporal lobes, and unfused thalami with the remainder of the supratentorium all representing fluid
   3. Molecular genetic analysis for Fowler syndrome
3. Management: symptomatic

Fig. 1 (**a**, **b**, **c**) Transillumination of the skull in a neonate with hydranencephaly in a dark room shows the light illuminates the entire brain from the forehead through the back of the head. The transillumination is most drastic

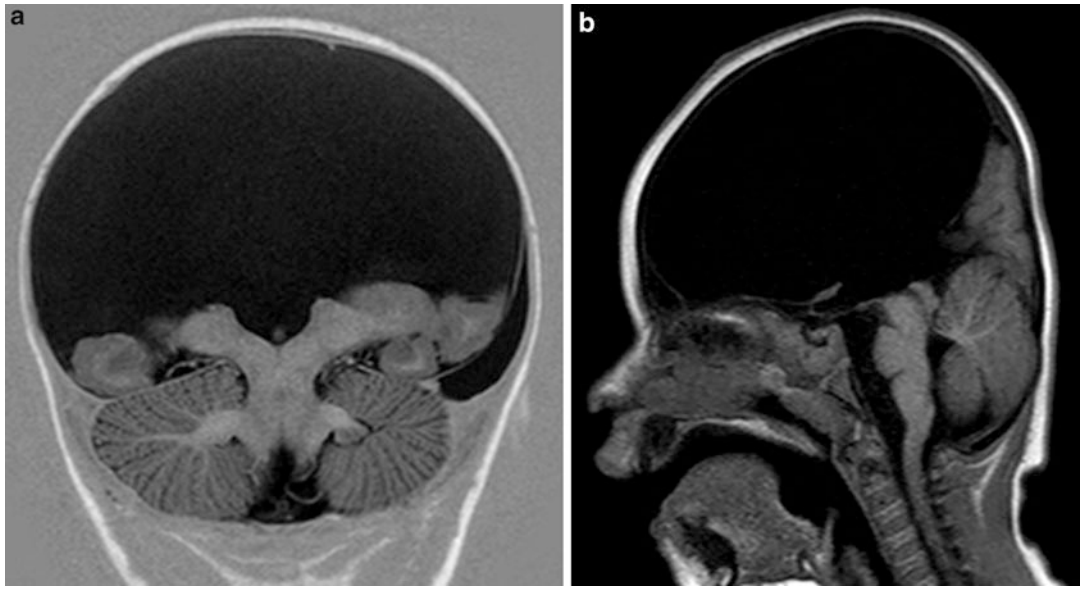

Fig. 2 (**a**, **b**) These two MRI images of the brain was from 1-year-old girl with seizures. Coronal image shows complete absence of the cerebral hemispheres with the exception of some portions of the inferior temporal lobes. The cerebellum is normal (**a**). The sagittal image shows absence of most of the cerebrum with a portion of occipital lobe present. Brainstem appears diffusely atrophic (**b**). The separated bilateral thalami are present (Courtesy of Dr. Grace Guo)

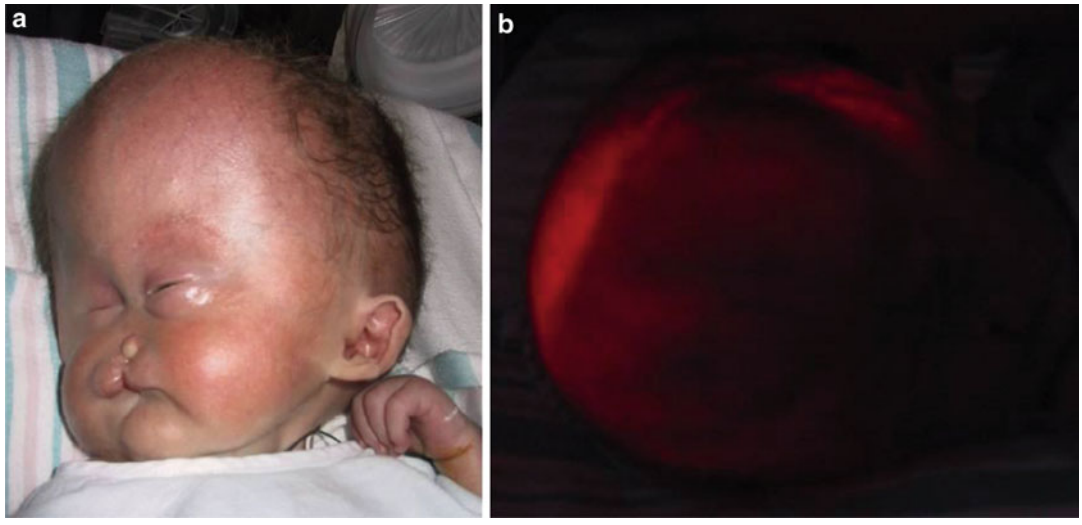

Fig. 3 (**a**, **b**) Transillumination of the skull in a neonate with alobar holoprosencephaly, difficult to differentiate from hydranencephaly

Fig. 4 (**a**, **b**, **c**) Transillumination of the skull in a neonate with massive hydrocephaly, difficult to differentiate from hydranencephaly

Hydrolethalus Syndrome

Contents

Hydrolethalus syndrome was coined by Salonen et al. in 1981 in patients with severe CNS malformations, hydrocephalus, micrognathia, cleft lip/palate, lung hypoplasia club foot, and polydactyly, distinguishable from the Meckel syndrome by the absence of polycystic kidneys (Salonen et al. 1981). The majority of cases were reported from Finland, rarely from other races (Adetoro et al. 1984; Shotelersuk et al. 2001).

Synonyms and Related Disorders

Salonen-Herva-Norio Syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Anyane-Yeboa et al. 1987; Salonen and Herva 1990)
2. Hydrolethalus syndrome locus: assigned to 11q23–11q25 in Finnish families (Visapaa et al. 1999)
3. *HYLS1* gene mutation (Mee et al. 2005; Paetau et al. 2008)
    1. Responsible for hydrolethalus syndrome in the Finnish population
    2. *HYLS1* c.632A > G (D211G) mutation: the common mutation carried in the Finnish population

Clinical Features

1. A lethal condition: stillborn or died within a few hours of birth in majority of cases.
2. Rarely, a mild case may survive over 5 months (Aughton and Cassidy 1987).
3. Hydramnios.
4. Severe midline CNS malformations:
    1. A midline cerebral cleft: more common
    2. The absence of the corpus callosum
    3. The absence of the septum pellucidum
    4. Holoprosencephaly (Bachman et al. 1990)
    5. Hydrocephalus secondary to aqueductal stenosis
    6. Dorsal midline defect of the foramen magnum, forming a keyhole-shaped opening (occipitoschisis)
    7. Cerebellar heterotopias

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_122

8. Brain stem malformations
9. Cerebral gyral abnormalities
10. Absent olfactory lobes
11. Hypothalamic hamartomas
12. Dandy-Walker malformation (Morava et al. 1996)
13. Optic nerve coloboma and hypoplasia (Kivela et al. 1996)

5. Craniofacial features:
   1. Microphthalmia
   2. Nasal anomalies
   3. Small mandible
   4. Cleft lip/palate
   5. Small tongue
   6. Low-set, malformed ears
6. Pulmonary anomalies:
   1. Abnormal larynx, trachea, and bronchi
   2. Pulmonary hypoplasia/agenesis (Toriello and Bauserman 1985)
   3. Defective lung lobulation
7. Congenital heart defects:
   1. Ventricular septal defect
   2. Open foramen ovale
   3. Common atrioventricular canal
8. Renal anomalies.
9. Duplex/bicornis uterus.
10. A typical "keyhole" occipital bone defect.
11. Polydactyly (Bachman et al. 1990):
    1. Hands: always postaxial
    2. Feet: almost always preaxial
12. Differential diagnosis (Muenke et al. 1991):
    1. Acrocallosal syndrome (Christensen et al. 2000):
       1. Macrocephaly.
       2. Craniofacial anomalies.
       3. Hallux duplication.
       4. Postaxial polydactyly.
       5. Absence of corpus callosum.
       6. Mental retardation.
       7. Reported to display a *GLI3* mutation.
       8. Mutations in the KIF7 gene, encoding a molecule within the Sonic hedgehog (SHH) pathway, have been identified as causative for acrocallosal syndrome but also for the fatal hydrolethalus syndrome and some cases of Joubert syndrome (Ibisler et al. 2015).
    2. Smith-Lemli-Opitz syndrome (severe form) (Rakheja et al. 2004):
       1. Hydrocephalus
       2. Cerebellar hypoplasia
       3. Cardiac anomalies
       4. Genital anomalies
       5. Polydactyly
    3. Orofacialdigital syndrome, type VI:
       1. Cerebellar anomalies
       2. Hypertelorism
       3. Micrognathia
       4. Midline cleft lip
       5. Cleft palate
       6. A small tongue with lingual nodules and multiple frenula
       7. Laryngeal anomalies
       8. Cardiac anomalies
       9. Preaxial polysyndactyly of the hands and feet
       10. Postaxial polysyndactyly of the feet
    4. Pallister-Hall syndrome (Paetau et al. 2008).
       1. Caused by nonsense and splicing mutations of *GLI3* gene at chromosome 7p13
       2. Hypertelorism
       3. Micrognathia
       4. Midline cleft lip
       5. Cleft palate
       6. A small tongue with lingual nodules and multiple frenula
       7. Hamartoma/hamartoblastoma
       8. Laryngeal anomalies
       9. Lung segmental anomalies
       10. Cardiac anomalies
       11. Postaxial polysyndactyly of the feet
    5. Overlap between short-rib polydactyly syndromes and hydrolethalus syndrome (Sharma et al. 1992).
    6. Walker-Warburg syndrome:
       1. Overlapping features
          1. Encephalocele
          2. Agenesis of midline brain structures
          3. Hydrocephalus
       2. Features usually not seen
          1. Eye abnormalities
          2. Polydactyly

7. Pseudotrisomy 13 syndrome (Verloes et al. 1991; Dincsoy et al. 1995).
8. Endocrine-cerebro-osteodysplasia (ECO) syndrome (Oud et al. 2016):
    1. Caused by a recessive mutation (p. R272Q) in intestinal cell kinase (ICK).
    2. Showing significant clinical overlap with ciliary disorders.
    3. Similarities are strongest between ECO syndrome, the Majewski and Mohr-Majewski short-rib thoracic dysplasia (SRTD) with polydactyly syndromes, and hydrolethalus syndrome.
9. Mutations in *KIAA0586* cause lethal ciliopathies ranging from a hydrolethalus phenotype to short-rib polydactyly syndrome (Alby et al. 2015).

Diagnostic Investigations

1. Radiologic studies (Herva and Seppanen 1984)
    1. Skull
        1. Microcephaly
        2. Occipital bone defect continuous with the foramen magnum
        3. A keyhole-shaped defect at the base of the skull
    2. Digital anomalies
        1. Postaxial polydactyly of the hands
        2. Preaxial polydactyly or hallux duplication of the feet
2. Ultrasound or MRI of the brain for delineation of brain anomalies
3. Echocardiogram for delineation of congenital heart defects
4. Molecular genetic study: target mutation analysis of *HYLS1* gene (c.632A > G)

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Recurrence risk: 25%
        2. Unaffected sibs of a proband: two thirds chance of being heterozygotes
    2. Patient's offspring: a lethal entity not surviving to reproduction
2. Prenatal diagnosis
    1. Prenatal ultrasonography (Hartikainen-Sorri et al. 1983; Siffring et al. 1991; Pryde et al. 1993; Aughton 1994; Ammala and Salonen 1995; Norgard et al. 1996; de Ravel et al. 1999; Chan et al. 2004)
        1. Polysyndactyly
        2. CNS abnormality
        3. Congenital heart defects (atrioventricular septal defect or common atrioventricular canal)
    2. Possible for pregnancies at risk when the disease-causing mutation in the family is known
3. Management
    1. Supporting care
    2. No treatment available for the underlying lethal disorder

Hydrops Fetalis

Contents

Hydrops fetalis is a condition in which fluid accumulates in the serous cavities and/or in the soft tissues of the fetus. It is classified as immune if there is an indication of a fetomaternal blood group incompatibility, otherwise it is classified as nonimmune. The incidence of nonimmune hydrops fetalis is estimated to be approximately 1 in 2,500 to 1 in 3,500 neonates.

Synonyms and Related Disorders

Hydrops fetalis syndrome; Immune hydrops; Nonimmune hydrops

Genetics/Basic Defects

1. Causes of immune hydrops (IH)
    1. Rh-D disease (approximately 90% of immune hydrops)
        1. Prior to the 1960s, this is the most common cause (up to 80%) of all cases with hydrops fetalis. The incidence of rhesus isoimmunization has declined steadily because of the widespread use of anti-D gamma globulin. The majority of hydrops is now of the nonimmune type (Holzgreve et al. 1985).
        2. Mother (Rh−), father (Rh+), and fetus (Rh+).
        3. After sensitization, maternal Rh antibody (IgG anti-D) crosses the placenta and destroys the Rh-positive fetal red blood cells. It results in fetal anemia.
        4. Previous pregnancy, including maternal-fetal blood mixing.
        5. Previous abortion (spontaneous, missed, therapeutic).
        6. First trimester bleeding.
        7. Trauma.
        8. Blood transfusion.
    2. ABO incompatibility (rare, overall incidence about 1%)
        1. ABO incompatible pregnancies (about 20%) in which only 5% of these cases lead to hydrops
        2. Mother (nearly always O+ with antibodies to A, B, or both)
        3. Fetus (A, B, or AB)
    3. Other autoimmune causes (targeting other RBC antigens)
        1. Anti-Lewis antibodies: benign ("Lewis lives")

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_123

2. Anti-Kell antibodies (the second most common type accounting for about 10% of antibody-mediated severe fetal anemia): mild to severe hydrops ("Kell kills")
3. Anti-Duffy antibodies: mild to severe hydrops ("Duffy dies")

2. Pathophysiology of immune hydrops
   1. Sensitization of the mother to an antigen (usually Rh-D)
      1. Presence of antigen on fetal RBC but not on mother's RBC
      2. Primary response generally a maternal IgM anti-RBC response
   2. Production of IgG antibodies by the mother on the secondary exposure. The IgG antibodies can cross the placenta
   3. Destruction of fetal RBC by maternal anti-fetal RBC antibodies
      1. A Coombs' positive process
      2. Destruction most likely mediated by complement and macrophages
      3. Jaundice frequently observed secondary to increased bilirubin production
   4. Compensatory increase in fetal cardiac output due to decreased fetal hematocrit
   5. Heart failure resulting from high cardiac output by the fetal heart
      1. Edema
      2. Ascites
      3. Circulatory failure with fetal death *in utero*
3. Conditions associated with nonimmune hydrops fetalis (NIHF). Nonimmune type now represents majority of hydrops fetalis after the practice of anti-D gammaglobulin prophylaxis since the 1960s (Holzgreve et al. 1985; Watson and Campbell 1986; Poeschmann et al. 1991; Anandakumar et al. 1996; Heinonen et al. 2000; Ismail et al. 2001).
   1. Cardiovascular disorders (5.3–26%, the most frequent underlying cause of NIHF) (Knilans 1995; Bukowski and Saade 2000)
      1. Tachyarrhythmia (supraventricular tachycardia, atrial flutter)
      2. Bradyarrhythmias (complete heart block)
      3. Congenital heart block
      4. Hypoplastic left heart syndrome (31%)
      5. Endocardial cushion defects (13%)
      6. Agenesis of the ductus venosus
      7. Other anatomic defects of the heart
      8. Premature closure of the ductus arteriosus
      9. Generalized arterial calcification
      10. Cardiomyopathy
      11. Myocarditis (Coxsackie virus or CMV)
      12. Cardiac rhabdomyoma
      13. Intracardiac teratoma
   2. Chromosome abnormalities (7.5–77.8%, the second most frequent underlying causes of NIH)
      1. Trisomies
         1. Trisomy 21
         2. Trisomy 18
         3. Trisomy 13
      2. Turner syndrome (most common chromosome anomaly)
      3. Triploidies
      4. Deletions
      5. Others
   3. Recognizable syndromes (2.2–27.6%)
      1. Skeletal dysplasias (van Maldergem et al. 1992)
         1. Thanatophoric dysplasia
         2. Arthrogryposis multiplex congenita
         3. Asphyxiating thoracic dystrophy
         4. Hypophosphatasia
         5. Osteogenesis imperfecta
         6. Achondrogenesis
         7. Saldino-Noonan syndrome
         8. McKusick-Kaufman syndrome
         9. Klippel-Trenaunay-Weber syndrome
         10. Conradi syndrome
         11. Other types of skeletal dysplasias
      2. Metabolic diseases (Stone and Sidransky 1999)
         1. Mucopolysaccharidosis type IV Morquio disease (β-galactosidase deficiency)
         2. Mucopolysaccharidosis Type VII (β-glucuronidase deficiency)
         3. I-cell disease
         4. Niemann-Pick disease
         5. Gaucher disease

6. Sialidosis
7. Galactosialidosis
8. Salla disease (Finnish type sialuria)
9. Wolman disease
10. Farber disease
11. Carnitine deficiency
12. Disorder of glycosylation (Léticée et al. 2010)

3. Other genetic syndromes
   1. Pena-Shokeir syndrome
   2. Neu-Laxova syndrome
   3. Recessive cystic hygroma
   4. Multiple pterygium syndrome
   5. Meckel syndrome
   6. Caudal regression syndrome
   7. Noonan syndrome
   8. Tuberous sclerosis
   9. Myotonic dystrophy
   10. X-linked dominant disorders with male lethality (e.g., hypomelanosis of Ito)
   11. Other single-gene disorders

4. Twin pregnancy (twin-twin transfusion syndrome) (3–8%)
5. Hematologic disorders (10–27%) (Arcasoy and Gallagher 1995)
   1. Intrinsic hemolysis
      1. α-thalassemia syndromes (Homozygous α-thalassemia-1 is the most common cause of hydrops fetalis in Southeast Asia) (Lam et al. 1999)
      2. G6PD deficiency
      3. Pyruvate kinase deficiency
      4. Glucosephosphate isomerase deficiency
      5. Spectin abnormalities
   2. Extrinsic hemolysis (Kasabach-Merritt syndrome)
   3. Hemorrhage
      1. Fetomaternal hemorrhage
      2. Twin-twin transfusion syndrome
      3. Fetal hemorrhage
   4. Fetal liver and bone marrow replacement syndromes
      1. Transient myeloproliferative disorder
      2. Congenital leukemia
   5. Red cell aplasia and dyserythropoiesis
      1. Parvovirus B19 infection
      2. Blackfan-Diamond syndrome
      3. Congenital dyserythropoiesis
6. Thoracic abnormalities (2.5–13%)
   1. Diaphragmatic hernia
   2. Congenital cystic adenomatous malformation of the lung
   3. Extralobar pulmonary sequestration
   4. Congenital hydrothorax or chylothorax
   5. Mediastinal teratoma
   6. Laryngeal atresia
   7. Pulmonary hypoplasia
7. Genitourinary malformations (2.5–3.5%)
   1. Urethral obstruction
   2. Posterior urethral valves
   3. Neurogenic bladder with reflux
   4. Ureterocele
   5. Prune belly syndrome
   6. Upper urinary tract obstruction
   7. Renal dysplasia
   8. Cloacal malformations
8. Gastrointestinal anomalies
   1. Jejunal atresia
   2. Midgut volvulus
   3. Malrotation of the intestine
   4. Duplication of the intestinal tract
   5. Meconium peritonitis
   6. Gastroschisis
   7. Tracheoesophageal fistula
9. Hepatic diseases
   1. Polycystic disease of the liver
   2. Hepatic fibrosis
   3. Cholestasis
   4. Biliary atresia
   5. Hepatic vascular malformations
   6. Familial cirrhosis
10. Neurological abnormalities
    1. Encephalocele
    2. Intracranial hemorrhage
    3. Cerebral aneurysm
    4. Intracranial arteriovenous malformation
11. Maternal diseases/complications
    1. Medications (indomethacin taken to stop premature labor causing fetal ductus closure and secondary non-immune hydrops fetalis)
    2. Mirror syndrome
       1. Maternal edema

2. Preeclampsia
3. Systemic diseases
    1. Severe diabetes mellitus
    2. Severe anemia
    3. Hypoproteinemia
4. Antepartum/postpartum hemorrhage
5. Theca lutein cyst development

12. Placenta-umbilical cord abnormalities
    1. Chorioangioma
    2. Chorionic vein thrombosis
    3. Fetomaternal transfusion
    4. Placental and umbilical vein thrombosis
    5. Umbilical cord torsion
    6. True cord knots
    7. Angiomyxoma of the umbilical cord
    8. Aneurysm of umbilical artery
13. Intrauterine infections (2–17.5%)
    1. Viruses
        1. Parvovirus B19
        2. CMV
        3. Rubella
        4. Adenovirus
        5. Enteroviruses
        6. Coxsackie virus
        7. Polio
        8. Influenza B
        9. Respiratory syncytial virus
        10. Congenital hepatitis
        11. Herpes simplex, type I
    2. Bacteria/spirochetes
        1. *Treponema pallidum*
        2. *Listeria monocytogenes*
        3. *Leptospira interogans*
    3. Parasites
        1. *Toxoplasma gondii*
        2. *Trypanosoma cruzii*
    4. Other
        1. Chlamydia
        2. *Ureaplasma urealyticum*
14. Miscellaneous conditions
    1. Congenital lymphedema
    2. Congenital hydrothorax or chylothorax
    3. Polysplenia syndrome
    4. Amniotic band syndrome
    5. Congenital neuroblastoma
    6. Tuberous sclerosis
    7. Ovarian cyst torsion
    8. Fetal trauma
    9. Large fetal angioma
    10. Sacrococcygeal teratoma
    11. Cloacal malformation
15. Idiopathic (without an identifiable cause)

4. Pathophysiology of nonimmune fetal hydrops
    1. Cardiac failure directly involving the heart
        1. Arrhythmias
        2. Malformations
        3. Myocarditis
        4. Infarction
        5. Cardiomyopathy
    2. Abnormal vascularization causing high-output cardiac failure
        1. Twin-twin transfusion syndrome
        2. Acardiac twinning
        3. Tumors
        4. AV fistulas
        5. Placental vascular anomalies
    3. Profound anemia
        1. Hemolytic anemias
        2. Parvovirus B19 (fifth disease)
        3. Fetal-maternal hemorrhage
        4. Alpha-thalassemia, hemoglobin Bart's
        5. G6PD deficiency
        6. Glucose-6-phosphate isomerase deficiency
        7. Pyruvate kinase deficiency
        8. Defects of red cell membrane
    4. Decreased plasma oncotic pressure
        1. Congenital nephrosis
        2. Hepatic necrosis
    5. Fetal infections
        1. Increased capillary permeability (anoxia due to congenital infection)
        2. Infection of erythroid progenitor cells (e.g., parvovirus B19)
        3. Myocarditis (e.g., adenovirus, Coxsackie virus)
        4. Hepatic destruction (e.g., syphilis)
    6. Obstruction of venous return
        1. Congenital cystic adenomatoid malformation
        2. Fetal closure or restriction in the size of the ductus arteriosus, foramen ovale or ductus venosus

3. Diaphragmatic hernia
4. Pulmonary sequestration
5. Tumors of the heart, lungs, abdomen, or pelvis
6. Umbilical cord lesions
7. Obstruction of lymphatic flow (e.g., Turner syndrome)

5. Etiologies and mechanisms of nonimmune hydrops fetalis (Norton et al. 2015)
   1. Cardiovascular (17–35%): increased central venous pressure
   2. Chromosomal (7–16%): cardiac anomalies, lymphatic dysplasia, abnormal myelopoiesis
   3. Hematologic (4–12%): anemia, high-output cardiac failure; hypoxia (alpha thalassemia)
   4. Infectious (5–7%): anemia, anoxia, endothelial cell damage, and increased capillary permeability
   5. Thoracic (6%): vena caval obstruction or increased intrathoracic pressure with impaired venous return
   6. Twin-twin transfusion (3–10%): hypervolemia and increased central venous pressure
   7. Urinary tract abnormalities (2–3%): urinary ascites; nephrotic syndrome with hypoproteinemia
   8. Gastrointestinal (0.5–4%): obstruction of venous return; gastrointestinal obstruction and infarction with protein loss and decreased colloid osmotic pressure
   9. Lymphatic dysplasia (5–6%): impaired venous return
   10. Tumors, including chorioangiomas (2–3%): anemia, high-output cardiac failure, hypoproteinemia
   11. Skeletal dysplasias (3–4%): hepatomegaly, hypoproteinemia, impaired venous return
   12. Syndromic (3–4%): various mechanisms
   13. Inborn errors of metabolism (1–2%): visceromegaly and obstruction of venous return, decreased erythropoiesis and anemia, and/or hypoproteinemia
   14. Miscellaneous (3–15%)
   15. Unknown (15–25%)

Clinical Features

1. Maternal history associated with hydropic infants
   1. Previous history of hydrops
   2. Severe maternal anemia
   3. Associated polyhydramnios in at least 50% of hydropic fetuses
   4. Size-date discrepancy
   5. Twin gestation
   6. Maternal diabetes mellitus
   7. Maternal pregnancy-induced hypertension/preeclampsia
   8. Fetal arrhythmia
   9. Placentomegaly
   10. Positive antibody screen
   11. Syphilis or other TORCH infections
2. Edema due to right-sided heart failure
   1. Circulatory failure
   2. Ascites
      1. First sign of fetal hydrops caused by anemia
      2. Hypertension
      3. Hypoalbuminemia
      4. Prune belly secondary to marked fetal ascites
   3. Pleural effusions
   4. Pericardial effusions
   5. Jaundice (hyperbilirubinemia)
3. Hemolysis with extramedullary hematopoiesis
4. Hepatosplenomegaly
   1. A hallmark for immune hydrops
   2. Absent in nonimmune hydrops fetalis
5. Fetal prognosis: presence of fetal hydrops often indicating fetal compromise with a significant risk of mobility and death
   1. Cardiovascular disorders
      1. Best prognosis among abnormalities underlying nonimmune hydrops.
      2. Cumulative survival rate: 29%.
      3. Treatment of tachycardia improves prognosis.
   2. Chromosome abnormalities: 2% survival rate
   3. Syndromes: 5% survival rate
   4. Fetal infections: 19% cumulative survival rate
   5. Thoracic lesions: one of the best cumulative prognosis, 26%

6. Fetofetal transfusion syndrome: 20% survival rate
7. Extremely poor prognosis
    1. Anemia secondary to parvovirus infection.
    2. Anemia resulting from fetomaternal hemorrhage.
    3. α-thalassemia: All fetuses with the Hb Bart's hydrops fetalis syndrome succumb to severe fetal hypoxia in utero during the third trimester of gestation or within hours after birth (Chui and Waye 1998).
8. Good prognosis for psychomotor development in survivors with nonimmune hydrops fetalis (Haverkamp et al. 2000)

6. Morbidity (Bukowski and Saade 2000)
    1. Morbidity depending on the underlying disorder
    2. Short-term morbidity high (neonate requires difficult resuscitation, long and intensive hospitalization, and multiple invasive procedures)
    3. Relatively low long-term morbidity in NIHF in children diagnosed prenatally
7. Mortality (Hutchinson et al. 1982)
    1. Mortality rate: 50–98%
    2. Contribute to 3% of perinatal mortality
    3. Mortality depending on the underlying disorder

Diagnostic Investigations

1. Diagnostic evaluation of immune hydrops
    1. ABO and Rh typing and a serum antibody screen (positive indirect Coombs test) for every pregnant woman as early as possible during each pregnancy
    2. Spectrophotometric estimation of bilirubin pigments in the amniotic fluid, obtained by amniocentesis in selected patients, to estimate the risk of severe hemolytic disease while the fetus is still in utero
    3. Direct Coombs test on cord blood
        1. Nearly always positive in Rh-induced hemolytic disease of newborns (HDN)
        2. Frequently but not always positive in ABO-induced HDN
    4. Usually increased cord blood bilirubin and decreased cord blood hemoglobin in severe HDN
2. Diagnostic evaluation of newborn babies with nonimmune hydrops (Carlton et al. 1989; Steiner 1995)
    1. Cardiovascular disorders
        1. Echocardiogram
        2. Electrocardiogram
    2. Thoracic abnormalities
        1. Chest radiographs
        2. Pleural fluid examination
    3. Hematologic disorders
        1. Complete blood cell count
        2. Differential
        3. Platelet count
        4. Blood type
        5. Coombs test
        6. Blood smear for morphology
        7. Hemoglobin electrophoresis
    4. Gastrointestinal abnormalities
        1. Abdominal radiographs
        2. Abdominal ultrasound
        3. Liver function tests
        4. Peritoneal fluid examination
        5. Total protein
        6. Albumin
    5. Renal malformations
        1. Urinalysis
        2. BUN
        3. Creatinine
    6. Genetics
        1. Chromosome analysis (Santolaya et al. 1992)
        2. Skeletal radiographs
    7. Congenital infections: viral cultures or serology (Barron and Pass 1995)
        1. Parvovirus B19
            1. Maternal infection: specific IgM and IgG
            2. Fetal/neonatal infection: specific IgM, virus detection by PCR
        2. Syphilis
            1. Maternal infection: RPR or VDRL
            2. Fetal/neonatal infection: RPR or VDRL, dark-field examination of material from lesions

3. CMV
   1. Maternal infection: CMV-IgM or IgG seroconversion
   2. Fetal/neonatal infection: isolation of virus from amniotic fluid, fetal, or neonatal body fluid
4. HSV
   1. Maternal infection: HSV culture of lesion
   2. Fetal/neonatal infection: HSV culture of amniotic fluid, fetal tissue, or neonate
5. Toxoplasmosis
   1. Maternal infection: capture IgM, specific IgG
   2. Fetal/neonatal infection: capture IgM ELISA
6. Rubella
   1. Maternal infection: specific IgM and IgG or proven exposure plus compatible illness
   2. Fetal/neonatal infection: isolation of virus from fetal or neonatal body fluid, rubella IgM

8. Autopsy indicated for stillbirth or perinatal death including examination of the placenta and babygram (Norton 1994; Rodriguez et al. 2002)

Genetic Counseling

1. Recurrence risk
   1. Patient's sib
      1. Immune hydrops fetalis: will be affected unless sensitization is prevented
      2. Nonimmune hydrops fetalis
         1. Sporadic: no increased risk
         2. Autosomal recessive disorder: 25%
         3. Autosomal dominant disorder: not increased unless a parent is affected
         4. Chromosome disorder: increased especially when a parent is a translocation carrier
   2. Patient's offspring
      1. Immune hydrops fetalis: recurrence risk not increased
      2. Nonimmune hydrops fetalis
         1. Sporadic: no increased risk
         2. Autosomal recessive disorder: not increased unless the spouse is a carrier
         3. Autosomal dominant disorder: 50%
         4. Chromosome disorder: increased if the patient survives to reproductive age
2. Prenatal evaluation of immune hydrops fetalis
   1. Rh testing and ABO typing indicated for all pregnancies
   2. Positive maternal antibody screen (indirect Coombs test)
   3. Suspicious for immune hydrops
      1. Cord blood for testing of hemolysis and hematocrit
      2. Amniocentesis for bilirubin
   4. Specific testing for antibodies in women with previous pregnancy losses
   5. Doppler ultrasonography (Mari et al. 2000)
      1. Used to measure peak velocity of systolic blood flow in fetus
      2. Increased peak systolic blood flow velocity in fetuses with anemia
      3. Increased systolic velocity: 100% sensitive to fetal anemia
   6. Prenatal diagnosis of fetal Rh-D status by molecular analysis (Lo et al. 1998)
3. Maternal evaluation of nonimmune hydrops fetalis (Holzgreve et al. 1984, 1985)
   1. Complete blood count and indices for hematologic disorders
   2. Hemoglobin electrophoresis (α-thalassemia)
   3. Kleihauer-Betke stain for evidence of fetomaternal hemorrhage
   4. Maternal blood chemistry for fetal red cell enzyme deficiency
      1. Glucose-6-phosphate deficiency screen
      2. Pyruvate kinase carrier status
   5. Infection screening
      1. Syphilis by VDRL
      2. TORCH titers
      3. Parvovirus titers
      4. Group B streptococcus
      5. Listeria monocytogenes
   6. Autoantibody screen
      1. Systemic lupus erythematosus

2. Anti-Ro (anti-SS-A) and Anti-La (anti-SS-B) antibody titers for Sjogren's syndrome
7. Fetal echocardiography for presence of congenital heart defects

4. Prenatal ultrasonography (Forouzan 1997)
   1. Immune hydrops secondary to α-thalassemia (Tongsong et al. 1996)
      1. Hepatosplenomegaly (>95%)
      2. Cardiomegaly (>95%)
      3. Edematous placenta (>95%)
      4. Ascites (>95%)
      5. Oligohydramnios (82%)
      6. Subcutaneous edema (75%)
      7. Decreased fetal movement (74%)
      8. Cord edema (63%)
      9. Enlarged umbilical vessel (62%)
      10. Pericardial/pleural effusion (15%)
   2. Nonimmune hydrops (McGillivray and Hall 1987; Jauniaux 1997)
      1. Fetal ascites
      2. Fetal pleural effusion
      3. Fetal pericardial effusion (the earliest finding)
      4. Fetal skin thickening
      5. Maternal polyhydramnios
      6. Placentomegaly, especially Rh disease or chorioangioma
      7. Cystic hygroma as early as 13 weeks of gestation
5. Fetal evaluation of nonimmune hydrops fetalis
   1. Fetal echocardiography, M-mode, pulsed, and color flow Doppler
      1. Congenital heart defects
      2. Fetal rhythmic abnormalities
      3. Cardiac biometry
   2. Doppler flow velocity studies
      1. Umbilical artery
      2. Middle cerebral artery
      3. Tricuspid ejection velocity
   3. Amniocentesis
      1. Amniotic fluid index
      2. Fetal karyotype (chromosome abnormality) (Jauniaux et al. 1990; Iskaros et al. 1997)
      3. Amniotic fluid viral cultures
      4. Alpha-fetoprotein (congenital nephrosis, sacrococcygeal teratomas)
      5. Isolation of CMV virus for identification of CMV DNA by PCR
      6. Specific metabolic tests
         1. Tay-Sachs disease
         2. Gaucher disease
         3. GM_1 gangliosidosis
      7. Metabolic disease screening panel
         1. Acid sphingomyelinase deficiency
         2. Deficient cholesterol esterification
         3. Acid β-glucosidase deficiency
         4. Acid β-galactosidase deficiency
         5. Acid sialidase deficiency
         6. Sialidase deficiency
         7. β-galactosidase deficiency
         8. Ceramidase deficiency
         9. Glucose phosphate isomerase deficiency
         10. *N*-acetylglucosamine phosphotransferase deficiency
      8. Restriction endonucleases tests (e.g., thalassemias)
   4. Fetal blood sampling
      1. Rapid karyotype (chromosome abnormality)
      2. Fetal complete blood count (fetal anemia)
      3. Blood group and Coombs test
      4. Hemoglobin electrophoresis (α-thalassemia)
      5. Fetal plasma analysis for specific IgM (e.g., CMV-specific IgM antibody, PCR)
      6. G6PD in male fetuses
      7. Fetal plasma albumin (fetal hypoalbuminemia)
      8. Metabolic testing
         1. Tay-Sachs disease
         2. Gaucher disease
         3. GM_1 gangliosidosis
   5. Fluid aspirated for biochemistry and viral screen
      1. Pleural effusion
      2. Ascites
      3. Amniotic fluid
   6. Placenta
      1. Morphology
      2. Thickness
6. Management (Machin 1989; Jones 1995)
   1. Immune hydrops fetalis

1. Prevent sensitization by Rhogam or Rh immune globulin
2. Prevent fetal heart failure when mother has sensitization reaction
3. Fetal transfusion for fetal anemia via cordocentesis (Socol et al. 1987; Saltzman et al. 1989; Sosa et al. 1998)
4. Induction of labor
5. Postpartum exchange blood transfusion to prevent kernicterus, the most feared complication of Rh-induced HDN

2. Nonimmune hydrops fetalis (Swain et al. 1999)
   1. Screen tests to detect couples at risk for having a fetus with the Hb Barts hydrops fetalis by simple blood counts and hemoglobin electrophoresis
   2. Neonatal resuscitation (McMahan and Donovan 1995)
   3. Intrauterine or immediate postdelivery transfusions to babies (e.g., homozygous α-thalassemia, Parvovirus B19 infection)
   4. Fetal cardiac arrhythmias treated by transplacental antiarrhythmic therapy
   5. Flecainide acetate for fetal supraventricular tachycardia with hydrops fetalis
   6. Continuous arteriovenous hemodilution for fluid overload in newborns with hydrops fetalis
   7. Pleurocentesis in utero to drain pleural effusion to minimize pulmonary hypoplasia
   8. Treatment of maternal infection (Barron and Pass 1995)
      1. Parvovirus B19: intrauterine transfusion
      2. Syphilis: IV penicillin
      3. CMV: No pharmaceutical regimens available for treatment of maternal and fetal CMV infections. Treatment with antiviral agents (ganciclovir, foscarnet) is limited to severe infections (CMV retinitis) in immunocompromised patients and not currently used in pregnancy
      4. HSV: acyclovir warranted in disseminated disease; fetal effect unknown
      5. Toxoplasmosis: spiramycin and/or pyrimethamine, sulfadiazine, and folinic acid
   9. Fetal surgery (Bullard and Harrison 1995) attempted for congenital cystic adenomatoid malformation, pulmonary sequestration, fetal pleural effusions, and sacrococcygeal teratoma
   10. In utero therapy (Anandakumar et al. 1996)
       1. Fetal intravascular blood transfusion
       2. Direct fetal drug therapy
       3. Fetal pleuro-amniotic shunting
   11. Fetal therapy options for selected etiologies of nonimmune hydrops (Norton et al. 2015)
       1. Cardiac tachyarrhythmia, supraventricular tachycardia, atrial flutter, or atrial fibrillation
          1. Maternal transplacental administration of antiarrhythmic medication(s)
          2. Treatment with antiarrhythmic medication unless gestational age is close to term or there is maternal or obstetrical contraindication to therapy
       2. Fetal anemia secondary to parvovirus infection or fetomaternal hemorrhage
          1. Fetal blood sampling followed by intrauterine transfusion
          2. Fetal intrauterine transfusion if anemia is confirmed, unless pregnancy is at an advanced gestational age and risks associated with delivery are considered to be less than those associated with procedure
       3. Fetal hydrothorax, chylothorax, or large pleural effusion associated with bronchopulmonary sequestration
          1. Fetal needle drainage of effusion or placement of thoracoamniotic shunt; if gestational age is advanced, needle drainage prior to delivery in selected cases

2. Consider drainage of large unilateral pleural effusion(s) resulting in NIHF or, if gestational age is advanced, consideration of needle drainage prior to delivery
4. Fetal CPAM (congenital pulmonary airway malformation)
    1. Macrocystic type: fetal needle drainage of effusion or placement of thoracoamniotic shunt; microcystic type: maternal administration of corticosteroids, betamethasone 12.5 mg IM q24h Â 2 doses, or dexamethasone 6.25 mg IM q12 h Â 4 doses
    2. Consider drainage of large macrocystic CPAM that has resulted in NIHF; if large microcystic CPAM has resulted in NIHF, management options include maternal corticosteroid administration
5. TTTS (twin-twin transfusion sequence) or TAPS (twin-anemia polycythemia sequence)
    1. Laser ablation of placental anastomoses or selective termination
    2. Consideration of fetoscopic laser photocoagulation of placental anastomoses for TTTS or TAPS that has resulted in NIHF <26 weeks
6. Twin-reversed arterial perfusion sequence
    1. Percutaneous radiofrequency ablation
    2. Referral for consideration of percutaneous radiofrequency ablation that has resulted in NIHF

12. Survival (Derderian et al. 2015)
    1. Fetal intervention in well-selected patients improves survival.
    2. Those who received medical therapy (percutaneous or fetoscopic intervention) were more likely to survive than those who received no treatment.
    3. There is still a high rate of mortality in hydropic fetuses undergoing open fetal surgery (possibly secondary to a significant inflammatory response from the surgery coupled with the underlying disease state, which often leads to preterm delivery).

Fig. 1 An 18-week gestation fetus with hydropic change of the scalp and chest

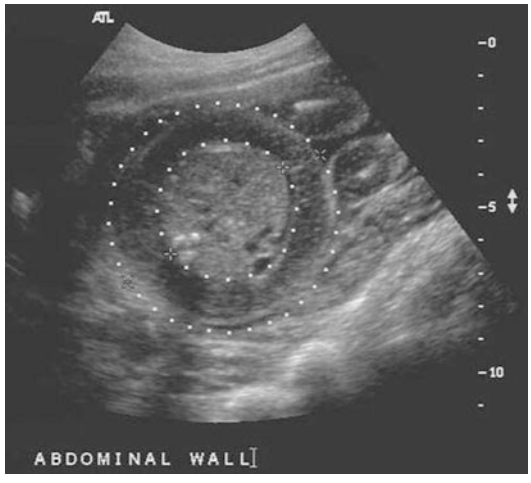

Fig. 2 A fetus showing hydropic change of the abdominal wall

Fig. 3 (**a**–**c**) A macerated fetus, a newborn, and an infant with nonimmune hydrops fetalis

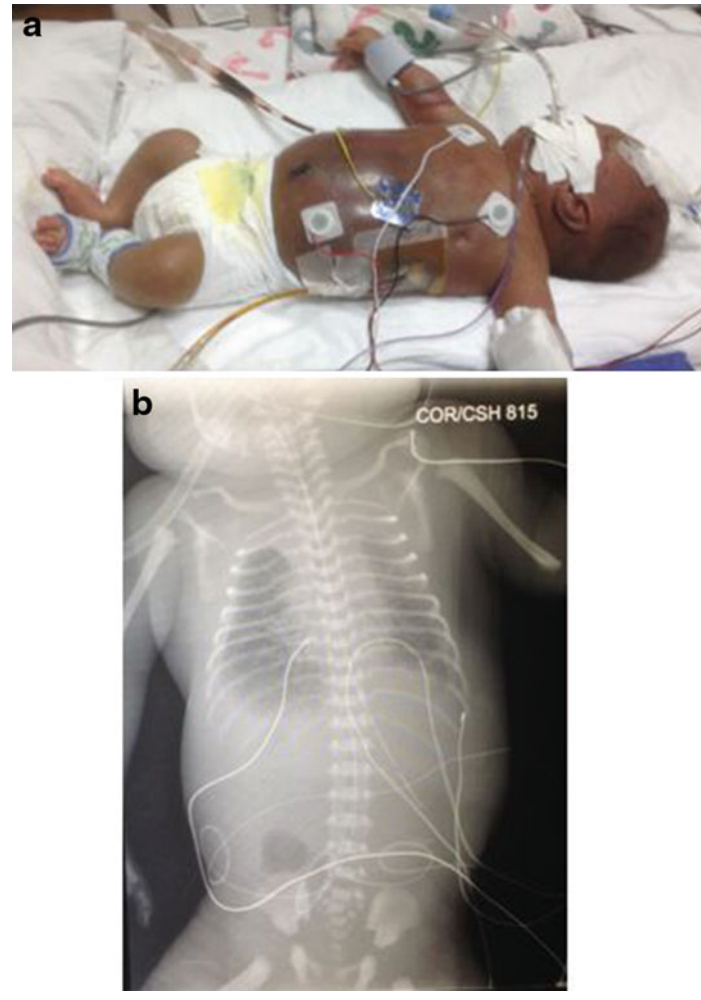

Fig. 4 (**a**, **b**) This premature baby boy was delivered at 29 and 5/7 weeks via cesarean section. Prenatal ultrasound examinations showed maternal polyhydramnios, intrauterine growth retardation, and hydrops with large pleural effusion and ascites. After birth, he was noted to have generalized edema in severe respiratory distress (**a**). There was a short neck with extra skin folds at the back of the neck. He was hypotonic and had acrocyanosis noted with mottled skin and micropenis with cryptorchidism. The AP view of the babygram (**b**) showed generalized edema, pleural effusion, ascites, and hemivertebra of the sacrum (Courtesy of Dr. Lea Bonifacio)

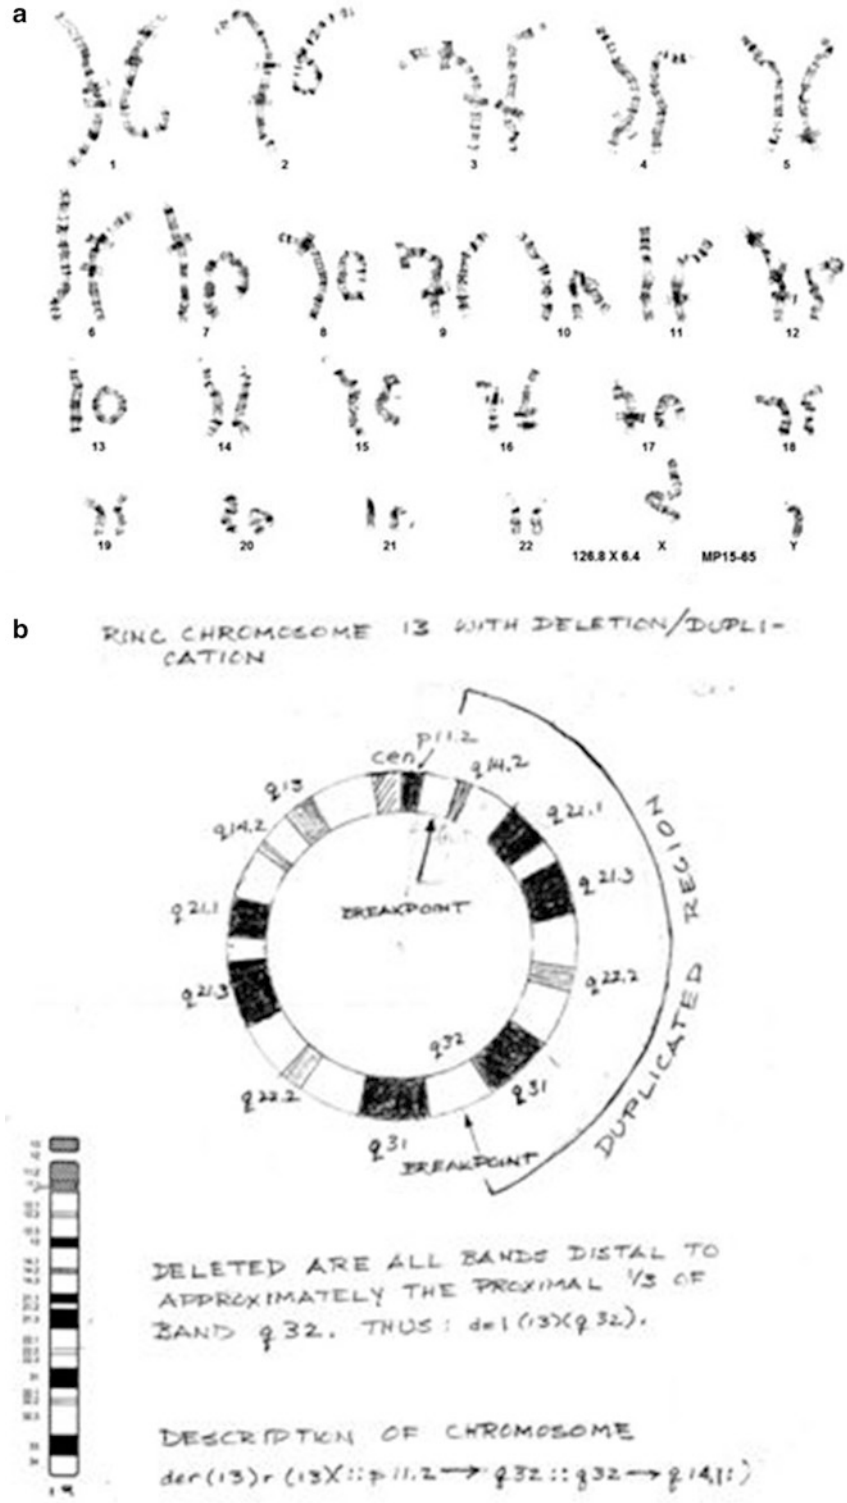

Fig. 5 (**a**, **b**) Chromosome analysis showed the presence of a normal chromosome 13 and a ring chromosome 13 with duplication of the region involving q14.1 through q32 and deletion involving all bands distal to approximately the proximal one-third of the band q32 (**a**). Idiogram (**b**) shows ring chromosome with deletion/

Fig. 5 (continued) duplication regions (Courtesy of Dr. Leonard Prouty).The cytogenetic finding was confirmed by chromosome microarray analysis (Mayo Clinic Laboratories), which indicated the presence of a complex ring chromosome 13 with a duplication of 42.7 megabases of material from 13q14.3[dup(13q14.3q32.1)] and an 18.6 megabase terminal deletion from 13q32.1 to 13q34[del (13q32.1q34)]

Hyper-IgE Syndrome

Contents

Hyper-IgE syndrome (HIES) is a rare, hereditary multisystem disorder characterized clinically by hyperimmunoglobulinemia E, recurrent infections, and eczematoid dermatitis. In 1966, Davis et al. reported two patients with Job's syndrome with recurrent, "cold," staphylococcal abscesses (Davis et al. 1966). In 1972, Buckley et al. expanded the clinical picture by adding elevated immunoglobulin E (IgE) (Buckley et al. 1972).

Synonyms and Related Disorders

Buckley syndrome; Job syndrome

Genetics/Basic Defects

1. Inheritance (Erlewyn-Lajeunesse 2000)
    1. Autosomal dominant with variable penetrance and expressivity
    2. Linkage to a region on chromosome 4q21demonstrated in several affected families (Grimbacher et al. 1999b)
    3. An upregulating mutation in the interleukin-4 receptor gene on chromosome 16, demonstrated in some patients with hyper-IgE syndrome
    4. Autosomal recessive hyper-IgE syndrome: a similar but distinct syndrome reported by Renner et al. (2004)
2. Autosomal dominant hyper-IgE syndrome (AD-HIES): caused by dominant-negative mutations in signal transducer and activator of transcription 3 (*STAT3*) in most cases of autosomal dominant HIES (Holland et al. 2007; Minegishi et al. 2007; Jiao et al. 2008; Renner et al. 2008)
    1. Most cases are sporadic.
    2. When familial, all individuals carrying the mutation have the HIES phenotype.
    3. Somatic mosaicism may be present in both STAT3- deficient and DOCK8-deficient HIES. Yet, while it may lead to an intermediate phenotype in STAT3-deficient HIES, mosaicism is usually insufficient to rescue DOCK8-deficient patients from severe affection (Farmand and Sundin 2015).
3. Autosomal recessive hyper-IgE syndrome (AR-HIES) (Freeman and Holland 2009; Engelhardt et al. 2009)
    1. Homozygous mutation of *Tyk2* with a four nucleotide deletion resulting in a premature stop codon reported in one patient

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_124

(Minegishi et al. 2006). This patient had the following common features of AR-HIES:
   1. Eczema
   2. Viral infections
   3. Recurrent sinopulmonary infections
   4. Bacille Calmette-Guerin and *Salmonella* infections, classic for IL-12/IFN-gamma defects
2. Mutations of Tyk2 have been absent in the other reported cases of AR-HIES (Woellner et al. 2007).
3. Recently, mutations in phosphoglucomutase 3 (encoding PGM3, which is involved in the protein glycosylation pathway) have been identified in autosomal recessive forms of hyper-IgE syndromes (Yang et al. 2014). Elevation of IgE in patients with *PGM3* mutations and atopic conditions might be caused by defective glycosylation of IgE or its receptors.
4. Homozygous mutations (large deletions and point mutations) in the dedicator of cytokinesis 8 (*DOCK8*) identified recently in most patients with AR-HIES (Engelhardt et al. 2009). Mutations in DOCK8 result in autosomal recessive hyper-IgE syndrome with combined immunodeficiency (Aydin et al. 2015)

Clinical Features

1. Classic triad (77%) (Grimbacher et al. 1999a; Erlewyn-Lajeunesse 2000)
   1. Abscesses
   2. Pneumonia
   3. An elevated IgE
2. Skin manifestations (Buckley 2001; Minegishi and Saito 2012)
   1. Onset with distinctive neonatal rash
      1. Newborn rash
      2. Typically pruritic, secondary to intradermal mast cell histamine release triggered by the elevation of available IgE
      3. Often lichenified
      4. A distribution atypical for true atopic dermatitis
   2. Chronic eczema and dermatitis
   3. Skin infections
      1. Frequent presentation in infancy
         1. Furuncles
         2. Occasional "cold" abscesses
         3. Cellulitis
      2. Multiple staphylococcal abscesses on the skin (furunculosis)
         1. Most common around the face
         2. Tender and warm to touch
      3. Cold abscesses (Davis et al. 1966; Donabedian and Gallin 1983)
         1. A large fluctuant mass that feels like a tumor or cyst
         2. Neither hot or tender
         3. Not associated with systemic symptoms, fever, or other signs of local or generalized inflammation
         4. Filled with pus that always grows *Staphylococcus aureus*
         5. Pathognomic to hyper-IgE syndrome
         6. Not essential to the diagnosis
   4. Skin abscesses
   5. Candidiasis
3. Infections
   1. Pulmonary infections
      1. Recurrent and severe
      2. Most common infecting organism: *Staphylococcus aureus* (Donabedian and Gallin 1983)
      3. Chronic infections
         1. Sinusitis
         2. Discharging otitis media
         3. Otitis externa
         4. Mastoiditis
      4. Long-term complications
         1. Bronchiectasis
         2. Bronchopleural fistulae
         3. Pneumatocele secondary to staphylococcal pneumonia
   2. Mucocutaneous candidiasis and fungal infection
      1. Chronic candidiasis (83%)
         1. Mucosa sites (oral moniliasis)
         2. Nail fungal infection and dystrophy secondary to *Candida albicans*
      2. *Aspergillus* infection
      3. Cryptococcal infection

3. Other serious infections
    1. Skin, sinopulmonary, and bone infections: most common
    2. Staphylococcus: the most frequently infecting organisms
    3. Encapsulated organisms
        1. Haemophilus
        2. *Streptococcus pneumoniae*
    4. Opportunistic infections: *Pneumocystis carinii*
4. Facial and dental abnormalities
    1. Characteristic coarse facies
        1. Frontal bossing
        2. Wide alar base of the nose
        3. Wide outer canthal distance
        4. Rare craniosynostosis
        5. Midline facial defects
        6. High-arched palate
    2. Red hair: uncommon finding
    3. Retained primary teeth (72%): failure or delay of shedding of the primary teeth secondary to lack of root resorption (Buckley 2001)
5. Skeletal abnormalities (Buckley 2001)
    1. Scoliosis (76%)
    2. Pathological fractures
        1. Secondary to minor trauma
        2. Associated with osteopenia
        3. Frequent recurrent fractures (57%) (Buckley 2001)
        4. Systemic infections at fracture sites
            1. Recurrent bacterial arthritis
            2. Staphylococcal osteomyelitis
    3. Generalized joint hyperextensibility (68%)
        1. Fingers
        2. Wrists
        3. Shoulders
        4. Hips
        5. Knees
        6. Genu valgum
6. Vascular features (Yavuz and Chee 2009): constitute one of the major clinical characteristics in HIES
    1. Types of vascular abnormalities
        1. Aneurysms (coronary, aortic, carotid, and cerebral)
        2. Pseudoaneurysms
        3. Congenital patent ductus venosus
        4. Superior vena cava syndrome
        5. Vasculitides
        6. Vascular ectasia
        7. Thrombosis
        8. Others
    2. May be congenital or acquired, in the veins and arteries, affecting both sexes.
    3. Can be seen in all subtypes of HIES.
    4. Can be fatal in children and adults.
    5. Limited pathological investigations revealed the presence of vasculitis.
    6. Presence of hypereosinophilia, vasculitis, and defective angiogenesis in HIES may contribute to the formation of vascular abnormalities in HIES.
7. Association with isolated reports of autoimmune disease
    1. Systemic lupus erythematosus
    2. Dermatomyositis
    3. Membranoproliferative glomerulonephritis
8. Malignant changes
    1. Hodgkin disease
    2. Lymphoma
    3. Leukemia
    4. Cancers of the vulva, liver, and lung
9. Autosomal recessive hyper-IgE syndrome (AR-HIES) (Renner et al. 2004)
    1. Similar features
        1. Extremely elevated serum IgE
        2. Severe eczema
        3. Recurrent skin bacterial and viral infections as well as sinopulmonary infection
    2. Distinctive features
        1. Lacks the somatic features, such as the characteristic facies, scoliosis, and the failure of baby teeth to exfoliate.
        2. Although pneumonias occur in AR-HIES, pneumatoceles do not form.
        3. Has a much higher rate of cutaneous viral infections such as *Molluscum contagiosum*, Herpes simplex, and varicella infections.
        4. Has frequent neurologic disease, ranging from facial paralysis to hemiplegia, in some cases due to CNS vasculitis.
        5. Mortality: high at a young age in AR-HIES with sepsis more frequent than in AD-HIES.

6. Eosinophilia and elevated serum IgE: the most consistent laboratory findings and may be more dramatic than in AD-HIES.
7. Autoimmune cytopenias may occur.

Diagnostic Investigations

1. Routine laboratory workup
   1. Grossly elevated serum polyclonal IgE: at least ten times normal (peak serum IgE >2,000 IU/mL)
   2. Accompanying eosinophilia
2. Radiographs, CT scan, and MRI imaging
   1. Pulmonary abnormalities (Jhaveri et al. 2000)
      1. Recurrent alveolar lung infections
      2. Pneumatoceles
      3. Occasional pneumothorax
   2. Skeletal abnormalities
      1. Full evaluations and monitor vigilantly for fractures after even minor trauma
      2. Scoliosis
   3. CNS abnormalities on brain MRI (Freeman et al. 2007)
      1. Remarkably common and previously unrecognized aspect of HIES.
      2. Several patients with lacunar infarcts in addition to focal hyperintensities suggest possible small vessel disease.
3. Skin biopsy (Chamlin et al. 2002)
   1. An eosinophilic infiltrate similar to that seen in eosinophilic pustular folliculitis
   2. Spongiosis
   3. Perivascular dermatitis
4. Molecular genetic diagnosis
   1. AD-HIES: investigate *STAT3* mutations
   2. AR-HIES: investigate *DOCK8* mutations in patients with a phenotype of elevated IgE, eosinophilia, and recurrent skin boils, pneumonia, and viral infections (especially molluscum contagiosum and herpes) (Engelhardt et al. 2009)

Genetic Counseling

1. Recurrence risk
   1. Autosomal recessive inheritance
      1. Patient's sib: 25%
      2. Patient's offspring: not increased unless the spouse is a carrier
   2. Autosomal dominant inheritance
      1. Patient's sib: not increased unless one of the parents is affected, in which case, there will be 50% risk of sibling affected
      2. Patient's offspring: 50%
      3. Challenges of genetic counseling in patients with autosomal dominant diseases such as the hyper-IgE syndrome (STAT3-HIES) because of possible presence of parental gonadal mosaicism (Spielberger et al. 2012)
2. Prenatal diagnosis for AD-HIES (Freeman et al. 2010)
   1. Possible for pregnancies at increased risk by analysis of DNA extracted from fetal cells obtained by amniocentesis or chorionic villus sampling (CVS): The disease-causing allele of an affected family member must be identified before prenatal testing can be performed.
   2. Preimplantation genetic diagnosis (PGD) may be available for families in which the disease-causing mutation has been identified previously.
3. Management (Erlewyn-Lajeunesse 2000; Freeman and Holland 2009)
   1. Largely supportive.
   2. Prompt treatment of infection with prolonged intravenous antibiotics.
   3. Treatment of eczema and prevention of *S. aureus* abscesses are most successfully accomplished with antiseptics such as bathing in bleach (120 mL of bleach in tub of water for 15 min three times weekly) or swimming in chlorinated pools.
   4. Active suspicion of pneumonia is necessary because systemic symptoms of illness are often lacking.
   5. Antimicrobial prophylaxis

1. Prevents recurrent sinopulmonary infections with trimethoprim-sulfamethoxazole, a frequent choice.
2. Pneumonias should be treated aggressively to try to prevent parenchymal damage.
3. If pneumatoceles and bronchiectasis are present, antimicrobial prophylaxis often needs to be broadened to cover Gram-negative bacteria and fungi.
4. Management of pneumatoceles is complex, as these cysts when secondarily infected carry significant risk for morbidity and mortality; however, surgery is not without risk, as HIES patients may have trouble re-expanding their lungs and silage of the pleural space can occur.

6. Cimetidine, the histamine receptor-2 (H2) antagonist (Mawhinney et al. 1980)
   1. Shown to reverse the hyper-IgE syndrome neutrophil chemotactic defect in vitro.
   2. A single patient showed a clinical improvement on treatment with improved neutrophil chemotaxis in spite of a clinical relapse.
   3. Another seven patients treated with H2 antagonist with benefit.
7. Cyclosporine may be helpful.
8. Bronchoscopy may help isolate causative pathogens and clear pus.
9. Dental extraction of primary teeth to avoid further complex orthodontic treatment (Esposito et al. 2012).
10. Surgical intervention by incision and drainage of abscesses.
11. Chest tube drainage and lobectomy for complications of pneumonias.
12. Orthopedic cares for fractures and scoliosis.
13. Dermatitis.
    1. Topical steroid
    2. Topical antifungals
    3. Emollient creams
14. Isotretinoin used to improve dermatitis.
15. High-dose intravenous γ-globulin for patients with aberrant humoral immunity (Kimata 1995): Intravenous immunoglobulin (IVIG) may decrease the number of infections for some individuals and is the most frequent immunomodulator used.
16. Invasive approach with plasmapheresis with temporary improvement of skin condition and free of infections (Dau 1988).
17. Bone marrow transplantation: only hope of cure at present, likely not fully corrective (Gennery et al. 2000).
18. A single report of a peripheral stem cell transplantation (Nester et al. 1998).
    1. Serum IgE returned to normal.
    2. Disappearance of symptoms.
    3. Unfortunately, patient died of interstitial pneumonia.
19. Hematopoietic cell transplantation (Gatz et al. 2010).
    1. Curative in patients with AR-HIES
    2. Should be considered early before life-threatening complications develop, which include malignancies
20. Antimicrobial treatment and IgG replacement are essential in the care for patients with STAT3-deficient HIES, whereas hematopoietic stem cell transplantation seems justified in DOCK8-deficient HIES (Farmand and Sundin 2015).

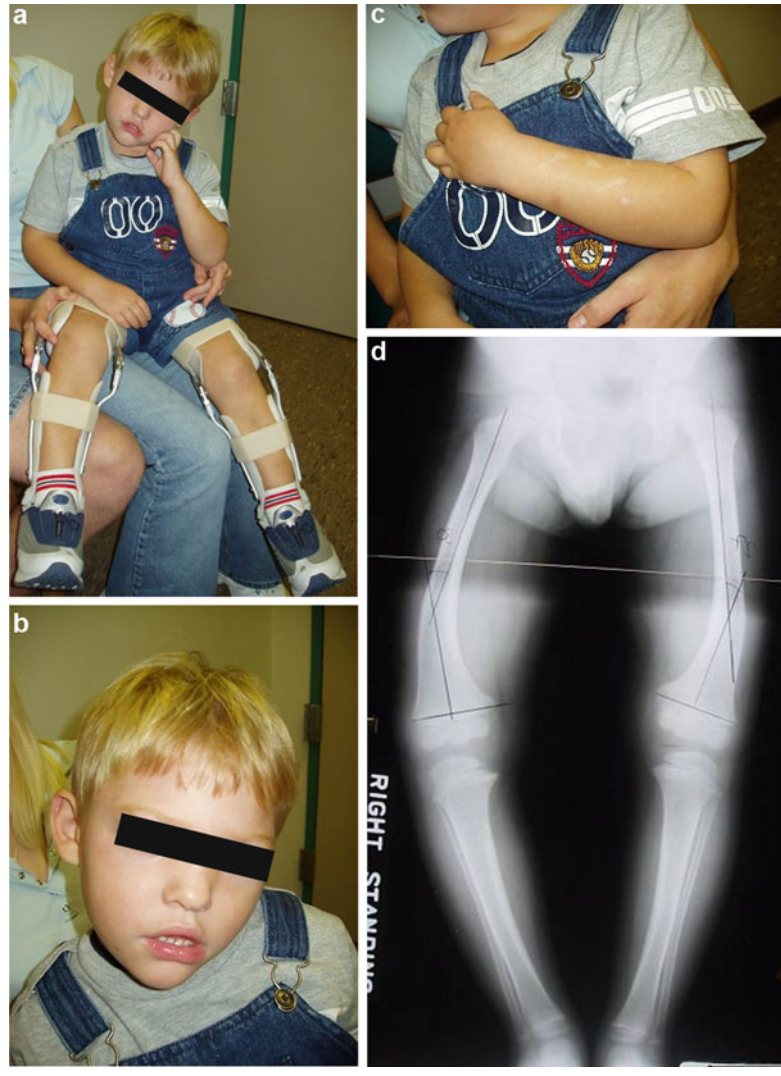

Fig. 1 (**a**–**d**) A 3-year-9-month-old patient with hyperimmunoglobulin E syndrome showing skin scars on his arm and bowing of the legs. Facial features included frontal bossing, wide alar basis of the nose, and wide outer canthal distance. He had history of recurrent pneumonias, otitis media, asthma, and fractures of the leg bones. At 2 years and 10 months of age, IgE was 15,610 (≤93 KU/L). He is currently on intravenous immunoglobulin therapy with antibiotic prophylaxis

Fig. 2 A 13-year-old boy had a history of recurrent pneumonias, a right hip infection, and significant atopic dermatitis. Facial features included frontal bossing, wide alar basis of the nose, and wide outer canthal distance. Laboratory tests showed hyperimmunoglobulin E

Fig. 3 A 3-year-old boy and a 9-year-old maternal half brother were evaluated for frequent infections. The young brother had a history of multiple abscesses. Immunoglobulin studies showed normal IgG of 540 (231–1,411 mg per deciliter) and a highly elevated IgE of 1,553 (0–15 IU/mL). He also had developmental delay. CT of the brain showed Dandy-Walker variant and corpus callosum agenesis. The older half brother had a history of chronic dermatitis, asthma, eczema, and food allergy. His recent IgE level was elevated at 8,670 IU/ml (0–90). The half brothers both have hyper-IgE syndrome

Hypertrophic Cardiomyopathy

Contents

Hypertrophic cardiomyopathy (HCM) is a disorder characterized by unexplained left ventricular hypertrophy associated with nondilated ventricular chambers in the absence of another cardiac or systemic disease that itself would be capable of producing the magnitude of hypertrophy evident in a given patient with the caveat that patients who are genotype positive may be phenotypically negative without overt hypertrophy (Gersh et al. 2011). The prevalence is estimated to be approximately 1 in 500 in the general population (Wallis and Fricker 2012). This is the most common monogenic cardiac disorder and the most frequent cause of sudden cardiac death in young people and trained competitive athletes (Maron et al. 1995; Maron 2003; Charron 2012; Figs. 1 and 2).

Synonyms and Related Disorders

Hypertrophic obstructive cardiomyopathy; Idiopathic subaortic stenosis

Genetics/Basic Defects

1. Inheritance: autosomal dominant (Jacoby and McKenna 2012) in most cases
    1. Marked phenotypic heterogeneity
    2. Age-dependent penetrance
    3. Variable expression
2. Caused by mutations in sarcomeric protein encoding genes and its constituent myofilament elements
    1. Intergenetic diversity is compounded by considerable intragene heterogeneity, with >1,400 mutations identified among at least 8 genes (Gersh et al. 2011).
    2. The distribution of pathogenic sarcomeric mutations is uneven (Richard 2003).
        1. Myosin heavy chain 7 (MYH7) and myosin-binding protein C3 (MYPBC3) making up about 25% each
        2. Cardiac troponin T (TNNT2), cardiac troponin I (TNNI), myosin ventricular regulatory light chain (MYL2), and myosin ventricular essential light chain (MYL3) accounting for most of the remainder
    3. 30–40% of the patients with clinical HCM do not have sarcomere mutations (Jacoby and McKenna 2012).
    4. Individuals with β-MHC mutations typically present in the first two decades of life.
    5. Individuals with cMyBP-C mutations may be asymptomatic until the fifth or sixth decades (Niimura et al. 1998).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_275

3. Pathophysiology (Gersh et al. 2011)
    1. Complex, consisting of multiple interrelated abnormalities
        1. Left ventricular outflow tract (LVOT) obstruction
        2. Mitral regurgitation
        3. Myocardial ischemia
        4. Arrhythmias
    2. Clinically important to distinguish between the obstructive and nonobstructive forms of HCM because management strategies are largely dependent on the presence or absence of symptoms caused by obstruction

Clinical Features

1. Significant variability in clinical presentation
    1. Asymptomatic
    2. Symptomatic
        1. Shortness of breath (particularly with exertion)
        2. Chest pain
        3. Palpitations
        4. Dizziness
        5. Orthostasis
        6. Presyncope
        7. Syncope
        8. Sudden cardiac death: ventricular fibrillation which is the most common cause (O'Mahony and Elliott 2014)
2. Left ventricular hypertrophy of HCM: most often becomes apparent during adolescence or young adulthood, although it may also develop late in life, in infancy, or in childhood
3. Potential dangers in HCM patients during labor (Turner et al. 1968; Krul et al. 2011)
    1. Reduced venous return because of the expulsive effort.
    2. Acute blood loss.
    3. Increased or new obstruction of the left ventricular outflow tract through increase in the contractile forces of the heart and tachycardia caused by physical stress.
    4. The chance of maternal cardiac complications increases in the presence of prior cardiac events, poor functional class, severe left ventricular systolic dysfunction, and left outflow tract obstruction.
4. Differential diagnosis of HCM with other cardiac conditions with left ventricular hypertrophy (Gersh et al. 2011)
    1. Hypertensive heart disease
    2. Physiologic remodeling associated with athletic training ("athlete's heart")
5. Syndromes associated with hypertrophic cardiomyopathy (Moak and Kaski 2012; Wallis and Fricker 2012)
    1. Malformation syndromes associated with HCM
        1. Noonan syndrome: see the chapter.
        2. Multiple lentigines (LEOPARD syndrome): please see the chapter.
        3. Beckwith-Wiedemann syndrome: please see the chapter.
        4. Trisomy 21 syndrome: please see the chapter.
        5. Costello (faciocutaneoskeletal) syndrome.
        6. Prune belly syndrome: please see the chapter.
    2. Neuromuscular disorders
        1. Friedreich ataxia: please see the chapter.
        2. Myotonic dystrophy: please see the chapter.
        3. Refsum disease.
    3. Metabolic disorders
        1. Glycogen storage disease type II (Pompe disease): please see the chapter.
        2. Fabry disease
            1. Caused by deficient activity of the enzyme alpha-galactosidase and progressive lysosomal deposition in cells throughout the body.
            2. Acroparesthesias (periodic crises of severe pain in the extremities) usually begins in childhood or adolescence.
            3. Angiokeratomas (vascular cutaneous lesions).
            4. Hypohidrosis.
            5. Characteristic corneal and lenticular opacities.
            6. Proteinuria.

7. Gradual deterioration of renal function to end-stage renal disease usually by 3rd to 5th decade.
8. In affected males, cardiovascular and/or cerebrovascular disease and cardiac variant phenotype (left ventricular hypertrophy, mitral insufficiency, and/or cardiomyopathy) may develop.

3. Danon disease
   1. An X-linked lysosomal storage disorder caused by mutations in the gene encoding lysosome-associated membrane protein-2 (*LAMP2*)
   2. Cardiomyopathy
   3. Skeletal myopathy
   4. Developmental delay
4. Mucopolysaccharidosis I, II, III, IV, and VII: HCM caused by accumulation of glycosaminoglycans within myocardial cells.
5. Severe hypertrophic cardiomyopathy caused by γ_2 subunit of the adenosine monophosphate-activated protein kinase (*PRKAG2*) gene mutation
   1. Hypertrophic cardiomyopathy
   2. Conduction abnormalities
   3. Ventricular preexcitation
   4. Skeletal myopathy associated with ragged red fibers on skeletal muscle biopsy
   5. Mortality related to thromboembolic stroke resulting from atrial fibrillation and sudden death

4. Fatty acid oxidation disorders
   1. Carnitine deficiency
   2. Carnitine palmitoyltransferase deficiency
   3. Medium-chain acyl-coenzyme A (CoA) dehydrogenase deficiency
   4. Very-long-chain acyl-CoA dehydrogenase deficiency
   5. Long-chain3-hydroxyacyl-CoA dehydrogenase deficiency
5. Mitochondrial cardiomyopathies
   1. Complex I, III, and IV defects
   2. MERRF (myoclonic epilepsy with ragged red fibers) syndrome
   3. MELAS (mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes) syndrome
   4. Adenine nucleotide translocator abnormalities

Diagnostic Investigations

1. Radiology: enlarged cardiac silhouette with central vascular congestion
2. Electrocardiogram: often shows left atrial enlargement and high voltages representing biventricular hypertrophy
3. Echocardiography
   1. HCM is usually recognized by maximal LV wall thickness $\geq$15 mm, particularly in the presence of other compelling information (e.g., family history of HCM) (Gersh et al. 2011).
   2. In children, increased LV wall thickness is defined as wall thickness $\geq$2 standard deviations above the mean (Z score $\geq$2) for age, sex, or body size.
   3. Characteristically shows biventricular hypertrophy which can be concentric or asymmetric.
   4. Hypercontractile ventricle with diastolic dysfunction.
4. Cardiovascular magnetic resonance (CMR): an emerging role in the contemporary evaluation of patients with hypertrophic cardiomyopathy (Maron et al. 2009)
5. Pathognomonic histopathologic findings in cardiac tissue: myocyte disarray and fibrosis
6. Family history: a key clinical predictor of a positive genetic diagnosis and has direct clinical relevance, particularly in the pretest genetic counseling setting (Ingles et al. 2013)
7. Molecular genetic analysis (Charron 2012)
   1. Identify first a disease-causing mutation in the proband: sequencing and deletion/duplication panel is available commercially.
   2. Predictive testing in asymptomatic apparently healthy relatives or in relatives with mild cardiac abnormalities of unknown significance.

1. Identified mutation carriers will benefit from regular cardiac screening and allow early cardiac expression to be diagnosed, and this may reduce mortality by the early discussion of prophylactic implantable cardioverter defibrillations (ICD).
2. Identified relatives without the causal mutation can be released from all future cardiac surveillance, and their children are likewise no longer at risk.

Genetic Counseling

1. Recurrence risk: according to autosomal dominant inheritance (Cirino and Ho 2014)
   1. Patient's sib
      1. 50% if a parent has the disease-causing mutation.
      2. The clinical severity and age of onset cannot be predicted from the mutation.
   2. Patient's offspring
      1. 50% risk of inheriting the mutation and therefore being at risk for developing HCM.
      2. Penetrance may be incomplete.
      3. Disease severity and age of onset cannot be predicted.
2. Prenatal diagnosis at increased risk is possible if the disease-causing mutation has been identified in an affected family member.
3. Preimplantation genetic diagnosis may be an option for families in which a definitive disease-causing mutation has been identified.
4. Management
   1. Beta-blockers (propranolol, metoprolol, bisoprolol, or atenolol): initial drug for medical therapy of symptomatic LV outflow tract obstruction (Moak and Kaski 2012).
   2. Beta-blockers and calcium channel blockers used to slow heart rate and increase diastolic filling time.
   3. Avoidance of competitive or highly strenuous exercise: usually recommended (Corrado et al. 2005).
   4. Implantable cardioverter defibrillators (ICDs) for secondary or primary prevention of sudden death in patients with risk factors (Maron et al. 2000; Maron et al. 2007; Maron and Spirito 2008; O'Mahony and Elliott 2014).
   5. Drugs appropriate to control heart failure symptoms (principally those of exertional dyspnea and chest discomfort) (Maron 2002; Maron et al. 2003).
   6. Surgical septal myotomy (myectomy) (Ommen et al. 2005) or alcohol septal ablation (Sorajja et al. 2008) for progressive and drug-refractory heart failure caused by left ventricular outflow tract (LVOT) obstruction.
   7. Heart transplantation for systolic (or less frequently intractable diastolic) dysfunction associated with severe unrelenting symptoms (Harris et al. 2006).
   8. Drug therapy or possibly radiofrequency ablation or surgical maze procedure for atrial fibrillation (AF) (Bunch et al. 2008; Gaita et al. 2007; Kilicaslan et al. 2006).
   9. Currently recommended follow-up strategy involves periodic evaluation of first-degree relatives every 1–5 years with echocardiography and ECG (Hershberger et al. 2009; Charron et al. 2010).

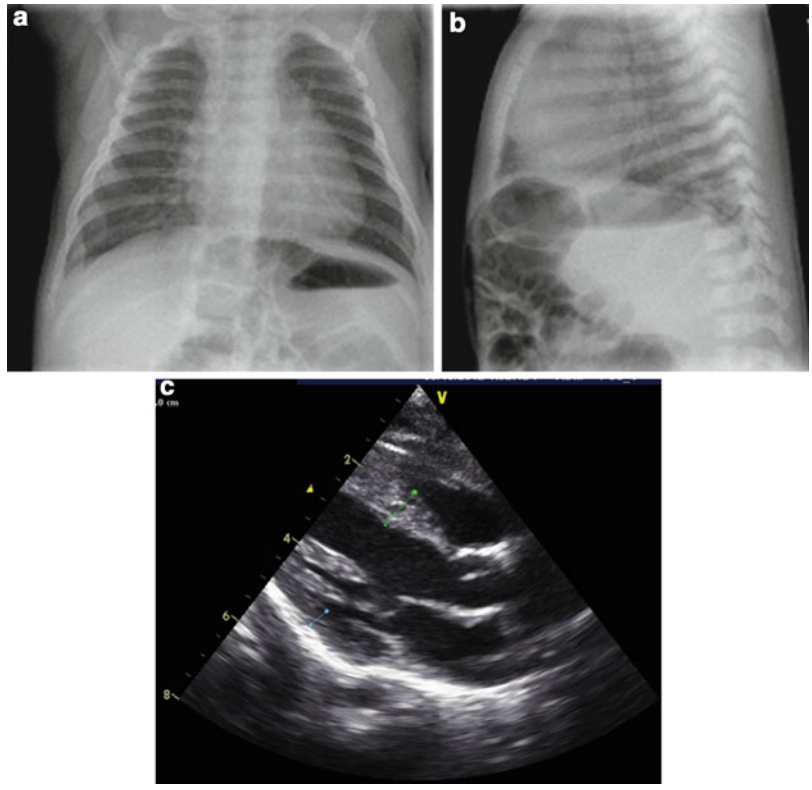

Fig. 1 (**a**–**c**) This 6-week-old male infant was evaluated for hypertrophic cardiomyopathy (HCM). Respiratory infections at 2 weeks of age which necessitated chest X-ray which showed left ventricular hypertrophy and thickened septum which was confirmed by CT scan of the chest. Echocardiogram showed left ventricular hypertrophy and moderate septal wall hypertrophy, suggestive of hypertrophic cardiomyopathy. No hypotonia was noted. Family history revealed that the mother has mitral valve prolapse and the maternal great grandfather has a brother and a sister died of sudden cardiac death early in life. Chest X-rays showed enlarged cardiac silhouette with mild central vascular congestion (**a**, **b**). Echocardiograms showed left ventricular hypertrophy with septal hypertrophy (**c**). Blood acid alpha-glucosidase (GAA) activity was noted to be low – 5.2 (10.0–49.0 pmol/punch/h). GAA sequencing for Pompe disease revealed no GAA mutations. However, the patient is heterozygous for a published missense mutation in the *MYBPC3* gene (p.Arg502Trp(R502W), c.1504C>T), consistent with a genetic form of HCM. He is also heterozygous for a novel missense variant of unknown significance in the *PRKAG2* gene. Mutations in the *MYBPC3* gene have been reported in 20–30% of patients with autosomal dominant familial hypertrophic cardiomyopathy and have been reported less frequently in patients with autosomal dominant familial dilated cardiomyopathy (Cirino & Ho 2011; Hershberger et al. 2009). Mutations in the *PRKAG2* gene are a rare cause of autosomal dominant familial hypertrophic cardiomyopathy and associated with ventricular preexcitation, Wolff-Parkinson-White (WPW) syndrome (Cirino & Ho 2011) (Courtesy of Dr. Ernest Kiel)

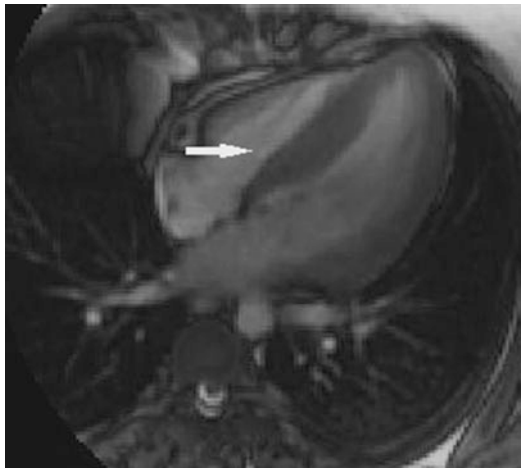

Fig. 2 A 15-year-old boy with hypertrophic cardiomyopathy presented with tachycardia. Cardiac MRI showed hypertrophy of the left ventricle with increased thickness of the septum (*arrow*). There is systolic anterior motion of the anterior mitral leaflet with associated mitral regurgitation and left ventricular outflow tract obstruction (Courtesy of Dr. Grace Guo)

Hypochondroplasia

Contents

Hypochondroplasia (HCH) is a disproportionate short stature disorder resembling achondroplasia but with less severe phenotype.

Synonyms and Related Disorders

FGFR3 mutation; Homozygous hypochondroplasia; Hypochondroplasia/achondroplasia compound heterozygote

Genetics/Basic Defects

1. Inheritance (Le Merrer et al. 1994).
    1. Autosomal dominant with full penetrance
    2. Sporadic in 90% of cases
    3. Observation of an increased paternal age effect at the time of conception, suggesting involvement of de novo mutations of paternal origin
    4. Presence of clinical and genetic heterogeneity (Rousseau et al. 1996)
2. Evidence supporting the view that hypochondroplasia and achondroplasia are allelic disorders (McKusick et al. 1973; Le Merrer et al. 1994).
    1. A remarkable inter- and intrafamilial variation in expression of hypochondroplasia with some cases resembling minor forms of achondroplasia
    2. Offspring of an achondroplastic parent and hypochondroplastic parent with severe neonatal achondroplasia resembling homozygous achondroplasia
    3. Similar histopathological aspects of the growth cartilage for the two disorders
3. Molecular defect (Bellus et al. 1996).
    1. About 70% of affected individuals who are heterozygous for a mutation in the fibroblast growth factor receptor 3 (*FGFR3*) gene, which is mapped on chromosome 4p16.3 (Francomano 2005)
    2. *FGFR3* mutations reported in hypochondroplasia (Prinos et al. 1995)
        1. 1620C-A (Asn540Lys): two thirds of cases
        2. 1620C-G (Asn540Lys): one third of cases
        3. 1658A-C (Asn540Thr) and other *FGFR3* mutations: rare
    3. *FGFR3* mutation reported in hypochondroplasia association with acanthosis nigricans (Castro-Feijóo et al. 2008;

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_125

Cossiez Cacard et al. 2016) and acanthosis nigricans and hyperinsulinemia (Blomberg et al. 2010): p.Lys650Thr mutation
   4. Homozygous *N540K* hypochondroplasia (Garcia De Rosa et al. 2014)
   5. Common mutations in FGFR3 gene also account for achondroplasia and thanatophoric dysplasia (Bonaventure et al. 1996; Cohen 1998)
4. Hypochondroplasia/achondroplasia compound heterozygote (Sommer et al. 1987; Chitayat et al. 1999; Huggins et al. 1999b).
   1. Born to a hypochondroplastic parent and an achondroplastic parent
   2. The severity of the child: clinical and radiographic findings more severe than achondroplasia (ACH) or hypochondroplasia alone but less severe than homozygous achondroplasia (Huggins et al. 1999b)
   3. Demonstration of both the hypochondroplasia (Asn540Lys) and achondroplasia (Gly380Arg) mutations at the *FGFR3* locus in a patient with the genetic compound

Clinical Features

1. Short stature (Francomano 2005)
   1. Evident by school age
   2. Adult height: 128–165 cm
2. Stocky build
3. Facial appearance
   1. Usually normal
   2. Mild macrocephaly may be present
4. Skeletal features
   1. General features: usually similar but milder to achondroplasia
   2. Limbs
      1. Disproportionately short compared with the length of the trunk
      2. Shortening of the proximal (rhizomelia) or middle (mesomelia) segments of the extremities
      3. Mild limitation of elbow extension
      4. Broad and short hands and feet (brachydactyly)
      5. Absence of trident hand deformity
      6. Bow legs (genu varum): usually mild
      7. Adult onset osteoarthritis: less common
   3. Spine
      1. Scoliosis
      2. Slight lumbar lordosis with a sacral tilt
5. Rare association with acanthosis nigricans
6. Medical complication
   1. Following complications: less frequent compared to achondroplasia
      1. Spinal stenosis with neurologic complications
      2. Tibial bowing
      3. Obstructive apnea
   2. Deficits in mental capacity and/or function: may be more prevalent than achondroplasia
7. Clinical criteria in hypochondroplasia (Song et al. 2012)
   1. Major criteria
      1. Short stature (3 SD below the mean height)
      2. Mesomelic dwarfism
      3. Limitation of elbow extension
      4. Generalized laxity
      5. Brachydactyly
      6. Genu varum
      7. Macrocephaly with relatively normal faces
   2. Minor criteria
      1. Scoliosis
      2. Lumbar lordosis with protruding abdomen
      3. Intelligence disability
8. Homozygous N540K hypochondroplasia (Garcia De Rosa et al. 2014)
   1. More severe clinical and radiological features than those described for heterozygous HCH, as expected.
   2. Height: between -4SD and -6SD.
   3. Facial appearance, hypotonia, and the narrowing of the inferior lumbar interpedicular distances: less severe than those of ACH/HCH complex patients.
   4. In contrast, clinical features seems to be more pronounced than those of the usual heterozygous ACH, especially in regard to cognitive development.

5. Gross motor and cognitive severe delay and also have temporal lobe abnormalities. This neurological severity could be attributed to having *N540K* mutation in double dose.

Diagnostic Investigations

1. Skin biopsy of the hyperpigmented skin and of a verrucous keratosis: hyperkeratosis and papillomatosis with moderate irregular acanthosis compatible with acanthosis nigricans (Cossiez Cacard et al. 2016)
2. Radiography (Hall and Spranger 1979; Kozlowski 1973; Mortier et al. 2000; Francomano 2005; Song et al. 2012)
    1. The most common features
        1. Short proximal (rhizomelic) and/or middle (mesomelic) segments of the long bones with mild metaphyseal flare, especially femora and tibiae
        2. Caudal narrowing or unchanged lumbar interpedicular distance
        3. Shortening (anterior-posterior) of the lumbar pedicles
        4. Posterior scalloping of the lumbar vertebral bodies
        5. Squared and shortened ilia
        6. Coxa breva
        7. Short and broad femoral neck
        8. Mild to moderate brachydactyly
    2. The less common but significant features
        1. Shortening of the distal ulna
        2. Low articulation of sacrum on pelvis with a horizontal orientation
        3. Flattened acetabular roof
        4. Elongation of the distal fibula
        5. Anterior-posterior shortening of the lumbar vertebrae
        6. Dorsal concavity of the lumbar vertebral bodies
        7. Long ulnar styloid in adults
        8. Prominence of muscle insertions on the long bones
        9. Shallow "chevron" deformity of distal femur metaphysis
    3. Criteria for radiologic diagnosis of hypochondroplasia in neonates (Saito et al. 2016)
        1. Short greater sciatic notches
        2. Broad femora
        3. Short ilia
        4. Horizontal acetabulum
        5. Femoral shortening
        6. Ovoid radiolucency of the femoral neck
3. Brain MRI (Philpott et al. 2013)
    1. Temporal lobe enlargement (9/9)
    2. Abnormal triangular-shape temporal horn (9/9)
    3. Deep transverse temporal sulci (9/9)
    4. Overly sulcated mesial temporal lobes (9/9)
    5. Megalencephaly (8/9)
    6. Mild ventriculomegaly (7/9)
    7. Globular amygdala (7/7)
    8. Hippocampal dysplasia (7/7)
    9. Deficient dentate gyrus (7/7)
    10. Extension of oversulcation to calcar avis (7/7)
    11. Abnormal G/W matter differentiation (2/3)
    12. Subependymal neuronal heterotopia (1/7)
    13. Aberrant sulcation of the inferior surface and deep transverse clefts in the mesial temporal lobe (Garcia De Rosa et al. 2014)
4. Molecular genetic testing
    1. Mutation analysis
        1. 1620C-A (Asn540Lys)
        2. 1620C-G (Asn540Lys)
        3. Other *FGFR3* mutations
    2. Sequence analysis of mutations in *FGFR3* exons 10, 13, and 15
    3. *FGFR3* mutation identified by next-generation sequencing (Wang et al. 2013)

Genetic Counseling

1. Recurrence risk (Francomano 2005; Bober et al. 2013)
    1. Patient's sib: an extremely low risk (<0.01%) of having an affected sib if

parents are not affected (germline mosaicism has not been reported for hypochondroplasia)
2. Patient's offspring
    1. 50% risk of having an affected offspring if the spouse is normal
    2. If the spouse is an achondroplastic:
        1. 25% chance of having an affected offspring with hypochondroplasia
        2. 25% chance of having an affected offspring with achondroplasia
        3. 25% chance of having an affected offspring with achondroplasia-hypochondroplasia genetic compound
        4. 25% chance of having a normal offspring
    3. If the spouse also has hypochondroplasia or other dominant form of skeletal dysplasia: genetic counseling becoming more complicated due to the high incidence of genetic heterogeneity and the lack of medical literature addressing these circumstances
2. Prenatal diagnosis (Bober et al. 2013)
    1. Prenatal diagnosis by amniocentesis or CVS for family with high-risk pregnancy with a parent who has hypochondroplasia
        1. When the spouse is normal: testing for disease-causing FGFR3 mutation in the fetus
        2. When the spouse is affected with another dominantly inherited skeletal dysplasia caused by a known gene mutation: testing for the known mutation for that skeletal dysplasia and the mutation for the hypochondroplasia in the fetus
    2. Prenatal diagnosis by ultrasonography, amniocentesis, or CVS in low-risk pregnancy without family history of affected individual
        1. Ultrasonography: short limbs detected by routine ultrasound examination late in pregnancy (Huggins et al. 1999a)
        2. DNA-based diagnosis of *FGFR3* mutations to confirm the diagnosis of hypochondroplasia
        3. Prenatal genetic diagnosis of highly suspected HCH fetuses with gene sequencing technologies (Zhao et al. 2015)
    3. Prenatal MRI detection of temporal lobes and hippocampal anomalies in a case of hypochondroplasia, molecularly confirmed through postnatal *FGFR3* analysis (Cesaretti et al. 2014)
    4. Preimplantation genetic diagnosis (PGD)
        1. May be an option for some families in which the disease-causing mutation has been identified
        2. Successful birth with preimplantation genetic diagnosis using single-cell allele-specific PCR and sequencing in a woman with hypochondroplasia due to *FGFR3* mutation (c.1620C > A, p. N540K) (Park et al. 2013)
3. Management
    1. Follow closely developmental milestones and signs of learning disability or mental retardation.
    2. Treatment of short stature
        1. Trials of growth hormone therapy with mixed results (Appan et al. 1990; Ramaswami et al. 1999)
        2. Surgical limb lengthening for severe case of hypochondroplasia
            1. An invasive procedure
            2. Entails considerable disability and discomfort over a long period of time
            3. Prefer postponement of the procedure until adolescence when the patient can make an informed decision

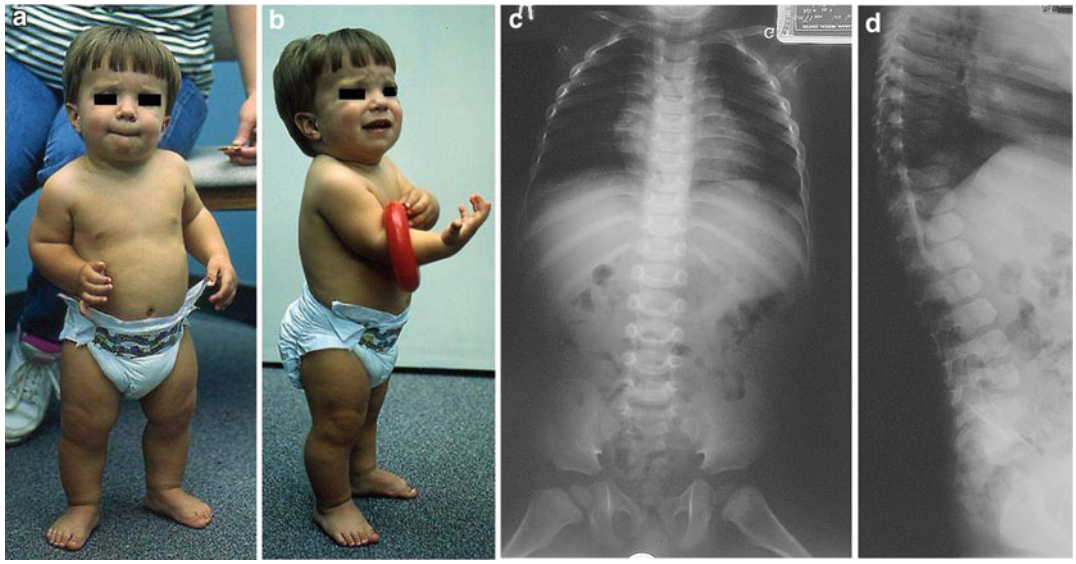

Fig. 1 (**a**–**d**) A young child affected with hypochondroplasia showing mild short stature and mild rhizomelic shortening of the extremities. Radiographs showed unchanged lumbar interpedicular distance

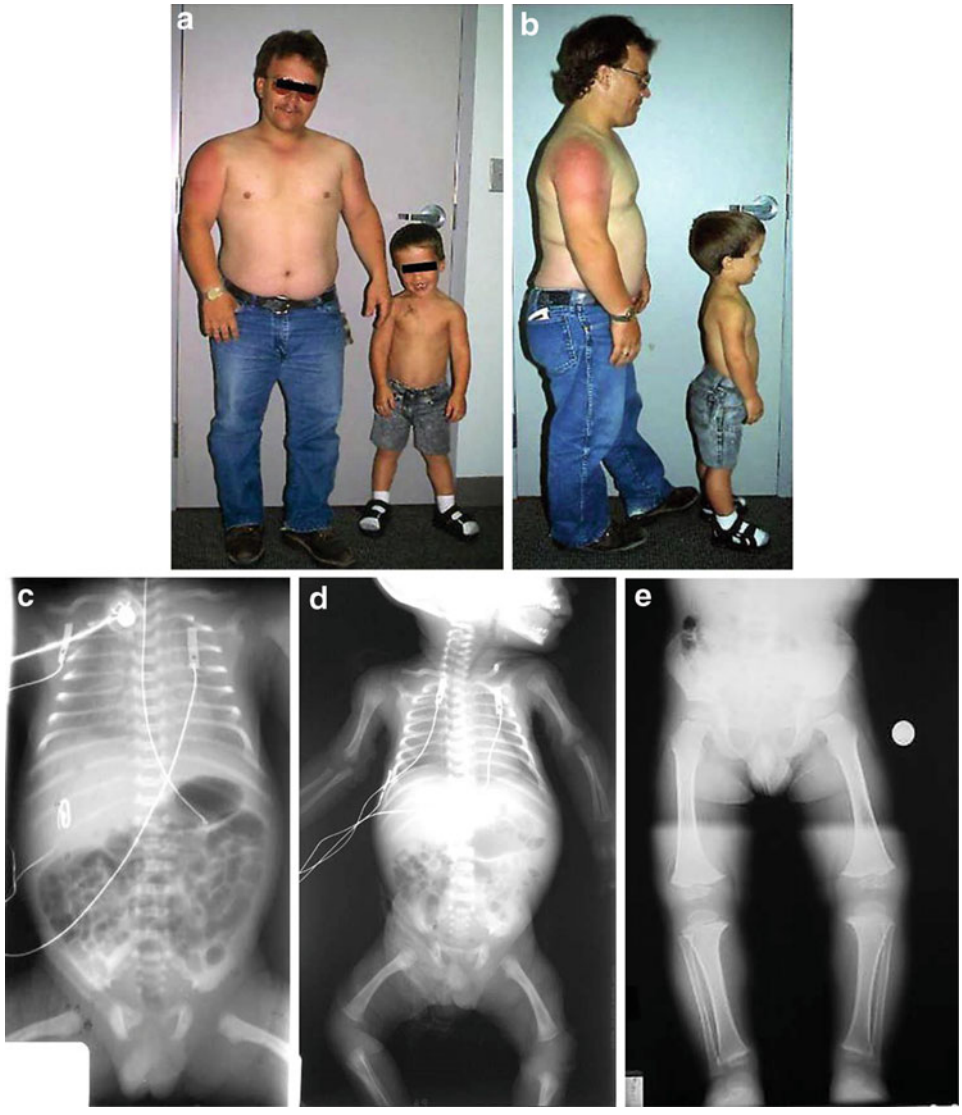

Fig. 2 (**a**–**e**) Father and son showing typical features of hypochondroplasia. The son's radiographs at birth, 17 days, and 2 years, and 6 months showing unchanged lumbar interpedicular distance, mild shortening of long bones, and short, squared ilia

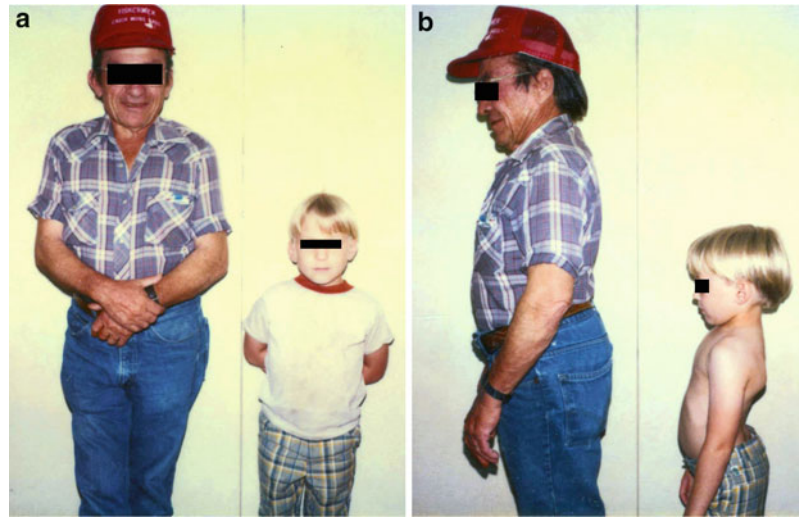

Fig. 3 (**a**, **b**) Father and son with clinical features of hypochondroplasia

Fig. 4 (**a**–**c**) Father, daughter, and son affected with hypochondroplasia showing stocky build, mild short stature, normal facial appearance, rhizomelic shortening of the extremities, and absence of trident hands

Fig. 5 A 2-year-old boy with disproportional short stature with relatively short upper arms and thighs and mild lumbar gibbus. Molecular testing identified the presence of a C > A transversion at nucleotide 1620 (c.1620 C > A) of the fibroblast growth factor receptor 3 (*FGFR3*) gene. The presence of this mutation is consistent with a clinical diagnosis of hypochondroplasia

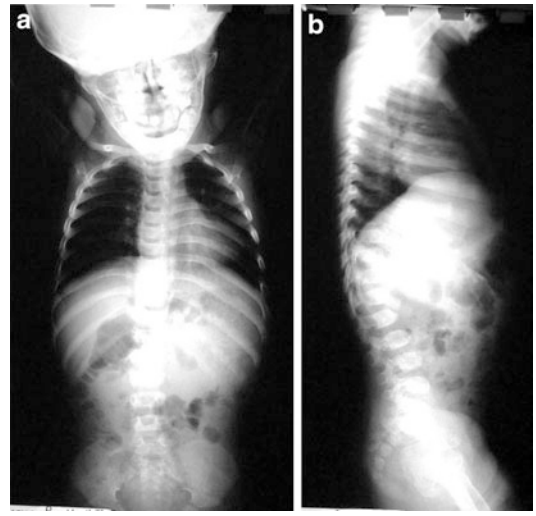

Fig. 6 (**a**, **b**) Radiographs of the spine (AP and lateral views) show caudal narrowing of lumbar interpedicular distance and the dorsal convexity of the lumbar vertebral bodies

Hypoglossia-Hypodactylia Syndrome

Contents

Hypoglossia-hypodactylia syndrome is an extremely rare condition characterized by a small tongue associated with distal limb deficiency. The syndrome is also called aglossia-adactylia syndrome, which is a misnomer since the tongue is never completely absent, and the term "adactylia" does not convey the variation in limb defects of affected individuals. The syndrome is also known as oromandibular-limb hypogenesis syndrome, a spectrum of congenital anomalies that affect the tongue, the oromandibular region, and the limbs.

Synonyms and Related Disorders

Aglossia-adactylia syndrome; Hanhart syndrome; Oromandibular-limb hypogenesis syndrome; Peromelia with micrognathia

Genetics/Basic Defects

1. Inheritance
    1. Sporadic in all reported cases (Nevin et al. 1975).
    2. Autosomal dominant inheritance cannot be ruled out.
2. Pathogenesis (Yasuda et al. 2003)
    1. Impairments or insults to fetus during the early fetal life (fourth to seventh week) may be responsible for the findings of tongue and limb abnormalities seen in hypoglossia-hypodactylia syndrome because of the close chronological relationship between the development of the tongue and the limbs.
    2. A hypoplastic mandible with concurrent hypoglossia could be explained by the fact that the mandible originates from the same visceral arch as the tongue.
    3. Vascular mechanism (either hemorrhage or vaso-oclusion) may be responsible for defects that are asymmetric and always distal.
3. Disruptive first-trimester factors associated with oromandibular-limb hypogenesis syndrome (OLHS)
    1. Disruptive first-trimester factors previously associated with OLHS include maternal teratogen exposures, hyperthermia, infec-

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_126

tion, and uteroplacental vascular insufficiency causing a transient hypoxic/ischemic insult to the fetus.
2. First-trimester disruption: severe illness with dehydration and hypovolemia in a mother with a bicornuate uterus and early gestational diabetes caused fetal ischemia and necrosis during the sixth week postconception (Milam et al. 2014).

Clinical Features

1. Mouth
   1. Mandible
      1. Micro-/retrognathia
         1. Minor feeding problems in infancy
         2. Minor speech impairment
      2. Oligodontia
      3. Absent mandibular incisors with concomitant hypoplasia of the associated alveolar ridge
      4. Other features
         1. Midline lower lip defect (a sulcus-like deformity with continuity of the orbicularis oris muscle disturbed at this location) (Coşkunfirat et al. 1999)
         2. Microstomia (markedly reduced mouth opening)
         3. Intraoral bands (Grippaudo and Kennedy 1998)
         4. Oral frenula
         5. Oral syngnathia
   2. Tongue
      1. Varying degrees of hypoglossia/aglossia: a reduction in tongue size (Harwin and Lorinsky 1970; Lustmann et al. 1981)
      2. Ankyloglossia
      3. Marked enlargement of the sublingual muscular ridges
      4. Hypertrophy of the sublingual and submandibular glands
2. Variable limb anomalies
   1. May involve any limb
   2. Distal reduction anomalies
      1. Oligodactyly (absence of some fingers and toes)
      2. Adactylia (congenital absence of the fingers and toes)
      3. Peromelia (severe congenital malformation of the extremity, including the absence of hand and foot)
   3. Syndactyly
3. Other associated anomalies
   1. Moebius syndrome
   2. Complex cardiopathy in severe form of hypoglossia-hypodactylia syndrome (Elalaoui et al. 2010)
   3. Fused labia majora
   4. Unilateral renal agenesis
   5. Imperforate anus
   6. Short stature caused by growth hormone deficiency (Goyal et al. 2014)
4. Normal intelligence
5. Hall's classification of syndromes of oromandibular and limb hypogenesis (Hall 1971)
   1. Type I
      1. IA: hypoglossia
      2. IB: aglossia
   2. Type II (Alexander et al. 1992)
      1. IIA: hypoglossia-hypodactylia
      2. IIB: hypoglossia-hypomelia (peromelia) (Meundi et al. 2013)
      3. IIC: hypoglossia-hypodactylomelia (Castelino et al. 2010)
   3. Type III
      1. IIIA: glossopalatine ankylosis
      2. IIIB: with hypoglossia
      3. IIIC: with hypoglossia-hypodactylia
      4. IIID: with hypoglossia-hypomelia
      5. IIIE: with hypoglossia-hypodactylomelia
   4. Type IV
      1. IVA: intraoral bands and fusion
      2. IVB: with hypoglossia
      3. IVC: with hypoglossia-hypodactylia
      4. IVD: with hypoglossia-hypomelia
      5. IVE: with hypoglossia-hypodactylomelia
   5. Type V (Herrmann et al. 1976; Robertson and Bankier 1999)
      1. VA: Hanhart syndrome
      2. VB: Charlie M syndrome (Jung et al. 2016)

3. VC: Pierre Robin syndrome
4. VD: Moebius syndrome
5. VE: amniotic band syndrome

6. Embryologic and clinical classification (Chicarilli and Polayes 1985)
   1. Type I: micrognathia (mandibular)
      1. Pierre Robin syndrome
      2. Hanhart syndrome
   2. Type II: microglossia
      1. Hypoglossia
      2. Hypoglossia-hypodactyly
   3. Type III: dysgnathia (maxillomandibular)
      1. Glossopalatine ankylosis
      2. Glossopalatine ankylosis-hypodactyly
   4. Type IV: others
      1. Moebius syndrome
      2. Charlie M syndrome
7. Differential diagnosis with other oromandibular-limb hypogenesis syndromes (Cohen et al. 1971; Bonneau et al. 1999)
   1. Hanhart syndrome (Bersu et al. 1976)
      1. Micrognathia
         1. Microglossia
         2. Hypodontia
      2. Limb anomalies
         1. Terminal deficiency of all limbs: ranging from stunted digits, oligodactyly, to more severe peromelia
         2. May affect any limb
      3. Imperforate anus
   2. Glossopalatine and ankylosis syndrome
      1. Tongue.
         1. Usually attached to the hard palate
         2. May adhere to the maxillary alveolar ridge
         3. Mildly cleft tongue tip
      2. High-arched or cleft palate.
      3. Hypoplastic mandible.
      4. Hypodontia principally affects the incisor teeth.
      5. Ankylosis of the temporomandibular joint.
      6. Facial paralysis.
      7. Extremely variable limb anomalies.
         1. Oligodactyly
         2. Syndactyly
         3. Polydactyly
         4. Peromelia
   3. Limb deficiency-splenogonadal fusion syndrome (Pauli and Greenlaw 1982; Bonneau et al. 1999; McPherson et al. 2003)
      1. Splenogonadal fusion
         1. A rare malformation in which the spleen is abnormally connected to the gonad or, more rarely, to a derivative of the mesonephros
         2. May occur as a rare malformation
      2. Association with other malformations, especially with terminal limb defects
   4. Moebius syndrome (please refer to the chapter of "Moebius Syndrome")

Diagnostic Investigations

1. Radiography (Johnson and Robinow 1978)
   1. Fusion of the temporomandibular joints
   2. Micro-/retrognathia
   3. Hypodontia
   4. Limb defects
      1. Variable distal limb deficiency
      2. Asymmetric reduction deformities of the distal extremities
      3. Severity ranging from hypoplastic digits to peromelia
   5. Other rare anomalies
      1. Dextrocardia
      2. Transposition of abdominal organs
      3. Jejunal atresia (David et al. 1992)
      4. Short bowel
      5. "Apple-peel" bowel
2. Reconstructed 3-D CT imaging of the craniofacial skeletal structures (Yasuda et al. 2003)
   1. Retruded and reduced mandible
   2. Steep inclination of the anterior surface of the mandible in relation to the lower mandibular plane
   3. Bone defect of the alveolar ridge at the midline area of the mandible
3. MRI of the tongue and the floor of the mouth (Yasuda et al. 2003)
   1. Degree of the hypoglossia

2. Space between the tongue and the inferior surface of the palate
3. Hypertrophy of the floor of the mouth

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: not increased
   2. Patient's offspring: not increased unless the condition represents an autosomal dominant inheritance, in which case there will be 50% risk to have an affected offspring
2. Prenatal ultrasonography at 19 weeks' gestation (Allanson et al. 2011)
   1. Severe micrognathia with almost complete absence of the mandible.
   2. Absent fluid-filled fetal stomach was identified.
   3. Absent bilateral radius, ulna, or hand.
3. Management (Yasuda et al. 2003; Cappellette et al. 2013)
   1. Early surgical intervention for the presence of severe anomalies that are life-threatening and interfere swallowing, breathing, and eating (Coşkunfirat et al. 1999)
   2. Extraction of the supernumerary tooth
   3. Dental alignment
   4. Orthopedic maxillary expansion
   5. Orthodontic expansion appliance for widening the mandibular dental arch
   6. Distraction osteogenesis to improve the size and shape of the hypoplastic mandible
   7. Mandibular advancement (Uğurlu et al. 2013)

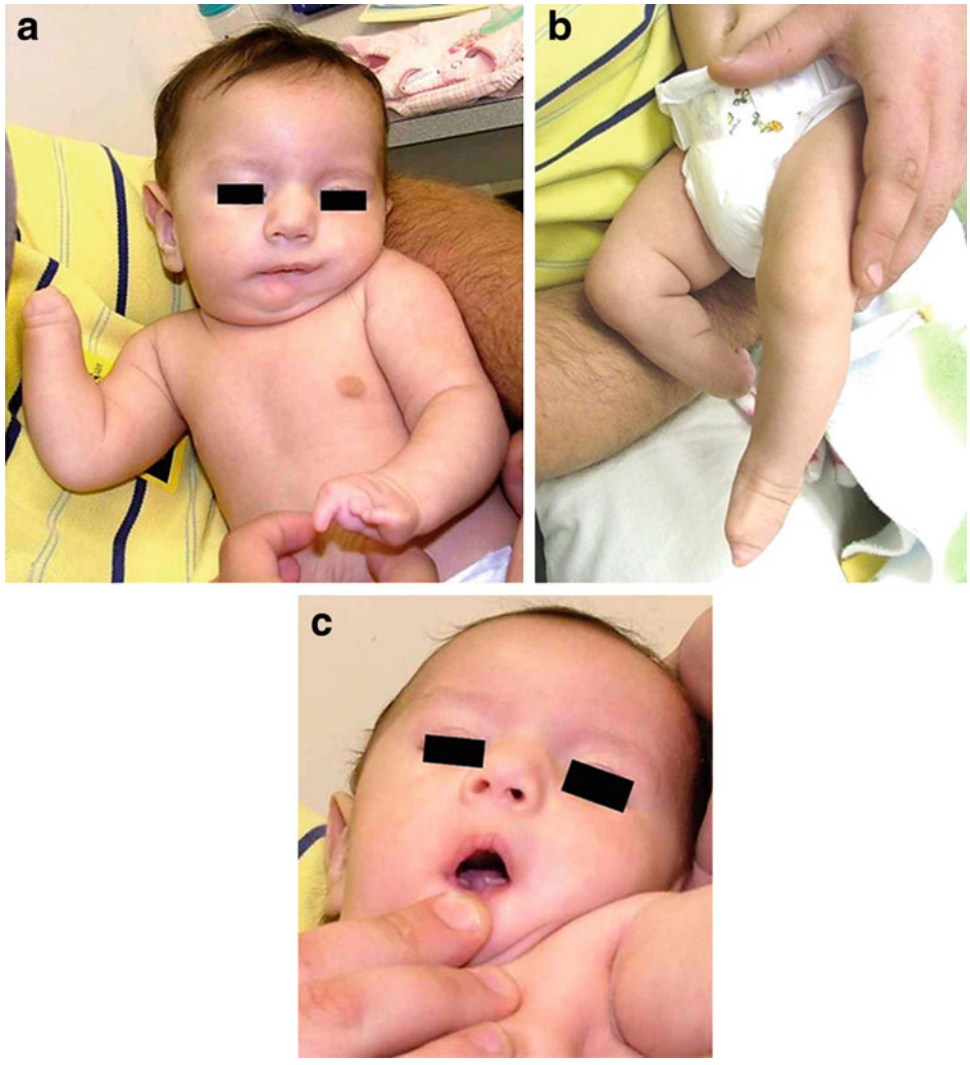

Fig. 1 (**a**–**c**) A 2-month-old female infant with hypoglossia-hypodactylia syndrome showing antimongoloid slant of the palpebral fissures, facial palsy, micro-/retrognathia, microstomia, hypoglossia, and limb anomalies with adactylia of the right hand and both feet and oligodactyly of the left hand

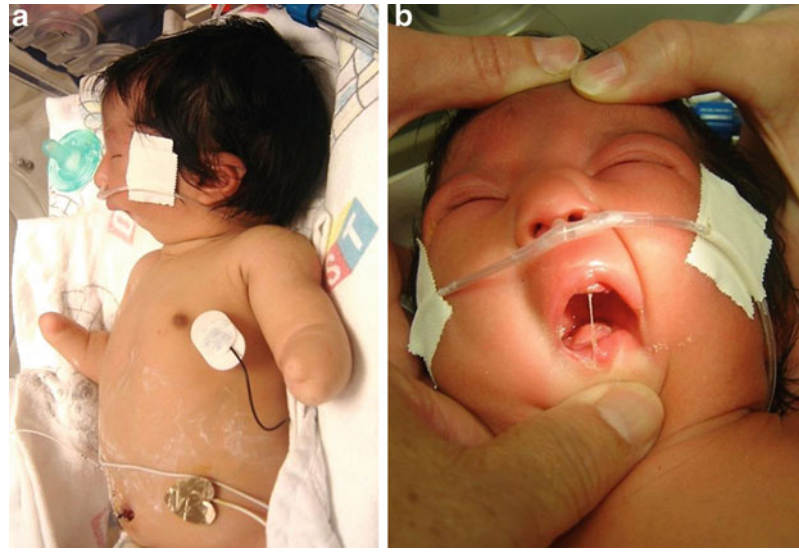

Fig. 2 (**a**, **b**) Another infant with hypoglossia-hypodactylia syndrome showing extreme micro-/retrognathia, hypoglossia, microstomia, and adactylia of both hands

Fig. 3 (**a**–**c**) A 3-month-old girl with hypoglossia-hypodactylia syndrome showing extreme micro-/retrognathia, hypoglossia, microstomia, and adactylia of both hands (*right upper* extremity showed a transverse growth arrest beyond the wrist, and *left upper* extremity showed a transverse arrest beyond the proximal one third of the forearm)

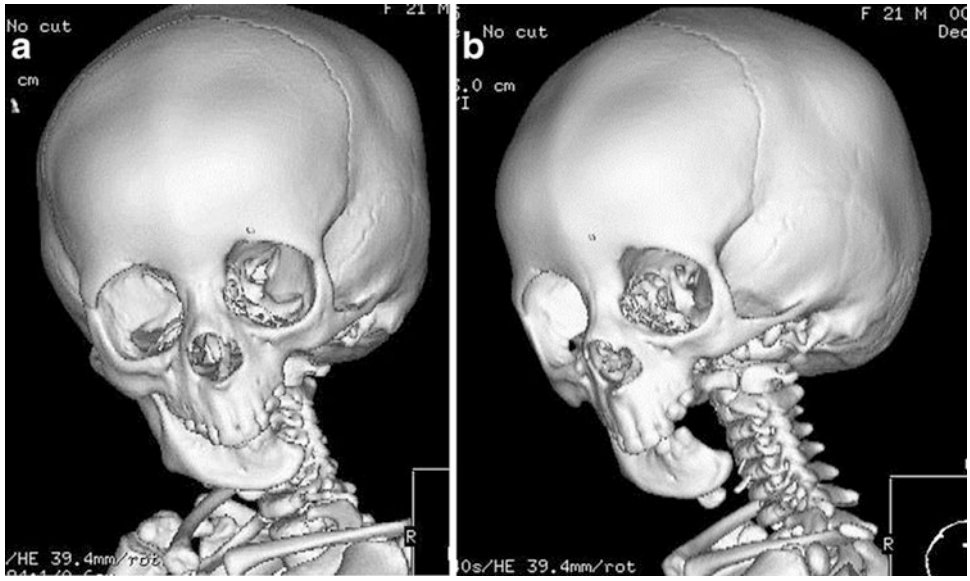

Fig. 4 (**a**, **b**) CT of the face (AP and lateral views) show left hemimandibular agenesis (complete absence of the body, angle, ramus, and condyle) and a significant aplasia of posterior maxilla on the *left*

Fig. 5 (**a**, **b**) Plain radiographs show transverse growth arrest past the proximal one third of the left forearm and V-shaped formation of the radius and ulna with growth arrest past the right wrist

Fig. 6 The previous girl was seen at 3 years of age

Fig. 7 (**a**, **b**) Preoperative photos at 5 years of age

Fig. 8 Preoperative CT at the age of 5

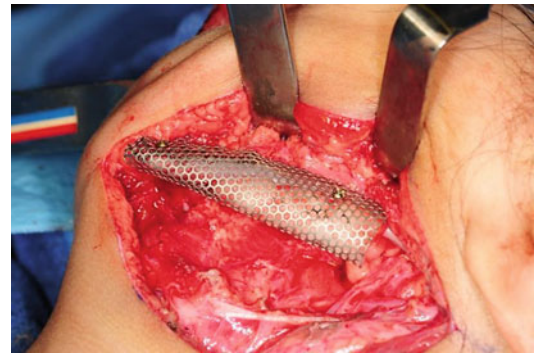

Fig. 10 Titanium mesh used as a crib for BMP at the inferior border of the rib graft

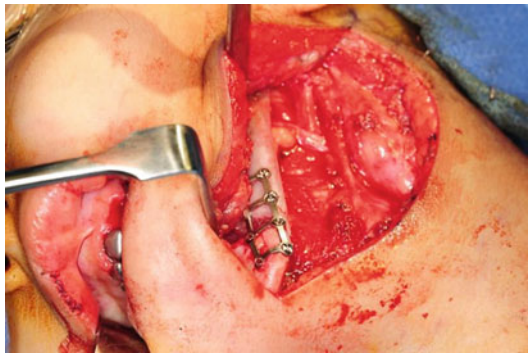

Fig. 9 Intraoperative photo. Costochondral graft fixated to the adjacent mandible. Cartilaginous cap seated in the glenoid fossa

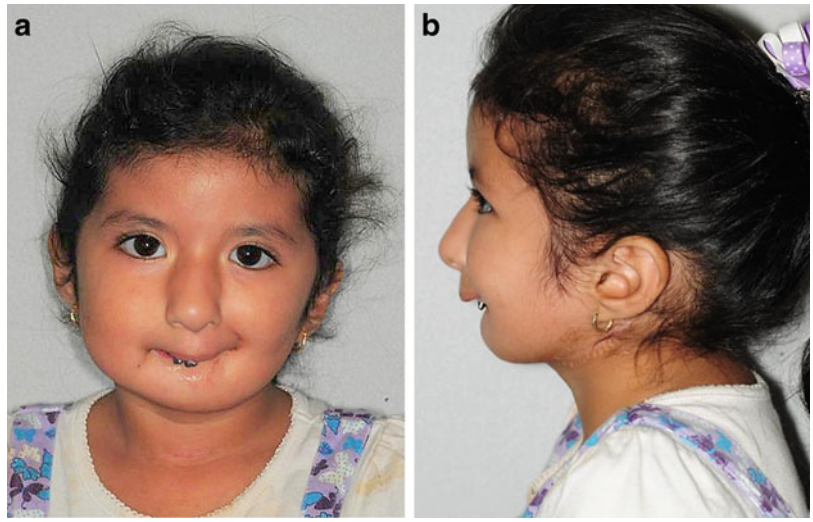

Fig. 11 (**a**, **b**) Postoperative photos at age 5. She was reconstructed with a right costochondral rib graft to replace the condyle and ramus region and established continuity of her mandible. This was combined with the use of a titanium mesh crib and some bone morphogenetic proteins (BMP) at the junction of the native mandible and the costochondral graft. Note the improved facial profile on the *left*. Despite improved result, the patient will require further surgery as she grows to correct her facial profile

Fig. 12 Three-month postoperative cone-beam CT. Cartilaginous cap not apparent on this view

Fig. 13 Note the broad intraoral band extending from the left subglossal region to the soft palate. This band also attaches to the left lower lip causing retraction of the lip

Fig. 14 The patient protruding her tongue past the intraoral band. Maximum protrusion. Based on the hypoglossia, the oral band extending from the floor of mouth and left cheek to the soft palate, and the limb abnormalities (hypodactylomelia), the patient would fit best as Hall's type IVD (intraoral bands and fusion with hypoglossia-hypodactylomelia). Thus, the patient is classified as a type IVD with hemimandibular agenesis (Qaisi et al., 2010, Oromandibular limb hypogenesis syndrome with a unique presentation of hemimandibular agenesis, personal communication)

Hypohidrotic Ectodermal Dysplasia

Contents

Hypohidrotic ectodermal dysplasia (HED) is a common form of ectodermal dysplasia characterized by a defect in the hair, in the teeth, and in mucosal and sweat glands. It is also known as anhidrotic ectodermal dysplasia. The incidence is estimated to be 1 in 10,000 to 1 in 100,000 male live births (Crawford et al. 1991).

Synonyms and Related Disorders

Anhidrotic ectodermal dysplasia; Christ-Siemens-Touraine syndrome

Genetics/Basic Defects

1. Inheritance: genetically heterogeneous (Pinheiro and Freire-Maia 1994)
    1. X-linked recessive type: the most common form of over 170 different ectodermal dysplasias
    2. Autosomal dominant type: less common
    3. Autosomal recessive type (Passarge et al. 1966): less common
2. X-linked HED: the most common form
    1. Caused by mutations in the ectodysplasin-A gene (*EDA1*) which (Monreal et al. 1998; Doffinger et al. 2001):
        1. Codes for the tumor necrosis factor (TNF) family member ectodysplasin-A (EDA)
        2. Maps to chromosome Xq12-q13.1 by a manifesting female with X linked hypohidrotic ectodermal dysplasia and an X;autosome balanced translocation (46,X,t(X;9)(q13.1;p24)) (Zonana et al. 1988) and X-autosome translocation of a female EDA patient [t(X;1)(q13.1;p36.3)] (Srivastava et al. 1996)
        3. Affects a transmembrane protein expressed by keratinocytes, hair follicles, and sweat glands
        4. Possibly has a key role in epithelial-mesenchymal signaling
    2. Over 94% of patients with X-linked HED carry mutations in the *EDA1* gene.
    3. Tabby phenotype is caused by mutation in mouse homolog of the human *EDA* gene (Priolo et al. 2000).
    4. X-linked anhidrotic ectodermal dysplasia with immunodeficiency is caused by impaired NF-kB signaling (Doffinger et al. 2001).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_127

5. Hemizygous males show severe forms of the disease, while heterozygous females often manifest mild to moderate symptoms because of X-chromosome inactivation.

3. Autosomal dominant form and some familial cases of autosomal recessive form of HED caused by at least two genes:
   1. *EDAR* (*EDA* receptor) gene (2q11-q13) (Ho et al. 1998; Baala et al. 1999)
      1. Cause either dominant or recessive forms
      2. Mutated in approximately 25% of non-EDA-related HED
   2. *EDARADD* (*EDAR*-associated death domain) gene (1q42-q43)
      1. Encodes a protein that interacts with the EDA receptor
      2. Known to cause either autosomal recessive or dominant HED
      3. Implicated in a very small number of HED patients (Chassaing et al. 2010)
4. Four genes (*EDA1*, *EDAR*, *EDARADD*, and *WNT10A*): account for 90% of hypohidrotic/anhidrotic ectodermal dysplasia cases (Cluzeau et al. 2011)

Clinical Features

1. General features
   1. Characterized by a triad of symptoms
      1. Atrichosis or hypotrichosis (missing or sparse hair)
      2. Anodontia, hypodontia, or misshapen teeth
      3. Absent or reduced sweating
   2. Variable clinical features
   3. Short stature
   4. Recurrent benign infectious disease seen in most patients with HED
   5. Unusually severe infections observed in:
      1. Anhidrotic ectodermal dysplasia with immunodeficiency: a distinct syndrome
      2. Ectodermal dysplasia with cleft lip/palate
      3. Ectrodactyly-ectodermal dysplasia-cleft lip/palate
   6. Otitis media
   7. Infantile fever of unknown etiology
   8. Hyperthermia
   9. Hoarse voice
2. Clinical features in X-linked recessive hypohidrotic ectodermal dysplasia
   1. Affected individuals
      1. Hemizygous males: affected
      2. Heterozygous female carriers: variable clinical symptoms (normal or mild or partially affected)
         1. Dental abnormalities, such as hypodontia
         2. Mild hypohidrosis
         3. Mild hypotrichosis
   2. Clinical evidence of the distribution of normal and abnormal skin along Blaschko lines in heterozygous and postzygotic mutation carriers of X-linked hypohidrotic ectodermal dysplasia
      1. The presence of two different cell lines in a female heterozygous for the XHED due to random inactivation of one of the two X chromosomes during embryogenesis, reflected by the presence of different skin areas, some normal and some showing the result of the genetic abnormality.
      2. These abnormal areas, disposed along Blaschko lines, reflect the lines of embryonal development of the epidermis and epidermal derivatives.
      3. This clonal inactivation ("lyonization") of the X chromosome results in variable degree of clinical expression of the disorder.
   3. Clinically differentiating X-linked HED from autosomal forms of HED
      1. Finding heterozygous females with XHED
      2. Finding parents with partial manifestations of the disorder due to a postzygotic mutation
   4. Clinical features
      1. Scalp hair
         1. Sparse
         2. Thin
         3. Light pigmented
         4. Slow growing

5. Excessive fragility of the shafts, breaking easily with the usual wear and tear of childhood
2. Body hair
1. Sparse
2. Normal sexual hair (beard, pubic hair)
3. Sweating
1. Greatly deficient sweating (hypohidrosis)
2. Leading to hyperthermia
4. Teeth
1. Congenital absence of teeth (hypodontia)
2. Teeth that are present (smaller than average and have conical crowns)
5. Facial features
1. Frontal bossing
2. A saddle nose (depressed nasal bridge)
3. Thick lips
4. Periorbital hyperpigmentation
6. Other features (Clarke et al. 1987)
1. Normal growth and psychomotor development
2. Atopic dermatitis
3. Bronchial asthma
4. Fever of unknown reason
5. Sudden death during infancy and early childhood

3. Clinical features in autosomal recessive hypohidrotic ectodermal dysplasia
1. Similar to (but indistinguishable from) the hemizygous form of X-linked hypohidrotic ectodermal dysplasia (Munoz et al. 1997)
1. Decreased sweating
2. Hypodontia
3. Conical teeth
4. Hypotrichosis of the scalp
5. Sparse or absent eyebrows and eyelashes
6. Sparse or absent body hair
7. Dry skin or eczema
8. Hypoplastic nails
9. Hypoplastic breasts
10. Atrophic rhinitis
11. Depressed nasal bridge
12. Hyperpigmented and wrinkled periorbital skin
2. Males and females equally affected

4. Clinical features in autosomal dominant hypohidrotic ectodermal dysplasia (Aswegan et al. 1997): milder in expression
1. Hypodontia, anodontia, microdontia, or other dental anomalies (100%)
2. Sparse eyelashes (100%)
3. Sparse eyebrows (96%)
4. Sparse, fine, slow-growing hair (89%)
5. Decreased sweating (85%)
6. Thin skin (78%)
7. Sparse body hair (62%)
8. Decrease heat tolerance (50%)
9. Onychodysplasia (39%)

5. Classification of ectodermal dysplasias (Deshmukh and Prashanth 2012)
1. Currently there are about 150 different types of ectodermal dysplasias. In an attempt to classify these, different subgroups are created according to the presence or absence of the four primary ectodermal dysplasia (ED) defects:
1. ED1: trichodysplasia (hair dysplasia)
2. ED2: dental dysplasia
3. ED3: onychodysplasia (nail dysplasia)
4. ED4: dyshidrosis (sweat gland dysplasia)
2. Based on clinical findings, different types of ectodermal dysplasia are more relevant and may be divided into two broad categories (Vasconcelos Carvalho et al. 2013):
1. Hypohidrotic ectodermal dysplasia (X-linked hypohidrotic ectodermal dysplasia or Christ-Siemens-Touraine syndrome).
2. Hidrotic ectodermal dysplasia (Clouston's syndrome)

Diagnostic Investigations

1. Radiography
1. Hypodontia and anodontia
1. Essential to determine the extent of hypodontia and anodontia

    2. Useful in the diagnosis of mildly affected individuals
  2. Recurrent respiratory infections
2. Normal hair morphology under electron microscopy
3. Starch-iodine test (Clarke and Burn 1991) to confirm a mosaic distribution of functional sweat glands in a heterozygous female carrier of X-linked HED (Cambiaghi et al. 2000)
4. Molecular analysis: clinically available
  1. Sequence analysis
    1. Mutation in *EDA* gene for the X-linked form
    2. Mutations in *EDAR* and *EDARADD* genes for the autosomal dominant or recessive forms
  2. Duplication/deletion testing: to detect exonic, multiexonic, or whole gene deletions in females which sequence analysis of *EDA* cannot detect

Genetic Counseling

1. Recurrence risk (Wright et al. 2014)
  1. Patient's sib.
    1. X-linked recessive: 50% of affected brothers if the mother is a carrier; otherwise the risk to sibs is low.
    2. Autosomal dominant: not increased unless a parent is affected, in which case the risk to the sibs is 50%.
    3. Autosomal recessive: 25% of the sibs affected.
  2. Patient's offspring.
    1. X-linked recessive
      1. Offspring of a male proband: none of the sons will be affected; 50% of the daughters will be carriers.
      2. Offspring of a female proband: 50% of her son will be affected, and 50% of her daughters will be carriers and may show minimal manifestations.
    2. Autosomal dominant: 50% risk to each child
    3. Autosomal recessive: not increased unless the spouse is also a carrier, in which case the risk to offspring is 50%
3. In X-linked form, carrier mothers exhibit minimal expression in the form of hypodontia and/or conical teeth and spottily reduced sweating (Deshmukh and Prashanth 2012).
4. Prenatal diagnosis.
  1. Three-dimensional ultrasonography to identify the distinct facial features during the third trimester (Sepulveda et al. 2003).
  2. Noninvasive prenatal diagnosis of hypohidrotic ectodermal dysplasia by Tooth Germ sonography (Wünsche et al. 2015).
  3. Analysis of fetal skin obtained from fetoscopy-guided skin biopsy in the second trimester.
  4. Prenatal diagnosis of X-linked hypohidrotic ectodermal dysplasia by linkage analysis (Zonana et al. 1990).
  5. Identification of the disease-causing mutation in the fetus.
  6. Preimplantation genetic diagnosis for at-risk pregnancies is possible, provided disease-causing mutations have been identified.
5. Management (Clarke 1987).
  1. Environmental modification to control temperature.
    1. Air condition for home, school, and work
    2. Adequate supply of water during the hot weather
  2. Control body temperature.
    1. Tepid sponging
    2. Showers
    3. Cold drink
    4. Antipyretics
    5. Wet clothing
  3. Use moisturizers to prevent xerosis or eczema for dry skin.
  4. Use artificial tears (eye drops) to prevent damage to the cornea in patients with defective tearing.

5. Remove nasal and aural concretions with suction devices or forceps and humidification of the ambient air to prevent their formation.
6. Treatment and prophylaxis for infections.
7. Dental evaluation and intervention.
    1. Early dental treatment
        1. Simple restoration
        2. Dentures
        3. Orthodontics
    2. Dental implants
    3. Orthodontic treatment
8. Wear wigs to improve appearance for patients with severe alopecia.
9. Avoid vigorous physical activities for patients with hypohidrosis.
10. Monitor growth.
11. Reconstruction surgery for saddle nose, sunken "dishpan face," and ear anomalies (Rossman and Johnson 1966).

Hypomelanosis of Ito

Contents

In 1952, Ito (1952) reported a female patient with a widespread, symmetric pattern of depigmented whorls and streaks, naming it incontinentia pigmenti achromians because the distribution of the depigmented lesions is the negative image of the hyperpigmented streaks of incontinentia pigment. Hypomelanosis of Ito (HI) is a relatively common disorder with a frequency of 1 in 8000–10,000 patients in a general pediatric hospital and 1 in 1000 patients in a pediatric neurology service (Küster and Konig 1999). HI is the third most common neurocutaneous syndrome, following neurofibromatosis and the tuberous sclerosis complex (Pascual-Castroviejo et al. 1998).

Synonyms and Related Disorders

Incontinentia pigmenti achromians

Genetics/Basic Defects

1. Inheritance
    1. Sporadic occurrence in nearly all cases with no affected sibs or parents (Küster and Konig 1999)
        1. Result of a de novo postzygotic mutation
        2. Mutation can only survive in a mosaic state
    2. Only a few cases with possible genetic inheritance reported
        1. X-linked dominant inheritance
        2. Autosomal dominant (Rubin 1972)
        3. Autosomal recessive
2. Pathogenesis
    1. Chromosome abnormalities (52%) (Janniger and de Menezes 2014)
        1. Mosaicism leading to generation of two cell lineages producing patterns of hypopigmented and hyperpigmented skin
        2. Balanced X/autosome translocations (Hatchwell et al. 1996)
        3. Supernumerary X chromosome/ring fragment
        4. Ring chromosomes (10, 14, 22)
        5. Mosaic triploidy
        6. Mosaic diploidy/tetraploidy
        7. Mosaic trisomies (2, 8, 13, 14, 18, 20, 22)
        8. Mosaic tetrasomy 13q
        9. Mosaic translocations

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_128

10. Mosaic deletions
11. Autosomal deletions and duplications involving chromosomes 7, 12, 13, 14, 15, and 18
12. Dup(Xp)

2. X chromosome abnormalities
   1. Inactivation
   2. Activation
   3. Mosaicism
3. Chromosome mosaicism
   1. Leads to variable phenotype
   2. Certain genes (9q33-qter, 15q11-q13, and Xp11 (Koiffmann et al. 1993) are implicated in hypomelanosis of Ito. However, no consensus exists about the identity of HI gene (Ratz 2014).

3. "Pigmentary mosaicism" (Flannery 1990; Ritter et al. 1990; Taibjee et al. 2004)
   1. Hypomelanosis of Ito and related disorders such as linear and whorled nevoid hypermelanosis are due to mosaicism for a variety of chromosomal abnormalities
   2. Classification of chromosome mosaicism
      1. Mosaicism with two or more different karyotypes, involving structural abnormalities of chromosomes
      2. Mosaicism involving structural abnormalities of chromosomes, where the chromosome was undetermined
      3. Chromosomal abnormality apparently affecting all cells, but where undetected mosaicism remains a possibility
      4. Balanced X/autosome translocations affecting all cells, with functional mosaicism due to ionization
      5. Polyploidy mosaicism (cells having different multiples of 23 chromosomes) can be associated with mosaic trisomy such as chromosome18
      6. Chimerism
4. A descriptive term rather than a true syndrome (Sybert 1994; Ruggieri and Pavone 2000)
   1. Suggested by the pattern of chromosomal aberrations and the polymorphic nature of the disease
   2. A term used for a phenotype
      1. Presence of linear streaks lighter than the patient's background skin color, extending around the trunk and down the long axes of the extremities, roughly following the lines of Blaschko
      2. Association with systemic findings

Clinical Features

1. Cutaneous symptoms (Küster and Konig 1999)
   1. Onset
      1. Recognizable at birth (54%)
      2. Visible during childhood (70%)
   2. No signs of inflammation or verrucous changes characteristically seen in incontinentia pigmenti
   3. Hypopigmented lesions
      1. Typical phenotype
         1. Cutaneous pattern: essentially the reverse of the third stage of incontinentia pigmenti
         2. Bilateral or unilateral whirls, patches, and streaks corresponding to the lines of Blaschko, often showing a midline cutoff
         3. Eruption not preceded by any inflammatory lesions (unlike incontinentia pigmenti)
      2. Unilateral skin lesions contralateral to the side of brain malformation in patients with HI and hemimegalencephaly
      3. Wood lamp useful in demonstrating hypopigmented lesions in persons with fair skin
      4. Atypical phenotype: checkerboard pattern zosteriform, dermatomal, or plaque-like arrangement
   4. Nonspecific skin lesions (20–40%)
      1. café-au-lait spots
      2. Persistent Mongolian blue spots
      3. Nevus of Ota
      4. Nevus marmoratus and angiomatous nevi
      5. Soft fibroma
      6. Pilomatrixoma
      7. Aplasia cutis
      8. Atopic dermatitis

2. Hair/nail/sweat gland anomalies
    1. Focal hypertrichosis
    2. Slow growth
    3. Diffuse alopecia
    4. Coarse, curly hair
    5. Trichorrhexis
    6. Widow's peak
    7. Generalized hirsutism
    8. Facial hypertrichosis
    9. Low hairline
    10. Ungual hypoplasia
    11. Hypohidrosis corresponding to hypopigmented areas
3. Associated extracutaneous anomalies (75%)
    1. CNS anomalies (Pascual-Castroviejo et al. 1988, 1998; Ruggieri and Pavone 2000)
        1. Mental retardation (50-75%)
        2. Seizures (50%)
        3. Autistic behavior (11%)
        4. Microcephaly
        5. Macrocephaly (Ross et al. 1982)
        6. Hypotonia
        7. Hyperkinesia
        8. Ataxia
        9. Deafness
        10. Hemimegalencephaly (Tagawa et al. 1997)
        11. Brain tumors: medulloblastoma, choroid plexus papilloma (Zajac et al. 1997)
        12. White matter abnormalities
        13. Cerebral, brain stem, or cerebellar atrophy
        14. Agenesis of the corpus callosum
        15. Periventricular lesions
    2. Ophthalmological abnormalities (20%) (Weaver et al. 1991)
        1. Microphthalmia
        2. Ptosis
        3. Nonclosure of the upper lid
        4. Symblepharon
        5. Dacryostenosis
        6. Strabismus
        7. Nystagmus
        8. Myopia
        9. Hyperopia
        10. Astigmatism
        11. Amblyopia
        12. Megalocornea
        13. Corneal opacification
        14. Cataracts
        15. Iridal heterochromia
        16. Scleral melanosis
        17. Heterochromia of the iris
        18. Optic atrophy
        19. Striated patchy hypopigmented fundi
        20. Retinal detachment
    3. Dental abnormalities
        1. Defective dental implantation
        2. Conical teeth
        3. Partial anodontia
        4. Dental dysplasia/hypoplasia
        5. Defective enamel
        6. Hamartomatous dental cusps
    4. Skeletal defects
        1. Short stature
        2. Facial and limb asymmetry (hemihypertrophy)
        3. Pectus carinatum or excavatum
        4. Scoliosis
        5. Syndactyly
        6. Polydactyly
        7. Brachydactyly
        8. Clinodactyly
    5. Congenital heart defect
        1. Tetralogy of Fallot
        2. Pulmonary stenosis
        3. Ventricular septal defect
        4. Atrial septal defect
        5. Incomplete right bundle branch block
        6. Cardiomegaly of unknown etiology
    6. Abdomen/gastrointestinal anomalies
        1. Diastasis recti
        2. Hepatomegaly
        3. Segmental dilation of the colon
        4. Diaphragmatic, umbilical, and inguinal hernias
    7. Genitourinary anomalies
        1. Hypospadias
        2. Micropenis
        3. Single kidney
        4. Urethral duplication
        5. Cryptorchidism
        6. Precocious puberty
        7. Gynecomastia

8. Asymmetrical breasts
9. Nephritis

4. Diagnostic criteria (Ruiz-Maldonado et al. 1992)
   1. Sine qua non criterion: congenital or early acquired nonhereditary cutaneous hypopigmentation in linear streaks or patches involving more than two body segments
   2. Major criterion
      1. One or more nervous system anomalies
      2. One or more musculoskeletal anomalies
   3. Minor criterion
      1. Two or more congenital malformations other than nervous system or musculoskeletal anomalies
      2. Chromosomal anomalies
   4. Definitive diagnosis: sine qua non criterion plus one or more major criteria or two or more minor criteria
   5. Presumptive diagnosis: sine qua non criterion alone or in association with one minor criterion
5. Classification of linear pigmentary disorders distributed along the Blaschko lines (Nehal et al. 1996; Di Lernia 2007)
   1. Linear and whorled hypermelanosis (Harre and Millikan 1994)
      1. Hyperpigmentation
      2. Diffuse distribution
      3. Presence of mosaicism
      4. Associated abnormalities ($\leq$30%)
   2. Hypomelanosis of Ito
      1. Hypopigmentation
      2. Diffuse distribution
      3. Presence of mosaicism
      4. Associated abnormalities ($\geq$30%)
   3. Progressive cribriform and zosteriform hyperpigmentation
      1. Hyperpigmentation
      2. Segmental distribution
      3. Associated abnormalities: very low incidence
   4. Segmental nevus depigmentosus
      1. Hyperpigmentation
      2. Segmental distribution
      3. Associated abnormalities: very low incidence
6. Differential diagnosis (Barbel et al. 2015)
   1. Pityriasis alba
      1. Affects approximately 5% of the pediatric population (Moreno-Cruz et al. 2012)

Diagnostic Investigations

1. Cytogenetic investigation
   1. Peripheral blood karyotyping indicated especially when systemic manifestations are present
   2. Fibroblast karyotyping by sampling the dark and light skin for demonstrating mosaicism or chromosomal abnormalities
   3. Presence of a wide variety of karyotypic abnormalities
2. Histopathology
   1. Decreased numbers of melanocytes
   2. Decreased numbers and size of pigmented melanosomes
   3. Neuropathological features
      1. Polymicrogyria
      2. Disarray of cortical lamination
      3. Heterotopic neurons in the white matter
      4. Giant cells (Glover et al. 1989; Pascual-Castroviejo et al. 1998)
3. CT and MRI of the brain
   1. White matter abnormalities somewhat predictive of a poor neurological outcome (Ruggieri et al. 1996)
   2. Neuroblast migration
      1. Heterotopia
      2. Pachygyria
      3. Polymicrogyria
   3. Localized or generalized cerebral atrophy
   4. Cerebral hemiatrophy
   5. Hemimegalencephaly
   6. Other rare anomalies
      1. Noncommunicating hydrocephalus
      2. Megacisterna magna
      3. Arteriovenous malformation (Urgelles et al. 1996)
      4. Cerebellar hypoplasia (hemispheres and vermis)
      5. Brainstem hypoplasia
      6. Brain tumors (Steiner et al. 1996)

4. Radiography for musculoskeletal anomalies
5. EEG for seizures

Genetic Counseling

1. Recurrence risk (Ruggieri 2000)
   1. Patient's sib: not increased unless a parent shows chromosomal abnormalities
   2. Patient's offspring
      1. Not increased unless the patient has chromosomal abnormalities
      2. Guarded counseling in women with a phenotype similar to HI who have nonmosaic balanced X/autosome translocations
2. Prenatal diagnosis: undetermined for affected mother who has a specific type of chromosome abnormality
3. Management
   1. Early intervention programs including physical, occupational, and speech therapies
   2. Special education
   3. Seizure control
   4. Surgical treatment of cataracts and retinal detachment
   5. Pharmacoresistant epilepsy in hypomelanosis of Ito: Palliative surgical treatment with modified anatomic posterior quadrantic resection (Manjila et al. 2014)

Hypophosphatasia

Contents

Hypophosphatasia is a heritable metabolic disease, characterized by impaired ossification of the bones, reduction in tissue and plasma levels of alkaline phosphatase, and the presence of phosphoethanolamine in the urine. The incidence is estimated to be about 1 in 100,000 live births (Fraser 1957). The incidence of severe disease is especially high in Canadian Mennonites (1 in 2,500 newborns) (Gehring et al. 1999).

Synonyms and Related Disorders

Adult hypophosphatasia (mild hypophosphatasia, odontohypophosphatasia); Childhood hypophosphatasia; Perinatal lethal hypophosphatasia; Phosphoethanolaminuria

Genetics/Basic Defects

1. Genetic heterogeneity (Bianchi 2015)
    1. Perinatal lethal hypophosphatasia form: autosomal recessive
    2. Prenatal benign hypophosphatasia form: autosomal recessive and dominant
    3. Infantile hypophosphatasia form: autosomal recessive
    4. Childhood hypophosphatasia form: autosomal recessive (frequent) and dominant (rare)
    5. Adult hypophosphatasia form: autosomal recessive and dominant with variable penetrance
    6. Odontohypophosphatasia form: autosomal recessive and dominant
2. Cause
    1. Caused by mutations in the alkaline phosphatase gene (*ALPL*) which (Barcia et al. 1997):
        1. Codes for tissue nonspecific ("liver/bone/kidney") alkaline phosphatase (TNSALP) (Henthorn and Whyte 1992)
        2. Is mapped on chromosome 1p36.1-p34
    2. Typically, the other isoenzymes (placental and intestinal forms) are not affected (Gehring et al. 1999)
3. Pathophysiology
    1. Defects in mineralization
        1. Caused by deficiency in TNSALP
        2. Resulting in increased urinary excretion of phosphoethanolamine and inorganic pyrophosphate and an increase in serum pyridoxal 5'-phosphate

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_129

2. Alkaline phosphatase (ALK) has a significant role in skeletal mineralization in humans. How ALP acts was clarified by the discoveries that several phosphocompound substrates for tissue-nonspecific ALP (TNSALP) accumulate endogenously in this inborn error of metabolism (Whyte 1995)
3. Osteoclasts, although morphologically normal, lack membrane-associated alkaline phosphatase activity on histochemical analysis (Barcia et al. 1997)
    1. Impede the proper incorporation of calcium into newly formed bone matrix
    2. Result in bone demineralization and hypercalcemia when the impaired matrix calcification process occurs with a rapid rate of bone resorption
4. Genotype-phenotype correlations (Hu et al. 2000)
    1. A number of different mutations account for the clinical heterogeneity
        1. Individuals with recessive hypophosphatasia with both defective TNSALP alleles
            1. In general, manifest more severe symptoms, with many of those affected being stillborn or expiring shortly after birth
            2. Exception when consanguineous marriage is a factor: the two defective alleles tend to have distinct point mutations resulting in different amino acid substitutions in the alkaline phosphatase protein
        2. Individuals with dominant hypophosphatasia with only one defective TNSALP allele: usually manifest moderate symptoms, such as the premature exfoliation of fully rooted primary teeth
        3. Division between dominant and recessive hypophosphatasia sometimes is not well defined because the heterozygous siblings with one defective TNSALP allele in kindreds with recessive hypophosphatasia may show mild or moderate symptoms of the disease
        2. Missense mutations in the TNSALP gene have been observed in some hypophosphatasia kindreds, particularly those families with the more severe perinatal and infantile forms of the disease
        3. Autosomal recessive inheritance has been observed in most cases of hypophosphatasia with affected individuals being compound heterozygotes for two different mutant hypophosphatasia alleles
        4. Autosomal dominant alleles cause a few relatively mild cases of hypophosphatasia
        5. Mild hypophosphatasia (Fauvert et al. 2009)
            1. Can result from either compound heterozygosity for severe and moderate mutations but also in a large part from heterozygous mutations with a dominant negative effect
            2. A sequence variation in linkage disequilibrium with haplotype E could in addition play the role of an aggravating factor resulting in loss of haplosufficiency

Clinical Features

1. Presence of a wide phenotypic variability (interfamilial and intrafamilial) ranging from intrauterine death and extreme hypomineralization of the skeleton to lifelong absence of clinical symptoms (Gehring et al. 1999; Hoffmann et al. 2014; Plotkin 2014)
    1. The following six different forms of hypophosphatasia have been defined (Bianchi 2015):
        1. Perinatal lethal form
        2. Perinatal benign form
        3. Infantile form
        4. Childhood form
        5. Adult form
        6. Odontohypophosphatasia
    2. In general, the earlier the age of presentation, the more severe the presenting features
2. Perinatal lethal form (Bianchi 2015)
    1. The most severe form: stillbirth or death within days/weeks after birth
    2. Skeletal deformities: presenting features

1. A profound lack of skeletal mineralization (severe hypomineralization) in utero
2. Derangements in calcium/phosphate metabolism
3. Skin-covered spurs extending from the forearms or legs (skin dimples) (Shohat et al. 1991): these spurs are often diagnostic for hypophosphatasia
4. Markedly shortening and bowing of the long bones (short-limbed dwarfism)
5. Fractures (perinatal)
6. Rickety rosary
7. Metaphyseal swelling
8. Soft, pliable cranial bones ("vault like a balloon")
9. Bulging anterior fontanelle

3. Respiratory distress due to severe hypoplastic lungs and rachitic deformities of the chest and rib fractures
4. Other features
   1. Hypotonia
   2. High-pitched cry
   3. Vomiting
   4. Constipation
   5. Unexplained fever
   6. Apnea
   7. Cyanosis
   8. Irritability
   9. Seizures
5. Prognosis
   1. Lethal in utero or within a few days of birth
   2. In the rare prenatal benign form, despite prenatal symptoms, there is a spontaneous improvement of skeletal defects (Pauli et al. 1999; Moore et al. 1999; Wenkert et al. 2007)

3. Infantile form (Fallon et al. 1984; Bianchi 2015)
   1. Appears normal at birth
   2. Onset of symptoms
      1. Before 6 months of age
      2. Poor feeding
      3. Failure to thrive (growth failure)
      4. Hypotonia
      5. Convulsions
   3. Associated with progressive bony demineralization
      1. Abnormal skull with apparent wide separation of the cranial sutures and a wide, bulging anterior fontanelle
      2. Tendency toward developing craniosynostosis
         1. Formation of a sagittal ridge
         2. A bony prominence at the position of the anterior fontanelle
      3. Rachitic skeletal deformities manifesting by age 6 months
      4. Flail chest
      5. Pulmonary insufficiency
   4. Premature craniosynostosis
      1. Chiari I malformation
      2. Hydrostatic hydrocephalus
      3. Hydrosyringomyelia
   5. Swallowing disorders
   6. Irritability
   7. Seizures
   8. Severe muscular hypotonia
   9. Late in walking
   10. Development of genu valgum
   11. Short stature
   12. Complications
      1. Recurrent pneumonia
      2. Increased intracranial pressure
      3. Renal compromise secondary to:
         1. Hypercalcemia
         2. Hypercalcinuria
         3. Nephrocalcinosis
   13. Prognosis:
      1. Fatal in approximately 50% of cases by the age of 1 year
      2. Survivors
         1. Tend to improve symptomatically
         2. Deformities persist and often become worse

4. Childhood form (Fallon et al. 1984; Bianchi 2015)
   1. Appears normal at birth
   2. Often present after 6 months of age
   3. History of delayed walking and waddling gait
   4. Early loss of deciduous teeth (before age of 5 years): the most consistent clinical sign

5. Frequent bone pain
6. Defective bone mineralization presenting clinically as rickets in children
7. Respiratory complications due to rachitic deformities of the chest
8. Premature craniosynostosis despite open fontanelle resulting in increased intracranial pressure
9. Dolichocephalic skull
10. Enlarged joints
11. Short stature
12. Muscular hypotonia
13. Failure to thrive
14. Lack of appetite, nausea, and gastrointestinal problems
15. Delayed walking
16. Repeated bone fractures
17. Waddling gait due to bone deformities
18. Chronic lower extremity bone pain
19. Presence of hypercalcemia causes increased excretion of calcium resulting in renal damage
20. Prognosis: improving both clinically and radiographically with age in some childhood hypophosphatasia patients

5. Adult form (Fallon et al. 1984; Wendling et al. 2001; Berkseth et al. 2013; Bianchi 2015)
    1. Variable age of onset and severity
    2. Onset usually during middle age
    3. A wide spectrum of clinical manifestations: 1/3 of patients asymptomatic at the time of diagnosis
    4. The most common presenting features
        1. Musculoskeletal pain (40.9%)
        2. Fractures (18.2%)
        3. Whereas classic features of childhood forms of HPP such as dental abnormalities and a history of rickets are relatively uncommon
    5. Fractures
        1. Stress fractures of metatarsals, tibia
        2. Femur pseudofractures
        3. Fragility fractures
        4. History of delayed fracture healing in childhood; often mild "rickets"
    6. Defective bone mineralization presents clinically as osteomalacia and osteoporosis in adults
    7. Premature loss of deciduous teeth
    8. Usually presents clinically with loss of adult teeth
    9. Foot pain due to stress fractures of the metatarsals
    10. Thigh pain due to pseudofractures of the femur
    11. Delay in healing after a fracture
    12. Joint pain due to deposition of calcium pyrophosphate dihydrate (chondrocalcinosis)
    13. Pseudogout
    14. Chondrocalcinosis
    15. Osteoarthritis
    16. Myopathy/weakness
    17. Renal abnormalities
        1. Reduced GFR
        2. Nephrocalcinosis and kidney stones
    18. Psychiatric symptoms
        1. Insomnia
        2. Restlessness
        3. Anxiety
        4. Depression
6. Odontohypophosphatasic form (Bianchi 2015)
    1. Premature loss of adult teeth; the only physical finding in this form
    2. Not associated with bone, articular, or muscular problems
7. Craniosynostosis
    1. Considered a known feature in the infantile and childhood types of hypophosphatasia (Whyte 1995; Mornet 2007; Collmann et al. 2009), while it is missed in the adult and odontohypophosphatasia forms
    2. Often progressively involves all cranial sutures and poses significant functional risks to the optic nerves, as well as the spinal cord
8. Differential diagnosis of hypophosphatasia and osteomalacia (Silver et al. 2012)
    1. Osteomalacia
        1. Serum alkaline phosphatase: high

2. Serum levels of vitamin D and parathormone (PTH)
    1. low serum vitamin D
    2. Elevated PTH
3. Serum levels of calcium and phosphate
    1. Hypercalcemia
    2. Hypophosphatemia
4. Biopsy
    1. Discontinuous atrophic changes in the muscle fibers
    2. Loss of myofibrils
    3. Type II fiber atrophy

2. Hypophosphatasia
    1. Serum alkaline phosphatase: low
    2. Serum levels of vitamin D and parathormone: normal
    3. Serum levels of calcium and phosphate: normal
    4. Biopsy
        1. No atrophic signs
        2. Peripheral nucleus
        3. Type I fiber predominance
3. Both conditions
    1. Similar radiologic abnormalities
    2. Muscle hypotonia
    3. Waddling gait
    4. Diffuse bone pain worse with the cold and the exercise
    5. Proximal muscular weakness of the pelvic girdle and the lower limbs

Diagnostic Investigations

1. Laboratory tests
    1. Low serum alkaline phosphatase levels in all types of hypophosphatasia
    2. Increased levels of urinary phosphoethanolamine levels
    3. Elevated plasma levels of pyridoxal 5'-phosphate
    4. Normal serum calcium, except in infantile cases where hypercalcemia can be seen due to renal failure
    5. Normal serum phosphate: hyperphosphatemia in various forms of hypophosphatasia reported
2. Skeletal survey (James and Moule 1966; Kozlowski et al. 1976).
    1. Lethal perinatal form
        1. Near absence of skeletal mineralization
        2. Skull: tiny ossification of occipital and/or frontal bones or complete absence of ossification
        3. Teeth: very poorly formed
        4. Spine
            1. Some vertebrae frequently unossified
            2. Occasionally unossified vertebrae
            3. Abnormally shaped vertebrae: rectangular, round, flattened, sagittally cleft, or butterfly-shaped vertebrae
        5. Shortening and bowing of the long and tubular bones
        6. Diaphyseal spurs
        7. Skin-covered spurs extending from the medial and lateral aspects of the knee and elbow joints
        8. Fractures
        9. Rachitic changes
            1. Pathology most evident at metaphyses as in rickets where growth is most rapid, namely the wrists, knees, hips, and proximal humeri
            2. Defective, irregular ossification of the metaphysis: the most diagnostic feature of the disease
            3. Nearly absent provisional zone of calcification
            4. Irregular widening of the epiphyseal plate
            5. Grossly irregular ossification of metaphysis giving a “frayed” or “tufted” appearance: a distinguished feature in hypophosphatasia. In rickets, the decalcification is usually regular and may give a “ground glass” effect to the affected metaphysis (metaphyseal cupping)

2. Infantile form
    1. Deficient skeletal mineralization
    2. Congenital bowing of the long bones
    3. Bands of decreased density in metaphyses
    4. Widened cranial sutures
    5. Later craniosynostosis: premature craniosynostosis occurs despite an open fontanelle
    6. Asymmetrical, moderate to severe rickets-like metaphyseal changes
    7. Metaphyseal and epiphyseal ossification defects
    8. Distorted bone trabeculation with areas of decreased and increased transradiancy
    9. Thin cortical bone
    10. Diaphyseal spurs
3. Childhood form
    1. Mild, asymmetrical, metaphyseal changes resembling rickets or metaphyseal dysplasia
    2. Distorted bone trabeculation with areas of decreased and increased transradiancy
    3. Thin cortical bone
    4. Hypotubulation and bowing of long bones
    5. Stress fractures
    6. Radiolucent projections from the epiphyseal plate into the metaphysis
4. Adult form
    1. Pseudofractures often occur in the lateral aspect of the proximal femur: a hallmark of this form
    2. Osteomalacia
    3. An increased incidence of poorly healing stress fractures, especially of the metatarsals
5. Odontohypophosphatasic form: normal radiographic findings

3. Radiography and ultrasound screening for nephrocalcinosis
4. Whole body magnetic resonance imaging (WB-MRI) on the childhood form of HPP (Beck et al. 2011)
    1. Long bones: presence of deformities and defects
    2. All patients showed radiological lesions in the metaphyses of the long bones predominantly in the lower extremities being consistent with hyperemia and edema
5. Histology
    1. Growth plates
        1. Rachitic abnormalities
        2. Poorly mineralized and ossified columns with broad osteoid seams in metaphysis
        3. Osteoblasts lacking membrane-associated alkaline phosphatase activity on histochemical testing, disrupting incorporation of calcium into the matrix
    2. Teeth
        1. A decrease in cementum
        2. Enlarged pulp chamber
        3. Incisors tend to be affected
6. Molecular genetic diagnosis (Monet and Nunes 2016): ALPL, the gene-encoding alkaline phosphatase, tissue nonspecific isozyme (TNASALP), is the only gene known to be associated with hypophosphatasia
    1. Single-gene testing
        1. Sequence analysis of ALPL is performed first
        2. Followed by gene-targeted deletion/duplication analysis if only one or no pathogenic variant is found
    2. A multi-gene panel that includes ALPL and other genes of interest may also be considered: The genes included in the panel and the diagnostic sensitivity of the testing used for each gene vary by laboratory and over time
    3. More comprehensive genomic testing (when available) including whole-exome sequencing (WES) and whole-genome sequencing (WGS) may be considered if single-gene testing (and/or use of a multigene panel that includes ALPL) fails to confirm a diagnosis in an individual with features of hypophosphatasia. Such testing may provide or suggest a diagnosis not previously considered (e.g., mutation of a

different gene that results in a similar clinical presentation)

Genetic Counseling

1. Recurrence risk: genetic counseling is complicated by the inheritance that may be autosomal dominant or autosomal recessive, the existence of the uncommon prenatal benign form, the variable expression of the disease, and the incomplete penetrance of the trait (Mornet 2007; Simon-Bouy et al. 2008; Monet and Nunes 2016)
    1. Patient's sib
        1. Autosomal recessive: 25%
        2. Autosomal dominant: not increased unless a parent is affected in which case the recurrence risk is 50%
    2. Patient's offspring
        1. Autosomal recessive: not increased unless a spouse is a carrier in which case the recurrence risk is 50%
        2. Autosomal dominant: 50%
2. Prenatal diagnosis (Mulivor et al. 1978)
    1. Fetal radiography (Leroy et al. 1982)
    2. Prenatal ultrasonography
        1. 2D-ultrasonography
            1. Failure to visualize a well-defined skull
            2. Other fetal skeletal structures not readily discernable
        2. 3D-ultrasonography: can demonstrate specific osseous spurs in a lethal form (Sinico et al. 2007)
    3. Prenatal ultrasonography for benign prenatal hypophosphatasia (Matsushita et al. 2014)
        1. Normal skeletal mineralization
        2. Normal chest and abdominal circumferences, despite the limb bowing and shortening
    4. Fetal cordocentesis in the first trimester: undetectable fetal alkaline phosphate concentration (Tongsong and Pongsatha 2000)
    5. Assay of the alkaline phosphatase activity: a useful complementary and independent method, especially when a mutation is unidentified and DNA from the index case is unavailable
        1. Assay of the tissue nonspecific alkaline phosphatase activity in chorionic villus samples in the first trimester (Maxwell et al. 1985; Brock and Barron 1991; Mornet et al. 1999)
        2. Absent alkaline phosphatase activity in the amniotic fluid and cultured amniotic fluid cells in the second trimester
    6. Prenatal diagnosis and preimplantation genetic diagnosis: mutation analysis of fetal DNA from amniocentesis or CVS where the disease-causing mutation has been identified in the family (Monet and Nunes 2016)
3. Management
    1. No specific treatment available: efforts to effect improved mineralization in patients with hypophosphatasia have not been successful (Barcia et al. 1997)
        1. Nonsteroidal anti-inflammatory drugs for control of the bone pain
        2. Dietary phosphate restriction may be helpful (Wenkert et al. 2007)
        3. Large dose of vitamin D: reversal of improvement in the bony architecture upon withdrawal of the drug (Anderton 1979)
        4. Oral cortisone: reversal of improvement in serum alkaline phosphatase level and radiographic appearance of the bones upon withdrawal of the drug (Anderton 1979)
        5. Avoid saline solution, furosemide diuresis, steroid therapy, or a low-calcium diet because these approaches may actually worsen bone mineralization and nephrocalcinosis
        6. Inhibition of osteoclastic activity with calcitonin: continued demineralization despite returning of normal serum calcium concentration

7. Plasma infusions designed to supplement alkaline phosphatase activity or induce alkaline phosphatase production: not consistently improve bone mineralization
8. Pyridoxine and/or pyridoxal phosphate in neonates with intractable seizures (Balasubramaniam et al. 2010)

2. Benign prenatal hypophosphatasia (Matsushita et al. 2014)
   1. A treatable disease not to be missed
   2. Marked bowing of the long bones at birth but showed a relatively benign postnatal course with spontaneous improvement of bowing
3. A clinical trial of marrow cell transplantation for infantile hypophosphatasia (Whyte et al. 2003)
   1. A significant, prolonged clinical and radiographic improvement followed soon after receiving a boost of donor marrow cells
   2. Biochemical features of hypophosphatasia, however, remain unchanged to date
   3. The most plausible hypothesis for the patient's survival and progress: transient and long-term engraftment of sufficient numbers of donor marrow mesenchymal cells form functional osteoblasts and perhaps chondrocytes, to ameliorate the skeletal disease
4. Enzyme replacement therapy with asfotase alfa: associated with improved findings on skeletal radiographs and improved pulmonary and physical function in infants and young children with life-threatening hypophosphatasia (Millán and Plotkin, 2012)
5. Enzyme replacement therapy for congenital hypophosphatasia allows for surgical treatment of related complex craniosynostosis (Kosnik-Infinger et al. 2015)
6. Surgical care
   1. Rachitic deformities
   2. Gait abnormalities
   3. Adult form
      1. Rod placement for pseudofractures of the adult type results in the union and relief of the pain
      2. Primary bone grafting and plating for midshaft fractures
      3. Anticipate delayed union of fractures

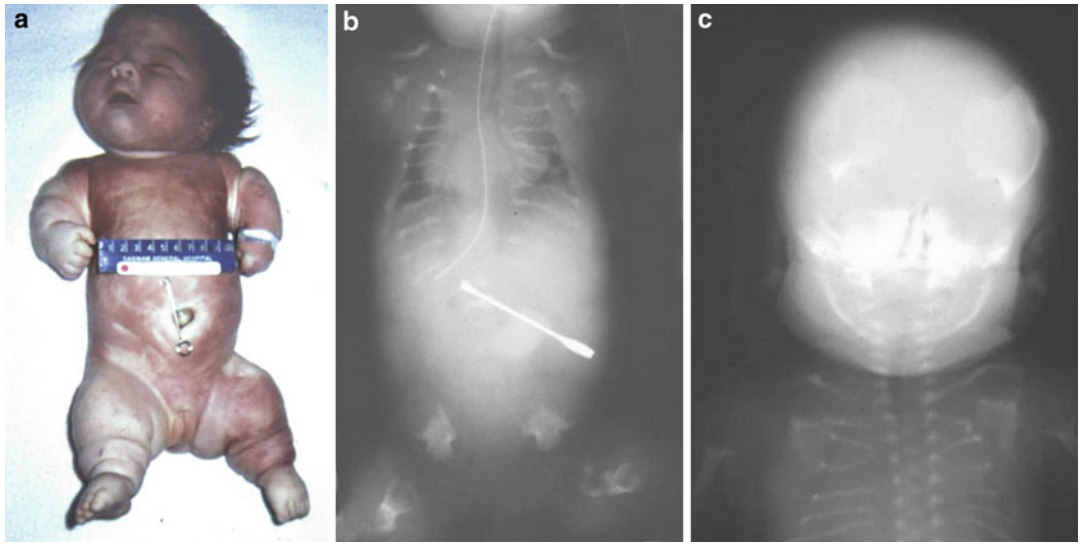

Fig. 1 (**a**–**c**) A neonate with perinatal lethal form of hypophosphatasia showing severe shortening of limbs. Radiograph shows markedly deficient ossification and abnormal bone development similar to achondrogenesis type I

Fig. 2 Radiograph of another neonate with hypophosphatasia shows rickets-like metaphyseal cupping (spurs) and poor mineralization of cranial bones

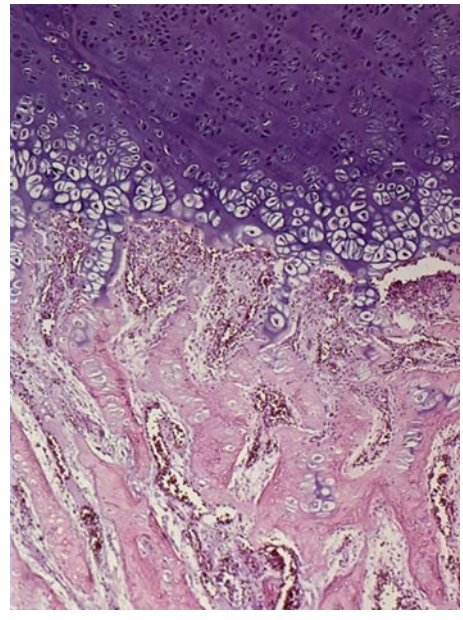

Fig. 3 Photomicrograph of a rib. Broad columns of hypertrophic chondrocytes with osteoid seams are present in the metaphysis. These columns are poorly mineralized and ossified

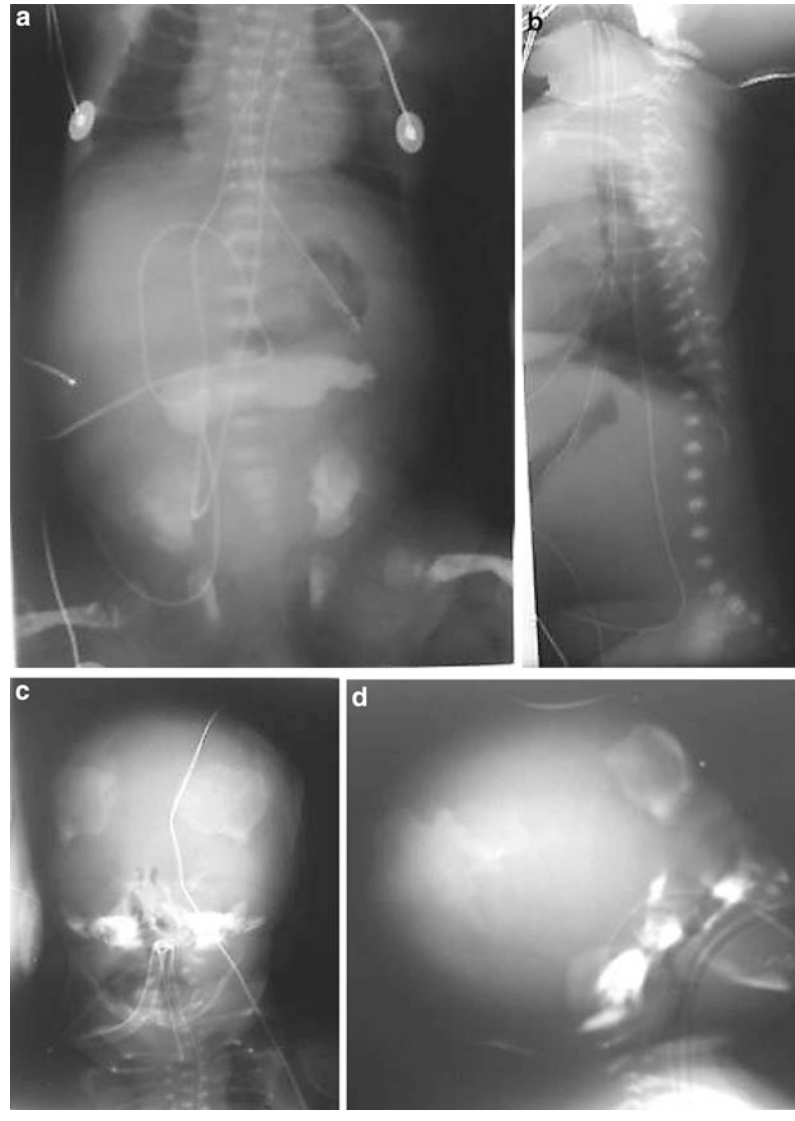

Fig. 4 (**a**–**d**) Radiographs of another neonate with perinatal lethal form of hypophosphatasia showing marked deficient skeletal mineralization, prenatal fracture of the left femur, and abnormal metaphyseal ossification of the proximal femurs

Fig. 5 Childhood hypophosphatasia in two brothers showing short stature and bowed legs

Hypopituitarism

Contents

Hypopituitarism is a term used to describe the deficiency of one or more of the hormones of the anterior or posterior pituitary gland. It can vary in severity and age at presentation. These hormonal deficits can also be present as part of a syndrome, with patients manifesting extrapituitary abnormalities such as in the eye and forebrain.

In clinical practice, panhypopituitarism is used to describe patients deficient in growth hormone (GH), gonadotropins, corticotropin, and thyrotropin in whom posterior pituitary function remains intact.

Hypopituitarism is rare, with an estimated annual incidence rate of 4.2 cases per 100,000 and with a prevalence rate of 45.5 per 100,000 (Regal et al. 2001).

Synonyms and Related Disorders

Adrenocorticotropin deficiency; Gonadotropin deficiency; Growth hormone deficiency; Pituitary hormone deficiency; Primary empty sella syndrome; Prolactin deficiency; Sheehan's syndrome; Thyrotropin deficiency

Genetics/Basic Defects

1. Pituitary cell types and hormones produced (Webb and Dattani 2011)
    1. Anterior lobe hormone produced action target tissue
        1. Somatotrophs
            1. Growth hormone: growth promotion and metabolic action
            2. Target tissue: liver, adipose tissue, bone
        2. Thyrotrophs
            1. Thyroid-stimulating hormone: stimulates thyroxine production
            2. Target tissue: thyroid gland
        3. Lactotrophs
            1. Prolactin: lactation
            2. Target tissue: breast ductal tissue
        4. Gonadotrophs
            1. Follicle-stimulating hormone and luteinizing hormone: stimulate gonadal maturation and hormonal cycling

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_130

   2. Target tissue: gonads (testis, ovary)
5. Corticotrophs
   1. Adrenocorticotropic hormone: stimulates cortisol production and promotes renal reabsorption of water
   2. Target tissue: adrenal cortex

2. Intermediate lobe: melanotrophs
   1. Pro-opiomelanocortin, the precursor to melanocyte-stimulating hormone and endorphins: increases skin pigmentation
   2. Target tissue: skin
3. Posterior lobe: axonal projections of neurons
   1. Cell bodies reside in the hypothalamus and secrete arginine vasopressin and oxytocin
   2. Vasopressin: essential for reabsorption of water in collecting ducts
   3. Oxytocin: important for parturition

2. Heterogeneous causes (Schneider et al. 2007; Kelberman and Dattani 2007; Toogood and Stewart 2008; Fernandez-Rodriguez et al. 2012; Corenblum 2014; Kim 2015)
   1. Brain damage
      1. Traumatic brain injury (trauma to hypophysis)
      2. Subarachnoid hemorrhage
      3. Neurosurgery
      4. Radiation: progressive and irreversible neuroendocrine dysfunction following radiation-induced damage to the hypothalamic–pituitary axis (Darzy 2013)
      5. Stroke
   2. Intrasellar tumors
      1. Adenomas
      2. Craniopharyngiomas
   3. Parasellar tumors
      1. Meningiomas
      2. Optic gliomas
      3. Chordomas
      4. Ependymomas
      5. Metastatic tumors: breast, lung, melanoma, renal cell carcinoma
   4. Infections
      1. Abscess
      2. Hypophysitis
      3. Meningitis
      4. Encephalitis
      5. Tuberculosis
      6. Syphilis
      7. Fungal disease
      8. Malaria
      9. HIV
   5. Vascular
      1. Infarction (postpartum): Sheehan's syndrome
      2. Diabetes mellitus
      3. Pituitary apoplexy
      4. Cavernous sinus thrombosis
      5. Aneurysms of intracranial internal carotid artery
   6. Autoimmune disorders: lymphocytic hypophysitis
   7. Infiltrative processes
      1. Hemochromatosis
      2. Granulomatous diseases
      3. Histiocytosis X
      4. Secondary amyloidosis
   8. Empty sella or arachnoidocele (Guitelman et al. 2013): herniation of the subarachnoid space within the sella turcica, associated with elongated pituitary stalk and flattening of the pituitary gland (De Marinis et al. 2005; Guinto et al. 2007).
      1. Primary empty sella: results from postpartum pituitary necrosis (Sheehan's syndrome) or lymphocytic hypophysitis
      2. Secondary empty sella: usually results from a pituitary adenoma that shrinks after different treatments (surgery, radiotherapy, or drugs) or spontaneous regression
   9. Perinatal insults
   10. Pituitary hypoplasia or aplasia
   11. Idiopathic causes (GH, ACTH, TSH, others): frequently monohormonal
3. Genetic causes (mutations) of multiple pituitary hormone deficiencies (Cohen and Radovick 2002; Dattani 2005; Mehta and Dattani 2008; Higham et al. 2016)
   1. *POU1F1* (*PIT-1*) (Andersen and Rosenfeld 2001): genetic combined pituitary hormone deficiency (CPHD) caused by mutations within the pituitary-specific transcription factor 1

1. Combine pituitary hormone deficiencies
    1. GH
    2. Thyrotropin (TSH)
    3. Prolactin
2. Inheritance
    1. Autosomal dominant (AD)
    2. Autosomal recessive (AR)
3. Phenotypes
    1. Hormone deficiencies: severe
    2. Thyrotropin secretion: initially normal, but secondary hypothyroidism inevitable
    3. Variable anterior pituitary hypoplasia

2. *PROP1* (Sornson et al. 1996): the most common cause of CPHD caused by mutations of *Prophet of PIT1*
    1. Combine pituitary hormone deficiencies
        1. GH
        2. TSH
        3. LH
        4. FSH
        5. Prolactin
        6. Occasional ACTH deficiency
    2. Inheritance: AR
    3. Phenotypes
        1. Deficiencies tend to be milder than in *POU1F1* mutations
        2. Evolving corticotropin deficiency with increasing age
        3. Enlarged pituitary size with later involution (transient anterior pituitary hyperplasia)
        4. Can be associated with a mass lesion (Turton et al. 2005)
3. *HESX1* (Dattani et al. 1998)
    1. Hormone deficiencies: range from isolated GH deficiency to CPHD (panhypopituitarism, including diabetes insipidus)
    2. Inheritance: AD, AR
    3. Phenotypes
        1. May be associated with septo-optic dysplasia, combined pituitary hormone deficiency (CPHD), and isolated growth hormone deficiency.
        2. Mutations result in a variable phenotype: anterior pituitary hypoplasia, ectopic posterior pituitary, and midline forebrain abnormalities.
        3. Environmental factors, such as drugs and alcohol, are implicated.
4. *LHX3* (Netchine et al. 2000)
    1. Combine pituitary hormone deficiencies
        1. GH
        2. TSH
        3. LH
        4. FSH
        5. Prolactin
        6. ACTH
    2. Inheritance: AR
    3. Phenotypes
        1. Elevated and anteverted shoulders giving the appearance of a stubby neck with limited rotation of the neck and head (short rigid cervical spine)
        2. Sensory neural deafness
        3. Hypoplasia of anterior pituitary gland
        4. Preservation of corticotropin secretion
5. *LHX4* (Machinis et al. 2001)
    1. Combine pituitary hormone deficiencies
        1. GH
        2. TSH
        3. Cortisol
        4. Gonadotropin deficiency
    2. Inheritance: AD
    3. Phenotypes (MRI of the brain)
        1. Small sella
        2. Persistent craniopharyngeal canal
        3. Hypoplastic anterior pituitary and ectopic posterior pituitary
        4. Pointed cerebellar tonsils

4. Genetic causes (mutations) of isolated pituitary hormone deficiencies
    1. *TBX19* (*TPIT*) (Pulichino et al. 2003)
        1. Hormone deficiencies: corticotropin
        2. Inheritance: AR
        3. Phenotypes
            1. Presentation in neonatal period with severe hypoglycemia and prolonged cholestatic jaundice
            2. Undetectable corticotropin and cortisol levels
            3. Failure to respond to corticotropin-releasing hormone

4. High incidence of neonatal death in affected families

2. *SOX2* (Maheshwari et al. 1998)
   1. Hormone deficiencies: hypogonadotropic hypogonadism
      1. LH
      2. FSH
      3. Variable GHD
   2. Inheritance: de novo mutation reported
   3. Phenotypes
      1. Anophthalmia or microphthalmia
      2. Hypothalamic hamartoma
      3. Learning difficulties
      4. Developmental delay
      5. Genital abnormalities
      6. Esophageal atresia
      7. Sensorineural hearing loss
      8. Diplegia
3. *SOX3* (Hamel et al. 1996; Laumonnier et al. 2002)
   1. Hormone deficiencies: isolated growth hormone deficiency or CPHD
   2. Inheritance: X-linked recessive
   3. Phenotypes
      1. Intellectual disability
      2. Anterior pituitary hypoplasia
      3. Ectopic posterior pituitary
      4. Infundibular hypoplasia
      5. Midline abnormalities
4. *GHRHR* (Maheshwari et al. 1998)
   1. Hormone deficiencies: GH
   2. Inheritance: AR
   3. Phenotypes
      1. Short stature
      2. Proportionate growth
      3. Anterior pituitary hypoplasia
5. *GH1* (Cogan et al. 1993)
   1. Hormone deficiencies: GH
   2. Inheritance: AR
   3. Phenotypes
      1. Short stature
      2. Abnormal facies
      3. Respond to exogenous GH treatment, but may develop antibodies
6. *KAL-1* (Legouis et al. 1991; Franco et al. 1991)
   1. Hormone deficiencies
      1. GnRH
      2. FSH
      3. LH
   2. Inheritance: X-linked
   3. Phenotypes
      1. Failed or arrested puberty
      2. Anosmia
      3. Synkinesis
      4. Unilateral renal agenesis
7. *FGFR-1* (*KAL-2*) (Dode et al. 2003)
   1. Hormone deficiencies
      1. GnRH
      2. FSH
      3. LH
   2. Inheritance: AD
   3. Phenotypes: failed or arrested puberty
8. *GNRHR1* (Beranova et al. 2001)
   1. Hormone deficiencies
      1. FSH
      2. LH
   2. Inheritance: AR
   3. Phenotypes: variable, determined by the sensitivity of the mutant receptor to GnRH
9. *DAX1* (Lin et al. 2006)
   1. Hormone deficiencies
      1. FSH
      2. LH
   2. Inheritance: AR, X-linked
   3. Phenotypes
      1. Presents initially with severe neonatal hypoadrenalism
      2. Subsequently fail to enter puberty or suffer delayed or arrested puberty
10. *GPR54* (de Roux et al. 2003)
    1. Hormone deficiencies
       1. FSH
       2. LH
    2. Inheritance: AR
    3. Phenotypes: presents with absent or delayed puberty

11. *POMC* (Krude et al. 1998)
    1. Hormone deficiencies: corticotropin
    2. Inheritance: AR
    3. Phenotypes (clinical triad)
        1. Early-onset obesity
        2. Adrenal hypoplasia
        3. Cortisol deficiency
12. *Thyrotropin-β* (Vuissoz et al. 2001)
    1. Hormone deficiencies: thyrotropin
    2. Inheritance: AR
    3. Phenotypes: severe congenital hypothyroidism if not detected and treated early on
13. *GLI2*
    1. Hormone deficiency
        1. GH
        2. TSH
        3. LH
        4. FSH
        5. ACTH
    2. Inheritance: haploinsufficiency
    3. Phenotypes
        1. Holoprosencephaly
        2. Craniofacial abnormalities
        3. Polydactyly
        4. Hypogonadotropic hypogonadism
        5. Partial agenesis of the corpus callosum
14. *FGF8*
    1. Hormone deficiency
        1. LH
        2. FSH
        3. Diabetes insipidus
    2. Inheritance: AR, AD
    3. Phenotypes
        1. Hypogonadotropic hypogonadism
        2. Anosmia
        3. Holoprosencephaly
        4. Moebius syndrome
        5. Septo-optic dysplasia
15. *OTX2*
    1. Hormone deficiency
        1. IGHD
        2. CPHD
    2. Inheritance: AD
    3. Phenotypes
        1. Anophthalmia or microphthalmia
        2. Coloboma
        3. Developmental delay

Clinical Features

1. Nonspecific symptoms (Toogood and Stewart 2008)
    1. Feeling of general ill health
    2. Being abnormally tired
    3. Increased lethargy
    4. Feeling cold
    5. Weight loss
    6. Reduced appetite
    7. Abdominal pain
2. Symptoms related to local effects of any underlying tumor
    1. Headaches
    2. Visual disturbance (typically a bitemporal hemianopia)
    3. Cerebrospinal fluid rhinorrhea
3. Clinical presentation (Higham et al. 2016)
    1. Acute hypopituitarism
        1. Pituitary apoplexy, acute pituitary inflammation, and Sheehan's syndrome can all cause acute hypopituitarism
        2. If untreated, have a high risk of mortality, usually secondary to loss of ACTH and subsequent hypoadrenalism.
        3. This presentation is rare but crucial to recognize.
    2. Chronic hypopituitarism
        1. Onset: usually insidious, and
        2. Nonspecific clinical presentation
        3. Pattern of symptoms and signs: depends on the order and extent of hormonal loss
4. GH deficiency
    1. Neonates with congenital GH deficiency (or hypopituitarism).
        1. Severe neonatal hypoglycemia often associated with convulsions, presenting

most frequently in the first 24 h of life (birth trauma)
2. Prolonged conjugated hyperbilirubinemia
3. Hypothermia
4. Possibly a micropenis (Ogilvy-Stuart 2003)

2. Neonates with midline birth defects should be considered at risk for isolated or multiple pituitary hormone deficiencies.
3. Older babies who escape early diagnosis may present with failure to thrive and poor weight gain.
4. Older children.
   1. Proportional short stature with height more than 2–3 standard deviations (SD) below the mean for the age
   2. Reduced growth velocity for their age
   3. Delayed bone maturation in the absence of an inherited skeletal dysplasia or chronic disease
   4. Characteristic craniofacial appearance in patients with severe GH deficiency: a prominent forehead and depressed midface development caused by the lack of GH effect on endochondral growth at the base of the skull, occiput, and sphenoid
   5. Delayed dentition
   6. Presence of other features attributable to the underlying etiology of the GH deficiency
5. Adults
   1. Multiple symptoms and pathophysiologic changes affecting a variety of biologic systems (none are pathognomonic) are attributed to GH deficiency in adult life (Molitch et al. 2006).
   2. Impaired quality of life (Burman et al. 1995; Holmes and Shalet 1995)
      1. Complaining of tiredness.
      2. Lack of energy.
      3. Emotional lability.
      4. Reduced sleep quality.
      5. A degree of disability consistent with psychiatric illness requiring treatment (up to 30% of patients) (McGauley et al. 1990).
      6. Patients who have childhood-onset GH deficiency do not seem to suffer the same degree of impairment in quality of life as those who have adult-onset GH deficiency (Attanasio et al. 1997).
5. Gonadotropin (LH, FSH) deficiency
   1. Male infants with congenital hypogonadotropic hypogonadism: effect of relative androgen deficiency occurring during the third trimester
      1. Unilateral or bilateral cryptorchidism
      2. Microphallus
   2. Adolescent boys
      1. Pubertal development
         1. Fail to initiate or abnormal with failure to progress normally
         2. Testicular volumes vary between prepubertal boys (<4 cm^3) and normal adult size
         3. Pubic hair (mediated by testicular or adrenal androgens): present but unlikely to be normal
   3. Adolescent girls
      1. Gonadotropin deficiency becoming apparent in teenage years
      2. Delayed breast development
      3. Primary amenorrhea
   4. Isolated gonadotropin deficiency
      1. Normal growth during childhood.
      2. Slow growth during adolescence when the growth spurt fails to occur.
      3. Epiphyses, however, fail to fuse at the usual age, and the long bones continue to grow, ultimately resulting in tall stature and a eunuchoid habitus.
   5. Men with acquired gonadotropin deficiency during adult life
      1. Usually achieve a normal height with proportionate growth.
      2. Adult secondary sexual characteristics are present, although the testes may become soft and reduced in size because the FSH deficiency causes atrophy of the seminiferous tubules.
      3. Slowing of beard growth with less frequent shaving.
      4. Loss of body hair.

5. Skin becoming thin with development of thin wrinkles if the gonadotropin deficiency is severe and prolonged.
6. Libido may be reduced, and the ability to achieve and maintain an erection may be compromised.
7. Testosterone deficiency can lead to nonspecific symptoms, for example:
    1. Tiredness
    2. Reduced muscle bulk
    3. Reduced exercise capacity
8. Decreased bone mineral density with a risk for:
    1. Osteopenia or osteoporosis
    2. Increased fractures
9. Azoospermia: usually present in prolonged gonadotropin deficiency, although there are exceptions.
10. Symptoms of hypogonadotropism: nonspecific and may not become evident for many years, particularly if fertility is not an issue.

6. Women with secondary gonadotropin deficiency
    1. Diagnosed quickly when oligomenorrhea or amenorrhea develops.
    2. Symptoms of estrogen deficiency.
        1. Vaginal dryness
        2. Dyspareunia
        3. Hot flashes
        4. Breast atrophy
    3. Pubic and axillary hair remains unless there is coexistent corticotropin deficiency with adrenal androgen deficiency.

6. Adrenocorticotropin (ACTH) deficiency
    1. Results in secondary hypoadrenalism.
    2. The most serious of anterior pituitary hormone deficits.
    3. During an intercurrent illness.
        1. May develop an adrenal crisis with severe hyponatremia and hypovolemic shock
        2. Can result in death if not diagnosed and treated appropriately
    4. Decompensation and shock occur during periods of illness or physical stress, such as surgery.
    5. Other symptoms of cortisol deficiency.
        1. Lethargy.
        2. Fatigue.
        3. Weight loss.
        4. Nonspecific abdominal pain.
        5. Hypoglycemia.
            1. Feelings of hunger
            2. Light-headedness
            3. Sweating
            4. Hypotension and complain of postural symptoms
        6. Absence of the pigmentation associated with primary adrenal failure in patients with corticotropin deficiency: the skin may be pale with an alabaster-like appearance (Arlt and Allolio 2003).
    6. Patients who have hypopituitarism are protected somewhat from developing severe, acute hypoadrenalism compared with patients who have primary adrenal failure, as the angiotensin–aldosterone axis remains intact.

7. Thyrotropin (TSH) deficiency
    1. Symptoms and signs
        1. Similar to those of primary hypothyroidism but usually are less severe, as there often is some residual thyrotropin secretion.
        2. Tiredness.
        3. Cold intolerance.
        4. Weight gain.
        5. Constipation.
        6. Dry skin and hair are common features.
    2. With the exception of traumatic brain injury (TBI), thyrotropin deficiency usually occurs late in the evolution of hypopituitarism and often is seen with other anterior pituitary hormone deficits.
    3. In children, secondary hypothyroidism contributes to poor growth, delayed bone age, and failure of secondary dentition.

8. Prolactin deficiency
    1. Prolactin is inhibited predominately by dopamine; as a consequence, prolactin levels frequently are raised in the presence of hypothalamic–pituitary disease because of compression or transection of the pituitary stalk.

2. Hypoprolactinemia is found in patients who have mutations of the transcription factors, PIT1 and PROP1.
3. However, in patients with structural pituitary disease, prolactin deficiency is a marker of severe pituitary damage (Mukherjee et al. 2003; Toledano et al. 2007).
4. In women, prolactin deficiency can cause failure of lactation in the postpartum period.
5. Although prolactin is an important hormone in the animal world with multiple identified roles in growth, water homeostasis, reproduction, behavior, and growth and immune modulation (Bole-Feysot et al. 1998), a phenotype attributable to prolactin deficiency in man has yet to be established.

9. *PROP1*-related combined pituitary hormone deficiency (De Graff 2014)
   1. Most affected individuals are ascertained because of growth failure and failure to thrive starting in infancy or early childhood.
   2. Hypothyroidism.
      1. Usually mild
      2. Occurs in later infancy and childhood
   3. Absent or delayed and incomplete secondary sexual development with infertility.
      1. Males: usually have a small penis and small testes.
      2. Females: some experience menarche but subsequently require hormone replacement therapy.
   4. GH deficiency.
      1. Neonatal hypoglycemia
      2. Proportionate short stature
      3. Delayed bone age
   5. TSH deficiency.
      1. Suspected in children with growth failure, poor weight gain, and delayed bone maturation
      2. Large posterior fontanelle
      3. Jaundice lasting more than 1 week after birth
      4. Macroglossia
      5. Hoarse cry
      6. Distended abdomen
      7. Umbilical hernia
      8. Hypotonia
   6. LH and FSH deficiency.
      1. Newborn males
         1. Micropenis without hypospadias
         2. With or without cryptorchidism
      2. Adolescent males
         1. Delayed onset of puberty (after age 14)
         2. Cessation of secondary sexual development
      3. Adolescent females: lack of breast development or menses by age 14
   7. Prolactin deficiency: suspected in females with impaired lactation.
   8. ACTH deficiency.
      1. Less common
      2. Usually occurs in adolescence or adulthood
      3. Suspected in children with persistent weakness, abdominal pain, anorexia, and weight loss
      4. Signs of acute ACTH deficiency
         1. Acute hypotension
         2. Dehydration
         3. Shock accompanied by hyponatremia, hyperkalemia, and hypoglycemia

10. *POU1F1* combined pituitary hormone deficiency (De Graff et al. 2014)
    1. Normal birth weight and birth length and uncomplicated perinatal course
    2. Growth failure in early infancy in most affected individuals
    3. Growth hormone deficiency: usually severe
    4. Proportional short stature
    5. Hypothyroidism
       1. Can be congenital
       2. Can be mild and later onset
       3. Progressive loss of TSH occurring over time
    6. Distinctive facies (Aarskog et al. 1997)
       1. Prominent forehead
       2. Marked midface hypoplasia
       3. Depressed nasal bridge
       4. Deep-set eyes
       5. Short nose with anteverted nostrils

7. MRI of the brain: pituitary usually appears hypoplastic

Diagnostic Investigations

1. Brain MRI (Toogood and Stewart 2008).
    1. To exclude tumors and other lesions of the sellar and parasellar region after confirmation of hypopituitarism.
    2. Normal MRI of the sellar and parasellar region cannot exclude hypopituitarism.
2. Hypopituitarism is diagnosed based on baseline blood sampling for thyroid stimulating hormone, gonadotropin, and prolactin deficiencies, whereas for ACTH, growth hormone, and antidiuretic hormone deficiency dynamic stimulation tests are usually needed. Repeated pituitary function assessment at regular intervals is needed for diagnosis of the predictable but slowly evolving forms of hypopituitarism (Higham et al. 2016).
3. Growth hormone deficiency.
    1. The definition of GH deficiency in adulthood differs from that in childhood.
        1. In children, the diagnosis of GH deficiency is made in the presence of a reduced growth velocity.
        2. In adults, the clinical features attributed to GH deficiency are numerous and nonspecific; there is no single pathognomonic feature that alerts clinicians to the diagnosis.
        3. Diagnosis of GH deficiency should be considered only in adults who have a history of pituitary disease, secondary to neoplastic disease, surgery, or cranial radiation or in those who have had a history of treatment with GH during childhood and adolescence (Growth Hormone Research Society 1998).
        4. Results of dynamic tests of GH status are affected by obesity (all stimuli) (Shalet et al. 1998) and age (Toogood et al. 1998) and could lead to an inappropriate diagnosis.
    2. The insulin tolerance test (ITT).
        1. Considered the gold standard used to diagnose GH deficiency in adults, using a diagnostic threshold of 3 mg/L.
        2. Not suitable for use in all patients and is contraindicated in patients who have a history of seizures or ischemic heart disease.
        3. Consequently, the majority of endocrinologists do not use the ITT in patients over 65 in case undiagnosed heart disease is present.
    3. Insulin-like growth factor (IGF-1).
        1. A GH-dependent peptide, although the level of dependence seems to diminish with increasing age.
        2. In young adults who have childhood-onset GH deficiency, 95% (de Boer et al. 1994) have serum IGF-1 below the normal range, whereas 82% of GH-deficient patients over 60-year-old have a normal IGF-1 (Toogood et al. 1998).
4. Gonadotropin deficiency.
    1. Women with gonadotropin deficiency
        1. In women of postmenopausal age, low or undetectable levels of FSH and LH are sufficient to make a diagnosis.
        2. In younger women, amenorrhea with low estradiol levels and low or normal gonadotropins is consistent with the diagnosis of gonadotropin deficiency.
        3. Failure to induce a withdrawal bleed after a progesterone challenge confirms the presence of a hypoestrogenic state.
    2. Men with gonadotropin deficiency
        1. Diagnosed in the presence of low or normal serum gonadotropin levels and a low serum testosterone.
        2. Semen analysis is useful when considering fertility and may demonstrate oligospermia or azoospermia.
5. Adrenocorticotropin deficiency.

1. The activity of the hypothalamic–pituitary–adrenal (HPA) axis exhibits a diurnal rhythm; serum cortisol levels often are undetectable at midnight during sleep, rising and reaching peak at approximately 5:00 a.m. and declining gradually over the course of the day.
2. The insulin tolerance test (ITT).
    1. A peak response to hypoglycemia (blood glucose 2.2 mmol/L) of greater than 20 mg/dL: considered a normal response (Tuchelt et al. 2000; Nelson and Tindall 1978).
    2. Tests the integrity of the whole HPA axis and has the advantage of simultaneously assessing the GH status of patients.
3. Short Synacthen test (SST): an alternative test to ITT
    1. Measures the serum cortisol response after an intramuscular injection of cosyntropin (Synacthen) (250 mg) (Stewart et al. 1988; Clayton 1996; Kane et al. 1995).
    2. Based on the premise that corticotropin deficiency results in atrophy of the adrenal cortex and subsequently becomes unresponsive to a single pulse of corticotropin.
    3. A serum cortisol value of 22 mg/dL (550 nmol/L) or higher 30 min after administration of Synacthen: consistent with normal corticotropin reserve.
    4. Risk for a false-negative result (a perception that patients have normal corticotropin reserve): the SST should not be performed until at least 6 weeks after surgery or an apoplectic event.
6. Thyroid-stimulating hormone deficiency.
    1. Diagnosed based on the presence of a low or normal serum thyrotropin measurement with a low serum free thyroxine (fT4) level.
    2. Measurement of serum fT3: not required but may be low or normal.
    3. In patients treated with radiotherapy, sequential falls in the serum fT4 toward the lower end of the normal range associated with evolving symptoms of hypothyroidism may be sufficient to warrant instigation of levothyroxine.
    4. The thyrotropin response to thyrotropin-releasing hormone: used less frequently since the introduction of sensitive thyrotropin assays.
7. *PROP1*-related combined pituitary hormone deficiency (CPHD) (De Graff et al. 2014).
    1. Testing for deficient secretion of GH, TSH, LH, FSH, prolactin, and ACTH: establishes the diagnosis
    2. *PROP1* is the only gene associated with *PROP1*-related CPHD
        1. Targeted mutation analysis for the common recurring deletion in which three AG repeats are reduced to two repeats: available clinically
        2. This mutation accounts for 55% of familial cases and 12% of nonfamilial cases

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Autosomal dominant inheritance
            1. Recurrence risk of 50% if a parent is affected
            2. Low recurrence risk if both parents are normal
        2. Autosomal recessive inheritance: risk of recurrence 25%
        3. X-linked recessive: 50% of male sibs affected if the mother is a carrier
    2. Patient's offspring
        1. Autosomal dominant inheritance: a 50% risk of offspring affected.
        2. Autosomal recessive inheritance: low recurrence risk unless the spouse is affected or a carrier.
        3. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal.
2. Prenatal diagnosis (De Graff 2014)
    1. Prenatal diagnosis is possible for pregnancies at increased risk for various conditions such as *PROP1* or *POU1F1* CPHD when

the disease-causing mutation in the family is known.
2. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified in an affected family member.

3. Management (Toogood and Stewart 2008)
   1. Replacement treatment exists in the form of thyroxine, hydrocortisone, sex steroids, growth hormone, and desmopressin. If onset is acute, cortisol deficiency should be replaced first. Modifications in replacement treatment are needed during the transition from pediatric to adult endocrine care and during pregnancy (Higham et al. 2016).
   2. Pituitary hormone replacement therapy
      1. Growth hormone replacement
         1. GH replacement in children who have GH deficiency results in an increase in linear growth, and its use for that purpose is accepted universally.
         2. Recombinant human GH has allowed GH replacement to be used in adults.
         3. In the event of side effects (peripheral edema, arthralgia, and headaches) during the titration phase, the dose of GH should be reduced or, if severe, treatment should be withdrawn.
      2. Sex steroid and gonadotropin replacement
         1. The aim of androgen replacement in men: to maintain secondary sexual characteristics, restore a sense of well-being, prevent loss of and optimize bone mass, and improve sexual function (Bhasin et al. 2006).
         2. Women who have gonadotropin deficiency require sex steroid replacement to alleviate the symptoms of estrogen deficiency and to optimize bone health.
         3. Induction of fertility can be achieved in men and women using exogenous gonadotropins. In men, human chorionic gonadotropin can be used initially to stimulate spermatogenesis (Vicari et al. 1992). In women, ovulation induction is initiated with FSH or human menopausal gonadotropin.
      3. Adrenocorticosteroid replacement
         1. Cortisol: hydrocortisone is the glucocorticoid of choice for patients who have secondary adrenal insufficiency
         2. Optimize and monitor glucocorticoid replacement therapy
      4. Dehydroepiandrosterone
         1. In addition to cortisol, the adrenal cortex produces androgens regulated by corticotropin.
         2. Patients who have corticotropin deficiency also are deficient in dehydroepiandrosterone (DHEA) (Arlt et al. 1999).
      5. Thyroxine replacement
   3. Long-term consequences of hypopituitarism
      1. Patients who have hypothalamicpituitary disease and are receiving a combination of sex steroids, glucocorticoids, and thyroxine, but not GH replacement, for a range of anterior pituitary hormone deficiencies have an approximately twofold increase in mortality compared with the general population (Rosen and Bengtsson 1990; Bates et al. 1996; Tomlinson et al. 2001).
      2. In the largest study to date, there was an increase in deaths from cardiovascular, cerebrovascular, and respiratory disease (Tomlinson et al. 2001).
      3. GH replacement therapy improves short-term individual cardiovascular risk profiles.
   4. Long-term follow-up of patients with hypopituitarism
      1. Continued follow-up under the care of a physician (endocrinologist) who has expertise in the field
      2. Annual assessment to determine their cardiovascular risk once hormone replacement treatments are optimized
      3. Attention to blood pressure and cholesterol levels and treatment with

antihypertensives and cholesterol lowering agents instigated as appropriate

5. Adult GH deficiency and hypopituitarism (Crespo et al. 2015)
    1. Untreated
        1. Abnormal body composition: decreased bone and muscle mass, greater body fat
        2. Decreased exercise capacity and muscle strength with increased fatigue
        3. Increased insulin resistance
        4. Unfavorable lipid profile
        5. Impaired quality of life
        6. Cognitive problems: decreased memory and concentration and increased irritability
    2. Replacement therapy with recombinant GH
        1. Quality of life improvement
        2. Decreased use of healthcare resources
        3. Increased vitality, energy, and emotional state
        4. Recovery of physical performance
        5. Decreased waist circumference
        6. Improved metabolic profile

Fig. 1 A 16-year-old female was evaluated for pituitary hormone deficiency. She had short stature for which she received growth hormone therapy since 3 years of age. MRI scan of the brain showed a very small (hypoplastic) pituitary gland. Endocrine investigations revealed the following: low serum IGF-1 (somatomedin-C): <10 ng/mL (normal 11–206 ng/mL); low free T4: 0.67 ng/dL (normal 0.71–1.85 ng/dL); low TSH: 0.02 μU/mL (normal 0.47–5.01 μU/mL); normal cortisol: 7.5 μg/dL (normal 3.0–21 μg/dL); low ACTH-ICMA: 9.0 pg/mL (normal 10.0–60.0 pg/mL); low estradiol: < 0.5 ng/dL (normal 0.7–6.0 ng/dL); low FSH: 1.3 mIU/mL (normal 1.5–12.8 mIU/mL); normal LH: 0.38 mIU/mL (normal 0.10–12.0 mIU/mL). Molecular genetic testing for *POU1F1* gene mutation revealed no sequence variants. However, a different genetic basis for combined pituitary hormone deficiency cannot be ruled out

Fig. 2 A 6-year-old boy was evaluated for pituitary hormone deficiency. He had a history of hypoglycemia and a micropenis. He was noted to be very short, for which he received growth hormone shots daily. He was also treated for hypothyroidism. Past lab results: TSH: 3.16 μU/mL; low free T4: 0.56 ng/dL; normal IGF-1: 66 ng/mL; low IGFBP-3: 0.7 mg/L; normal cortisol: 5.5 μg/dL; normal ACTH-ICMA: 17 pg/mL. Molecular genetic testing for *POU1F1* gene mutation showed no sequence variation

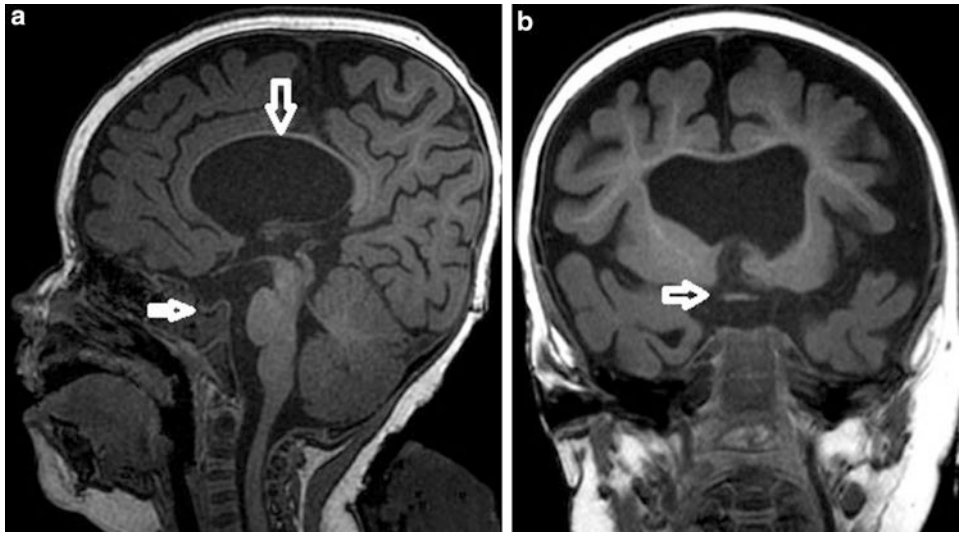

Fig. 3 (**a**, **b**) A 9-month-old boy with a history of encephalopathy and epilepsy. The molecular genetic study identified a 143 kilobyte interstitial duplication of an Xp11.4. MRI of the brain demonstrates the complete absence of the septum pellucidum with ventriculomegaly and white matter thinning. There is absence of the normal posterior pituitary bright spot (**a**, *small arrow*) and diffuse thinning of the corpus callosum (**a**, *large arrow*). The optic nerves, optic chiasm, and optic tracts are markedly atrophic (**b**, *arrow*). The above dysmorphic changes are compatible with septo-optic dysplasia and hypopituitarism (Courtesy of Dr. Grace Guo)

I(1p), I(1q) Syndrome

Contents

In 1999, Chen et al. (1999) first described uniparental (paternal) isodisomy, resulting from 46,XX,i(1p),i(1q) in a woman with short stature, ptosis, micro-/retrognathia, myopathy, deafness, and sterility.

Synonyms and Related Disorders

I(1p), I(1q) uniparental (paternal) isodisomy: isochromosome 1p and isochromosome 1q syndrome

Genetics/Basic Defects

1. Uniparental disomy (UPD): inheritance of both homologues from one parent. Several types of errors in chromosome segregation during gamete formation may be responsible for uniparental disomy (Spence et al. 1988).
2. Uniparental isodisomy: caused by isochromosome formation from misdivision of the centromere (Bernasconi et al. 1996; Eggerding et al. 1994; Lindenbaum et al. 1991; Shaffer et al. 1997). Although maternal UPD (Pulkkinen et al. 1997; Turner et al. 2007) and paternal UPD (Gelb et al. 1998; Takizawa et al. 2000) of chromosome 1 have been reported previously, none of these involved an isochromosome.
3. Cytogenetic analysis from the peripheral blood of the patient demonstrated one i(1p) and one i(1q) without normal chromosome 1 homologues (Figs. 1, 2, 3, and 4, Table 1).
4. The most likely mechanism of formation of the rearranged chromosomes in our patient (Fig. 5) is as follows:
    1. The zygote contained a chromosome 1 from the father and none from the mother due to nondisjunction resulting in a monosomy 1 conceptus.
    2. Subsequently, misdivision at the centromere may have occurred, leading to two isochromosomes, one of each chromosome arm.
    3. At the next mitotic division, both went into the same daughter cell.
    4. In the following cell cycle, normal replication took place. This would produce two isochromosomes, made up of one i(1p) and one i(1q), with uniparental isodisomy.
5. Additionally, many mechanisms could account for the finding of isochromosomes, as put forward by Bernasconi et al. (1996) regarding two isochromosomes and UPD 2. Except for the possibility of homozygosity for recessive mutations, maternal uniparental disomy 2 appears to have no adverse impact on the phenotype.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_131

6. Mechanisms of formation of the two isochromosome, maternal i(2q) and paternal i (2p) Albrecht et al. 2001; (Baumer et al. 2007):
   1. The initial maternal meiotic I error may have been a nondisjunction event of chromosome 2.
   2. Trisomy rescue may have occurred during the recombination event that led to the isochromosomes, or, alternatively, the formation of the maternal i(2q) preceded that of the paternal i(2p). In this case, the formation of the paternal i(2p) would rescue the trisomy 2q and monosomy 2p.
   3. A third possibility: the initial meiotic I rearrangement consisted in the formation of the maternal isochromosome; rescue of the trisomy 2q/monosomy 2p would have occurred postzygotically through the formation of a paternal i(2p).
7. To the best of our knowledge, our patient is the first case of uniparental isodisomy resulting from i(1p) and i(1q):
   1. Our patient, therefore, has allelic homozygosity for all paternal chromosome 1 loci, demonstrated in part by our molecular studies.
   2. However, the possibility of areas of heterodisomy through meiotic recombination likely exists.
   3. The patient's abnormal phenotype is most likely due to unmasking of rare recessive mutations through isodisomy, but the possibility of genomic imprinting and the presence of mosaicism cannot be ruled out.
   4. The presence of myopathy in this patient suggests the possibility that the potential gene(s) involved may be localized on chromosome 1.

Clinical Features

1. Short stature
2. Bilateral conductive hearing loss
3. Facial features
   1. Downward slant of palpebral fissures
   2. Bilateral ptosis
   3. Malar hypoplasia
   4. Severe micro-/retrognathia
   4. High-arched palate
   5. Cervical vertebral anomaly
   6. Slightly short fingers
   7. Scoliosis
   8. Normal intelligence
   9. Normal secondary sex characteristics
10. Menarche at 11 years with regular menstruation but never conceived in three marriages with different partners

Diagnostic Investigations

1. Cytogenetic analyses: to demonstrate one i (1p) and one i(1q) without normal chromosome 1 homologues by:
   1. GBG banding
   2. CBG banding
   3. FISH analysis using whole-chromosome 1 probe
2. Molecular investigations to demonstrate isochromosomes with complete homozygosity of either paternal or maternal markers

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: not increased
   2. Patient's offspring: the presence of two isochromosome 1 s would virtually exclude viable offspring since either duplication of the long arm with deletion of the short arm or duplication of short arm with deletion of long arm would be lethal to the fetus.
2. Prenatal diagnosis: demonstration of i(1p) and i(1q) without two normal chromosome 1 s by either CVS or amniocentesis
3. Management: supportive

Idic(Yq) Syndrome

Contents

Dicentric chromosomes are among the most common structural changes of the Y chromosome (deletions, rings, Y-autosomal or Y-X translocations, isochromosomes, and dicentrics). Among these structural abnormalities, dicentric Y chromosomes are the most commonly found (Hsu 1994; Yoshida et al. 1997).

The dicentric Y chromosomes have two different types: dic(Yq), resulting from the fusion between the short arms of two Y chromosomes in which some Yp material is maintained, and dic (Yp) in which only the Yq arms fuse (Codina-Pascual et al. 2004). If the dicentric has completely symmetric arms, it is considered an isodicentric chromosome. The sites of breakage and fusion at Yp and Yq are variable (Robinson et al. 1999).

Isodicentric Y chromosomes are one of the most commonly reported structural abnormalities of the Y chromosome (Hsu 1994), consisting of two identical arms that are positioned as mirror images to one another, with an axis of symmetry lying between two centromeres. Due to the presence of two centromeres, these chromosomes are often unstable during cell division (Daniel et al. 1980; Buchanan et al. 1976). As a result, chromosomal mosaicism is common and most patients have a 45,X cell line (Hsu 1994; Tuck-Muller et al. 1995).

Synonyms and Related Disorders

Isodicentric chromosome Yq syndrome

Genetics/Basic Defects

1. Isochromosome (DesGroseilliers et al. 2006)
    1. A chromosome with identical chromosome material in which two arms are mirror images and are of equal length
    2. An isochromosome can be monocentric or dicentric
2. Isodicentric chromosomes (dicentric isochromosomes)
    1. Likely resulting from a single break in the paracentric region followed by chromatid duplication and the joining of chromatids from one side of the break (Guevarra et al. 2009)
    2. Usually unstable during cell division and remain so until one of their centromeres is inactivated (Daniel et al. 1980; Therman

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_132

et al. 1986), resulting in various types of cell lines (Kohn et al. 1997)
3. Consequently, most reported patients have alternate cell lines, including 45,X (95% of cases) (Bouayed Abdelmoula and Amouri 2005a)
4. The resulting phenotype depends on the proportion of each cell line and on the localization of the breakpoints (Alvarez-Nava et al. 2003; Bouayed Abdelmoula and Amouri 2005b)
5. The most likely mechanism of formation of the isodicentric chromosome (Bouayed Abdelmoula and Amouri 2005a)
    1. An isochromatid break, followed by a U-type exchange
    2. Breakpoints in the short arm lead to a duplication of the entire long arm and a part of the short arm
    3. Breakpoints in the long arm lead to the duplication of the entire short arm and part of the long arm

3. Isodicentric Y chromosome [idic(Y)]
    1. Isodicentric Y chromosome: formed by homologous crossing over between opposing arms of palindromes on sister chromatids (Lange et al. 2009)
        1. These ectopic recombination events occur at nearly all Y-linked palindromes
        2. Intrapalindrome sequence identity is maintained via noncrossover pathways of homologous recombination
        3. DNA double-strand breaks that initiate these pathways can be alternatively resolved by crossing over between sister chromatids to form idic (Y) chromosomes, with clinical consequences ranging from spermatogenic failure to sex reversal and Turner syndrome
    2. Isodicentric Yq (Guevarra et al. 2009)
        1. Refers to a dicentric Y chromosome with two complete long arms and two symmetric incomplete portions of the short arms, arranged in a mirror image
        2. The breakpoints are in the short arm of Y
        3. When two centromeres are not closely located, only one is active; the other is suppressed
    3. Most dicentric Y chromosomes (90%) are present in mosaic form due to the instability of isodicentric chromosomes during cell division (Kohn et al. 1997)
        1. The mosaicism may be more or less complex depending on its meiotic or postzygotic origin and on its mitotic stability, and it usually includes a 45,X, in addition to idic(Y), idic(Y)*x*2, del(Y), or 46,XY cell lines (Ying and Ives 1971; Daniel et al. 1980; Chandley et al. 1986; Stankiewicz et al. 2001; Codina-Pascual et al. 2004; Bouayed Abdelmoula and Amouri 2005a)
        2. Errors occurring during gametogenesis, before the spermatid stage, or in the first mitotic division after fertilization would result in a mosaicism without a normal 46,XY cell line
        3. Errors occurring after the first zygotic division, a normal 46,XY cell line can be present (Fernandez et al. 2002)
        4. Patients carrying a dicentric Y chromosome have a wide range of somatic, genital, and gonadal phenotypic manifestations, depending on the structure of the dicentric Y chromosome, the Yp and Yq breakpoints, and the types of mosaicism (Tuck-Muller et al. 1995)
        5. Of affected individuals, 40.9% were phenotypical females, 31.8% were phenotypical males, and 27.3% had different degrees of intersexuality (Hsu 1994)
    4. The absence or mutation of SRY (sex-determining region on the Y chromosome) gene on the isodicentric Y chromosome: another factor adding to diversity of the phenotype, illustrated by case studies by DesGroseilliers et al. (2006)
        1. In one case of idic(Y), the female phenotype and Turner stigmata can be explained by the localization of the breakpoint, which is proximal to the SRY gene, in Yp11.2 or p11.31

2. In three patients, who do not have a predominant 45,X cell line but possess two copies of SRY (as breakpoints are in the long arm) usually develop as males: They are often infertile due to the absence of one of the azoospermia factor (AZF) regions or the incorrect pairing between the rearranged Y and the X chromosome during meiosis I (Chandley et al. 1986)

5. Nonmosaic 46,X,idic(Y) with breakpoints in the long arm has been reported in rare cases of females: dicentric chromosome Y associated with Leydig cell agenesis and sex reversal (female phenotype) (Genuardi et al. 1995)
6. A complex mosaic karyotype, 48,XX,+idic (Yq)*x*2/47,XX,+idic(Yq)/46,XX has been reported in twin girls (Hipp et al. 2016)
    1. Fluorescence in situ hybridization (FISH): negative for SRY located at Yp11.3 and positive for two copies of the centromeric probe DYZ3, confirming the dicentric structure
    2. A SNP microarray performed on twin A with a focus on further delineating Y chromosome breakpoints to determine gonadoblastoma risk: A 39.3 Mb gain of material from region Yq11.222-q12 was identified, with no detection of genomic material from Yp or the pericentromeric region of Yq extending to Yq11.221, suggesting a final isodicentric Yq structure with incomplete duplication of the q arm. No additional copy number variants or large regions of homozygosity were detected

4. The putative gonadoblastoma locus (GBY) (Page 1987)
    1. Thought to correspond to the TSPY (testis-specific protein, Y-linked) gene (Lau et al. 2003), which has clusters in several loci on both the short and the long arms of the Y chromosome (Tsuchiya et al. 1995; Rottger et al. 2002)
    2. Presence of multiple GBY loci on the Y chromosome could explain why such tumors have been reported in both idic with breakpoints in the long and short arms (Hsu 1994; Tuck-Muller et al. 1995)

Clinical Features

1. Extremely variable physical and genital features (52 cases with dicentric Yq, studied by Guevarra et al. 2009) (Hsu 1994; Tuck-Muller et al. 1995; Bouayed Abdelmoula and Amouri 2005b; DesGroseilliers et al. 2006)
    1. Twelve phenotypic males (23%)
        1. Age/presenting symptoms
            1. Six adults: infertility (5), short stature (1)
            2. Six children: short stature (6)
        2. Gonads
            1. Normal testes (10)
            2. Not reported (2)
            3. Gonadoblastoma (0)
        3. Stature
            1. Short (6)
            2. Normal (3)
            3. Borderline (1)
            4. Not reported (2)
        4. Turner syndrome stigmata (3)
    2. 17 phenotypic ambiguities (33%)
        1. Age/presenting symptoms
            1. Two adults: inguinal mass/gynecomastia (1), ambiguous genitalia (1)
            2. Sixteen children: short stature (4), ambiguous genitalia (12)
        2. Gonads
            1. Normal testes (2)
            2. Abdominal testes (2)
            3. Mixed gonadal dysgenesis (10)
            4. Not reported (3)
            5. Gonadoblastoma (3)
        3. Stature
            1. Short (9)
            2. Normal (3)
            3. Not reported (5)
        4. Turner syndrome stigmata (2)

3. Twenty-three phenotypic females (44%)
    1. Age/presenting symptoms
        1. Six adults: short stature (1), primary amenorrhea (5)
        2. Thirteen children: short stature (9), primary amenorrhea (3), not reported (1)
    2. Gonads
        1. Normal ovaries (0), mixed gonadal dysgenesis (15)
        2. Gonadoblastoma (6)
    3. Stature
        1. Short (16)
        2. Normal (3)
        3. Not reported (4)
    4. Turner stigmata (10)
2. Karyotype-phenotype correlations
    1. Sexual differentiation of patients: depends on the distribution of the 45,X cell line in various tissues, including gonads
        1. Three cases reported by Alvarez-Nava et al. (2003):
            1. 45,X/46,X,idic(Y) positive for the same Y chromosome molecular markers, with various degrees of abnormal sexual differentiation
            2. A predominant 45,X cell line was found in the streak gonads of the female with Turner stigmata, while the dysgenetic testes of the male had a predominant 46,X,idic(Y) cell line
            3. The individual with sexual ambiguity had a streak gonad with a predominant 45,X cell line on one side and a dysgenetic testis with a predominant 46,X,idic(Y) cell line on the other side
        2. Nine female patients studied by DesGroseilliers et al. (2006)
            1. An increase in the proportion of 45,X cells in the gonads compared to blood in four patients (93% vs. 64%, 80–100% vs. 39%, 82% vs. 60%, and 79% vs. 8%), thus could explain their female or ambiguous phenotypes
            2. A similar increase of the 45,X cell line was found in fibroblasts compared to blood in three patients (96% vs. 39%, 92% vs. 8%, and 95% vs. 23%)
    2. Great phenotypic variations observed in patients with an isodicentric Y chromosome greatly limit the genotype-phenotype correlation
        1. The variability is explained by the degree of mosaicism in different tissues and the various locations of the breakpoints
        2. To improve the genotype-phenotype correlation
            1. Analyze more than one tissue, as significantly different proportions of various cell lines can be found
            2. Perform histological studies of the gonads
            3. Molecular definition of the breakpoints (Stuppia et al. 1996) will provide more information, allowing for a better genetic counseling
3. Differential diagnosis of idic(Yp) (Bruyere et al. 2006)
    1. Adult males with idic Yp invariably present with a history of infertility
        1. Likely, a result of loss or disruption of all or part of the Yq11.2 AZF gene cluster, which is crucial for spermatogenesis (Siffroi et al. 2000; Stankiewicz et al. 2001; Marrocco et al. 2003; Yoshitsugu et al. 2003; Patsalis et al. 2005)
        2. Pairing dysfunction between the X and Y chromosomes during meiosis: proposed as an alternate mechanism for azoospermia in these men (Yoshida et al. 1997)
        3. All idic Yp cases in which paternal chromosome testing has been performed have been de novo (Schintzel 2001; Bruyere et al. 2006). This further supports the concept that males with an idic Yp are usually infertile. With the exception of cases, whose mosaicism included the presence of a structurally normal Y chromosome in a significant proportion of cells, normal fertility in these boys is unlikely

2. Phenotype
    1. Normal male phenotype with sterility with rare exception
    2. Rare ambiguous genitalia

Diagnostic Investigations

1. Cytogenetic analysis by high-resolution banding techniques (Q-, G-, and C-bandings)
    1. Blood
    2. Skin fibroblasts
    3. Gonadal tissues
2. Fluorescence in situ hybridization (FISH) and SKY (spectral karyotyping), using DNA probes specific for Y chromosome sequences present in Yp, in Yq, and in the centromeric Y region, allow the structural characterization of abnormal Y chromosomes (Robinson et al. 1999)
3. Molecular studies
    1. Use of PCR to determine the presence or absence of specific Y chromosome sequences: may not provide enough information to determine the structure of the abnormal Y chromosome
        1. Amplify genes or chromosome regions (SRY, ZFY, DYZ1) which are needed for the male development
        2. Y centromere sequence (DYZ3) (Tuck-Muller et al. 1995; Robinson et al. 1999)
    2. Comparative genomic hybridization (CGH)
4. Hormonal investigations (Udler et al. 2001)
    1. Estradiol level
    2. Follicle-stimulating hormone level
    3. Luteinizing hormone level
    4. Testosterone level
5. Abdominal ultrasonography and MRI (Mizuno et al. 2009): suspect the presence of a testicular component and the possibility of mixed gonadal dysgenesis or true hermaphroditism in a phenotypic girl without gonad (especially with a history of a high testosterone level, enlargement of the clitoris, response to human chorionic gonadotropin stimulation test, and the presence of SRY), followed by laparoscopic evaluation and biopsy of the specimen: laparoscopic bilateral gonadectomy when dysgenetic gonad is found

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Since reported cases so far have been de novo, recurrence risk to sib is not likely increased.
        2. However, several sets of affected identical twins have been reported.
            1. Monozygotic twins with 47,X,idic(Y)(q11.2),idic(Y)(q11.2)/46,X,idic(Y)(q11.2)/45,X from peripheral blood: twin A (phenotypic female with 42% of Y-containing cells); twin B (phenotypic male with 94% of Y-containing cells) (Nonomura et al. 2002)
            2. Monozygotic twins with 45,X/46,X,idic(Y)(p11) from peripheral blood and skin fibroblasts: twin A (phenotypic female with 0–57% Y-containing cells); twin B (phenotypic male with 22–60% Y-containing cells) (Fujimoto et al. 1991)
    2. Patient's offspring: not likely increased since affected individuals are infertile
2. Prenatal diagnosis: possible via amniocentesis or CVS (Wu et al. 2007)
    1. Cytogenetic analysis
    2. FISH
    3. SKY
    4. Molecular studies using specific Y chromosome sequence
3. Management
    1. Gender assignment after careful evaluation of the patient when there is a genital ambiguity
    2. Advise surgery to remove gonads in women with gonadal dysgenesis and Y material at young age since they are at higher risk (15–20%) of developing gonadoblastoma and seminoma (Verp and Simpson 1987; Fallat and Donahoe 2006)

3. A boy with 45,X/46,XidicY(p11) mosaicism and short stature who has shown an improved final adult height as a result of long-term growth hormone treatment (Guevarra et al. 2009)

Fig. 1 (**a**, **b**) An 18-year-old female was evaluated for primary amenorrhea and short stature (Tuck-Muller et al. 1995). She was noted to be obese. Laboratory findings included prepubertal female levels of estradiol (below 10 pg/mL) and high levels of luteinizing hormone (72 mU/mL with normal of 4–30 mU/mL), follicle-stimulating hormone (53 mU/mL with normal of 4–30 mU/mL), and testosterone (103 ng/dL with normal adult female value of 6.0–86 ng/dL). Laparoscopic exploration revealed an infantile uterus, a left streak gonad, and a right gonadal enlargement. Histological examination of the right gonad showed gonadoblastoma merged with a diffuse germ cell component diagnosed as dysgerminoma. The specimen leveled as left streak ovary consisted of vestigial Wolffian ducts. The analysis of genomic DNA from the patient indicated that sequences derived from the short arm (using SRY and ZFY mapped at Yp11.32), centromere (using Y97 mapped at Y centromere), and the middle and terminal portions of the long arm of the Y chromosome (using eD6 mapped at Yq11; 1 F5 mapped at Yq11.2; pY3.4 mapped at Yq12) were present

Fig. 2 Her external genitalia was characterized by clitoromegaly, rudimentary labia minora, hypoplastic labia major, and a narrow but patent vagina

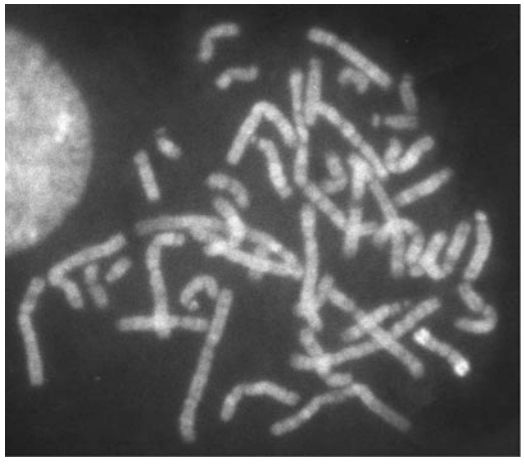

Fig. 3 The predominant cell line in the patient's blood (29 of 40 cells), skin (33 of 35 cells), and right (31 of 33 cells) and left (25 of 25 cells) gonadal tissues had monosomy X. The second cell line had 46 chromosomes with one X and one abnormal Y chromosome, illustrated in this Q-banded spread showing isodicentric Y chromosome. Brightly fluorescent bands were present at the terminus of both arms of the abnormal chromosome, which stained darkly by C-banding (Fig. 4). The abnormal chromosome was interpreted to be a dicentric isochromosome composed of two copies of the long arm, centromere, and proximal portion of the short arm of the Y chromosome. Both parents were karyotypically normal

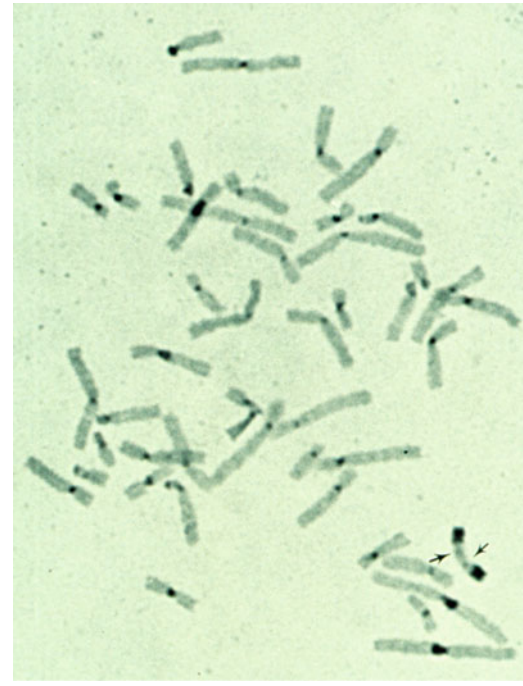

Fig. 4 The isodicentric Y chromosome (*arrows*) is illustrated in this C-banded spread

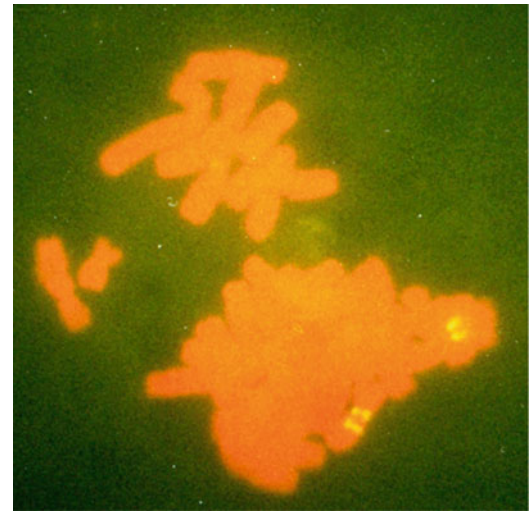

Fig. 5 The Y-specific α-satellite probe hybridized to the two centromeric regions of the abnormal Y chromosomes. The chromosome spread illustrates the presence of two idic(Y)

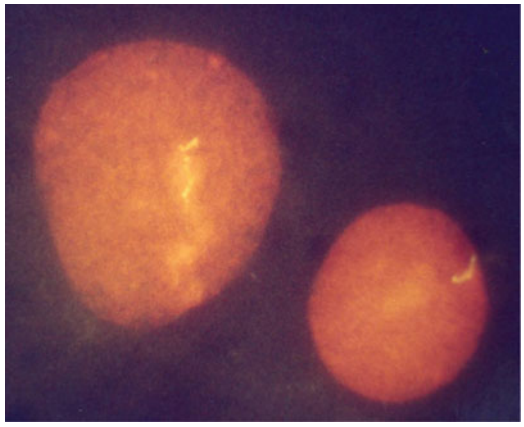

Fig. 6 FISH on interphase cells using Y probe shows idic (Yq) signals

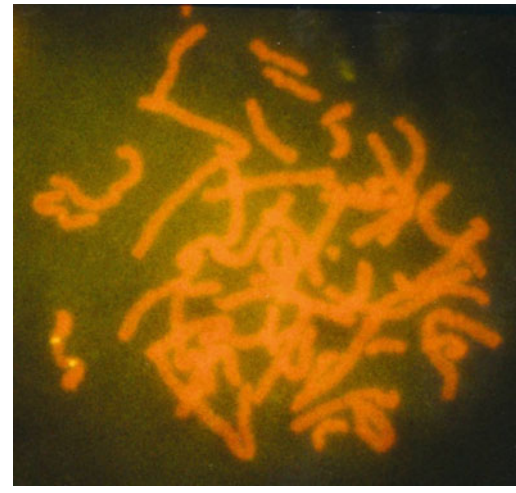

Fig. 7 FISH on a metaphase spread using Y centromeric probe shows idic(Yq) chromosome

Incontinentia Pigmenti

Contents

Bloch and Sulzberger, in 1926 and 1928, respectively (Bloch 1926; Sulzberger 1928), were credited for the first description of the clinical syndrome of incontinentia pigmenti (IP), known as Bloch-Sulzberger syndrome. It is a rare genodermatoses occurring in approximately 1 in 50,000 newborns (Aradhya et al. 2001b).

Synonyms and Related Disorders

Bloch-Sulzberger syndrome

Genetics/Basic Defects

1. Inheritance (Berlin et al. 2002):
    1. X-linked dominant transmission, usually prenatally lethal in males (Devriendt et al. 1998), suggested by pedigree analyses (Curth and Warburton 1965; Wiklund and Weston 1980; Wettke-Schäfer and Kanter 1983)
    2. A high affected female/affected male ratio
    3. Instances of female-to-female transmission
    4. 1:1:1 affected female/normal female/normal male ratio in the offspring of an affected mother
    5. Increased incidence of miscarriages in patients with incontinentia pigmenti, presumably representing affected male conceptuses that typically fail to survive past the second trimester
2. Female patients with IP mutations:
    1. Dizygosity for the X chromosome
    2. Skewed X-inactivation (Happle 1985)
        1. Cells expressing the mutant X chromosome are eliminated selectively around the time of birth so that females with IP exhibit extremely skewed X-inactivation, based on the Lyon hypothesis (random inactivation of one X chromosome in each cell of the female at an early developmental stage, resulting in an X-chromosomal mosaic for each female with one X functioning in some of the cells and the other X functioning in the rest of the cells).
        2. Female heterozygous for an X-linked incontinentia pigmenti gene: the pigmented areas on the skin represent cell populations in which the abnormal

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_133

gene is active and the areas of normal skin tissue in which the normal gene is active.
3. Highly variable phenotype explainable by the chance variability in the number and position of the cells carrying the active incontinentia pigmenti gene.

3. The gene for IP: linked genetically to the *factor VIII* gene in Xq28 (Sefiani et al. 1989; Smahi et al. 1994).
4. Molecular pathophysiology (Fryssira et al. 2010):
   1. Attributed to mutations in the gene of nuclear factor kappa B (*NF-kB*) essential modulator (*NEMO*) currently known as *IKBKG* (inhibitor of kappa light polypeptide gene enhancer in B cells, kinase gamma) (Aradhya et al. 2001a; Smahi et al. 2000; Jain et al. 2001; Jentarra et al. 2006; Fusco et al. 2008).
   2. The *IKBKG* gene is located on chromosome X, band q28. It spans 23 kb and consists of 10 exons.
   3. An intrachromosomal rearrangement that deletes exons 4–10 of the gene accounts for approximately 90% of new mutations (Aradhya et al. 2001a).
   4. The *IKBKG* gene encodes a protein which is essential for the activation of NF-jB transcription factor, which protects cells against tumor necrosis factor-induced apoptosis.
   5. The *IKBKG* gene also regulates the expression of various cytokines, chemokines, and adhesion molecules (Smahi et al. 2000; Berlin et al. 2002).
5. Mechanisms for occasional survival of affected males (Kenwrick et al. 2001; Berlin et al. 2002):
   1. Presence of an extra X chromosome (47, XXY Klinefelter syndrome) (Ormerod et al. 1987; Garcia-Dorado et al. 1990)
   2. Skewed X-inactivation
   3. Hypomorphic alleles
   4. Mosaics for common mutations (somatic mosaicism). Somatic mosaicism of a novel *IKBKG* mutation (nonsense mutation) has been reported in a male IP patient (Hull et al. 2015)
   5. A parent with gonadal mosaicism (Kirchman et al. 1995)
6. Anhidrotic/hypohidrotic ectodermal dysplasia with immunodeficiency (EDA-ID) (Zonana et al. 2000; Doffinger et al. 2001):
   1. A disorder allelic to incontinentia pigmenti but with different phenotype due to various natures of genetic mutations underlying the two disorders
   2. A rare X-linked recessive disorder affecting only males
   3. Caused by mutations in the *NEMO* gene
   4. Possible family history of IP in boys with EDA-ID
   5. Presentation with severe recurrent infections caused by common encapsulated bacterial pathogens, suggesting functional defects in the immune response
   6. Rare opportunistic diseases
      1. Mycobacterial infections
      2. Cytomegaloviral infections
      3. *Pneumocystis carinii* pneumonitis
   7. Immunologic studies
      1. Normal or increased levels of B cells
      2. Normal T-cell counts
      3. Normal to low levels of IgG
      4. Elevated levels of either IgM or IgA
7. Eosinophil recruitment through eotaxin release by activated keratinocytes.
8. Incontinentia nomenclature: the localization of the gene for IP to Xq28, coupled with reports of children with "incontinentia pigmenti" and X-autosome translocations with breakpoints at Xp11 (Hodgson et al. 1985), resulting in a nomenclature differentiation of IP1 (sporadic) and IP2 (familial). However, IP1 and IP2 designation should be abandoned (Happle 1998):
   1. IP1
      1. Disorder applied to cases associated with X-autosome translocations with Xp11 breakpoints (Gilgenkrantz et al. 1985; Kajii et al. 1985; Cannizzaro and Hecht 1987; Sybert 1998) and r(X) (de Grouchy et al. 1985; Bitoun et al. 1992; Shastry 2000)
      2. Skin changes different from patients to patients

3. Serves no useful purpose either causally or clinically
4. More appropriately using descriptive phrase "X-autosome translocation associated with pigmentary abnormalities" (Sybert 1994)

2. IP2: applied to cases of familial IP mapped to Xq28

Clinical Features

1. Highly variable clinical presentations among affected female family members (Berlin et al. 2002)
    1. Attributed to lyonization in females, resulting in functional mosaicism
    2. Clonal expansion of the progenitor cell along lines of embryonic development in that each cell determines which X chromosome to express during the first weeks of gestation
        1. Manifesting along the curvilinear lines of Blaschko in the skin (Jackson 1976; Harre and Millikan 1994)
        2. Percentage of progenitor cells that express the mutated X chromosome reflecting the extent of expression
        3. Mutation in a high percentage of ectodermal cells in severe cases
2. Clinical expression among small number of live-born male patients
    1. Generally not severer than that in affected females
    2. Many male patients with disease expression limited to cutaneous involvement of one or two limbs
3. Cutaneous manifestations: most often the first observed sign of IP and are present in nearly all patients. They are classically subdivided into the following four classic cutaneous stages (Minić et al. 2014):
    1. Vesicular, vesiculobullous, or inflammatory stage
        1. Frequency: about 90% of cases
        2. Age of onset: within first 2 weeks of life (92%), by 6 weeks of age (4%), starting after the first year of life (several cases)
        3. Age at resolution: blisters generally clearing by 4 months, recurrence usually short-lived and less severe than the original eruption
        4. Clinical features: erythema, superficial vesicles in linear distribution on torso and extremities (64%) and extremities alone (33%)
        5. Differential diagnosis: dermatoses with blistering in early infancy (e.g., different types of epidermolysis bullosa and bullous bacterial infection), herpes simplex, and varicella/herpes zoster
    2. Verrucous (wartlike) stage
        1. Frequency: about 70% of cases
        2. Age of onset: peak of onset between 2 and 6 weeks of age
        3. Age at resolution: clearance by 6 months (80%)
        4. Clinical features: verrucous hyperkeratotic papules and plaques (Bessems et al. 1988), almost exclusively involving extremities
        5. Differential diagnosis: verrucae vulgares (simple warts), nevus verrucosus, molluscum contagiosum, X-linked-dominant chondrodysplasia punctata, and linear epidermal nevi
    3. Hyperpigmented stage
        1. Frequency: nearly all patients with IP (98%)
        2. Age of onset: 12–26 weeks of age
        3. Age at resolution: puberty
        4. Clinical features: whorls and streaks of brown pigmentation following lines of Blaschko (multiple lines on the human body corresponding to the distribution of linear nevi and dermatoses) on torso and extremities (65%) and torso alone (27%)
        5. Differential diagnosis: hypomelanosis of Ito, Naegeli syndrome, and pigment mosaicism
    4. Atrophic/hypopigmented (dermal scarring) stage

1. Frequency: 42%
2. Age of onset: early teens to adulthood
3. Age at resolution: permanent lesion
4. Clinical features: pale, hairless, atrophic patches, and/or hypopigmentation
5. Differential diagnosis: vitiligo with localized alopecia and different types of ectodermal dysplasia

4. Hair abnormalities (50%)
   1. Vertex alopecia
      1. The most common hair manifestation
      2. Most commonly mild and unnoticed
      3. Follows inflammation and vesiculation
      4. May be associated with scarring
   2. Agenesis of eyebrows and eyelashes: infrequent
5. Nail abnormalities (7–40%)
   1. Ridging, pitting, or nail disruption
      1. Starting early childhood and involving all or most of the fingernails and toenails
      2. Tends to regress and disappear with age
   2. Subungual and periungual keratotic tumors (Mascaro et al. 1985; Adeniran et al. 1993)
      1. Appear at a later stage.
      2. Affect fingers more than toes.
      3. Continued growth results in pain, nail dystrophy, and destruction of the underlying bone of the terminal phalanx.
      4. Bone lytic lesions caused by pressure from the overlying tumor.
6. Dental anomalies (>80%) (Russell and Finn 1967)
   1. Partial adontia or adontia (43%)
   2. Pegged and conical teeth (30%)
   3. Late eruption of teeth (18%)
   4. Enamel hypoplasia
7. Ophthalmologic anomalies (35%)
   1. Blindness (7.5%)
   2. Nonretinal manifestations
      1. Strabismus (18–33%)
      2. Optic atrophy (4%)
      3. Cataracts (4%)
      4. Pseudoglioma (3.5%)
      5. Microphthalmia (3%)
      6. Rare conjunctival pigmentation (McCrary and Smith 1968), iris hypoplasia, nystagmus, and uveitis
   3. Retinal manifestations (Francois 1984; Goldberg and Custis 1993)
      1. Foveal hypoplasia.
      2. Mottled or hypopigmented retinal pigment epithelium.
      3. Avascular retina.
      4. Neovascularization (Rosenfeld and Smith 1985).
      5. Vitreous hemorrhages.
      6. Fibrovascular proliferation.
      7. Retinal detachment (3%).
      8. Asymmetric retinal disease between eyes in the same individual and variable retinal findings within the kindred. These differences may be explained by random inactivation of the X chromosome or other epigenetic modifications (Chen et al. 2015).
8. Neurologic deficits (30%)
   1. Infantile spasms and seizure disorder (13%)
   2. Learning disability (12%) (Pizzamiglio et al. 2014)
   3. Spastic paralysis (11%)
   4. Motor retardation (7.5%)
   5. Microcephalus (5%)
   6. Infrequent manifestations
      1. Cerebellar ataxia
      2. Congenital hearing loss
      3. Muscle paresis
      4. Aseptic encephalomyelitis
9. Other associated anomalies
   1. Nipple anomalies
      1. Supernumerary nipple
      2. Nipple hypoplasia
      3. Breast hypoplasia/aplasia
   2. Oral anomalies
      1. High-arched palate
      2. Cleft lip/palate
   3. Skeletal anomalies
      1. Dwarfism
      2. Chondrodysplasias
      3. Short stature
      4. Spina bifida
      5. Skull defects
      6. Club foot
   4. Increased risk of serious and unusual infection in some patients

5. Occasional hypohidrosis with increased rates of bacterial skin infections: may be evidence of the continuum between IP and the allelic anhidrotic ectodermal dysplasia-immune deficiency
6. Cardiovascular abnormalities (Miteva and Nikolova 2001)
    1. Tricuspid insufficiency
    2. Pulmonary vein-to-superior vena cava shunt

10. Diagnostic criteria for incontinentia pigmenti (Landy and Donnai 1993; Minić et al. 2014)
    1. Negative family history (no evidence of IP in a first-degree female relative): at least one major criterion is necessary to make a firm diagnosis of sporadic incontinentia pigmenti. The minor criteria, if present, will support the diagnosis. Because of their high incidence, complete absence of minor criteria should induce a degree of uncertainty:
        1. Major criteria: typical IP skin stages distributed along Blaschko's lines
            1. Vesiculobullous stage
            2. Verrucous stage
            3. Hyperpigmented stage
            4. Atrophic/hypopigmented stage
            5. Landry and Donnai's original major criteria: typical neonatal rash (erythema, vesicles, eosinophilia), typical hyperpigmentation (mainly trunk, Blaschko's lines, fading in adolescence), and linear, strophic, hairless lesions
        2. Minor criteria (supportive evidence)
            1. Dental anomalies
            2. Ocular anomalies including retinal disease
            3. CNS anomalies
            4. Alopecia
            5. Abnormal hair (sparse hair, wooly hair, anomalies of eyebrows and eyelashes)
            6. Abnormal nails
            7. Palate anomalies
            8. Nipple and breast anomalies
            9. Multiple male miscarriages
            10. Typical skin pathohistological findings
    2. Positive family history (evidence of IP in a first-degree female relative)
        1. Any single major or at least two minor criteria.
        2. In all cases, eosinophilia and skewed X chromosome inactivation support diagnosis.

Diagnostic Investigations

1. Major histopathologic features from skin biopsy samples (Berlin et al. 2002):
    1. Vesicular, vesiculobullous, or inflammatory stage
        1. Spongiotic dermatitis
        2. Dermal and epidermal eosinophilia
        3. Eosinophil-filled vesicles
    2. Verrucous stage
        1. Papillomas
        2. Epidermal hyperplasia
        3. Hyperkeratosis
        4. Dyskeratotic cells
    3. Hyperpigmented stage
        1. Dermal melanophages
        2. Vascular changes in basal layer of epidermis
    4. Atrophic stage
        1. Loss of rete ridges
        2. Loss of dermal sweat coils
        3. Skin biopsy helpful for the diagnosis of IP at late stage (IV) (Fraitag et al. 2009)
            1. Slight atrophy and some scattered apoptotic cells in the epidermis, epidermal hypopigmentation, and reduced melanocyte number.
            2. The dermis appeared thickened and homogeneous and revealed a complete absence of hair follicles (23/26) and sweat glands (22/26).
            3. There was no melanin incontinence or inflammatory cells, and the elastic network was normal.
2. Light microscopy (Zillikens et al. 1991):
    1. Hypopigmented streaks with slight epidermal atrophy

2. A reduced number of melanocytes and skin appendages
3. Electron microscopy (Schaumburg-Lever and Lever 1973):
   1. Dyskeratosis
   2. Phagocytosis of dyskeratotic cells and of melanosomes by macrophages
   3. Presence of melanophages in the upper dermis
   4. Abnormal cutaneous nerves (Worret et al. 1988)
   5. Amorphous material resembling colloid, suggesting degeneration of basal keratinocytes (Zillikens et al. 1991)
4. CBC: marked peripheral blood leukocytosis and eosinophilia (Cohen 1994)
5. Abnormal immune system (Jessen et al. 1978; Menni et al. 1990): not a consistent finding
6. CT/MRI imagings of the brain:
   1. Optic atrophy
   2. Retinal vasculopathy
   3. Hypoplasia of the corpus callosum (Pascual-Castroviejo et al. 1994)
   4. Ventriculomegaly
   5. Periventricular white matter lesions
   6. Ischemic strokes
   7. Hemorrhagic necrosis (Chatkupt et al. 1993)
   8. Porencephalic cyst
   9. Brain atrophy (Avrahami et al. 1985)
7. Magnetic resonance angiography/spectroscopy for cerebral ischemia and a vaso-occlusive phenomenon (Lee et al. 1995)
8. Single photon emission computed tomography: detection of cerebral infarction (Kasai et al. 1997)
9. Fluorescein angiography for retinal vascular abnormalities
10. EEG for seizures
11. Chromosome analysis in male patients with IP (Scheuerle 1998)
12. Molecular genetic testing: mutation detection for the majority of families, facilitated by the high frequency of specific deletion, using Southern blotting, PCR amplification, or DNA sequencing:
    1. X-inactivation assay and Xq28 marker studies: X-inactivation analysis is indicated wherever a recombination event between Xq28 markers and the disease locus is suspected. The absence of recombination between the disease locus and Xq28 loci suggests that mosaicism is responsible for the discrepancy where Xq28 marker studies are at odds with the clinical assessment.
    2. Identification of the *IKBKG* (also known as *NEMO*) gene mutation as a biological marker for a molecular diagnosis of IP (Scheuerle and Ursini 2015):
       1. Deletion/duplication analysis.
       2. Sequence analysis.
       3. Targeted mutation analysis for common deletions.
       4. Carrier testing for the mother who has an affected daughter with a known mutation.
       5. Determine whether the miscarried or stillborn male fetus has IP.
       6. Prenatal testing of a fetus at risk.

Genetic Counseling

1. Recurrence risk
   1. Patient's sib
      1. Recurrence risk: $<1\%$, provided that the mother is not a carrier of the gene: a small increased risk due to either a new mutation in a second child or germ line mosaicism in a parent
      2. Recurrence risk of 50% for sisters to be affected when the mother is a carrier of the gene
      3. Recurrence risk of 50% for brothers to be affected (prenatally aborted fetuses or stillborns) when the mother is a carrier of the gene
   2. Offspring of an affected female
      1. Daughters: 50% affected, 50% normal
      2. Sons: 50% affected (prenatally aborted fetuses or stillborns), 50% normal (all the live-born sons will be normal)
   3. Offspring of an affected male
      1. All daughters affected

   2. All sons normal
2. Prenatal diagnosis possible if the disease-causing mutation has been detected in the families at risk (Scheuerle and Ursini 2015)
   1. Determination of the fetal sex by amniocentesis or CVS.
   2. An increased risk of miscarriage or stillborn for an affected male fetus (fetal karyotype 46,XY).
   3. If the fetal karyotype is 47,XXY: more severe IP phenotype in males and of Klinefelter syndrome.
   4. Molecular genetic testing of a female fetus: if the fetal karyotype is 46,XX, there is 50% of fetuses that are likely to be affected with IP.
   5. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified previously: a healthy delivery of twins by assisted reproduction followed by preimplantation genetic screening was reported in a woman with X-linked dominant incontinentia pigmenti (Kim et al. 2014).
3. Management
   1. Reduce the risk of secondary infection of blisters.
   2. Keep lesions dry.
   3. Avoid trauma to blisters.
   4. Dental care.
   5. Early photocoagulation or cryotherapy in cases of retinal involvement.
   6. Laser treatment of the ischemic peripheral retina: good outcome, resulting in stability of vision (Neto et al. 2014).
   7. Intervention programs for learning disabilities and developmental delay.
   8. Antiseizure medications for seizures

Infantile Myofibromatosis

Contents

Infantile myofibromatosis, previously known as congenital generalized fibromatosis, is the most common fibrous tumor of infancy (Wiswell et al. 1988). It is characterized by the formation of tumors, either in a solitary or in a multicentric fashion, in the skin, muscle, viscera, bone, and subcutaneous tissue.

Synonyms and Related Disorders

Congenital generalized fibromatosis; Juvenile myofibromatosis

Genetics/Basic Defects

1. Etiology: Unknown but appears to originate in utero. Fetal estrogenic hormone stimulation or hamartomas of myofibroblasts have been considered.
    1. Sporadic in most cases.
2. Several reports of familial cases (Bračko et al. 1992; Zand et al. 2004):
    1. Autosomal dominant (Jennings et al. 1984) with variable penetrance (Kulkarni et al. 2012)
    2. Autosomal recessive (Baird and Worth 1976; Venencie et al. 1987; Narchi 2001)
3. Recently, mutations in platelet-derived growth factor receptor β gene (*PDGFRB* located on chromosome 5q31-q32) have been identified in familial autosomal dominant forms of infantile myofibromatosis (infantile myofibromatosis 1) (Cheung et al. 2013; Martignetti et al. 2013). The role of a second gene, *NOTCH3* located on chromosome 19p13.12, is suspected in one family (infantile myofibromatosis 2) (Martignetti et al. 2013), suggesting genetic heterogeneity. Long arm and interstitial deletion of chromosome 6 (q12q15) and a published translocation between chromosomes 9 and 16 confirm the genetic heterogeneity of infantile fibromatosis (Stenman et al. 1999; Sirvent et al. 2004).
4. Homozygous variant in *NDRG4* (identified by exome sequencing) may be the causative variant of the autosomal recessive form of infantile myofibromatosis in the studied family (Linhares et al. 2014).
5. CD34-positive infantile myofibromatosis with hemangiopericytoma-like pattern tumors reported (Kiyohara et al. 2016).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_134

2. Three types of infantile myofibromatosis (Larralde et al. 2010):
    1. Solitary infantile myofibroma
        1. A single lesion affecting mainly the skin or muscle of the head, neck, or trunk
        2. More common in males (approximately 75% of all cases)
    2. Multiple infantile myofibromatosis without visceral involvement (multicentric lesions limited to skin and muscle)
    3. Multiple infantile myofibromatosis with visceral involvement or generalized (multicentric lesions arising not only on the skin and muscle but also on the bone, lung, heart, and most frequently gastrointestinal tract)
3. Spontaneous regression of tumors (Teng et al. 1963; Schaffzin et al. 1972; Brill et al. 1982), possibly due to apoptotic cell death (Fukasawa et al. 1994).

Clinical Features

1. Affects almost exclusively infants and young children
    1. Sixty percent noted at birth or shortly thereafter
    2. Eighty percent occurred before the age of 2 years
2. Characteristics of tumors
    1. Superficial
        1. Palpable, rubbery, firm, and freely moveable nodules
        2. Fibrotic, plaque-like, indurated, and crusted lesions
    2. Deeper lesions: generally immovable
    3. Nontender and painless
3. Overlying skin
    1. Erythema or a purple discoloration resembling a hemangioma
    2. Ulceration and atrophic scar
4. Dermatological presentations (Stanford and Rogers 2000)
    1. Most lesions were dermal or subcutaneous, although some were intramuscular and intraosseous.
    2. The clinical appearance was nonspecific leading to frequent misdiagnosis.
    3. While most patients presented with nodules, atrophic depressed lesions and warty pedunculated lesions were also seen.
5. Affected bones
    1. Radiolucent lytic lesions (cystic defects)
    2. Most commonly involved skeletal locations (Inwards et al. 1991)
        1. Cranium (Hasegawa et al. 1995; Shnitka et al. 1958; Duffy et al. 1997; Söylemezoglu et al. 2001)
        2. Femurs
        3. Tibias
        4. Spine (Wada et al. 1998)
        5. Ribs
    3. Circumscribed lytic tumors not present at birth but develop quickly over the first few days or weeks of life
6. Solitary form (myofibroma)
    1. About 80% of the cases
    2. Boys more commonly affected
    3. Mostly involves the skin and bones (Hasegawa et al. 1993), and rarely the CNS (Kaplan 2002) and viscera
    4. A good outcome provided there is no visceral involvement
    5. Natural history of myofibromas of the CNS without visceral involvement: frequently characterized by a period of initial rapid growth, subsequent stabilization, and spontaneous regression in many cases
7. Multicentric form (myofibromatosis)
    1. Without visceral involvement
        1. Girls more commonly affected
        2. Typically undergoing spontaneous regression within the first 1 or 2 years of life when limited to the skin or bone
        3. A good outcome
    2. With visceral involvement (Roggli et al. 1980; Wiswell et al. 1985; Coffin et al. 1995)
        1. One-fourth of cases of multicentric cases
        2. Multiple nodules distributed throughout the body
            1. Soft tissues such as multicentric myofibromatosis presenting as a large congenital eyelid myofibroma (Macintosh et al. 2016)

2. Bone
3. Skeletal muscle
4. Viscera (kidney, pancreas, retroperitoneum, lungs, gastrointestinal tract (Alberti et al. 2012), peritoneum, diaphragm, heart, tongue, lymph nodes, peripheral nerves, liver, ovary (Ng et al. 2001) uterus (Bhatkule et al. 2015))

3. Fatal outcome with visceral involvement usually within 4 months of life
   1. Localized mass effect on the lung, gastrointestinal tract, or within the conduction system of the heart.
   2. Mortality rate approaches 75%.
4. Possible survival: spontaneous resolution of visceral lesions within the first year of life
5. Disseminated pathologic process including proliferation of multiple nodules of collagen-forming fusiform cells
6. Likely origin of proliferating cells: myofibroblast (displaying both smooth muscle and fibroblast features)

8. Differential diagnosis (Johnson et al. 1997)
   1. Bone lesions
      1. Fibrous dysplasia
      2. Neurofibromatosis
      3. Metastatic neurofibroma
      4. Hemangiomatosis
      5. Lymphangiomatosis
      6. Letterer-Siwe disease
      7. Eosinophilic granuloma
      8. Familial multiple osteogenic fibromas
   2. Soft tissue lesions (Schrodt and Callen 1999)
      1. Leiomyomas
      2. Neurofibroma
      3. Soft tissue sarcomas
      4. Metastatic neuroblastomas
      5. Hyaline fibromatosis
      6. Deep hemangiomas
      7. Other fibromatoses of infancy
9. Prognosis depending on the extent of involvement and location of the lesions (Orozco-Covarrubias et al. 2002)
   1. Solitary forms usually cause little morbidity and virtually no mortality. However, a solitary nodule involving the central nervous system (CNS) may be fatal.
   2. Lesions confined to soft tissue and bone are usually self-limited with good prognosis.
   3. Good prognosis with frequent spontaneous regression when viscera are not involved (Bellman et al. 1991; Zeller et al. 1997).
   4. Poor prognosis with infantile myofibromatosis with multiple visceral involvement.
      1. May cause significant morbidity
      2. Progression to death: usual outcome
      3. Fatal in neonates (up to 75% of cases) (Wiswell et al. 1998)
      4. Death resulting from complications due to cardiopulmonary or gastrointestinal involvement

Diagnostic Investigations

1. Radiography, US, CT, and MRI (Johnson et al. 1997)
   1. Soft tissue lesions: round and well defined on US and MRI
   2. Invaluable in assessing the extent and progression or regression of the disease
      1. Soft tissue lesions (multiple subcutaneous and intramuscular tumors)
      2. Bone lesions
      3. Visceral lesions
   3. Radiography: lesions appearing as multiple areas of osteolysis with a sclerotic margin (Inwards et al. 1991)
   4. Ultrasonography: hyperechoic nodules with peripheral hyperperfusion on color Doppler
   5. CT scan
      1. Masses: isoattenuating with muscle or as low attenuating with slight enhancement in the periphery (Koujok et al. 2005)
      2. Brain (Tamburrini et al. 2003)
         1. Partially calcific masses or isodense cystic lesions with intense peripheral contrast enhancement and smoothly marginated bone erosion
         2. The typical absence of sclerosis of the margins

6. MRI: intramuscular, subcutaneous, and visceral (liver, lungs) lesions (Counsell et al. 2002; Tamburrini et al. 2003; Koujok et al. 2005)
    1. Low signal on T1-weighted images
    2. High or low signal of the center on T2-weighted images
    3. All masses showed peripheral enhancement after gadolinium administration (Spadola et al. 2002)
    4. Intraparenchymal brain lesions, epidural spinal masses, and/or vertebra plana or lytic lesions of the calvarium and spine (Holzer-Fuehwald et al. 2012)
2. Histology (biopsy of tumors) (Chung and Enzinger 1981; Fletcher et al. 1987)
    1. Gross appearance of tumors is well demarcated.
    2. Lesion consisting of bundles of elongated cells with features of both fibroblasts and smooth muscle cells.
    3. Staining characteristics are intermediate between fibroblasts and smooth muscle.
    4. Central part of the tumors is often necrotic.
    5. Ultrastructurally, the localized form of congenital generalized fibromatosis is composed of myofibroblasts (Liew and Haynes 1981).
3. Electron microscopy
    1. Characteristic intracytoplasmic myofilaments
    2. Dense bodies
    3. Focal basal lamina and macula adherens

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. Sporadic form: not increased
        2. Autosomal recessive form: 25% risk
        3. Autosomal dominant form: not increased unless a parent is affected
    2. Patient's offspring
        1. Sporadic form: not increased
        2. Autosomal recessive form: not increased unless the spouse is a carrier
        3. Autosomal dominant form: 50% risk
2. Prenatal diagnosis by ultrasonography
    1. Solitary or multicentric tumors in soft tissue (Kubota et al. 1999; Meizner et al. 2000), bones, or viscera
    2. A superficial head tumor at 13 weeks' gestation (Arabin et al. 2009)
    3. A splenic mass (Muraoka et al. 2008)
    4. An upper arm mass (Kubota et al. 1999)
    5. A solid paraspinal mass (Meizner et al. 2000)
    6. A mass on the lung parenchyma (Yeniel et al. 2013)
3. Management
    1. Observation.
        1. Spontaneous regression
        2. Possible sequelae (tissue loss or damage) resulting from spontaneous regression
    2. Surgical excision (Stanford and Rogers 2000).
        1. To prevent complications and improve prognosis.
        2. Sometimes required for obstructive or locally destructive tumors.
        3. Reserved for symptomatic lesions or if vital organs are compromised, in view of the tendency to spontaneous regression.
        4. Radical resection reserved for those lesions posing an immediate threat due to their locations or massive size and those showing obvious progression.
        5. Seven to ten percent of lesions recurred after excision (Tamburrini et al. 2003).
        6. Decompressive surgery of the spinal cord may improve the neurological outcome in patients with infantile myofibromatosis involving the spinal cord (Kim et al. 2013).
        7. While solitary infantile myofibromatosis may be cured surgically, multicentric/generalized forms require ongoing clinical evaluation (Mashiah et al. 2014).
    3. Chemotherapy with or without radiotherapy.
        1. Necessary for recurrent or unresectable lesions.
        2. A combination of chemotherapy with vincristine, adriamycin-D, and

cyclophosphamide produces regression of fibromatosis in some children with recurrent or unresectable lesions (Raney et al. 1987).

3. Well-tolerated, successful outcomes in a series of patients with high-risk infantile myofibromatosis in need of life sustaining interventions treated with a combination of vincristine and dactinomycin (Weaver et al. 2015).
4. The successful use of a combination of vinblastine and low-dose methotrexate in an infant with generalized infantile myofibromatosis (Day et al. 2002; Azzam et al. 2009).

4. Limited success has been achieved with radiation treatment, steroid injection, and chemotherapy in aggressive cases (Johnson et al. 1997).

Isolated Growth Hormone Deficiency in Children

Contents

Among children with significant short stature (height of ≤ -2.5 standard deviations (SD)), 16–20% have growth hormone deficiency (GHD), which may be isolated (IGHD) or combined (CGHD) with deficiency of other pituitary hormones (Desai et al. 1991). Congenital IGHD occurs in 1 in 4,000 to 1 in 10,000 live births, with prevalence of 1 in 3,500 in school-age population (Lindsay et al. 1994). It is often sporadic and nonfamilial (NFIGHD) but may be familial (FIGHD) in 3–30% (Mullis 2007; Rimoin and Phillips 1997) (Figs. 1, 2, and 3).

Synonyms and Related Disorders

Dwarfism of Sindh; Hypogammaglobulinemia and isolated growth hormone deficiency, X-linked; Isolated growth hormone deficiency, Types IA, IB, II, and III; Pituitary dwarfism due to isolated growth hormone deficiency, autosomal dominant; Pimordial dwarfism

Genetics/Basic Defects

1. Causes of IGHD (Dattani and Preece 2004; Wit et al. 2011; Alatzoglou and Dattani 2012; Desai et al. 2013)
    1. Congenital: often due to genetic mutations
        1. Associated with structural defects of the brain
            1. Agenesis of the corpus callosum
            2. Septo-optic dysplasia
            3. Holoprosencephaly
            4. Encephalocele
            5. Hydrocephalus
        2. Associated with midline facial defects
            1. Cleft lip or palate
            2. Single central incisor
    2. Acquired
        1. Trauma
        2. Infections
        3. CNS tumors
        4. Langerhans cell histiocytosis
        5. Postcranial irradiation
        6. Postchemotherapy
        7. Pituitary infarction
        8. Neurosecretory dysfunction
        9. Psychosocial deprivation
        10. Hypothyroidism
2. Gene implicated in the etiology of IGHD
    1. Growth hormone 1 gene (*GH1*)
        1. Located on chromosome 17q22-q24
        2. Mutating the coding region and/or either entire or partial deletions of the *GH1* gene lead to IGHD

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_274

2. Mutations in the receptor of growth hormone–releasing hormone gene (*GHRHR*)
3. Mutations caused by other genetic factors
    1. Genetic defects associated with multiple pituitary deficiencies: e.g., PROPHET OF PIT1 gene (*PROP1*) and POU Domain, Class 1, Transcription Factor 1 gene (*POU1F1*)
    2. Rare causes: mutations in the transcription factors
        1. Homeobox Gene Expressed in Es Cells gene (*HESX1*): associated with septo-optic dysplasia (McCabe et al. 2011) or may cause IGHD with or without optic nerve hypoplasia
        2. SRY-Box 2 gene (*SOX2*): usually associated with anophthalmia/severe microphthalmia and part of the endocrine spectrum (hypogonadotrophic hypogonadism), a hypoplastic anterior pituitary, and growth hormone deficiency (Kelberman et al. 2006)
        3. Homologue of Orthodenticle, Drosophila, two gene (*OTX2*): variable phenotype ranging from IGHD to hypopituitarism with or without ocular malformations (Ashkenazi-Hoffnung et al. 2010; Dateki et al. 2010; Tajima et al. 2009)
    4. Mutations in known genes account only for a small percentage of cases; other as yet unidentified factors may be implicated in its etiology
3. Classification of four genetic forms of IGHD
    1. Autosomal recessive type IA
        1. Gene: *GH1* (17q23.3)
        2. Phenotype
            1. Undetectable GH
            2. Anti-GH antibodies on treatment
    2. Autosomal recessive type IB
        1. Gene: *GH1*, *GHRHR* (7p14.3), Growth Hormone Secretagogue Receptor gene (*GHS*R), *HESX1*
        2. Phenotype
            1. Low detectable GH
            2. No antibodies to recombinant human GH (rhGH) treatment
    3. Autosomal dominant Type II
        1. Gene: *GH1*
        2. Phenotype
            1. Less severe short stature
            2. Variable phenotype
    4. X-linked recessive Type III
        1. Gene: *SOX3*, Bruton tyrosine kinase gene (*btk*) (Xq22.1), or other yet unknown genes (Stewart et al. 2008)
        2. Phenotype
            1. With or without mental retardation
            2. Ectopic posterior pituitary

Clinical Features

1. Principal mode of presentation of IGHD: proportional short stature and a low/decreased growth velocity for age and pubertal stage (Pinto et al. 1999; Shalet et al. 1998; Alatzoglou and Dattani 2012)
2. Additional criteria
    1. Absence of bone dysplasias
    2. Absence of chronic disease
    3. Skeletal maturation: usually delayed in proportion to height retardation
3. Age of presentation
    1. Highly variable from the first few months of life to adolescence
    2. Highly influenced by the time of onset and the degree of GFD (Adan et al. 1994)
4. IGHD Type IA
    1. At birth: may or may not have short length
    2. By the first 6 months of life: present with severe growth failure (height SD < -4.5)
    3. Infancy: may or may not have hypoglycemia
    4. Puppet (baby doll) facies
5. IGHD Type IB
    1. Less severe and more variable phenotype compared to those with type IA
    2. Marked short stature
    3. Poor growth velocity
6. IGHD Type II
    1. Commonest genetic form of IGHD
    2. Exhibiting significant variability in time of presentation and severity of GHD

7. IGHD Type III
    1. Variable phenotype: ranging from IGHD to hypopituitarism
    2. With or without mental retardation
    3. Infections
        1. Sinusitis
        2. Chronic otitis media leading to hearing loss
        3. Conjunctivitis
        4. Pneumonia
        5. Enteroviral hepatitis
        6. Diarrhea
        7. Epididymitis
        8. Prostatitis
        9. Urinary tract infections
        10. Septic arthritis
        11. Pyoderma
        12. Meningitis/encephalitis
    4. Immunology
        1. Frequent bacterial infections
        2. Severe enteroviral infections
        3. Absent B lymphocytes in all organs
        4. Absent antibody production
        5. Small tonsils
        6. Panhypogammaglobulinemia
        7. Susceptive to infections starting in the first week of life
8. Consensus statement criteria to initiate evaluation for GHD (Consensus Guidelines for the Diagnosis and Treatment of GHD in Childhood and Adolescence from the GH Research Society (2000))
    1. "Severe" short stature [height < -3 standard deviation (SD) below mean]
    2. Height less than -1.5 SD below midparental height
    3. Height less than -2 SD below mean and either height velocity less than -1 SD below mean over past year or decrease in height SD of more than 0.5 SD over past year
    4. In the absence of short stature, height velocity less than -2 SD below mean over 1 year OR less than -1.5 SD below mean over 2 years
    5. Signs of an intracranial lesion
    6. Signs of multiple pituitary hormone deficiency
    7. Neonatal signs and symptoms of GHD, including hypoglycemia, prolonged jaundice, microphallus, or craniofacial midline abnormalities

Diagnostic Investigations

1. Consensus Guidelines for the Diagnosis and Treatment of GHD in Childhood and Adolescence from the GH Research Society (2000)
    1. The degree of short stature
    2. Growth velocity
    3. Radiographic assessment of bone age
        1. Bone age: delayed
        2. Degree of delay: related to the severity and duration of GHD
    4. Measurement of insulin-like growth factor I (IGF-I) and IGF-binding protein 3 (IGFBP-3)
        1. Considerable overlap between IGF-I and IGFBP-3 values in children with GHD compared to normal children
        2. These measures have reasonable specificity and are useful in conjunction with other diagnostic criteria
    5. Provocative growth hormone (GH) testing (postexercise, L-DOPA, insulin tolerance, arginine, insulin–arginine, clonidine, glucagon, and propranolol protocols): The results are poorly reproducible and dependent on
        1. The assay used
        2. The pubertal and nutritional status of the child
        3. The GH secretion pattern prior to testing
    6. Testing for concomitant deficiencies of LH, FSH, TSH, and ACTH
2. If growth hormone deficiency is congenital and complete, the diagnosis is relatively easy to confirm (Rogol 2014)
    1. Affected children present with severe growth failure and very low serum concentrations of growth hormone, insulin-like growth factor I (IGF-I), and its major binding protein, IGFBP-3.
    2. If diagnosed in infancy, they may also manifest hypoglycemia, prolonged jaundice,

microphallus in males, and giant cell hepatitis.
3. In those diagnosed late, delayed bone age is characteristic.

3. MRI of the hypothalamic–pituitary region: detects anomalies in about 12% of patients with IGHD
   1. Abnormal findings on pituitary MRI indicate
      1. A relatively high likelihood that GHD will persist in adulthood
      2. That subsequent pituitary deficiencies may develop
   2. Anterior pituitary may appear aplastic or hypoplastic
   3. Posterior pituitary may be ectopically sited
   4. Septo-optic dysplasia
4. Genetic testing for children with isolated GHD and a family history of GHD (Stanley 2012)
   1. Screening for growth hormone 1 (GH1) and growth-hormone-releasing hormone receptor (GHRHR) mutations (Wit et al. 2011; Kempers et al. 2013)
   2. Other genetic testing is not yet widely applicable in the diagnosis of GHD but may contribute to the diagnosis in the future
5. If there is no clue for a specific gene, consider a whole genome approach, using an SNP array or Array CGH

Genetic Counseling

1. Recurrence risk
   1. Patient's sib
      1. Acquired: not increased
      2. Autosomal recessive: 25% of siblings affected, 50% of siblings carriers, and 25% of siblings normal
      3. Autosomal dominant: not increased unless a parent is affected, in which case the recurrence risk is 50%
      4. X-linked recessive
         1. If the mother is a carrier: 50% of brothers affected and 50% of sisters carriers
         2. If the mother is not a carrier: the recurrence risk is probably low
   2. Patient's offspring
      1. Acquired: not increased
      2. Autosomal recessive: not increased unless the spouse is also a carrier, in which case the recurrence risk is 50%
      3. Autosomal dominant: 50%
      4. X-linked recessive: None of the sons will be affected; all daughters will be carriers.
2. Prenatal diagnosis by molecular genetic analysis
   1. Prenatal testing for pregnancies at increased risk is possible if the family's specific disease-causing mutation is known
   2. Molecular characterization in a case of isolated growth hormone deficiency leading to prenatal diagnosis of an unknown sibling (Nadar et al. 2013)
3. Management (Rogol 2014)

1. Growth hormone promotes linear growth in children by stimulating cartilage growth, particularly at the epiphyseal plate. In addition, growth hormone increases lean body mass and bone mass and reduces fat mass while increasing plasma and liver lipid content.
2. Replacement using exogenous, biosynthetic (recombinant) growth hormone
3. A majority of children with idiopathic isolated growth hormone deficiency (67–78%) with partial growth hormone deficiency initially had normal serum growth hormone responses to insulin-induced hypoglycemia at the completion of their growth hormone therapy (Wacharasindhu et al. 1996; Tauber et al. 1997).

Fig. 1 A 10-year-old Caucasian boy was originally evaluated for unusual facies, small for age, and tight hamstrings and heel cords. He has been seen by an endocrinologist and received growth hormone short daily. Chromosome microarray showed Arr cgh 3q22.1 (RP11-883MS) × 1 variant

Fig. 2 This 2 year and 8 month old Caucasian boy was evaluated for growth hormone deficiency. He received Humatrope 0.5 mg IM/day since 2 years and 3 month. At 11 years of age, He was receiving 2.4 MG a day (growing at 8 cm a year) and Lupron 15 MG/28 days for his early puberty. His bone age was 13.5 years and IGF-1 was 962NG/ML. He also had acanthosis nigricans

Fig. 3 (**a**–**d**) A 3-years-old girl was diagnosed with isolated growth hormone deficiency. She initially presented for small stature and abnormal MRI of her pituitary gland. Her height was 66.9 cm, which is less than the 3rd percentile. The weight was 7.3 kg, which is less than the 3rd percentile. Blood pressure 88/56, pulse 86. Systemic review was unremarkable for any systemic symptoms. There is decreased level of Insulin-like growth factor 1 (*IGF-1*) and IGF binding protein (*IGFBP-3*). Chromosomal study was reported as normal. MRI images showed hypoplasia of the pituitary lobes which lies within a shallow/small pituitary fossa (*arrow*) (**a**). Marked thinning of the pituitary stalk was noted with ectopic posterior pituitary which is located at the level of the infundibular recess of the third ventricle (*arrow*) (**b**). These findings are compatible with the pituitary stalk interruption syndrome. Cleft lip and cleft palate were also seen (*arrow*) (**c**). PA view of the left hand (**d**) was performed for bone age evaluation. It showed markedly delayed bone age (female standard for 9 months) (Courtesy of Dr. Grace Guo)

Ivemark Syndrome

Contents

Ivemark syndrome consists of visceroatrial heterotaxia associated with asplenia (Ivemark 1955). It is also known as asplenia syndrome, heterotaxy syndrome, cardiosplenic syndrome, right atrial isomerism (two morphologically right atrial appendages), or bilateral right-sidedness. The incidence of the syndrome is estimated to be 1/10,000–1/40,000 live births (Rose et al. 1975; Noack et al. 2002). Ivemark syndrome accounts for 1–3% of all congenital heart defects (Cesko et al. 1997).

Synonyms and Related Disorders

Asplenia syndrome; Asplenia with cardiovascular anomalies; Cardiosplenic syndrome; Familial isolated congenital asplenia; Heterotaxy syndrome; Right atrial isomerism

Genetics/Basic Defects

1. Inheritance.
    1. Autosomal recessive (Simpson and Zellweger 1973; Hurwitz and Caskey 1982; McChane et al. 1989) suggested by
        1. Reports of multiple affected siblings, both males and females, born to normal parents
        2. Reports of several instances of parental consanguinity
        3. Report of mutations in the gene encoding connexin 43 (Cx43) (Britz-Cunningham et al. 1995)
    2. Autosomal dominant: familial isolated congenital asplenia (Lindor et al. 1995; Gilbert et al. 2002)
2. Genes associated with human heterotaxy syndrome (Shiraishi and Ichikawa 2012).
    1. *ZIC3* (Zhu et al. 2007)
    2. *NODAL* (Mohapatra et al. 2007)
    3. *CFC1* (Bamford et al. 2000)
    4. *ACVR2B* (Kosaki et al. 1999a)
    5. *LEFTY2* (Kosaki et al. 1999b)
    6. *CITED2* (Bamforth et al. 2004)
    7. *GDF1* (Kaasinen et al. 2010).
3. Other possible cause: maternal diabetes.
4. Heterotaxy syndrome: heterotaxy results from failure of the embryo to establish normal left-right asymmetry (Bartram et al. 2005).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_135

1. A rare congenital disorder occurring in approximately 0.8% of patients with congenital heart disease
2. Often associated with complex cyanotic heart disease and an abnormal cardiac conduction system
3. Consisting of the following two groups of disease: two syndromes are causally and pathogenetically related to each other (Niikawa et al. 1983)
    1. Right isomerism (asplenia syndrome)
        1. Commonly has a combination of complete atrioventricular canal defect, total anomalous pulmonary venous return, double-outlet right ventricle, and pulmonary stenosis
        2. Often has paired atrioventricular nodes that may serve as the substrate for a special reentrant tachycardia ("nodal-to-atrioventricular nodal tachycardia")
    2. Left isomerism (polysplenia syndrome)
        1. Tends to have few complex cardiac anomalies and therefore a better prognosis
        2. Likely to have defective sinus and atrioventricular nodes that may result in sinus node dysfunction, junctional escape rhythm, and atrioventricular block
5. Morphological characteristics of heterotaxy syndrome (Shiraishi and Ichikawa 2012).
    1. Right isomerism
        1. Cardiovascular malformations
            1. Common atrium with bilateral right atrial appendages
            2. Mesocardia/dextrocardia
            3. Atrioventricular (AV) discordance
            4. Single right ventricle
            5. AV septal defect
            6. Common AV connection associated with AV valve regurgitation
            7. Double-outlet right ventricle
            8. Malposition of the great arteries
            9. Pulmonary stenosis or atresia
            10. Total anomalous pulmonary venous drainage (with/without pulmonary venous obstruction)
            11. Right aortic arch
            12. Bilateral superior vena cava
            13. Bilateral sinus node
            14. Paired (anterior/posterior) AV nodes with sling formation
        2. Extracardiac malformations/dysfunctions
            1. Bilateral right-sided lungs and bronchi
            2. Asplenia (susceptibility to *Streptococcus pneumoniae*)
            3. Symmetrical liver
            4. Right-sided stomach
            5. Malrotation of the intestine
            6. Bronchial cilia dysfunction
    2. Left isomerism
        1. Cardiovascular malformations
            1. Bilateral left atrial appendages
            2. Complete/incomplete AV septal defect
            3. Unbalanced ventricles
            4. Persistent left superior vena cava sometimes draining into the left atrium
            5. Interrupted hepatic portion of the inferior vena cava
            6. Partial anomalous pulmonary venous drainage
            7. Hypoplastic sinus node (sick sinus syndrome)
            8. Single/paired AV nodes
            9. Interruption between AV node and His bundles (congenital AV block)
        2. Extracardiac malformations
            1. Bilateral left-sided lungs and bronchi
            2. Bilateral hyparterial bronchi
            3. Polysplenia
            4. Midline liver
            5. Extrahepatic portal vein atresia

Clinical Features

1. Congenital absence of the spleen (asplenia) and associated anomalies (Putschar and Manion 1956)
2. Congenital heart malformations (Durairaj et al. 1976)

1. Cardiac malpositions (44%)
    1. Dextrocardia
    2. Right-sided aortic arch/aortic valve anomaly (Freedom 1974)
2. Venous system
    1. Systemic veins: bilateral superior vena cava (53%)
    2. Pulmonary veins
        1. Total anomalous pulmonary venous drainage (72%)
        2. Partial anomalous pulmonary venous drainage (6%)
3. Great vessels
    1. Transposition of the great arteries (Marino et al. 2002) (72%)
    2. Pulmonary stenosis or atresia (78%)
4. Coronary arteries: single coronary artery (19%)
5. Intracardiac defects
    1. Single ventricle (44%)
    2. Single AV valve (87%)
    3. Absent coronary sinus (85%)
    4. Endocardial cushion defect
    5. Double-inlet ventricle
    6. Discordant ventriculoarterial connection
6. Systemic and pulmonary venous connections in visceral heterotaxy with asplenia (Rubino et al. 1995)
7. Acute pulmonary embolism in an adult (Petitpierre et al. 2013)

3. Maldevelopment of the abdominal organs (Freedom 1972; Mishalany et al. 1982)
    1. Abnormalities of the mesenteric attachment (intestinal malrotation) (Ditchfield and Hutson 1998), a major predisposing cause of midgut volvulus
    2. Situs inversus (heterotaxia)
    3. A midline (central) liver
    4. Tubular stomach
    5. Imperforate anus
    6. Annular pancreas and obstructing duodenal bands
    7. Esophageal varices
    8. Duplication of stomach
    9. Congenital pancreatic cyst (Chahed et al. 2012)
    10. Agenesis of gallbladder
    11. Rudimentary pancreas
    12. Meckel diverticulum
    13. Esophageal atresia and TE fistula
    14. Hiatus hernia
    15. Gastric hypoplasia
    16. Malrotation/volvulus of bowel (Moller et al. 1971; Markowitz et al. 1977)
    17. Acute gastric volvulus (Nakada et al. 1997): a rare complication
    18. Cleft palate
    19. Duplication of the hindgut
    20. Aganglionosis
4. Bronchopulmonary isomerism
    1. Abnormal lobation of the lungs
        1. Bilaterally trilobed
        2. Bilaterally bilobed
    2. Bilateral eparterial bronchi
    3. Pulmonary hypoplasia
5. CNS malformations: uncommon
    1. Agenesis of the corpus callosum
    2. Porencephalic cyst
    3. Cerebellar cysts
    4. Focal cerebellar dysplasia
    5. Hydrocephalus
    6. Septum pellucidum abnormality
6. Genitourinary anomalies
    1. Horseshoe kidney
    2. Cystic kidney
    3. Bilobed urinary bladder
    4. Hydroureter
    5. Posterior urethral valves
    6. Ureteral valve with hydronephrosis
    7. Double collecting system
    8. Rectourethral fistula
    9. Bicornuate uterus
    10. Ovarian cysts
7. Endocrine abnormalities
    1. Fused or horseshoe adrenal
    2. Absent adrenal
8. Musculoskeletal abnormalities
    1. Equinovarus deformity
    2. Overlapping toes
    3. Clubbing of hands
    4. Absent radii
9. Miscellaneous
    1. Microphthalmia
    2. Single umbilical artery
10. Prognosis (Tkebuchava et al. 1997)
    1. Prognosis related to cardiac malformations

1. Severe and incompatible with life (as a rule).
2. Anoxia.
3. Cyanotic neonates die from cardiac insufficiency.
4. Most die from cardiac disease during the first year of life (usually the first month).
5. Complications of surgery.
6. Hemorrhage.

2. Prognosis related to asplenia (Gilbert et al. 2002)
   1. Greater risk from infection for those who survive the first 12 months (Waldman et al. 1977).
   2. Persistent thrombocytosis is present in patients with asplenia syndrome (Yamamura et al. 2013). It may greatly contribute to the development of thromboembolism during the management of congenital heart disease than expected.
   3. Sudden death in infancy (Kiuchi et al. 1988) from sepsis and impaired resistance to infection.
3. Long-term prognosis of heterotaxy patients (Shiraishi and Ichikawa 2012)
   1. Protein-losing enteropathy: one of the most severe manifestation of the failing Fontan circulation, occurring in 5–10% of the total postoperative cases
   2. Arrhythmias
   3. Heart failure
   4. Hepatic dysfunction
4. Perinatal and infant outcomes of prenatal diagnosis of heterotaxy syndrome (Escobar-Diaz et al. 2014)
   1. Bradyarrhythmia: the only predictor of fetal death
   2. Pulmonary vein stenosis and noncardiac anomalies: predictors of postnatal death

Diagnostic Investigations

1. Echocardiography for delineating congenital heart defects (Biggar et al. 1981)
2. Diagnosis of asplenia
   1. No splenic uptake on technetium sulfur colloid scan
   2. The presence of Howell-Jolly bodies in a peripheral blood smear after the first week of life
3. Radiography of visceral patterns (Freedom and Fellows 1973)
4. Immunologic assessment in congenital asplenia
   1. Quantitation of serum immunoglobulins
   2. Most common pathogens
      1. In children less than 6 months of age
         1. *Escherichia coli*
         2. *Klebsiella*
      2. In children surviving past 6 months of age
         1. *Haemophilus influenzae*
         2. *Pneumococci* (Gilbert et al. 2002)

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: 25%
   2. Patient's offspring: not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis of right atrial isomerism by fetal echocardiography (Colloridi et al. 1994; Noack et al. 2002)
   1. No identifiable spleen (the fetal spleen can usually be detected at 20 weeks of gestation in the left gastrorenal angle) (Chitayat et al. 1988)
   2. Visceral heterotaxy
   3. Visualization of the pulmonary venous return and outflow obstruction and characterization of the rhythm disturbances (Lin et al. 2002)
   4. Levocardia
   5. Complete atrioventricular septal defect
   6. Double-outlet right ventricle
   7. Dextro-malposition of the great arteries
   8. Pulmonary atresia/stenosis
   9. Other cardiac anomalies
3. Management
   1. Although the leading causes of death in fetuses and children with heterotaxy

syndromes are cardiac, a small subset of fetuses has extracardiac anomalies with significant impact on the outcome. These anomalies often escape prenatal detection; therefore, neonates at risk have to be monitored for bowel obstruction, biliary atresia, and immune dysfunction in order to allow timely intervention in a multidisciplinary approach (Gottschalk et al. 2015).

2. In asplenic children, early diagnosis, antibiotic prophylaxis, and immunization for encapsulated bacteria can decrease the risk of morbidity and mortality due to invasive infections (Erdem et al. 2015).
3. Palliative cardiac surgery for congenital heart defects (Ando et al. 1976).
4. Surgical intervention for gastrointestinal malformations and other anomalies (Aoyama and Tateishi 1986).
5. Cardiac transplantation may be the only option for patients with severe heart failure, intractable arrhythmias, or recurrent protein-losing enteropathy (Shiraishi and Ichikawa 2012).

Fig. 1 A 3-month-old with Ivemark syndrome who has asplenia with complex cardiovascular malformations (AV canal, single ventricle, transposition of the great vessels, pulmonary atresia, and total anomalous pulmonary venous return). She also has malrotation of intestine

Fig. 2 A 19-month-old boy with Ivemark syndrome. He had heterotaxy syndrome with asplenia, situs inversus, and complex congenital heart defects consisting of a single ventricle, atrioventricular septal defect with small ostium primum ASD, pulmonary stenosis, interrupted IVC with azygous continuation to a left SVC, right aortic arch, and congenital complete heart block

Fig. 3 A 25-month-old girl with Ivemark syndrome. She had dextrocardia, situs inversus, complete AV canal, interrupted inferior vena cava, trachea compression by aorta, and status post pulmonary artery banding. Her complete AV canal was surgically repaired. Chromosome analysis was normal with normal FISH for DiGeorge syndrome

Jarcho-Levin Syndrome

Contents

In 1938, Jarcho and Levin (1938) first described a syndrome of malformations with abnormal fusion of thoracic vertebrae and ribs associated with a short trunk and respiratory insufficiency. At present, Jarcho-Levin syndrome is an eponym used to describe a variety of clinical phenotypes, consisting of short-trunk dwarfism associated with rib and vertebral anomalies. Two phenotypic subtypes of spondylothoracic dysostosis and spondylocostal dysostosis have recently been proposed.

Synonyms and Related Disorders

Costovertebral dysplasia; Costovertebral segmentation anomalies; Spondylocostal dysostosis/dysplasia (Jarcho-Levin syndrome); Spondylothoracic dysostosis/dysplasia (Lavy-Moseley syndrome)

Genetics/Basic Defects

1. Inheritance and molecular defects (Cornier et al. 2003)
    1. The presence of considerable genetic heterogeneity with varied clinical presentations and associated abnormalities (Roberts et al. 1988)
    2. Spondylothoracic dysostosis or Lavy-Moseley syndrome
        1. Autosomal recessive inheritance (Romeo et al. 1991; Bautista et al. 1997)
        2. Linked to chromosome 2q32.1
        3. More severe respiratory compromise
        4. Largely linked to Puerto Rican cohorts and is thought to be associated to the *MESP2* gene, also a Notch pathway gene
    3. Spondylocostal dysostosis or Jarcho-Levin syndrome (Whittock et al. 2004; Turnpenny and Young 2013)
        1. Inheritance: either autosomal recessive (Turnpenny et al. 1991; Turnpenny and Young 2013) or autosomal dominant (Rimoin et al. 1968).
        2. Mutations in the delta-like three gene (*DLL3*) on chromosome 19q13.1-q13 (Bulman et al. 2000; Turnpenny et al. 1999, 2003; Bonafe et al. 2003).
            1. As the major cause of autosomal recessive spondylocostal dysostosis.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_136

2. *DLL3* (Dunwoodie et al. 2002) encodes a ligand in the Notch gene signal pathway. When mutated, defective somitogenesis occurs resulting in a consistent and distinctive pattern of abnormal vertebral segmentation affecting the entire spine.
3. Mutated mesoderm posterior two homolog gene (*MESP2*) that codes for a basic helix-loop-helix transcription factor was found to cause spondylocostal dysostosis in one consanguineous family with two affected children (linkage to 15q21.3-15q26.1) (Whittock et al. 2004; Cornier et al. 2008).
4. Mutation of the Lunatic Fringe gene in humans causes spondylocostal dysostosis with a severe vertebral phenotype (Sparrow et al. 2006).
5. Autosomal dominant spondylocostal dysostosis is caused by mutation in *TBX6* (Sparrow et al. 2013a).
6. Mutation of HES7 in a large extended family with spondylocostal dysostosis and dextrocardia with situs inversus (Sparrow et al. 2013b)

2. Pathogenesis
   1. Vertebral anomalies: probably attributed to defective segmentation of the somite at about the fourth or fifth week of intrauterine life.
   2. Costal anomalies: probably secondary to the vertebral anomalies.
   3. *Pax1* and *Pax9* might be required for the phenotypic expression of Jarcho-Levin syndrome (Bannykh et al. 2003).

Clinical Features

1. Spondylothoracic dysostosis (Herold et al. 1988; Karnes et al. 1991; Mortier et al. 1996; Cornier et al. 2004)
   1. Vertebral segmentation and formation defects throughout cervical, thoracic, and lumbar spine
      1. Hemivertebrae
      2. Block vertebrae
      3. Unsegmented bars
   2. Fusion of all the ribs at the costovertebral joints bilaterally
   3. Absence of intrinsic rib anomalies
   4. Other clinical features
      1. Short-trunk dwarfism
      2. Craniofacial features
         1. Brachycephaly
         2. Low posterior hairline
         3. Prominent nasal bridge
         4. High-arched palate
      3. Short and rigid neck
      4. Short thorax
      5. Protuberant abdomen
      6. Inguinal and umbilical hernias
      7. Urinary tract abnormalities
      8. Talipes equinovarus
   5. Prognosis: poor but not an invariably lethal condition with 56% of survival among the prospectively evaluated patients
      1. Normal intelligence
      2. Progressive kyphosis and neurologic compromise complicating spondylothoracic dysplasia in infancy (Jarcho-Levin syndrome) (Mooney and Emans 1995; Martinez-Frias and Urioste 1994)
      3. Respiratory complications such as pneumonia
      4. Congestive heart failure
      5. Pulmonary hypertension
2. Spondylocostal dysostosis (Karnes et al. 1991; Mortier et al. 1996)
   1. Constitutes a heterogeneous group of radiologic phenotypes with axial skeletal malformations
   2. Generally milder phenotype
   3. Multiple vertebral segmentation and formation defects
   4. Typical findings
      1. Intrinsic asymmetric rib anomalies
         1. Broadening
         2. Bifurcation
         3. Fusion
      2. No symmetric fusion of the ribs
      3. Do not display a fanlike configuration of the thorax
      4. No cervical spine anomalies in some patients

5. Short-trunk dwarfism
5. Associated anomalies
    1. Congenital heart disease
    2. Urogenital and anal anomalies
    3. Limb abnormalities
    4. Torticollis
    5. Diaphragmatic, umbilical, and inguinal hernias
6. Prognosis (Hayek et al. 1999)
    1. A good prognosis, due in part to the asymmetry of the thoracic anomalies resulting in a less restrictive thorax
    2. Long survival
    3. Normal intelligence

Diagnostic Investigations

1. Radiography (Cornier et al. 2003)
    1. Spondylothoracic dysostosis
        1. Bilateral fanning of the ribs with posterior fusion, giving the appearance of a common origin of ribs at the posterior thoracic spine
        2. A decreased number of cervical, thoracic, and lumbar vertebrae
        3. Multiple vertebral segmentation and formation defects
            1. Block and wedge vertebrae
            2. Unsegmented bars
            3. Hemivertebrae
            4. Anterior-posterior-lateral failure of closure
        4. Symmetric posterior fusion of the ribs: characteristic radiographic finding (Berdon et al. 2011)
    2. Spondylocostal dysostosis
        1. Multiple vertebral formations and segmentation defects along the entire spine
            1. A decreased number of cervical, thoracic, and lumbar vertebrae
            2. Block and wedge vertebrae
            3. Agenesis of the coccygeal region
            4. Progressive scoliosis of the thoracic spine due to tethering effect secondary to the rib anomalies
        2. Asymmetric intrinsic rib malformations
            1. Broadening
            2. Bifurcation
            3. Fusion
            4. Do not display a fanlike configuration of the thorax as in spondylothoracic dysostosis
        3. Asymmetrical abnormalities of the vertebral bodies and ribs: characteristic radiographic finding (Berdon et al. 2011)
2. Reconstructed tridimensional CT scan of the chest
    1. Spondylothoracic dysostosis
        1. Bilateral rib fusion at the costovertebral junction.
        2. Segmentation and formation defects in all cervical, thoracic, and lumbar vertebrae. Sacrococcygeal regions are spared from any abnormality.
        3. Increase in the coronal diameter of the thoracic and lumbar vertebrae which acquire a sickle-like appearance.
    2. Spondylocostal dysostosis
        1. Varying extent of the thoracic fusion
        2. Thoracic fusion always asymmetric with respect to each side of the thorax
        3. Increase in the coronal diameter of the thoracic and lumbar vertebrae which acquire a sickle-like appearance
3. Pulmonary function tests for restrictive lung disease
4. Molecular genetic analysis (Turnpenny and Young 2013)
    1. *DLL3* mutations in spondylocostal dysostosis (homozygous or compound heterozygous mutations).
    2. Other subtypes are defined by identification of two mutant alleles in other three genes known to be associated with autosomal recessive spondylocostal dysostosis: *MESP2*, *LFNG*, and *HES7*.

Genetic Counseling

1. Recurrence risk
    1. Autosomal recessive inheritance (spondylothoracic dysostosis and spondylocostal dysostosis)

1. Patient's sib: 25%
2. Patient's offspring: not increased unless the spouse is also a carrier; in which case, there is a 50% risk of having an affected offspring

2. Autosomal dominant inheritance (spondylocostal dysostosis)
   1. Patient's sib: not increased unless a parent is affected; in which case, there is a 50% risk of having an affected sibling
   2. Patient's offspring: 50%

2. Prenatal diagnosis by ultrasonography
   1. Ultrasonography (Tolmie et al. 1987; Marks et al. 1989; Eliyahu et al. 1997; Lawson et al. 1997; Kauffmann et al. 2003).
      1. Grossly distorted thoracic and lumbar spine
      2. Marked kyphoscoliosis
      3. Multiple vertebral segmentation anomalies
      4. Fanned ribs from fused thoracic vertebral bodies (Wong and Levine 1998)
      5. A small chest with foreshortened spine
      6. Increased fetal nuchal translucency thickness (Hull et al. 2001)
      7. Inguinoscrotal hernia in a fetus with vertebral anomalies: a clue for Jarcho-Levin syndrome and other pathologies that increase abdominal pressure (Basaran et al. 2010)
   2. Three-dimensional computed tomography of fetal spondylothoracic dysostosis at 23 weeks' gestation (Ranes et al. 2012).
   3. Prenatal diagnosis by molecular genetic analysis of *DLL3* (Whittock et al. 2003), *MESP2* (Whittock et al. 2004), *LFNG*, or *HES7* gene mutations by sequencing entire coding region of fetal DNA obtained from amniocentesis or CVS, provided the disease-causing allele has been previously identified.
   4. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have identified previously.

3. Management (Cornier et al. 2003)
   1. Minimize positive end-expiratory pressure to avoid bronchopulmonary dysplasia.
   2. Continuous feeding instead of in boluses to avoid stomach distension that will lead to increase diaphragmatic pressure.
   3. Aggressive treatment of infections.
   4. Treat the spinal deformities.
   5. Management of thoracic insufficiency syndrome in patients with Jarcho-Levin syndrome using VEPTRs (vertical expandable prosthetic titanium ribs): improves thoracic symmetry, control spinal deformity, and was associated with improved clinical respiratory function (Karlin et al. 2014).

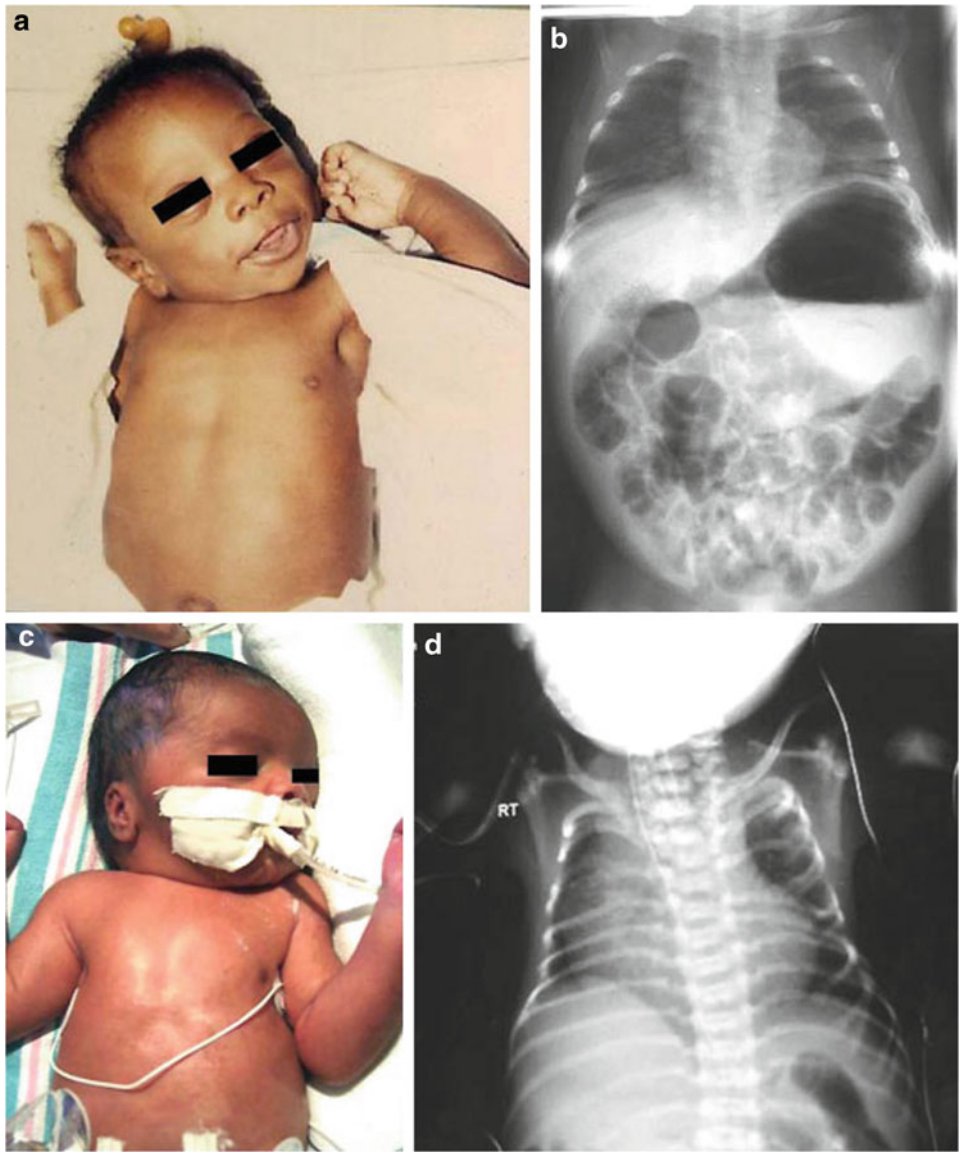

Fig. 1 (**a**–**d**) Two infants (**a**, **c**) with spondylocostal dysostosis with typical crablike deformities of the chest with fused ribs (radiographs) (**b**, **d**)

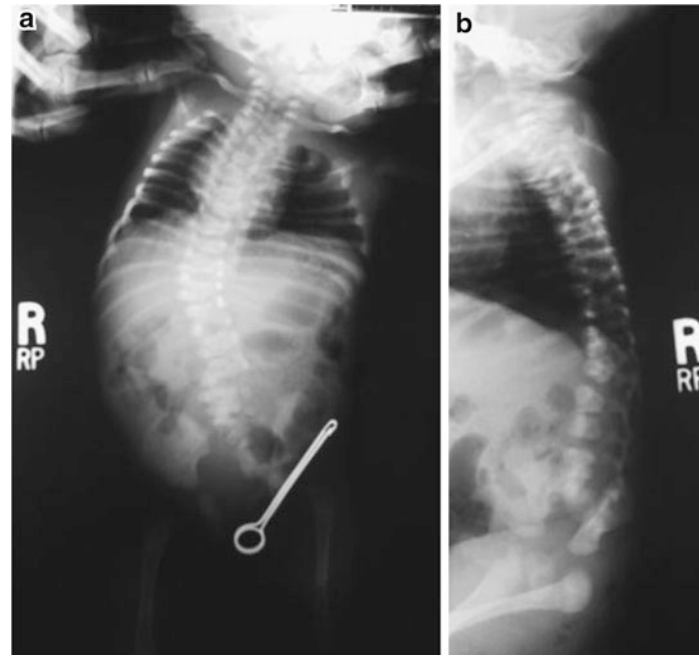

Fig. 2 (**a**, **b**) Radiographs of another infant with spondylocostal dysostosis showing fused ribs and fused vertebrae

Fig. 3 Radiographs of another infant with spondylothoracic dysostosis showing severe chest deformity

Fig. 4 (**a**–**d**) An Arabic female newborn (**a**) was evaluated for multiple vertebral and rib anomalies. Her prenatal ultrasound showed vertebral anomalies, hydramnios, and possible TE fistula. Postnatally, she was noted to have short neck, short chest, and protuberant abdomen. The postnatal radiographs (**b**–**d**) showed vertebral segmentation and formation defects throughout cervical, thoracic, and lumbar spine. Fusion of the ribs was present. Clinical diagnosis of Jarcho-Levin syndrome was made. The parents are first cousins. Molecular genetic diagnosis showed positive *DLL3* mutation. This patient is apparently homozygous in the *DLL3* gene for a frameshift mutation defined as c.329delT which is predicted to result in premature protein termination (p.Val110GlyfsStope22). This particular mutation has not been reported previously. However, it is the type expected to be pathogenic (e.g., Turnpenny et al. 2003). The homozygous c.329delT mutation is very likely the cause of recessive spondylocostal dysostosis

Fig. 5 (**a**–**c**) The previous infant (**a**) at 3 months of age with follow-up X-rays (**b**, **c**)

Joubert Syndrome

Contents

In 1969, Joubert et al. (1969) first documented three brothers and one sister who had episodic hyperpnea, abnormal eye movements, ataxia, mental retardation, and cerebellar vermian hypoplasia and aplasia. Later in 1977, Boltshauser and Isler (1977) reported three more cases with variable degrees of clinical symptoms and suggested the syndrome be called Joubert syndrome.

The prevalence in the United States has been estimated at approximately 1:100,000 (Parisi et al. 2006). This is likely to be an underestimate due to lack of recognition of the clinical signs or MRI findings and failure to diagnose the condition in more mildly affected individuals (Parisi et al. 2007).

Synonyms and Related Disorders

Cerebello-oculo-renal syndrome; Cerebelloparenchymal disorder; Joubert syndrome and related disorders (JSRD); Joubert-Boltshauser syndrome

Genetics or Basic Defects

1. Predominantly inherited in an autosomal recessive manner
2. JSRD caused by mutation of *OFD1*: inherited in an X-linked recessive manner
3. Causative gene defects (genetic complexity) in individuals with Joubert syndrome and related disorders (JSRD) (Parisi et al. 2006; Harris 2007)
    1. *NPHP1* (nephronophthisis 1, 2q13) gene homozygous deletion associated with juvenile nephronophthisis present in a subset of individuals with Joubert syndrome (Parisi et al. 2004; Castori et al. 2005) (1–2%)
    2. *AHI1* (Abelson helper integration site, 6q23.11) gene mutations (Dixon-Salazar et al. 2004; Parisi et al. 2006) (10–15%)
    3. *CEP290* (encoding centrosomal protein, 12q21.3) gene mutations causing pleiotropic forms of Joubert syndrome (Valenti et al. 2006) (approximately 10%)
    4. *NPHP6* (encoding centrosomal protein nephrocystin-6, 12q21.3) gene mutations in Joubert syndrome (Sayer et al. 2006)
    5. *ARL13B* cilia gene mutation leading to classical form of Joubert syndrome (Cantagrel et al. 2008)
    6. Mutations in three genes (MKS3, CC2D2A, and RPGRIP1L) in COACH syndrome (Joubert syndrome with congenital hepatic fibrosis) (Doherty et al. 2010)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_137

7. Mutations in *CSPP1* lead to classical Joubert syndrome (Akizu et al. 2014)
8. Overall, sequence variants in one of the *TCTN* genes (*TCTN1*, *TCTN2*, and *TCTN3*) represent rare causes for Joubert syndrome and Meckel-Gruber syndrome. Interestingly, all patients have a clear neurological phenotype with either vermis hypoplasia or occipital encephalocele (Huppke et al. 2015)
9. Mutations in *B9D1* and *MKS1* cause mild Joubert syndrome: expanding the genetic overlap with the lethal ciliopathy Meckel syndrome (Romani et al. 2014)

Clinical Features

1. Clinical features often cited as necessary for the diagnosis of classic Joubert syndrome (Joubert et al. 1969; Saraiva and Baraitser 1992; Steinlin et al. 1997; Maria et al. 1999a, b; Parisi et al. 2006, 2007).
    1. Cranial MRI findings of molar tooth sign (100%)
        1. Midline cerebellar vermis hypoplasia
        2. Deepened interpeduncular fossa
        3. Thick, elongated superior cerebellar peduncles
    2. Hypotonia in infancy (100%)
    3. Developmental delay or mental retardation, of variable severity (100%)
    4. Autism and autistic behavior (Holroyd et al. 1991; Ozonoff et al. 1999; Takahashi et al. 2005)
    5. One or both of the following (not absolutely required but supportive of the diagnosis):
        1. Irregular breathing pattern in infancy (episodic tachypnea and/or apnea)
        2. Abnormal eye movements (including nystagmus, jerky eye movements, and oculomotor apraxia or difficulty with smooth visual pursuits) (Sturm et al. 2010)
2. Typical facial features during childhood (Maria et al. 1999a; Braddock et al. 2007).
    1. Long face
    2. Frontal prominence
    3. Bitemporal narrowing
    4. High rounded eyebrows
    5. Broad nasal bridge
    6. Mild epicanthus
    7. Anteverted nostrils
    8. Triangular-shaped open mouth with the tongue frequently resting on the lower lip
    9. Lower lip eversion
    10. Low-set and coarse ears
3. Joubert syndrome may be considered a cerebello-oculo-renal syndrome because of the coincident involvement of all three organ systems (Valente et al. 2003).
4. JSRD: disorders sharing the MRI molar tooth sign (Gleeson et al. 2004; Brancati et al. 2010). Clinical features in JSRD with the molar tooth sign (MTS) (Maria et al. 1997; Chance et al. 1999; Parisi et al. 2007) are:
    1. Other central nervous system anomalies
        1. Hypotonia
        2. Mental retardation
        3. Oculomotor apraxia
        4. Breathing abnormalities
        5. Encephalocele
        6. Polymicrogyria (Dixon-Salazar et al. 2004; Glordano et al. 2009)
    2. Ocular abnormalities (Tusa and Hove 1999)
        1. Ocular coloboma
        2. Retinal dystrophy
        3. Leber congenital amaurosis (Ivarsson et al. 1993)
    3. Renal diseases
        1. Cystic dysplastic kidneys
        2. Nephronophthisis
    4. Hepatic fibrosis
    5. Polydactyly
    6. Tongue hamartomas/oral frenula
5. Proposed classification system for Joubert syndrome and related disorders (Zaki et al. 2008).
    1. Primary criteria include:
        1. Neurological signs
            1. Hypotonia/ataxia
            2. Developmental delay
            3. Oculomotor apraxia
        2. Radiological hallmark of molar tooth sign
        3. Occasional features (seen in all forms)

1. Mental retardation
2. Breathing abnormalities
3. Postaxial polydactyly
4. Mild retinopathy
5. Polymicrogyria
6. Corpus callosum abnormality

2. Secondary criteria.
   1. Joubert syndrome may include
      1. Mild ocular sign (retinopathy)
      2. Mild renal sign
      3. Postaxial polydactyly
   2. Cerebellar vermis hypo-/aplasia-oligophrenia-ataxia-ocular coloboma-hepatic fibrosis (COACH syndrome): at least one (typically both)
      1. Hepatic fibrosis
      2. Coloboma (choroidal or retinal)
   3. Cerebello-oculo-renal syndrome (CORS): at least one ocular sign and at least one renal sign
      1. Ocular signs: retinopathy (typically congenital blindness), coloboma
      2. Renal signs: cysts, nephronophthisis, and renal failure
   4. Orofaciodigital syndrome type VI (OFD-VI): at least one orofacial sign and at least one digital sign
      1. Orofacial signs: cleft lip/palate, tongue tumors, and notched upper lip
      2. Digital signs: mesoaxial polydactyly (most specifically), preaxial polydactyly, and bifid digits
3. The presence of the primary criteria and the secondary criteria is used to support the diagnosis of a specific type of JSRD.

Diagnostic Investigations

1. Molar tooth sign, demonstrated by a high-quality MRI scan of the brain (Zaki et al. 2008) (Parisi et al. 2007)
   1. Result from images of cerebellar vermis hypoplasia, thick and maloriented superior cerebellar peduncles, and an abnormally deep interpeduncular fossa (Maria et al. 1999b)
   2. Disorders presenting as "molar tooth sign" (Brancati et al. 2010; Dirik et al. 2013)
      1. Jubert syndrome
      2. Cerebello-oculo-renal syndrome (Satran et al. 1999)
      3. Dekaban-Arima syndrome (chorioretinal coloboma with cerebellar vermis aplasia)
      4. COACH syndrome (coloboma, oligophrenia (mental retardation), ataxia, cerebellar vermis hypoplasia, and hepatic fibrosis) (Verloes and Lambotte 1989; Satran et al. 1999)
      5. Varadi-Papp syndrome (orofaciodigital type VI): tongue hamartomas, mesoaxial hand polydactyly, and preaxial foot polysyndactyly with bifid hallux
      6. A minority of cases with Senior-Loken syndrome (nephronophthisis and Leber congenital amaurosis)
   3. Extraordinarily useful in differentiating JSRD conditions from other hindbrain malformations
      1. Dandy-Walker malformation (Maria et al. 2001)
      2. Isolated cerebellar vermis hypoplasia
      3. Pontocerebellar hypoplasia
      4. Rhombencephalosynapsis
2. High-resolution diffusion tensor imaging and tractography (Hsu et al. 2015)
   1. The absence and/or thinning of the dorsal pontocerebellar tract
   2. Abnormal thickening of the ventral pontocerebellar tract
   3. Abnormal decussation of superior cerebellar peduncles and the absence of red dot sign: a further indication that they represent a spectrum of abnormal midline axonal migration
3. Medical genetics evaluation
   1. Family history
   2. Demonstration of congenital anomalies
      1. Micro-/macrocephaly
      2. Facial dysmorphism
      3. Clefts
      4. Lingual nodules

5. Polydactyly
6. Genital anomalies
7. Others

4. Developmental assessment
5. Neurologic evaluation for cerebellar function
6. EEG for seizures
7. Polysomnogram for abnormal sleep history (apnea/hyperpnea)
8. Ophthalmological evaluation
   1. Eye malformations such as coloboma
   2. Retinopathy or blindness
   3. Abnormal eye movement such as nystagmus or oculomotor apraxia
9. Abdominal ultrasonography
   1. Renal cystic disease
   2. Liver fibrosis
10. Clinical laboratory tests
    1. BUN
    2. Creatinine
    3. CBC for anemia
    4. First-morning void urinalysis with specific gravity
11. Liver function tests
    1. Transaminases
    2. Albumin
    3. Bilirubin
    4. Prothrombin time
12. Chromosome analysis: no consistent chromosomal aberrations identified
13. Molecular genetic testing
    1. FISH or microsatellite marker analysis for homozygous deletion of the *NPHP1* gene associated with juvenile nephronophthisis (Hildebrandt et al. 2001; Parisi et al. 2004) identified in only 1–2% of subjects with JS (Parisi et al. 2006).
    2. Molecular testing for mutations in the *AHI1* gene and the *CEP290* gene: clinically available. Each of these genes is estimated to account for about 10% of cases of JSRD. Mutations in both *AHI1* and *CEP290* are more likely to be associated with retinal disease, with *CEP290* implicated in some cases with congenital blindness or Leber amaurosis (den Hollander et al. 2006; Sayer et al. 2006).
    3. Other tests used in JSRD (Parisi and Glass 2013). To date, biallelic pathogenic variants in one of the following 19 genes are identified in about 50% of individuals with a JSRD: *TMEM67* (*MKS3*), *RPGRIP1L*, *CC2D2A*, *ARL13B*, *INPP5E*, *OFD1*, *TMEM216*, *KIF7*, *TCTN1*, *TCTN2*, *TMEM237*, *CEP41*, *TMEM138*, *C5orf42*, *TMEM231*, and *TCTN3*.
    4. In rare families with a large number of affected children and/or known consanguinity, linkage analysis may be feasible on a research basis.
    5. Using a combination of linkage mapping and massively parallel sequencing of the X-chromosome exome, an 18-bp deletion was identified in exon 8 of the orofaciodigital syndrome type 1 (*OFD1*) gene in a family with X-linked Joubert syndrome (Field et al. 2012).
    6. The diagnostic utility of whole-exome sequencing in Joubert syndrome and related disorders (Tsurusaki et al. 2013).

Genetic Counseling

1. Recurrence risk (Parisi and Glass 2013).
   1. Autosomal recessive inheritance
      1. Patient's sib: a 25% risk
      2. Patient's offspring: low recurrence risk unless the partner is a carrier or affected
   2. X-linked recessive inheritance
      1. Patient's sib: If the mother of the proband has a pathogenic variant, the chance of transmitting it in each pregnancy is 50%. Males who inherit the pathogenic variant will be affected; females who inherit the pathogenic variant are unlikely to be affected; however, no carrier females have been identified. If the proband represents a simplex case (i.e., a single occurrence in a family) and if the pathogenic variant cannot be detected in the leukocyte DNA of the mother, the risk to sibs is low but greater than

that of the general population because of the possibility of maternal germline mosaicism.
    2. Offspring of a male proband: No affected male has reproduced. Males with X-linked JSRD will pass the pathogenic variant to all of their daughters and none of their sons.
2. Prenatal diagnosis.
    1. Possible for pregnancy at risk, provided the disease-causing mutations have been identified in the affected individual
    2. Prenatal imaging for all other at-risk pregnancies
        1. Prenatal diagnosis of Joubert syndrome has been accomplished as early as the first trimester on the basis of extracranial anomalies, such as polydactyly or renal cysts, and major structural CNS malformations such as encephalocele (Wang et al. 1999).
        2. Early diagnosis: more challenging when extracranial abnormalities are not present, because cerebellar vermis hypoplasia cannot be reliably diagnosed until 18–20 weeks gestation (Bromley et al. 1994) and the MTS has not been observed before 27 weeks gestation (Fluss et al. 2006).
    3. Prenatal diagnosis: suspected at 32 weeks gestation in the absence of a family history by observation of vermian agenesis, bilateral ventriculomegaly, postaxial polydactyly, and episodes of tachypnea (Aslan et al. 2002)
    4. Sensitivity and specificity of prenatal imaging findings for JSRD: not known (Doherty et al. 2005)
3. Preimplantation genetic diagnosis may be an option for some families in which the pathogenic variant(s) have been identified.
4. Management.
    1. No specific treatments for Joubert syndrome exist.
    2. Supportive treatments with interventions for individuals with developmental disabilities:
        1. Special education programs
        2. Physical, occupational, and speech therapy
        3. Adaptive equipments as needed
        4. Seizure control
    3. Dialysis and renal transplantation for nephronophthisis.
    4. Specific surgical interventions for esophageal varices or portal hypertension in liver fibrosis.
    5. Liver transplantation for COACH syndrome.

Fig. 1 Patient 1 with Joubert syndrome. This 6-week-old boy presented with respiratory distress, tachypnea with episodes of apnea, and abnormal eye movement. Ultrasound revealed multiple bilateral renal cysts

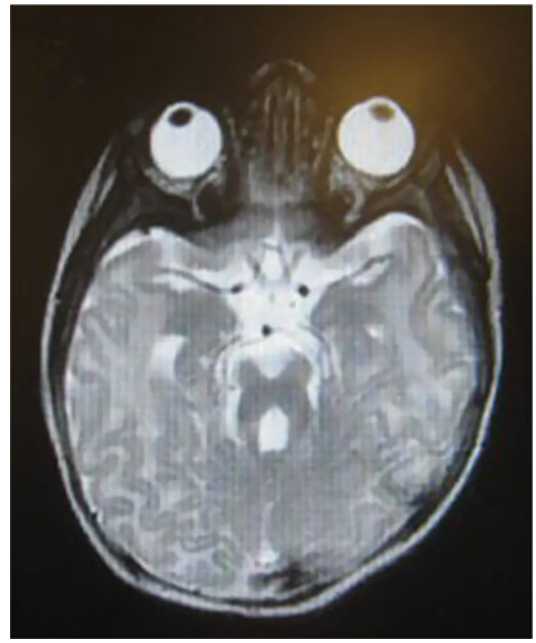

Fig. 3 MRI of the brain showed hypoplasia of cerebellum with "molar tooth sign" leading to diagnosis of Joubert syndrome

Fig. 2 Lateral view of the patient

Fig. 4 This 22-month-old boy was evaluated for Joubert syndrome. He was delivered at 41 weeks of gestation via cesarean section with cord wrapping around the neck twice. Birth weight was 4,035 g and birth length 55 cm. Fetal ultrasound examination showed possible cerebellar hypoplasia. Follow-up MRI of the brain showed "molar tooth sign" consistent with Joubert syndrome. He had neonatal breathing dysregulation, delayed psychomotor development, hypotonia, and macrocephaly with a prominent forehead, high-round eyebrows, low set and "tilted" ears, abnormal jerky eye movement with right chorioretinal coloboma, epicanthal folds, and ptosis. FISH using a probe to the *NPHP1* locus showed no deletion of the *NPHP1* region. The result does not exclude the clinical diagnosis of Joubert syndrome and does not exclude a mutation in the *NPHP1* gene or other genes not detectable with this assay

Fig. 5 Note psychomotor retardation

Fig. 6 Note the genital hypoplasia

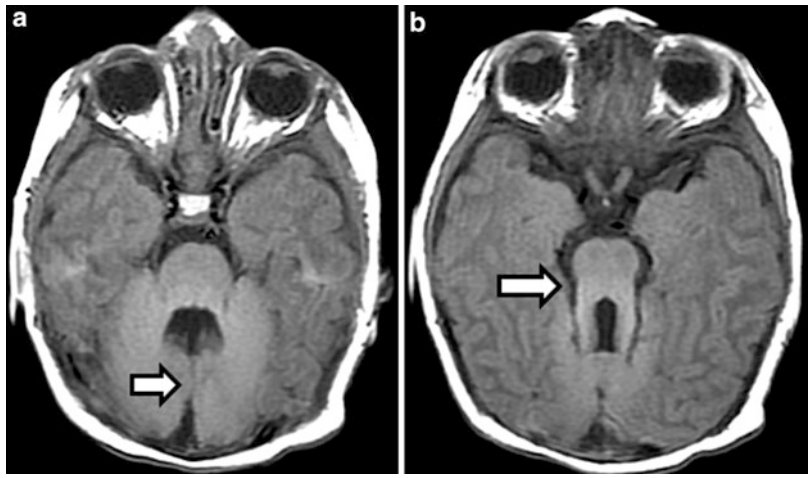

Fig. 7 (**a**, **b**) A 5-day-old boy was presented with exaggerated periodic breathing and developmental delay. The MRI of the brain demonstrated the absence of the vermis (**a**) (*arrow*) with enlarged superior cerebellar peduncles producing a molar tooth configuration of the midbrain (**b**) (*arrow*). The findings are compatible with Joubert syndrome. Genetic tests showed that this patient was heterozygous in the *AH11* and *CEP290* genes for the missense variants. While clinical significance of these missense variants is unknown, it is likely that both missense variants together are the cause of the recessive Joubert syndrome. The *NPHP1* gene mutation study was negative (Courtesy of Dr. Grace Guo)

Kabuki Syndrome

Contents

In 1981 and 1982, Niikawa (Niikawa et al. 1982) and Kuroki (Kuroki et al. 1981) independently described a previously unrecognized mental retardation-malformation syndrome, characterized by a unique combination of craniofacial anomalies, congenital heart defects, skeletal anomalies, persistent fetal fingertip pads, dermatoglyphic abnormalities, mental retardation, and short stature. Because the peculiar facial appearance resembles the makeup of Kabuki actors in a traditional Japanese theater, the Niikawa-Kuroki syndrome is also known as Kabuki or Kabuki makeup syndrome. The prevalence of the syndrome is estimated to be 1 in 32,000 live births in Japan (Niikawa et al. 1988). The syndrome is increasingly recognized in other parts of the world.

Synonyms and Related Disorders

Autosomal dominant type-1 Kabuki syndrome; Kabuki makeup syndrome; Niikawa-Kuroki syndrome; X-linked type-2 Kabuki syndrome

Genetics/Basic Defects

1. Sporadic in most cases (Schrander-Stumpel et al. 1994)
2. Autosomal dominant inheritance suggested in a few families (Halal et al. 1989; Kobayashi and Sakuragawa 1996; Tsukahara et al. 1997; Courtens et al. 2000)
3. Other hypotheses:
   1. Postzygotic mutation, suggested by discordance between the twins, although multifactorial causes, cannot be ruled out.
   2. Several instances of chromosomal abnormalities have been reported in the literature but without identical break points in those autosomal abnormalities.
   3. Microdeletion involving several contiguous genes, suggested by sporadic cases in the majority of patients and a wide spectrum of clinical manifestations. So far, no chromosomal deletion was detected at the sites of the DiGeorge/velocardiofacial chromosomal region within 22q11.2 or flanking the van der Woude syndrome region at 1q32-q41.
   4. 8p23.1-p33 duplication, detected by comparative genomic hybridization (CGH) and fluorescence in situ hybridization (FISH) in six unrelated patients with Kabuki syndrome (KS), was postulated to be a common etiology for the syndrome (Milunsky and Huang 2003). However, studies by Miyake et al. (2004) detected no

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_138

aberrations of the 8p region by either CGH or FISH on other patients and suggested that the patients studied by Milunsky and Huang had either atypical Kabuki syndrome or possibly an "8p23.1-p33 duplication syndrome."

5. It is possible that Kabuki syndrome is a heterogeneous disorder and abnormalities not only on chromosome 8 but also on other chromosomes, such as the X chromosome, which could lead to similar Kabuki syndrome features (Adam and Hudgins 2004).
6. Molecular karyotyping in 17 patients and mutation screening in 41 patients with Kabuki syndrome revealed no causative gene, but the locus of 9q21.11-q21.12, including *TRPM3*, *KLF9*, *SMC5*, and *MAMDC2*, may contribute to the cleft palate of Kabuki syndrome (Kuniba et al. 2009).

4. *KMT2D* (histone-lysine *N*-methyltransferase 2D) (12q12-q14) (*MLL2*) mutations in patients with autosomal dominant type 1 Kabuki syndrome (KS1) (Banka et al. 2012):
   1. *MLL2* mutations are detected in 55–80% of patients with Kabuki syndrome (KS).
   2. In 20–45% patients with KS, the genetic basis remains unknown, suggesting possible genetic heterogeneity.
   3. The majority of mutations are truncating and the pathogenic missense mutations are commonly located in exon 48.
   4. KS can be phenotypically variable, and therefore *MLL2* testing should be considered even in atypical KS patients.
5. Mutations in *KDM6A* (lysine-specific demethylase 6A) (Xp11.3) (*UTX*): a less frequent, recently discovered genetic abnormality causing X-linked type-2 Kabuki syndrome (KS2) (Lederer et al. 2012; Banka et al. 2015).

Clinical Features

1. Craniofacial abnormalities (Wessels et al. 2002; Matsumoto and Niikawa 2003):
   1. Peculiar facial appearance (100%). The most striking feature of the syndrome:
      1. Peculiar face that consists of eversion of the low lateral eyelid that is reminiscent of a Kabuki actor's makeup and arched eyebrows with sparseness of their lateral one third
      2. Long palpebral fissures
      3. Depressed nasal tip
      4. Prominent, large ears
   2. Microcephaly (26%)
   3. Eye abnormalities:
      1. Long palpebral fissure (99%)
      2. Lower palpebral eversion (92%)
      3. Arched eyebrow (85%)
      4. Ptosis (50%)
      5. Epicanthus (46%)
      6. Strabismus (36%)
      7. Blue sclerae (31%)
   4. Nasal abnormalities:
      1. Short nasal septum (92%)
      2. Depressed nasal tip (83%)
   5. Ear abnormalities:
      1. Prominent ears (84%)
      2. Malformed ears (87%)
      3. Preauricular dimple/fistula (22%)
   6. Oral abnormalities:
      1. High-arched palate (72%)
      2. Abnormal dentition (68%)
      3. Micrognathia (40%)
      4. Cleft palate/lip (35%) (Handa et al. 1991)
      5. Lower lip pit (27%)
   7. Low posterior hairline (57%)
2. Skeletal abnormalities (88%):
   1. A novel sign, namely, the attenuation and/or congenital absence of the distal interphalangeal (IPD) crease of the third and fourth fingers associated with limitation of flexion of the corresponding joints, which seem to be specific of KS and could help the clinician to diagnose KS (Michot et al. 2013)
   2. Pilonidal sinus (83%)
   3. Short fifth phalanxes (80%)
   4. Short fifth fingers (79%)
   5. Joint laxity (74%)
   6. Clinodactyly of fifth fingers (50%)

7. Sagittal cleft of the vertebral body (36%)
8. Scoliosis (35%)
9. Short metacarpals (35%)
10. Deformed vertebra/rib (32%)
11. Foot deformity (24%)
12. Spina bifida occulta (19%)
13. Hip dislocation (18%)
14. Rib anomaly (18%)
15. Coarse carpal bone (17%)
16. Cone-shaped epiphyses (13%)
17. Patellar dislocation
18. Craniosynostosis: rare (6%) (Armstrong et al. 2005; Martinez-Lage et al. 2010)

3. Dermatoglyphic abnormalities:
   1. Abnormal dermatoglyphics (96%):
      1. Frequent fingertip ulnar loop patterns
      2. Absence of digital triradius "c" or "d"
      3. An interdigital triradius "bc" or "cd"
      4. Fourth interdigital area patterns:
         1. Hypothenar loop patterns
         2. Ulnar loop patterns
   2. Presence of fingertip pads (89%): possible remnants of fetal pads
4. Neurologic abnormalities:
   1. Mild to moderate mental retardation (IQ <80) (84%)
   2. Hypotonia (68%)
   3. Neonatal hypotonicity (28%)
   4. Seizures (17%)
   5. Brain atrophy (4%)
   6. Retinal pigmentation (3%)
5. Short stature (55%)
6. Visceral abnormalities:
   1. Cutaneous abnormalities:
      1. Hyperpigmented nevus (22%)
      2. Generalized hirsutism (11%)
   2. Cardiovascular anomalies (42%) (Digilio et al. 2001):
      1. Ventricular septal defect
      2. Atrial septal defect
      3. Coarctation of the aorta
      4. Transposition of great vessels
   3. Gastrointestinal abnormalities:
      1. Umbilical hernia (9%)
      2. Inguinal hernia (7%)
      3. Malrotation of the colon (6%)
      4. Anal atresia/rectovaginal fistula (5%)
   4. Genitourinary abnormalities:
      1. Kidney/urinary tract malformations (28%) (Courcet et al. 2013)
         1. Horseshoe kidney (27%)
         2. Renal dysplasia (15%)
         3. Hydronephrosis (23%)
      2. Undescended testes (24%)
      3. Small penis (10%)
7. Other features:
   1. Susceptibility to infections:
      1. Recurrent otitis media (63%)
      2. Repeat upper respiratory tract infections and pneumonias
   2. Most KS patients show increased susceptibility to infections and have reduced serum immunoglobulin levels, while some suffer also from autoimmune manifestations, such as idiopathic thrombocytopenic purpura, hemolytic anemia, autoimmune thyroiditis, and vitiligo (Stagi et al. 2016).
   3. Precocious puberty: early breast development (28%) (Kuroki et al. 1987).
   4. Hearing loss (27%).
   5. Neonatal hyperbilirubinemia (20%).
   6. Obesity (19%).
   7. Anemia (9%).
   8. Polycythemia (4%).
   9. Cystic fibrosis (2%).
   10. Primary ovarian dysfunction (2%).
8. Genotype-phenotype correlation (Makrythanasis et al. 2013):
   1. Patients with likely pathogenic nonsense or missense *MLL2* mutations were usually more severely affected.
   2. Several typical facial features such as large dysplastic ears, arched eyebrows with sparse lateral third, blue sclerae, a flat nasal tip with a broad nasal root, and a thin upper and a full lower lip were observed more often in mutation positive patients.

Diagnostic Investigations

1. Blood sugar during infancy for neonatal hypoglycemia (7%).
2. Humoral immunodeficiency in patients with type-1 Kabuki syndrome (KS1) caused by

autosomal dominant KMT2D mutations is well described and resembles common variable immunodeficiency (CVID) (Lin et al. 2015; Lindsley et al. 2015):
    1. More than 80% of KS1 patients display hypogammaglobulinemia and diminished memory B-cell populations.
    2. Impaired somatic hypermutation in IgG transcripts and disrupted terminal differentiation can also be demonstrated in primary B cells (Lindsley et al. 2015).
3. Mild humoral immunodeficiency observed in a patient with X-linked Kabuki syndrome (Frans et al. 2016).
4. Thyroid profile for rare thyroxine-binding globulin (TBG) deficiency (2%).
5. Growth hormone determination for rare growth hormone deficiency.
6. Workup for autoimmune hemolytic anemia, if present.
7. Audiologic screening for hearing loss.
8. Radiography for skeletal abnormalities (Niikawa et al. 1981):
    1. Frequent features:
        1. Abnormalities of the spinal column:
            1. Thoracic or lumbar scoliosis
            2. Sagittal cleft vertebra
            3. Narrow disk space
            4. Cervical ribs
            5. Schmorl's node
        2. Dislocation of the hip joints
        3. Abnormalities of the hands:
            1. Brachymesophalangy of the fifth fingers
            2. Short fifth metacarpals
            3. Cone-shaped epiphysis of proximal phalanges II–V
    2. Less frequent features:
        1. Defective dentition
        2. Underpneumatized mastoids
        3. Sacral spina bifida occulta
        4. Osteoporotic changes of the carpal bone and metacarpals
        5. Underdeveloped ulnar styloids
        6. Dysplastic acetabulum
        7. Horseshoe kidney
        8. Bifid renal pelvis
9. Renal ultrasonography and renal function screening for renal abnormalities (Courcet et al. 2013).
10. Echocardiography for congenital heart defects.
11. EEG for seizures: characteristic features are focal seizures more frequently origin in fronto-central area (Lodi et al. 2010).
12. MRI/CT scan for rare central nervous system (CNS) anomalies.
13. Dermatoglyphic analysis.
14. *KMT2D* (*MLL2*) mutations study (Banka et al. 2012; Bögershausen and Wollnik 2013):
    1. Sequence analysis of *KMT2D* as a standard molecular genetic test in patients with suspected KS (Banka et al. 2012; Bögershausen and Wollnik 2013).
    2. For mutation negative patients, array-CGH should be performed (Bögershausen and Wollnik 2013):
        1. Multiple ligand probe amplification (MLPA) for *KMT2D* and *KDM6A* as a third-line diagnostic tool after Sanger sequencing of *KMT2D* and array-CGH.
        2. As an alternative, high-resolution array-CGH might be a powerful diagnostic tool to detect structural chromosomal aberrations as well as specific deletions in *KMT2D* and *KDM6A*.
        3. The finding of low-level mosaic mutations in *KMT2D* might lead to the establishment of deep-sequencing strategies for *KMT2D* molecular diagnostics in the near future.
        4. These next generation sequencing (NGS)-based strategies will also facilitate the sequencing of *KDM6A* in parallel to *KMT2D*, in order to detect rare single nucleotide alterations.
15. FISH analyses (Yang et al. 2016):
    1. To determine whether the deleted copy of *KDM6A* was located on the active or inactive X chromosome, FISH analysis was performed simultaneously using a

KDM6A probe (RP11-531L8 labeled with SpectrumOrange) and Xqter probe (labeled with SpectrumOrange) on the X chromosomes that had been differentially labeled by the incorporation of 5-bromo-2-deoxyuridine (BrdU) following established protocols (Lederer et al. 2012). The inactive X chromosome appears brighter than the active X chromosome after the BrdU staining.

2. FISH, using a bacterial artificial chromosome (BAC) clone (RP11-531L8, Xp11.3, 154 kb) within the deletion region for each of the family members, validated the presence of the deletion in the patient and the absence of the deletion in her parents, suggesting that the deletion on chromosome Xp11.3 in the patient was de novo.

Genetic Counseling

1. Recurrence risk (Kawame et al. 1999):
   1. Patient's sib: low recurrence risk, unless a parent has an autosomal dominant form of the syndrome
   2. Patient's offspring: low recurrence risk, unless the patient has an autosomal dominant form of the syndrome
2. Prenatal diagnosis: none described to date
3. Management:
   1. Multidisciplinary approach to developmental delay and mental retardation.
   2. Hearing aids for hearing loss.
   3. Treat infections.
   4. Growth hormone replacement therapy for growth hormone deficiency.
   5. Orthopedic intervention for scoliosis, dislocations, and foot deformities.
   6. Cardiac surgery for severe congenital heart defects.
   7. Surgical repair of cleft lip/palate, gastrointestinal, anorectal, and craniosynostosis anomalies.
   8. Naturally occurring nonsense mutations in

Fig. 1 (**a**–**c**) A 12-year-old girl with Kabuki syndrome (**a**, **b**) showing arched eyebrows, long palpebral fissures, everted lateral half of the lower eyelid, short nasal septum, post-cleft lip repair, prominent ears, and prominent finger pads (**c**)

Fig. 2 A 1-year-old girl with Kabuki syndrome showing arched eyebrows, long palpebral fissures, short nasal septum, and hypertrophic breasts. The infant also has cleft palate, large ears, and congenital hip dislocations

Fig. 3 A 1-year-old boy with Kabuki syndrome showing arched eyebrows, long palpebral fissures, everted lateral half of the lower eyelids, blue sclera, strabismus, short nasal septum, small chin, and large and prominent ears

Fig. 4 (**a**–**c**) A 12-year-old boy with Kabuki syndrome (**a**, **b**) showing characteristic facial features consisting of long palpebral fissures, arched eyebrows, bilateral lower lateral palpebral eversion, short nasal septum, high-arched palate, low hairline, and prominent finger pads (**c**). Other anomalies include mild mental retardation, neonatal hypotonia, recurrent otitis media and upper respiratory infections, joint laxity, ventricular septal defect, hip dysplasia, and short and clinodactyly of the fifth fingers

Kasabach–Merritt Syndrome

Contents

Kasabach–Merritt syndrome (or phenomenon) is the association of a vascular tumor and thrombocytopenic coagulopathy (Enjolras et al. 2000). It is a life-threatening, acute, or chronic consumptive coagulopathy, characterized by profound thrombocytopenia and microangiopathic hemolytic anemia (Esterly 1983).

In *1940*, Kasabach and Merritt (1940) described the first case of Kasabach–Merritt syndrome with a case report of consumptive coagulopathy associated with a hemangioma. However, it is now recognized that Kasabach–Merritt syndrome is usually associated with Kaposiform hemangioendothelioma and tufted angioma, rather than the classic involuting hemangioma of infancy (Enjolras et al. 1997).

Synonyms and Related Disorders

Hemangioma–thrombocytopenia syndrome; Kaposiform hemangioendothelioma; Kasabach–Merritt phenomenon; Tufted hemangioma

Genetics/Basic Defects

1. Genetics
    1. Sporadic in majority of cases
    2. Autosomal dominant inheritance in rare reports
    3. Can be a part of recognized syndromes
2. Pathophysiology (Hall 2001)
    1. Platelet trapping by abnormally proliferating the endothelium within the hemangioma, resulting in the activation of platelets with a secondary consumption of clotting factors
    2. Continued consumption of both platelets and clotting factors along with the initiation of fibrinolysis eventually resulting in intralesional bleeding which manifests as rapid enlargement of the hemangioma

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_139

Clinical Features

1. Diverse clinical presentation (Enjolras et al. 2000; Hall 2001)
    1. Type of hemangiomas
        1. Kaposiform hemangioendothelioma (O'Rafferty et al. 2015)
            1. A rare vascular tumor of infancy
            2. Often found in noncutaneous sites such as the retroperitoneum, mediastinum, and pelvis, as well as the skin (Gianotti et al. 1999)
            3. Platelet trapping within the lesion: associated with rapid enlargement
            4. Associated with Kasabach–Merritt syndrome: can be life-threatening
        2. Tufted angioma
        3. Mixture of Kaposiform hemangioendothelioma and tufted angioma
        4. Not "true" common hemangioma of infancy
    2. Reddish-brown skin lesion progressing to a violaceous bulging mass
        1. Often painful
        2. Aggressive infiltration with ulceration
        3. Bruising in other areas
        4. Possible infection
    3. Bleeding from thrombocytopenia and intravascular coagulopathy
    4. Increase in size and becoming tense, woody, and purplish of preexisting hemangiomas during pregnancy
2. Cutaneous involvement of Kaposiform hemangioendothelioma
    1. Smooth, shiny, dark purple, indurated, tender, and poorly delineated
    2. Nearly always single
3. Visceral involvement of hemangiomata
    1. Single
    2. Multiple
    3. Isolated within one organ as single or diffuse lesions
    4. Retroperitoneal hemangiomata
        1. Often giant in size
        2. Easily missed clinically: diagnosis suspected in patients presenting with an unexplained thrombocytopenia and coagulopathy
        3. Generally associated with high mortality
4. Diffuse and multiple nature
    1. Diffuse infantile (neonatal) hemangiomatosis
        1. Presence of multiple cutaneous and visceral hemangiomata
        2. High morbidity and mortality
    2. Intraosseous and soft tissue hemangiomata
5. Lifelong hemangioma in adults
    1. Hormone alterations and increase in blood volume in pregnancy may affect preexisting lesions, triggering episodes of acute disseminated intravascular coagulation (DIC).
    2. Development of acute consumptive coagulopathy after surgery of other unrelated tumor.
6. Primary angiosarcoma of the breast (Malolan et al. 2016) and metastatic angiosarcoma (Massarweh and Munis 2014) presenting as Kasabach–Merritt syndrome
7. Thrombocytopenic coagulopathy in patients with hemangiomata as a part of a recognized syndrome
    1. Klippel–Trenaunay syndrome
        1. A rare congenital generalized mesodermal abnormality
        2. Macular vascular nevus, skeletal/soft tissue hypertrophy
        3. Venous and lymphatic anomalies including viscera and facial hemangiomata
    2. Blue rubber bleb nevus syndrome
        1. Multiple cutaneous cavernous hemangiomata
        2. Cutaneous and occasional visceral hemangiomata
    3. Gorham-Stout disease ("vanishing bone disease")
        1. Massive osteolysis (Gorham sign)
        2. Followed by replacement of the bony matrix by proliferating thin-walled vascular and lymphatic channels
        3. Extension of these angiomatous masses into soft tissues
8. Differential diagnosis: Kaposiform hemangioendotheliomas and tufted angiomas should be part of the differential diagnosis in any infant presenting with purpura and an

unexplained profound thrombocytopenia (O'Rafferty et al. 2015).

9. Prognosis/complications (Cheerva 2016)
    1. Incomplete regression of the lesion after months or years
    2. Visceral involvement
        1. Mediastinum
        2. Neck
        3. Retroperitoneum
        4. Pelvis
    3. Hemorrhage by aggressive invasion
    4. Ulceration and bleeding into the vascular lesion
    5. Petechiae, ecchymoses, or purpura
    6. Profound thrombocytopenia (platelet count $<5 \times 10^{9}$/L ($<$5000/μL)
    7. Bleeding secondary to disseminated intravascular coagulation and unresponsive to platelet transfusions (potentially fatal)
    8. Anemia
    9. Congestive heart failure (potentially fatal)
    10. Severe infections
    11. Toxicity from the agents used to treat Kasabach–Merritt syndrome (e.g., secondary malignancy from radiation therapy)
    12. Pregnancy complicated by Kasabach–Merritt syndrome (Lee and Kirk 1967; Phillippe et al. 1980; Singh and Rajendran 1998)
    13. Residual lesions after "cure" of Kasabach–Merritt phenomenon (Enjolras et al. 2000)
        1. Common after the resolution of thrombocytopenia and coagulopathy
        2. Clinical patterns
            1. Cutaneous red stain with or without associated red papules
            2. Telangiectatic streaks and swelling
            3. A minor, firm, irregular subcutaneous mass assessed by palpation or deep infiltration evidenced by CT scan or MRI
            4. Sequelae in muscles and/or joints
    14. Overall mortality (estimated to be 20–30%) (El-Dessouky et al. 1988) due to complications such as (Enjoiras et al. 1990):
        1. Disseminated intravascular coagulation
        2. Respiratory failure due to a pressured airway
        3. High-output heart failure due to presence of a huge tumor

Diagnostic Investigations

1. Laboratory studies (Hall 2001; Cheerva 2016)
    1. A complete blood count (CBC) count with differential, reticulocyte count, platelet count, and peripheral smear is obtained to evaluate for microangiopathic hemolytic anemia and thrombocytopenia.
    2. Platelets may be larger than normal when they are released early from the bone marrow.
    3. Burr cells and schistocytes may be present in patients with microangiopathic hemolytic anemia.
    4. Generally severe thrombocytopenia occurs in 1–2 per 300–700 cases of hemangioma.
    5. Prothrombin time (PT) and activated partial thromboplastin time (aPTT) are prolonged in patients with significant DIC.
    6. Consumptive coagulopathy
        1. Prominent fibrinogenopenia
        2. Usually elevated fibrin split (degradation) products
        3. Usually elevated D-dimers (a measure of fibrin split products)
        4. Depressed clotting factors V and VII
    7. Radioisotopic study with Cr-51 tagged platelets: demonstration of platelet sequestration in giant hemangioma with thrombocytopenia (Brizel and Raccuglia 1965).
2. Ultrasound, MRI, or CT
    1. To assess extent of the lesions
    2. To identify the occult lesions
3. Histology to determine subtypes of vascular tumors found in Kasabach–Merritt syndrome (Alvarez-Mendoza et al. 2000)
    1. Kaposiform hemangioendothelioma of infancy and childhood (46%)
        1. The most frequently reported histological type
        2. A locally aggressive, low-grade malignant tumor

3. Lobules or sheets of tightly packed spindle cells or more rounded endothelial cells and pericytes
4. Infiltrative pattern of the cellular areas in the dermis and subcutaneous fat and muscles, generally containing few obvious vascular lumina
5. Aggregates of rounded dilated capillaries, lined by attenuated endothelial cells with small dark nuclei and filled with red blood cells
6. Containing lymphatic-like vessels

2. Tufted angioma (31%)
   1. A benign lesion
   2. Small tufts or lobules of rounded capillaries with small lumina
   3. Tufts: discrete and evenly distributed in a cannon ball pattern, characterized by peripheral crescentic slit-like vessels and fibrosis
   4. Aggregates of rounded dilated capillaries, lined by attenuated endothelial cells with small dark nuclei and filled with red blood cells
3. Infantile (juvenile) hemangioma (23%)

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: not increased unless a parent is affected
   2. Patient's offspring: 50% in case of autosomal dominant inheritance
2. Prenatal diagnosis
   1. Prenatal diagnosis of fetal facial hemangioma in a case of Kasabach–Merritt syndrome (Respondek-Liberska et al. 2002)
   2. Prenatal diagnosis of Klippel–Trenaunay–Weber syndrome with Kasabach–Merritt syndrome in utero (Tanaka et al. 2015)
3. Management (Larsen et al. 1987; Ryan et al. 2010; Cheerva 2016)
   1. General premise regarding treatment: Resolution of the lesion will lead to a correction of the consumptive coagulopathy, which is heralded by a recovery in the platelet count.
   2. Principle of management of thrombocytopenia in Kasabach–Merritt syndrome should be to "treat the patient and not the numbers."
   3. Prompt and vigorous management.
      1. Help to optimize the outcome
      2. No one treatment modality established as consistently efficacious
   4. Blood product support in the presence of sudden decompensation or enlargement of the lesion.
      1. Fresh frozen plasma.
      2. Cryoprecipitate (de Terlizzi et al. 1988) if fibrinogen is still less than 1.0 g/L.
      3. Platelet transfusion should be reserved for thrombocytopenic patient who is actively bleeding or in preparation for a surgical procedure.
      4. Tranexamic acid for profound fibrinolysis.
   5. Coagulation-directed treatment (O'Rafferty et al. 2015)
      1. Platelet transfusions
      2. Antiplatelet agents
      3. Antifibrinolytics, fibrinogen, and anticoagulants
   6. Simple or single lesion
      1. Vascular ligation
      2. Embolization of a giant liver hemangioma (Billio et al. 2001)
      3. Surgical excision
         1. Surgical removal of a giant hemangioma: usually hazardous in the presence of an uncontrolled consumptive coagulopathy.
         2. Supporting and stabilizing hemostasis while trying to remove or ablate the lesion.
         3. Partial resection of tumor, reduction of tumor blood, and vincristine chemotherapy (Shen et al. 2010): Since the huge tumor is the major cause of rapid platelet destruction, the partial removal of the tumor and U-shaped

suture to reduce tumor blood supply would reduce the platelet destruction and, therefore, improve the clinical condition, followed by skin graft or flaps of the wound, and vincristine chemotherapy necessary to prevent the enlargement of the remaining tumor.

4. Mechanical compression of Kaposiform hemangioendothelioma and tufted angioma lesions located on the extremities (O'Rafferty et al. 2015)
   1. Can decrease flow
   2. May assist in high-output cardiac failure
   3. Can be a useful temporizing method while other interventions are initiated

7. Diffuse or extensive lesions
   1. Prednisone (Dresse et al. 1991; Ozsoylu 2002)
   2. Alpha interferon (Hatley et al. 1993; Frevel et al. 2002; Biban 2003)
8. Adjuvant therapies
   1. Vincristine (Haisley-Royster et al. 2002)
   2. Localized radiotherapy (Ogino et al. 2001; Frevel et al. 2002; Hesselmann et al. 2002)
   3. Combination chemotherapy (vincristine, cyclophosphamide)
   4. Antifibrinolytic or antiplatelet agents (tranexamic acid, epsilon aminocaproic acid, pentoxifylline, ticlopidine)
   5. Vincristine and dual antiplatelet therapy durable responses in Kaposiform hemangioendothelioma (O'Rafferty et al. 2015)
   6. Interventions involving embolization, systemic interferon, cyclophosphamide, epsilon aminocaproic acid, and compression therapy (Blei 1998)
9. Potential future therapies
   1. Laser therapy
   2. Antiangiogenic agents
   3. Pegylated recombinant human megakaryocyte growth and development factor (peg-rHuMGDF)

KID Syndrome

Contents

KID syndrome is an acronym for the syndrome characterized by *k*eratitis, *i*chthyosis, and *d*eafness, a term proposed by Skinner et al. in 1981 (Skinner et al. 1981).

Synonyms and Related Disorders

Hystrix-like ichthyosis-deafness (HID) syndrome; Keratitis-ichthyosis-deafness (KID) syndrome

Genetics/Basic Defects

1. Genetic heterogeneity
    1. Sporadic in most cases (Langer et al. 1990)
    2. Existence of familial cases suggesting a genetic etiology
        1. A vertical transmission suggesting an autosomal dominant disease (Kelly et al. 2008)
        2. The occurrence in two sisters born to consanguineous, unaffected parents suggesting an autosomal recessive inheritance (Kone-Paut et al. 1998)
2. Caused by germline mutations in the connexin-26 gene, *GJB2*, which is implied in the normal corneal function, hair growth, and carcinogenesis and in the *GJB3* (encoding connexin-31) (Richard 2000)
    1. Mutations in *GJB2* were identified de novo in 13 unrelated patients with KID and in a case of transmission of the disease from father to son (Richard et al. 2002; Van Steensel et al. 2002; Alvarez et al. 2003; Yotsumoto et al. 2003).
    2. Mutations in several other genes [*GJB3* (connexin-31), *GJB6* (connexin-30)], which encode members of the connexin family of gap junction proteins, are shown to be responsible for hearing impairment and skin disorders (Kelsell et al. 2001).
    3. *GJB6* mutation also causes hidrotic ectodermal dysplasia (Clouston syndrome) (Kutkowska-Kaźmierczak et al. 2015).
3. Occurrence of parental germline mosaicism in the lethal form of KID syndrome: suggested by three affected children (carry the same G45E mutation) born to healthy parents (mutation not detected) (Sbidian et al. 2010)
4. Fatal form of KID syndrome (Janecke et al. 2005)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_140

1. A fatal course of KID in the first year of life, due to severe infections of the skin lesions and septicemia, has been reported in at least nine patients (Gilliam and Williams 2002; Janecke et al. 2005).
2. Caused by G45E mutation of *GJB2* gene.
3. The phenotype bears similarities to cutaneous disorders associated with sensorineural hearing loss (HL) known to be caused by mutations in genes encoding gap junction proteins (connexins).
    1. Vohwinkel syndrome (Maestrini et al. 1999)
    2. Dominant HL associated with palmoplantar keratoderma (Heathcote et al. 2000)
    3. Keratoderma without HL
        1. Clouston syndrome (Lamartine et al. 2000)
        2. Erythrokeratodermia variabilis (Richard et al. 1998)
5. Pathogenesis: failure in development and differentiation of multiple stratifying epithelia
6. Hystrix-like ichthyosis deafness (HID) and KID syndromes are associated with the same connexin 26 mutation (Van Geel et al. 2002).
    1. These disorders are distinguished mainly on the basis of electron microscopic findings.
    2. KID and HID syndromes may be genetically related.

Clinical Features

1. Cutaneous features (McGrae 1990)
    1. The abnormal skin at birth: red, dry, thickened, and leathery
    2. Subsequent development of keratodermatous, nonscaly plaques
        1. Generally develop during the first year of life
        2. Described as verrucous, ichthyotic, doughy, rugal, or elephant skin-like
        3. Develop primarily on the face and extremities
        4. Plaques sharply demarcated and maplike in contour
        5. Plaques symmetrically located on the face
            1. Especially the cheeks
            2. With variable involvement of the forehead, ears, chin, and nose
            3. Furrows in the thickened skin of the chin and around the mouth
        6. Transverse ripples marking the surface of plaques over the knees
        7. Follicular keratoses, occasionally with spine like projections, on the extremities, eyebrows, scalp, earlobes, neck, and nose
    3. Distinct keratoderma of the palms and soles
        1. Pebbly excrescences and an intervening coarsely stippled pattern analogous to heavily grained leather
        2. Patulous stippling rendering a moth-eaten appearance
    4. Abnormal hair
        1. The sparse, fine, and sometimes absent scalp, eyebrow, and eyelash hair
        2. Pattern of patch scalp alopecia resembling pseudopelade
        3. Body hair may be absent
        4. Nails
            1. Thickened
            2. Hypoplastic
            3. Absent
            4. White
            5. Infrequently normal
2. Ophthalmologic features (Ghadially and Chong 1992)
    1. Invariably involving epibulbar structures with inflammation of the cornea
        1. Vascularized keratitis in majority of cases
        2. Secondary pannus formation
    2. Photophobia
    3. Varying degree of visual impairment
    4. Onset: usually before adolescence
3. Auditory features
    1. Sensorineural deafness
    2. Repeat otitis media and externa
4. Other ectodermal abnormalities
    1. Dental abnormalities
        1. Carious
        2. Brittle

3. Malformed
4. Delayed adult dentition

2. Hypohidrosis

5. Neuroectodermal abnormalities
   1. Short heel cord
   2. Cerebellar hypoplasia
6. Other associated features
   1. Normal intelligence
   2. Growth delay
   3. Increased risk of developing squamous cell carcinoma (Grob et al. 1987) and trichilemmal tumors (Coggshall et al. 2013)
   4. Increased susceptibility to viral, bacterial, and mycotic infections (Coggshall et al. 2013)
      1. The most commonly reported pathogens.
         1. *Staphylococcus aureus*
         2. *E. coli*
         3. *Pseudomonas aeruginosa*
         4. *Trichophyton rubrum*
         5. *Candida albicans*
      2. Invasive and overwhelming infection may be present in infancy and early childhood. Death secondary to overwhelming sepsis has been reported in infancy.
      3. Infections are typically persistent and recurrent but usually limited to the skin in older children and adults.
      4. No consistent pattern of immunologic dysfunction demonstrated in patients with KID syndrome.
7. Fatal form of KID syndrome
   1. A fatal course of KID has been reported in the first year of life due to severe infections of the skin lesions and septicemia.
   2. Characteristic severe neonatal phenotype (Sbidian et al. 2010).
      1. Facial dysmorphism
      2. Severe cornification with massive focal hyperkeratosis of the skin with erythroderma
      3. Dystrophic nails
      4. Complete atrichia (absence of hair)
      5. Absence of the foreskin

Diagnostic Investigations

1. Dental examinations for teeth abnormalities
2. Ophthalmological examination for corneal pathology and visual acuity
3. Audiologic examination to demonstrate sensorineural hearing loss
4. Histopathology of the skin (McGrae 1990)
   1. Findings not specific.
   2. Stratum corneum.
      1. Always hyperkeratotic, usually with a basket weave pattern
      2. Orthokeratotic and occasionally parakeratotic
   3. Stratum granulosum: generally intact.
   4. Eccrine sweat glands appearing normal, although a diminished number and aberrant morphology have been noted.
   5. Absent or atrophic hair follicles indicating the customary state of alopecia.
   6. Follicular plugging is the rule.
5. Histopathological, immunohistochemical, and molecular analysis of precancerous and cancerous skin lesions (Bergman et al. 2012)
6. Molecular genetic study to detect connexin-26 gene (*GJB2*) mutation: clinically available

Genetic Counseling

1. Recurrence risk.
   1. Patient's sib
      1. Autosomal dominant inheritance: not increased unless a parent is affected or parental germline mosaicism exists
      2. Autosomal recessive inheritance: 25%
   2. Patient's offspring
      1. Autosomal dominant inheritance: 50%
      2. Autosomal recessive inheritance: not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis: Prenatal molecular genetic diagnosis of the lethal form of KID syndrome relating to a G45E mutation has been reported (Sbidian et al. 2010).
3. Management.
   1. No specific treatment for the skin lesions.
   2. Isotretinoin with inconsistent results.

1. May cause exacerbation of eye lesion
    1. Marked increase in pannus formation
    2. Marked increase in vascularization
2. Side effects of higher doses of isotretinoin
    1. Corneal opacities
    2. Punctate erosions
    3. Blepharoconjunctivitis
3. Excellent response to acitretin treatment of the hyperkeratosis of the scalp, trunk, and extremities (Patel et al. 2015) and alitretinoin treatment of dissecting cellulitis of the scalp (Prasad and Bygum 2013)

3. Ophthalmologic evaluations and follow-up. Corneal grafts revascularize rapidly with subsequent loss of vision.
4. Treat infections vigorously.
5. Surveillance for skin and mucosal malignancy.
6. Hearing aids.
7. Appropriate school placement.

Fig. 1 (**a**–**b**) A 26-year-old woman with keratitis, ichthyosis, and deafness. Cutaneous manifestations show sharply demarcated red-brown hyperkeratotic plaques on the central face, around both eyes, and upper and lower extremities

Fig. 2 Marked hyperkeratosis is visible around the eye and the outer rim of the ear

Fig. 3 Chronic *Candida albicans* onychia and paronychia with hypertrophy of the distal digits and hyperkeratosis of the skin are apparent on both hands

Klinefelter Syndrome

Contents

In 1942, Klinefelter et al. (1942) published a report on nine men who had enlarged breasts, sparse facial and body hair, small testes, and an inability to produce sperm. In 1959, these men with Klinefelter syndrome were discovered to have an extra sex chromosome (genotype XXY) instead of the usual male sex complement (genotype XY).

Klinefelter syndrome is the most common sex chromosomal disorder associated with male hypogonadism and infertility. Approximately 1 in 500–1,000 males is born with an extra X chromosome. Over 3,000 affected males are born yearly in the USA.

Synonyms and Related Disorders

47,XXY syndrome; Klinefelter syndrome mosaicism (46,XY/47,XXY, 46,XY/48,XXXY, 47,XXY/48,XXXY); Klinefelter syndrome variants (48,XXYY, 48,XXXY, 49,XXXYY, 49,XXXXY); Klinefelter syndrome with structurally abnormal X chromosome [47,X,i(Xq)Y, 47,X,del(X)Y]

Genetics/Basic Defects

1. Caused by at least an additional X chromosome in a male
2. The XXY form of Klinefelter syndrome:
    1. Due to meiotic nondisjunction of the sex chromosomes during gametogenesis in either parent
    2. Responsible meiotic nondisjunction (Carothers and Filippi 1988; Harvey et al. 1990):
        1. About 40% occur in the father.
        2. About 60% occur in the mother:
            1. Meiosis I errors (75%) when origin is maternal
            2. The presence of maternal age effect in the maternally derived cases
3. The mosaic forms of Klinefelter syndrome:
    1. Due to mitotic nondisjunction after fertilization of the zygote
    2. Can arise from a 46,XY zygote or a 47,XXY zygote
4. The variant forms:
    1. 48,XXXY: nondisjunction occurring either at the first or second meiotic divisions of oogenesis, resulting in an XXX ovum which is then fertilized by a Y-bearing sperm.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_141

2. 49,XXXXY: Please refer to 49,XXXXY chapter.
3. 48,XXYY and 49,XXXYY: occurrence of nondisjunction in paternal meiosis to have two Y chromosomes:
    1. An X ovum fertilized by an XYY sperm arising from successive nondisjunction in the first and second meiotic divisions
    2. An XX ovum from 47,XXX mother fertilized by a YY sperm

5. Pathophysiology (Chen 2015):
    1. The X chromosome carries genes that play roles in many body systems, including testis function, brain development, and growth (Giedd et al. 2007).
    2. The addition of more than one extra X or Y chromosome to a male karyotype results in variable physical and cognitive abnormalities.
    3. In general, the extent of phenotypic abnormalities, including mental retardation, is directly related to the number of supernumerary X chromosomes.
    4. As the number of X chromosomes increases, somatic and cognitive development are more likely to be affected.

Clinical Features

1. Growth (Chen 2015):
    1. Infants and children: normal heights, weights, and head circumferences
    2. Adolescents and adults:
        1. Eunuchoid body habitus
        2. Usually taller than average
        3. Disproportionately long arms and legs (Ratcliffe et al. 1982)
2. Mild developmental, learning, and behavioral difficulties (70% of patients) (Geschwind et al. 2000):
    1. Delayed speech and language acquisition
    2. Academic and reading difficulties
    3. Attention deficit disorder
    4. Poor self-esteem
    5. Insecurity
    6. Shyness
    7. Poor judgment
    8. Inappropriate assertive activity
    9. Decreased ability to deal with stress
    10. Fatigue
    11. Weakness
    12. Impeded psychosocial adaptation (Bender et al 1995)
3. CNS:
    1. Normal intelligence in most cases
    2. Subnormal intelligence or mental retardation associated with a higher number of X chromosomes
    3. Diminished short-term memory
    4. Prone to epilepsy and essential tremor (Boltshauser et al. 1978)
    5. Psychiatric disorders involving anxiety, depression, neurosis, and psychosis: more common than general population
4. Taurodontism (enlargement of the molar teeth by an extension of the pulp): present in about 40% of patients (vs. 1% in normal XY individuals)
5. Cardiac and circulatory problems:
    1. Mitral valve prolapse (55% of patients)
    2. Varicose veins (20–40% of patients):
        1. Venous ulcers
        2. Deep vein thrombosis
        3. Pulmonary embolism
6. A slightly increased risk of autoimmune disorder:
    1. Rheumatic diseases (Rovensky et al. 2010):
        1. Inflammatory rheumatic diseases
        2. Rheumatoid arthritis
        3. Juvenile idiopathic arthritis
        4. Psoriatic arthritis
        5. Polymyositis/dermatomyositis
        6. Systemic lupus erythematosus
        7. Systemic sclerosis
        8. Mixed connective tissue disease
        9. Antiphospholipid syndrome
        10. Ankylosing spondylitis
    2. Thyroid disease (Campbell and Price 1979)
    3. Sjogren syndrome
    4. Diabetes mellitus
7. Sexual characteristics:
    1. Gynecomastia secondary to elevated estradiol levels and increased estradiol/testosterone ratio:

1. Develop by late puberty in 30–50% of boys with Klinefelter syndrome
2. Risk of developing breast cancer: at least 20 times higher than normal

2. Lack of secondary sexual characteristics secondary to decrease in androgen production:
   1. Sparse facial, body, and sexual hair
   2. High-pitched voice
   3. Female type of fat distribution
3. Male psychosexual orientation in most patients
4. Subnormal libido
5. Erectile dysfunction
6. Oligospermia or azoospermia
7. Testicular dysgenesis in postpubertal patients (Schwartz and Root 1991):
   1. Small, firm testes
   2. Testis size <10 mL
8. Infertility and azoospermia resulting from atrophy of the seminiferous tubules:
   1. Seen practically in all patients with a 47, XXY karyotype.
   2. Klinefelter syndrome mosaics (46,XY/47,XXY) can be fertile.

8. Other characteristics:
   1. Some KS males present with no severe clinical features and lead normal lives, while others exhibit developmental, physical, behavioral, and learning disabilities and disorders (Bird and Hurren 2016).
   2. An increased prevalence of extragonadal germ cell tumors in the mediastinum (Völki et al. 2006) and brain.
   3. More common varicose veins, venous stasis ulcers (Verp et al. 1983; Veraart et al. 1995), and thromboembolic disease.
   4. The syndrome may go undiagnosed in the majority of affected men.
9. Klinefelter syndrome mosaics and variants:
   1. Klinefelter syndrome mosaic (46,XY/47,XXY):
      1. Less severe manifestations
      2. May have normal-sized testes
      3. Less severe endocrine abnormalities
      4. Less common gynecomastia and azoospermia
      5. Occasional fertile men
   2. Klinefelter syndrome variants (Visootsak and Graham 2006):
      1. 48,XXYY variant (Tartaglia et al. 2008):
         1. Tall stature.
         2. Disproportionately long lower extremities.
         3. Clinodactyly.
         4. Pes planus.
         5. Hypertelorism.
         6. Dental problems.
         7. Gynecomastia.
         8. Intention tremor.
         9. Neurodevelopmental disorders, including developmental delays, ADHD, autism spectrum disorders, mood disorders, and tic disorders.
         10. Unusual dermatoglyphic patterns.
         11. Peripheral vascular disease, especially varicose veins and stasis dermatitis.
         12. Poorly developed secondary sexual characteristics.
         13. Hypogonadism.
         14. Testicular histology similar to that of 47,XXY patients.
         15. The sex chromatin pattern indistinguishable from that of the 47,XXY patients except two fluorescent Y bodies is present in a high proportion of somatic nuclei.
      2. 48,XXXY variant (Venkateshwari et al. 2010):
         1. Moderate to severe mental retardation
         2. Behavior: often immature and consistent with IQ level, typically described as passive, cooperative, and not particularly aggressive
         3. Normal to tall stature
         4. Dysmorphic facies
         5. Radioulnar synostosis
         6. Fifth finger clinodactyly
         7. Hypergonadotropic hypogonadism
         8. Small testes
         9. Signs of androgen deficiency
      3. 49,XXXYY variant:
         1. Mental retardation
         2. Somatic anomalies
         3. Small testes

4. 49,XXXXY variant (Zaleski et al. 1966; Peet et al. 1998): severity and frequency of somatic anomalies increase as the number of X chromosomes increases:
    1. Mental retardation
    2. Microcephaly
    3. Short stature
    4. Hypotonia with lax joints
    5. Facial dysmorphic features: ocular hypertelorism, flat nasal bridge, epicanthal folds, bifid uvula, or cleft palate
    6. Short neck
    7. Congenital heart defects
    8. Radioulnar synostosis
    9. Genu valgum
    10. Pes cavus
    11. Fifth finger clinodactyly
    12. Hypergonadotropic hypogonadism with small genitalia
    13. Behavioral disorders: shy, friendly, occasional irritability, temper tantrums, low frustration tolerance, and difficulty in changing routines

10. Natural history of Klinefelter syndrome: estimated prevalence of phenotypic features (Herlihy et al. 2011; Groth et al. 2013; Nahata et al. 2013; Herlihy and McLachlan 2015):
    1. Prepubertal:
        1. Decreased penile size (10–25%)
        2. Cryptorchidism (27–37%)
        3. Delayed speech and motor development (69–75%)
        4. Learning difficulties (>75%)
    2. Postpubertal:
        1. Infertility (99%).
        2. Small testes (>95%).
        3. Decreased testosterone (63–85%) may present as low mood, reduced libido, fatigue, poor muscle development, generalized weakness, or erectile dysfunction.
        4. Decreased facial and body hair (<80%): often perceived as pubertal delay or incomplete virilization.
        5. Gynecomastia (<56%).
        6. Metabolic syndrome (46%).
        7. Diabetes (10–39%).
        8. Osteopenia (40%) – osteoporosis in up to 10%.

Diagnostic Investigations

1. Cytogenetic studies (Kleczkowska et al. 1988):
    1. Commonest indications: hypogonadism and/or infertility (Abramsky and Chapple 1997).
    2. 47,XXY (80–90%).
    3. Mosaicism (10%): Insisting on an adequate number of cells (at least 50) to be examined during karyotyping is important so as not to miss diagnosing mosaicism (Nor and Jalaludin 2016):
        1. 46,XX/47,XXY
        2. 46,XY/47,XXY
        3. 46,XY/48,XXXY
        4. 47,XXY/48,XXXY
    4. Variants (Linden et al. 1995):
        1. 48,XXYY
        2. 48,XXXY
        3. 49,XXXYY
        4. 49,XXXXY
    5. Structural abnormal X in addition to a normal X and Y:
        1. 47,X,i(Xq)Y
        2. 47,X,del(X)Y
2. Endocrinologic studies:
    1. A variable degree of feminization and insufficient androgenization (Vorona et al. 2007):
        1. Elevated plasma FSH, luteinizing hormone, and estradiol levels
        2. Low plasma testosterone levels in patients age 12–14 years
    2. Subnormal increased testosterone in response to human chorionic gonadotropin administration
3. Imaging studies:
    1. Testis ultrasound (US) (Rocher et al. 2016): The testes of KS men are smaller, more nodular, and more vascularized, and they contain more microliths than those of non-KS infertile men. This combination of US results should lead physicians to request a karyotyping.

2. Echocardiography to demonstrate mitral valve prolapse.
3. Radiography:
    1. Lower bone mineral density
    2. Radioulnar synostosis
    3. Taurodontism
4. Histology:
    1. Small, firm testes
    2. Seminiferous tubular hyalinization, sclerosis, and atrophy with focal hyperplasia of mostly degenerated Leydig cells
    3. Deficient or absent germ cells
    4. Rare spermatogenesis (azoospermia)
    5. Progressive degeneration and hyalinization of seminiferous tubules after puberty in mosaic patients
5. Majority of cases of Klinefelter syndrome are detected via one of the following scenarios (Herlihy et al. 2011; Nahata et al. 2013; Herlihy and McLachlan 2015):
    1. Prenatal (21% of diagnoses):
        1. Klinefelter syndrome may be an incidental finding when a karyotype is conducted following chorionic villus sampling or amniocentesis due to increased risk in pregnancy (high risk of Down syndrome, increased maternal age).
        2. More recently, through chromosomal analysis in noninvasive prenatal testing, which women with both low-risk and high-risk pregnancies are choosing because of high accuracy, low risk to pregnancy, and the rapidly decreasing cost of this testing (Simpson and Samango-Sprouse 2013).
    2. Childhood (12% of diagnoses):
        1. Global developmental delay in infancy (delayed walking or speech development)
        2. Behavioral or learning difficulties in childhood [attention deficit hyperactivity disorder (ADHD), autism]
    3. Puberty (16% of diagnoses):
        1. Incomplete (or perceived delayed) puberty in adolescence
        2. Hypogonadism, gynecomastia, or poor virilization noted by the astute physician
    4. Adulthood (51% of diagnoses):
        1. Fertility investigations
        2. Androgen deficiency in different contexts (e.g., sexual dysfunction, depression, osteoporosis)
    5. Incidental at any age: Karyotyping is carried out where Klinefelter syndrome is not the suspected diagnosis (e.g., investigation of an alternate genetic syndrome or hematological malignancy).

Genetic Counseling

1. Recurrence risk:
    1. Patient's sibs: recurrence risk not increased for nonmosaic patients
    2. Patient's offspring:
        1. Recurrence risk not increased since all 47,XXY individuals are infertile
        2. Report of paternity in nonmosaic 47, XXY males (no other tissues were examined for possible mosaicism with a 46, XY cell line)
    3. A risk of having a 47,XXY offspring in a few 46,XY/47,XXY mosaic patients who fathered a child
2. Prenatal diagnosis:
    1. Cytogenetic analysis of fetal cells obtained from amniocentesis and CVS.
    2. Dilemma for parents since prognosis for the fetus with XXY is good but the possibility of phenotypic abnormalities does exist.
    3. Explanation to each couple about the genetic risks resulting from intracytoplasmic sperm injection (ICSI) (increased risk of sex chromosome and autosome abnormalities).
    4. Sperm fluorescence in situ hybridization analysis in a patient with mosaic Klinefelter's syndrome can provide a rough estimate of the risk of transmission of sex chromosomal aberrations to his offspring. This estimate can be of help to the patient and his female partner in deciding on ICSI and prenatal diagnosis (or preimplantation diagnosis) (Kruse et al. 1998).

5. Preimplantation genetic diagnosis by embryo biopsy offers an efficient tool for embryo selection (Friedler et al. 2001).
6. Preimplantation genetic diagnosis (PGD) is generally offered to couples with KS who undergo successful testicular sperm extraction and intracytoplasmic sperm injection. This technique allows for selecting chromosomally abnormal embryos in order to avoid transferring abnormal embryos (Aksglaede and Juul 2013).
7. Low rates of pregnancy termination for prenatally diagnosed Klinefelter syndrome and other sex chromosome polysomies (Meschede et al. 1998).

3. Management (Mandoki and Sumner 1991):
   1. Speech therapy.
   2. Physical therapy.
   3. Occupational therapy.
   4. Educational services.
   5. Stable and supportive family environment (Bender et al. 1995)
   6. Reassurance of patients that most of the clinical features can be explained by the diminished ability of the testes to produce testosterone.
   7. Testosterone replacement (Nielsen et al. 1988; Winter 1990; Smyth and Bremner 1998): Optimal time to initiate therapy is at age 11–12 years of age to allow for the maximum effect and permit boys to experience pubertal changes with their peers:
      1. Corrects hormone imbalance (symptoms of androgen deficiency)
      2. Improves self-image
      3. Positive effect on mood and behavior (Myhre et al. 1970)
      4. Increase in masculinity
      5. Increase in strength
      6. Increase in libido
      7. Increase in facial and pubic hair
      8. Diminish fatigue and irritability
      9. No positive effect on infertility
   8. Management of gynecomastia:
      1. Androgen replacement therapy effective in achieving regression of less severe gynecomastia in some patients
      2. Reduction mammoplasty or liposuction for severe or psychologically disturbing gynecomastia
   9. Management of infertility (Lanfranco et al. 2004):
      1. Nowadays patients with Klinefelter syndrome, including the nonmosaic type, need no longer be considered irrevocably infertile because intracytoplasmic sperm injection offers an opportunity for procreation even when there are no spermatozoa in the ejaculate.
      2. In a substantial number of azoospermic patients, spermatozoa can be extracted from testicular biopsy samples, and pregnancies and live births have been achieved.
      3. The frequency of sex chromosomal hyperploidy and autosomal aneuploidies is higher in spermatozoa from patients with Klinefelter syndrome than in those from normal men. Thus, chromosomal errors might in some cases be transmitted to the offspring of men with this syndrome.
      4. The genetic implications of the fertilization procedures, including pretransfer or prenatal genetic assessment, must be explained to patients and their partners.
      5. Banking testicular tissue from prepubertal KS boys should be performed only in a research framework (Gies et al. 2016).

Klippel-Feil Syndrome

Contents

In *1912*, Klippel and Feil (1912) described a patient with a short neck, a low posterior hairline, and a severe restriction of motion of the neck due to complete fusion of the cervical vertebrae. These features now constitute a clinical triad of the Klippel-Feil syndrome (KFS) (Hensinger et al. 1974).

Synonyms and Related Disorders

Cervical vertebral fusion; Cervico-oculo-auditory (Wildervanck) syndrome

Genetics/Basic Defects

1. Genetic etiology unknown;
    1. Sporadic in majority of cases
    2. Rare autosomal dominant transmission: identification of a familial KFS gene locus on 8q [inv(8)(q22.2q23.3)] segregated with congenital vertebral fusion (Clarke et al. 1995)
2. Mechanism: failure in the process of segmentation of the vertebra.
3. Possible causes of phenotypic variation (Pourquie and Kusumi 2001):
    1. Variable expression of single genes
    2. Associated phenotypes due to deletions or large-scale rearrangements that disrupt several genes
    3. Secondary phenotypes resulting from disruption of normal cervical vertebral patterning
4. Familial Klippel-Feil syndrome (Clarke et al. 1995, 1996):
    1. Characterized by congenital fusion of spinal vertebrae in addition to other congenital anomalies:
        1. Otolaryngological abnormalities
        2. Craniofacial abnormalities
    2. The first KFS gene (*SGM1*) locus identified on chromosome 8q [inv(8)(q22.2q23.3)] segregating with vertebral fusions and associated vocal impairment within the family
5. Suggestion of a possible role of *PAX1* haploinsufficiency in Klippel-Feil syndrome (McGaughran et al. 2003):
    1. Observation that the mouse *PAX1* mutant phenotype *undulated* is characterized by vertebral segmentation defects reminiscent of the human disorder Klippel-Feil syndrome

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_142

2. Observation of differences in the *PAX1* sequence (missense, silent, or intronic changes not represented in the control panel tested) in 6 out of 63 patients
6. Mutations in growth/differentiation factor 6 (*GDF6*, on chromosome 8q22.1) are associated with vertebral segmentation defects in Klippel-Feil syndrome (Tassabehji et al. 2008):
   1. Mutations at the *GDF6* gene locus in familial and sporadic cases of KFS including the recurrent missense mutation of an extremely conserved residue c.866 T > C (p.Leu289Pro) in association with mirror movements and an inversion breakpoint downstream of the gene in association with carpal, tarsal, and vertebral fusions.
   2. *GDF6* is expressed at the boundaries of the developing carpals, tarsals, and vertebrae and within the adult vertebral disc.
   3. *GDF6* knockout mice are best distinguished by fusion of carpals and tarsals, and *GDF6* knockdown in *Xenopus* results in a high incidence of anterior axial defects consistent with a role for *GDF6* in the etiology.
7. Mutations in *MEOX1*, encoding mesenchyme homeobox 1, cause Klippel-Feil anomaly (Mohamed et al. 2013).

Clinical Features

1. Triad seen in <50% of patients indicating almost complete cervical involvement and may be clinically evident at birth (McBride 1992; Herman and Pizzutillo 1999):
   1. Short, webbed neck
   2. Low posterior hairline
   3. Limitations of cervical motion (lateral bend and rotation) with associated congenital cervical fusions
2. Facial asymmetry
3. Torticollis
4. Associated anomalies:
   1. Congenital scoliosis (60%) (Winter et al. 1984)
   2. Sprengel deformity (30%):
      1. Congenital elevation of the scapula resulting from interruption of the normal caudal migration of the scapula
      2. Hypoplastic scapula
      3. Scapula fixation
      4. Associated anomalies including absent or fused ribs, chest wall asymmetry, Klippel-Feil syndrome, cervical ribs, congenital scoliosis, cervical spina bifida, and presence of omovertebral bone
   3. Cervical ribs (Hazra et al. 2016):
      1. Although mostly asymptomatic, these are the most common cause of compression of the subclavian vessels producing an arterial thoracic outlet syndrome (Roos 1979). Neurogenic (brachial plexus compression) and venous (subclavian or axillary vein compression) can also occur.
      2. Associated with 30% of the patients with Klippel-Feil syndrome (Sudhakar et al. 2008).
      3. Reports of thoracic outlet syndrome: rare (Konstantinou et al. 2004).
   4. Hearing impairment (audiologic testing) (30%)
   5. Synkinesia (mirror movements) (20%)
   6. Renal anomalies (35%) (renal ultrasound)
      1. Unilateral renal agenesis (most common renal anomaly) (Moore et al. 1975)
      2. Renal malrotation
      3. Horseshoe kidney
      4. Ectopic kidney
      5. Renal pelvic and ureteral duplication
      6. Renal dysgenesis
   7. Congenital heart disease (14%): most common being ventricular septal defect
   8. Hemifacial microsomia
   9. Neural tube defects
   10. Ptosis
   11. Cervico-oculo-auditory (Wildervanck) syndrome (Danilidis et al. 1980; Cremers et al. 1984)
      1. Mixed hearing loss
      2. Fused cervical vertebra
      3. Bilateral abducens palsy with retracted bulb (Duane syndrome)

12. Lateral rectus palsy
13. Facial nerve palsy
14. Association with malformed larynx (Clarke et al. 1994)
15. Upper extremity anomalies

5. Complaints
    1. Issues of appearance
    2. Torticollis (head tilt)
    3. Neck pain
    4. Changes in exercise tolerance
    5. Excessive instability of the upper cervical spine
    6. Problems related to associated anomalies
    7. Neurological problems from direct irritation of or impingement on a nerve root or from compression of the spinal cord
        1. Cranial nerve abnormalities
        2. Cervical radiculopathy from involvement of the nerve root
        3. Symptoms from spinal cord compression
            1. Spasticity
            2. Hyperreflexia
            3. Muscle weakness
            4. Complete paralysis
        4. At risk of sustaining a neurologic deficit including quadriplegia after minor trauma (Elster 1984)
6. Three clinical subtypes (Gunderson et al. 1967):
    1. Type I characterized by massive cervical and thoracic vertebral fusions into bony blocks
    2. Type II with fusion at one or two vertebral junctures, occipitoatlantal fusion, lower thoracic abnormalities, and more severe cervicothoracic fusions
    3. Type III with both cervical and lower thoracic or lumbar fusions
7. Risk factors
    1. Types I and III fusions
        1. Various neurologic, cutaneous, cardiac, skeletal, and oral anomalies
        2. Difficulty in the birth process
        3. Marked abnormal facial appearance with Sprengel deformity, accessory ear lobes, and pterygium colli
        4. Serious neurologic anomalies with early death or long-term neurologic deficits
    2. Type II fusion
        1. Normal appearance
        2. Normal lives
        3. Incidental symptoms from osteoarthritis, basilar impression, or occipito-atlas fusion
    3. Hypermobility of the upper cervical spine at increased risk of neurologic injury with presentation of neurologic sequelae in the teens or 20s (Pizzutillo et al. 1994)
    4. Lower cervical involvement at risk of developing cervical spondylosis at more advanced ages

Diagnostic Investigations

1. Audiologic evaluation for hearing loss
2. Renal ultrasonography
3. Radiography (Hensinger et al. 1974)
    1. Cervical spine fusion on flexion and extension views: roentgenographic hallmark of the Klippel-Feil syndrome
        1. Type I cervical fusion (C2–C3 fusion with occipitalization of the atlas)
        2. Type II cervical fusion (long cervical fusion with an abnormal occipitocervical junction)
        3. Type III cervical fusion (two blocked vertebral segments with a single open interspace)
    2. Other associated skeletal anomalies
        1. Flattening and widening of involved vertebral bodies
        2. Absent disc spaces
4. CT scan helpful in diagnosing nerve root and spinal cord impingement by osteophyte
5. MRI to evaluate instability and the risk of neurological compromise
    1. Spinal stenosis
    2. Cord compression
    3. Syringomyelia
6. CT and MRI for workup of cervicothoracic spinal dysraphism with diastematomyelia (Hudson and Makis 2016)
    1. An 18F-NaF bone positron emission tomography scan done as part of the

metastatic workup showing the characteristic sagittal bone spur
2. MRI demonstrated a complete split of the cervical and upper thoracic spinal cord.

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: not increased unless a parent has an autosomal dominant disorder
   2. Patient's offspring: not increased unless the patient has an autosomal dominant type of the disorder
2. Prenatal diagnosis
   1. Ultrasonography: difficult to diagnose cervical vertebral anomalies and torticollis by ultrasonography
   2. Molecular genetic analysis on fetal DNA obtained from amniocentesis or CVS for *GDF6* mutation, provided the disease-causing allele of an affected family member has been identified prior to prenatal diagnosis
3. Management
   1. Treat renal, cardiovascular, and auditory anomalies accordingly
   2. Mechanical symptoms caused by degenerative joint disease
      1. Traction
      2. Wearing a cervical collar
      3. Analgesics
   3. Neurological symptoms
      1. Surgical stabilization with or without decompression
      2. Surgical correction of Sprengel deformity to improve appearance
   4. Surgery for congenital conductive deafness (Van Rijn and Cremers 1988)

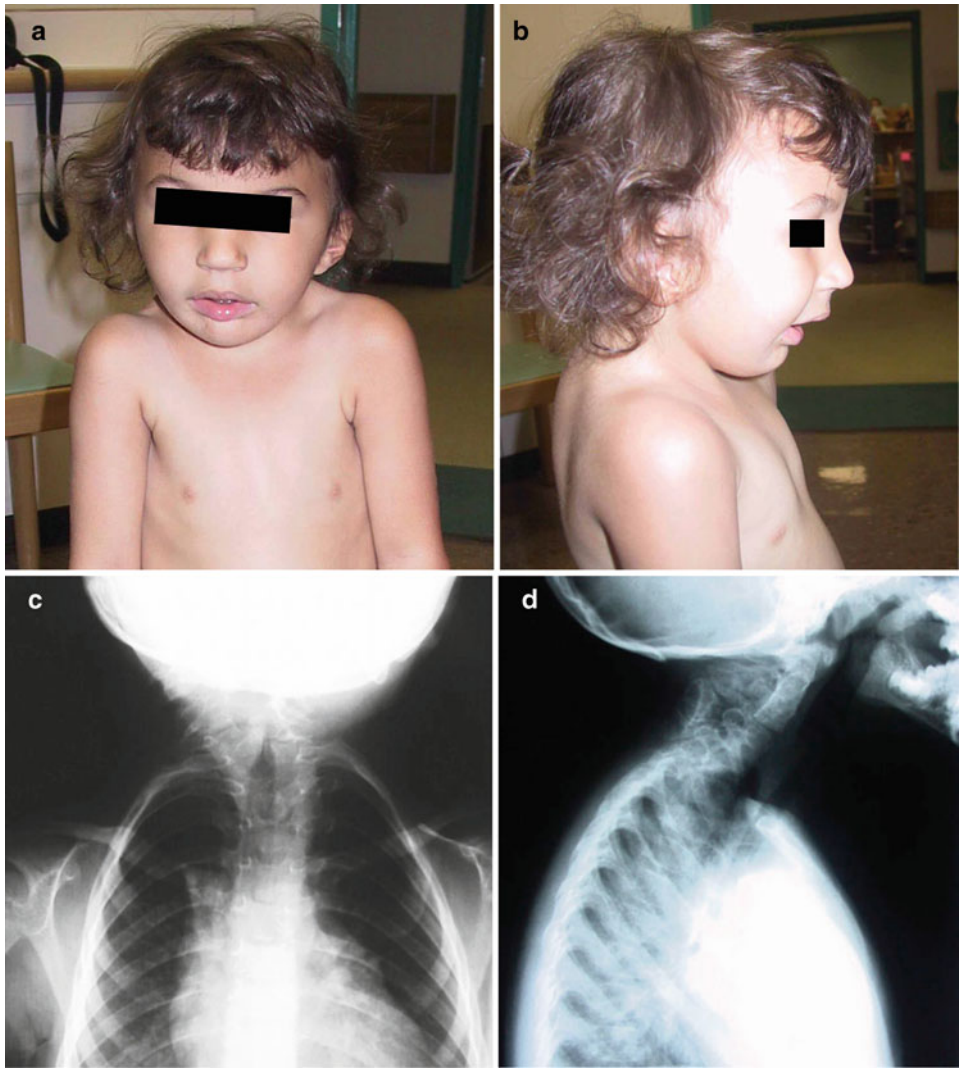

Fig. 2 (**a**–**d**) A girl with Klippel-Feil syndrome showing torticollis; short, webbed, and stiff neck (**a**, **b**); and cervical fusion (failure of segmentation) demonstrated by radiographs (**c**, **d**)

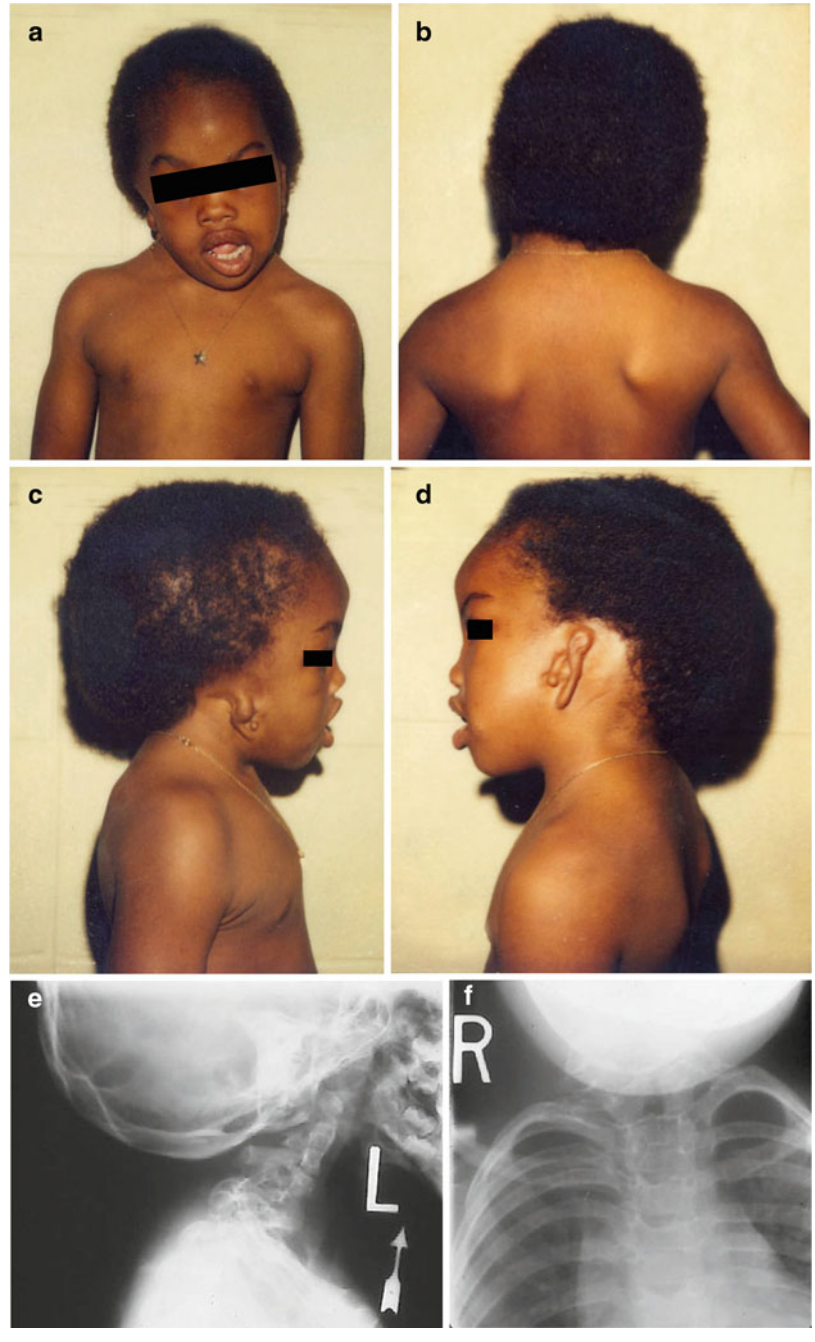

Fig. 3 (**a**–**f**) A child with Klippel-Feil syndrome showing hemifacial microsomia and torticollis (**a**); short, webbed, and stiff neck (**b**); microtia (**c**, **d**); and cervical fusion demonstrated by radiographs (**e**, **f**)

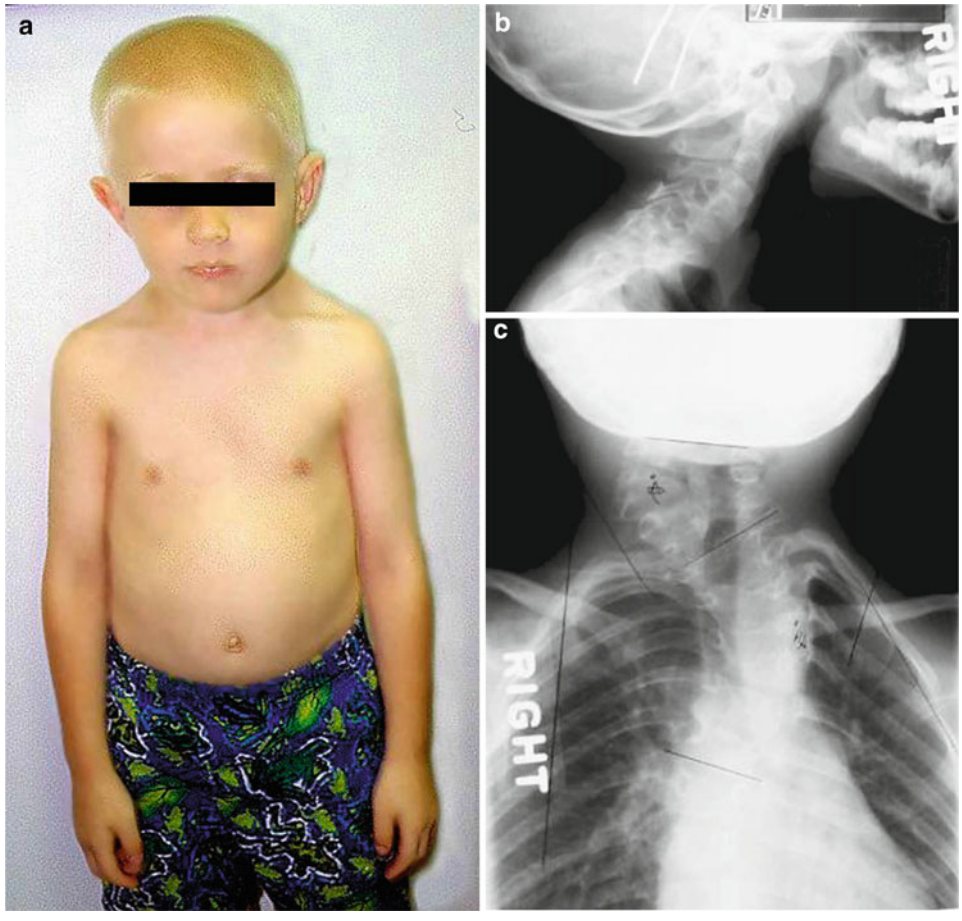

Fig. 4 (**a**–**c**) A 10-year-old boy with Klippel-Feil syndrome (**a**) showing torticollis; short, webbed, and stiff neck; low posterior hairline; elevated left scapula; failure of segmentation (fusion) of the cervical vertebrae; and cervicothoracic scoliosis demonstrated by radiographs (**b**, **c**). He has no neurologic defects or cervical discomfort

Fig. 5 A 15-year-old girl with Klippel-Feil syndrome, Sprengel deformity, and deafness

Klippel-Trenaunay Syndrome

Contents

Klippel-Trenaunay syndrome (KTS) is primarily a rare congenital capillary-venous vascular malformation associated with altered limb bulk and/or length. In 1900, Klippel and Trenaunay first reviewed systematically a condition consisting of capillary nevus, early onset of varicosities, and hypertrophy of tissues and bones of the affected limb. These three features constitute the primary diagnostic criteria of the syndrome today. The additional name Weber is sometimes added to describe those individuals who also have clinically significant arteriovenous malformations as a component of the syndrome, an association noted by Weber in 1918. More than 1,000 cases of Klippel-Trenaunay syndrome have now been reported in the literature (Berry et al. 1998).

Synonyms and Related Disorders

Angioosteohypertrophy syndrome; Klippel-Trenaunay-Weber syndrome; Parkes-Web syndrome; *PIK3CA*-related overgrowth spectrum

Genetics/Basic Defects

1. Etiology
    1. Sporadic occurrence
    2. Somatic mutation of an as-yet-unknown gene
    3. Multifactorial inheritance
    4. Autosomal dominant inheritance with variable expression
2. Genetics of KTS (Wang 2005): three chromosomal abnormalities reported in three different KTS patients
    1. Two balanced translocations t(5;11)(q13.3;p15.1) (Tian et al. 2004)
        1. Chromosomal breakpoints involved in translocation t(5;11)(q13.3;p15.1) have been fully characterized, which has led to the identification of a susceptibility gene, *AGGF1* (previously known as *VG5Q*), for KTS

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_143

   2. *AGGF1* is located on chromosome 5q13.3 and encodes an angiogenic factor
   3. *AGGF1* as the first susceptibility gene that confers a risk to the development of KTS and suggests that that the molecular mechanism for the pathogenesis of KTS is the "increased" angiogenesis. These results are consistent with histological studies that showed an increase in both the number and diameter of the venules in the dermis and subdermal fat of KTS tissues (Baskerville et al. 1985)
2. Translocation t(8;14)(q22.3;q13) (Wang et al. 2001) and an extra supernumerary ring chromosome 18 (Timur et al. 2004) were reported in patients with KTS
   1. Shown to arise de novo, which strongly suggests that genetic factors contribute to the pathogenesis of KTS
   2. The specific vascular gene disrupted by either 8q22.3 or 14q13 breakpoint remains to be identified
   3. The ring chromosome 18, r(18), was mostly derived from the short arm of chromosome 18, and further analyses of the genes on the r(18) may lead to the identification of a vascular gene
3. Terminal deletion 2q37.3 (by comparative genomic hybridization) reported in a patient with Klippel-Trenaunay-Weber syndrome (Puiu et al. 2013)
4. Sporadic occurrence of KTS and a mosaic pattern of KTS features may be explained by the two-hit hypothesis and the concept of paradominant inheritance proposed by Happle (1986, 1987, 1993)
   1. Germline mutations in a KTS gene (e.g., *AGGF1*) are important for development of KTS but not sufficient
   2. A "second hit," somatic mutation in the same KTS gene or in a different gene is required for the development of KTS features
5. Klippel-Trenaunay syndrome belongs to the *PIK3CA*-related overgrowth spectrum (Vahidnezhad et al. 2015)
3. Possible mechanisms/pathogenesis leading to overgrowth of the affected limb: poorly defined
   1. Two phases of manifestations
      1. Increased bulk or girth
      2. Increased length accompanied by bone enlargement
   2. Increased girth and size of bone due to venous hypertension, based on observations following hind leg deep vein ligation in dogs
   3. Atresia of the venous system leading to stasis, edema, varicosities, and ultimately to limb elongation and hypertrophy
   4. Limb enlargement seen in children following thrombosis or ligation of a deep vein postnatally
   5. Overgrowth in fetal life promoted by increased blood flow through the abnormal capillary network and cutaneous venous channels
   6. A mesodermal defect acting on angiogenesis leading to the formation of hemangiomas and varicose veins (Martin et al. 2001)
   7. A defect in the process of vessel remodeling during embryogenesis

Clinical Features

1. Triad (Berry et al. 1998; Cohen 2000)
   1. Combined vascular malformations of the capillary, venous, and lymphatic types
   2. Varicosities of unusual distribution, in particular the lateral venous anomaly observed during infancy or childhood
   3. Limb enlargement
2. Cutaneous manifestations
   1. Primarily a diffuse capillary malformation
   2. Typically present on an affected limb
   3. May be present on any body part
   4. Often presenting as an irregular but relatively linear border
   5. Rarely crossing the midline when present on the trunk, sometimes exhibiting a sharp demarcation

3. Vascular malformations
    1. Typically combined with cutaneous capillary malformation
    2. Persistence of abnormal superficial veins associated with deep venous hypoplasia/duplications and abnormal venous valve formation
    3. Presence of mixed vascular malformations including capillary, venous, arterial, and lymphatic systems
    4. Classification of vascular malformations by Mulliken and Glowacki (1982)
        1. Capillary-venous malformation (CVM): typical finding
        2. CVLM (CVM + lymphatic malformation): common finding
        3. CLAVM (including arterial malformation): uncommon
    5. Congenital in nature
    6. Not responding to agents used in the treatment of hemangiomas such as prednisone or interferon-α
4. Limb hypertrophy
    1. Due to an increase in bulk of the subcutaneous tissues
    2. Bony hypertrophy
5. Sites of involvement (Mueller-Lessmann et al. 2001)
    1. Lower limb most common (about 95%)
    2. Upper limb (about 5%)
    3. Trunk only: uncommon
    4. Orofacial involvement
        1. Jaw enlargement
        2. Facial asymmetry
        3. Malocclusions
        4. Premature tooth eruption
        5. Hemangioma of the lips, tongue, and oral mucosa
6. Sex ratio: males and females affected equally
7. Complications
    1. Abnormal vasculature
        1. Thrombosis
        2. Coagulopathy
        3. Pulmonary embolism
        4. Heart failure (in the presence of significant AVM)
        5. Bleeding from abnormal vessels in gut, kidney, or genitalia
    2. Gastrointestinal varicoses
        1. Bleeding: uncommon but can be fatal (Samo et al. 2013)
        2. Pain
        3. Diarrhea
    3. Protein-losing enteropathy secondary to intestinal lymphangiectasia
    4. Infection is a particular risk for patients with abnormal lymphatic drainage. Antibiotics indicated in:
        1. Cellulitis
        2. Surgery
        3. Injury in an affected limb
    5. Pain due to venous insufficiency or lymphedema in some older children and adults
    6. Venous thromboembolism
        1. Chronic thromboembolic pulmonary hypertension
        2. Subsequent right ventricular failure
    7. Occurrence of ulceration on affected leg
    8. Rare occurrence of skin tumors on the affected limb
        1. Squamous cell carcinoma possibly secondary to a long-standing venous ulcer (De Simone et al. 2002)
        2. Basal cell carcinoma
    9. Pregnancy and KTS: known perinatal risks to both the mother and fetus (Fait et al. 1996; González-Mesa et al. 2012; Stein et al. 2006)
        1. Hemorrhage secondary to increased hemangiomas and varices
        2. Coagulopathy including deep and superficial thrombosis
        3. Acute and chronic disseminated intravascular coagulation
        4. Kasabach-Merritt syndrome (Neubert et al. 1995)
        5. Placental abnormalities
8. Four levels of severity of Klippel-Trenaunay syndrome (You et al. 1983)
    1. Venous dysplasias: phlebectasic dysplasias (Klippel-Trenaunay syndrome)
    2. Arterial dysplasias
    3. Arterial and associated venous dysplasias:
        1. Phlebarterectasia (no arteriovenous shunt)
        2. Angiodysplasias with shunt (Klippel-Trenaunay-Weber syndrome)

4. Mixed angiodysplasias: a typical Klippel-Trenaunay syndrome
9. Diagnostic criteria: Presence of two of the three following cardinal features is sufficient to make a diagnosis (Jacob et al. 1998)
   1. Capillary malformations (98%)
   2. Venous malformations or varicose veins (72%)
   3. Hypertrophy of the affected tissues (67%)
10. Diagnostic criteria and proposed definition: two major features at least one from congenital vascular malformations, which should always include either capillary malformations or venous malformations and at least one from disturbed growth (bi or bii) (Oduber et al. 2008)
    1. Congenital vascular malformations
       1. Capillary malformations (CMs). This includes port-wine stains
       2. Venous malformations (VMs): This includes hypoplasia or aplasia of veins, persistence of fetal veins, varicosities, hypertrophy, tortuosity, and valvular malformations
       3. Arteriovenous malformations (AVMs): This includes only very small AVMs or arteriovenous fistulas (AVF)
       4. Lymphatic malformations (LM): This includes any LM
       5. Localization
          1. CM can be located anywhere on the body, although location in the face is exceedingly rare
          2. AVM, VM, and LM are mainly located on the extremities and adjacent parts of the trunk (pelvis, shoulder) but in expressed forms of KTS also elsewhere (bladder, rectum, lower GI tract, penis, uterine, vulva, vagina, liver, kidneys, lung, spine)
          3. AVM, VM, and LM are not located in the face or brain
    2. Disturbed growth
       1. Disturbed growth of bone in the length or girth
       2. Disturbed growth of soft tissue in the length or girth
       3. The disturbed growth includes:
          1. Hypertrophy (frequent) of a small body part (isolated finger, macrodactyly) or larger body part (total limb, half of the total body)
          2. Hypotrophy (infrequent) of a small or larger body part
       4. Can be present both on the same site as the vascular malformation(s) (frequent) and at another site (infrequent)
11. Four commonly held conceptions about Klippel-Trenaunay syndrome challenged
    1. Renaming Klippel-Trenaunay-Weber syndrome by addition of arteriovenous fistulas (Meier 2009)
       1. Significant arteriovenous communications not observed in Klippel-Trenaunay syndrome in large surgical series
       2. Parkes Weber syndrome
       3. Parkes Weber syndrome (PWS)
          1. Characterized by enlarged arteries and veins, capillary or venous malformations and enlargement of a limb
          2. Closely associated with and similar to Klippel-Trenaunay syndrome, except that high-flow arteriovenous malformation (AVM) (resulting in high-output heart failure) occurs in association with a cutaneous capillary malformation (increased chance of skin ulcerations) and skeletal or soft tissue hypertrophy with increased limb-length discrepancies (Ziyeh et al. 2004; Sunderkrishman 2015)
          3. Lymphatic malformations found in Klippel-Trenaunay syndrome not observed in Parkes Weber syndrome
    2. Overlap with Sturge-Weber syndrome
       1. Characteristics of Sturge-Weber syndrome: craniofacial angiomatosis, port-wine nevus, and cerebral calcification
       2. Overgrowth in Sturge-Weber syndrome tends to be minor and is always secondary to the vascular anomaly. In contrast,

overgrowth in Klippel-Trenaunay syndrome is striking
3. Presence of a bleeding diathesis of the Kasabach-Merritt type
    1. Kasabach-Merritt syndrome erroneously applied to patients with extensive venous or lymphaticovenous malformations who develop a localized intravascular coagulopathy in which the platelet count is minimally depressed (varying from 50,000 to 150,000/mm^3)
    2. Profound thrombocytopenia in true Kasabach-Merritt phenomenon (varying from 3,000 to 60,000/mm^3)
    3. Klippel-Trenaunay-Weber syndrome with Kasabach-Merritt coagulopathy and hydronephrosis (Bhat et al. 2015)
        1. Rare
        2. Mortality: high with development of Kasabach-Merritt syndrome
4. Familial aggregation with various genetic interpretations
    1. Inadequate documentation of cases
    2. Over interpretation of minor manifestations in relatives, including "nevus flammeus," hemangiomas, and varicosities (common manifestations in general populations)
    3. Klippel-Trenaunay syndrome defined as a capillary malformation with or without "hemihypertrophy" without mentioning of lymphatic malformations, lateral venous anomaly, lymphatic vesicles, or venous flares within the capillary malformation, or macrodactyly
5. Klippel-Trenaunay syndrome, Parkes Weber syndrome, and Sturge-Weber syndrome
    1. Each occurring sporadically
    2. Each considered separate entity because clinical manifestations and types of complications are different

12. Cutaneous vascular anomalies in the neonatal period (Hook 2013)
    1. Nevus simplex
    2. Port-wine stain
    3. Vascular malformation syndromes with overgrowth
        1. Sturge-Weber syndrome
        2. Klippel-Trenaunay syndrome
        3. Parkes Weber syndrome
        4. Capillary malformation-macrocephaly syndrome
        5. Proteus syndrome
        6. Beckwith-Wiedemann syndrome
    4. Cutis marmorata telangiectatica congenita
    5. Capillary malformation-arteriovenous malformation syndrome
    6. Blue-rubber-bleb nevus syndrome
    7. Vascular tumors
    8. Infantile hemangioma
    9. Congenital hemangioma
    10. Tufted angioma
    11. Kaposiform hemangioendothelioma

Diagnostic Investigations

1. Color duplex ultrasonography (Berry et al. 1998)
    1. AV malformation
    2. Deep venous hypoplasia (a decrease in caliber of at least 50% of a vein along its length)
    3. Venous duplication
    4. Variable varicosities
2. Radiography
    1. Enlargement of the limb bones
    2. Yearly to monitor evidence of leg length discrepancy
3. Noninvasive imaging and endoscopy for severe gastrointestinal bleeding
4. Lymphoscintigraphy using radionuclide tracers
    1. Indication: edema or a girth discrepancy more than 4 cm
    2. No uptake of tracer along major lymphatics of the affected limb during repeated scans over at least a 1-h period
5. MRI
    1. Pelvis: to look for vascular malformations involving the kidneys, bladder, or intestines
    2. MRI with gadolinium to distinguish lymphatic from venous malformations
    3. Magnetic resonance venogram or phlebography/venography to document the

lateral venous anomaly and any abnormalities that may be present in the deep veins of the leg
4. Able to demonstrate arteriovenous fistulas in Parkes Weber syndrome
5. Diffuse venous malformation of the uterus in a pregnant woman with Klippel-Trénaunay syndrome diagnosed by DCE-MRI (dynamic contrast-enhanced MRI) (Yara et al. 2016)

6. Angiography (Sunderkrishman 2015)
   1. Arteriography: primarily indicated when spinal cord or brain involvement is suspected
   2. Venography: rarely indicated

Genetic Counseling

1. Recurrence risk
   1. Patient's sib: not increased
   2. Patient's offspring: not increased (doubtful that autosomal dominant inheritance exists)
2. Prenatal diagnosis
   1. 2D/3D ultrasonography (Paladini et al. 1998; Roberts et al. 1999; Cakiroglu et al. 2013)
      1. Asymmetric limb hypertrophy associated with cutaneous or subcutaneous multiloculated cystic or multicystic lesions. Color Doppler examination reveals the presence of persistent embryonic lateral marginal veins
      2. Limb edema
      3. Cardiac failure ranging from isolated cardiomegaly to severe hydrops
      4. Prenatal sonographic diagnosis of Klippel-Trenaunay-Weber syndrome with cardiac failure (Zoppi et al. 2001)
      5. Prenatal ultrasound diagnosis of Klippel-Trenaunay-Weber syndrome with Kasabach-Merritt syndrome which caused acute hemolytic anemia, leading to high-output cardiac failure and fetal hydrops, in utero (Tanaka et al. 2015)
   2. MRI
      1. Limb hypertrophy
      2. Multiple subcutaneous and internal hemangiomas
      3. Good definition of soft tissue lesions
      4. Identify vascular malformations and their extent
      5. Presence of low signal indicating flow voids, hemosiderin deposits, or calcification indicative of vascular malformations
3. Management (James et al. 1999; Gloviczki and Driscoll 2007; Sharma et al. 2015; Sunderkrishman 2015)
   1. Normally conservative
   2. Elastic garment or compression bandage: beneficial in managing both lymphedema and chronic venous insufficiency
   3. Physical therapy using massage treatment and intermittent pneumatic compression therapy
   4. Local wound care, compression dressings, special orthopedic footwear, and lifestyle modification
   5. Prednisolone
      1. Used to treat coagulopathy
      2. Decreases inflammation by suppressing migration of polymorphonuclear leukocytes and reducing capillary permeability
   6. Psychological support: participate in the activities of a support group
   7. Stripping of superficial varicose veins
   8. Successful pulmonary thromboendarterectomy in a patient with Klippel-Trenaunay syndrome (Walder et al. 2000)
   9. Pulsed dye laser treatment for superficial hemangioma component (Jih 2003)
   10. Sclerotherapy and embolotherapy
   11. Reduction of significant arteriovenous malformations
   12. Rare reconstructive surgery at sites of deep venous obstruction
   13. Orthopedic procedures for overgrowth
      1. Epiphysiodesis: to prevent (stop) overgrowing of limb and correction of bone deformity
      2. Excision of soft tissue hypertrophy
   14. Use of thromboembolic prophylaxis with low-molecular-weight heparin is generally recommended, mainly in the postpartum (Güngor Gündoğan and Jacquemyn 2010; González-Mesa et al. 2012)

Fig. 1 A newborn with Klippel-Trenaunay syndrome showing overgrowth of left leg with vascular malformation

Fig. 2 A neonate with Klippel-Trenaunay syndrome showing left leg overgrowth with vascular malformation

Fig. 3 (**a**, **b**) A boy with Klippel-Trenaunay syndrome showing overgrowth of the right arm and leg with vascular malformation (**a**, **b**)

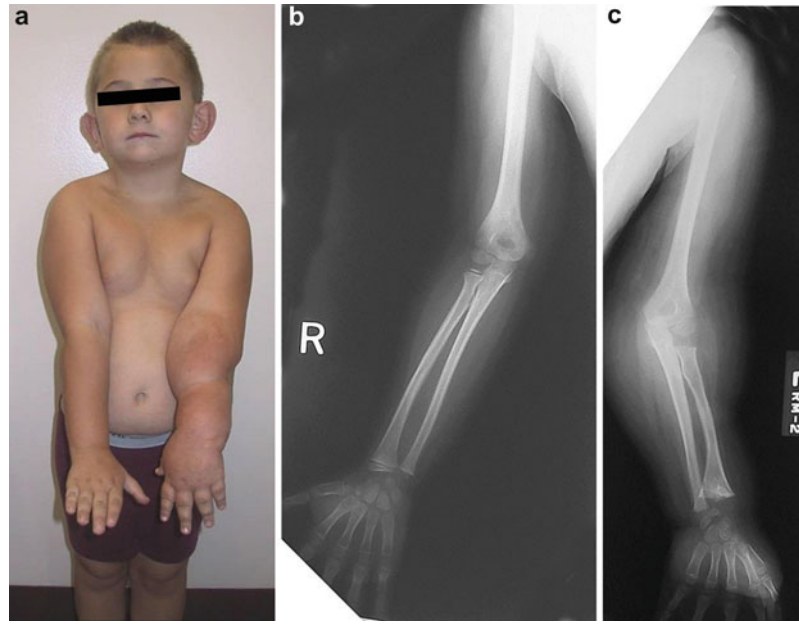

Fig. 4 (**a**–**c**) A 6-year-old boy with Klippel-Trenaunay syndrome showing overgrowth of left arm associated with vascular malformation (**a**), illustrated by radiographs (**b**, **c**)

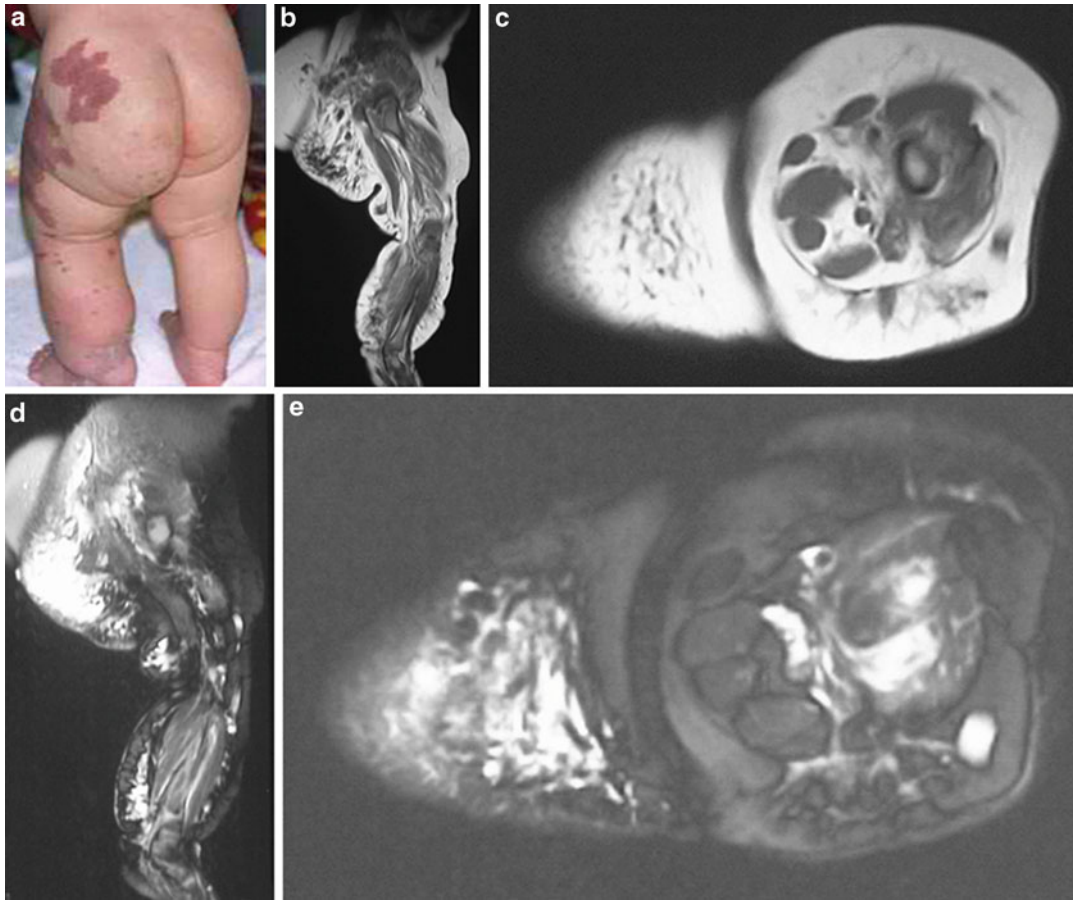

Fig. 5 A 1-year-old infant with Klippel-Trenaunay syndrome showing asymmetric lower extremities with hypertrophic left lower extremity associated with vascular malformation (**a**). T1-enhanced MRI (**b**, **c**) and T2-enhanced MRI (**d**, **e**) images at thigh level show cystic and vascular lesions, indicated by high signals suggesting lymphangiomas and hemangiomas

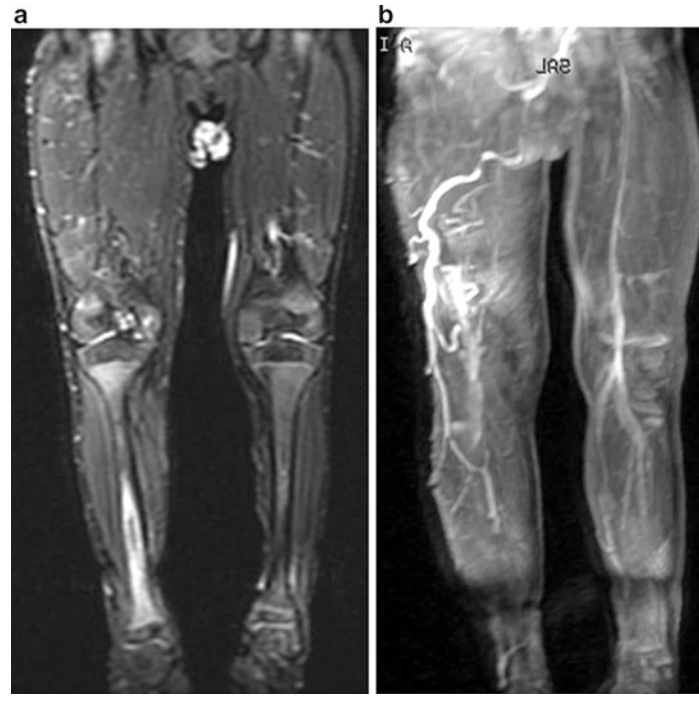

Fig. 6 (**a**, **b**) A 2-year-old boy with a history of Klippel-Trenaunay syndrome. MR image of the bilateral lower extremities demonstrates that the right lower extremity is larger than the left, with greater muscle mass in both legs and larger circumference (**a**). There is a length discrepancy in legs. A tortuous abnormal venous system is identified within the superficial fat along the posterior lateral aspect of the leg, which is seen draining through the gluteal and perineal regions into the pelvis (**b**). The deep venous system on the right is smaller than that on the left, although it is seen in its entirety (Courtesy of Dr. Grace Guo)

Kniest Dysplasia

Contents

In 1952, Kniest (1952) described an unusual form of disproportional dwarfism, called "atypical chondrodystrophy." Kniest dysplasia is a type II collagenopathy with characteristic clinical, radiographic, and histological findings. Kniest dysplasia is distinguished by platyspondyly and delay in ossification of the proximal epiphyses. After ossification, the epiphyses are enlarged resulting in dumbbell-shaped long bones.

Genetics/Basic Defects

1. Inheritance
    1. Autosomal dominant (Wilkin et al. 1999)
    2. New dominant mutations in most cases (Gilbert-Barnes et al. 1996)
2. Molecular basis (Wilkin et al. 1994; Cole 1997; Spranger et al. 1997)
    1. Caused by mutations in the gene (*COL2A1*) that encodes type II collagen, the predominant protein of cartilage
    2. A specific type of mutation and/or position of mutation within the collagen chain may explain the unique features of Kniest dysplasia among the type II collagenopathies
3. Kniest dysplasia in the middle of the following phenotypic spectrum of disease (type II collagenopathy caused by *COL2A1*) (Spranger et al. 1994a, b; Nagendran et al. 2012; Barat-Houari et al. 2015)
    1. Achondrogenesis type II/hypochondrogenesis at the severe end.
    2. Spondyloepiphyseal dysplasia/spondyloepimetaphyseal dysplasia Strudwick type in the middle.
    3. Genetically heterogeneous: Stickler syndrome type I, nonsyndromic predominantly ocular (Winterpacht et al. 1993) and familial adult early-onset osteoarthritis at the milder end.
    4. Characterized by abnormalities of variable severity in the ocular, skeletal, orofacial, and audiological systems. Clinical variability is common, and phenotypic overlap between *COL2A1*-associated disorders may be seen within the same family (Winterpacht et al. 1993).
    5. Phenotypic variability can be explained in some families by somatic mosaicism.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_144

Clinical Features

1. Skeletal anomalies (Wilkin et al. 1999; Siggers et al. 1974; Spranger and Maroteaux 1974; Lachman et al. 1975)
    1. Disproportionate dwarfism
    2. A short trunk
    3. Short, slightly bowed limbs
    4. More severe rhizomelic shortness in the lower limbs
    5. Prominent joints
    6. Delayed motor milestones secondary to joint deformities
    7. Progressive and painful joint enlargement accompanied by joint contractures
    8. Muscle atrophy resulting from disuse
    9. Short and broad thorax with sternal protrusion
    10. Kyphoscoliosis
        1. Dorsal kyphosis
        2. Accentuated lumbar lordosis
        3. Thoracic scoliosis
    11. Odontoid hypoplasia resulting in atlantoaxial instability
    12. Clubfoot
    13. Small pelvis
    14. Premature osteoarthritis that restrict movement
    15. Waddling gait
2. Craniofacial characteristics
    1. Relatively large head
    2. Flat face
    3. Shallow supraorbital ridges
    4. Prominent eyes
    5. Flat nasal bridge
    6. Short nose
    7. Micrognathia
    8. Cleft palate
3. Ocular manifestations: very similar to those in other disorders of type II collagen such as Stickler syndrome (Douglas 1985; Maumenee and Traboulsi 1985; Sergouniotis et al. 2015)
    1. Abnormal long axial length causing high early-onset myopia
    2. Vitreoretinal degeneration
    3. Retinal detachment
    4. Cortical and posterior subcapsular opacity of the lens
    5. Veil-like vitreous opacity in the periphery
    6. Congenital glaucoma
    7. Blindness
4. Hearing loss
5. Prognosis: phenotype varying significantly
    1. Frequently potentially life-threatening complications
        1. Early postnatal tracheomalacia resulting in respiratory insufficiency and feeding difficulties (Hicks et al. 2001)
        2. Secondary failure to thrive
    2. Can lead a relatively normal life with mild disproportionate short stature, kyphoscoliosis, and/or craniofacial manifestations

Diagnostic Investigations

1. Radiography (Lachman et al. 1975; Kozlowski et al. 1977; Gilbert-Barnes et al. 1996; Wilkin et al. 1999)
    1. Distinguishing radiographic features from other type II collagenopathies identifiable at birth
        1. Coronal clefts of the vertebrae
        2. Dumbbell-shaped femora
    2. Other radiographic features
        1. Narrowed joint spaces
        2. Platyspondyly
        3. Kyphoscoliosis
        4. Short tubular bones
        5. Dysplastic epiphyses and metaphyses
            1. Broad metaphyses
            2. Enlarged and deformed epiphyses
2. MR imaging of both unossified and ossified epiphyses reveals a similar pattern of lakes of bright T2 signal against a relatively normal background, representing an interesting analogue to the histologic and radiographic features (Dwek 2005)
3. Histopathology (Gilbert-Barnes et al. 1996)
    1. Pathologic changes of cartilage
        1. "Swiss cheese" appearance of the cartilage matrix (a bizarre pattern of

chondrocytes lying amid a highly vacuolated matrix) (Horton and Rimoin 1979; Dwek 2005)
    2. Ossified epiphyses: unusual in showing clouds of dense punctuate calcifications randomly distributed throughout
    3. Soft crumbly cartilage
  2. Microscopic changes
    1. Disorganization of the growth plate.
    2. Deficiency of collagen matrix.
    3. Poorly staining cartilage with myxoid degeneration.
    4. PAS positive cytoplasmic inclusions in many chondrocytes. Ultrastructurally, the inclusions correspond to pools of proteinaceous material within dilated rough endoplasmic reticulum (Horton and Rimoin 1979).
4. Hearing test
5. Visual evaluation
6. Molecular genetic analysis of *COL2A1* gene mutation
  1. Targeted mutation analysis
  2. Mutation scanning
  3. Sequencing of entire coding region

Genetic Counseling

1. Recurrence risk
  1. Patient's sib: low recurrence risk unless a parent is affected or has gonadal mosaicism
  2. Patient's offspring: 50%
2. Prenatal diagnosis
  1. Difficult to diagnose Kniest dysplasia by early sonography since the biometry does not become notably abnormal until the third trimester (Bromley et al. 1991).
  2. Combined use of 3D-CT with ultrasonography (Wada et al. 2011).
  3. Fetal MRI findings: By delineating the cartilaginous abnormalities, fetal MRI can contribute to the prenatal diagnosis of chondrodysplasias (Yazici et al. 2010).
    1. Enlarged hyaline cartilaginous structures with abnormally high T2 signal intensity
    2. Delayed ossification of the pubic and ischial bones
    3. Platyspondyly
  4. Molecular genetic analysis of *COL2A1* mutation on fetal DNA obtained from amniocentesis or CVS for previously characterized disease-causing gene mutation in the proband
3. Management
  1. Cleft palate repair
  2. Hearing aid for hearing loss
  3. Vitrectomy and silicon oil injection for reattaching the retina from retinal detachment (Yokoyama et al. 2003)
  4. Orthopedic care for clubfoot and kyphoscoliosis

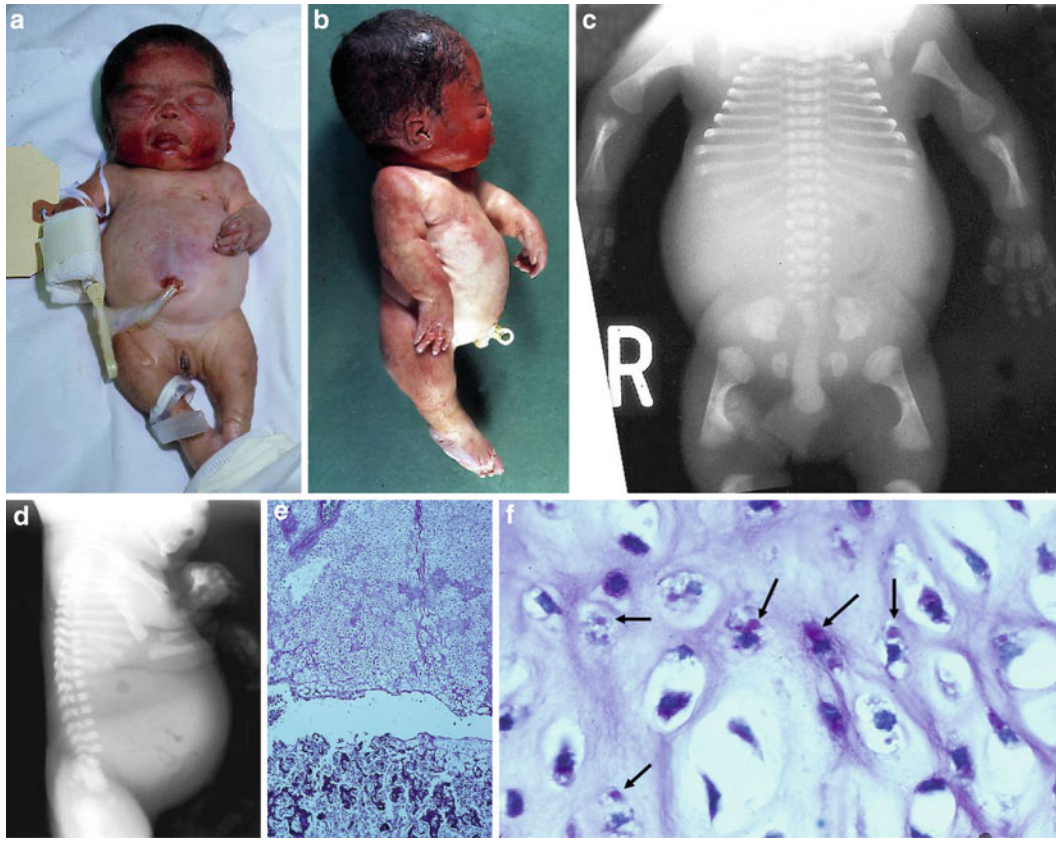

Fig. 1 (**a**–**f**) A neonate with Kniest dysplasia showing short trunk and large head, similar to SED congenita. However, the moderately shortened limbs show prominent joints (**a**, **b**). Radiographs show enlarged metaphyses of limb bones (dumbbell-shaped femora) and coronal clefts of the vertebrae (**c**, **d**). The remaining findings are similar to those of SED congenita. The physeal growth zone of femur is hypercellular and disorganized (**e**). The transverse cleft beneath the physis is an artifact. Many chondrocytes contain cytoplasmic inclusions (**d**) (*arrows*); they are seen in the resting cartilage and the zone of proliferation, similar to those of SED congenita (Chen et al. 1980)

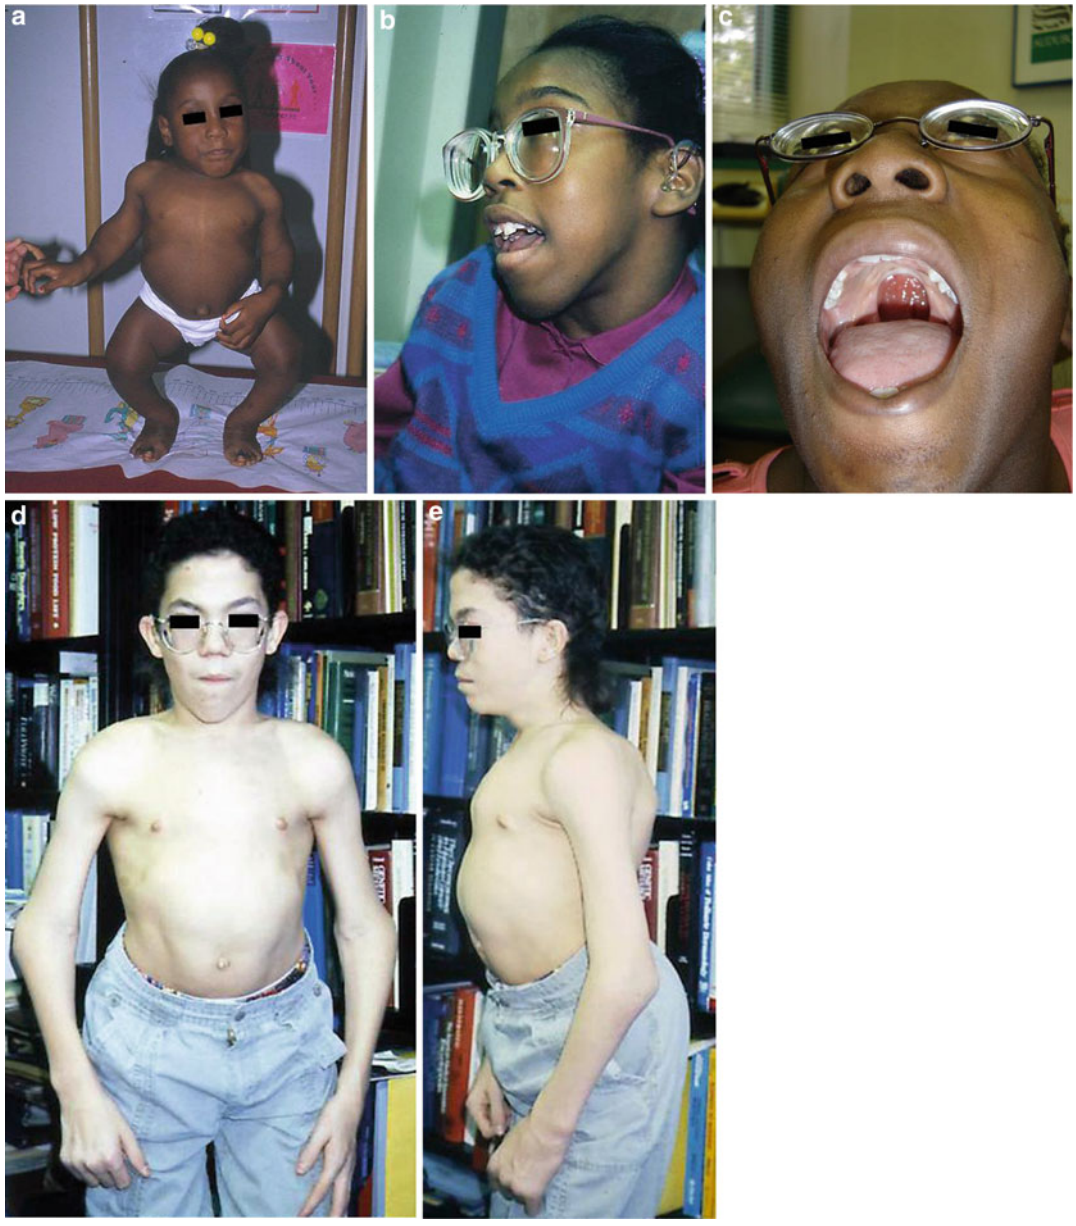

Fig. 2 (**a**–**e**) Three children (**a**, **b**, **c**, **d**, **e**) with Kniest dysplasia showing varying features of the dysplasia: short trunk dwarfism, flat facies, myopia, cleft palate, deafness requiring hearing aids, dorsal kyphosis, accentuated lumbar lordosis, short and broad thorax with sternal protrusion, and prominent joints with restricted joint mobility

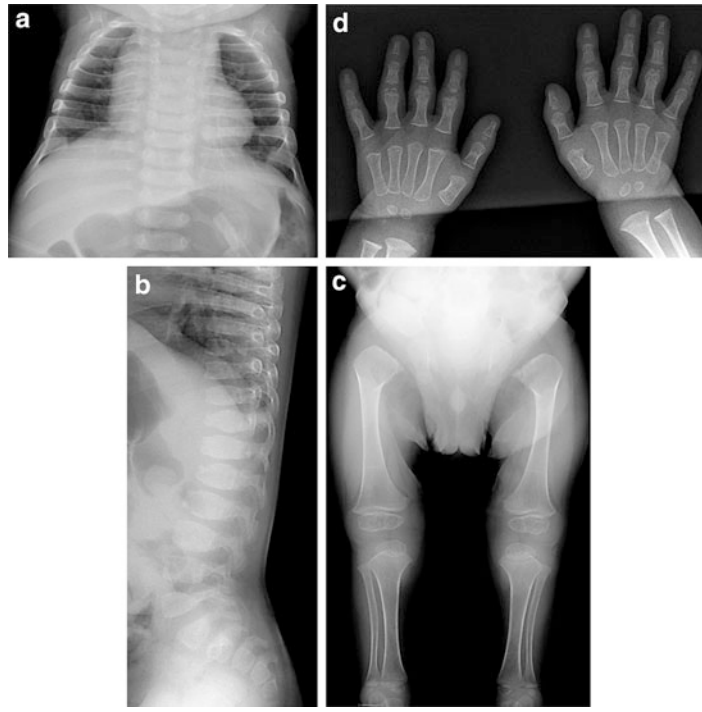

Fig. 3 (**a**–**d**) A 15-month-old white male with diagnosis of Kniest dysplasia. He is the second child in the family and was born at 38-1/2 weeks by cesarean section. His mother was diagnosed to have polyhydramnios during pregnancy. An antenatal ultrasound demonstrated short limbs and genetic tests confirmed that he positively had Kniest dysplasia. DNA testing showed a gene change within the *COL2A1* gene, consistent with the diagnosis of a Type II collagenopathy. The exact gene change identified was Alal02Val. This change is predicted to cause a small deletion within the amino acid sequence of the protein. He has had a number of medical issues during his early infantile course. He was born with a cleft palate, bilateral hearing impairment, myopia, esophageal reflux, respiratory issues (apneic episodes), and swallowing difficulty. Radiographies demonstrate foreshortening of the ribs which appear slightly flared (**a**). There is irregularity of the vertebral bodies of the lower thoracic and upper lumbar spine anteriorly (**b**). There is flaring of the ilia with dysplasia of the acetabulum. There is widening of the metaphyses and irregularity of the epiphyses of foreshortening long bones (**c**). Bilateral hands imaging demonstrates osteoporosis, large carpals, and bulbous phalangeal joints with narrow spacing (**d**) (Courtesy of Dr. Grace Guo)

Larsen Syndrome

Contents

In 1950, Larsen et al. described a condition characterized by multiple large joint dislocations and flat face (Larsen et al. 1950). The condition occurs in approximately 1 in 100,000 births.

Synonyms and Related Disorders

FLNB-related disorders (boomerang dysplasia; atelosteogenesis type I; atelosteogenesis type III; spondylocarpotarsal synostosis syndrome; Larsen syndrome); Lethal Larsen-like syndrome; Multiple joint dislocations, short stature, craniofacial dysmorphism, and congenital heart defects

Genetics/Basic Defects

1. Subtypes:
    1. Sporadic form
    2. Autosomal dominant form (Harris and Cullen 1971; Habermann et al. 1976; Stanley and Seymour 1985; Fryns et al. 1993; Al-Kaissi et al. 2003)
    3. Autosomal recessive form (Steel and Kohl 1972; Strisciuglio et al. 1983; Topley et al. 1994; Knoblauch et al. 1999): clinical phenotype more debilitating with higher mortality than the autosomal dominant form
    4. Craniosynostosis: a previously unreported association with *CHST3*-related skeletal dysplasia (autosomal recessive Larsen syndrome) (Searle et al. 2014)
    5. Possible parental germ-line mosaicism (Petrella et al. 1993)
    6. Possible lethal form (Chen et al. 1982)
2. The first known gene mutated in Larsen syndrome, *LAR1*, for autosomal dominant form: mapped to 3p21.1-14.1 in the proximity of, but distinct from, the *COL7A1* locus (Vujic et al. 1995).
3. Clinical similarities between Larsen syndrome and a group of lethal osteochondrodysplasias including atelosteogenesis types I (AOI) and III (AOIII) and boomerang dysplasia suggested that they represent an allelic series of conditions (Hunter and Carpenter 1991; Sillence et al. 1997):
    1. These more severe dysplasias are characterized by underossification of skeletal elements, hypoplastic or absent limb bones, joint dislocations, and craniofacial abnormalities.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_145

2. These observations, with the phenotypic similarities between Larsen syndrome and otopalatodigital syndrome type 1 (OPD1), an X-linked skeletal disorder caused by mutations in *FLNA* (Robertson et al. 2003), the gene encoding filamin A, led to the description of mutations in the paralogous gene filamin B (*FLNB*) gene underlying Larsen syndrome, AOI, AOIII, and boomerang dysplasia (Bicknell et al. 2005; Krakow et al. 2004).
3. Mutations leading to AOI and AOIII were clustered in calponin homology domain 2 (CH2) and repeats 13–17 (Farrington-Rock et al. 2006).

4. Molecular and clinical study of Larsen syndrome caused by mutations in *FLNB* (Bicknell et al. 2007):
   1. The clinical signs most frequently associated with an *FLNB* mutation are the presence of supernumerary carpal and tarsal bones and short, broad, spatulate distal phalanges, particularly of the thumb.
   2. All individuals with Larsen syndrome-associated *FLNB* mutations are heterozygous for either missense or small inframe deletions:
      1. Three mutations are recurrent, with one mutation, 5071GRA, observed in 6 of 20 subjects.
      2. The distribution of mutations within the *FLNB* gene is nonrandom, with clusters of mutations leading to substitutions in the actin-binding domain and filamin repeats 13–17 being the most common cause of Larsen syndrome.
   3. These findings collectively define autosomal dominant Larsen syndrome and demonstrate clustering of causative mutations in *FLNB*.
   4. The *FLNB*-related disorders include a spectrum of phenotypes ranging from mild (spondylocarpotarsal synostosis syndrome and Larsen syndrome) to severe (atelosteogenesis types I and III, boomerang dysplasia) (Robertson 2013).

5. Molecular basis of recessive Larsen syndrome (Hermanns et al. 2008; Unger et al. 2010):
   1. Eight *CHST3* (carbohydrate sulfotransferase 3, also known as chondroitin 6-sulfotransferase) mutations, causing CHST3 deficiency, were identified in unrelated individuals who presented at birth with congenital joint dislocations:
      1. These patients had been given a diagnosis of either Larsen syndrome (three individuals) or humero-spinal dysostosis (three individuals), and their clinical features included congenital dislocation of the knees, elbow joint dysplasia with subluxation and limited extension, hip dysplasia or dislocation, clubfoot, short stature, and kyphoscoliosis developing in late childhood.
      2. Analysis of chondroitin sulfate proteoglycans in dermal fibroblasts showed markedly decreased 6-*O*-sulfation but enhanced 4-*O*-sulfation, confirming functional impairment of CHST3 and distinguishing them from diastrophic dysplasia sulfate transporter (DTDST)-deficient cells.
   2. These observations provide a molecular basis for recessive Larsen syndrome and indicate that recessive Larsen syndrome, humero-spinal dysostosis, and spondyloepiphyseal dysplasia Omani type form a phenotypic spectrum.
6. Unilateral manifestation of typical skeletal defects in some patients indicates that this condition might represent unilateral somatic cell-line mosaicism (Debeer et al. 2003).

Clinical Features

1. Broad inter- and intrafamilial clinical variability (Becker et al. 2000; Al-Kaissi et al. 2003)
2. Characteristic flat facial appearance ("dish face"):
   1. Prominent forehead (frontal bossing)
   2. Hypertelorism
   3. Hypoplastic midface
   4. Depressed nasal bridge

5. Micrognathia
6. Occasional cleft palate, lip, or uvula

3. Bilateral multiple joint dislocations (Latta et al. 1971; Silverman 1972; Robertson et al. 1975):
   1. Shoulders
   2. Elbows
   3. Wrists
   4. Hips
   5. Patella
   6. Ankles
   7. Knees
4. Variable handicap due to joint luxations
5. Hand abnormalities:
   1. Long, cylindrical, and tapering fingers (pseudoclubbing)
   2. Spatulate/bifid thumbs
   3. Dislocation of distal radioulnar joint
   4. Delayed carpal ossification
   5. Supernumerary ossification centers
   6. Brachymetacarpia
   7. Brachytelephalangia
   8. Hyperextension of distal interphalangeal joints
6. Feet abnormalities:
   1. Spatulate hallux
   2. Equinovarus or valgus deformities of the feet
7. Respiratory distress due to tracheolaryngomalacia (Rock et al. 1988):
   1. Stridor:
      1. Inspiratory reflecting laryngomalacia or extrathoracic cervical tracheomalacia
      2. Expiratory reflecting intrathoracic tracheomalacia
   2. Cyanosis
   3. Obstructive apnea
   4. Possibly life threatening
8. Bronchomalacia:
   1. Lobar atelectasis
   2. Hyperinflation
   3. Pneumonias
9. Respiratory embarrassment in infancy due to soft tracheolaryngeal cartilage
10. Soft/collapsing thorax
11. Cardiovascular abnormalities (similar to Marfan syndrome) (Kiel et al. 1983):
    1. Congenital defects:
       1. Bicuspid aortic valve
       2. Subaortic stenosis
       3. Atrial septal defect
       4. Ventricular septal defect
       5. Patent ductus arteriosus
       6. Pulmonary stenosis
       7. Endocardial fibroelastosis
    2. Acquired lesions:
       1. Dilated aortic root
       2. Elongated aorta (Liang and Hang 2001)
       3. Mitral valve prolapse
       4. Aneurysm of ductus arteriosus
       5. Arterial tortuosity and dilatation
12. Associated spinal anomalies (Bowen et al. 1985; Banks et al. 2003):
    1. Cervical spine involvement:
       1. More often affected than thoracic or lumbar spine
       2. Results in:
          1. Midcervical kyphosis, usually at the C4–C5 region
          2. Cervicothoracic lordosis
          3. Spinal instability
       3. Flattened, hypoplastic, and often bifid cervical vertebrae
    2. Atlantoaxial instability/dislocation (Le Marec et al. 1994):
       1. A rare finding
       2. May be associated with other abnormalities of the upper cervical spine:
          1. Occipitalization of the atlas
          2. Basilar impression
    3. Subaxial kyphotic deformity itself may not be the cause of cord compression in all cases of adult Larsen syndrome. Adjacent-level degenerative changes may be responsible for cord compression (Sahoo et al. 2016).
    4. Lumbosacral dysraphism: may lead to neurological impairment.
    5. Dural ectasia (Jain et al. 2014): an abnormal expansion of the dural sac surrounding the spinal cord and may result in spinal morphologic changes, instability, and spontaneous dislocation.
    6. Thoracic scoliosis.
    7. Hypoplasia of the vertebral bodies or posterior elements.

8. Quadriplegia secondary to segmentation abnormalities of the vertebrae.
13. Mixed hearing loss due to ossicular abnormality
14. CNS anomalies:
    1. Hydrocephalus (rare)
    2. Glial proliferation in the brain
15. Short stature
16. Normal intelligence
17. Possible lethal form (Chen et al. 1982; Clayton-Smith and Donnai 1988; Mostello et al. 1991):
    1. Tracheomalacia
    2. Pulmonary hypoplasia
    3. Collagen fiber dysmaturity
18. Prognosis:
    1. Generally good after aggressive orthopedic management, except some lethal cases due to tracheolaryngomalacia and/or lung hypoplasia
    2. Compatible with successful pregnancy if the maternal and fetal safety issues are properly considered
19. Differential diagnosis (*FLNB*-related disorders) (Robertson 2013):
    1. Spondylocarpotarsal synostosis syndrome (Langer et al. 1994):
        1. Characteristic clinical features:
            1. Disproportionate short stature
            2. Vertebral anomalies with block vertebrae
            3. Scoliosis and lordosis
            4. Carpal and tarsal synostosis
            5. Clubfeet
            6. Mild facial dysmorphisms with round face, frontal bossing, and anteverted nares
        2. Other manifestations can include the following:
            1. Midline cleft palate
            2. Conductive hearing loss
            3. Joint laxity
            4. Dental enamel hypoplasia
        3. Diagnostic radiographic features:
            1. Fusion of adjacent vertebrae and posterior elements that can involve noncontiguous areas of the cervical, thoracic, and lumbar spine.
            2. Carpal and tarsal synostosis. Carpal synostosis is usually capitate-hamate and lunate-triquetrum (Langer et al. 1994).
            3. Delayed ossification of epiphyses (especially of carpal bones) and bilateral epiphyseal dysplasia of the femur: reported in two individuals (Honeywell et al. 2002; Mitter et al. 2008).
    2. Atelosteogenesis type I (AOI) and type III (AOIII) (Farrington-Rock et al. 2006):
        1. Once thought to represent distinct entities, they now appear to be part of a phenotypic continuum (Farrington-Rock et al. 2006).
        2. AOIII:
            1. Milder than AOI, commonly with survival beyond the neonatal period
            2. Clinical findings: dislocated hips, knees, and elbows and clubfeet
            3. Radiographic features: distal tapering of the humeri and femora, short and broad tubular bones of the hands and feet, and mild vertebral hypoplasia
        3. AOI:
            1. Characterized by perinatal lethality with severe short-limbed dwarfism; dislocated hips, knees, and elbows; and clubfeet
            2. Radiographic features: marked platyspondyly; hypoplastic pelvis; incomplete or absent, shortened, or distally tapered humeri and femora; absent, shortened, or bowed radii; shortened and bowed ulnae and tibiae; absent fibulae; and unossified or partially ossified metacarpals and middle and proximal phalanges
    3. Boomerang dysplasia (Bicknell et al. 2005):
        1. A perinatal lethal bone dysplasia with close similarities to AOI
        2. Distinguished primarily by characteristic bowing of the femora and, occasionally, extraskeletal manifestations

including encephalocele and omphalocele

20. Other differential diagnoses (Robertson 2013):
    1. Otopalatodigital syndrome type 1 (OPD1) differs chiefly from Larsen syndrome in the following ways:
        1. X-linked inheritance of OPD1
        2. Absence of dislocation of the large joints (except dislocation of the radial heads) and cervical spine dysplasia in OPD1
        3. Absence of radiologically supernumerary ossification centers within the carpus and/or tarsus in OPD1
    2. *CHST3*-related skeletal dysplasia (also known as spondyloepiphyseal dysplasia, Omani type) (Thiele et al. 2004):
        1. Characterized by short stature of prenatal onset, joint dislocations (knees, hips, radial heads), clubfeet, and limitation of range of motion that can involve all large joints.
        2. Kyphosis and occasionally scoliosis with slight shortening of the trunk develop in childhood.
        3. Minor heart valve dysplasia has been described in several persons.
        4. Intellect, vision, and hearing are normal.
        5. The chief differences are the presence of the following in *CHST3*-related skeletal dysplasia and not in Larsen syndrome:
            1. Epiphyseal dysplasia
            2. Progressive spondylodysplasia in early and mid-childhood
            3. Rhizomelic shortening of the limbs
    3. Desbuquois dysplasia is a chondrodysplasia in which affected individuals have severe prenatal and postnatal growth retardation, progressive scoliosis, joint laxity, joint dislocations, and short extremities. A majority of affected individuals have biallelic mutations in CANT1 (Huber et al. 2009; Nizon et al. 2012). Desbuquois dysplasia differs from Larsen syndrome in the following ways:
        1. Short stature (< -3 SD)
        2. Advanced carpal bone age
        3. Characteristic radiographic manifestations in the hips, pelvis, and hands
    4. B3GAT3 deficiency (Baasanjav et al. 2011) is characterized by dysmorphic facial features, short stature, bilateral dislocations of multiple joints (elbows, hips, and knees), clubfeet, and cardiovascular defects. Unlike Larsen syndrome, B3GAT3 deficiency may include the following features:
        1. Brachydactyly
        2. Cardiac defects, including bicuspid aortic valve and dilatation of the aorta
    5. Chondrodysplasia with joint dislocations, GPAAP type, is characterized by short stature, congenital joint dislocations, chondrodysplasia with brachydactyly, dysmorphic facial features, micrognathia, and cleft palate. This condition is caused by biallelic mutations in IMPAD1 (Vissers et al. 2011). Differences from Larsen syndrome include the following:
        1. Pronounced brachydactyly
        2. Asymmetry in the hands
        3. Short stature

Diagnostic Investigations

1. Radiography (Kozlowski et al. 1974; Al-Kaissi et al. 2003):
    1. Bilateral dislocations of the shoulders, elbows, wrists, hips, patella, ankles, and knees (anterior dislocation of the tibia on the femur, most characteristic)
    2. Genu recurvatum
    3. Talipes deformities (clubfeet)
    4. Spatulate thumbs
    5. Shortened metacarpals
    6. Multiple supernumerary carpal ossification centers (short, small, and increased in number)
    7. Poor ossification of phalanges
    8. Delayed coalescence (duplication) of calcaneal ossification centers

9. Occasional abnormal segmentation of vertebrae (+/− fusion defects of cervical spine)
10. Cervical kyphosis
11. Spina bifida occulta
12. Scoliosis
13. Multiple coronal cleft vertebrae (Wieisenbach and Melegh 1996)
14. Craniofacial disproportion

2. Audiometry to assess hearing.
3. Polysomnography for assessing the severity of airway obstruction.
4. Echocardiography for cardiovascular lesions.
5. MRI of the brain for cerebral malformations.
6. Diagnosis: based on clinical and radiographic findings and confirmed by *FLNB* molecular genetic testing (Girisha et al. 2016). A molecular diagnosis for Larsen syndrome can be achieved by testing selected exons of the *FLNB* gene, such as exons 2–5, exons 27–33, as well as exon 13.

Genetic Counseling

1. Recurrence risk:
    1. Patient's sib:
        1. Sporadic form (consider germ-line mosaicism when neither parent appears to be affected)
        2. Autosomal dominant inheritance: risk not increased unless a parent is affected
        3. Autosomal recessive inheritance: 25% risk of having sibs affected
    2. Patient's offspring:
        1. Sporadic form: risk not increased unless the patient has germ-line mosaicism
        2. Autosomal dominant inheritance: 50% risk of having offspring affected
        3. Autosomal recessive inheritance: risk not increased unless the spouse is also a carrier
2. Prenatal diagnosis (Robertson 2013):
    1. Ultrasonography: prenatal diagnosis accomplished in rare cases by ultrasonography in pregnancies at risk (Mostello et al. 1991; Tongson et al. 2000; Ghazle 2012):
        1. Multiple joint dislocations:
            1. Elbow
            2. Knees
            3. Hips
        2. Flat facial profile (Becker et al. 2000):
            1. Prominent forehead
            2. Hypertelorism
            3. A depressed nasal bridge
            4. Micrognathia
            5. Cleft palate
        3. Genu recurvatum (Lewit et al. 1995)
        4. Clubfeet
    2. Molecular genetic testing:
        1. De novo case (Winer et al. 2009):
            1. Genomic DNA was extracted from cultured amniocytes using a standard protocol. FLNB polymerase chain amplification reactions and sequence analysis were performed using previously published conditions (Krakow et al. 2004).
            2. Heterozygosity for a missense mutation, c.502G > A (p.Gly168Ser), was identified.
        2. Possible for at-risk pregnancies provided that prior identification of the disease-causing mutation(s) in the family is done
    3. Preimplantation genetic diagnosis may be an option for some families in which the disease-causing mutation(s) has been identified.
3. Management:
    1. Supporting therapy for airway difficulty:
        1. Antibiotics as needed
        2. Supplemental oxygen
        3. Chest physiotherapy to augment mucus clearance
        4. Require intubation for severe respiratory distress with positive end-expiratory pressure (PEEP) to maintain a patent airway (Rock et al. 1988)
    2. Anesthetic considerations (Malik and Choudhry 2002):
        1. Optimize respiratory status prior to the anesthetic and careful postoperative management.
        2. Patients with subglottic stenosis may benefit from perioperative intravenous

steroids, and nebulized racemic epinephrine may be necessary in the postoperative period to treat postextubation stridor.
3. If a surgical procedure does not truly warrant tracheal intubation, administration of anesthetic with a face mask or a laryngeal mask airway may avert complications associated with tracheal intubation and minimize manipulation of the neck.
4. Skeletal deformities, contractures, and cervical instability necessitate gentle handling and careful positioning.
5. Cervical instability with cord myelopathy may be associated with distal muscle weakness. Hence, care should be taken during administration of depolarizing neuromuscular blocking agents (i.e., succinylcholine) due to the possibility of hyperkalemia.

3. Cleft palate repair
4. Closed or open reduction and stabilization of dislocated joints (Lutter 1990):
   1. Securing stability of the knee joints for weight-bearing: primary importance
   2. Correction of foot deformities through operative and nonoperative measures
5. Stabilization of the cervical spine (Banks et al. 2003):
   1. Early bracing and stabilization.
   2. Stabilization of the neck may be required before surgical correction of joint abnormalities to prevent possible complications associated with the induction of anesthesia.
6. Surgical decompression and stabilization of the spine for dural ectasia (Jain et al. 2014)
7. Care for possible poor wound healing
8. Obstetrical care of an affected mother and fetus (Rochelson et al. 1993):
   1. Regional anesthesia for possible difficulty in intubation and the cervical spine may be subluxated during extension of the neck for intubation.
   2. Cesarean section if the patient is unable to abduct the hips, making vaginal delivery potentially traumatic for both the mother and infant.
   3. Risk of fetal injury includes cervical spine instability.

Fig. 1 (**a**–**d**) An infant with Larsen syndrome (**a**, **b**) showing characteristic flat facies with hypertelorism, depressed nasal bridge, cleft palate, dislocations of hips, knees, and talipes equinovarus, demonstrated by radiographs (**c**, **d**)

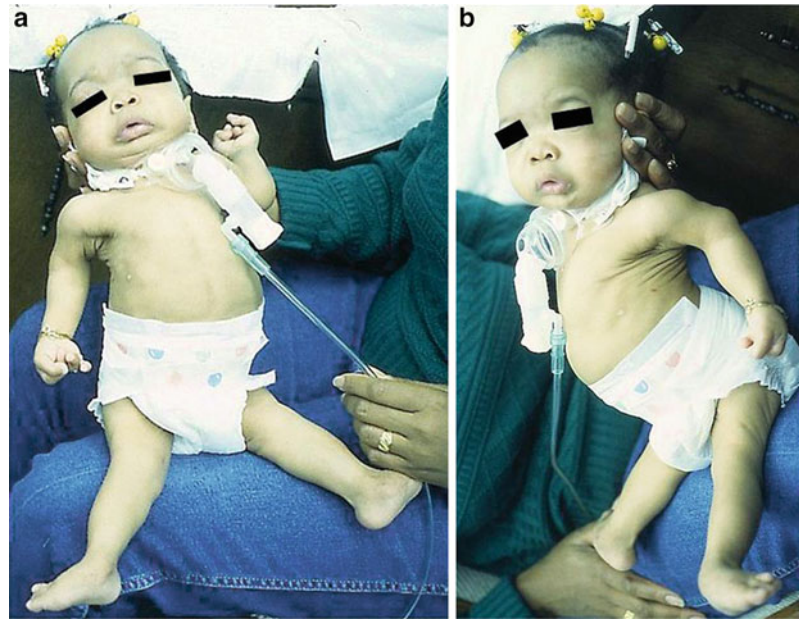

Fig. 2 (**a**, **b**) Another infant with Larsen syndrome (**a**, **b**) showing flat facies with prominent forehead, hypertelorism, depressed nasal bridge, micrognathia, tracheostomy for tracheomalacia, scoliosis, dislocation of knees, and clubfeet

Fig. 3 (**a**–**e**) A girl with Larsen syndrome showing characteristic flat facies (**a**, **b**) with prominent forehead, depressed nasal bridge, bilateral knee dislocations, and long, cylindrical fingers with spatulate thumbs (**c**) and great toes (**d**). Radiograph shows lateral and anterior dislocation of both knees (**e**)

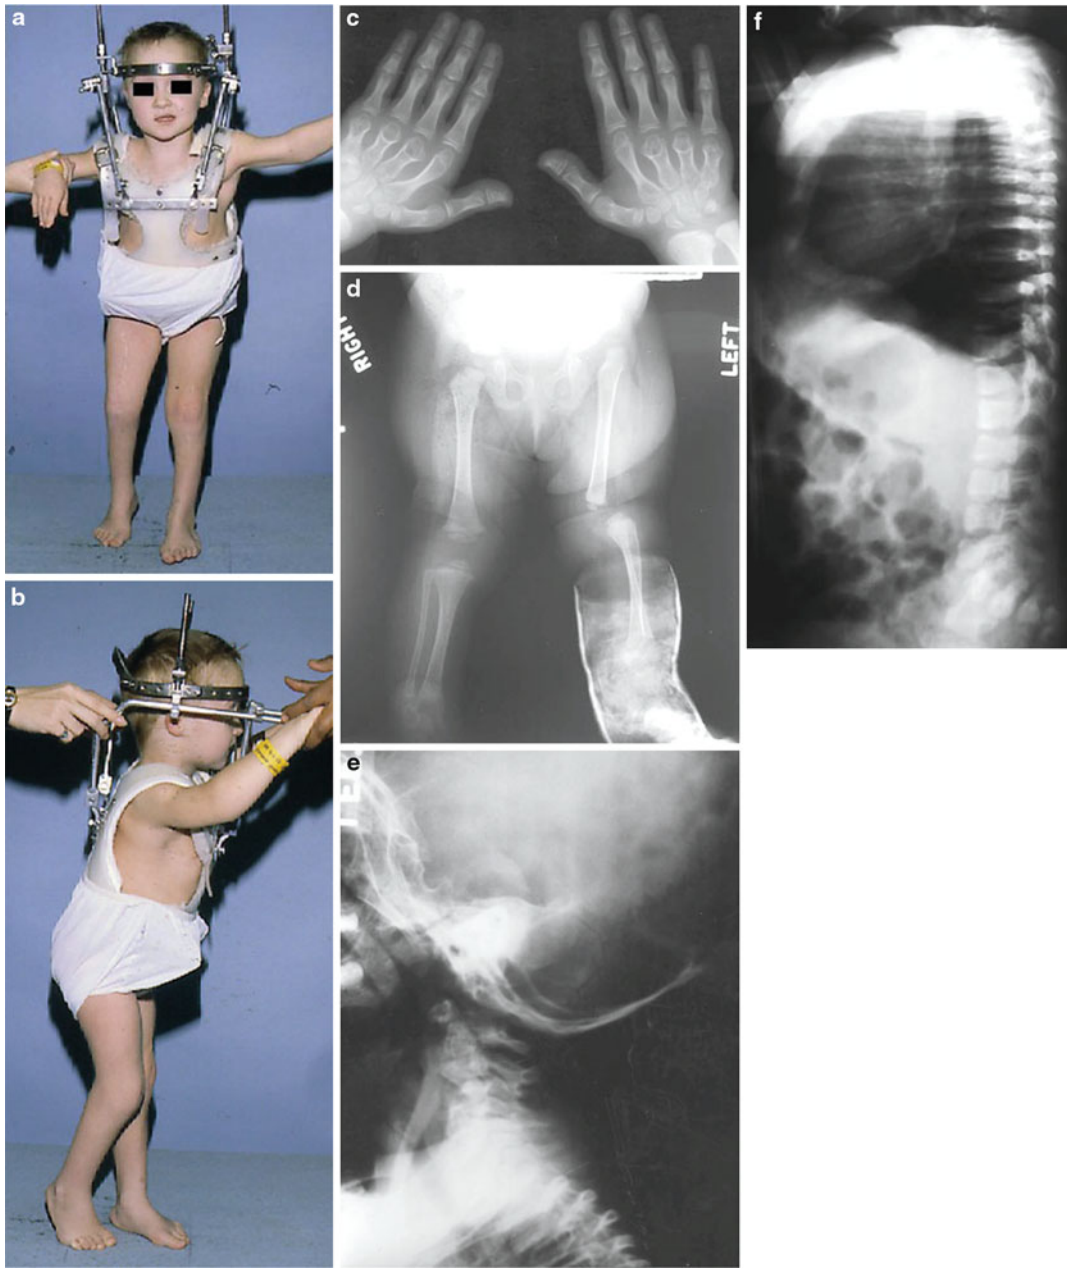

Fig. 4 (**a**–**f**) A girl with Larsen syndrome (**a**, **b**) wearing orthosis, showing flat facies. Radiographs show an increased number of carpal bones (**c**), anterior and lateral dislocation of tibiae (**d**), hyperextended cervical vertebrae (**e**), and coronal clefting of the lumbar vertebrae (**f**)

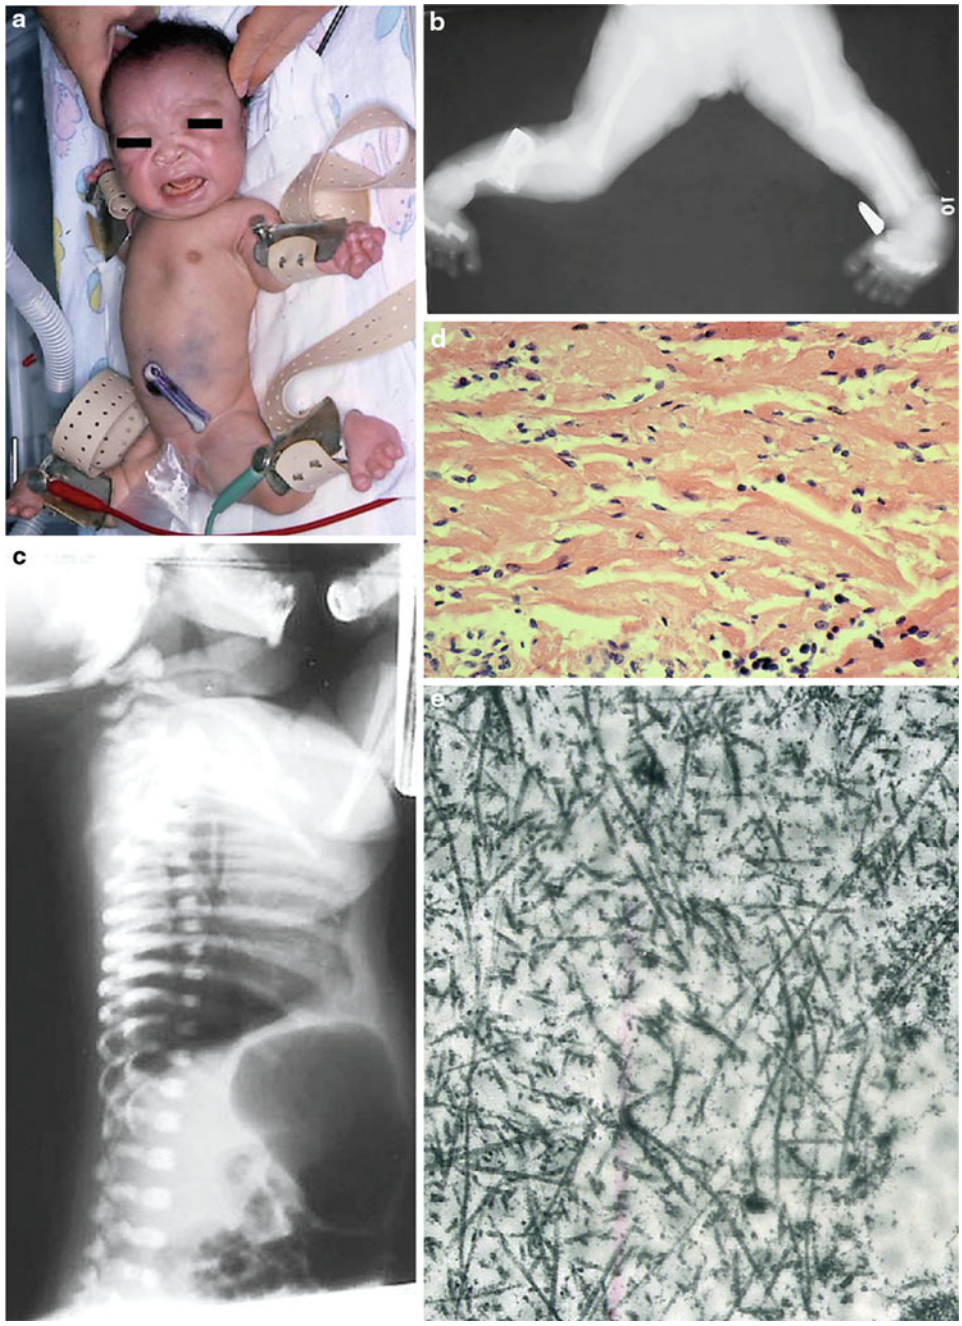

Fig. 5 (**a**–**e**) An infant with lethal, Larsen-like syndrome (**a**) showing characteristic flat facies (prominent forehead, hypertelorism, depressed nasal bridge, micrognathia, and cleft palate); multiple dislocations involving shoulders, elbows, wrists, knees, ankles, and hips; and talipes equinovarus. The radiographs showed anterior dislocation of the tibia, lateral dislocation of the hips, hypoplasia of fibulae and of distal ends of the fibulae (**b**), cervical kyphosis with the apex at C4, and coronal clefts of the lower lumbar vertebrae (**c**). Necropsy showed tracheomalacia. The dermal histology showed relatively broad and smudgy collagen bundles (**d**). The electron microscopic study (**e**) showed a relative increase in small short fibers with a reduction of mature collagen fibers in the hyaline cartilage of the trachea (Chen et al. 1982)

LEOPARD Syndrome

Contents

The acronym "LEOPARD syndrome," coined by Gorlin et al. (1969), is derived from clinical features which include *l*entigines, *e*lectrocardiographic conduction abnormalities, *o*cular hypertelorism, *p*ulmonary stenosis, *a*bnormal genitalia, growth *r*etardation, and sensorineural *d*eafness. It is also known as multiple lentigines syndrome and Moynahan syndrome and classified as a cardiocutaneous syndrome of neural crest origin (Moynahan 1970).

Synonyms and Related Disorders

Cardiocutaneous lentiginosis syndrome (Jóźwiak et al. 1996); Cardiocutaneous syndrome of neural crest origin (Nordlund et al. 1973); Cardiomyopathic lentiginosis; Moynahan syndrome; Multiple lentigines syndrome; RASopathies

Genetics/Basic Defects

1. Inheritance:
   1. An autosomal dominant disorder with high penetrance and variable expressivity (Char 1971; Seuanez et al. 1976; Begić et al. 2014)
   2. Multiple siblings affected with the lack of features of LEOPARD syndrome in the parents may represent mosaicism of the germinal cells or, more probably, incomplete penetrance of the gene (Jóźwiak et al. 1998)
   3. Allelic to Noonan syndrome (Sarkozy et al. 2003)
2. Caused by mutations in the protein tyrosine phosphatase nonreceptor type 11 (*PTPN11*) gene (Legius et al. 2002), mapped on chromosome 12q22-qter, which is known to be mutated in the Noonan syndrome (Digilio et al. 2002):
   1. Worldwide recurrent missense mutation (c.836A/G; p.Tyr279Cys) in exon 7: associated with high phenotypic diversity (Nemes et al. 2015).
   2. Missense mutation (1403C → T; Thr468Met) in exon 12.
   3. Both mutations affect the PTPN11 phosphotyrosine phosphatase domain, which is involved in <30% of the Noonan syndrome *PTPN11* mutations.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_146

3. LEOPARD syndrome is caused in 85% of patients by a heterozygous missense mutation in the *PTPN11* gene leading to reduced SHP2 phosphatase activity. Given the implication of germline, RAS–mitogen-activated protein kinase mutations in RASopathies and tumorigenesis, the link between LEOPARD syndrome and multiple granular cell tumors could be explained by gene mutation within this signaling pathway (Aragüés et al. 2016).
4. Also can be caused by mutations in the V-RAF-1 murine leukemia viral oncogene homologue 1 (*RAF1*) gene (mapped on chromosome 3p25).
5. RASopathies or RAS/mitogen-activated protein kinase (MAPK) syndromes: a group of phenotypically overlapping syndromes caused by germline mutations that encode components of the RAS/MAPK signaling pathway. Recently, novel gene variants, including *RIT1*, *RRAS*, *RASA2*, *A2ML1*, *SOS2*, and *LZTR1*, have been shown to be associated with RASopathies, further expanding the disease entity. These disorders include (Aoki et al. 2008, 2016):
    1. Neurofibromatosis type I
    2. Legius syndrome
    3. Noonan syndrome
    4. Noonan syndrome with multiple lentigines (formerly called LEOPARD syndrome)
    5. Costello syndrome
    6. Cardiofaciocutaneous (CFC) syndrome
    7. Noonan-like syndrome
    8. Hereditary gingival fibromatosis
    9. Capillary malformation–arteriovenous malformation

Clinical Features

1. Cutaneous features (Sarkozy et al. 2008; Abdelmalek et al. 2002):
    1. Lentigines:
        1. Dark brown irregularly shaped macules ranging from pinpoint size to 5 cm in diameter
        2. Noted in infancy or childhood
        3. Continue to increase in number until puberty
        4. Primarily on the face, neck, and upper trunk with some involvement of the extremities
        5. Less commonly on the palms, soles, genitalia, iris, and sclera, but sparing oral mucosa
        6. Generalized symmetric distribution of lentigines
    2. Other cutaneous abnormalities (Jóźwiak et al. 1996):
        1. Café au lait spots (38% of patients)
        2. Café noir spots (a term proposed by Gorlin et al. (1971)): by analogy to café au lait spots to describe larger and more pigmented lentigines in patients with LEOPARD syndrome (Bujaldón 2008)
        3. Melanoma
        4. Localized hypopigmentation
        5. Interdigital webs
        6. Dermatoglyphic abnormalities
        7. Onychodystrophy
        8. Multiple granular cell myoblastomas
        9. Steatocystoma multiplex
        10. Hyperelastic skin
2. Noncutaneous features:
    1. Cardiac anomalies (Gorlin et al. 1971):
        1. Valvular pulmonary stenosis (40% of cases) and hypertrophic cardiomyopathy: the most frequent anomalies observed (Coppin and Temple 1997; Martinez-Quintana and Rodriguez-González 2012)
        2. Subaortic stenosis
        3. Subpulmonic stenosis
        4. Mitral valve involvement
        5. Left and right ventricular outflow tract obstructions
        6. Atrial septal defect
        7. Atrial myxomas
        8. Variable conduction abnormalities:
            1. Benign asymptomatic arrhythmia
            2. Malignant arrhythmias resulting in sudden cardiac death
        9. Cardiac symptoms:
            1. Dyspnea on exertion
            2. Congestive heart failure

3. Paroxysmal atrial tachycardia
4. Sudden death
5. Death at cardiac surgery

2. Noncardiac anomalies:
   1. Craniofacial features:
      1. Ocular hypertelorism (25%)
      2. Epicanthic folds
      3. Ptosis
      4. Mandibular prognathism
      5. High-arched palate
      6. Dental abnormalities
      7. Low-set posteriorly rotated ears
   2. Skeletal abnormalities:
      1. Joint hypermobility
      2. Short webbed neck
      3. Winging of the scapula
      4. Pectus excavatum and carinatum
      5. Rib anomalies
      6. Cervical spine fusion
      7. Syndactyly
      8. Scoliosis
   3. Genitourinary abnormalities (26% of cases):
      1. A small penis
      2. Cryptorchidism
      3. Hypospadias
      4. Ovarian disorders
   4. Neurologic abnormalities:
      1. Learning disability
      2. Mild mental retardation
      3. Sensorineural deafness
      4. Nystagmus
      5. Seizures
      6. Hyposmia
      7. Mild atrophy of the brain
      8. Neuropathic pain associated with hypertrophic roots and plexi (Spatola et al. 2015)
   5. Retardation of growth (short stature)
   6. Delayed puberty
3. Diagnostic criteria (Voron et al. 1976):
   1. Multiple lentigines plus two other features
   2. Immediate family member with LEOPARD syndrome plus at least three other features in the absence of lentigines
4. Although the diagnosis can be suspected clinically, confirmation requires the identification of a heterozygous germline mutation occurring in the first and third coding exons in the proto-oncogene *HRAS* (Aoki et al. 2005; Gelb and Tartaglia 2015).
5. Differential diagnosis with other neuro-cardio-facial-cutaneous syndromes (RASopathies) (Kalev et al. 2010; Santoro et al. 2014; Aoki et al. 2016):
   1. Noonan syndrome (Please see chapter on "▶ Noonan Syndrome")
   2. Noonan syndrome with multiple lentigines (NSML) (van den Berg et al. 2016):
      1. Rare association with multiple giant cell lesions (MGCL).
      2. A mutation p.Thr468Met in the *PTPN11* gene mutation.
      3. Despite a different molecular pathogenesis and effect on the RAS/MEK pathway, NSML shares the development of MGCL, with other RASopathies.
   3. Costello syndrome:
      1. Causative genes: *HRAS*, *KRAS*, *BRAF*, and *MEK1*
      2. Autosomal dominant
      3. Phenotype:
         1. Short stature
         2. Congenital heart defect
         3. Characteristic facies with more coarse features
         4. Mental retardation: more severe
         5. Distinctive skin involvement – curly, sparse hair, loose soft skin, and papillomata
   4. Cardio-facio-cutaneous syndrome:
      1. Causative genes: *KRAS*, *BRAF* (most frequent, 5–75% of cases), *MEK1*, and *MEK2*
      2. Autosomal dominant, de novo
      3. Phenotype:
         1. Short stature.
         2. Congenital heart defect.
         3. Cardiomyopathy.
         4. Characteristic facies.
         5. Mental retardation: more severe.
         6. Distinctive features: hyperkeratotic dry skin and sparse, curly hair.
         7. Phenotype overlaps most with Noonan syndrome, but facial appearance tends to be coarse.

8. Cardiac problems overlap mostly with LEOPARD syndrome.
5. Neurofibromatosis type 1-like syndrome
6. Costello syndrome (Martinez-Quintana and Rodriguez-González 2012):
    1. Clinical features:
        1. Neonatal atrial arrhythmias
        2. Ulnar deviation
        3. Excess skin which darkens with age
        4. Papillomata, usually after the age of 2 years
        5. Childhood cancers, particularly embryonic rhabdomyosarcoma and bladder carcinoma, the latter typically from teenage years onward (Kerr et al. 2006)
6. Although each one of the RASopathies exhibits typical phenotypic features, they share many clinical signs, including craniofacial anomalies, congenital heart defects, short stature, varying degrees of neurocognitive impairment, cutaneous and musculoskeletal abnormalities, and predisposition to malignancies (Santoro et al. 2014). Thus, differential diagnosis can represent a clinical dilemma, particularly among neurofibromatosis 1, Noonan syndrome, LEOPARD syndrome, and neurofibromatosis type 1-like syndrome.

Diagnostic Investigations

1. ECG abnormalities (Torres et al. 2004):
    1. Left axis deviation
    2. Bundle branch block
    3. Abnormal P wave
    4. Prolongation of the P-R interval
    5. Right or left ventricular hypertrophy
    6. Infarction patterns
    7. Ischemic patterns with nonspecific ST and T wave changes
    8. Isolated ventricular ectopic beats
    9. Ventricular fibrillation
    10. Bradycardia
    11. Paroxysmal atrial fibrillation
2. Careful cardiac assessment including echocardiography.
3. Hearing tests.
4. Histology of lentigines:
    1. Large membrane-bound accumulations of melanin granules within the Langerhans cells (Fryer and Pope 1992)
    2. Giant melanosomes rarely seen within keratinocytes and melanocytes
5. LEOPARD syndrome in the first months of age can be suspected in patients presenting with HCM, characteristic facial features, and café au lait spots, but the clinical diagnosis should be confirmed by molecular testing of *PTPN11* gene (Digilio et al. 2006).
6. Molecular testings (blood, chorionic villi, or amniotic fluid samples) can be used to confirm the diagnosis (Martinez-Quintana and Rodriguez-González 2012). The following order of testing is recommended:
    1. *PTPN11* sequence analysis of coding exons 7, 12, and 13 (these exons encompass all the codons of the *PTPN11* gene identified to be mutated in LEOPARD syndrome thus far)
    2. If no mutation is identified, sequence analysis of coding exons 6, 13, and 16 of *RAF1* and coding exons 6 and 11–17 of *BRAF*
    3. If no mutation is identified, sequence analysis of the remaining coding exons of *PTPN11*, *RAF1*, and *BRAF* (Gelb and Tartaglia 2015).
7. Diagnosis of Noonan syndrome and related disorders using target next-generation sequencing (Lepri et al. 2014), enabling a prompt diagnosis especially for those patients with mild, nonspecific, or atypical features, in whom the detection of the causative mutation usually requires prolonged diagnostic timings when using standard routine.

Genetic Counseling

1. Recurrence risk:
    1. Patient's sib: low unless a parent has the syndrome (possibility of germline mosaicism exists)
    2. Patient's offspring: 50%
2. Prenatal diagnosis (Gelb and Tartaglia 2015):
    1. Available clinically by mutation analysis of *PTPN11*, *RAF1*, *BRAF*, or *MAP2K1* genes

on fetal DNA obtained by amniocentesis or CVS, provided the disease-causing allele has been identified in an affected family member.
2. Preimplantation genetic diagnosis (PGD) may be available for families in which the disease-causing mutation has been identified.

3. Management:
1. Avoid strenuous physical exercise when outflow tract obstruction or significant cardiac dysrhythmias are present.
2. β-Adrenergic receptor or calcium channel blocking agents to reduce cardiac outflow tract obstruction and adrenergic responsiveness.
3. Amiodarone treatment in cases of life-threatening ventricular ectopy.
4. Severe arrhythmias: the most common perioperative complications (Yeoh et al. 2014).
5. Surgery may be needed to relieve severe cardiac outflow tract obstruction.
6. Surgery for cryptorchidism or severe skeletal deformity.
7. Hearing aids for sensorineural deafness.
8. Dermabrasion for cosmetic correction on the face.

Lesch-Nyhan Syndrome

Contents

In 1964, Lesch and Nyhan provided the first detailed clinical description of Lesch-Nyhan syndrome with a report of two brothers with hyperuricemia and a characteristic neurobehavioral syndrome that included motor dysfunction and self-injurious behavior. The prevalence of the syndrome is estimated to be approximately 1:380,000.

Synonyms and Related Disorders

Hypoxanthine-guanine phosphoribosyltransferase 1 deficiency; Lesch-Nyhan disease

Genetics/Basic Defects

1. Inheritance: X-linked recessive
2. Enzymatic defect (Jinnah and Friedman 2001; Jinnah 2013)
    1. Caused by deficiency of the enzyme hypoxanthine-guanine phosphoribosyltransferase (HPRT), which catalyzes the conversion of hypoxanthine to inosine monophosphate and guanine to guanine monophosphate in the presence of phosphoribosyl pyrophosphate
    2. Three major clinical elements associated with Lesch-Nyhan syndrome
        1. Overproduction of uric acid
        2. Neurologic disability
        3. Behavioral problems
3. Hypoxanthine-guanine phosphoribosyltransferase gene (*HPRT1*) (Jinnah et al. 2000)
    1. Mapped to chromosome Xq26-q27.2
    2. The only gene known to be associated with Lesch-Nyhan syndrome
    3. Heterogeneous mutations
        1. Single base substitutions
        2. Deletions
        3. Insertions
        4. Substitutions
4. Heterogeneity of clinical phenotype (Sarafoglou et al. 2010)
    1. An approximately inverse relationship exists between HPRT enzyme activity measured in intact cells and clinical severity (Page et al. 1981; Puig et al. 2001).
    2. Affected patients with classic Lesch-Nyhan disease, the most severe and frequent form, have the lowest HPRT enzyme activity (<1.5% of normal) in intact cultured

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_147

fibroblasts, and the patients display the full spectrum of clinical abnormalities.
3. Patients with partial HPRT deficiency, designated as Lesch-Nyhan variants (LNVs), have HPRT enzyme activity ranging from 1.5% to 8.0% (Nyhan 2008).
4. Individuals with the intermediate form of LNV (also known as neurologic variants) have a variable clinical phenotype and, in most cases, are neurologically indistinguishable from patients with Lesch-Nyhan disease (Puig et al. 2001; Nyhan 2009).
5. However, they do not have self-injurious behaviors, and their intelligence is normal or near normal. The least-affected patients with LNV have residual HPRT enzyme activity exceeding 8%, and their only manifestations have been attributed to hyperuricemia and include gout, hematuria, and nephrolithiasis.
6. There is another LNV, HPRT Salamanca, that is characterized by spastic gait, mental retardation, and skeletal abnormalities (Nyhan 2008; Page et al. 1987).

5. Pathogenesis
   1. Metabolic basis of overproduction of uric acid: results from changes in the regulation of purine synthesis and degradation (Nyhan 1997).
   2. Pathogenesis of neurologic and behavioral features remains incompletely understood. Growing evidence suggests that these features result from dysfunction of the dopamine transmitter systems of the basal ganglia (Baumeister and Frye 1985).

Clinical Features

1. Normal prenatal and perinatal course.
2. Early developmental milestones (Nyhan 1973, 1976, 1978).
   1. Hypotonia and developmental delay: most common presenting features evident by 3–6 months of age
   2. Failure to reach normal motor milestones, such as delayed in crawling, sitting, and walking
3. Within the first few years (Watts et al. 1982)
   1. Extrapyramidal involvement
      1. Dystonia
      2. Choreoathetosis
      3. Opisthotonus
      4. Ballismus
   2. Pyramidal involvement
      1. Spasticity
      2. Hyperreflexia
      3. Extensor plantar reflexes
      4. Ankle clonus
      5. Scissoring of the legs
4. Between 2 and 3 years
   1. Impaired cognition
      1. Moderate to severe mental retardation in most patients
      2. Varying degree of impairment
      3. Difficult to obtain adequate assessments of cognitive abilities
   2. Compulsive behavioral disturbances
      1. Aggressiveness
      2. Vomiting
      3. Spitting
      4. Coprolalia
      5. Copropraxis
      6. Manipulative behavior
   3. Persistent self-injurious behavior: a hallmark of the disease
      1. Biting the fingers, hands, lips, and buccal mucosa
      2. Banging the head or limbs
5. Overproduction of uric acid: hyperuricemia-related renal and articular symptoms. These symptoms are present in all HPRT-deficient patients and are not related to the severity of the enzyme defect (Torres and Puig 2007; Torres et al. 2012b).
   1. Uric acid crystalluria noted as orange crystals in the diaper during the first weeks of life.
   2. Deposition of uric acid crystals or calculi in the kidneys, ureters, or bladder.
   3. Leading to nephrolithiasis, obstructive uropathy, and azotemia if untreated.

4. Gouty arthritis develops later in the course of the disease.
5. All characteristic findings associated with gout may be present (acute arthritis, tophi, nephrolithiasis or urolithiasis, and renal disease). However, nowadays, allopurinol treatment prevents the development of gouty manifestations.

6. Other features
   1. Delayed growth and puberty
   2. Testicular atrophy in most affected males
   3. Associated orthopedic problems
      1. Hip subluxation or dislocation
      2. Fractures
      3. Autoamputation
      4. Infections
      5. Minor scoliosis
      6. Contractures
   4. Nephrocalcinosis and renal failure reported in two familial cases (Vargiami et al. 2016)
7. Life expectancy
   1. Most surviving into the second or third decade of life if properly managed
   2. No evidence suggesting disease progression over time
   3. Complications
      1. Aspiration pneumonia
      2. Chronic nephrolithiasis
      3. Renal failure
      4. Sudden unexpected death
8. The classical phenotype of Lesch-Nyhan disease (Fu et al. 2014a, b)
   1. Overproduction of uric acid
      1. Resulting in elevated serum levels of uric acid and increased excretion of uric acid in the urine
      2. Because uric acid is near its limit of solubility in the body, it tends to precipitate in vulnerable body regions. Precipitation in the urogenital system, where it is concentrated by excretion, results in nephrolithiasis and associated problems such as urinary obstruction and renal failure.
      3. Precipitation in the subcutaneous tissues due to temperature gradients leads to solid masses known as tophi.
      4. Precipitation in the joints of the hands and feet with subsequent inflammation elicited by phagocytosis of the crystals by polymorphonuclear cells leads to gouty arthritis.
   2. Neurobehavioral phenotype
      1. Severe and recurrent self-injurious behaviors: self-biting, self-hitting, eye poking, and others.
      2. Severe motor handicap resembling dystonic cerebral palsy.
9. The milder Lesch-Nyhan variants (Fu et al. 2014a, b)
   1. Some clinical features are absent or sufficiently mild that they may escape clinical detection.
   2. The mildest clinical phenotype of hypoxanthine-guanine phosphoribosyltransferase (HGprt)-related hyperuricemia (HRH) includes only overproduction of uric acid and its associated problems. These patients do not have clinically overt neurological or behavioral abnormalities, although many have minor motor clumsiness or mild cognitive impairments that can be detected with appropriate neurological or psychometric testing.
   3. In between the severe Lesch-Nyhan disease phenotype and the mild HRH phenotype is a broad spectrum of phenotypes with varying degrees of neurological and behavioral abnormalities known as HGprt-related neurological dysfunction.
10. Lesch-Nyhan syndrome in females
    1. Extremely rare
    2. Female carriers
       1. Generally considered to be asymptomatic
       2. Have increased uric acid excretion
       3. Develop symptoms of hyperuricemia in later years
    3. Affected females
       1. Affected carrier females: considered to have nonrandom X chromosome inactivation or skewed inactivation of the normal *HPRT1* allele.

2. The first female case reported was caused by a microdeletion of the maternally derived *HPRT* gene and nonrandom inactivation of the paternally derived X chromosome.
3. Two additional cases were caused by a point mutation in one allele and markedly reduced mRNA expression from the other allele.

Diagnostic Investigations

1. EEG: nonspecific changes of slowing or disorganization (Nicklas et al. 2010).
2. CT and MRI of the brain: nonspecific changes of atrophy of the basal ganglia or cerebrum.
3. Positron emission tomography to demonstrate a selective decrease of 50–70% in dopamine transporters in the caudate and putamen.
4. Hyperuricuria or hyperuricemia (serum uric aids concentration >8 mg/dL): often present but not sensitive or specific enough for diagnosis.
5. 24-h uric acid excretion (>20 mg/kg): characteristic but not diagnostic.
6. Uric acid to creatinine ratio >2.0: characteristic for patients under 10 years of age.
7. In males: hypoxanthine-guanine phosphoribosyltransferase enzyme activity <1.5% of normal enzyme activity in cells from any tissue (blood, cultured fibroblasts, or lymphoblasts): establishes the diagnosis.
8. In females: measurement of HPRT enzyme activity for carrier detection is technically demanding and not widely used. Measurement of HPRT enzyme activity on hair bulbs from women at risk has had both false-positive and false-negative results.
9. Molecular genetic testing of the *HPRT1* gene (Nyhan et al. 2014; Torres and Puig 2007).
    1. Purposes
        1. To define the mutation in the affected males
        2. To determine carrier status in at-risk females: requires prior identification of the disease-causing mutation in the family (Alford et al. 1995)
    2. Sequence analysis or mutation scanning to detect *HPRT1* mutations in males affected with Lesch-Nyhan syndrome: available on clinical basis
    3. Deletion/duplication analysis
        1. To detect exonic or whole-gene deletions
        2. Between 21% and 24% of mutations in *HPRT1* are large deletions that cannot be detected in females by sequence analysis

Genetic Counseling

1. Recurrence risk
    1. Patient's sib
        1. When the mother is not a carrier: not increased unless the mother has germ line mosaicism in which case there is an undetermined, but real, risk of having future affected sons or carrier daughters
        2. When the mother is a carrier
            1. A 25% risk of having an affected male
            2. A 25% risk of having a carrier female
            3. A 50% risk of having an unaffected male or female
    2. Patient's offspring
        1. Severely affected males: not surviving to reproductive age
        2. Less severely affected males: all of his daughters are obligatory carriers and none of his sons affected
2. Prenatal diagnosis available to at-risk pregnancies (Torres and Puig 2007; Liu et al. 2015).
    1. Fetal sex determination by amniocentesis or CVS
    2. Confirmation of a previously known *HPRT1* disease-causing mutation in a male fetus
        1. Perform HPRT enzyme activity
        2. Perform molecular genetic testing
    3. Assay of HPRT enzyme activity in cultured amniocytes or chorionic villus cells (Graham et al. 1996): the method of choice if the *HPRT1* mutation has not been identified in the family
    4. Carrier and prenatal diagnosis of Lesch-Nyhan disease due to a defect in HPRT

gene expression regulation (Torres et al. 2012a)
5. Preimplantation genetic diagnosis possible for a previously characterized disease-causing mutation (Ray et al. 1999)

3. Management (Seegmiller 1968; Crawhall et al. 1972; Nicklas et al. 2010)
   1. Hyperuricemia
      1. Control hyperuricemia to reduce the risk of nephropathy, nephrolithiasis, and gouty arthritis.
      2. Allopurinol
         1. To block the conversion of oxypurines into uric acid
         2. To prevent uric acid accumulation and subsequent arthritic tophi, renal stones, and nephropathy
         3. Has no effect on behavioral and neurologic symptoms
   2. Renal stones
      1. Lithotripsy
      2. Surgery
   3. Neurologic dysfunction
      1. No medication known to be consistently effective in controlling the extrapyramidal motor features
      2. Baclofen or benzodiazepine for spasticity
   4. Neurobehavioral symptoms
      1. No effective intervention available
      2. Use behavioral modification techniques
      3. Control self-injurious behavior
         1. Requires physical restraints.
         2. Removal of teeth.
         3. A noninvasive approach with a special appliance fabricated for the prevention of damage to oral and perioral soft tissues (Fardi et al. 2003).
         4. Carbamazepine to attenuate the behavioral manifestations.
   5. Surgery for orthopedic problems (Sponseller et al. 1999).
   6. Bone marrow transplantation or red blood cell transfusions do not significantly ameliorate the neurologic disorder.
   7. Successful unrelated umbilical cord blood transplantation in Lesch-Nyhan syndrome (Kállay et al. 2012).

Lethal Multiple Pterygium Syndrome

Contents

Lethal multiple pterygium syndrome (LMPS) is a lethal hereditary disorder characterized by a distinct constellation of multiple anomalies, consisting of multiple pterygia, flexion contractures of multiple joints, characteristic facial appearance, cystic hygroma, hydrops, and pulmonary and cardiac hypoplasia.

Synonyms and Related Disorders

Chen syndrome; Gillin-Pryse-Davis syndrome; Herva syndrome; Lethal fetal akinesia deformation sequence syndrome (FADS); Multiple pterygium syndrome/Escobar syndrome (Chen et al. 1980); Van Regemorter syndrome

Genetics/Basic Defects

1. Inheritance: possible heterogeneity
    1. Autosomal recessive inheritance
    2. Possible X-linked recessive inheritance (Tolmie et al. 1987; Meyer-Cohen et al. 1999)
2. Mutations in genes encoding components of the neuromuscular junction (NMJ) have been described in FADS and/or LMPS (Kariminejad et al. 2016a). This includes:
    1. Mutations in the genes *CHRNA1* (Michalk et al. 2008), *CHRND* (Michalk et al. 2008), and *CHRNG* encoding the alpha, delta, and gamma subunits of the acetylcholine receptor (AChR), respectively.
    2. Mutations in *RAPSN* (Vogt et al. 2008), encoding a postsynaptic protein that connects and stabilizes AChR at the NMJ, *DOK7* (Vogt et al. 2009), and recently identified *MuSK* (Wilbe et al. 2015), encoding muscle skeletal receptor tyrosine kinase, have been associated with LMPS and/or FADS.
3. Lethal multiple pterygium syndrome: the extreme end of the *RYR1* spectrum (Kariminejad et al. 2016b)
    1. *RYR1* encodes the skeletal muscle isoform ryanodine receptor 1, an intracellular calcium channel with a central role in muscle contraction.
    2. Mutations in *RYR1* have been associated with congenital myopathies, which form a continuous spectrum of pathological features including a severe variant with onset in utero with fetal akinesia and arthrogryposis.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*,
DOI 10.1007/978-1-4939-2401-1_148

3. Germline mutations in *RYR1* are associated with fetal akinesia deformation sequence/ lethal multiple pterygium syndrome (McKie et al. 2014).
4. Classification by Hall et al. (1982), Hall (1984), Froster et al. (1997), and Entezami et al. (1998)
   1. Based on the following concomitant abnormalities
      1. Age of onset of intrauterine growth retardation
      2. Timing and extent of neck swelling
      3. Presence or absence of bony fusions and bone modeling errors
   2. Type I (Gillin-Pryse-Davis syndrome) (Gillin and Pryse-Davis 1976)
      1. Multiple pterygia
      2. Pulmonary hypoplasia
      3. Genital anomalies
      4. Facial anomalies
      5. Strongly flexed extremities with a reduced muscle mass
   3. Type II (Chen syndrome) (Chen et al. 1984)
      1. Multiple pterygia
      2. Hygroma colli
      3. Facial anomalies
      4. Shortened extremities
      5. Undermodeled long bones
      6. Cartilaginous fusion of joints and bony fusion of the spinous processes of the vertebrae
      7. Polyhydramnios
      8. Hypoplastic lungs and heart
      9. Diaphragmatic hernia
   4. Type III (van Regemorter syndrome) (Van Regemorter et al. 1984)
      1. Multiple pterygia
      2. Pulmonary hypoplasia
      3. Facial anomalies
      4. Thin extremities with reduced muscle mass
      5. Fusions of the long tubular bones
   5. Type IV (Herva syndrome) (Herva et al. 1985)
      1. Multiple pterygia
      2. Degeneration of the anterior horn cells of the spinal cord
      3. Found particularly in Finland
5. Classification by de Die-Smulders et al. (1990a)
   1. Early LMPS
      1. A group with presumed genetic heterogeneity
      2. Lethality in the second trimester
      3. Hydrops fetalis
      4. Cystic hygroma
   2. Late LMPS
      1. Survival into the third trimester
      2. Absence of fetal hydrops
   3. Finnish-type LMPS
      1. Fetal hydrops from the 15th gestational week
      2. Lethality at average gestation of 29 weeks
      3. Occasional pterygia of the neck and elbows
      4. Distinct neuropathologic findings
6. Pathogenesis (Moerman et al. 1990)
   1. Combination of the following two sequences:
      1. Fetal akinesia deformation sequence
         1. Resulting from myoneural dysfunction (generalized amyoplasia) and/or intrauterine growth constraint leading to fetal akinesia
         2. Fetal akinesia, in turn, leading to growth retardation, pulmonary hypoplasia, short umbilical cord, limb positional defects, and facial anomalies
      2. Jugular lymphatic obstruction sequence: delay in development of the connection between jugular lymph sacs and the internal jugular vein resulting in dilatation of tributary lymphatics and peripheral lymphedema
   2. Fragile collagen proposed as a possible pathogenesis (Hartwig et al. 1989; Gericke 1991)
7. A gene responsible for some cases of lethal MPS (LMPS) and Escobar variant of MPS has now been identified.
   1. Caused by mutation in the *CHRNG* gene (Hoffmann et al. 2006; Morgan et al. 2006)
   2. Caused by mutations in the *CHRNA1* and *CHRND* genes (Michalk et al. 2008)

Clinical Features

1. Prenatal history
   1. Nonimmune fetal hydrops
   2. Diminished fetal activity
   3. Maternal hydramnios
   4. Often presented with fetal demise
2. Characteristic facial features
   1. Ocular hypertelorism
   2. Antimongoloid slant of the palpebral fissures
   3. Epicanthal folds
   4. Markedly flattened nasal bridge with hypoplastic nasal alae
   5. Micrognathia
   6. Lethal pterygium syndrome with facial clefting (Bartsocas-Papas syndrome) (Francesco and Nicola 1988; Turnpenny and Hole 2000)
   7. Apparently low-set malformed ears
3. Neck
   1. Short
   2. Cystic hygroma
4. Chest
   1. Small chest
   2. Hypoplastic lungs
   3. Hypoplastic heart
5. Multiple pterygia
   1. Symmetrical
   2. Sites
      1. Chin-to-sternum
      2. Cervical
      3. Axillary (Froster-Iskenius et al. 1988)
      4. Antecubital
      5. Crural
      6. Popliteal
6. Other limb anomalies
   1. Multiple contractures: always present
   2. Camptodactyly
   3. Calcaneovalgus foot deformities
7. Gastrointestinal anomalies
   1. Intestinal malrotation
   2. Short bowel
   3. Thin colon
   4. Colonic atresia
   5. Absent vermiform appendix
8. Genitourinary anomalies
   1. Hydronephrosis
   2. Unilateral renal dysplasia
   3. Cryptorchidism
9. Other associated anomalies
   1. Kyphoscoliosis
   2. Near-complete absence of diaphragmatic muscle
   3. Aortic coarctation
   4. Absent abdominal wall muscle
   5. Adrenal hypoplasia
   6. Short umbilical cord
   7. Rare cerebral anomalies
      1. Hydranencephaly (Mbakop et al. 1986)
      2. Holoprosencephaly
      3. Dilated ventricles with intracerebral cyst

Diagnostic Investigations

1. Radiography
   1. Craniofacial abnormalities
      1. Scalp edema
      2. Microbrachycephaly
      3. Flattened mandibular angle
   2. Hypoplasia and undermodeling of the bones
      1. Thin crowded ribs
      2. Markedly hypoplastic scapulae
      3. Hypoplastic iliac wings, ischia, and pubic bones
      4. Lack of normal curvature at the cervicothoracic junction
   3. Bony fusion
      1. Marked bony fusion of posterior spinous processes
      2. Radioulnar synostosis
2. Histologic studies of the skeletal system
   1. Cartilaginous and bony fusion of the spinous processes
   2. Fusion of epiphyseal cartilages of distal humerus and proximal ulna
   3. Poorly developed joint space
   4. An abnormal growth plate
   5. Weak safranin staining of the resting cartilages
   6. Placenta (Brink et al. 2003)
      1. Scalloped chorionic villi
      2. Intravillous trophoblast invaginations

7. Muscular and neural abnormalities (Spearritt et al. 1993; Cox et al. 2003)
3. Chromosome analysis: normal
4. Molecular diagnosis for *CHRNA1*, *CHRND*, *CHRNG*, *RAPSN*, *DOK7*, *MuSK*, and *RYR1* gene mutations (McKie et al. 2014; Kariminejad et al. 2016a)

Genetic Counseling

1. Recurrence risk
   1. Patient's sib
      1. Autosomal recessive inheritance: 25%
      2. X-linked recessive inheritance: 50% risk of having an affected brother if the mother is a carrier
   2. Patient's offspring: a lethal entity not surviving to reproductive age
2. Prenatal diagnosis by ultrasonography: possible (Isaacson et al. 1984; Hogge et al. 1985; Martin et al. 1986; Lockwood et al. 1988; de Die-Smulders et al. 1990b; Entezami et al. 1998; Sciarrone et al. 1998; Hertzberg et al. 2000)
   1. Nonimmune fetal hydrops
   2. Cystic hygroma
   3. Diminished fetal activity/absent limb movement
   4. Short and fixed limbs (multiple joint contractures with cutaneous webs)
   5. Maternal hydramnios
   6. Other ultrasonographically detectable anomalies
      1. Diaphragmatic hernia
      2. Scoliosis
      3. Pterygia
      4. Malformed ribs
   7. Ultrasonographic features at first trimester of pregnancy (Meizner et al. 1993; Chen et al. 2005; Gundogan et al. 2006)
      1. Cystic hygroma
      2. Generalized edema
      3. Ascites
      4. Markedly increased nuchal translucency
      5. No fetal movement/fetal posture (Anthony et al. 1993)
      6. Flexed upper and lower limbs
      7. Cutaneous webs across both elbow joints
      8. Hypoplastic left heart
3. Management: a lethal entity
