Eysenck, H. J.

NAVA R. SILTON, GABRIELLE IMMORDINO
Marymount Manhattan College, New York, NY, USA

Eysenck, Hans Jurgen (March 4, 1916–September 4, 1997) was a British psychologist of German origin who worked in a variety of areas, but is most known for his work on intelligence and personality.

Biographical Information

Hans Jürgen Eysenck was born on March 4, 1916, in Berlin, Germany. He was born to Eduard Anton Eysenck and Ruth Werner Eysenck; both were actors, who divorced when he was 2 years old. As the son of actors and celebrities, however, he was initially encouraged to pursue the field of acting. Eysenck was raised by his grandmother, but at age 18, after graduating high school, he fled the growing Nazi regime and resettled in England, where he studied psychology, pioneered English practice of clinical psychology, became a leading critic of Freud's theories, and developed his own behavioral genetics, intelligence, and personality theories.

Eysenck's early interests in life might have lead one to believe that he would devote his life to the study of psychology. However, he initially was drawn to the study of literature and history and hoped to declare his major as physics, but failed to meet the requirements for admission into the University of London. He only entered into a psychology program of persons in authority. Despite being indifferent to the subject at first, Eysenck grew to enjoy the field of psychology. He studied under the well-respected psychologist Sir Cyril Burt, an early advocate of statistical studies, and statistician Karl Pearson. Eysenck graduated from the University of London in 1938, where he also received his doctorate in 1940. He served as a research psychologist during World War II at an emergency hospital near London, used to treat mentally disturbed service personnel. Following the war, the psychologist worked for London's well-known hospital, Maudsley Hospital. Eysenck worked his way to the head of the hospital's psychology department in 1947 and in 1950, after relocating to the University of London; he was deemed head of the new psychiatric institute, which was located at Maudsley Hospital. Not only did he contribute his knowledge to psychology in Britain, he also worked as a visiting professor at the University of Pennsylvania and the University of California-Berkeley.

With respect to his family life, Eysenck's marriage to the former Margaret Malcolm Davies ended in divorce. Today, he is survived by his wife, the former Sybille Bianca Giulietta Rostal, whom he married in 1950 and who lives in London; by a daughter from his second marriage, Connie Eysenck of Bethesda; a son from his first marriage; three sons from his second marriage; and eight grandchildren.

Major Contributions

Eysenck was an incredibly prolific writer, who contributed significantly to a diverse array of psychological topics, including personality, intelligence theories, homosexuality, paranormal phenomena, causes of smoking-related illnesses, and the effects of behavioral therapy on cancer and heart disease (Mclaughlin 2000). Some of his many book publications included *The Structure of Human Personality* (1953), *Uses and Abuses of Psychology* (1953), *Sense and Nonsense in Psychology* (1956), *The Structure of Human Personality* (1960), *Handbook of Abnormal Psychology* (1960), *Manual of the Eysenck Personality Inventory* (1964, with Sybil Eysenck), *Fact and Fiction in Psychology* (1965), *The Biological Basis of Personality* (1967), *The Structure of Human Personality* (1970), *Race, Intelligence and Education* (1971), *The Psychological Basis of Ideology* (1978, with G. D. Wilson), and *The Transparent Man: How We See Psychologist* (1983, with Michael Eysenck). In addition, he also contributed articles to the “Encyclopedia of the Social Sciences” and in 1962, he founded and began a long stint as editor of the journal *Behavior Research and Therapy*. Eysenck spent decades as the head of the Psychology Department of the University of London’s Institute of Psychiatry.

Some of Eysenck’s most notable achievements include his significant criticism of psychotherapy, his meticulous measurement-based approach to the field of personality, his success in popularizing psychological concepts in the press, and finally his papers on human intelligence. With respect to his controversial stance on psychotherapy, he advocated behavioral approaches to therapy and argued that psychoanalysis may be no more successful than no treatment at all. In terms of personality, he believed that the “supertraits” of extroversion and neuroticism could account for all of human personality. Finally, with regard to intelligence, Eysenck believed that much of intelligence could be inherited. In fact, he experienced a large amount of criticism for supporting his student, Arthur Jensen’s controversial paper on racial differences in intelligence scores, but later moderated his perspectives to account more for environmental influences on intelligence.

Eysenck advocated Donald Hebb’s theory of human intelligence, which was expounded upon by Phillip Vernon. Eysenck proposed that culturally bounded tests and tests based on educational attainment were likely to encapsulate Hebb’s Intelligence B, while physiological measures like electroencephalography (EEG) and Positron Emission Tomography (PET) with Intelligence C, more of the biological substrate of human cognitive ability. Overall many perceive Eysenck as a controversialist, who was an incredibly productive writer in a plethora of areas related to psychological study.

F

Fite, Warner

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: March 5, 1867; Died: June 23, 1955.

Fite was born in Philadelphia and educated at Haverford College (AB 1889). He studied in the Philadelphia Divinity School for a year and then began graduate studies in philosophy at the University of Pennsylvania, where, after 2 years at Berlin and Munich, he obtained the Ph.D. in 1894. He then taught at Williams, at Chicago between 1897 and 1903, at Texas from 1903 to 1906, at Indiana from 1906 to 1915, and then at Princeton for the remainder of his career, where he held the Stuart Professorship in Ethics (Flewelling 1999).

Major Accomplishments/Contributions

For most of his career he was solely a professor of philosophy with a specialty in ethics, but earlier, in Chicago, he taught in psychology and was a laboratory assistant to James Angell. There, too, he came into contact with American functionalist psychology and sociology in its nascent stages. His connections with psychology came mostly during the first 2 decades of his career, centering around the concepts of consciousness and instinct and the views of William James and John Dewey. For the most part, Fite's work was tangential to psychology as he was more concerned with constructing a philosophy of individualism, but he provided several critiques which, viewed in historical perspective, constitute an alternative interpretation of psychology from within contemporary philosophy. Of these, the most apposite was his address to the

American Psychological Association in December 1902, *The Place of Pleasure and Pain in the Functional Psychology* (Fite 1903) an evaluation of the pleasure concept in psychology as it had developed in the leading American psychologies up to that time. Fite neatly capsulized the developing functionalist view and anticipated several later developments, including adaptation-level theory: he observed that getting to things through overcoming obstacles produces pleasure or pain, but attaining them causes them to vanish. Conflict, maintained Fite, is necessary for consciousness, and both pain and pleasure determined by their contexts within conflict. Very weak and very strong opponents may produce pain either of boredom in the former instance or frustration in the latter, while extremely strong opponents may produce resignation and withdrawal if one withdraws, or continued frustration and anger if the opposition is maintained internally. Fite took the view that conflict leading to activity is the "realest" of mental activities, and thus relegated pure sensory pleasure to a secondary role, its source to be determined through more fine-grained physiological analysis rather than through the analysis of the relation of agent and environment. Fite's most significant anticipation of future developments in this area was his conclusion that, due to its evanescent nature, pleasure cannot be an end in itself. This foreshadowed subsequent developments both in behavioristic formulations of action and emotion in which pleasure was considered epiphenomenal at best, and in which hedonism was exclusively based on pleasure contingent on action rather than on pleasure as a motivation toward action. Drive and tension states conceived as unpleasant became a more frequent formulation in psychology from this time forward and only very much later were they counterbalanced by views emphasizing the positive value of pleasurable activity in its own right and the context-dependent adaptation-level theorizing implicit in Fite's view. His main contribution after this was his

book *Individualism* (Fite 1911), in which he contended for the necessity of consciousness and individual decisions in the creation of society. Here again, Fite appeared prescient in incorporating psychological theories of development and intelligence into the argument: differences in intelligence, Fite claimed, militated against egalitarian conceptions of the “common good.” Against this Fite proposed an equitable distribution of social goods arrived at by negotiation between independent intellects. After this Fite’s activity was mainly philosophical, but he continued to critique aspects of psychology with which he disagreed, sometimes rather stridently (e.g., Fite 1915). After 1918, he turned away from specifically psychology-related concerns and developed a friendship with the Spanish writer and philosopher Miguel de Unamuno, with whose iconoclastic individualistic perspective Fite was in accord and whose novel *Niebla* (*Mist*) Fite translated in 1928.

Flourens, Pierre

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Flourens (1794–1867) was born in Maureilhan, France. Somewhat of a prodigy, he earned a medical degree at the age of 19 from the *Faculté de Médecine* at Montpellier. Subsequently, Flourens became a protégé of Georges Cuvier (1769–1832), the eminent scientific paleontologist and leader of the comparative method in organismal

biology. Under Cuvier’s guidance, Flourens began the work for which he is most recognized, comparative experimental brain research. Flourens articles on brain research in 1822 and 1823 were presented to the *Académie des Sciences* by Cuvier. These were then assembled together with a newly written preface to become Flourens’ first important book, *Recherches expérimentales sur les propriétés et les fonctions du système nerveux dans les animaux vertébrés* (1824). By 1828, with Cuvier’s sponsorship, Flourens was admitted to the *Académie des Sciences*, and upon Cuvier’s death in 1833 and by his recommendation, Flourens was appointed *secrétaire perpétuel* of the *Académie*. In 1840, he was elected over Victor Hugo to the *Académie de France*. Flourens soon had a professorship in comparative anatomy at the museum of the Jardin de Roi, and in 1855, he was appointed professor of natural history in the College de France where he remained until his death (Pearce 2008).

Major Accomplishments/Contributions

Flourens is best remembered for his pioneering brain-behavior research and for his vigorous opposition to phrenology which contributed to the demise of phrenology’s scientific acceptability. Among many others, Boring (1950) wrote that Flourens was the first comparative, experimental brain researcher, and he is usually credited with developing the method of experimental ablation. Like many alleged “firsts,” Flourens’ brain ablation research was well preceded by sophisticated experimental brain research by another Frenchman, François Pourfour du Petit (1664–1741) (Kruger and Swanson 2007; Neuberger 1981). Nevertheless, Flourens impact on brain physiology was such that Neuberger titled his book, *The Historical Development of Brain and Spinal Cord Physiology Before Flourens*, obviously regarding Flourens to be a transformational person in that field.

Flourens was a meticulous surgeon and a careful behavioral observer, and he used his ablation and observational skills on animals such as frogs, pigeons, and rabbits to determine some of the primary functions of the major regions of the brain. His behavioral observations did not include behavioral experiments, an innovation that was left to Shepherd Ivory Franz (1874–1933) in 1902. But Flourens’ pre- and

post-surgical observations enabled him to identify, reasonably correctly, the predominant functions of structures such as the cerebrum, midbrain colliculi, cerebellum, and medulla oblongata. Referring to the structures' predominant functions, he called them their *action propre*, but his overriding conclusion was that they acted in common (*action commune*); that is, most actions involve most if not all regions of the brain.

Armed with careful experimental data and with a conclusion (*action commune*) that clearly questioned the extreme localizationist views of brain function advocated by the phrenologists (notably Franz Josef Gall and J. G. Spurzheim), Flourens was in a unique position to attack phrenology. Such an attack was highly desired by the French in general, as no less than Emperor Napoleon Bonaparte encouraged Flourens in his research and criticism of phrenology. Phrenology was highly susceptible to criticism, as its methods were questionable and were tied to questionable functional categories, namely, a list of mental faculties that originated with philosophers, Thomas Reid and Dugald Stewart, who did not base them on brain research. Furthermore, the "brain" evidence used by Gall and Spurzheim was derived from bumps on, and recesses in, the skull. While, theoretically, that might have provided for legitimate correlational research (e.g., correlating bumps and faculties) the method was poorly employed. A single case of dubious validity might be the basis for assigning a particular faculty to a particular area of the brain. Before describing how Flourens criticism destroyed phrenology, it is only fair to say that Gall and Spurzheim made many legitimate contributions to neuroanatomy, that Gall's clinical observations led to the discovery of the location of the human speech in the cerebral cortex, and that despite the failure of phrenology, Gall's advocacy for localization of brain function continues to have significant impact.

Flourens attack on phrenology began with his 1824 book (see above). His careful experimental method compared to the deficiencies of phrenological research was obvious. Not only did Flourens provide a clearer basis for interpreting brain function, he provided a strongly contrasting theory of brain function. Additionally, due to the questionable practices of many phrenologists, phrenology developed the reputation of charlatanism. It became easy for the majority of medical and scientific researchers to disavow phrenology and all who were

associated with it. Flourens best remembered attack on phrenology was his book *Examen de la phrenology* (1842) where he displayed writing that was admirable in its precision, brevity, and clarity in identifying all that was wrong with phrenology. He also left a legacy of good advice to be followed in scientific writing. In the Preface he wrote, *J'ai voulu etre court. Il y a un grand secret pour etre court: c'est d'etre clair* (I wish to be brief. It is a grand secret to be brief is to be clear). Flourens' views prevailed until 1860 when localization of function experienced a revival following Ernst Auburtin's, Jean-Baptiste Bouillard's, and Paul Broca's discovery of the human speech center in the cerebral cortex.

Flournoy, Théodore

DAVID D. LEE

Amsterdam, The Netherlands

Basic Biographical Information

Flournoy was born August 15, 1854, in Geneva (Switzerland) and died on November 5, 1920, in Geneva (Switzerland). He studied medicine at the

University of Strasbourg as well as with Wilhelm Wundt in Leipzig (1879). As Professor of Psychology at the University of Geneva (1891–1919), he taught physiological and experimental psychology as well as the history and philosophy of science. An influential investigator of psychic and parapsychological phenomena, he is best known for establishing one of the first experimental psychological laboratories and an important psychological journal, the *Archives de Psychologie*.

Major Accomplishments/Contributions

Known primarily for his research into religious phenomena, Flournoy applied his scientific training to religious and parapsychological phenomena. After studying experimental psychology at Wilhelm Wundt's laboratory in Leipzig, Flournoy was convinced of the efficacy of Wundt's method. When he accepted the first position for experimental psychology at the University of Geneva in 1891, he ensured it was within a science rather than an arts faculty. He then established one of the first experimental psychology laboratories and the very first in Switzerland (1892) (Nicolas and Charvillat 1998). Flournoy published many important works on religion and psychology, including *Métapsychique et Psychologie* (1890), *Des Phénomènes de Synapsie* (1893), *Des Indes à la Planète Mars* (Flournoy 1900), *Les Principes de la psychologie religieuse* (1903), *Le Génie religieux* (1904). The third of these, translated into English as *From India to the Planet Mars* in 1901, caused a sensation upon publication, was enormously influential among psychologists, and remains one of the most remarkable books in the history of psychology. It deals with the late nineteenth-century popular medium Hélène Smith (pseudonym of Catherine Élise Müller) who claimed to have visited Mars and whose automatic writing and speaking in tongues (glossolalia) Flournoy took seriously, though not at face value. Ultimately, he rejected a spiritualist explanation arguing that her abilities were subconscious impersonations and that her fantastic imagination accounted for her linguistic legerdemain. Yet he did not doubt the existence of her telekinetic, telepathic, or clairvoyant abilities. This work influenced many psychologists' thinking about occult and parapsychology (e.g., Carl Jung). At his own expense, he and his cousin Edouard Claparède founded (1901) and

edited what is now one of the oldest journals in psychology: *Archives de Psychologie de la Suisse Romande* (since 1902, *Archives de Psychologie*). Flournoy was respected by many of the greatest psychologists and philosophers of his age such as William James (see Letters [LeClair 1966]). In 1909, he was President of the Congress of Experimental Psychology. His continued works include *Esprits et Médiums, Mélanges de Métapsychique et de Psychologie* (Flournoy 1911 and 2010, in English 1911, 2009), and *La Philosophie de William James* (1911; in English 1917, 2009), many of which continue to be issued in multiple languages.

Fordham University, History of Psychology at

MARK E. MATTSON

Fordham University, New York, NY, USA

Basic History of the Department

As proclaimed in its logo, Fordham University is the Jesuit University of New York. Psychology at Fordham has been influenced by Catholic and Jesuit traditions and by its location in New York City, with campuses in the Bronx and Manhattan. The university began in 1841 as St. John's College at Fordham, the Bronx, and a course in Catholic philosophical psychology was introduced in 1862. This mental philosophy course and its successors were required of all seniors up to the Class of 1966.

Two of the long-term teachers of this course were Rev. Joseph A. Murphy, S.J., one of the founders of the Psychology Department, and Rev. Joseph F. Donceel, S.J., Ph.D., a philosopher who integrated experimental psychology with Thomism and European phenomenology in his text *Philosophical Psychology* (Donceel 1961).

The first Physiological Psychology course was offered in 1899. This course was often taught at undergraduate and graduate levels by James J. Walsh, M.D., a Fordham alum who later served as Dean of the Medical School. He invited Carl Jung to lecture at Fordham in 1912; these lectures were published as *The Theory of Psychoanalysis* (Jung 1915). Walsh (1912) published one of the first psychotherapy texts, along with dozens of other books on medicine, history, science and the Church, and other topics.

As the college grew to become Fordham University, schools of medicine and law were founded in 1905, followed in 1916 by graduate schools of social service and education at the Woolworth Building in lower Manhattan. Both of these schools offered psychology courses and eventually departments of applied psychology: the Department of Psychology, Measurement, and Elementary School Supervision (1928) in Education, and the Department of Mental Hygiene in Social Services. Three strands were brought together in the founding of the graduate Department of Psychology in 1932 and 1933: a dry run took place under the auspices of philosophy in 1932, and the stand-alone department made its debut in 1933, founded by faculty from philosophy (Murphy and the chair, Rev. Walter G. Summers, S.J.), education (Robert T. Rock, Ph.D., Dorothea A. McCarthy, Ph.D., and Jack W. Dunlap, Ph.D.), and social services (Frank J. O'Brien, Ph.D., M.D. and Michael P. Lonergan, M.D.). Fordham was the fourth American Catholic university and the fourth New York state university to establish a graduate program in psychology. By 1939, the lines between education, philosophy, and psychology had been redrawn, and the Arts and Sciences graduate programs in psychology and philosophy had moved to the main campus in the Bronx. This led to the development of undergraduate majors, including psychology, in the undergraduate college in the Bronx. Today the Graduate School of Education offers degrees in educational psychology, counseling psychology, and school psychology at the Lincoln Center campus.

Among the founders, Rock earned his Ph.D. under Thorndike at Columbia in 1935, and moved from education to psychology to serve as chair from 1939 to 1949, except while serving in the Army's Psychological Research Unit 2 during World War II. McCarthy earned her Ph.D. in developmental psychology at Minnesota, moved to psychology in 1942, represented the department at the Boulder Conference in 1949, and developed the McCarthy Scales of Children's Abilities.

Since 1937, over 800 students have earned Ph.D.s in the Arts and Sciences Psychology Department, and there were more than 70 psychology dissertations in Graduate Education before 1957, beginning in 1923 with Sr. Mary Antonita Emge, S.S.N.D.: *Psychology of Attention and Its Application to Classroom Problems*. The department's first two Ph.D. students were Joseph A. Sherlock and Joseph F. Kubis, both in 1937. Kubis joined the faculty, served as interim chair after the sudden death of his mentor, Summers, in 1938 and again in the 1970s, and retired in 1981. Kubis continued Summers' research on lie detection, and worked with NASA on the human response to space travel.

When Rev. Joseph G. Keegan, S.J., Ph.D. took over as chair in 1949, the faculty consisted of Keegan (Ph.D. 1949 Yale), Rock, McCarthy, Kubis, Anne Anastasi, Ph.D. (Columbia 1930), Rev. William C. Bier, S.J., Ph.D. (Catholic University 1948), Rev. Richard T. Zegers, S.J., Ph.D. (Columbia 1948), and Rev. Henryk Misiak, Ph.D. (Fordham 1946). This was a time of growth in higher education, and Fordham was no exception, with increasing enrollment in undergraduate and graduate programs. At the graduate level, specializations in general/theoretical psychology, experimental psychology, psychometrics, and clinical psychology were offered.

Bier took over as chair in 1958, and worked successfully to attain APA accreditation of the clinical psychology program. His research applied personality testing to members of Catholic religious orders, and he was a founder and from 1949 to 1970 served as the executive secretary of the American Catholic Psychological Association (ACPA). He authored a brief history of the department for the ACPA newsletter (Bier 1953). Misiak (1963) provided an update 10 years later. Misiak and Staudt's (1954) *Catholics in Psychology: A Historical Survey* covered international psychologists missing from mainstream coverage of the history of psychology.

Misiak and Zegers supervised many dissertations on critical flicker fusion and other topics in sensation and perception. Anastasi became the best-known Fordham psychologist, with her widely used text on *Psychological Testing*, and served as department chair (1968–1974) and as President of the American Psychological Association in 1972 (see her biographical entry).

After Kubis, John F. Walsh, Ph.D. served as chair from 1976 to 1982, followed by Marvin Reznikoff, Ph.D. (1983–1986), Kurt Geisinger, Ph.D. (1986–1991), and Nancy Busch, Ph.D. (1991–1996). During these years the Experimental Psychology Program was dropped and the Applied Developmental Psychology Program was initiated. In 1969 an undergraduate college was established at the new Lincoln Center campus in Manhattan, with a Division of Social Sciences that eventually included six psychologists. Trustee-mandated restructuring led to the merger of the Lincoln Center psychologists and the Department of Psychology into a university-wide department in 1995, with Busch as the first chair for one year. Mary Procidano, Ph.D., Frederick J. Wertz, Ph.D. and now Kathleen Schiaffino, Ph.D. have chaired since 1996. A common undergraduate curriculum emphasizing a natural science approach to psychology was developed under Procidano's leadership.

Significance

Fordham psychology is significant in at least three ways: first, in the large number of undergraduate and graduate students who learned about psychology at Fordham; second, in the impact of individual faculty, especially Anastasi, on the field; finally, due to its leadership in the area of the relationship between psychology and religion, beginning in 1862, including the work of Bier, Misiak, and Staudt, and continuing today with the work of Rev. John J. Cecero, S.J., Ph.D.

Forel, Auguste-Henri

DAVID D. LEE

Amsterdam, The Netherlands

Basic Biographical Information

Forel was born September 1, 1848, in La Gracieuse (Switzerland) and died on July 27, 1931, in Yvorne (Switzerland). After a gymnasium education in Lausanne, he studied medicine at the University of Zurich (1866–1871). His doctorate in neuroanatomy was written under the guidance of Theodor Meynert in Vienna (1872). After 7 years in Munich working with Europe's leading brain researcher Bernhard von Gudden, Forel was appointed Professor of Psychiatry at the University of Zurich, a post which included the directorship of the university's psychiatric clinic the Burghölzli (1879–1898). In addition to his contributions to psychiatry, he was a noted myrmecologist (the scientific study of ants), sexologist, brain anatomist, philosopher, and social reformer (e.g., eugenics, temperance). He is generally considered the father of Swiss psychiatry.

Major Accomplishments/Contributions

Forel's early interest was in the anatomy, physiology, geographic distribution, and behavior of ants (Forel 1900). He was the first to describe parabiosis (the natural or artificial joining or grafting of two organisms) and lestobiosis (when colonies of a small species nest in the walls of the nest of a larger species). He continued to work on this subject throughout his life, publishing *Les Fourmis de la Suisse* (Ants of Switzerland) in 1874 and a five-volume work in 1923 (Lustig 2004). After studying medicine in Zurich, he turned to human brain anatomy (Forel 1907). In 1875, Forel made the first complete section of the whole

brain. In 1877, he named a horizontally elongated region below the thalamus whose connections project extensively over the brain from the cerebral cortex down into the spinal cord the “zona incerta,” now known as the “fields of forel.” Forel understood his position as Director of the Burghölzli (1879–1898) as one with a social component which compelled him to speak out on issues as diverse as eugenics (of which he was a proponent) (Küchenhoff 2008), criminal behavior (he was one of the first to put forward the idea of “diminished responsibility”), and psychiatric incarceration. In 1885, he discovered the origin of the acoustic nerve in the brain. In 1887, Forel described cellular functions within the brain, and this work, along with studies by Wilhelm His and Fridtjof Nansen, is considered the beginning of modern neuron theory. Forel was not only a research scientist and director of a major European psychiatric institute, he was an active social reformer publishing papers on prison reform (including penal code legislation) and social morality, in particular, alcoholism; in 1889, he established an institute for the medical treatment of alcoholism, and 2 years later he founded a temperance journal. Like many psychologists, Forel was fascinated by hypnotism and believed suggestion therapy to be a major medical breakthrough. He wrote extensively on the subject and cofounded the *Zeitschrift für Hypnotismus* in 1897. Five years later, this journal was renamed the *Journal für Psychologie und Neurologie*, and it survived as the *Journal für Hirnforschung* and later still as the *Journal of Brain Research*. Forel was also interested in sexuality and hygiene and his influential *The Sexual Question: a Scientific, Psychological, Hygienic and Sociological Study* was published in 1905 (Forel 1905), the same year as Freud’s “Three Essays on Sexuality”. In 1909, he established the *Internationalen Verein für medizinische Psychologie und Psychotherapie*. He was a lifelong proponent of psychotherapy and trained Eugen Bleuler (his successor at the Burghölzli) as well as Adolf Meyer (later president of the American Psychiatric Association). In addition to being an academic polymath, Forel was an active Socialist, internationalist, pacifist and advocate of Esperanto.

Forensic Psychology

HAROLD TAKOOSHIAN¹, THOMAS A. CAFFREY²

¹Fordham University, New York, NY, USA

²Forensic Psychologist (Private Practice), New York, NY, USA

Forensic psychology is psychology applied to the law, derived from the Latin “forensis” – pertaining to a forum, or court of law. This specialty is currently in transition between two very different definitions.

1. The traditional, broad definition of forensic psychology: “the science and practice of psychology applied to legal issues,” including all aspects of law – criminal law (offenders, victims, witnesses, police, attorneys, courts, corrections), civil law (competence, disability, personal injury), family law (child custody, guardianship), and other branches.
2. The more modern and narrow definition of forensic psychology is simply that part of clinical psychology focused on the mentality and behavior of individuals in the legal system. More formally, the 1991 Specialty Guidelines define this as: “all forms of professional psychological conduct when acting, with definable knowledge, as a psychological expert on explicitly psycholegal issues, in direct assistance to courts, parties to legal proceedings, correctional and mental health facilities, and administrative, judicial, and legislative agencies acting in an adjudicative capacity” (Section I.B.1.b).

This more focused definition emerged in 1991 in the “Specialty guidelines for forensic psychology” (Committee on Ethical Guidelines for Forensic Psychologists 1991). In 2000, this was part of a successful petition to the American Psychological Association (APA) by its Division 41 (the American Psychology-Law Society, or AP-LS) to recognize those qualified “to provide psychological expertise to the judicial system.”

In this essay, the term “law-psychology” refers to the traditional broad definition (Rieber 1987), and “forensic psychology” is reserved for the more modern and focused definition. In both cases, this is a small yet fast-growing area within modern psychology, judging by available resources – training programs, organizations, textbooks, and journals.

Law-psychology. The application of scientific psychology to law dates back to its very origins before 1900, in Europe as well as the USA (see Table 1). This is best seen as a “curvilinear” history, since early turn-of-the-century enthusiasm dissipated by 1910, only to rekindle slowly in the 1960s, and then rapidly in the 1990s.

Before 1900, many leading psychophysics researchers quickly saw the value of their new findings on human perception, memory, and reporting for the legal process. For example, in Paris, in 1901, Alfred Binet published an essay on the “Science of testimony,” as did Wilhelm Stern in Leipzig in 1903. In Vienna, in 1906, Sigmund Freud sought supporters for his new method of psychoanalysis when he addressed an audience in University of Vienna Law School on its unique value on “the ascertaining of truth in courts of law,” helping to detect liars from their subtle nonverbal cues. Most notably in 1908 in the USA, Wilhelm Wundt’s redoubtable student Hugo Munsterberg, the Director of the Harvard Laboratory of Applied Psychology, published his classic book, *On the Witness Stand*, attacking American courts of law as “pre-scientific” for ignoring the value of new research on eyewitness evidence and hypnosis. Almost immediately in 1909, John Henry Wigmore headed an onslaught of US attorneys who mounted a blistering academic counterattack, successfully stifling Munsterberg and others’ further development of this topic.

Law-psychology re-emerged in the 1960s, with the publication of *The American Jury* in 1966. This landmark volume co-authored by attorney Harry Kalven

and sociologist Hans Zeisel provided a brilliant behavioral science analysis of the operations of the Chicago criminal courts (Kalven and Zeisel 1966). For example, by analyzing 3,000 actual criminal trials, the authors found that judges and juries agreed on 78% of verdicts – thus resolving the long-unanswered question “Does a judge versus jury trial make a difference?” Also in 1966, New York attorney James Marshall’s volume, *Law and Psychology in Conflict*, reissued a call for more scientific research on the troubling problem of flawed eyewitness evidence in court. Along with the formation of the American Psychology-Law Society in 1969, a few pioneering authors, schools, and books began to redevelop the law–psychology interface. But throughout the 1970s, there were clear tensions when lawyers and psychologists tried to collaborate and to apply behavioral research to legal issues. This “uneasy courtship” grew into a “marriage” by 1999, when both national psychology associations in North America were headed by an attorney-psychologist: President Patrick H. DeLeon of the American Psychological Association and President James R.P. Ogloff of the Canadian Psychological Association.

Forces. The attractive forces binding law and psychology seem clear. If psychologists seek to do work of value to individuals and society, what can be more valuable than helping to decide the fate of individuals on trial in criminal and civil courts? Similarly, in their effort to improve procedural and distributive justice, these courts naturally welcome any assistance behavioral scientists can offer.

The repellent forces also seem clear, in two ways – the very different goals and methods of law and psychology. (1) *Goals.* The goal of law is to judge human behavior, whereas the goal of psychology is to simply understand without judgment. (2) *Methods.* The classic philosopher C.E. Pierce asks “How do we know facts?” and limns four methods to ascertain facts: (a) “Tenacity” – what has been done in the past, (b) “Authority” – relying on expert opinions, (c) “Intuition,” (d) “Empiricism” – what empirical tests reveal. It is notable that lawyers are trained to rely on the first three, while psychologists are taught to rely exclusively on the fourth – empiricism. For instance, “Is it best to allow TV cameras in the courtroom for high-profile trials, or is this disruptive?” While courts rely on past precedents (*stare decisis*), testimony by experts, and

Forensic Psychology. Table 1 Background of law-psychology

1879 – Wilhelm Wundt “founds” the science of psychology by forming the first psychology lab in Leipzig.
1901 – In Paris, Alfred Binet publishes his article on the “Science of testimony.”
1903 – In Leipzig, Wilhelm Stern publishes his research on the use of psychology in obtaining testimony.
1906 – In Vienna, Sigmund Freud addresses law students on “Psychoanalysis and the ascertaining of truth in courts of law.”
1908 – At Harvard, the Director of its Laboratory of Applied Psychology, Hugo Munsterberg, publishes <i>On the Witness Stand</i> , his pioneering book on psychology applied to the courts.
1909 – In Chicago, Northwestern Law Professor John H. Wigmore counterattacks in the <i>Illinois Law Review</i> against Munsterberg’s 1908 attack on pre-scientific law.
1909–17 – In the <i>Psychological Bulletin</i> , G.M. Whipple publishes an annual review of psychology research on testimony.
1916 – Psychologist Edwin G. Boring begins publishing the <i>Journal of the American Institute of Criminal Law</i> .
1920 s–30 s – Occasional treatises appear, such a lawyer Robert Hutchins and psychologist Donald Slesinger’s <i>Legal Psychology</i> (1929), M.E. Burr’s <i>Legal Psychology</i> (1931), E.S. Robinson’s <i>Law and the Lawyers</i> (1935). (. . . Forensic psychology wanes, then re-emerges in the 1960s . . .).
1955–66 – Chicago lawyer Harry Kalven and sociologist Hans Zeisel research and publish <i>The American Jury</i> (1966), their classic empirical studies of the Chicago court system (Kalven and Ziesel 1966).
1966 – New York attorney James Marshall publishes <i>Law and Psychology in Conflict</i> .
1969 – Psychologists and lawyers form the American Psychology-Law Society, APA Division 41.

Forensic Psychology. Table 2 Background of forensic psychology

1896 – Psychologist Albert von Schrenck-Notzing testified on suggestibility of witness testimony in a murder trial.
1908 – In Pennsylvania, clinician Lightner Witmer, a student of Wilhelm Wundt, introduces a course on psychology of crime.
1909 – In Chicago, neurologist William Healy and psychologist Grace Fernald form the Chicago Juvenile Psychopathic Institute to assist the Cook County Juvenile Court.
1923 – The exclusion of psychologist William Marston’s polygraph testimony creates a new rule in <i>Frye v US</i> , 293 F. 1013 (DC Cir. 1923).
1962 – Psychologists are allowed to testify on insanity, based on expertise rather than a specific credential, in <i>Jenkins v US</i> , 307 F.2d 637.
1991 – APLS publishes its Specialty Guidelines for Forensic Psychology (Committee on Ethical Guidelines for Forensic Psychologists 1991).
1993 – The admission of scientific evidence into US courts is expanded in the <i>Daubert</i> decision.

judicial intuition, psychologists are taught to look only at objective evidence from actual tests of this question. The very different goals and methods of these two fields of law and psychology can complement or conflict, depending on the care with which they are paired.

Topics. Since the 1960s, psychologists in diverse specialties (such as social, clinical, industrial, perception) have applied their research to legal issues (Wright et al. 1980; Rieber 1987). These law-psychology researchers have shown no lack of creativity in the diverse topics they have researched on all aspects of the legal system. In criminal law, for example, behavioral researchers have studied the *offender* (assessment, motivation, competence, terrorism, profiling), *victims* (second-injury, victim-blame, victim services, VORP victim-offender reconciliation programs), *witnesses* (bystander behavior, good Samaritans, citizens arrest, witness assistance, duty-to-aid policies), *police* (selection, training, styles of policing, stress, burnout, corruption, community relations, domestic violence), *attorneys* (prosecution, defense, methods of persuasion, voir dire), *courts* (juries, judges, negotiated pleas, jury work consultation, pretrial publicity),

evidence (eyewitness identification, line-ups, hypnosis, polygraphy, confessions, entrapment, false/recovered memories), *corrections* (punishment, rehabilitation, sentencing, capital punishment).

Forensic psychology. In law, the emphasis on an accused offender's mental state long predates the advent of psychology – stretching back to the 1700s. For example, “Can a wild bull be put on trial for killing a farmer?” In *Rex v. Arnold* (1723), an English court's “wild beast test” found a demented person lacks the requisite mentality to commit the crime of murder. Similarly, in 1843, despite public outcry of the “M’Naghten rule,” a London court found Daniel M’Naghten “not guilty by reason of insanity” in the killing of Prime Minister Robert Peel’s secretary, due to “a mental disease or defect” that rendered him unable “to know right from wrong.” (Interestingly, M’Naghten was immediately adopted by US courts by 1851, and remains the test used in most of the 50 US states 160 years later.)

In its judgments, law does not separate one's behavior from the mental state associated with it. For example, the same behavior (a killing) may be murder, manslaughter, or no crime at all depending on the mental state of the killer. So modern textbooks in criminal law are saturated with hundreds of terms referring to mental states – knowingly, deliberate, premeditated, duress, reckless, negligent, voluntary, incompetent, and insane. Has the accused a “guilty mind” (*mens rea*)? At the same time, psychologists have typically been discouraged if not barred from testifying as consultants in courts of law across most of the twentieth century because, unlike psychiatrists, they are not licensed medical doctors recognized as experts by the court. This is gradually changing, as forensic psychology and its unique scientific knowledge base achieve greater recognition. When the historic 1993 *Daubert* decision clarified five new rules on the admission of science into US courts of law, this possibly opened a new chapter in the expanding role of forensic psychology (*Daubert v Merrill Dow Pharmaceuticals* 1993).

Besides their shared history, the modern specialties of clinical and forensic psychology share some clear similarities and differences. (1) *Similarities.* In both, the practitioner uses the same skill set to apply scientific concepts and methods to assess clients, and possibly help plan appropriate interventions to benefit their

behavior and mental state. (2) *Differences.* The forensic psychologist is typically an expert consultant hired by the court, so her/his primary duty is to the court (not the individual), confidentiality is moot, the primary goal may be assessment or treatment, there is likely a time limit, the client may not be voluntary and may be more of an adversary than ally in this process.

In practice, individual practitioners vary in how much they balance the interests of the court versus the person with whom they are working.

Topics. Using this more narrow conception, forensic psychologists have shown vigor in applying their clinical and related skills to help the legal system better understand the individuals in it. For example: *investigations* (criminal profiling, crime scene analysis, psychological autopsies, hypnosis, polygraphy), *mental states* (competence, insanity, malingering), *dangerousness* (risk assessment, at-risk juveniles, stalking, bullying, sexual offenders), *syndromes* (battered women, rape, child sex abuse, posttraumatic stress disorder), *discrimination* (racial, sexual, hate crimes, sexual harassment), and *families* (mediation, child custody, guardianship, child abuse/neglect).

Future trends. Like other practicing psychology specialties, the forensic specialty normally requires a state license. Depending on each state, this typically means a doctorate in psychology, suitable internship, a year or 2 of supervised professional experience, and a passing score on the EPPP – the Examination for the Professional Practice of Psychology. Judging by the number of practitioners and training programs, forensic psychology is a small but unusually fast-growing specialty compared with other practice specialties, for at least a few reasons: (1) *Openings.* There are many openings to work with correctional facilities, if not state or federal courts. (2) *Fees.* Since fees are paid by a third party, the psychologist need not deal with the uncertainties of “managed care” or a client's insurance company, which are known to pressure practitioners. (3) *Forensics.* There is a growing public fascination with forensic science in general, of which forensic psychology is one part.

At the same time, the demands of forensic work require special talents to survive in working with courts, as Dr. Gerald Koocher warns: “So you really want to practice forensic psychology? Forensic psychologists are by nature an argumentative bunch, with abundant self-confidence and strongly held opinions.

Why else would they readily subject themselves to the high degree of scrutiny and challenge that goes along with presenting oneself as an expert in the legal system (e.g., challenging cross-examination, withering criticism of peers consulting to the opposing side, and increased risk of ethical complaints)?” (Goldstein 2007, p. x).

Foucault, Michel

DENNIS R. BRYSON

Bilkent University, Ankara, Turkey

Michel Foucault (1926–1984) was one of the major thinkers of the twentieth century. He was born, educated, and lived in France. He held a chair at the prestigious Collège de France; he also taught at universities around the world, including the University of California at Berkeley.

Foucault was not a psychologist, but his formulations on such issues as discipline and the care of the self, as well as the emergence of psychology and the human sciences more generally, continue to possess great relevance for psychology. In addressing Foucault’s work, perhaps the best place to start is his *Discipline and Punish* (1975/1979). The book dealt with the emergence of the “disciplines” in the Western world from the seventeenth century on. The disciplines involved such practices and procedures as fixing in place and

confining, observation and surveillance, training and exercise, judging and classifying according to norms (“normalization”), and examination. The disciplines avoided violent methods and public displays. They were geared toward enhancing and guiding human capacities, aptitudes, and energies, not repressing them. Nevertheless, the disciplines deployed power over the individual in order to enhance the utility and docility of the individual for institutions such as prisons, hospitals, factories, schools, and the military, and for society more generally. The disciplines were thus applied to the bodies of prisoners, students, patients in hospitals, inmates in madhouses, workers, and others – but the effects of the disciplines also produced certain forms of selfhood “within” these individuals. Indeed, Foucault described his book as “a correlative history of the modern soul and of a new power to judge” (p. 23).

The schools provide a good example of how discipline produced effects of selfhood within the individual, effects that simultaneously tended to homogenize and to differentiate individuals. Thus, in the schools, students were observed, examined, compared, and categorized with regard to norms of behavior and performance. In this process, the individual student was both pressured to conform to standardized norms, and thus in a sense homogenized with respect to his or her schoolmates, while, at the same time, the student developed a differentiated sense of self – as, for example, being an industrious, well-behaved, superior student, or a lazy, misbehaved, mediocre student.

The emergence of psychology and the other human sciences was closely connected to the deployment of the disciplines and their production of selfhood, especially from the eighteenth century onward. Prisoners, students, workers, the “insane,” and others were subjected to hierarchical observation within their respective institutional contexts; their behaviors, the results of examinations conducted on them, and so on were recorded, compiled, and classified; and the resulting records and case files were examined and compared. According to Foucault, it was precisely from such “ignoble” procedures that human sciences such as criminology, educational psychology, psychiatry, and industrial psychology originated. Foucault used the term “power-knowledge” to designate the complex of technologies of power and forms of knowledge that

emerged in the West. The term aptly indicated the manner in which disciplinary power and the human sciences interacted with each other, mutually reinforcing each other in their development during the modern era.

With the publication of the introductory volume of *The History of Sexuality*, Foucault (1976/1978) supplemented his treatment of discipline with the notion of “biopower.” According to Foucault, biopower came to combine disciplinary techniques with the regulation of the population. The disciplines were thus incorporated within biopolitical strategies directed at enhancing the health and welfare of the population while simultaneously managing the population. As the “pivot” that connected the discipline of the individual’s body with the enhancement and management of the population, sexuality played an important role in the rise of biopower. Moreover, it assumed a special significance for the modern sense of selfhood. Arguing against the “repressive hypothesis,” Foucault thus claimed that in the modern Western world, sexuality had, by the nineteenth century, come to be elicited, observed, and disciplined – while individuals had come by then to see sexuality as the key to the inner truth of their psyches.

In his later work, Foucault (2003a, b) elaborated on what he called the “technologies of the self.” According to Foucault, the ancient Greeks and Romans were concerned not primarily with knowing the self in the modern sense, but with the care of the self. For the ancients, the care of self involved a kind of esthetic self-fashioning; that is, they focused on the art of living – which involved mastering themselves and their passions, avoiding excess, and, at least during the era of the *polis*, caring for their fellow citizens – in order to live in an ethical manner. To be sure, during the Hellenistic and Roman eras, the emphasis shifted toward detailed self-examination, but the concern with the art of living remained. In the fourth and fifth centuries A.D., however, the Christians formulated and implemented a very different mode of the care of self. Stressing purification and self-renunciation, they turned inward, searching the deepest recesses of their souls for forbidden desires. According to Foucault, Christianity thus initiated the Western project of subjecting the self to constant scrutiny in order to decipher its hidden truth. The implications of these developments for the history of Western

civilization were great: the emergence of the modern self, with its unceasing hermeneutic quest for meaning within the psyche, and the emergence of the modern human sciences, especially psychology, psychiatry, psychoanalysis, and related fields, came to be inextricably intertwined in the West during the modern era.

As suggested above, Foucault’s work is valuable both for providing an understanding of the historical context for the emergence of psychology and for the critical examination of the practices that came to be associated with this field. In addition to his own writings, those interested in exploring Foucault’s critical approach to psychology and its history will find the work of Nikolas Rose instructive. Rose has done extensive work on the rise of the “psy” disciplines, as he has put it. See especially his *Inventing Our Selves* (Rose 1998).

Fowler, Orson

TORY HOFF
Psychologist, Toronto, ON, Canada

Biographical Information

Orson Fowler was born on October 11, 1809, in upstate New York. Along with Henry Ward Beecher, his classmate at Amherst College, Massachusetts, Orson Fowler went to Boston in 1832 to hear the lectures of Johann Gaspar Spurzheim. As a result, he abandoned his plans to become a minister and became a convert to phrenology. After graduating in 1834, Fowler began a career

as an itinerant lecturer and phrenological demonstrator throughout New England, eventually traveling as far as Mississippi, Upper Canada, and later on California, Nova Scotia, and London, England.

In 1838, Fowler founded the *American Phrenological Journal* in Philadelphia, and in 1842 moved it to New York City, at which time he resigned as its editor and became its publisher along with his younger brother, Lorenzo. They turned it into the most widely read phrenological periodical in America. Fowler & Fowler (1836) preached a philosophy of personal improvement under the motto “self made or never made.” Their practical Yankee ingenuity inspired entrepreneurial endeavors, the primary one being their publishing firm located in the center of Manhattan commerce, which became Fowlers and Wells after their sister, Charlotte, and her husband, Samuel Wells, joined in 1844. From their successive buildings came their books on phrenology as well as those by associates promoting related alternative movements. By the early 1850s, Fowlers and Wells had the largest mail order list of any business in New York City and thus contributed to the large increase in reading material for the populace. Early on they also established a Phrenological Cabinet, reportedly containing numerous casts of heads and more than a thousand skulls. In 1854, however, Orson Fowler left the company evidently because Wells refused to publish on the forbidden topic of “self-abuse,” that is, masturbation. Fowler set up his own “matrimonial intelligence office” where people could come and receive a phrenological analysis from him regarding marriage suitability but also about other matters such as career. He conducted a rudimentary sort of psychological assessment whereby his customer purchased his book and he used its chart to indicate from one to seven the strength or weakness of each of the phrenological faculties. This information was the basis for his intuitive advice regarding the best type of marriage partner, career choice, etc. In 1863, he moved his office to Boston. He died on August 18, 1887.

Major Contributions

Orson Fowler promoted many populist social movements of Jacksonian America. He embraced nearly every alternative cause of the 1840s including botanical medicine, hydropathy, vegetarianism, bathing using a new contraption now called a shower, temperance

including with respect to tobacco, tea, and coffee, a new phenomenon called exercise, women’s reform within limits (he once wrote, “only laying hens have the right to cackle,” *Sexual Science*, 1870, p. 141), shorthand at work, and mesmerism including before surgery. A notable exception is that he did not support the back-to-nature utopian communes or fringe religious communities of the era. He was the first to promote octagonal residences, and built his own four-story, 60-room unadorned octagonal mansion near Fishkill, New York, overlooking the Hudson River. He described his plans in *A Home for All* (1848), and in a second edition recommended using a new construction material, “gravel walls,” which we now call concrete.

Fowler readily accepted the vitalistic psychophysiology that supported the phrenological perspective. As he wrote in his book, *Sexual Science* (1870), “Spirit life is that architect which first makes the bodily structures and then uses it” (p. 60). Specifically regarding phrenological theory, he changed his mind over the years about the number of faculties and cerebral organs, but he maintained the common theory that the signs of the domestic propensities are grouped at the back of the skull, the moral sentiments at the top, and the intellectual faculties at the forehead, which he reasoned was proved by the fact that animals have no foreheads.

Like many in the educated populace, Fowler incorporated the old belief in temperaments into his phrenological perspective. Unlike Spurzheim, however, he was part of a shift in the emerging popular culture whereby three temperaments rather than the classic four were employed. Put too simply, this trend dropped the sanguine temperament, which in one version of the old theory was the balanced ideal, and considered the other three to be variations. Fowler and others, however, employed new nomenclature, namely, the vital, motive, and mental temperaments, each with their corresponding body and head types. (In the next century these types reappeared in the form of Sheldon’s somatotypes.) Phrenologists such as Fowler used differences in temperament to assess variations in behavior that were not explainable using only their craniology. The combination enabled them to explain almost anything.

As time passed Fowler became less concerned about establishing a specific set of organs and corresponding faculties and more interested in using his phrenological

perspective to give people guidance and advice. As more time passed his organology played less of a role, and a much revised set of faculties in their various manifestations and behavioral expressions became his emphasis (cf. *Human Science or Mental Philosophy*, 1873).

More than most contemporary phrenologists but reminiscent of Gall, Fowler gave great attention to that most primary of faculties, namely, amativeness, the sex instinct. Interested in promoting both personal enhancement and better hereditary endowment, he became a spokesperson for improving the human race by following natural laws that he considered to be based on phrenological science. As such, Fowler was a forerunner of the eugenics movement. Improving humanity as well as marriages, thought Fowler, requires the development of a spiritual rapport between a man and woman such that their enhanced “parental sexuality” results in creating “better souls” (*Sexual Science*, p. 12). The sex act itself is of utmost importance because “the magnetic-spiritual rapport between partners during the conjugal interview determines the progeny” (*Sexual Science*, p. 637). Fornication and self-abuse are sins of commission, whereas celibacy is a sin of omission. He considered education in phrenological science to be absolutely essential for producing superior progeny and avoiding various sins of a sexual nature. Fowler emphasized that the sins of sensuality and their opposite, prudery, both stem from a perverted organ of amativeness, the cerebellum, which in turn is sometimes caused by “interrupted love” due to, for instance, a broken heart or disappointed love especially regarding the opposite-sexed parent. By the social standards of the early twenty-first century, the sexual mores of Fowler appear quaint and conservative including because he believed that sexual intercourse is for the purposes of propagation only, but in his day he was considered by many to be a libertine. Even one of his former coauthors reviled him, and in some circles he became known as “The Foulest Man on Earth.” Nevertheless, Fowler (1878) continued to practice his own personal philosophy when, for instance, he married for a third time at the age of 72 and his new wife gave birth to three more children. But his reputation declined and he died in debt.

Fraisse, Paul

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/ Major Accomplishments

Eminent French experimental psychologist Paul Fraisse was also an active member of the Socialist Party. He joined Albert Michotte’s laboratory (1935–1937) where he did experiments on visual perception and getting his doctorate. In 1940, he was captured by the Germans and liberated in 1943. Fraisse occupied many positions in French and international psychology. He was director of the experimental psychology department at Sorbonne University where he promoted a variety of directions in psychological sciences such as abnormal psychology, industrial psychology, differential psychology, educational psychology, child psychology, and experimental psychology. He was a very active member of International Congress of Psychology, International Union of Scientific Psychology, French Society of Psychology, and editor of *l’Année Psychologique*. He was a successful mentor, he supervised over 50 PhD students several of them became most prominent psychologists. He co-edited nine volumes on *Treatise of Experimental Psychology* (1963–1976) with Jean Piaget. He founded the *International Journal of Psychology* and directed a series of psychological books “*Le Psychologue*” at the famous French University Press. He had excellent contact with Soviet psychologists as well as North American psychologists, South American psychologists, and European and African

psychologists. In April 1955, he was invited to spend 3 months in the Soviet Union visiting psychology departments and psychology laboratories. He was accompanied by Jean Piaget and René Zazzo. Paul Fraisse was a most respected psychologist to the best of my knowledge his efforts resulted in fruitful exchanges for the unity and greater advances of psychology. His contributions were in the field of perception, estimation of duration, time, rhythm, and memory for drawings or words indicating the same objects, images in memory for concrete and abstract sentences. He conceived time as a regulator of human activities. He promoted the experimental method in psychology. He was appointed as an honorary professor of psychology at Sorbonne University and received honorary doctorates from many national and international universities (Bonn, Lisbon, Rio de Janeiro, Barcelona). He was a regulator active participant in psychological seminars, congresses, and publications until his death, at 85, in 1996. He was editor of volumes, monographs, series including over 200 scientific articles, and more than 40 books. Fraisse's work has been translated into many languages. Readers interested in learning more about Fraisse's life and evolution of his ideas should consult the following publications (Fraisse 1963/1957, 1983, 1984, 1991).

Franz, Shepherd Ivory

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: May 27, 1874; Died: October 14, 1933.

Franz took his Bachelor's degree (1894) and Ph.D. (1899) at Columbia, studying mainly with Cattell with an interim stay at Leipzig with Wundt in 1896. He then went first to Harvard, where he was assistant in physiology with Henry P. Bowditch and W. T. Porter between 1899 and 1901 and undertook some of the earliest behavioral neuropsychological studies. In these, he experimentally removed trained behavior through brain ablation in cats, then retrained them, demonstrating the ability of undamaged regions to take over the functions of damaged parts (Franz 1902). He then taught physiology at Dartmouth until 1904 when Edward Cowles, founder of the psychological laboratory at the McLean Hospital in Waverly (Belmont), Massachusetts, nominated Franz to a position there in pathological psychology. There he served until 1906, when he moved to Washington D.C. The next year, on the invitation of the psychiatrist William Allan White, Franz became chief clinical psychologist at the Government Hospital for the Insane (St. Elizabeth's) in Washington D.C. In conjunction with his duties there, he also taught at George Washington University as professor of physiology and psychology from 1906, mentoring several graduate students there and at St. Elizabeth's. Franz remained at George Washington and St. Elizabeth's, eventually becoming director of the laboratories there, until 1924 when he moved to Los Angeles, where he joined the faculty of the University of California at Los Angeles, playing a significant role in founding the Graduate School at UCLA as well as the graduate psychology program in 1931. He remained there until his death from amyotrophic lateral sclerosis in 1933.

Major Accomplishments/Contributions

Franz was important to the development of two psychological specialties, clinical psychology and neuropsychology. Regarding clinical psychology, Franz, along with Wells and others at the time, established the role of the clinical psychologist in a psychiatric hospital setting. Franz wrote one of the earliest manuals for clinical testing and authored several articles on clinical practice as it evolved. Franz exemplified the ambiguous relation psychology had with medicine at the time. On the one hand, he was considered a valuable contributor in the hospital setting and even was awarded an honorary M.D. from George Washington University in 1915. Yet he was very much aware of the tension generated in the partnership of psychiatry and psychology. His pithy comment, “Up to the present time, so far as my knowledge goes, most psychiatrists as such will not kiss a psychologist, nor will most psychologists kiss a psychiatrist as such (Franz 1922, p. 242),” was often quoted. As a pioneer neuropsychologist, Franz won a priority dispute against Otto Kalischer regarding his ablation technique (Thomas 2000). He maintained his scientific skills alongside his clinical practice and contributed to establishing the scientist-practitioner model as a norm for clinical psychology. He also authored many theoretical and empirical papers in which he refined his views on the functional equivalence of cortical regions in learning and memory. Franz was particularly critical of strict localizationist approaches to brain structure and function and decried what he termed “new phrenology” (Franz 1912). Franz continued to lecture and write on neuropsychology after moving to UCLA: he also made significant contributions to the theory and practice of rehabilitation after brain injury, emphasizing neural plasticity (Franz 1929; Colotla and Bach-y-Rita 2002). Franz’s most significant contribution, however, came through his teaching of Karl Lashley, whom he instructed in ablation techniques. The publication of their collaborative work (Franz and Lashley 1917; Lashley and Franz 1917) in the new journal *Psychobiology* marks the starting point for Lashley’s subsequent trajectory as a neuropsychological theorist.

Freud, Anna

JAKE KAUFMAN, ROBERT W. RIEBER
Fordham University, New York, NY, USA

Basic Biography

Anna Freud. British Psychologist. Born in Vienna, Austria, 3 December 1895: daughter of Sigmund Freud, *q.v.*: emigrated to England in 1938, later naturalized. Educated at the Cottage Lyceum. Vienna. Chairman, Vienna Institute of Psycho-Analysis until 1938. Member, London Institute of Psycho-Analysis. From 1938; worked with the Hampstead War Nursery during World War II and in 1952 founded the Hampstead Child Therapy Course and Clinic. London. Recipient: Grand Decoration of Honour in Gold, Austria, 1975. Honorary doctorate: Clark University, Worcester. Massachusetts. 1950; University of Sheffield, 1966; Jefferson Medical College. Philadelphia, 1964; University of Chicago, 1966; Yale University. New Haven. Connecticut, 1968; University of Vienna. 1972; Columbia University. New York. 1978; Harvard University. Cambridge. Massachusetts. 1980. *Died* (in London) 9 October 1982.

Major Accomplishments

One of the areas with which Anna Freud was most concerned throughout her career was the relationship between theory construction and phenomenology. Yet, because she so rarely addressed this matter directly, this important area of her work also has been perhaps the least attended to and the least appreciated. This is unfortunate since it may well be that her constant focus on the connection between the life of the mind and theoretical descriptions of that life will prove to be one of her most important and enduring contributions to the field of psychology.

In the sciences, one of the most important goals of a theory is to break down and simplify (without oversimplifying) the phenomenon that it describes, creating an ordered foundation out of a chaotic whole. This breaking down facilitates data collection and presents a viable means of approaching hierarchical organization. Moving on, the investigator begins a reintegration of the parts into an ordered whole. The utility of a theory depends on the paths it opens up for investigators following in the footsteps of the theoretician. Without this continual flow of new insights, the whole process of breaking down and building up reaches a dead end.

With time, a good theory comes more and more to resemble the phenomenon it describes as succeeding investigators fine-tune it with the conceptions of their own. It is possible, however, for us to forget that we are dealing with concepts which had authors, rather than life as it is lived. When this happens, theories harden, taking on a reality of their own divorced from the world of experience.

Anna Freud was continually aware of this possible split, and she always struggled to maintain a connection between her ideas and the world she was trying to describe. From her first efforts to help teachers, on through her response to war-torn families and their children, to her most abstract level of theory building, there remained for her a deep commitment to developing psychoanalysis to help the development of children, and using this material to help the development of psychoanalysis. This effort led Anna Freud to pioneer in the development and use of additional research techniques to supplement and complement classical psychoanalytic methods. These extend from the development of child analysis and the use of the

nursery school, residential care center, day care center, and hospital, to the investigation of the developmental impact of such sensory deprivations as blindness and deafness.

What appears in Anna Freud as practicality is not fortuitous. It is a calculated but rare combination of lucidity, humanism, and science, and a remarkable appreciation and utilization of the reciprocal relationship between theory and phenomenology. Speaking at Yale University in 1966, she addressed just this matter:

- ▶ It is serious that the division between theory and practice is widespread. There are many people who work on the theory of child development, and there are many other people who work practically with children, but not enough people have the opportunity to apply their theories or to be taught developmental theory while the practical work with children goes on. I may say that in this last respect. I have been especially fortunate all my life.

From the very beginning I was able to move back and forth between practice and theory. I started as an elementary school teacher. I changed from there into the field of analysis and therapy; and then, from then on I changed constantly back from the theoretic study of these problems to their practical application.

This openness to new experiences gave Anna Freud a wider perspective of the world and a resiliency and flexibility that allowed her to build anew without relinquishing the hard-won knowledge of the past. This, combined with an unfettered and articulate intellect, allowed her to cut through a mass of complexities and organize troublesome material into a coherent whole.

In her developmental Profile schema, Anna Freud was aware of these complexities, arising from the difficulty of dealing theoretically with many factors. Her concern was with presenting a useable organizational model which would facilitate the gathering, storage, and assessment of data. Such an instrument imposes balance, completeness, and comparability, not only for individual cases but also for comparisons between analysts. This is an instrument with many potential uses, including the assessment of change over time, compilation of similar cases, comparison of differing ones, and as a training aid.

It was in coming to grips with this question of data collection, storage, and analysis that Anna Freud came to the concept of developmental lines. Before this, psychoanalytic methods rested primarily on the conceptualizations of the structural model, which was an attempt to disentangle and articulate individual functions. Although concerns with interrelationships were present, they were not the primary focus at that time. With the concept of developmental lines, Anna Freud forcefully reintroduced organization and hierarchy as major concepts.

Few within or without psychoanalysis have contributed so large a body of theoretical propositions so pertinent and useful to the field as Anna Freud.

Froeschels, Emil

JUDITH FELSON DUCHAN

State University of New York, Buffalo, NY, USA

Emil Froeschels was an influential otolaryngologist who specialized in speech, language, and hearing disorders. He adapted existing psychological and physiological theories to explain communication problems and designed innovative methods for carrying out speech therapy. Froeschels' work spanned a broad range of communication problems including dysarthria (e.g., speech of the cerebral palsied), stuttering, voice, language, and hearing impairment.

It was in Vienna, Austria around 1909 that Froeschels began to develop and write about his theories and clinical practices. He continued his considerable publishing record after his emigration to America in 1938, where he moved to avoid the threat of Nazi persecution. By the time of his death in 1972, he had published some 24 books and 320 chapters and articles, mostly on topics related to breakdowns in speech perception and production and to therapies aimed at remediating them. He also had established and served as director of several speech, language, and hearing clinics in both Europe and America, founded and led several important professional organizations in the field of what he termed logopedics, and served as mentor to a number of clinicians and researchers who themselves became important contributors to the speech–language pathology field in both Europe and America.

Froeschels was born in Vienna, Austria on August 24, 1844 and died in New York City on January 18, 1972. He was educated in Vienna, receiving his medical degree from the University of Vienna in 1907. It was an exciting time for the medical profession, since physicians of his day were exploring and expanding the boundaries of the medical enterprise. Doctors in both Austria and Germany were establishing a subspecialty within medicine for diagnosing and treating children and adults with speech, language, and hearing disorders. Among them were Albert Liebmann, Leopold Treitel, and Hermann Gutzmann Sr. in Berlin and Raphael Coen in Vienna. These “speech doctors” were

all well known to Froeschels (Rieber 1980). Preyer had already published his detailed study of his own child's language development (Preyer 1882, trans. 1898) and Liebmann had, by then, published an influential subclassification of childhood language disorders (Liebmann 1898; Weiner 1986). Coen had also founded a special school for children with speech and language disabilities (Coen 1886; Weiner 1986) and Gutzmann had established his renowned Berlin School of Speech and Voice Therapy (Rieber and Froeschels 1966).

In Austria at the time, there also was path-breaking work going on in the field of otology and education of the hearing impaired. Viktor Urbantschitsch (1847–1921), one of Froeschels' teachers, was developing and successfully using intensive auditory training methods with deaf students in his school, with the aim of wakening their “dormant auditory senses” (Urbantschitsch 1894).

Watershed innovations in neuroanatomy were also part of Froeschels' intellectual milieu. Paul Broca (1824–1880) and Carl Wernicke (1848–1905) had already made public their discoveries of areas of the brain that were involved in different types of aphasia, and Ludwig Lichtheim (1845–1928), Adolf Kussmaul (1822–1902), and Carl Wernicke had published their diagrammatic schemas that offered a theory for how the brain worked for normal language processing and how it was implicated in different types of speech and language breakdowns (Head 1926, Vol. 1, p. 65).

Finally, the psychoanalytic movement had just taken root. Freud had already published his *Interpretation of Dreams* (Freud 1900) and he and his followers were having regular Wednesday meetings at Freud's home in Vienna. This Wednesday group evolved into Vienna Psychoanalytic Society in 1908, with Alfred Adler as its first president. Eventually, Adler broke away from Freud to form his own school of Individual Psychology – a theoretical orientation that Froeschels was closely affiliated with both in Austria and in the United States. Indeed, in 1948, Froeschels became the first director of the influential Alfred Adler Institute in New York City.

Emil Froeschels' built upon these various twentieth-century innovations. He took the ideas of the diagram makers and the diagnostic typologies of Alfred Liebmann to hypothesize about the causes of language disorders in children and adults (Froeschels 1918).

He designed remedial approaches for his clients based on the sensory training methods of Urbantschitsch and Raphael Coen (Froeschels 1918). And he emphasized the emotional side of speech, hearing, and language disorders drawing upon psychoanalytic theories of Sigmund Freud and Alfred Adler (Froeschels 1945).

Perhaps Froeschels' was most recognized within the field of speech pathology for his clinical techniques involving muscular functioning and articulatory positioning. He devised a means for teaching his patients to assume naturally occurring articulatory and rhythmic functioning by having them simulate the movements involved in chewing food (Froeschels 1952). He and his followers used this chewing technique with those who stuttered, had dysarthria, and voice disorders. Another widely used speech therapy approach designed by Froeschels was his "pushing technique" to strengthen the laryngeal muscles of his voice patients and override the excessive closure of the vocal folds involved in vocal paralysis (Froeschels et al. 1955; Stathopoulos and Duchan 2006). Finally, Froeschels' "F method" provided clinicians with a way for teaching their young patients how to position their articulators for the production of "s" sound (Froeschels 1947).

G

Gall, Franz Josef

CHIARA BARTOLUCCI, GIOVANNI PIETRO LOMBARDO
Sapienza University, Rome, Italy

Basic Biographical Information

Joseph Franz Gall was born on March 9th, 1758, in Tiefenbronn, in the German Grand Duchy of Baden, to a family of Catholic immigrants of Italian origin with the family name Gallo.

Gall received a degree in medicine in 1785 in Vienna and produced his first scientific publication in 1791 (*Philosophisch-medizinische Untersuchungen über Natur und Kunst, im kranken und gesunden Zustande des Menschen*). Between 1796 and 1801 he held private courses in anatomy and craniological demonstrations in Vienna that made him famous, during which he met his future disciple and collaborator Johann Caspar Spurzheim. In 1798 Gall published *Neue Teutsche Merkur*, an important work in which he presented the fundamental principles of his encephalic-craniological conceptualization, as an open letter to Baron von Retzer who was the imperial officer for censorship and Gall's mentor. In 1801, Emperor Francesco II of Habsburg condemned Gall's doctrine, retaining that it induced materialism and contradicted the primary moral and religious principles; in 1802 an imperial rescript ordered Gall to stop teaching and prohibited him from publishing other writings on the matter.

Having left Vienna definitely, Gall traveled across Europe between 1805 and 1807, accompanied by Spurzheim, during which time Gall visited psychiatric hospitals, colleges, and prisons in various countries and held conferences and lectures at academic circles and institutes to full audiences. Gall reached Paris in 1807 where he remained for the rest of his life; he became a naturalized French citizen in 1819. He began teaching to the public in 1808, first at the Athénée des Arts and

subsequently at the Hôtel du Belloy. His research results, published in *Mémoire*, which he edited together with Spurzheim, were presented to a commission at the Institut de France the same year. The commission, whose members included Georges Cuvier, Philippe Pinel, and Raphael Bienvenu Sabatier, judged Gall's theory as being scientifically groundless.

Gall published his principal works between 1810 and 1825: *Anatomie et physiologie du système nerveux en general et du cerveau en particulier* (4 vols., Paris 1810–1819) – the first two volumes (1810–1812) of which were written in collaboration with Spurzheim – and *Sur les fonctions du cerveau et sur celles de chacune de ses parties* (6 vols., Paris 1822–1825). Gall died August 22, 1822, in Montrouge (in Paris) following a period of vascular hemiplegia; he was buried in the Père-Lachaise cemetery in Paris and his skull was conserved at the Musée de l'Homme (Lombardo & Duichin 1997).

Major Accomplishments/Contributions

Influenced by Johann Gottfried Herder's dynamic-vitalistic perspective, Charles Bonnet's organological theory, and Johann Kaspar Lavater's physiognomy, Gall founded a new discipline at the end of nineteenth century that focused on the study of the functional relationships between *mental faculties*, *cerebral areas*, and *cranial morphology* (Lesky 1970). His controversial encephalic-craniological doctrine – which was initially spread in the Germanic area as *Schädellehr* (“craniology”) – is today commonly known as *phrenology*. The term “phrenology,” which Gall rejected as inappropriate, was used, in a completely independent manner, by the American Benjamin Rush (1805) and the Englishman Thomas Forster (1815); Gall's student Spurzheim subsequently adopted and spread the term, making it canonic.

Gall developed an observational method based on palpation and the visual inspection of protuberances and indentations of the cranium (the so called

“cranioscopy) that, theoretically, made it possible to identify the underlying areas of the cerebral cortex and the specific faculties connected to each area. Gall’s encephalic-craniological theory was schematically based on four fundamental postulates: (1) mental faculties are innate, (2) these faculties are based in the brain, (3) the specific form of the encephalus depends on the various extensions and the distribution of cerebral organs, and (4) cranial morphology is completely shaped by the conformation of the brain, which develops continuously from infancy to adulthood. According to Gall’s *organological* perspective, the attention was essentially on the physiological-anatomical structure of the *brain* and its *organs*; the *cranium* was given secondary consideration and seen as being the faithful imprint of the underlying cerebral mantle. By means of the *cranioscopical* method (which constitutes the *pars caduca* of Gall’s doctrine) it was possible to localize the individual cerebral organs, to which the individual dispositions were correlated (Young 1970).

Building upon his competencies as an expert anatomist, Gall traced an innovative topography of the brain that included not only an exam of the brain’s structure and faculties, but also the correlated mental dispositions. Through a comparison of numerous human and animal craniums, Gall identified 27 faculties or fundamental dispositions, considered “primitive forces,” that he divided in two groups: (a) the first, comprised of 19 functions that were common to humans and all vertebrates, was the product of the organs in the posterior and central regions of the brain, and (b) the second, comprised of eight intellectual and moral faculties only present in humans, was ascribable to the organs in the anterior region. The naturalistic and observational method allowed Gall to empirically connect the mental faculties of various areas of the brain, thus disproving the theory that saw the faculties of the cortex as being homogenous and rooting the signs of personality within the cerebral neurophysiology and cranial morphology (Lanteri-Laura 1970).

With this, Gall opposed the doctrine of sensualism with its roots in the Enlightenment, while sustaining a *nativistic* conceptualization of the individual dispositions and faculties that could be modified by education and socio-environmental factors. At the same time, he distanced himself from the traditional assumption of Faculty Psychology, according to which the *faculties*

were *general attributes* of the human mind (e.g., cognition, affection, conation) and not *distinctive characteristics*, in terms of intensity and degree of development, of the personality of each individual (Spoerl 1936).

Despite the attempt to summarize the two epistemological paradigms, the anatomic (based on dissection) and the semeiotic and clinical (evidence based), Gall’s methodology lacked adequate statistical and experimental comparisons and was not able to provide us with anatomical proof that various functions were based in the areas of cerebral cortex. The credit that Charles Spearman and Gordon Allport gave Gall was no less than that of being the first to indicate the distinctive elements of human subjects, analyzed both in normal and pathological cases, delineating a pioneering expression of the psychology of individual differences (Lombardo & Duichin 1997).

Galton, F.

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Galton (1822–1911) was born near Birmingham, England, and died in Haslemere, England. He shared

a grandfather, Erasmus Darwin, with Charles Darwin, but Charles's grandmother was Erasmus's first wife, Mary, and Galton's was second wife, Elizabeth. After medical apprenticeships in Birmingham, he enrolled for further medical studies at Kings College, London, but interrupted his studies to travel. Galton then enrolled in Trinity College, Cambridge, emphasizing mathematics, but illness prevented him from completing his course, and he took a poll degree (bachelor's degree without honors) in 1844 (Anonymous 1911; Darwin 1912). That same year Galton's father died leaving him financially independent, and he abandoned his proposed medical career.

Lewis Terman estimated Galton's IQ to be 200, which well reflects the breadth and depth of his accomplishments. Appendix III in Forrest's (1974) biography of Galton consists of a chronological list of more than 300 publications including 17 books. A few examples will suggest that seemingly anything that got Galton's attention might become a subject for study or invention. Articles included "Statistical inquiries into the efficacy of prayer" (1872), "Thoughts without words" (1887), and "Arithmetic by smell" (1894), and inventions included a heliostat (a device for signaling), bicycle speedometer, supersonic whistles, diving spectacles, and a periscope. Other inventions were made to assist in his more concentrated areas of study, such as, geographic exploration, meteorology, behavioral genetics, and mental measurement. Methods and devices for fingerprint identification and composite portraiture aided both his studies of human genetics and the forensic sciences.

After abandoning medical study, Galton traveled extensively, for example, up the Nile to Khartoum and then to Syria, as well as a self-financed exploration trip in equatorial Africa. Reports of his travel and exploration were well regarded by the Royal Geographical Society that made him a Fellow in 1856, and his books *Tropical South Africa* (1853) and *The Art of Travel* (1855) were well received.

Major Accomplishments/Contributions

Galton's importance in the history of psychology resulted from combining interests in anthropometry, genetics, statistical methods, applying Darwin's theory of evolution to human intelligence, and methods of

mental measurement. The "spirit" of Galton's legacy was summarized in his obituary in *Nature* (02/02/1911, p. 440).

The unity of those contributions lay largely in the idea that exact quantitative methods could be applied, nay, rather must be applied, to many branches of science, which had been beyond the field of either mathematical or physical treatment.

Genetically, Galton believed that "genius" (a term he later abandoned for "eminence") and other traits, both desirable and undesirable, ran in families (e.g., *Hereditary Genius*, 1869), and he recognized the difference between abilities that were due to "patent" (phenotypic) versus "latent" (genotypic) influences. In conjunction with his interests in genetics and behavior, he collected anthropometric measures both morphological and of sensory, motor, and memorial abilities; the latter three were essential in his conceptualization of intelligence. He was the first to study twins and other familial relationships in the context of human behavioral genetics.

Galton sought effective ways to quantify, interpret, and communicate his findings, favoring graphical presentations and statistical summaries. He was well aware of the such methods being developed to assess variability among astronomers' observations (also known as "error") as well as Adolph Quetelet's use of such methods to summarize large samples of anthropometric measurements (e.g., chest girths of 5,758 Scottish soldiers obtained from tailors' measurements for the soldiers' jackets). Galton also recognized the value of quantifying relationships so that predictions from one set of measures might be based on a set of related measures. To do that he developed the first statistical measure of "co-relation," and he provided the commonly used means of expressing correlation coefficients as two-digit decimal numbers between -1.0 and $+1.0$. Galton's correlation coefficient was based on quartile distributions; his protégé, Karl Pearson, put it on a sounder basis by using the normal distribution. Pearson and other notable pioneers in statistics such as Sir Ronald Fisher and Charles Spearman benefitted from Galton's influence and from funds left in his will to University College, London. Galton's legacy eventually included the development of the departments of statistics and genetics at UC, London.

Unfortunately, Galton's legacy will be tainted by his association with eugenics, a term he coined in

Inquiries into Human Faculty and Its Development, (1883, pp. 24, 44). Galton was interested in identifying youth with high potential for intellectual development and cultivating their development. However, taken to such intolerable extremes as discriminative immigration, sterilization, and miscegenation laws in the USA (and elsewhere) and to the horrifying extremes of genocide represented by Nazi Germany (and elsewhere), eugenics arouses disgust today. Despite that, it should be acknowledged that much of what Galton advocated continues to be represented today as merit scholarships and other means of recognizing and rewarding abilities deemed to be worthy of fostering.

and highly noted private school in Massachusetts. However, Gardner chose to attend a prep school closer to home in Kingston, Pennsylvania. He excelled in his academics, and was stimulated by educators employed by the school. Gardner was accepted and attended Harvard University, where he was enrolled as a history major, which would allow him to further delve into the study of law.

While at Harvard, however, Gardner was guided by Erik Erikson, a world-renowned psychologist, who introduced Gardner to the study of psychology and social sciences. In 1965, Gardner graduated from Harvard summa cum laude. Upon graduation, Gardner furthered his education in Harvard's doctoral program, and found himself researching alongside Jerome Bruner, who was heading a study on arts education, which was named Project Zero. As of today Gardner is still heavily involved with Project Zero, and is a professor of cognition and education at Harvard, along with teaching at Boston University's School of Medicine where he teaches neurology (Smith 2008).

Gardner, Howard

JACOB WEBBER

Marymount Manhattan College, New York, NY, USA

Gardner, Howard (1943–) is a leading theorist in cognitive development, an activist in education, and is best known for his Multiple Intelligence Theory.

Biographical Information

Howard Gardner was born in Scranton, Pennsylvania, in 1943, to his mother and father who had managed to flee Germany in 1938 at the heart of World War II. Howard was the second of two children, but his older brother Eric, was killed just prior to Howard's birth. Gardner personally expressed that as he grew up and came to terms with his brother's death, and his family's Jewish traditional values and faith, he had a hard time relating to his parents and peers (Smith 2008).

Gardner grew up in a house where education was praised and something sought after. His parents encouraged him to attend Philips Andover, a superior

Major Contributions

It was in the late 1990s that Gardner introduced his Theory of Multiple Intelligences. After his own soul searching, coupled with his educational research, Gardner strongly rejected this traditional mindset that intelligence is measured by a person's ability to perform on a standardized test, one of the most common being the I.Q. Test. Gardner first developed seven intelligences, that he felt better synthesized an individual's level of intelligence:

Linguistic: Those who excel through language, whether that is written or vocal; realistic or fictional; and those who have a mastery of expression through different modes of writing (authors, poets, lawyers).

Logical/Mathematical: Individuals who are able to use mathematical equations to solve problems, and who use science and logical thinking to solve and analyze problems (scientists, mathematicians, researchers).

Musical: Individuals who strive to compose, perform, or analyze musical patterns (musicians, composers, conductors).

- Bodily Kinesthetic:** Individuals who use their bodies, and are consciously aware of their physical being and abilities (dancers, actors).
- Spatial:** Those who have an ability to observe their surroundings and understand how to solve a problem within the space they are given, or within an allotted space (architects).
- Interpersonal:** Those who are in tune with the feelings of others, and have an understanding of the needs and wants of those around them (educators, counselors, sales).
- Intrapersonal:** Those who have an understanding of themselves. These individuals are in tune with their own emotions and fears (therapists, religious leaders) (Gardner, 1973).

Gardner later added an eighth intelligence of Naturalistic, which involves those who look toward nature and the natural sciences to solve problems.

Gardner has said in his book *Frames of Mind*, as well as in interviews, that individuals do not just fit into one of the intelligences, but realistically many of us find that a couple of the intelligences define our beings. The main idea behind Gardner's theory is that people do not learn the same way and that as humans exploring the world through different exercises will allow for a full mastery of our educational endeavors, along with our cognitive and personal growth.

Some schools in North America have been developing curriculums to encourage this MI (Multiple Intelligence) learning. Gardner is still developing more intelligence theories, which include Spiritual Intelligence, Naturalist Intelligence, and Existential Intelligence.

Gardner continues to research and write about his experience in the education field. Over the years he has earned recognition and countless awards for his work. In an autobiography, he suggests that it has been the union of his inquisitive mind and drive for perfection, with his creativity that has led him to find so much joy and passion in his research.

With now 25 published books, and hundreds of journals and articles, it seems as though followers seem to be waiting eagerly to see what Gardner will produce next. This unique and gifted mind has risen from childhood sadness, a confusion of personal identity, and a challenging educational journey. He has greatly influenced and redefined the meaning of intelligence.

Geissler, L. R.

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Geissler (1879–1932) was born in Leipzig, Germany. After being graduated from the 8th grade in the public schools in Leipzig, he was graduated from the King of Saxony's Teachers Seminar at Loebau in 1901. He also received a State Teacher's Certificate and permission to enroll at the University of Leipzig; however, he began teaching and never enrolled at the University. He attended a few of Wilhelm Wundt's lectures as a *Hospitant* (Guest listener); Wundt is the generally acknowledged founder of psychology as an independent academic discipline. In 1902, Geissler immigrated to Galveston, Texas, where he had a brother, and in 1903 he enrolled in the University of Texas. Transferring course credits from the King of Saxony's Teachers Seminar enabled Geissler to be graduated from the University of Texas in 1905. In 1905, he enrolled at Cornell University as a student of Edward Bradford Titchener, who had earned his Ph.D. under Wundt. Geissler earned his Cornell Ph.D. degree in 1909, and his dissertation "The Measurement of Attention"

was published in 1909 in the *American Journal of Psychology*. It also provided the basis for one of the tests included by G. M. Whipple in his pioneering *Manual of Mental Tests* (1910) to which Geissler also contributed in other ways (Thomas, in press).

Geissler remained as an instructor at Cornell until 1911, in part working with Whipple, before moving on to work as a research psychologist for the National Electric Lamp Association in Detroit, Michigan in 1911–1912. This appeared to have marked the beginning of Geissler's interests in applied psychology, the area in which he would make his greatest contributions. From 1912 to 1916, Geissler was an Associate Professor at the University of Georgia in Athens, Georgia. He served on the faculty at Clark University in Worcester, Massachusetts, from 1916 to 1920, and he served at Randolph-Macon Woman's College in Lynchburg, Virginia, from 1920 until his death in 1932.

Major Accomplishments/ Contributions

Throughout his career, Geissler kept his hand in basic research and theory, but his emphasis was on applied psychology. Despite not heretofore being recognized as such (Thomas 2009), Geissler was the principal founder and coeditor (together with Granville Stanley Hall and James W. Baird) of the *Journal of Applied Psychology*; functionally, Geissler served as both the chief and the managing editor of the journal for the first 4 years. Geissler began working to found the journal while at the University of Georgia in early 1916. He moved to Clark University in September 1916, where the journal's first issue (March 1917) was published. Each of the founders contributed an article to the first issue, but it was Geissler's "What Is Applied Psychology?" that helped further define the field of applied psychology as well as the journal's intended scope. In the article Geissler compared and contrasted "general or pure or theoretical sciences" versus "practical or applied sciences and technology" in terms of "aim," "standpoint," "scope," "problem," and "method." His analysis of these differences between pure and applied psychology holds up well today. The following year in the journal, Geissler published "A Plan for the Technical Training of Consulting Psychologists" in which he outlined potential programs of study at the bachelors', masters', and doctoral degree levels where one might become an

"assistant consulting psychologist," a "consulting psychologist," or an "expert consulting psychologist," respectively. Financial and other turmoil at Clark University that came to light in 1920 led Geissler to relocate to Randolph-Macon Woman's College, and when Hall retired as president of Clark University that year, the new president, Wallace Atwood, wrested the *Journal of Applied Psychology* from Geissler's hands.

In addition to his academic duties at Randolph-Macon, Geissler served in several consulting capacities during his remaining years, and he continued to publish both pure and applied research. He was elected president of the Southern Society for Philosophy and Psychology, and his presidential address, "The Objectives of Objective Psychology" was published in the *Psychological Review* (1929). It is an unheralded but modern discussion that bears meaningfully, for example, on theoretical tensions that arise today between cognitive psychologists and behavioral neuroscientists.

Gelb, Adhemar

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: November 18, 1887; Died: August 7, 1936.

Gelb, born in Russia, began philosophical studies at Munich in 1906 and moved next to Berlin in 1909

where he took his doctorate in 1910. His thesis was a summary and analysis of the trajectory of Gestalt theory up until that date and anticipated the full bloom of the Gestalt psychological movement. His primary dissertation supervisor was Alois Riehl who was a profound influence not only on the first generation of Gestalt psychologists but also on the philosophers who formed the nucleus of the unity of science wing of logical positivism including Hans Reichenbach and Herbert Feigl (Heidelberger 2007). After serving for a time as an assistant at the Berlin Psychological Institute, Gelb began a long association with the University of Frankfurt in 1912. In 1915, he began a long partnership with Kurt Goldstein at the Institute for Research on the Aftereffects of Brain Injury, which evolved from Edinger's neurological institute. There they conducted groundbreaking research on the relation of brain damage to changes in and recovery of higher order cognitive functions. Much of this work was founded on Gelb's perceptual expertise (Gelb et al. 1920). After becoming part of the regular faculty at Frankfurt in 1919, Gelb continued this neuropathological work alongside a comprehensive program of perceptual investigations including studies of perception in the colorblind, of visual agnosia, of simultaneous contrast, of object and form perception, of color constancy, and of the relation between space, time, and touch. In 1929, Gelb became the director of the Frankfurt Psychological Institute. Called to Halle in 1931, he was dismissed from his position there by the Nazis in 1933, and, ill and stateless, moved first to the Netherlands, lectured for a time to Sweden, and died of tuberculosis in a German sanatorium under conditions of great privation (University of Halle n.d.).

Major Accomplishments/Contributions

Gelb favored collaborative work and did not thrust himself into the foreground: nonetheless, his work had a profound and lasting effect on developments in both neuropsychology and perception. In neuropsychology, his work with Goldstein was the foundation for much subsequent work on the longitudinal effects of brain damage: the work of Hans-Lukas Teuber in the 1950s and later was a direct descendant of the Frankfurt program. As part of the Frankfurt faculty, Gelb was the

psychology instructor for many of the leading members of what became the "Frankfurt School" including Friedrich Pollack, Max Horkheimer, and Theodor Adorno. His most enduring contribution is the eponymous Gelb Effect, which he described in a 1929 chapter on the perception of objects (Gelb 1929). Gelb contended that the perception of lightness depended on, among other things, field relationships and not on perception of absolute magnitudes of energy in isolation. If it did, he claimed, then we should perceive a weakly illuminated white paper as blacker than a strongly illuminated black velvet surface, but we do not. As a demonstration, Gelb arranged a darkened room with indirect strong lighting falling on a black velvet disk, which in these circumstances appears silvery like the full moon on a dark night. Introduction of a white paper into the illuminating beam reveals, suddenly and strikingly, the actual surface colors of the objects. The Gelb Effect has been the starting point of many subsequent studies attempting to explain its perceptual and cognitive mechanisms (e.g., Brussell and Festinger 1973). Gelb was also an influence on the development of phenomenological psychology in North America through his influence on Robert MacLeod, with whom he collaborated when MacLeod was a student in Berlin (Gelb 1933).

George Mason University's Arch Lab

DEBORAH A. BOEHM-DAVIS

George Mason University, Fairfax, VA, USA

Basic History of the Arch Lab

The Arch Lab is the research arm affiliated with the Human Factors and Applied Cognition Program at George Mason University. Although the human factors program had its origins in the 1970s, starting with the approval of a Master's degree in 1977 under the direction of Dr. John Allen, the Arch Lab did not come into existence until much later. The Lab was founded in the spring of 1996 by Drs. Deborah A. Boehm Davis and Wayne D. Gray. At that time, Wayne and Deborah were the only two faculty members primarily identified with the human factors and applied cognitive program. The two faculty members chose to merge their labs under one umbrella, merging Gray's C-A-T (Cognition-Artifact-Task) laboratory with Boehm-Davis' less colorfully named Human Factors Laboratory. The goal of the merger was to build a central laboratory to encourage collaboration and cross-fertilization of ideas among the students and faculty of the human factors and applied cognitive program.

A number of different names were initially proposed for the lab. The first proposal, from Wayne, was CoSTAR – Cognitive Science: Theory, Application, and Research. However, the students in the program at that time wanted the term human factors included in the name. We challenged them to create such alternatives; they are shown below.

ORCHESTRAL – ORganization of Cognitive science and Human Engineering; Theory, search, and Application Labs (pertaining to the arrangement, coordination, or manipulation of elements to achieve a goal or effect)

COHERENT– COgnitive science and Human Engineering; REsearch, ENgineering, and Theory (logically connected; consistent; harmonious)

ARCH – Application and Research of Cognitive science and Human factors (a curved structure spanning two sides)

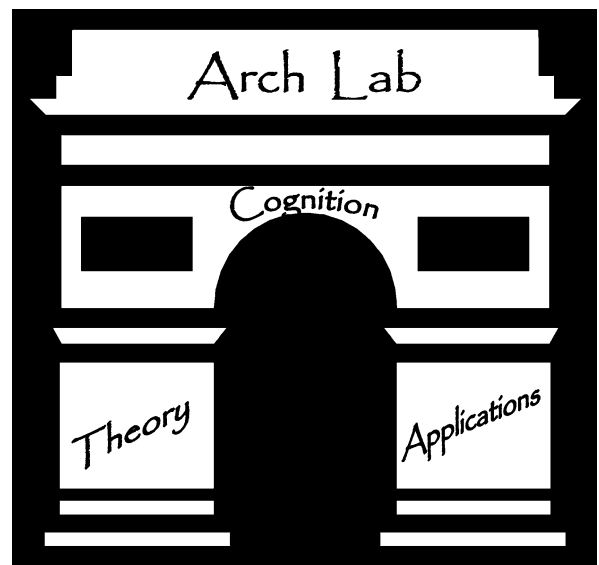

COGENT – COGnitive science and Ergonomics: (something) and Theory (forcefully convincing due to validity)

TORCH – TheOry and Research of Cognitive science and Human factors (anything that serves to enlighten, guide, or inspire)

HECTARE – Human Engineering and Cognitive science: Theory, Application, and REsearch (a metric measure of area equal to 100 acres)

The eventual winner was ARCH, with a slight change in wording to “Applied Research in Cognition and Human factors.” Along with the new name, a logo was developed (see Fig. 1). As can be seen in the figure, one pillar of the arch represented the development of theory while the other pillar represented application domains. The arch provided a bridge between the two types of work through cognitive psychology.

Some years later, a decision was made to update the logo and to use the word “Arch” without using it as an acronym. The arch remained the bridge between theory and applications; some faculty members are primarily engaged in basic research, some are engaged primarily in applied research, and some are heavily engaged in both areas of endeavor. The new logo, reflecting

George Mason University's Arch Lab. Fig. 1 Original ARCH Lab logo

George Mason University's Arch Lab. Fig. 2 Current Arch Lab logo

this change and a more modern “look and feel” is shown in [Fig. 2](#).

The Research

When the lab was established, there were two primary application foci – human-computer interaction and transportation (driving), each using two primary approaches to the development of theory – behavioral experiments and computational cognitive modeling. Over the years, our research has expanded to incorporate numerous other application domains including automation, aviation, medical, human factors, and robotics. It has also grown to encompass a wider range of basic research, including work on biological motion, eye movements, and visual perception. Although research in the lab continues to be primarily focused on behavioral and computational methods of research, convergent evidence from cognitive neuroscience (ERP, fMRI, TCD, fNIRS) plays an integral role in many of our research programs. This focus on neuroscience led to the establishment of the Center of Excellence in Neuroergonomics, Cognition, and Technology (CENTEC) in 2010. CENTEC research is focused on enhancing human effectiveness in air, space, and cyberspace operations through research in neuroergonomics, technology, and cognition. This center, and the majority of our research, has been funded by a number of different government agencies, both public and private, as well as by industrial partners.

Arch Lab Membership

To date, the Arch Lab has been home to 33 tenure-line and research faculty members and 3 staff members. Student engagement in the lab has grown over the years, from roughly 5 undergraduate and 30 graduate students at the start to our current numbers of roughly 15 undergraduate and roughly 45 graduate students in any given year, for a total of over 250 students over the years. The graduate program in human factors and applied cognition which is affiliated with the lab was initially directed by Wayne Gray. Deborah Boehm-Davis assumed leadership of the program in 2002 when Dr. Gray left the university. She remained in that role until 2006 when Dr. Raja Parasuraman became director of the program.

The Facilities

The Arch Lab originally consisted of approximately eight rooms and a shared conference room housed in a “modular building” on campus (the Chesapeake Module). In 1997, with the award of a large grant from the Department of Defense, the lab was moved to a dormitory (yes, a dormitory!) on the Mason campus (Carroll Hall). The lab moved to its current home in David King Hall in 2002 with the acquisition and renovation of roughly 5,000 square feet of space that had previously housed another department adjacent to the remainder of the Psychology Department.

The lab is equipped with state-of-the-art technology including an acoustically shielded room for auditory research, infrared eye-tracking systems (some with magnetic head trackers), a high-speed (500 Hz) gaze-contingent display system, and other devices for auditory and visual stimulus presentation. Capabilities in the laboratory include low-fidelity part-task simulations, medium-fidelity simulations for aviation (commercial and general), air traffic control, driving, robotics, distributed (individual and team) decision making, and unmanned vehicle applications and high fidelity simulations for driving and general aviation.

Significance

Arch Lab researchers have made significant research contributions to both cognitive psychology and human factors. Perhaps as important, the faculty has trained a significant proportion of the human factors practitioners working in the Washington metropolitan

region. Former students are working in research and teaching positions in the academic, public, and private sectors, which includes industry, government, consulting, and research and development organizations. These students have been taught not only by the program faculty, but also by distinguished practitioners working in the region. These lecturers have included Jack Adams, Marilyn Sue Bogner, Alphonse Chapanis, Steve Fadden, Susanne Furman, Jack Laveson, Tom Mayfield, and David Meister. As the Arch Lab continues to thrive at Mason, it hopes to inspire new generations of researchers and practitioners to excel in the professional community.

Gergen, Kenneth

SUZANNE R. KIRSCHNER

College of the Holy Cross, Worcester, MA, USA

Kenneth Gergen was born in 1934 and grew up in Durham, North Carolina. He was the second of four brothers; his father was chair of the Department of Mathematics at Duke University. He holds a B.A. from Yale University and a Ph.D. in experimental social psychology from Duke University, where his advisor was Edward E. Jones. Between college and graduate school, Gergen served for 2 years as an officer in the United States Navy. From 1963 to 1967, he was an Assistant Professor and Head Tutor in the Department of Social Relations at Harvard University. In 1967, he moved to Swarthmore College, where he served as chair of the Psychology Department for 10 years and for many years held the Gil and Frank Mustin Professorship. Currently he is a Senior Research Professor at Swarthmore. Gergen is also a founder and President of the Board of the Taos Institute, a nonprofit, educational organization dedicated to fostering relational practices compatible with constructionist theory. He holds several honorary degrees and has been the recipient of numerous awards, fellowships, grants, and visiting professorships at universities all over the

world. Among these honors are the Guggenheim and Alexander Humboldt Fellowships, several awards from the American Psychological Association, and election to the presidencies of two divisions of the APA. He has served on 35 editorial boards, was an Associate Editor of *American Psychologist*, and is a founding editor of *Theory & Psychology*. He is married to the feminist psychologist, Mary Gergen, and has collaborated with her on numerous projects.

Gergen is a leading social constructionist and relational theorist. He has spent much of his long and prolific career contributing to the critique of individualist and empiricist models in psychology and to promoting a reconstruction of the field that emphasizes relational processes. Gergen argues that the emergence of all intelligible action (including claims to mental states) occurs within relationships. He is also known for his view that psychological and social theories should be evaluated in terms of their potential to transform social life, rather than their alleged correspondence to objective realities. Among his most influential books are *Toward Transformation in Social Knowledge* (Gergen 1982, 1994b), *The Saturated Self* (1991; 2nd edition, 2001), *Realities and Relationships* (1994a), *An Invitation to Social Construction* (1999; 2nd edition, 2009), and *Relational Being: Beyond Self and Community* (2009). Gergen's work has had international impact in various subdisciplines of psychology (including social, developmental, theoretical-philosophical, and cultural psychology), as well as in other fields. These include psychotherapy (especially systems and family therapy), organizational development, education, and religious and cultural studies. He also has a longstanding commitment to reaching out not only to scholarly audiences, but also to other professionals and the lay public.

During the early years of his career, Gergen did experimental research in social psychology. His approach underwent a major shift in 1973, with the publication of his seminal and provocative paper, "Social Psychology as History" (Gergen 1973). In this article, Gergen argued that social psychological research and theory do not reflect universal behavior patterns. Rather, they describe historically and culturally variable modes of conduct. He also argued that psychologists' theories circulate back into society, thereby playing an active role in transforming

patterns of action. Subsequent writings on generative theory – e.g., *Toward Generative Theory* (1978) and *Toward Transformation in Social Knowledge* (1982) – elaborated upon these themes. During the 1970s and 1980s, Gergen devoted much of his work to challenging existing assumptions about psychologists' theories and practices. He drew on critical and literary theory, along with recent developments in the philosophy of science, to argue that knowledge is socially constructed, and thus that conventional understandings of psychology as an empirical and value-free science are not sustainable (*The Social Constructionist Movement in Psychology*, 1985). Simultaneously, he proposed that the longstanding Euro-American belief in a unitary, autonomous self is eroding, largely as a result of the ways in which contemporary communication technologies increase dependency on networks of relationships (*The Saturated Self*, 1991). By the 1990s, he had begun to give more prominence to a corollary theme: the primacy of relationship over individuality (*Realities and Relationships*, 1994a). Thus, in recent years, his writings have promoted a move away from framing the mind and self as interiorized subjectivity and toward theorizing forms of sociality designed to promote greater collaboration and well-being (*Relational Being*, 2009).

Since the dominant self-understanding of psychology has been that it is an empirical and cumulative science, it is not surprising that Gergen's theories have been the subject of controversy and debate. Experimentalists have argued against his framing of psychology as an interpretive and sociohistorical discipline, instead reaffirming their commitment to the view that psychology's methods should emulate those of the natural sciences and inquire into universal laws of behavior. Some interpretive, critical, and feminist psychologists (though they hold much in common with social constructionists) have suggested that Gergen's language-oriented theories lack an appreciation of human embodiment and subjectivity, and that his radically anti-foundationalist stance can lead to moral relativism. In his recent writings, he has addressed these concerns more directly, and his work continues to attract new constituencies, most recently in the fields of theology and gerontology. Gergen has been a powerful force in theoretical and qualitative psychology during the late twentieth and early twenty-first

centuries. His creative, synoptic, and lucid contributions have helped to catalyze a number of intellectual and social movements, both within and outside the field. In addition, his work has paved the way for the increasing legitimacy of narrative, discursive, sociocultural, and other qualitative, self-reflexive approaches in psychology.

Gesell, Arnold L.

JOHN D. HOGAN, ERICA M. TORRES
St. John's University, Jamaica, NY, USA

Basic Biographical Information

Arnold Gesell was considered one of the leading experts on childhood in his day. Trained in both psychology and medicine, he established normative data for many areas of early development, with a particular emphasis on motor development. His theory of development placed a heavy emphasis on maturation, that is, an innate timetable of growth and development. Although much of his normative data is still used by childhood professionals, his approach was later eclipsed by more dynamic theories.

Gesell was born in Alma, Wisconsin on June 21, 1880. He graduated from the University of Wisconsin

in 1903 and worked for a time as a high school teacher and principal. He later enrolled at Clark University to study for a Ph.D. degree in psychology which he received in 1906. His mentor was G. Stanley Hall, one of the founders of developmental psychology. Hall was well-known for his belief that evolutionary principles played a major role in explaining development and Gesell continued in his tradition, although in a less obvious way. After graduating from Clark, Gesell returned to teaching for several years and then accepted a position as director of the Yale Clinic of Child Development (1911–1948). During this period, he also began medical training and eventually received an MD degree from Yale University in 1915 (Gesell 1952).

While directing the Yale Clinic, he and his associates conducted an extensive series of observations of children, resulting in many articles and books. He and his team, including Louise Bates Ames and Frances Ilg, were known for their careful and detailed observation. The Clinic also made use of filmed records, using a specially constructed photographic “dome” to conduct some of their observations. Several of their experiments, particularly the so-called co-twin studies, are considered classics of child psychology. Gesell also conducted various assessments of children around the state in his position as school psychologist for the State Board of Education in Connecticut. He is often identified as the first school psychologist in the USA.

Shortly after Gesell’s retirement in 1948, Yale discontinued funding for the clinic. Several of his remaining colleagues moved to the newly formed Gesell Institute, near the Yale campus, and continued their work there with private funding (Ames 1989). Gesell died in New Haven, Connecticut, on May 29, 1961.

Major Accomplishments/ Contributions

Although Gesell recognized the contribution of the environment to development, his emphasis was on maturation. For him and his followers, it was clear that development proceeded in fixed patterns, guided by an inner timetable. This approach was consistent with the writings of Jean Jacques Rousseau (1712–1778), often considered the philosophical father of classical developmental psychology.

Much of Gesell’s work consisted of gathering extensive normative data on children. He popularized the practice of developmental testing. From the standpoint of child-rearing, Gesell recommended that parents always take into account the developmental level of the child before acting. For example, he argued that parents should never begin toilet training before the child is prepared for it maturationally. To do so is to invite trouble. If, on the other hand, the parents are patient and wait for the appropriate time, toilet training will proceed more easily and effectively. Gesell also believed that the child was capable of engaging in a great deal of self-regulation. Rather than subjecting the child to rigid and predetermined times for feeding and sleeping, parents were advised to let infants play a greater role in establishing their own schedules (Gesell and Ilg 1949). Many of these ideas about the “wisdom” of the child have been prominent in contemporary writing. Gesell’s emphasis on maturation level has also had important implications for early education.

One of Gesell’s classic experiments involved studies with identical twins. In these studies, one twin was given training in a motor activity, for example, step climbing or walking, while the other twin received no such training. At the end of the experimental period, the twin who received training could, in fact, engage in more effective motor behavior than the twin who received no training. However, the superiority was short lived. As the other twin matured, the apparent differences in ability between them disappeared. For Gesell, the implications were obvious. Maturation had the governing role in motor development, not experience and training. The key to successful development was matching experience and learning to maturational readiness.

Although most of Gesell’s work concentrated on motor development, he believed that similar principles applied to all aspects of development. In fact, he wrote books and articles describing development well into adolescence (Gesell and Ilg 1956). Gesell was criticized because his samples consisted largely of middle-class Caucasian children from New Haven, but he felt they were a good standard against which other development could be compared. Despite the limitations of his sample, his data appear to have held up well over the years.

His critics also felt that he paid little attention to individual differences, and his use of norms encouraged this belief. In fact, Gesell always emphasized the individual nature of children and warned parents and professionals that normative data were only broad guidelines. Although he argued that all children passed through the same stages in development, he emphasized that they could differ significantly in their rate of development. Moreover, he recognized that children had biologically derived individuality, resulting in different temperamental and personal styles (Thelen and Adolph 1992).

Gestalt Psychology

DAVID J. MURRAY

Queen's University, Kingston, ON, Canada

Introduction

The history of experimental psychology in the English-speaking world, especially in North America, was dominated from about 1913 to 1956 by behaviorism, neobehaviorism, associationism, and neoassociationism. The year 1913 was the year of publication of the first article on behaviorism by J. B. Watson (1878–1958); 1956 was the year nominated both by Baars (1986) and by Murray (1995) as the year in which the so-called Cognitive Revolution began. The subtleties of nomenclature hinted at by the distinction made above between behaviorism, neobehaviorism, associationism, and neoassociationism were not really incorporated into the literature until Anderson and Bower (1974) were

obligated to explain how their computer model of Human Associative Memory (HAM) differed from the Hullian model that had dominated research on human and animal learning between 1940 and 1956.

According to Anderson and Bower (1974, Chaps. 1–3), the word “behaviorism,” as used by its inventor J. B. Watson, incorporated four features that had also characterized “associationism,” a term that had been used by Locke (1701/1947, book 2, Chap. 33), Hamilton (1852, pp. 889–914), and many others to refer to the notion, first clearly propagated by Aristotle, that the thinking experienced by humans cannot be described as random but as connected. The first of these features is just that: mental experiences are indeed *connectionistic*. The flow of ideas can ultimately be decomposed into a basic stock of simple ideas; so associationism is *reductionistic*. These simple ideas can be identified with sensations (either from the external world or from interior feelings such as those of emotion); associationism is therefore *sensationalistic*. And it is possible for a theorist to derive simple, additive rules that will predict the properties of combined associative configurations from the properties of the underlying simple ideas; thus, associationism is *mechanistic*. Anderson and Bower (1974) claimed, therefore, that “associationism is a historical tradition distinguished by its attempts to reconstruct the human mind from sensory experience with minimal theoretical assumptions” (p. 11). They went on to point out, influenced by Bever et al. (1968), that, in behaviorism, there is an additional assumption, namely, that all observable behavior can be explained in terms of chained associations of habits; in humans these habits often include verbal chains, experienced as silent “talking to oneself.” This last assumption is what has caused most disagreement *vis-à-vis* the identification of Watsonian behaviorism with traditional associationism.

Anderson and Bower (1974), however, contrasted the above account of associationism with what they called rationalistic theories. Whereas associationism had been connectionistic, rationalist theories tend to be *nativistic*; instead of being reductionist, rationalist theories tend to be *holistic*; instead of sensationalistic bases for thought processes, we have *intuitionistic* bases; and instead of mechanistic properties, we have *vitalistic* properties.

“Vitalism” was a word originally used in the nineteenth century to refer to a putative “life force” that characterized living, as opposed to inanimate, objects. But, as Murray and Farahmand (1998) showed, the Gestalt psychologist Wolfgang Köhler wrote at length against the idea that any forces other than those known in physics and chemistry played any part in determining events in the mind–brain system. But Anderson and Bower went on to explain that, when they used the term “vitalistic,” they were referring to the fact that many human thought processes appear to be determined by future goals and purposes; the role played by goals and purposes as motivating forces underlying not only human, but also animal behavior, would, of course, be one of the major issues dividing the Watsonian behaviorists from the Gestalt psychologists. Here, we replace Anderson and Bower’s term “vitalistic” with “purposivistic.”

Anderson and Bower (1974), in developing their HAM model of long-term memory storage and retrieval, were forced to include the fact that a memory search by a human necessarily involves a rough knowledge of the end point of that search. At the same time, Anderson and Bower did not want to abandon the mechanistic properties that allow for sequences of causal propositions to connect those successive steps in the modeling that parallel the successive steps experienced by a thinking human (whether the modeling be neural, computer, or mathematical in nature). As a consequence of having to incorporate motivational properties into an otherwise mechanistic system, they proposed to brand their version of associationism, *neoassociationism*.

This was not the first time this word had appeared in experimental psychology. Berlyne (1965) took the view that, not only humans, but also animals, were motivated by a desire for novel stimulation; in order to add this view to his otherwise mechanistic model of human and animal behavior, he had used “neoassociationism” as a word describing how, in his theory of behavior, he considered motivational and planning procedures to be elements that had to be integrated with S-R connections of the more conventional type. Indeed, a major contributor to the success of the cognitive revolution had been Miller et al. (1960) book entitled *Plans and the Structure of Behavior*.

Gestalt psychology was considered by Anderson and Bower (1974) to be a stimulating, but flawed rationalistic theory that had attempted to rival behaviorism in rigor but had failed to do so largely because its major theorists, Max Wertheimer (1880–1943), Kurt Koffka (1886–1941), and Wolfgang Köhler (1887–1967), had failed to produce an axiomatic quantification of Gestalt theory that could rival the axiomatic quantification of behavioristic theory produced by Clark L. Hull (1884–1952). A recently published correspondence between Hull and Max Wertheimer clearly attests to Hull’s own demands for a quantified treatment of Gestalt psychology (King and Wertheimer 2005, pp. 267–270).

Because Hull’s theory had been initiated as a straightforward rendering of Pavlovian ideas in the context of human paired-associates learning, and had then been adapted for application in animal learning tasks such as running down an alley to get food, or making a choice as to which way to turn in a T-maze, the validity of Hull’s animal model had to be questioned when evidence was obtained concerning the reinforcement value of rewards that did not necessarily satisfy an animal’s physiological needs. It was also found that rats placed in mazes more complicated than those mentioned above were able to make use of sensory cues so cleverly as to suggest that the choice of which way to turn was based on more than the mere repetition of a set of limb movements that had been rewarded on the previous trial. Discoveries like these led Koch (1961) to coin the term “neobehaviorism” to distinguish Hullian and other theories of the 1930–1960 period from Watsonian behaviorism; the word was rapidly taken up by learning theorists. One of the most eminent neobehaviorists E. C. Tolman (1886–1959) actually invented words like “sign-Gestalt” and “cognitive map” to describe the sophistication that even rats seemed to apply when given the task of finding their way through a radial maze. These ideas were expressed in a book with the revealing title, *Purposive Behavior in Animals and Men* (Tolman 1932).

The following survey of Gestalt psychology begins with a brief historical account of how Wertheimer, Koffka, and Köhler contributed, in their own individual ways, to the general narrative of the growth of Gestalt psychology. Subsequent research that has been strongly influenced by the discoveries of these investigators will

then be described in the framework that includes, for reasons to be explained, a distinction between inanimate and animate stimulus configurations.

The Achievements of Wertheimer, Koffka, and Köhler

According to *Cassell's German and English Dictionary*, the noun *Gestalt* can be translated as “form; shape, figure; stature; mien, air; aspect, manner; vision” (Breul 1952, p. 246). Given the plethora of meanings, it is not surprising that the word *Gestalt* has been left untranslated in many psychological texts.

Even harder to translate is the term *Gestaltqualität*, introduced by von Ehrenfels (1890) to refer to the fact that a visual input that would be described by a geometer as “four lines” might be so connected on a page that a viewer would judge them to represent a “square”; or that an auditory input that would be described by an acoustician as a sequence of tones varying in frequency would be so connected in mental experience that a listener would judge them to represent a “tune.” The lines constituting the “square” could be moved en bloc to a different location on the page, but the “square” would, phenomenologically speaking, remain a “square”; the sequence of sounds constituting the “tune” could be played at opposite ends of a piano’s keyboard but the “tune” would, phenomenologically speaking, remain the same “tune.” Von Ehrenfels insisted that the “squareness” of the elemental lines or the “tuneness” of the elemental tones was not necessarily the result of a conscious effort to “make sense of” the respective conjunctions of lines or tones, but were perceived immediately, with the immediacy itself determined by the “Gestalt quality” of the four-lines-viewed-together or the four-tones-heard-as-a-sequence. An abridged version of von Ehrenfels’s (1890) article reveals how Gestalt quality can be expressed in English (von Ehrenfels 1937).

To describe the perceived “square” or “tune” as examples of “configurations” of lines or of tones seems as good a translation of *Gestalt* as can be hoped for in this psychological context; but it has proved easier, historically, to preserve *Gestalt* as an untranslated import into the English language, as noted above. Indeed, the word “Gestalt” has been adopted so enthusiastically that it has acquired a new

usage as a synonym for “holistic” in certain therapeutic circles; historically speaking, the term “Gestalt therapy” has little to do with the Gestalt movement. But its founder, Fritz S. Perls (1893–1970) did work in Berlin in 1926 with Kurt Goldstein (1878–1965), a Gestalt-influenced neuropsychiatrist, prior to Perls’s emigration to South Africa in 1942 and then to the USA in 1946. Here, Perls founded both the New York Institute of Gestalt Therapy and, in 1966, the Esalen Institute in California (Sahakian 1975, pp. 202–204).

The range of referents to which the word *Gestalt* was applied by members of the Gestalt movement was also, not surprisingly, wide. Brunswik (1929) was critical of what he considered to be the over-wide range of phenomena to which the word was being applied, and drew up, in a tabular format, a survey of Gestalt phraseology. This table was translated into English by Hartmann (1935, p. 285). It begins by distinguishing between two fundamental usages of the word *Gestalt*. In the first, the word *Gestalt* is applied to the outer, external world; Köhler (1920/1938b) was fond of talking about “physical Gestalten”; for example, when an electric current is passed into a block of conductive material, the current is able *instantaneously* to charge the block as a whole. In the second fundamental usage, the word *Gestalt* is applied to the inner world of private experience. In one such context, the word *Gestalt* characterizes the holistic manner in which sensory inputs are responded to; good examples would be those of “squareness” and “tuneness” described earlier. In a second context, the word characterizes the unity given to a series of actions that are carried out sequentially with the aim of attaining a particular purpose. In the context of sensory processing are included the laws of grouping in perception, often met for the first time by readers in introductory psychology texts. These laws of perceptual grouping are closely related to the organization of visual inputs into “figure” and “ground,” and the organization of auditory inputs into the musical language of rhythm, melody, and harmony. In the context of describing sequences of mental events, Gestalt phenomena include moments of insight (“Aha” experiences) during problem-solving by apes and humans. In a moment, we shall see how the word *Gestalt* can also be used in a context of social psychology.

Max Wertheimer

Max Wertheimer obtained his Ph.D. from the University of Berlin in 1904; his dissertation was about the potential usefulness of word-association tests in detecting criminal guilt. He also spent a few years studying Aboriginal cultures, including their music, with Carl Stumpf (1848–1936) before spending a year at Würzburg, where he interacted with Oswald Külpe (1862–1915) and other members of the Würzburg School; he also worked at Vienna with Sigmund Exner (1846–1926), who was studying apparent movement with the aid of a tachistoscope that allowed two electrical sparks to be presented with a very short time interval between them. His first publications were about the music of the Vedda people in what is now Sri Lanka (Wertheimer 1910) and about number concepts in Aboriginal peoples (Wertheimer 1912; King and Wertheimer 2005, p. 96) claim that Max Wertheimer took the group ethos as representing a general Gestalt; Wertheimer's task was to display the artistic, linguistic, and other expressions of intellectual endeavor as parts within a general whole.

But he was still not qualified to teach a university course; the article that earned him the title of *Privatdozent* at the University of Frankfurt in 1912 was his exploration of the cognitive components of the visual perception of apparent movement. Exner had already established that, between two identical visual stimuli, displayed one after the other at differing locations, there was an optimal time interval between the stimuli that would lead to an appearance of movement from the first to the second. Wertheimer (1913/1961) restructured the problem by seeing it, not so much as establishing the limits of when two stimuli could be detected as occurring separately in time, but as a method for exploring how the mind grouped successive stimuli into a unified visual experience or “whole.”

Apparent movement was, of course, the physiological underpinning of the new art of cinema; its importance for Gestalt psychology lay not only in its being the first demonstration of an emergent “whole” arising from a temporospatial concatenation of parts, but also for its usefulness for showing the influence of mental expectation on the perception of “what happened” when a stimulus seemed to shift from one location to another. For example, if dots 1, 2, 3 (...) are illuminated first together, and then dots 2, 3, 4 (...)

are illuminated second, the line of dots seems to shift as a whole to the right and participants do not necessarily detect that dots 2 and 3 were illuminated twice. This is the paper in which the notion of mental “organization” is introduced in the context of the mental “set” (*Einstellung*) with which a display is viewed/parsed/interpreted/labeled by the viewer. In particular, two lines illuminated one after the other will be seen to yield apparent motion, the closer they are together (later, this would be called the “law of proximity” as a determinant of perceptual grouping). At this stage in Wertheimer's theorizing, *Gestaltqualität* was just one of several theories that he considered might be applicable to the phenomena of apparent movement.

One of Wertheimer's teaching colleagues at Frankfurt was Friedrich Schumann (1863–1940), who had originally worked with G. E. Müller (1850–1934) at Göttingen. Müller and Schumann (1889) had collaborated on research demonstrating the role of *Einstellung* in determining judgments of subjective heaviness; if a light weight were picked up after a series of heavy weights had been picked up, the light weight was judged to be much lighter than was an equal weight that was picked up without having been preceded by a series of heavy weights. More details about this research have been given by Murray (1999). Müller and Schumann (1893) had also shown the importance of rhythmization during the learning by heart of successive pairs of nonsense syllables in a long list. Schumann had not only developed a memory drum for use in experiments on rote learning, but had also developed Exner's tachistoscope for application in Wertheimer's studies of apparent movement.

Yet, neither Schumann nor G. E. Müller himself counted themselves as members of the growing “Gestalt movement.” G. E. Müller, in particular, developed the notion that what we normally call “memorizing” was largely a matter of “organizing” the to-be-remembered material into groups he called “complexes” (Müller 1923). His contributions to our understanding of organization in learning tasks were fully acknowledged by Köhler (1929, p. 287 ff; 1947, p. 157 ff). But Müller himself considered it unnecessary to load an accretion of “Gestalt formation” onto the rather simple conceptualization that grouping during learning could be facilitated by rhythmizing, semantic-association forming, and reliance on one's unusually

good retention of the initial item of a to-be-remembered list. Müller's rather neglected contributions to the role of organization in memorizing were reviewed by Katona (1940) and by Murray and Bandomir (2000).

In 1916, Wertheimer left Frankfurt to teach at Berlin, where he was later joined by Köhler in 1922. Wertheimer's best-known paper, in which he delineated the principles of organization in perception (including the laws of proximity, similarity, closure, and "common fate"), was published in the fourth volume of a new Gestalt journal entitled *Psychologische Forschung*; the title of the paper was "Investigations of the doctrine of Gestalt" (Wertheimer 1923/1938a). Hartmann (1935) wrote that Wertheimer's study leads to a summary statement that

- ▶ In psychology, the right formula is, *Constellation of stimuli* → *Organization* → *Reaction to results of organization*, rather than the usual *S* → *R* type. The organism is not barren functionally, it is not a box containing conductors each with a separate function; it responds to a situation, first, by dynamical events peculiar to it as a system and, then, by behavior which depends upon the results of that dynamical organization and order. (p. 100)

According to Hartmann, underlying all of the laws of grouping is the more general law of figure-ground organization, which had most notably been written about by Edgar Rubin (1886–1951), who had been working in G. E. Müller's laboratory at the time (Rubin 1915/1921).

Gottschaldt (1926/1938a; 1929/1938b) famously demonstrated that even if a participant has viewed a distinctive figure several hundred times, so that it must have been in some sense "overlearned," the figure would not be spontaneously identified if it were embedded in a novel context. The existence of camouflage in the natural world can be considered as proving the overriding power of the notion that a "constellation of stimuli" (the embedding context) is "organized" as a whole, so that the participant's "reaction to the results of that organization" is that the embedding context is also judged as a whole, with the consequence that the embedded figure is simply not noticed.

Wertheimer (1925/1938b) wrote a monograph on problem-solving which was followed 20 years later by

a (posthumously published) book entitled *Productive Thinking* (Wertheimer 1945). Wertheimer insisted that an S-R account of problem-solving was too restrictive to deal with those moments of sudden insight or "Aha experience" that frequently accompany a solution. Insight experiences involve seeing the problem in a new light (a process Wertheimer subsumed under the label of a "restructuring" of the problem). Any attempts at solutions that remain "in a rut," as we might say, or that fail to consider that the elements in the problem might be utilized or reorganized in novel or unconventional ways, will work against the likelihood that a productive restructuring of the problem will be attained. The classic Gestalt demonstrations of "functional fixedness" in problem-solving were those described in the English-language monograph of Karl Duncker (1945), though it had actually been written in German 10 years earlier. Also carried out in Germany shortly before Duncker's research were the investigations reported, in English, by Norman R. F. Maier (1930, 1931, 1945) on functional fixedness.

Duncker and Maier, like Wertheimer, were refugees from the Nazi period; Duncker emigrated to work with Bartlett at Cambridge before moving to the USA, where he joined Köhler at Swarthmore College in Massachusetts; Maier had moved from Berlin to the University of Michigan; and Wertheimer went from Frankfurt to the New School for Social Research in New York City. A detailed account of the "intellectual migration" of Gestalt scholars from Germany to the USA and other English-speaking countries has been provided by Mandler and Mandler (1969). An account of the contributions of the Gestalt psychologists to the study of problem-solving, along with an account of later events that took place during the cognitive revolution, when Michael Wertheimer (1985) criticized Newell and Simon's (1970) book entitled *Human Problem Solving* for not having allotted sufficient consideration to Gestalt views on restructuring, will be found in Murray (1995, Chap. 5). Simon (1987) himself, however, remained unpersuaded; he believed that insight experiences could be modeled using appropriate computer programs.

Kurt Koffka

We now turn the clock back to 1903, when Koffka spent a year in Edinburgh, studying Anglo-American

literature; he was the first of the major Gestaltists to emigrate to the USA (to Smith College in Northampton, Massachusetts, in 1925) and the first to write a summary of Gestalt principles in English (Koffka 1922). His early research was on color vision, a topic that allowed him to work as an assistant to J. von Kries (1853–1928), to whom we owe the “duplicity theory” of how the rods and cones determine visual processing. Koffka’s Ph.D. research was on the effects of grouping among visual stimuli presented in such a way that one could, for example, beat out a rhythm by tapping one’s foot in time with those visual stimuli; this investigation was an extension of the work of Carl Stumpf on the role of rhythm in musical perception. Following a short stay at Würzburg, where Koffka would have absorbed the emphasis that faculty members placed on the role of set in determining the course of the successive mental experiences involved in problem-solving and in introspective activity, he joined Wertheimer and Köhler at Frankfurt in 1910, but for only a brief time; he received a faculty appointment at the University of Giessen in 1911. It was here that the neobehaviorist E. C. Tolman visited him as a graduate student between 1911 and 1913, and where Tolman clearly absorbed many of the Gestalt concepts that would characterize his purposivistic neobehaviorism; a particularly useful account of the influence of the Gestalt movement on Tolman’s ideas is given by Malone (1990, Chap. 7). Koffka’s move to the USA in 1925 was a major event that paved the way for the reception of, and the controversies surrounding, the writings of the Gestaltists in North America.

While at Giessen, Koffka had become embroiled in a polemic literature with Vittorio Benussi (1878–1927), who had argued that a stimulus aroused a constellation of sensory impressions, but had also contended that the constellation had not been organized as part of the perceiving process, but was an outcome of various psychological associations to which the stimulus had given rise. Benussi was by no means the only person to assert that it was unnecessary to postulate that Gestalt organization was intrinsic to the very initial stages of perceptual processing; several individuals insisted that the traditional processes of mental associations sufficed just as well as did Gestalt processes to account for the immediacy with which a large number of simultaneous receptor inputs could be “simplified” by our brains in

such a way as to let us “make sense” of our experiences of the external world. Others included G. E. Müller and E. Brunswik (1903–1955), as already noted, as well as E. Rignano (1870–1930), K. Bühler (1879–1963), and M. Scheerer (1900–1961). Scheerer (1931) complained that the focus on the Gestalt organization of a perceived figure “disembodied” that figure from the viewer’s own active self. As Hartmann (1935) phrased it, “A curve drawn on a piece of paper is a physical process, a symbol of some trigonometric function, an aesthetic ornament, or a religious symbol” (p. 284). Koffka (and, of course, Wertheimer and Köhler) devoted considerable efforts to fending off criticisms like these, and Koffka’s (1935) magnum opus, the book written in English entitled *Principles of Gestalt Psychology*, epitomizes, in its inclusion of armchair theorizing along with an amazing array of experimental findings, the defensive stance that the Gestalt psychologists felt obliged to adopt when confronted with the claims, initially of traditional associationists in Germany, and, later, of Hullian neobehaviorists in North America. These German claims have been eloquently summarized by Ash (1995, Chap. 18).

Koffka was among the first to extend the use of the word “configuration” from a perception context to an action context. He believed that very young children learned to respond not just to what the behaviorists had called individual “stimuli” (whether unlearned or conditioned), but to a total situation in which a combination of stimuli that, together, had aroused an emotional association in the past, are judged *as* a combination, that is, as a “configuration.” Watson and Rayner’s (1920) “conditioned emotional responses” served the same purpose, but Koffka’s configuration phraseology allowed for combinations of stimuli to exercise one emotional effect if they were combined in one particular way, but a different effect if the stimuli, despite remaining identical when considered in isolation, were combined in a different way. Koffka’s view was most clearly expressed in his book on child development entitled *The Growth of the Mind*, originally written in 1921 in German, but made available in English at just about the same time as Koffka began his career at Smith College in the USA (Koffka 1921/1925). Murray and Farahmand (1998) have claimed that Koffka’s use of “configurations” prefigured many of the concepts of the late twentieth-century “dynamic

systems theory” that has been so influential in present-day developmental psychology. Elsewhere, Murray wrote that:

- ▶ Koffka ... described the growth of the child’s mind over the first few years of life in terms that were not behavioristic: children were assumed to have goals that directed their actions, to be adaptive and versatile in their learning of motor skills and language, to be selective in what they attended to particularly with respect to their observations of other persons, and to be capable of ‘ideation’, including image-formation. These images permitted them to form a mental representation of reality. (Murray 1995, p. 36)

To these remarks, Murray added that Koffka laid considerable emphasis on the importance of the imitation, by the child, of actions, gestures, and vocalizations carried out by other persons.

Wolfgang Köhler

Köhler’s Ph.D. thesis, obtained under Carl Stumpf at the University of Berlin, was designed to test Stumpf’s theory that vowel quality is associated with particular combinations of overtones. Köhler’s findings, which were obtained using a novel apparatus for measuring the response of an eardrum to incoming sounds, instead seemed to show that vowel quality depended on the frequency of individual tones, rather than on combinations of tones. He argued that the human ear had evolved for the purpose of conveying information to the brain about the sounds of nature (including animal vocalizations and human speech) rather than about individual tone frequencies; he used this hypothesis to explain why musical ability varies so widely from individual to individual. A more detailed summary of Köhler’s neglected theory of the evolution of human audition is given by Murray and Farahmand (1998); the theory itself was published in German in three parts (Köhler 1909, 1910, 1915). It was a predecessor to a similar theory put forward later by Yilmaz (1967, 1968), who, however, may not have known about Köhler’s hypothesis.

In 1913, Köhler was appointed Director of a research station for the study of anthropoid behavior. It was located on the island of Tenerife (off the Atlantic coast of North Africa), where he stayed for many years, partly because the outbreak of World War I in 1914

prevented him from returning to Germany. It was not until 1919 that he was able to return, briefly, to the University of Göttingen, before moving to the University of Berlin in 1920, where he succeeded Stumpf as the Director of the Psychological Institute. His tenure there lasted from 1922 to 1935, when, as Koffka and Wertheimer had already done, he emigrated to the USA. Hopes that he might be hired at Harvard were not realized (Sokal 1984), so he spent the remainder of his life at Swarthmore College in Pennsylvania, where he influenced a new generation of Gestalt-oriented psychologists that included the learning theorist David Krechevsky, the acoustician J. C. R. Licklider, the historian Mary Henle, and the prominent spokesman for the cognitive revolution Ulric Neisser.

On Tenerife, Köhler was responsible for at least three major contributions to Gestalt psychology, namely, his discovery of relational responding by animals in discrimination tasks (Köhler 1918/1938a); his observations on how chimpanzees solve problems (Köhler 1917/1925); and his theoretical book (Köhler 1920/1938b), in which he used his background in physics to show how parallels could be drawn between physical Gestalten (as when a current charges a medium *en masse*) and psychological Gestalten (as when a visual pattern is interpreted as a “whole”).

In relational responding, chickens that had elected, given a choice between gray and black, to choose gray for a food reward, would, when given a new choice between gray and white, choose the white twice as often as they would choose the original gray. For Köhler, the co-presence of the two original stimuli, gray and black, constituted a Gestalt rather than a twosome; the chickens perceived the two stimuli in a “togetherness” relation at the time of choice. In everyday words, the chickens were choosing the “lighter” rather than the “gray” cue on the earlier trials, and transferred their preference to the “lighter” cue, namely, the white, on the trials with the new choice.

Köhler’s work on problem-solving by chimpanzees made him world famous. Essentially, his goal was to offer an account of anthropoid behavior that would contrast with Thorndike’s (1898) theory of cat behavior that was currently dominating animal learning theory. According to Thorndike, a cat in a puzzle box tries to escape from the box by random attempts to open it until one of the attempts is successful, and the

movement(s) that led to the escape were “reinforced” by the ensuing state of satisfaction. Köhler felt that it was unfair to expect that cats, limited to a partial viewing of the various latches that, when manipulated, would open the cage door, would solve the problem in ways other than by trial and error. Using his chimpanzees as subjects, Köhler claimed that an animal must be able to see all the elements of a problem in an overview, and that solutions would not necessarily come about by trial and error, but by the chimpanzee’s viewing the elements of the problem in a new light that would lead to the successful solution of the problem. For example, seeing, in one visual sweep, a banana suspended from the cage’s ceiling (too high to reach or jump for) plus two large wooden crates side by side on the cage’s floor could lead the chimpanzee to stack one box on top of the other and clamber up them till the banana *could* be grasped. A “good error” consisted of stacking the boxes slightly askew, with the result that chimpanzee’s early reaching-attempts were unsuccessful because the stack tipped over under the chimpanzee’s weight. Köhler also reported that the chimpanzee often accomplished the stacking smoothly, rather than in a haphazard “trial-and-error” fashion. Because the smooth sequence of stacking movements often followed a few moments’ silent contemplation of the visual field, Köhler claimed that the chimpanzee could experience an “Aha solution” to the problem.

But Pavlov (1935/1957, pp. 592–599) argued that those few moments were simply the animal’s way of resting, rather than of meditating; and he added that an ape studied by Pavlov himself, not only took 2 months to learn to stack boxes on top of each other, but did so by the “method of trial.” Later, Birch (1945) demonstrated that the speed of a solution varied directly with the degree of experience a chimpanzee had previously had with the elements of the problem (in Birch’s study, sticks). Köhler also claimed that he had evidence that his chimpanzees could learn by imitating others, whereas Thorndike (1898) had claimed that his cats could not learn, by imitation, to escape from their cages’ confines.

Once back in Berlin, Köhler began to study human memory from a Gestalt perspective. He demonstrated that the apparent forgetting of a “brightness” over time could be ascribed not to a passive decay process, but to the mental assimilation of the memory of the

brightness to the brightness of the ongoing background (Köhler 1923). That is, in memory tasks involving the reproduction or identification of nonverbal stimuli, each to-be-remembered stimulus was retained *as* a part of the whole spatiotemporal context. When the to-be-remembered stimuli are verbal, each stimulus is the better recalled, the more it is isolated from the “crowd” of other to-be-remembered items in the sequence of verbal stimuli (von Restorff 1933; see Hunt 1995, for an English translation). In recognition tasks, the more a nonsense shape differs from the nonsense shapes surrounding it, the more accurate the recognition performance (Köhler and von Restorff 1937). A detailed examination of the influence of this crowding/isolation approach upon later interference theories of verbal learning has been provided by Murray (1995, Chap. 4). It might be noted that Hedwig von Restorff (1906–1962), after having studied philosophy and having obtained her Ph.D. in psychology with Köhler in Berlin, transferred into medical studies after Köhler’s departure, and eventually became a family doctor practicing in Freiburg in Southwest Germany.

After he had arrived in North America, Köhler was asked to give a series of lectures at Harvard, which were subsequently published as a book entitled *The Place of Value in a World of Facts* (Köhler 1938c). This work drew attention to the way in which feelings of mental incompleteness and indecision can be resolved by the finding of a solution one somehow “knows” to be correct; Köhler gave the special name “requiredness” to that property of the mind that seems to understand when a problem has been satisfactorily solved, or when a thought is “fitting” in a semantic context. In memory theory, a similar emphasis had been placed by G. E. Müller on the importance of the resolution of feelings of “vagueness” during memory search (on this, please see Murray and Bandomir 2000). A summary of Köhler’s 1938c book has been offered by Murray (2005).

Köhler’s final years were occupied with developing a theory of how brain processes that did not necessarily involve synaptic events could explain figural aftereffects in vision (Köhler and Wallach 1944). This theory has rarely attained favor among neurophysiologists, even though he maintained it steadfastly right up to his final lecture series, and published posthumously as *The Task of Gestalt Psychology*. His final words in that book were:

- ▶ ... why do brain-processes tend to produce perceptual organizations of remarkable clearness of structure? At least this part of nature, the human brain, seems to operate in a most selective fashion. It is the *direction* of its operations which is truly remarkable. (Köhler 1969, p. 164)

The Present-Day Relevance of Gestalt Psychology

After Köhler's death in 1967, Gestalt psychology continued to be practiced in both Europe and North America. Many of the graduate students who had known Wertheimer, Koffka, Köhler, and, we wish to add, Tolman established prominent academic careers (Ash 1995, Appendix 2; King and Wertheimer 2005, p. 370; Mandler and Mandler 1969). The influence of Gestalt psychology continued to be strong in the experimental psychology of sensation and perception, memory, and problem-solving; a detailed account of this influence was provided by Murray (1995). Under the influence of Kurt Lewin (1890–1947), who, like his colleagues Wertheimer and Köhler at Berlin, had studied under Carl Stumpf, and who had emigrated to Stanford University in 1932, both social psychology and child psychology were immeasurably supplemented by Lewin's holistic approach, which was so broad as to consider a person's lifetime as a "whole." A useful introduction to Lewin's work is given by Sahakian (1975, pp. 213–222).

The persistence of Gestalt psychology in Europe was attested to in the works of Wolfgang Metzger (1899–1979), who was Catholic and had stayed on in Germany during the war years. Metzger's adaptive responses to political changes have been authoritatively described by Ash (1995, pp. 346–354). Instead of repeating what is readily available in these secondary sources, I wish here to offer a perspective according to which the contributions of Gestalt psychologists, both during and after Köhler's lifetime, are related to a picture of contemporary psychological science that includes some recently discovered evidence on genetically determined aspects of the development of the human brain.

As noted in the above discussion of his book, *The Growth of the Mind* (Köhler 1921/1925) introduced into experimental psychology a verbal notation for

the description of learned habits by animals, human children, and human adults that stressed the inadvisability of divorcing the raw sensory constituents of a perceptual experience from the emotional feelings that accompany them. This new kind of "behavioral whole" was called a "configuration," and its value in psychological learning theory has been attested to by its adoption in the hands of cognitive psychologists developing a model of human long-term memory (Anderson and Bower 1974), and in the hands of child psychologists developing models of learned emotional responses during the first few years of life (Lewis 1995). A distinction can be made here between two kinds of configuration: configurations that refer to inanimate objects and configurations that refer to animate objects. The reason for making this distinction is that new discoveries in neuroscience include an innate component to the responses given by an observer's brain to the behavior patterns of other individuals conspecific with that observer.

Discrimination Responses to Inanimate Configurations

Very simple inanimate sensory inputs (such as a drawn line, or a patch of color of a given brightness, or a pure tone of a given intensity) are typically used in psychophysical tasks concerned with establishing, and possibly measuring, absolute and differential thresholds. For example, two adjacent patches of white might differ so little when viewed together that an observer judges them to be "equal" in subjective brightness even though it is the case that they are not equal in physical luminance as measured by a photometer. Lipps (1905/1926) argued that the two patches are not judged as "two" patches, but as one unitary sensory whole which may or may not appear equally bright within its constituent parts. If the subjective brightness appears to vary within the totality, the observer judges that the total experience involves "different" subjective brightnesses; otherwise, he judges the total configuration to possess the "same" subjective brightness all over. A same/different judgment, according to Lipps, is made on the basis of processing the two patches as if they constituted a single entity.

On the other hand, the ease with which a same/different judgment can be made is not necessarily reflected in the ease with which a "different" judgment

can be measured, that is, assigned a numerical magnitude that is an index of the subjective magnitude of the difference in subjective brightness between the two patches. Such a judgment of the size of the difference depends on the observer's being mentally capable of conceptualizing each patch as an agglomerate of "units" of subjective magnitude. How this can be achieved – if, indeed, it can – is the question at the heart of all psychophysics. In his editorial introduction to Lipps's (1905/1926) book, Knight Dunlap described Lipps's hypothesis as having "... an importance demonstrated by the recent rise in interest in the "Gestalt" theory, on which Lipps' discussion bears to a considerable extent, although written before the promulgation of that theory" (p. 7).

Choice Responses to Inanimate Configurations

If organisms were to respond relationally at all times, life-threatening errors of response could occur. If it were *only* the "louder" of two spatially or temporally contiguous sounds that were to elicit a defensive reaction, a thunderclap might be attended to by a small forest animal instead of the quiet crackle of a twig that betrayed a nearby predator. For effective adaptation to a world in which survival is sustained by a steady regimen of feeding and of seasonally appropriate breeding, some cognitive device had to evolve that permitted particular sense data to be interpreted as being the most "salient" at any given moment (given the organism's need state), and not merely as the most "physically intense."

In animals, it would appear that the salience of a cue can be signaled by the fact that a memory reproduction of that cue can be linked, via neurons in the animal's hippocampal formation, with individual places the animal has visited. The extraordinary ability of animals to remember "what" happened "where" has been well documented (Paivio 2007). Historically, however, the first book-length account of the role of the hippocampus in aiding animals (such as rats or mice) to learn which arm of a radial maze it should choose in order to attain a food reward if it is hungry was that of O'Keefe and Nadel (1978). Not only do these authors acknowledge their indebtedness to Tolman, they also contend that Immanuel Kant (1724–1804) was the first major thinker of modern times to have appreciated that there

would almost necessarily *have* to be a brain mechanism for organizing the sensory contents stimulated by one's spatial surround, a mechanism that operated in such a way that orientation in space was not a skill subservient to the hazards of chance experience, but was contingent upon an unlearned understanding of how to orient in space. By linking each incoming sensation to the animal's retention of previous events that had happened in the same spatial environment, animals can learn to discriminate between sensations that savor of danger and those that harbingers safety; and the dominance of relational responding is replaced by experience-based responding.

In humans, not only is place memory used as a device for determining whether some classes of sensory input are harmless as compared with harmful, but a particular kind of auditory-verbal-linguistic memory has also evolved that adds to our repertoire of experience-based responses. It is not difficult to conceive that an event might have occurred in the evolution of human speech that facilitated the transformation of articulated phonemes into carriers of salience information in a world where inter-human communication would have included warnings about what places were dangerous, what plants were good to eat, and so on. It has been discovered that a particular mutation, known as the FOXP2 gene, may have been associated with the elaboration of the anatomy of the larynx and oral cavity of protohumans in such a way that the number of distinct speech sounds that could be vocalized by humans vastly outnumbered the number of distinct vocalizations that could be vocalized by the great apes (Corballis 2004).

If this theory, only framed broadly at the present time, should receive confirmatory support, not only would an increase in survival strategies ensue as a consequence of the evolution of language; it would also mean that planning for the future would be vastly improved because of the existence of linguistic memory representations of the past that could be conceptually remolded in the mind so as to represent a possible future event. Not only would Köhler's assimilation of chimpanzees' problem-solving abilities with those of humans be vindicated, but so would the views of Koffka on how language is acquired in young human children by associations between the sounds of particular articulated responses with particular perceived objects,

associations that become so tightly bound that, when the child hears a word, the word and its meaning form a “configuration” that can activate an appropriate linguistic or behavioral response, on the part of the child, to whatever is referred to by that word.

Considerable plausibility was given, by the work of Kendler and Kendler (1968), to an explanation of the usefulness of language for determining experience-based degrees of salience in childhood. These authors had been trained in the Hull–Spence tradition, but were clearly intrigued by the need to integrate relational responding (as exemplified by Köhler’s chickens and apes) into the corpus of information about learning in human children. They showed that very young children, like Köhler’s animal subjects, will choose the “brighter” of two grays (selecting gray over black, and then white over gray); but when the children are old enough to enunciate words like “black,” “gray,” and “white,” they can learn to go against relational responding because they can learn to select gray over black by naming the former “gray,” and then continuing to identify the gray by the word “gray” when the choice is between gray and white.

Grouping Responses to Inanimate Configurations

Any drawing is necessarily two-dimensional; much of the history of figurative art has to do with the learning of techniques (the laws of perspective) that make the viewer of a drawing respond to it as if it represented an event taking place in three dimensions (Gregory 1970, Chap. 6). The pervasiveness with which two-dimensional drawings can be interpreted (sometimes involuntarily) as if they were in three dimensions, can be illustrated, according to Tausch (1954), by studying well-known two-dimensional visual illusions.

For example, the Müller-Lyer illusion shows two equal-length lines one above the other; but outward-stretching fins are added at each end of the top line and backward-reaching fins are added at each end of the bottom line. The top line gives the illusion of being longer than the bottom line. According to Tausch, the total configuration presented by the top line is that presented, in real life, by the line representing the junction of a wall with a ceiling, with each fin looking like a corner of the wall. The total configuration presented by the bottom line is that presented, in real

life, by the spine of a book held close-up, with the fins looking like the pages of the book receding from the viewer. A mechanism called “size constancy” then operates in such a way that the top line (apparently far away) is made to seem longer in order to compensate for the small size it apparently possesses because of its distance. The bottom line (apparently close to the viewer) is made to seem shorter in order to compensate for the large size it apparently possesses because of its proximity.

Tausch bolstered his arguments with photographs of real-life scenery, including train-tracks that seemed to converge in the distance although the tracks were objectively parallel; some well-known illusions could be explained if two straight lines that were slanted so as to nearly converge at the top were mentally interpreted as being lines that, in three-dimensional space, would normally be parallel. Crucial to Tausch’s interpretation is an acceptance of the existence of size constancy, whose presence is more likely to be established when there are cues to distance than when there are not (Holway and Boring 1941). A detailed account of Gestalt views on size constancy was presented by Koffka (1935, Chap. 6).

When two static configurations are presented in succession, the phi phenomenon (Wertheimer’s term for the neuronal events presumed to underlie any apparent movement that is perceived) ensures that the configuration of the first display “moves” to the visual location represented by the second display. But Ternus (1926/1938) showed that when two configurations of six dots each are successively displayed, what the apparent movement “looks like” is determined by the way the first configuration of six dots was mentally organized. For example, the six dots might be mentally organized into the pattern of a regular hexagon; alternatively, they might be mentally organized into the pattern of an irregular quadrilateral on the left, flanked on the right by a straight line. When the organization was that of a hexagon, the hexagon seemed to shift en bloc toward the right when the second display was illuminated; when the organization was that of a quadrilateral flanked by a line, the line seemed to stay still, and the quadrilateral seemed to “flip” over the line toward the right. This illustration of the effect of *Einstellung* on the interpretation of an incident of apparent movement is a good example of what

Pylyshyn (1984) meant when he asserted that certain aspects of cognition were “cognitively penetrable,” whereas others, because they were part of the “functional architecture” of the brain/mind system, would not be influenced by any mental attitude or predisposition to respond.

Discrimination Responses to Animate Configurations

Whereas much of the “art” exhibited in galleries attempts to represent nature, nature does not always provide material that is good for art. Imagine a toad concealed on a forest floor, its skin coloration melding so perfectly with the subdued hues of the leaves and earth on which the toad sits that it is almost invisible to a predator. A photograph is of scientific value as a representation of the adaptive usefulness in nature in camouflage; but few artists would present for exhibition a painting in which the toad could hardly be discriminated from its background. In the post-Köhler era, the book by Metzger (1936/2006) entitled *The Laws of Seeing* made its mark particularly by its photographic demonstrations on the usefulness of camouflage for the protection of potential prey from their potential enemies.

But camouflage is only effective as a defense in the natural world because both animals and humans perceive in terms of figures and grounds, and, within figures, in terms of wholes rather than parts. As noted above, the experimental support for this assertion had been produced by Gottschaldt (1926/1938a; 1929/1938b). A neurologist raised in the Gestalt tradition, Lauretta Bender (1897–1987) devised a Hidden Figures test, now known as the Bender–Gestalt test, that requested participants to draw pictures that contained embedded figures; poor performance on the test was interpreted as a sign of the early onset of certain brain disorders, including dementias (Bender 1938; see also King and Wertheimer 2005, pp. 83, 372–373).

Natural camouflage can be disrupted if a camouflaged animal or object is moved. A photograph of a white Dalmatian dog with black spots can show the dog as being almost invisible if the dog is lying still on a white floor covered with black spots of the same size as those of the dog. But if the tail of the dog is then moved even slightly, and the nose of the dog is lifted slowly, the “whole” of the dog is clearly perceived; even

those parts of the body that are not moved are judged by a viewer to be part of the dog rather than part of the floor. The reduced visibility of a stationary animal can explain why many species are as capable of standing stock-still as they are of running very quickly; movement can be as important a cue for figure-ground organization as are brightness contrast, color contrast, or the presence of clear contours (Koffka 1935, pp. 380–405).

Choice Responses to Animate Configurations

In *The Growth of the Mind*, Koffka had stressed that perhaps some configurations require so little in the way of repeated experiences if they are to be responded to appropriately, that there may be an innate tendency for certain configurations to trigger reflex-like responses. Koffka singled out the mother’s face as an example of a configuration that seemed to be almost immediately attractive to a neonate. Other researchers have emphasized, however, that exposure to the sound of the mother’s voice in the womb might have primed the baby’s auditory system to respond to the voice after the birth, and that very few pairings of voice and face need then be required for the mother’s face to attract the baby’s attention (Murray and Farahmand 1998).

When a child is old enough, he or she might respond to their own reflection in a mirror as if they “recognize themselves” (the classic criterion for self-recognition is whether they try to wipe off a spot from their own forehead that had been put there beforehand unbeknownst to the child). The development of the idea of a “self” goes hand in hand with the learning of personal pronouns like “I” and “you”; it might even be that the breakdown of a unified conceptualization of the world-and-me-are-one can be precipitated by, say, a household accident that forces the child to separate, in his mind, the “world” from the “me” (Romanes 1888; Murray 1995, pp. 177–182). In Gestalt psychology, the most extensive treatment of the origination of self-consciousness will be found in Koffka (1935), who used the term “Ego” to characterize a whole field of retained experiences. Coming out of a state of coma and/or concussion can be like going from a world of inchoate sensations to a world where a “me” is “looking at” those sensations (Koffka 1935, pp. 323–324).

In discussing the case of a patient with Korsakoff's psychosis and who, therefore, was very unlikely to retain any new information for more than a few seconds, Claparède (1911/1951) reported that, when he first met this patient and shook her hand, he administered to her hand a minor pinprick. The next day, when normally she would have shown no sign of recognizing that Claparède was the doctor who had seen her the day before, she actually flinched as if remembering the pain of the pinprick. Claparède ascribed this forgetting to a dissociation between the memory representation of the pinprick and the huge complex of memory representations sharing the common element of being part of the patient's "self"; the pinprick was remembered, but not recalled because of the dissociation.

Koffka (1935, pp. 591–604) reported that, when he had been younger, he had dismissed Claparède's account of a failure of recognition as being the failure of a connection between a stimulus and its memory representation in the *moi*. But later, as he developed Gestalt theory, Koffka found himself forced to return to Claparède's theory and finally came to admit that theories of recognition failure ought to include failures of repeated stimuli to leave memory representations that had made contact with the Ego. In particular, the role of recency in determining recognition accuracy could not be ascribed entirely to a "law of proximity" in time and to a "law of similarity" that operated to "group" memory representations that had been set up at different times; recency effects were related, by Koffka, to the order in time when the original representations had each been associated with the Ego, because what is most recent is usually what is most important in a person's interpretation of what is happening in the here and now.

Late twentieth-century research on memory has devoted little time to accounts of amnesia that emphasize the "self," despite Tulving's (1983) distinction between episodic memory (storing self-related incidents) and semantic memory (storing abstract memory for words and facts) and despite Baddeley's (1986) conceptualization of a "central executive" in working memory theory. Yet in working memory theory, the role of a "central executive" in determining memorizing activities is almost impossible to separate from the role played by "oneself" in determining what will be voluntarily rehearsed during a memorization

process. The best-known exponent of the modern physiological account of memory has written that he originally became interested in the topic as a result of asking "where" in the brain Freud's Ego and id might be located (Kandel 2006, pp. 53–59). But after describing his life's work on the cellular aspects of memory storage, Kandel wrote that

- ▶ Cellular and molecular approaches . . . cannot by themselves unravel the secrets of internal representation in neural circuits or the interactions of circuits . . . we will need to determine how neural networks are organized and how attention and conscious awareness regulate and reconfigure the actions of the neurons in those networks. (Kandel 2006, p. 423)

Nothing in this quotation need lead us to turn away from a Koffka-like approach to human memory that includes an "Ego" as a crucial component of the memory system.

Even more challenging to a purely associationistic account of infant behavior, whether in animals or humans, is the evidence that certain so-called mirror neurons in the premotor cortex, neurons with strong synaptic connections to the emotional centers of the amygdala, respond to the seeing, by monkey A, of an action made by monkey B, by activating the neural processes needed for monkey A to imitate that action even though that action may be new in monkey A's repertoire of motor actions. Neuroimaging techniques have also made it possible to show that a 5-year-old human child can use their mirror neurons in the processes of categorizing the emotions expressed, facially or gesturally, by another child. These apparently innate determinants of learning by imitation and of learning by interpreting the emotional expressions of others are sure to add fuel to any urge the reader may have felt to once again consult Koffka's *The Growth of the Mind*. The roles played by the imitations of the actions of others, and of the understanding of the emotions expressed by others, are currently the object of intense investigation, for two reasons. First, cooperation between individuals is increasingly being viewed as a corrective to the brutality of hierarchical animal groups in which "community spirit" is in a sense coerced by the existence of competition between the young males and the older and larger "alpha" males at the head of the hierarchy (de Waal 2009). Second, there

is growing evidence that the family of autistic disorders might involve disturbances in the normal functioning of the mirror neurons.

The second generation of Gestalt psychologists, many of whom had escaped the authoritarian horrors of Fascistic countries, naturally sought to understand why, when applied to human communities, social psychology, instead of being mainly about cooperation, was mainly about coercion. Experimental and statistical works on the authoritarian personality Adorno et al. (1950), on the way people will lie in order not to seem at odds with a consensus of a group of people who are immediately in their presence (Sherif 1935), and on the ways in which cognitive dissonance can lead to seemingly irrational conclusions (Festinger 1957), dominated much of the academic psychological literature of the post-World War II period (King and Wertheimer 2005, pp. 373–375).

Grouping Responses to Animate Configurations

The recognition of faces is clearly an important component of one's everyday social life, and plays an important role in eyewitness testimony. An interesting development in the area is the incorporation of the word "configural" into several current theories of face recognition. Experimental evidence has shown that, for a given individual who has to recognize whether or not he has seen a (photograph of) a given face before, increased accuracy of performance depends on that individual's personal judgment of the internal features of a face (eyes, nose, and mouth) seen, however, not as individual features, but in relation to each other; that is, the accuracy of recognition that two pictures are of the same face (even when photographed from different angles) depends on a "configuration" that unites the eyes/nose/mouth features into a Gestalt. The more the photographs belong to a group familiar to the individual, the more valuable are the configural cues for the accuracy of "same" judgments. Exterior features of a face, for example, the hair, the shape of the face, and the ears only appear to become important as retrieval cues when the ensemble of to-be-recognized faces belongs to a group well removed from, or novel to, that individual. Evidence for all the above assertions has been collated by Hanley and Cohen (2008).

Standing back from the above, we can see more clearly how Anderson and Bower's (1974) characterization of the Gestalt movement as being "rationalistic," rather than "associationistic," has been validated. The movement was *nativistic* in its emphasis on the innate nature of figure-ground organization, and of the laws of perceptual grouping that are sometimes considered themselves to be examples of figure-ground organizations. Koffka's suggestions that some response patterns given by human babies are not learned have received surprising support from recent work on mirror neurons. The movement was *holistic* in the sense that ambiguous visual patterns and many difficult intellectual problems are judged by participants to be "wholes" that sometimes needed reorganizing or restructuring if they were to be understood or solved. Even a list-learning task has to be treated as a "whole" for which any part has to be ascertained as belonging to a particular list; this approach has led to a fruitful understanding of retroactive inhibition. Lipps (1905/1926) argued that many psychophysical tasks should be regarded as dealing with the Gestalt constituted by two stimuli perceived together, rather than as cases where one stimulus was compared with a (nearly identical) second stimulus. The movement was *intuitionistic* because the solutions of problems were often arrived at by a combination of deductive logic and a sudden "intuition" of how the problem should be restructured; Köhler's work on problem-solving by chimpanzees gave a strong impetus to this research area. And the movement was *purposivistic* because almost all activities, human or animal, were goal-driven; the more evolved an animal's ability to use mental representations of reality, the more successful would be the attainment of goals and purposes envisaged to take place in the near future. Without Tolman's Gestalt-influenced research on "cognitive maps," we might not have arrived at an understanding of the important role of the hippocampal formation in mediating place memory both in animals and humans (Kandel 2006, pp. 136–143, 280–294). More generally, new research on the functions of individual brain cells in mediating how humans and animals interpret reality is bound to have a favorable influence on the value placed upon Gestalt psychology by future historians of science.

The Secondary Literature on Gestalt Psychology

The one book that must be acquired by anyone researching the history of Gestalt psychology is that of Ash (1995). Of particular archival interest is Ash's Appendix 2 listing all German-language dissertations supervised by Stumpf, Wertheimer, Koffka, Köhler, and other Gestaltists. The book goes into admirable detail on the philosophical issues that were the soil from which the Frankfurt/Berlin Gestalt school arose, and contains a wealth of material on the survival of Gestalt psychology in Europe during and after World War II. For an evaluation of how Gestalt accounts of perception have had a sustained long-term influence on the contemporary neurophysiology of sensation and perception, an article by Westheimer (1999) and King and Wertheimer's (2005, pp. 380–388) abridged translation of articles by Spillmann (1999) are strongly recommended. Murray (1995) gives an account, rather technical in places, of how Gestalt ideas about memory and problem-solving can be shown to make connections with some ideas arising from the late twentieth-century “cognitive revolution” on those topics. An older work, still useful for its information on German critiques of the Gestalt movement, and for reports of neglected Gestalt experiments, is that of Hartmann (1935). Ellis's (1938) collection of abridged translations of key Gestalt articles should be a component of any English-language collection of primary sources concerning Gestalt psychology.

Gibson, Eleanor J.

ELISSA N. RODKEY

York University, Toronto, ON, Canada

Basic Biographical Information

Born: December 7, 1910, Died: December 30, 2002

Eleanor Jack had an unremarkable middle class childhood in Peoria, Illinois, then followed family tradition to Smith College where she discovered her love for experimental psychology. Eleanor met her future husband, James J. Gibson, who would later become well known for his ecological theories of perception, at a graduation garden party at Smith when he was a professor and she was a junior. Taking his advanced experimental psychology class the next year was influential in Eleanor's decision to pursue psychology; after graduating from Smith in 1931, she stayed on for graduate studies under James Gibson's supervision. They married in 1932, and Eleanor completed her master's degree the next year (Gibson 1980).

Eleanor Gibson was interested in learning and comparative psychology, so after a few years teaching at Smith, she took a year's leave to get her Ph.D. at Yale University's Institute of Human Relations where she hoped to work with Robert Yerkes and his chimpanzees. However, Yerkes flatly refused to have women in his laboratory, so Gibson worked under Clark Hull, although she did not entirely agree with his behaviorist project. Her dissertation was on stimulus generalization and differentiation in verbal learning, but her

functional perspective had to be disguised by behaviorist vocabulary in order to gain Hull's approval (Gibson 2002).

After receiving her Ph.D. from Yale in 1938, Gibson returned to teaching at Smith where the Gibsons remained until 1942 when James Gibson was recruited by the Air Force to do perceptual research to create pilot selection tests. This military research was influential in the formulation of James Gibson's ecological psychology views; during this period, Eleanor served as a homemaker, taking care of their two young children.

Soon after the war the Gibsons left Smith when Cornell University recruited James Gibson. Since the Cornell's antinepotism rules prevented Eleanor from obtaining a faculty position, Eleanor became a research associate at Cornell, which meant she was largely unpaid and had to manufacture her own research opportunities. For 2 years, she worked at Cornell's Behavior Farm, and later ran distance judgment experiments outdoors with military recruits, creatively working to overcoming her lack of lab space and subjects (Caudle 1990). Even the experiment for which Gibson became famous, the Visual Cliff Experiment, took place in 1957 while she was still a research associate and had to partner with another Cornell professor for laboratory space. After her visual cliff research, Gibson spent the following 12 years on another project that also did not require her to have a lab, researching reading as a part of an interdisciplinary project on the subject, which resulted in the 1975 book *Psychology of Reading* (Gibson and Levin 1975). It was not until 1965, after 16 years as a research associate at Cornell, Gibson was made a full professor and was able to freely conduct research.

Major Contributions

The Visual Cliff Experiment, for which Gibson is best known, originated when Gibson and Richard Walk, a young Cornell professor, began a series of experiments testing whether being reared in an enriched environment would enhance rats' later discrimination (Gibson and Walk 1960). One experiment called for dark-rearing, and the invention of the visual cliff research was the serendipitous result of Gibson and Walk's attempt to get more use out of painstakingly dark-reared rats. To their surprise, the dark-reared rats avoided the glass-covered drop off portion of the cliff,

showing that they could perceive depth despite their lack of visual experience (Gibson 1991). Gibson and Walk expanded on the initial study, testing a variety of animals and experimenting with details of the cliff apparatus, which provided a significant advance over prior methods of testing depth perception that required animals to jump down from a height. Gibson and Walk found that a variety of species could discriminate depth by the time they could locomote, so precocial animals like chicks and goats could perceive depth at birth. Eventually, Gibson and Walk tested crawling babies on the cliff, using the presence of the babies' mothers to motivate the infants to crawl on the cliff. Like the animal subjects, most babies tested avoided the apparent drop off, demonstrating depth perception. The research, featuring compelling photos of the babies on the cliff, was published in *Scientific American* and covered in the popular press, including a feature in *Life* magazine. It quickly became one of psychology's most famous experiments, recounted in numerous introductory textbooks.

Over the course of her career, Gibson's research interests converged on perceptual learning, and in 1969, she published *Principles of Perceptual Learning and Development*, in which she argued for her differentiation theory of perceptual learning, in contrast to the traditionally dominant associationist theories (Gibson 1969). This pioneering book laid out what Gibson believed to be the essential characteristics of perceptual learning: increasing specificity of discrimination, optimization of attention, and increasing economy of information pickup and search for invariance (Pick 1992). At the time of the book's publication, accurate methods for studying perceptual development in infants were a relatively recent development and therefore there was a limited body of relevant research. Gibson's review of the field and methodological suggestions in *Principles* thus served to galvanize the field and to define perceptual learning as a distinct research focus. The book received that year's Century Award and was later named a citation classic.

Gibson's emphasis in *Principles* on infants' active search for invariants and structure showed the influence of James Gibson's ecological theorizing on her thinking. She and James had an active intellectual relationship, each influencing the other's thinking throughout the course of their careers. Aware of

common assumptions about husband–wife scientific teams, they both took pains to emphasize that their ideas were distinct and they only occasionally collaborated. However, both consistently opposed an associationist account of perception and learning, taking a functionalist, and later, as James Gibson articulated the theory, ecological psychology approach.

Once Gibson had a lab of her own, she conducted the type of research she had called for in *Principles*, for example, investigating infants' differentiation of the rigidity or flexibility of real objects or their detection of the affordances of surfaces, such as a rigid versus a deforming walkway. In 2000 she reviewed the field again, taking an even more explicitly ecological perspective in *Perceptual Learning and Development: An Ecological Approach* (Gibson and Pick 2000). Gibson saw the perceiving infant as active in its environment, intrinsically motivated to discover the information, or affordances, available to it in the environment.

Today Gibson's achievements are remembered in the context of the persistent institutional sex discrimination she experienced. Gibson was a second-generation woman in psychology, and her struggles with antinepotism rules and her nonconfrontational, yet stubbornly persistent response to these obstacles exemplify both the challenges and attitude of the second generation. Although Gibson was for much of her career not allowed to sign forms for the students she advised, her influence in developmental psychology lives on in the graduate students she mentored, notably developmental psychologists Elizabeth Spelke and Karen Adolph. Despite the delay in her career, in her later life Gibson received frequent recognition for her accomplishments, culminating in her receiving the National Medal of Science in 1992, an honor rarely bestowed on psychologists.

Gibson, James J.

HARRY HEFT

Denison University, Granville, OH, USA

Basic Biographical Information

James J. Gibson was born on January 27, 1904, in McConnellsville, Ohio, and he spent most of his childhood years in Wilmette, Illinois, near Chicago. After attending Northwestern University for 1 year (1921), he enrolled in Princeton University, where he was an undergraduate philosophy major, graduating in 1925. Gibson took his first psychology course in his senior year and stayed on at Princeton for graduate studies, which he completed under H.S. Langfeld in 1928. In the fall of that year, Gibson accepted his first academic position at Smith College, where he remained for much of the next two decades. Among his outstanding students at Smith was Eleanor Jack, whom he married in 1932.

In 1941, Gibson joined the Army Air Force to help develop selection procedures for pilots, and during that time, he conducted groundbreaking research in perception that would shape the remainder of his career. Returning briefly to Smith College after the war, Gibson then joined the psychology faculty at Cornell University (1949). Soon after, he published the acclaimed *The Perception of the Visual World* (Gibson 1950), much of which grew out of his perceptual research during the war years. Over the ensuing decade

at Cornell, Gibson spent a semester (1954) as a visiting Professor at the University of California at Berkeley, and a year (1955–1956) as a Fulbright Fellow at Oxford University. By the early 1960s, his thinking began to shift toward what would eventually become his ecological approach. The groundwork for that perspective appeared in his landmark book, *The Senses Considered as Perceptual Systems* (Gibson 1966), which was followed in 1979 by his final book, *The Ecological Approach to Visual Perception*. Gibson died on December 11, 1979, at the age of 75.

Major Contributions

James Gibson was an innovative twentieth century experimental psychologist whose research on visual perception culminated in an original theoretical perspective, the *ecological approach to perceiving*. By offering a rich account of the visual information available for perceivers at an ecological level of analysis (*ecological optics*) and a reconceptualization of perceiving as the operation of perception–action processes (*perceptual systems*), the ecological approach provides theoretical grounds and empirical support for the epistemological position of *direct realism*. This position holds that the environment is perceived without the intervention of mediating mental representations or other constructive processes (*indirect realism*). Moreover, what is perceived most immediately are the functionally significant (meaningful) properties or *affordances* of the environment.

The dominant intellectual influences on Gibson during his graduate studies at Princeton were H.S. Langfeld, who had worked with the experimental phenomenologist Carl Stumpf, and the philosophical behaviorist E.B. Holt, a student of William James as well as a central figure among the New Realist philosophers (Heft 2001; Reed 1988). Holt's writings fused the non-dualistic metaphysics of James's philosophy of radical empiricism and James' emphasis on selectivity, with a molar and purposive behaviorism. At Smith College, Gibson's colleagues included the émigré Gestalt psychologist Kurt Koffka and the Austrian-trained psychologist Fritz Heider, who was at a nearby school for the deaf. Koffka's focus on organization in perceptual experience heightened Gibson's sensitivity to higher-order relations in patterns of sensory stimulation. Heider's landmark paper "Thing and Medium,"

which argued that that the structure of the object is *preserved* in the medium for perceiving, was to play a foundational role in Gibson's later ecological approach. Throughout his career, he shared an intellectual partnership with his wife, the experimental psychologist Eleanor J. Gibson.

During the war years, while working in a perceptual psychology research unit concerned with pilot selection, Gibson came to realize that measures based on *static* visual displays, as dictated by standard theories of perception, were inadequate for this purpose. In the process of utilizing *dynamic* displays (films) instead, Gibson became sensitized to the distinction between *form perception*, which involves static two-dimensional displays, and *object (shape) perception*, which results when the object, the perceiver, or both, are in motion. This work laid the foundation for Gibson's insight that the perceptual information specifying object shape is *invariant structure under transformation*. Moreover, Gibson's attention to perceptual experience from the vantage point of a pilot, as well as his attention to more mundane experiences such as driving a car, made him aware of the fact that as perceivers move through the environment, they generate an *optical flow* or streaming of surface layout that serves as information for self-movement. Concurrently, the point of outflow from which these streaming patterns originate specifies the direction of heading, and Gibson proposed that animals *guide* their locomotion by maintaining this point of expansion on the intended target. That the information for both object perception and optic flow is available in the optic array points to the possibility of direct perception.

After the war, Gibson began writing *The Perception of the Visual World* (1950), which further explored the possibility that there are higher-order structures in visual stimulation corresponding to environmental properties. Notably, he addressed the related problems of the perception of distance and of object-size constancy with reference to the ecological fact that surface textures tend to be stochastically regular, with the density among texture features increasing as the surface extends away from the perceiver. He demonstrated that these *texture gradients* correspond to perceived distance along a surface, and that the *ratio* of object size to surface texture background remains

invariant, independent of the object's location relative to the perceiver.

After moving to Cornell University in the early 1950s, Gibson collaborated with E. J. Gibson in offering an original account of *perceptual learning* as a process of differentiating structure available in the perceptual array. Furthermore, separate investigations by the Gibsons revealed that *meaningful* properties of the environment are available to be perceived in the perceptual array. E.J. Gibson and R.D. Walk demonstrated that newly crawling babies are sensitive to depth at an edge (the visual cliff experiments), and James Gibson found that animals perceive an expanding form in the visual field as a looming surface affording impending collision. Jointly, these investigations show that the functional significance of environmental features is available to be perceived over time in the course of object motion or self-generated motion.

By the early 1960s, Gibson fully abandoned the traditional (psychophysical) stance that stimulation is *imposed* on receptor surfaces in favor of an ecological approach. This reconceptualization, introduced in *The Senses Considered as Perceptual Systems* (1966), required two critical and innovative steps. First, drawing on Heider's distinction between object and medium, Gibson began to develop the program of *ecological optics*, which considers how surface properties can structure reflected light, giving rise to an array of structure specific to the environmental layout. Second, he proposed that perceiving is an activity of an embodied agent whose *perceptual systems* play an exploratory role in detecting structure (information) in the optic array.

Gibson's analysis was further refined in his last major work, *The Ecological Approach to Visual Perception* (1979). This book begins by addressing the question, "what is the environment to be perceived?" occasioning a more thorough analysis of ecological optics in relation to an active perceiver. Two other features of this book are especially noteworthy: (a) *occluding edge* phenomena – As a perceiver moves in relation to an object, the surfaces once hidden behind an object in the field of view are revealed over time at one edge, while once visible background surfaces are occluded at its opposite edge. From a perception–action perspective, this phenomenon demonstrates that perceiving is *temporally extended* rather than being an assemblage of discrete retinal snapshots. (b) *Affordances* – What is

perceived through the detection of perceptual information are the affordances of the environment, which are its functionally meaningful properties taken with reference to an individual. Affordances are *relational properties*, and conceptually, they suggest that meanings originate within the dynamics of an organism–environment system.

Gilbreth, Lillian

CHER THOMAS

California State University, Long Beach, CA, USA

Basic Biographical Information

Lillian Moller Gilbreth, the eldest of nine children, was born on May 24, 1878 in Oakland, California. A strong student, her father finally let her attend college only if she remained living at home. She attended the University of California at Berkeley, where she received a B.A. in English literature in 1900. She had an outstanding academic record and was the first woman to be invited to speak at Berkeley's commencement ceremonies. She continued her studies in New York City at Columbia University but an illness brought her home where she completed her M.A. in English literature at

U.C. Berkeley in 1902 and began a doctoral program in English with a minor in psychology. Her studies were altered after her marriage to Frank Gilbreth in 1904. Frank, the owner of a successful construction business, was becoming well known as a contributor to the emerging field of scientific management. Lillian began working with her husband and became as passionate as he was in addressing the problems of industrial management and productivity. Convinced of the importance of the human factor in this work, she switched her doctoral major to psychology. Due to her failure to fulfill a residency requirement for a doctorate at U.C. Berkeley (her dissertation had already been accepted), she was not granted her degree. The family moved to Rhode Island, and in 1915 she was granted Brown University's first doctorate in industrial psychology. Her four children were at her graduation ceremony, eight more would follow. Two of her children wrote of their experiences growing up in *Cheaper by the Dozen* (1948) and *Belles on their Toes* (1950). Both books were made into popular motion pictures in the 1950s, and *Cheaper by the Dozen* was remade in 2003.

When Frank Gilbreth unexpectedly died in 1924, Lillian carried on with their consulting business as best she could, given the era's prejudices against women. The quality of her work and her international reputation as an outstanding teacher of managerial techniques eventually overcame the general reluctance to utilize a woman's abilities in industry. She worked not only in the private sector, but applied scientific management techniques to home economics, physical therapy, agriculture, and various government functions. In 1935, she was appointed full professor at Purdue University in the management and the engineering schools. During her career, she also taught at the University of Wisconsin, Newark College of Engineering, Bryn Mawr, and Rutgers. She retired from Purdue in 1948 at age 70, but did not retire from professional pursuits until 1968. She died January 2, 1972 in Phoenix, Ariz (Kelly and Kelly 1990; Perloff and Naman 1996).

Major Accomplishments/ Contributions

Lillian Gilbreth was a pioneer in scientific management and one of the first to recognize the synergy of

combining a psychological analysis of individuals and groups with an engineering approach to develop truly effective management techniques. Along with her husband, she helped create job standardization, incentive wage plans, job simplification, and scientific production measurement techniques. She contributed to the development of the field of personnel management and career assessment through her promotion of the importance of identifying the behavioral qualities of effective managers and matching workers with suitable work. She initiated the study of the effects of worker stress and fatigue on productivity. She laid the groundwork for the humanistic revision to Taylor's scientific management system by recognizing the importance of involving workers in the redesign of their workplaces.

Lillian Gilbreth broadened the field of applied psychology. She demonstrated through her consulting and writing that the methods she had developed for improving the workplace were also effective in areas such as government, medicine, agriculture, and especially rehabilitation of the handicapped. Lillian was a leader in addressing the issue of balancing work and family. She and her husband applied the time and motion study methods they developed for industry to the management of their large family and Lillian's consulting work resulted in the redesign of kitchen appliances. She also wrote extensively on the management of the home and family for popular audiences.

An outstanding teacher, Lillian shaped the curricula of business and engineering schools throughout the country. Her workshops for managers were internationally renowned. She was one of the founding members of the International Academy of Management in 1954, and for years was its only female member.

Lillian Gilbreth received numerous awards for her accomplishments, among which were 20 honorary degrees. She was named a Fellow of the American Psychological Association in 1921, in 1924 she was the first woman elected to the American Society of Mechanical Engineers, in 1931 she was awarded first Gilbreth Medal for distinguished contributions to management by the Society of Industrial Engineers, in 1944, she was awarded the Gantt Gold Medal along with her husband posthumously by the American Society of Mechanical Engineers and the American Management Association, and in 1966, was the first

woman to receive the Hoover Medal of the American Society of Civil Engineers. In 1984, she was honored on a commemorative postal stamp, the first psychologist to be so honored in the USA (Gale 2000, 2009; Kelly and Kelly 1990; Perloff and Naman 1996).

Goldstein, Kurt

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: November 6, 1878; Died: September 19, 1965.

Kurt Goldstein was born in Kattowitz, Silesia (now Katowice, Poland) and trained as a physician and neurologist under Carl Wernicke at Breslau. He began his career as a postgraduate assistant to Ludwig Edinger at Frankfurt and then moved in 1906 to the Psychiatric Clinic of the University of Königsberg. In 1914, he returned as Edinger's first assistant at Frankfurt and

then, in 1916, established the Institute for Research on the Aftereffects of Brain Injury, which due to the prevalence of brain injury due to the First World War was a rich source of case material. There he began a collaboration with the Gestalt psychologist Adhémar Gelb. Together they created a unique program blending insightfully designed psychological tests of perceptual and cognitive function with exacting correlative neurological assessment. Goldstein's published account of this work in book form (Goldstein 1919) along with several joint articles with Gelb established the reputation of their research program around the world. During the 1920s, Gelb turned to specifically perceptual research and teaching, while Goldstein focused on the neuropsychology of aphasia and anxiety. He became allied with other Gestalt psychologists and joined them in founding the *Journal Psychologische Forschung* (Psychological Research) in 1921. Goldstein moved to the University of Berlin in 1929, and Gelb moved to Halle 2 years later. But Goldstein and Gelb, like many others, were in mortal danger in Germany beginning in 1933 and each fled Germany for the Netherlands. In 1935, Goldstein was able to leave Europe for the USA where he was active as a teacher and writer at Columbia and for a time, between 1940 and 1945, at Tufts University.

Major Achievements/Contributions

While in the Netherlands, Goldstein published his magnum opus *Der Aufbau des Organismus* (Goldstein 1934). This work expanded Goldstein's clinical observations of the integrated and interconnected nature both of brain injury and of the recovery process into a philosophy of the optimal development of human potential in transaction with its environment. In a sense this work was overdetermined both by Goldstein's close connection to Gestalt psychology and also by his deeply philosophical background. Goldstein was related to the Cassirer family, a source for the philosophical underpinnings of his clinical characterization of the relation of the brain to intellect, specifically of the relation of the brain's wholistic ability to symbolically represent the world (Metraux 1999). The *Aufbau* was issued in English in 1939 as *The Organism* with a foreword by Karl Lashley and was well received. His William James Lectures in 1938 at Harvard led to a second very influential philosophical book, *Human Nature in Light of Psychopathology*

(Goldstein 1940). This was followed by several more books and articles, including the reissue in English of his earlier clinical work on brain injuries, and also a comprehensive account of the relation of language and the brain as revealed by aphasia (Goldstein 1948). Within 10 years of his arrival in the USA, he had become a central figure in the development of modern clinical neuropsychology (Goldstein 1990). Among many others, he collaborated with Eugenia Hanfmann and Maria Rickers-Ovsiankina on their study of the sequelae of cortical injury *Case Lanuti* (Hanfmann, Rickers-Ovsiankina and Goldstein 1944), and with Jacob Kasanin and Martin Scheerer, a student of Wilhelm Stern and Fritz Heider, on language in schizophrenia. Goldstein was one of the first major figures in America to sound a warning against the use of lobotomy as a psychiatric treatment (Goldstein 1950). During the 1940s and 1950s, ideas of wholism and connectedness began to infuse parts of personality study and clinical psychology, and Goldstein's widely read philosophical work served as a programmatic background. Although the idea of "self-actualization" as the unfolding of purpose from within the self is much older than Goldstein, many writers have cited Goldstein as the first to employ this term in the context of the development of American "third force" psychology, and many of the major figures in the development of humanistic psychology acknowledged a debt to him (Pickren 2000). Goldstein's continuing popularity is attested by the reprinting of *The Organism*, with a new foreword by the neuropsychologist Oliver Sacks, in paperback as recently as 2000.

Great Plains Student Psychology Convention

ERIN McDONALD

Lynch School of Education, Boston College,
Chestnut Hill, MA, USA

Basic History of the Institution

The Great Plains Student Psychology Convention was initiated to provide a forum for undergraduate students in Kansas to present their research and interact with fellow psychology students and faculty, and thereby enhance their professional development. Dr. Ann Froese of Sterling College and Dr. Stephen F. Davis of Emporia State University began to discuss the establishment of an annual conference in the wake of the participation of a group of psychology students from Sterling College in Kansas at a lecture presented at Emporia State University.

The first Great Plains Student Psychology Convention was held on April 24 and 25, 1981 at Emporia State University in Emporia, Kansas, where 19 papers and one roundtable was presented. The keynote speaker was Dr. Jeffrey Seybert from the University of Missouri at Kansas City. It was again held at Emporia State for five of the next 6 years, from 1982 through 1987, and in 1985 was hosted by Pittsburg State

University. The convention has since been held at 15 other institutions, including the University of Nebraska at Kearney four times (1992, 1997, 2003, and 2009), and Missouri Western State University three times (1990, 2000, 2010). This conference is significant as it was the first such conference initiated for undergraduate psychology students in the middle and plain states. The 2011 Great Plains Student Psychology Convention will be held at Washburn University in Topeka, Kansas on March 18 and 19 (Davis 2000).

The Great Plains Student Psychology Convention continues to convene undergraduate presenters and participants for a 2-day program, held on a Friday and Saturday each year. There are generally five concurrent poster and paper sessions. Approximately 300 people attend each year, and the majority of presenters are undergraduates. A first and second place prize is awarded in each session to the best paper and poster, judged with high standards for excellent scholarly research. A keynote speaker presents on the Friday afternoon or Saturday morning of the convention, and the awards luncheon is held on Saturday. In 1999, it was decided by faculty organizers that the keynote speaker each year would be designated as the Stephen F. Davis Distinguished Speaker, named after the founder of the conference. There are no specific criteria for choosing the distinguished speaker, and the host institution each year is responsible for selecting the speaker.

The institutions whose students attend the conference each year generally make small donations to help offset costs, though the host institution provides the majority of financial support. Psi Chi, the National Honor Society in Psychology, often provides funding, as does the Nebraska Psychological Society (NPS) and the Association for Psychological and Educational Research in Kansas (PERK).

Significance

During the fourteenth meeting of the Great Plains Student Psychology Convention in 1994 at Rockhurst College in Kansas City, faculty members impressed by the quality of undergraduate research presentations at the conference proposed that a journal be established that would allow students to publish their work to help develop their communication skills and make them more competitive candidates for graduate study.

After meetings in the springs of 1994 and 1995, a group of graduate students and faculty established guidelines for the journal, and the first volume was published in 1996 (Ware 1996). All manuscripts submitted to the *Journal of Psychological Inquiry* must have an undergraduate listed as first author, although graduate students may submit papers they wrote as undergraduates. Papers written by undergraduates with coauthors who are faculty or graduate students can also be submitted to the journal. Manuscripts will only be submitted if they are written by students who attend an institution sponsoring the Great Plains Student Psychology Convention, or if the paper has been accepted for presentation at meetings of either the Great Plains Student Psychology Convention, the Nebraska Psychological Society, the Arkansas Symposium for Psychology Students, the ILLOWA Undergraduate Psychology Conference, or the Association for Psychological and Educational Research in Kansas (PERK).

Born in 1942 in Rochester, New York, Dr. Stephen F. Davis, founder of the Great Plains Student Psychology Convention, is now Roe R. Cross Distinguished Professor Emeritus at Emporia State University, Visiting Distinguished Professor at Texas Wesleyan University, and Distinguished Guest Professor at Morningside College. He received his bachelor's and master's degrees in psychology from Southern Methodist University in 1964 and 1966, respectively. In 1969, he received his doctorate from Texas Christian University. He has published over 300 articles and has presented over 900 conference papers. He is an APA fellow in four divisions and received the 1988 Distinguished Teaching of Psychology Award from the American Psychological Foundation (Buskist 2009).

Guthrie, Edwin

DAVID O. CLARK

Independent Scholar, Lincoln, NE, USA

Edwin Ray Guthrie Jr. (1886–1959) was a professor of psychology at the University of Washington in Seattle. Guthrie introduced his theory of psychology during the 1930s as psychology continued to develop from the analysis of the consciousness to the study of the more environmental and biological determinates of human activity. He based his psychology on learning, where learning was understood as the lawful functioning of the individual's mechanism of adjustment. Adjustment was manifest in newly constituted habits, where habits were considered organized behavior exercised in response to the demands of the environment. In 1945 Guthrie was the president of the American Psychological Association. In 1959 he received Psychology's prestigious Gold Medal Award for his contributions toward making psychology a science.

Guthrie was born in Lincoln, Nebraska, and he received both his bachelor's and master's degrees from the University of Nebraska. The early influences on his development can only be speculation, but at Nebraska Guthrie was a student of Harry Kirke Wolfe (1858–1918), who received his Ph.D. in 1886 from Wundt at the University of Leipzig, and it is probable he was a student of Thaddeus Bolton (1865–1948), who received his Ph.D. in psychology in 1895 from Clark University. Guthrie found Wolfe interesting, and he learned to hate psychophysics from the laboratory course he took in experimental psychology. During Guthrie's master's program, he taught high school mathematics. His master's thesis reflected his interests in mathematics, classical languages, and philosophy. It was a review of the Greek origins, and subsequent historical stages, of methods of demonstration in philosophy; Guthrie argued the current style logical argumentation evolved from early geometry proofs. Mathematics influenced a systematic proof in arguments in Western discourse. Guthrie's master's thesis at Nebraska foreshadowed the dissertation he completed in philosophy at the University of Pennsylvania.

In anticipating possible prejudices of Guthrie's education in philosophy, a comment on his education is necessary: Although his graduate degrees were in philosophy, the education he received had advanced beyond the classical education of the trivium and quadrivium. Often, his philosophy courses were natural philosophy, otherwise science. At the University of Pennsylvania, Guthrie's Ph.D. supervisor was Edgar Arthur Singer Jr. (1873–1954). Singer was a student of George S. Fullerton's (1857–1952). Fullerton was an early president of the American Psychological Association, and he participated in establishing the psychology laboratory at the University of Pennsylvania. Singer's dissertation addressed the debate to establish an object of study for psychology occasioned by the publication of William James's "The Principles of Psychology." As a post-doctor, Singer became William James's instructor for the psychology laboratory at Harvard during Munsterberg's sabbatical. If it was uncertain how much influence either Wolfe or Bolton had on his development, Singer's epistemology for psychology provided the foundation for Guthrie's career in psychology. However, Guthrie's dissertation was a critical review of Russell's paradox. In addition to his master's thesis and publications on logic, this suggests that Guthrie's focus was analytic philosophy. This answers to Guthrie's continued theoretical bias against empiricism, and his belief that a structural, or systematic, understanding of objective reality in science was the proper foundation for a scientific psychology.

Guthrie's theory of learning appeared in its nascent stage in 1930. It was published in the *Psychological Review* as "Conditioning as a Principle of Learning." His theory emerged as Guthrie observed psychologists divided into various dogmas, where allegiances and talking about psychology had replaced research. Behaviorism had offered some statements that the public was interested in, but there is no consensus about the facts. Guthrie's goal was a research paradigm that would give psychology the unity characteristic of the established sciences. The development of his theory can be observed in his journal publications of the early 1930s, and many of these articles were incorporated in his classic textbook *The Psychology of Learning* (Guthrie 1935).

Guthrie's psychology was based on the observation that individuals were able to adjust their characteristic

behavior patterns to meet changes in the environment. Darwin's influence was apparent. Conditioning as the principle of learning was construed as the individual reacting to the environment in a continuous struggle for survival, and the essential human mental activity was represented, and more importantly observed, in learning. The learned response was manifest in existing habits and the creation of new habits. Habit was the tendency of individuals to respond in similar ways under similar circumstances – this being necessary for sustaining life. In this sense, Guthrie proposed habits as the unit for psychological analysis. And in so far as his generalization served prediction, it answered to the essential characteristic of scientific knowledge for Guthrie. He argued that prediction was necessary to sustain life. Guthrie also turned to physiology for his theory. In Guthrie's reasoning, the term "conditioning" pointed to the importance of the reflex arc hypothesis and Pavlov's condition reflex. Consistent with these influences, Guthrie used the terms "stimulus" and "response" in his analysis and interpretation of the received facts of psychology.

Guthrie's principle of the conditioned response was deceptively simple; he stated that if you observe someone doing an activity of interest, note the circumstances in which it occurred. Upon the reoccurrence of the circumstances, the activity of interest could be anticipated. This assumption was supported. Guthrie intended this principle as a warrant for research. There exists scientifically supported reason to believe that people have a tendency to repeat their characteristic behaviors in the context of specific circumstances. The familiar expression has been: The best predictor of future behavior is past behavior. Often overlooked, this general principle served psychology for scientific prediction, and perhaps equally important, it provided the researcher with a control, that is a comparison condition for an $N = 1$ experimental paradigm.

Guthrie cleverly demonstrated the utility and power of this principle by presenting plausible alternative interpretations for Thorndike's law of effect and Pavlov's analysis of the conditioned reflex. Guthrie

also demonstrated the utility of the conditioned response by demonstrating how it could be used in applied settings for interventions to correct maladaptive behaviors. His solution to the problem of intervention was based on Charles S. Sherrington's (1857–1952) neurological research. Guthrie used Sherrington's concept of reciprocal innervation. In reciprocal innervation one muscle group relaxes allowing an opposing group to contract. In Guthrie's adaptation of reciprocal innervation, significant features present in the reoccurring situation for the behavior eventually become the stimuli for a new habit that was incompatible with the undesirable activity. This loss of the associative connection between the environment and the habit to be corrected was also called negative adaptation. Guthrie proposed three conditions for establishing inhibitory conditioning: one, maintain the relevant stimulus below the subject's threshold of awareness; two, maintain the situation and eliminate the unwanted response through the use of fatigue; three, the unwanted behavior could be inhibited by training an incompatible behavior to the specific circumstances.

For most of his career, Guthrie was involved in the practical concerns of teaching, and his style of explanation reflects his desire to communicate with a general audience. He emphasized a democratic spirit of science, and the necessity for psychology to address public concerns with understandable and useful explanations. Despite the fact that other learning theories have been more popular, Guthrie was able to demonstrate plausible alternative interpretations to many established facts in learning research. His practical approach to science, with his theoretical roots in a structural epistemology, was probably the reason for a modest but continued interest in his theory.

H

Hall, G. Stanley

JOHN D. HOGAN

St. John's University, Jamaica, NY, USA

Basic Biographical Information

Born: February 1, 1844; Died: April 24, 1924.

Granville Stanley Hall, a pioneer American psychologist, who is usually identified as the father of developmental psychology, was born on February 1, 1844, in Ashfield, Massachusetts. His parents were farmers who were descended from the earliest European settlers to the USA. Hall attended nearby Williams College, graduating in 1867. He then moved to New York City where he enrolled at Union Theological Seminary – his mother had always hoped he would become a minister. He traveled to Europe on borrowed money, and stayed for more than a year, returning to the seminary to complete his degree in 1870. By this time, he was certain that he was not destined for the ministry and, instead, planned to teach philosophy (Ross 1972).

Eventually, Hall was offered a teaching position at Antioch College in Yellow Springs, Ohio. Although he was popular and successful, he felt his future with the college was uncertain. He resigned from Antioch with the intention of studying in Europe again. He traveled as far as Harvard University, where he met William James, who only the year before had begun teaching the “new” psychology at Harvard. Hall enrolled in the philosophy program there in 1876, and graduated 2 years later with a doctoral degree. Although his degree was from the Department of Philosophy, he was given a degree in psychology because the subject matter of his dissertation, the muscular perception of space, was consistent with the new psychology. His

degree is often regarded as the first doctoral degree awarded in psychology in the USA, perhaps the world.

After receiving his degree, Hall left for Europe where he studied with a variety of people. He spent a brief period at the University of Leipzig with Wilhelm Wundt, the founder of experimental psychology, but he never took any formal courses with Wundt nor published anything with him. He met a former student from Antioch College, Cornelia Fisher, who had been studying in Europe, and they were married in Berlin. When he returned to the USA, he had no job prospects and his wife was expecting their first child (Ross 1972).

On his return, Hall presented a series of lectures on pedagogy and psychology. Before long, he had become the leader of the child-study movement, a social movement that had been gathering strength. Hall promised that psychology could show parents and educators the most scientific way to raise a child. Although there was little evidence to back up his claim, his words were welcome. Hall himself contributed some research to this movement, including a paper titled “The contents of children’s minds” (Hall 1883). The paper is considered one of the founding papers of developmental psychology.

Hall was offered a full-time position at Johns Hopkins University in 1884, where he began a psychology laboratory and later founded the *American Journal of Psychology* (1887) the first journal for psychology in the USA. In 1888, he was approached by Jonas Clark, a wealthy native of Worcester, Massachusetts, who was planning to fund a college in Worcester, and asked Hall to be the first president. Hall accepted and remained president of Clark University until 1920, when he was 76 years old. His tenure at Clark was often tumultuous, but it was also during these years that Hall did much to organize early psychology in the USA, and to promote and organize developmental psychology. Hall died on April 24, 1924, at the age of 80.

Major Accomplishments/ Contributions

Many of Hall's theoretical contributions grew out of his belief in evolution. He was drawn to the topic very early in his career and it dominated his thinking throughout his life. His approach, derived from the work of Ernst Haeckel, a German evolutionist, is usually referred to as "recapitulation theory" and its basic tenets are summed up in the phrase "ontogeny recapitulates phylogeny." Hall believed that individual human development goes through a reenactment of the evolutionary development of the species. For instance, he regarded adolescence as necessarily a time of storm and stress because it corresponds to a time when mankind was first becoming civilized.

Hall's most important work was his two-volume book on *Adolescence* (Hall 1904). For all practical purposes, he invented that period of life. The term "adolescence" was an archaic and little used word before the publication of his book. Afterward, the period was recognized as a separate stage of life. Toward the end of his life, Hall wrote a book titled *Senescence: The last half of life* (Hall 1922), establishing his credentials as an authority over the entire life span.

Hall contributed to the early growth of U.S. psychology in other important ways. In 1892, he sent out invitations that resulted in the establishment of the American Psychological Association, the first such national association in the world, and he became its first president. In 1909, he hosted a celebration for the 20th anniversary of the founding of Clark University. Among the distinguished guests invited to speak at that celebration were Carl Jung and Sigmund Freud, the latter in his only visit to America.

Hall's recapitulation theory was not readily accepted by his contemporaries, his questionnaire method also raised eyebrows, and his personal qualities often led to conflict among other notables of the period. But his impact on the development of psychology in its pioneer days cannot be minimized. More than anyone, Hall established the organizational groundwork for the new science, as well as creating the first scientific form of developmental psychology. In addition, many of his students, notably Lewis Terman, Henry H. Goddard, and Arnold Gesell, had a significant impact on the discipline (Hogan 2003).

Hamilton, G. V.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: 1877; Died: 1943.

Gilbert Van Tassel Hamilton was born in Ohio and after finishing college at Ohio Wesleyan in 1898 went to Philadelphia, where he studied at Jefferson Medical College with Francis X. Dercum, an innovator in the treatment of nervous diseases, including hysteria and other psychosomatic problems (Wozniak 1994). After obtaining his M.D. in 1901, Hamilton worked at hospitals, including one of the Pennsylvania state mental hospitals. There he conceived the idea to go to Boston to study the relation between psychology and mental disease, much against Dercum's recommendation. He found a position at McLean Hospital, where the chief psychologist was then Shepherd Ivory Franz, who had a background in neuropsychology, having done some of the earliest studies on brain lesioning's effects on learned behavior. They collaborated on a study on exercise and relief of depressive retardation, Hamilton's first published research (Franz and Hamilton 1905). Hamilton also attended Harvard and worked with Holt, Münsterberg, and most importantly R. M. Yerkes,

whom he credited as the source of his behavioral and comparative approach. Also at McLean, Hamilton befriended a very rich patient, Stanley McCormick, heir to the McCormick reaper fortune, who was by all accounts schizophrenic. McCormick's wife, Katherine McCormick, the first female student to graduate from MIT with a science degree (in Biology) desired to find a biological basis for her husband's condition, found Hamilton's treatment salutary, and together they invited him to McCormick's California estate, Riven Rock, near Montecito in Santa Barbara County, California as McCormick's personal physician. There Hamilton lived between 1908 and 1917, supported by grants from McCormick that allowed him to set up a laboratory and to conduct research on animal behavior as an independent investigator.

Major Accomplishments/ Contributions

Hamilton did some early comparative experimentation. Utilizing dogs, cats, monkeys, humans, and one horse (Hamilton 1911) he set up a situation in which he varied the escape procedure from a room with four exits in order to produce frustration. Hamilton described five different response patterns that he claimed cohered into classes based on the reaction to the frustrating situation: rational inference, searching, stereotyped searching, searching combined with motor impulse, and perseveration of both action and inhibition. Hamilton was also able to establish a primate colony, the first of its kind in the USA, which by 1913 contained 16 monkeys, 3 baboons, and an orangutan (Magoun and Marshall 2003). While Hamilton himself published little primate research – significantly in light of his later work, he did publish a detailed examination of sexual behavior in the colony (Hamilton 1914) – his invitation of Robert Yerkes for a 6-month stay there in 1915, after Yerkes was prohibited from working at Tenerife with Köhler's colony due to the First World War, was pivotal for the development of future comparative psychological research involving primates. Yerkes took advantage of the stay to conduct several studies culminating in several studies on learning and ideation in apes and monkeys (e.g., Yerkes 1916): this opportunity reinforced Yerkes's intention to establish his own laboratory several years later at Orange Park, Florida (Wozniak 1994). Hamilton had a disagreement with other psychiatrists

involved with McCormick's treatment, including Smith Ely Jelliffe, and was dismissed from their service in 1916, which led to the dissolution of the primate research. After military service in the First World War, he returned to the Midwest in 1921 where he engaged in the practice of psychotherapy and composed *An Introduction to Objective Psychopathology* (Hamilton 1925). In this work, Hamilton advanced a theory compounded of psychosexual ideas drawn from Freud, whom he had encountered during his McLean stay, and behavioral ideas of reaction tendencies and behavior under frustration derived from his earlier comparative work. It contains many case studies illustrating what Hamilton termed typical modes of reaction leading to maladaptive behavior: in some ways, Hamilton anticipated current learning-based theories of psychopathology, for instance learned helplessness. The layout of the book, with its very large number of illustrative cases matched to combinations of reaction tendency or behavioral style is reminiscent of Meehl and Hathaway's original MMPI casebook. After 1925, Hamilton moved to New York and was associated with diverse psychoanalytic and psychotherapeutic activities. He may have played some role in the literary community, as did many other psychotherapists at the time, and may have been an influence on the work of Eugene O'Neill (Silver 2001). One common theme woven into Hamilton's career and the careers of those around him was sex: Kathleen McCormick became, in the time that she and Hamilton worked to restore her marriage, a feminist activist and a birth-control advocate (later, she also funded the research leading to the first viable birth-control pill). Hamilton published one of the earliest precise descriptions of sexual behavior in an experimental primate group, and many of the case studies in *Objective Psychopathology* have a pronounced sexual dimension. After his move to New York he continued to focus on sex, publishing, with Kenneth Macgowan, the producer of several of O'Neill's plays, an article in *Harper's* on love affairs and sexuality (Macgowan and Hamilton 1928), and a survey study of marital sex problems issued by a popular trade publisher (Hamilton 1929). He also published on gerontological sexual issues in the later 1930s (Hamilton 1939). *Riven Rock*, a 1998 novel by T. Coraghessan Boyle, provides a fictionalized account of the events surrounding Hamilton's time in California (Boyle 1998).

Harlow, Harry

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Born Harry Frederick Israel in Fairfield, Iowa (1905–1981), and a member of the Methodist church, he was persuaded by one or more of his Stanford University professors to change his last name to avoid the anti-Semitic bias that plagued hiring in universities during the 1930s (Suomi and Leroy 1982). Beginning his college education at Reed College, Harlow transferred to Stanford University where he earned the B.A. (1927) and Ph.D. degrees (1930). In 1930, he accepted a position at the University of Wisconsin where he

remained until retirement in 1974. Thwarted initially in his effort to be a comparative psychologist studying rats, owing to the University closing the rat laboratory, Harlow soon turned to studying monkeys at the local zoo and soon thereafter converted a house near the campus to be a primate learning laboratory. Later he converted a former cheese factory into a large primate breeding and research facility.

Other positions held by Harlow included being a Carnegie Fellow in Anthropology at Columbia University and serving as Chief of Human Resources Research for the US Army during the Korean War. Among many forms of recognition and honors, Harlow became a member of the National Academy of Science (1951). And he received the National Medal of Science (1967). He led the Division of Anthropology and Psychology of the National Research Council (1952–1955). He received the American Psychological Association's (APA) Distinguished Scientific Contribution Award (1960), and he served as President of APA in 1957–1958 (Anonymous 1960). Harlow supervised 36 Ph.D. students, many of whom had distinguished careers within research areas for which Harlow was known. Perhaps his most distinguished student, Abraham Maslow, took a different career direction; however, Harlow's influence was clearly present in Maslow's development of his famous hierarchy of needs.

Major Accomplishments/Contributions

Harlow is best remembered for his research in learning set formation (LSF) and developmental psychobiology. The former was the focus of his research during the early and larger portion of his career, but both overlapped considerably as the latter focus grew out of his pioneering methods associated with primate husbandry. The developmental research included studies of attachment and love formation as well as familial relationships in rhesus monkeys. In recent times that research has come under severe criticism for its alleged cruelty associated with rearing infant monkeys in isolation and via artificial surrogate mothering devices that offered different degrees of contact comfort. Nevertheless, many aspects of social development were investigated that could never have been studied systematically using human infants as subjects.

Arguably, Harlow's most enduring theoretical legacy will be associated with learning set formation (LSF) and that will be emphasized here. Using his well-known Wisconsin General Testing Apparatus, designed to prevent inadvertent experimenter cues to the subject regarding correct choices among discriminanda, Harlow began studies in the 1930s–1940s that led to his ground-breaking presentation and publication on LSF in 1949. Harlow characterized LSF as “learning to learn,” a conceptualization for which he is usually credited with but which he was ably preceded (e.g., Gregory Bateson in a detailed explication in 1942 and Robert M. Yerkes in a lesser explication in 1943). To Harlow's credit, he showed how LSF could be measured, whereas Bateson thought it was experimentally difficult if not impossible to demonstrate. Harlow used different procedures, but the prototypical one involved presenting a series of two-object discrimination problems. After six trials, a new pair of objects was introduced, etc., until the subject showed LSF or seemed to be doomed to failure. Evidence for LSF involved learning what has been verbalized as a “win-stay, lose-shift” solution. The correct object for the six trials was chosen randomly before trial 1; thus, each subject's first trial choice occurs by chance. If the subject “wins” (food reward) on trial 1, the optimal solution to gain the most rewards is to “stay” with that object for the remaining five trials; if it “loses” on trial 1, the optimal solution is to “shift” to the other object for the remaining five trials. When subjects become near-perfect on trial 2 and subsequent trials, it is concluded that LSF has occurred.

A significant contribution was Harlow's theory that LSF depended on what he termed “error factor theory” (Harlow 1959). He meant that the animal must learn to eliminate response strategies that do not work (e.g., basing its choices on cues that prove to be irrelevant such as position preferences, color preferences, size preferences, etc.). LSF has been characterized variously as involving “concept learning,” “hypothesis learning,” “rule learning,” etc., but Thomas (in press) has offered a cautionary view of such. Harlow (1959) also wrote, “all concepts such as triangularity, middle-sizedness, redness, number, and smoothness evolve only from LS formation” and that “insightful learning through LS formation is a generalized principle . . . [that] . . .

appears in . . . oddity learning . . .” (p. 510). Thomas and colleagues have shown that LSF and oddity concept learning can be differentiated within the same experiment, so the relationship between LSF and oddity concept learning remains unresolved. The theoretical issues pertaining to LSF and conceptualization are sufficiently important that further research might prove to be invaluable.

Hebb, Donald O.

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Canadian psychologist. Born in Chester, Nova Scotia, July 22, 1904. Educated at Dalhousie University, Halifax, Nova Scotia, B.A. 1925; McGill University, Montreal, M.A. 1932; University of Chicago, 1934; Harvard University, Cambridge, Massachusetts, Ph.D. 1926. Married Marion Isabel Clark; Elizabeth Nichols Donovan in 1937; Margaret Doreen Wright in 1966; two daughters. Fellow Montreal Neurological Institute, 1937–39; Lecturer and Assistant Professor, Queen's University, Kingston, Ontario, 1939–1942; Research Associate, Yerkes Laboratory, Orange Park Florida,

1952–1947; Professor of Psychology, 1942–1972, Chancellor, 1970–1974, and since 1975 Professor-Emeritus, McGill University; since 1977, Honorary Research Associate in Psychology, Dalhousie University. President, Canadian Psychological Association, 1952, and American Psychological Association. 1960. Recipient: Medal.

Society of experimental Psychology, 1958; Award, American Psychological Association and Association for Research in Nervous and Mental Disease, 1962. Honorary doctorate: University of Chicago, 1951; University of Waterloo, Ontario, 1963; North-eastern University, Boston, 1963; Dalhousie University, 1965; York University, Toronto, 1966; McMaster University, Hamilton Ontario, 1967; Queen's University, 1967; University of Western Ontario, London, 1968; McGill University, 1975, Member, American Academy of Arts and Sciences, and the Royal Society of Canada. Address: RR 1, Chester Basin, Nova Scotia, Canada.

D.O. Hebb received his Ph.D. from Harvard in 1936. In his thesis, he compared the perceptions of rats raised in darkness with normally reared rats. In two papers published in 1937 based on this research, Hebb came to the conclusion that perceptive ability was not based on experience, that it was innate. From 1937 to 1939, he worked at the Montreal Neurological Institute with Wilder Penfield, where he studied the status of Penfield's patients following brain surgery. There he found that large lesions may in some cases have little effect on intelligence-test performance. Eventually he began edging toward the conclusion that intelligence itself, and not just the ability to do well on intelligence tests, was result of experience. This was a conclusion that ran counter not only to Hebb's own assumptions, but also to the general theories of the time. Yet he remained baffled about how to explain this matter neurologically.

In 1942, Hebb joined K.S. Lashley, with whom he had studied at the University of Chicago, at the Yerkes Laboratories of Primate Biology in Florida. Lashley's original plan was to train chimpanzees in a set of habits and then make brain lesions, conducting pre- and postoperative examinations to determine the effects of the lesions. The plan was seriously delayed, however, when they discovered that the initial training of the monkeys took an extremely long time. But this time spent training the chimpanzees proved useful to

Hebb, for it led him to consider the nature of emotion and behavior in them and, by extension, in people. Hebb also considered the matter of recognition of emotion in the monkeys by the staff members at the laboratories. Eventually he came to the conclusion that this recognition involved perception of the present behavior informed by that which had been usual in the past.

In 1944, he returned to the problem of thought and the brain which he had earlier considered while working with Penfield. Recent work by Rafael Lorente de Nó led Hebb to formulate the neurological explanation of a concept, which he had earlier been lacking. According to Hebb, a concept is "a group of cortical neurons exciting and re-exciting each other."

Hebb was now looking at thought as a sequence of brain events, each excited jointly by the preceding event and by the sensory stimulation of the moment, and approaching the conclusion that experience was an important factor in the nature of thought and behavior. This conclusion seemed to imply, however, that thought would be disrupted in a strange environment with unfamiliar contingencies. But as Hebb put it, even things should fall up rather than down, would it not still be possible to think clearly about what was going on? At this point, he remembered how the chimpanzees would become terrified at seeing a model of a portion of chimp anatomy. He concluded that such disturbances resulted from the lack of the usual contingencies (a head without a body) rather than conflict.

In 1947, Hebb was appointed Professor of Psychology at McGill University. It was during this time that he worked on his book *The Organization of Behavior*, which was published in 1949. The book was an immediate – and, for Hebb, an astonishing – success. Through certain physiological aspects of the book were inexact, the overall theory – that experience, among other things, played a key role in determining behavior, a refutation of the conclusion he had some 12 years earlier – remains fairly stable.

During the 1950s and 1960s, Hebb continued to produce important work, such as studies of the early environment of children that were instrumental in persuading psychologists that IQ was not innate, which was a major factor in the founding of the Head Start program.

Helson, Harry

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: November 9, 1898; Died: October 13, 1977.

Harry Helson, son of Ukrainian immigrants, began psychological studies at Bowdoin College and then went to Harvard as a graduate student during the early 1920s. His mentor was E. G. Boring, who at first resisted Helson's proposal to write a Ph.D. thesis on Gestalt psychological theory but in the end relented. The product, published in installments in the *American Journal of Psychology* in 1925 and 1926 was an important source of information about Gestalt theory to American psychologists. In a later article, Helson collected and organized over 100 Gestalt laws (Helson 1933). After obtaining the Ph.D., Helson went to Cornell in 1924 where he formed a close relationship with Karl Dallenbach and began a long and varied experimental career. After Cornell, he was at Illinois for 1 year and at Kansas for 2 years, where it is said he was instrumental in converting Raymond Wheeler, chair of the UK Department, to the Gestalt perspective which Wheeler then advanced during the early 1930s. In 1928, Helson went to Bryn Mawr where he stayed for 21 years, and after that spent a short time at Brooklyn College. He then joined Dallenbach in Texas for 10 years, and then went to Kansas State, to York University in Toronto, and to the University of Massachusetts at Amherst before retiring to California in 1971.

Major Accomplishments/Contributions

Helson's main experimental interest, which he developed at Cornell and pursued for the next 2 decades, was in the appearance of color. With Deane B. Judd, later to become a very influential color scientist, and other collaborators, Helson studied the effect of sensory context on color constancy, and advanced a theory which he termed color conversion. This theory states that color perception is the result of the combination of a number of factors specific to the stimulus (hue, saturation, lightness), factors external to the stimulus such as background illumination and reflection, and the perceiver's state of adaptation. Helson provided exact measurements of the amount of effect that contextual factors had on the perception of primary dimensions of color and of other color phenomena. Helson also studied the dynamics of changes in perception, and isolated an effect that he called Tau in which the distance between two cutaneous stimuli appeared longer or shorter based on the time interval between their presentations. Based on his many studies of color appearance plus his observations of the conditions under which change is observed, Helson then proposed, in 1948, a generalized psychophysical theory accounting for the effect of contextual factors on perception which, according to Helson's student, the theorist of intelligence and creativity J. P. Guilford, brought relativity into psychology (Helson 1948; Guilford 1979). Briefly, adaptation-level theory, the name by which it became known, states that perception in a field is the result of a comparison between the stimulus and a subjective neutral point, which is a geometric mean of characteristics of a reference stimulus, effects of background stimuli, and internal factors such as memory or expectation. Stimuli at the neutral point will eventually fade from consciousness due to adaptation or be perceived as neutral or indifferent, while stimuli above and below the adaptation level will be perceived as contrasting. The subjective adaptation level may shift quite far, and this will result in sometimes surprising perceptual results. For instance, perceivers who adapt to a cold-water bath will perceive slightly less cold water as warm water, which would be perceived as icy had they adapted to warmth. Helson extended the theory to anything psychologically assessable by a bipolar scale, including subjective preferences.

Further, he suggested that perceptions consequent on changes in adaptation level might explain larger social phenomena, for instance the rate and violence of major social change. The generality of this theory contributed to its wide acceptance as a conceptual tool across virtually all regions of psychological research, where it has been used as an explanatory construct for job satisfaction, the perception of happiness, economic perception, perception of aversive behavior, optimality in environmental design, self-regulation of emotion, and social perception, and in many other areas. Later in life, Helson contributed several historical memoirs on the fate of E. B. Titchener's psychology, on the success of Gestalt psychology against its competitors, and also, sympathetically, on the process by which E. G. Boring changed from an experimentalist to a historian in the 1920s (Helson 1970). The widespread acceptance of adaptation-level theory is in a sense the scientific legacy of E. G. Boring, who started Helson on the path of research in both classical psychophysics and Gestalt theory, which he transformed into the language of modern mainstream of experimental psychology.

Herbart, Johann Friedrich

ERWIN V. JOHANNINGMEIER

University of South Florida, Tampa, FL, USA

Basic Biographical Information

Herbart, widely known for his philosophy, psychology, and pedagogy, was born on May 4, 1776, in Oldenburg, Germany and died on August 11, 1841, in Göttingen.

He received his doctorate from Göttingen in 1805 and taught there until 1809 when he was called to Königsberg to take the chair earlier held by Immanuel Kant (1724–1824). In 1833, after his unsuccessful application to succeed Georg Wilhelm Friedrich Hegel (1770–1831) at Berlin, he returned to Göttingen. He began his university studies at Jena while Johann Gottlieb Fichte (1762–1814), Johann Gottfried Herder (1744–1803), Johann Wolfgang Goethe (1749–1832), and Friedrich Schiller (1759–1805) were still there. He was not a disciple of Fichte, for he adopted philosophical realism when the dominant fashion was idealism.

Major Accomplishments/Contributions

Sometimes described as an associationist, Herbart was one of the first to formulate psychology as a science. His psychology was neither experimental nor physiological. It was an empirical psychology based on observation and experience that can be seen as the transition between the speculative psychology of Kant, Fichte, and Hegel and the experimental psychology of Gustav Fechner (1801–1887), Herman von Helmholtz (1821–1894), and Wilhelm Wundt (1832–1920). He rejected faculty psychology, arguing that individuals only experienced thoughts and feelings. In 1816, he published *Lehrbuch zur Psychologie* (translated as *A Textbook in Psychology: An Attempt to Base the Science of Psychology on Experience, Metaphysics, and Mathematics*), the first textbook on psychology. In it, he attempted to apply mathematical formulations to mental life. He developed conceptions of the threshold of consciousness, the unconsciousness, and the apperceptive mass. His theory of apperception was his attempt to formulate a mathematical psychology and was likely the first such attempt. He also devoted significant effort toward applying psychology to education.

The theory of apperception held that when mind was presented with sense data (a series of “presentations”), they were attached to or interacted with those already there. Through what was essentially a mechanical process, elemental ideas were “perceived.” Once the new idea or experience was related to the already existing apperceptive mass, it was “apperceived.” The apperceptive process was the process whereby one's knowledge was created. Only those elemental ideas that crossed the threshold of consciousness contributed

to the building up of one's apperceptive mass. Thus, for Herbart, mind was not an active agent that produced changes in the world. Rather, mind was defined by its contents, by the assemblage of the manifold of self-preserving ideas or concepts that were representations of the impressions made upon individuals by the natural world. How mind functioned depended on its contents and how its contents were configured.

Herbart has been identified with Pestalozzi and Friedrich Daniel Ernst Schleiermacher (1768–1834) as one of the “founding fathers of modern educational theory” (Biesta and Burbules 2003, 1). He is of special interest to theoreticians of education, for as John Dewey (1916, 83) observed, Herbart was the first to demonstrate that education was an activity that could be studied directly. For Herbart's predecessors as well as his contemporaries, consideration of educational theory and educational practice (pedagogy) was an amateur endeavor. Educational theory and prescriptions for educational practice were based on the opinion of any learned and accomplished person whose authority derived from his or her achievements in some field other than education. Educational theory was not then scientific, not based on observation. Herbart held that: “the more education appears in the daily round of experience, the more necessary it is to bring our thoughts about it into more definite order and to fix them lest they be lost in the stream of opinion” (DeGarmo 1895, 181).

Like Fichte, Herbart was impressed by the educational work of Johann Heinrich Pestalozzi (1746–1827). He visited Pestalozzi in 1799 at Burgdorf after his 3-year tenure as tutor to the three sons of Herr von Steiger, Interlaken's governor. The five letters he wrote to Herr von Steiger about his children's progress, the works he subsequently published on Pestalozzi, and his subsequent work show that his long-standing interest in education, including the school he established in Königsberg, was an integral part of his agenda that included philosophy, psychology, and pedagogy.

Herbart changed how educational questions were framed and addressed. Dewey (1916, 83) clearly recognized Herbart's contribution when he wrote: “Herbart's great service was to take the work of teaching out of the region of routine and accident, and make it into a conscious business with a definite aim and procedure, instead of being a compound of

casual inspiration and subservience to tradition.” How Herbart addressed the relationships among philosophy, psychology, and pedagogy is different from current conceptualizations. The clear distinctions that now exist among them manifested in institutional arrangements, and professional organizations did not exist for Herbart. Psychology and pedagogy were then topics that belonged to philosophy, and institutional arrangements reflected that conceptualization. For example, when Dewey accepted his appointment at the University of Chicago in 1894, it was an appointment as chair of the department that included philosophy, psychology, and pedagogy.

The psychology Herbart developed and applied to education focused not on groups but on the individual. He was interested in the tutorial relationship and not on anything like modern classroom instruction. He was interested in how the individual became a moral person as opposed to educating citizens for the modern nation state, and experience was essential to the development of the individual. Education as a deliberate undertaking was the process whereby the right content was selected and organized into the proper configuration as well as the process that enabled teachers to control the human relationships under their charge, to present appropriate content, and to direct the student's interest. Interest led to learning. Besides primary interest, that which the student shows on his or her own without any encouragement from others, there was secondary interest, that which was to be created by the teacher.

Herbart maintained that his philosophy and psychology were related to his inquiries into education. Significantly, his pedagogy and psychology can be said to have issued not, as was then the fashion, from his metaphysics, but rather were possibly based on his experience and observations while tutoring the Steiger children. It has also been suggested that Herbart probably “developed his psychology out of his pedagogy rather than basing his pedagogy on psychology” (Dunkel 1970, 140).

Herbert Spencer and Introduction of Evolution into Psychology

ROBERT L. CARNEIRO

American Museum of Natural History, New York, NY, USA

Herbert Spencer (1820–1903) was the English philosopher-scientist principally responsible for the introduction of evolutionary thinking into scientific discourse. While Charles Darwin's treatment of evolution was limited to its role in biology, Spencer saw the process manifesting itself in all domains of nature. Though he wrote more than a dozen books during his lifetimes, Spencer did not have a literary background. He was taught at home by his father and never attended a university. His first employment was with the railroads, serving in the role of a civil engineer. In 1843, Spencer moved to London where he began his literary career in an editorial capacity with several journals. His first book, *Social Statics*, was published in 1850.

Spencer's first involvement with science was with geology when he examined fossils removed from railroad cuts during the course of his work. His interest in geology and paleontology thus aroused, he began reading Charles Lyell's *Principles of Geology*, which had recently appeared. It was this book that first made

him aware of the debate surrounding evolution, an interpretation of how animal species came to differ from each other, a theory which was at odds with the doctrine of special creation, then all but universally accepted. Describing the effect Lyell's book had on him, Spencer wrote:

- ▶ I had during previous years been cognizant of the hypothesis that the human race has been developed from some lower race; though what degree of acceptance it had from me, memory does not say. But my reading of Lyell, one of whose chapters was devoted to a refutation of Lamarck's views concerning the origin of species, had the effect of giving me a decided leaning to them. (Spencer 1926, I:176)

In 1851, while reviewing W.B. Carpenter's *Principles of Physiology* for the *Westminster Review*, Spencer had an experience which started him on his lifelong career as an expounder of evolution. This momentous turn of events he described as follows:

- ▶ In the course of such perusal as was needed to give an account of its contents, I came across von Baer's formula expressing the course of development through which every plant and animal passes – the change from homogeneity to heterogeneity. . . . [T]his phrase of von Baer expressing the law of individual development, awakened my attention to the fact that the law which holds of the ascending stages of each individual organism is also the law which holds of the ascending grades of organisms of all kinds. (Spencer 1926, I:384–385)

Hitting upon evolution as a master principle was the decisive event of Spencer's life. As he later wrote, "Once having become possessed by the conception of Evolution in its comprehensive form, the desire to elaborate and set it forth was so strong that to have passed life in doing something else would, I think, have been almost intolerable." (Spencer 1926, II:460)

In 1858, Spencer conceived the grand scheme of surveying the various fields of nature from an evolutionary perspective. This scientific enterprise, to which Spencer eventually gave the overall title of the *Synthetic Philosophy*, came to encompass 10 volumes and took more than 30 years to complete. In 1862, as an introductory volume to the series, he wrote *First Principles*, a book intended to build up, stone by stone, the edifice of evolution as a general conception. Spencer's

characterization of the evolutionary process as described in this book culminated in his classic definition: *Evolution is a change from an indefinite, incoherent homogeneity, to a definite, coherent heterogeneity; through continuous differentiations and integrations* (Spencer 1862:216).

This introductory volume to the *Synthetic Philosophy* was followed by *The Principles of Biology* (2 vols, 1864–1867), *The Principles of Psychology* (2 vols, 1870–1872), *The Principles of Sociology* (3 vols, 1876–1896), and *The Principles of Ethics* (2 vols, 1879–1891). In these works, Spencer showed how tracing the growth of these fields along evolutionary lines illuminated the course of their development. In an earlier article, “Progress, Its Law and Cause” (1857), Spencer had already painted a panoramic picture of the world seen from an evolutionary perspective:

- ▶ The advance from the simple to the complex, through a process of successive differentiations, is seen alike in the earliest changes of the Universe to which we can reason our way back, and in the earliest changes which we can inductively establish; it is seen in the geologic and climatic evolution of the Earth; it is seen in the unfolding of every single organism on its surface, and in the multiplication of kinds of organism; it is seen in the evolution of Humanity, whether contemplated in the civilized individual, or in the aggregate of races; it is seen in the evolution of Society in respect alike of its political, its religious, and its economical organization; and it is seen in the evolution of all those endless concrete and abstract products of human activity. (Spencer 1857:465)

Spencer’s interest in psychology appears to have begun in the 1840s with phrenology, a pseudo-science then very much in vogue. In 1843, he submitted two articles to the *Phrenological Journal*, both of which were rejected (Duncan 1908, I:51–52). In 1852, having turned away from phrenology, Spencer decided to write a treatise on psychology proper, in preparation for which he started reading John Stuart Mill’s *System of Logic*, which had appeared in 1843 (Spencer 1926, I:391). In August of the same year, he began the actual writing of *The Principles of Psychology* (Spencer 1926, I:456). Work on the book continued into the following year, and in October, 1853, he wrote to his father enthusiastically: “I am making further important

discoveries in psychology” (quoted in Duncan 1908, I:96). He continued working on the book into the following year, and in December 1854, he again wrote to his father, reporting that “[t]he theory of reasoning is working out beautifully” (Spencer 1926, I:461).

At this time, Spencer was in his mid-thirties and already imbued with the principles and objectives of science, as evidenced by his stated desire to treat psychology “after the spirit and methods of physical science” (quoted in Duncan 1908, I:115), unlike the way in which the subject had previously been dealt with.

Earlier – in 1852 – Spencer had published in *The Leader* (a new journal of liberal views) an article entitled “The Development Hypothesis” in which he rejected the idea of special creation, arguing instead for the gradual transformation of animal species by entirely natural means. In comparing the two alternate ways in which organisms could have obtained their present form he wrote:

- ▶ Which, then, is the most rational hypothesis? – that of special creation which has neither a fact to support it nor is even definitely conceivable; or that of modification, which is not only definitely conceivable, but is countenanced by the habitudes of every existing organism? (Spencer 1891:4)

In describing his progress on *The Principles of Psychology*, Spencer wrote, with the aforementioned article in mind, that “[a] large step was next made. The belief set forth in the early essay on The Development Hypothesis, implied that not only had bodily organization been naturally evolved, but [that] mental organization” had as well (Spencer 1926, II:10). The striking new idea that ran through the first edition of *The Principles of Psychology* was, of course, *evolution*. In the preface to his new book, which was finally published in 1855 – 3 years after work on it had begun and 4 years before the publication of Darwin’s *The Origin of Species* – Spencer boldly asserted that “Life under all its forms has arisen by a progressive, unbroken evolution . . . out of the lowest and simplest beginnings . . . and through the immediate instrumentality of . . . natural causes” (Spencer 1883, I:465n.).

Here, for almost the first time in his published writings, Spencer used the word “evolution.” It is worth noting that Darwin did not use the word in the first five editions of *The Origin of Species*, introducing it

only in the 6th edition (1872), 10 years after Spencer had carefully worked out its full meaning in *First Principles*.

Moreover, in his new work on psychology, Spencer proposed to go one giant step further and make an effort to follow “the successive phases of progressing Life,” exhibiting “that gradual differentiation of the psychic from the physical life which accompanies the evolution of Life in general” (Spencer 1883, I:viii). And in *The Principles of Psychology*, not only did Spencer propose to use evolution as an Ariadne’s thread in tracing the history of life and mind, he also chose to explore additional aspects of the evolutionary process itself. For instance, he would show that during the course of evolution, the nervous system had become more complex, developing greater means for adapting to and coping with the exigencies of living in an often hostile environment.

But in advocating this approach, Spencer met with stiff resistance, the emphasis on evolution proving to be distinctly premature. As Spencer later wrote, “The days were days when the special-creation doctrine passed almost unquestioned. Though for the interpretation of the structure of the Earth’s crust, miracle was no longer invoked, it was invoked for the interpretation of the fossils imbedded in the Earth’s crust.” And he added that even though “the evolutionary view of mind, though manifested throughout the whole argument of these chapters, was not put into the foreground,” it was salient enough to draw the fire of critics, and was “almost universally rejected and mostly ridiculed” (Spencer 1926, I:472).

Elaborating on the hostile reception accorded the evolutionary interpretations he had put forth in the first edition of *The Principles of Psychology*, Spencer later noted:

- ▶ In 1855, this view got scarcely any attention, and what little it did get brought upon me little else than vituperation. The tacit assumption, and towards the close of the work the avowed belief, that all organisms had arisen by evolution, and the consequent conception running throughout the whole work that the phenomena of mind were to be interpreted in conformity with that hypothesis necessarily, in 1855, roused not sympathy, but antipathy. It was only after the publication of Mr. Darwin’s *Origin of Species*, some 4 years

subsequently, and only after this work, drawing so much attention – causing so much controversy – began presently to affect deeply the beliefs of the scientific world, that the views contained in the *Principles of Psychology* came to be looked at more sympathetically.” (quoted in Duncan 1908, II:18)

Two more editions of *The Principles of Psychology* were to follow – the second in 1870–1872 and the third in 1880. In the preface to the second edition, Spencer commented on the sea change that had occurred in scientific opinion during the intervening years, and the effect that this shift had had on the reception given to his work:

- ▶ The great change of attitude toward the Doctrine of Evolution in general, which has taken place during the last ten years, has made the doctrine of Mental Evolution seem less unacceptable; and one result has been that the leading conceptions set forth in the First Edition of this work, have of late obtained considerable currency. (Spencer 1883, I:v)

The final edition of *The Principles of Psychology*, which appeared a quarter of a century after the first, was a work of impressive scope, its two volumes, 107 chapters, and 1,324 pages making it the largest and most comprehensive treatise on the subject attempted up to that time. In the second and third editions Spencer wove into his treatment of psychology a number of the elements he had previously worked out in his conception of the evolutionary process generally. He pointed out, for example, that in its evolution, mind had manifested an increase in heterogeneity, in definiteness, and in coherence, along with the integration of these elements – all characteristics prominently featured in his broadly encompassing definition of evolution.

In the third edition of *The Principles of Psychology* (1880), Spencer emphasized his regard for the study of psychology as a true science, like any other. Nonetheless, he noted that it was distinguishable from all other sciences in having an objective side and a subjective side. “Objective psychology,” he wrote, was “linked by [the] common element of consciousness, to the totally-independent science of subjective Psychology – the two forming together a double science which, as a whole, is quite *sui generis*” (Spencer 1883, I:141).

He further elaborated this distinction as follows:

- ▶ While, under its objective aspect, Psychology is to be classed as one of the concrete sciences, under its subjective aspect, Psychology is a totally unique science, independent of, and antithetically opposed to, all other sciences whatever. The thoughts and feelings which constitute a consciousness, and are absolutely inaccessible to any but the possessor of that consciousness, form an existence that has no place among the existences with which the rest of the sciences deal. (Spencer 1883, I:140)

The underlying feature of subjective psychology, Spencer held, was *mind*, the seat of consciousness, which he asserted would forever continue to be, if not completely inaccessible, at least enigmatic:

- ▶ Mind still continues to us a something without any kinship to other things; and from the science which discovers by introspection the laws of this something, there is no passage by transitional steps to the sciences which discover the laws of these other things. (Spencer 1883, I:140)

Intangible and elusive as its emanations might be, mind was, as far as its origins were concerned, still completely explainable. It had arisen out of a purely material substratum – the nervous system. “The form of life which we call mind,” Spencer wrote, “emerges out of bodily life” (1926, I:470). “Mind” he reiterated, “gradually evolves out of life” (Spencer 1908, II, 322). The purpose of both body and mind was clear enough: to adapt living organisms to their environment. This conception was in keeping with Spencer’s definition of life, which was “the continuous adjustment of inner relations to outer relations,” that is to say, the interaction of the organism with its enviring conditions (Spencer 1926, I:470).

Biology, then had laid the groundwork for psychology. Or, as Spencer put it, “The science of Life at large had to supply the data to the science of Mental Life” (Spencer 1908:347). Conspicuous among the elements that biology necessarily bequeathed to psychology was the “idea of adaptation as a universal principle of bodily life” (Spencer 1926, II:ii). And over countless generations of this adaptation there had resulted “an increase . . . in the complexity, of the adjustments of inner relations to outer relations,” so that “in tracing up

the increase we found ourselves passing without break from the phenomena of bodily life to the phenomena of mental life” (Spencer 1889, I:294). Evolution, then, had generated an uninterrupted flow, with no categorical breaks, only a rather striking degree of continuity. And seeing the nervous system as having been fully developed through this process, Spencer felt ready to tackle the specific elements of human psychology.

As previously noted, in several of his earlier articles Spencer had recognized evolution as a general process, manifesting itself in the various domains of nature. Now he saw it exemplified once again, this time in the field of psychology:

- ▶ The Law of Evolution holds of the inner world as it does of the outer world. On tracing up from its low and vague beginnings the intelligence which becomes so marvelous in the highest beings, we find that under whatever aspect contemplated, it presents a progressive transformation of like nature. (Spencer 1883, I:627)

Nor did Spencer ever tire of emphasizing this point. Searching for yet another way to portray the overriding evolutionary message he meant to convey in *The Principles of Psychology*, he wrote that “Mind gradually evolves out of Life. This was, I think, the thought which originated the book and gave its most distinctive character” (Spencer 1908:322).

It was all well and good to depict psychology as having revealed itself in the general features of evolution. Now, though, Spencer had to trace out these manifestations in their sequential developments. Thus he wrote that as “it is impossible truly to comprehend the organization of the body in general, or of the nervous system in particular, without tracing its successive stages of complication; so it must be impossible to comprehend mental organization without similarly tracing its stages” (Spencer 1883, I:292).

In studying the evolution of the nervous system, Spencer noted that “we see it advancing in integration, in complexity, in definiteness. If we turn to its functions, we find these similarly show an ever-increasing interdependence, an augmentation in number and heterogeneity, and a greater precision” (Spencer 1883, I:627–628). Summing up this process, he noted that “the development of Mind is fundamentally an increasing integration of feelings on successively-higher stages,

along with which there go increasing heterogeneity and definiteness” (Spencer 1899:191–192).

Applying this general framework to intelligence in particular, Spencer found that it showed “the *assimilation* of impressions. And the differences displayed in the ascending grades of intelligence are consequent upon the increasing complexity of the impressions assimilated” (Spencer 1897, II:299–300).

Spencer is often pictured as being “cerebral” to an inordinate degree, paying little heed to the emotions. This, however, is a mischaracterization of him. Indeed, we find him saying such things as, “But Mind is not wholly, or even mainly, Intelligence. We have seen that it consists largely, and in one sense entirely, of Feelings. And where Intellect is not present, or but little present, Mind consists of feelings that are unformed or but little formed. Intellect comprehends only the rational elements of Mind” (Spencer 1883, I:19–21). Years later, objecting to Auguste Comte’s views that “ideas govern and overthrow the world,” Spencer countered by saying that “Ideas do not govern and overthrow the world: the world is governed or overthrown by feelings, to which ideas serve only as guides” (quoted in Carneiro 1981:171).

Among the various aspects of human psychology that Spencer chose to explore at some length was *consciousness*, the various elements of which he found to be the “correlatives of . . . complex structures and functions” that had “arisen by degrees” in the nervous system (Spencer 1897:292) – meaning by this that they were clearly the product of a protracted evolution. And as with other products of evolution, “when we observe the correlative stages of consciousness, we discover that these, too, beginning as simple, vague, and incoherent, become increasingly-numerous in their kinds, are united into aggregates which are larger, more multitudinous, and more multiform, and eventually assume . . . [their] finished shapes” (Spencer 1883, I:628).

A necessary element of consciousness, Spencer argued, was that the ideas and feelings that comprised it were not static, but had to be continually changing. Change alone, however, was not enough. “If the changes are altogether at random, no consciousness, properly so called, exists. Consciousness is not simply a succession of changes, but an *orderly* succession of changes – a succession of ideas *combined and arranged* in special ways” (Spencer 1897:292).

Several chapters of *The Principles of Psychology* were devoted to the nature of intelligence, its development being traced from the simple reflex actions of the lower organisms to the highly complex powers of reasoning evinced by human beings. Here again, Spencer emphasized the evolutionary trajectory involved, showing how intelligence entailed successive adaptations of the organism to its many environmental demands. Over long stretches of time, Spencer asserted, the evolving mind had developed ever more refined ways to adjusting to its surroundings.

During the course of their history, Spencer argued, different groups of human beings had undergone different experiences and had adapted to them in a variety of ways. As a result of these varied experiences, he believed, such groups had developed different attitudes and responses, which in time had become part of their innate psychological makeup. Thus he was ready to entertain the belief that certain differences in intelligence existed among the various ethnic groups. He felt, however, that these differences were often overstated. Accordingly, he opposed the view of the “reigning school of mythologists,” led by Friedrich Max Müller, that there was “a fundamental difference in mode of action between the minds of the superior races and the minds of the inferior races” (Spencer 1901:693). On the contrary, he declared, “the laws of thought are everywhere the same: . . . given the data as known to him, the primitive man’s inference is the reasonable inference” (Spencer 1901:100). Thus he would have differed with the view expressed years later by the French psychologist Lucien Levy-Bruhl, in his book *How Natives Think* (1910), that in the workings of the mind of the simpler peoples one could see the operation of a “prelogical mentality.”

Still, that did not mean that Spencer was a firm believer in “the psychic unity of man.” Differences in the character and intelligence of the different races and ethnic groups, he thought, did in fact exist. For example, he thought that some tribal groups of India, such as the Todas, Santals, and Sowrahs, “have natures in which truthfulness seems to be organic” (Spencer 1890:234), and he argued that “the independence of the Greek nature” was “unlike Oriental natures,” and to this he attributed the fact that the ancient Greeks “did not readily submit to the extension of sacerdotal control over civil affairs” (Spencer 1900:265). Speaking

more generally, Spencer held that “the innate feelings and aptitudes of a race have large shares in determining the sizes and cohesions of the social groups it forms” (Spencer 1890:366). (In Spencer’s day, it should be noted, the purely cultural nature of ideas, beliefs, and attitudes had not yet become an established dictum of the social sciences.)

More defensible was the notion – which Spencer also entertained – that human sociality depended on certain biological and psychological predispositions. He argued that society itself was based on certain organic propensities on the part of its constituent units – human beings. And since the very nature and composition of society had as its basis the organic makeup of the society’s members, the science of society could not be considered an entirely autonomous one. It had to rely on the findings of the underlying sciences of biology and psychology. In this regard, Spencer wrote that “psychological truths underlie sociological truths, and must therefore be sought by the sociologist. . . . [W]ithout preparation in Mental Science there can be no Social Science” (Spencer 1886:382). And again he declared that “The Science of Life yields to the Science of Society, certain great generalizations without which there can be no Science of Society at all” (Spencer 1886:326). In his fullest expression of this view, he wrote:

- ▶ Society is made up of individuals; all that is done in society is done by the combined actions of individuals; and therefore, in individual actions only can be found the solutions of social phenomena. But the actions of individuals depend on the laws of their natures; and their actions cannot be understood until these laws are understood. These laws, however, when reduced to their simplest expressions, prove to be corollaries from the laws of body and mind in general. Hence it follows, that biology and psychology are indispensable as interpreters of sociology. (Spencer 1911:29–30)

Already in *Social Statics*, his first book, Spencer had written that “the very existence of society, implies some natural affinity in its members for such a union” (Spencer 1850:28) He returned to this theme more than 2 decades later in *The Study of Sociology*, writing that “the very possibility of a society depends on a certain emotional property in the individual” (Spencer 1886:52). Here and elsewhere, Spencer stood

staunchly by his contention that “the nature of an aggregate is determined by the natures of its units” (Spencer 1886:411).

Spencer maintained this position not only as a general proposition, but also as it manifested itself in specific instances. The particular attitudes, customs, and institutions of a society, he thought, sprang more or less directly from the particular organic properties of the group’s members. In keeping with this view, he wrote:

- ▶ We know that there are warlike, peaceful, nomadic, maritime, hunting, commercial, races – races that are independent or slavish, active or slothful; we know that many of these, if not all, have a common origin; and hence it is inferable that these varieties of disposition, which have evident relations to modes of life, have been gradually produced in the course of generations. The tendencies to certain combinations of psychical changes have become organic.

The more highly developed cultures could not have arisen just anywhere, Spencer argued. Such cultures required as a seedbed a society of individuals with “the constitutional energy needed for continuous labour, without which there cannot be civilized life.” Furthermore, this energy was not simply the happy gift of a few favored races, but “is an energy to be acquired only by inherited modifications slowly accumulated” (Spencer 1890:270).

Spencer thus did not see a society’s institutions as something static – once acquired, always retained – but as being involved in a continuous dynamic process. They were the result of “the increasing action and reaction of institutions and character, each slowly modifying the other through successive generations” (Spencer 1886:337). Moreover, the process took time to unfold, for “human nature, though indefinitely modifiable, can be modified but very slowly” (Spencer 1886:120). Accordingly, “before there arise in human nature and human institutions, changes having that permanence which makes them an acquired inheritance for the human race, there must go innumerable recurrences of the thoughts, and feelings, and actions, conducive to such changes” (Spencer 1886:402–403).

In the first instance, the mental and behavioral characteristics – indeed, the learning that Spencer believed was essential for this slow evolution to take

place – had been acquired through an individual’s own experience. However, because of Spencer’s adherence to the inheritance of acquired characteristics, he believed that the accumulated experiences of individuals had been transmitted to successive generations by those very individuals who had initially acquired them. The process by which this occurred he explained as follows:

- ▶ Though reflex and instinctive sequences are not determined by the experiences of the *individual* organism manifesting them; yet the experiences of the *race* of organisms forming its ancestry may have determined them. Hereditary transmission applies to psychical peculiarities as well as to physical peculiarities. While the modified bodily structure produced by new habits of life is bequeathed to future generations, the modified nervous tendencies produced by such new habits of life are also bequeathed.

This helped explain why, for Spencer, the various present-day branches of the human race were not all equally endowed, either intellectually or emotionally. There were indeed significant differences in the potentiality for cultural development among the existing ethnic groups. And from this assumption it followed that the institutions of a society reflected – and were limited by – the innate capacities of its members. Speaking specifically of the England of his day, Spencer expressed the view that “the existing type of industrial organization, like the existing type of political organization, is about as good as existing human nature allows” (Spencer 1886:252). Spencer was thus far from believing that Victorian England represented the highest summit to which the human race could ever rise. Indeed, not much improvement could be expected in the near term since “our existing industrial system,” being “a product of existing human nature, . . . can be improved only as fast as human nature improves” (Spencer 1886:254). Which, as we have seen, Spencer believed would be slow in coming.

But as much as human nature might vary from one ethnic group to another, it was not fixed and immutable. It could be modified. “[W]e have to get rid of the . . . belief,” Spencer argued, “that human nature is unchangeable.” “Man, in common with lower creatures, is held to be capable of indefinite change” (Spencer 1904:vi). The capacity to undergo the organic modifications required to reach the level needed to

produce civilization was thus not the unique possession of a single race, but was a potentiality present in all of them. This held out the prospect that, if subjected to the proper conditions for a long enough time, the inferior races might attain the same level as the highest ones among them. Subscribing in this way to the doctrine of human perfectibility took some of the edge off the racism with which Spencer is often charged.

The chapters of *The Principles of Psychology* covered many of the themes familiar to works on psychology: Instinct, Memory, Reason, Feeling, and the like. A particularly incisive chapter, for example, was devoted to the Will. In the nineteenth century – as it still is today – the issue of Free Will vs. Determinism was being warmly debated. Many persons found it a thorny issue, too difficult to resolve. One such individual was Charles Darwin, who wrote to his friend the American botanist Asa Gray, “I am in the same sort of muddle . . . as all the world seems to be with respect to free will” (quoted in Carneiro 2010:305). A thoroughgoing determinist, however, Spencer found himself in no such quandary. Free will, he asserted, was only an illusion, which was explainable in the following way:

- ▶ This subjective illusion in which the notion of free will commonly originates, is strengthened by a corresponding objective illusion. The actions of other individuals, lacking as they do that uniformity characterizing phenomena of which the laws are known, appear to be lawless – appear to be under no necessity of following any particular order; and are hence supposed to be determined by the unknown independent something called the Will. But this seeming indeterminateness in the mental succession is consequent on the extreme complication of the forces in action. The composition of causes is so intricate, and from moment to moment so varied, that the effects are not calculable. These effects are, however, as conformable to law as the simplest reflex actions. (Spencer 1883:502)

As the passage just quoted suggests, many of Spencer’s observations on psychology bordered on questions of philosophy. More than any writer before him – and quite possibly since – Spencer probed the intimate connection between the two fields. For instance, in a closely reasoned section of *The Principles*

of *Psychology*, he examined the polar opposites of Crude Realism and Absolute Idealism, deciding that his own position lay somewhere between the two, but tending more towards the realist end of the spectrum. The position he settled on he labeled Transfigured Realism (Spencer 1897:489–494).

Seeking to cut the ground out from under the idealist view of things, Spencer came to a rather striking conclusion. The world of everyday experience, he held, was too overwhelming a presence in the everyday life of even the most dedicated idealist for him ever to have really and truly maintained that philosophical position. “Anti-Realistic beliefs,” he boldly asserted, “have never been held at all. They are but ghosts of beliefs, haunting those mazes of verbal propositions in which metaphysicians habitually lose themselves” (Spencer 1897, II:500). Then, taking issue with those celebrated philosophers who purported to be steadfast idealists, he contended that, deep down, they never actually saw things in that light:

- ▶ Berkeley was not an Idealist: he never succeeded in expelling the consciousness of an external reality. . . . Hume did not in the least doubt the existence of Matter or of Mind: he simply persuaded himself that certain arguments ought to make him doubt. Nor was Kant a Kantist: that Space and Time are nothing more than subjective forms was with him, as it has been and will be with every other, a verbally-intelligible proposition, but a proposition which can never be rendered into thought, and can never therefore be believed. (Spencer 1897, II:500)

In 1901, near the end of his life, Spencer witnessed an abrupt, if temporary, about-face in the discipline to which he had contributed so substantially. The journal *Mind*, founded in 1876 by Alexander Bain, and long regarded as the leading journal devoted to scientific psychology and allied subjects – and to which Spencer himself had contributed a number of articles – suffered a sudden change of hands. It fell under the editorial control of English followers of Hegelian Idealism, a brand of philosophy which had recently been introduced into England from the continent and had become a dominant voice at both Oxford and Cambridge. With evident displeasure, Spencer wrote that those two great universities “have been captured by this old-world nonsense” (quoted in Duncan 1908, II:201).

And he commiserated with its founder, telling Bain, “I not unfrequently think of the disgust you must feel at the fate which has overtaken *Mind*. That you, after establishing the thing and maintaining it for so many years at your own cost, should now find it turned into an organ for German idealism must be extremely exasperating” (quoted in Duncan 1908, II:201).

Greatly displeased at this turn of events, Spencer canceled his subscription to the journal, justifying his decision to its new editor by arguing, “It cannot be expected that I should aid the survival of a periodical so largely devoted to the expression of views diametrically opposed to my own” (quoted in Duncan 1908, II:202).

What sort of reception did the various editions of *The Principles of Psychology* receive? We have seen that the first edition – published in 1855 – was roundly criticized. The intellectual climate of the day was simply unready to accept it. However, by the time of the second edition (1870–72) – and especially that of the third (1880) – prevailing opinions had shifted dramatically.

“Toward the end of the first edition of *The Origin of Species*,” wrote the historian John Fiske, Charles Darwin looked forward “to a distant future when the conception of gradual development might be applied to the phenomena of intelligence” (Fiske 1891:593). Darwin was then quite unaware that 4 years earlier Spencer had already taken the first steps in that direction. And by the time of the sixth edition of *The Origin* – 1872 – Darwin had greater reason to be optimistic, and accordingly could write that “In the future I see open fields for far more important researches. Psychology will be securely based on the foundation already well laid by Mr. Herbert Spencer, that of the necessary acquirement of each mental power and capacity by gradation” (Darwin 1958:449). John Stuart Mill, another leading figure of the day, was also favorably impressed by Spencer’s work. Writing to the psychologist Alexander Bain in 1863, he said that the first edition of *The Principles of Psychology* was “a remarkable one in many respects,” and that in “wide-reaching systematization of so many heterogeneous elements” it was “very imposing” (Mill 1910, I:273). Writing to Bain again 4 years later, Mill said he had been reading *The Principles of Psychology* for the third time and that “It is a satisfaction to find how closely his results coincide with ours” (Mill 1910, II:99). Addressing Spencer

himself, Mill observed that while he did not agree with everything in the book, “I cannot help expressing to you how much my opinion of it, though already high, has been raised” (quoted in Duncan 1908, I:150).

In his final appraisal of the volume, Mill noted that *The Principles of Psychology*, “in spite of some doctrines which he [Spencer] holds in common with the intuitive school,” the book as a whole was “one of the finest examples we possess of the Psychological Method in its full power” (Mill 1884:292).

For his part, William James, often a critic of Spencer, nonetheless, in evaluating the entire body of his works, wrote: “My impression is that, of the systematic treatises, the ‘Psychology’ will rank as the most original. Spencer broke new ground here in insisting that, since mind and its environment have evolved together, they must be studied together. He gave to the study of mind in isolation a definitive quietus, and that certainly is a great thing to have achieved” (James 1911:139–140).

Critics found various ways of emphasizing the originality of *The Principles of Psychology*, one of them saying that the book “was mainly written in the open air” (Saleeby 1906:167), meaning that, as George Henry Lewes expressed it, Spencer had “sat at the feet of no professors” (Lewes 1856:352). Years later, Harry Elmer Barnes echoed this verdict, declaring that Spencer had written the book “having read less formal psychology than the average elementary-school teacher” (Barnes 1921:295).

But of course, the book had not been written in a vacuum. Nor did it stand in splendid isolation. In the spectrum of views entertained about the nature of the human mind, Spencer’s position could be located somewhere between those labeled *intuitionism* and *sensationalism*. At one end of the scale were René Descartes and Immanuel Kant, who believed in the existence of innate ideas – as, for example, Kant’s notion of a “categorical imperative,” an inborn and insistent guide to right conduct. At the other end of the spectrum stood John Locke, John Stuart Mill, and Alexander Bain, for whom innate ideas did not exist, all knowledge being derived from personal experience. Their view was that the mind was a *tabula rasa* on which were inscribed only those things which the individual himself had experienced.

The question, then, was where Spencer was to be placed on this continuum? In his *History of English*

Rationalism in the Nineteenth Century, William Benn stated that Spencer “could not entirely agree with either party to the dispute” since he believed that each disputant saw only one side of the truth. On the one hand, Spencer agreed that all knowledge came from experience – indeed, it could have no other source. So on this point Spencer stood firmly with Mill and the empiricists. But experience, Spencer held, was of two kinds. There was the experience of the individual himself, to which he owed most of his ideas. But there was also the experience of the human race, to which he was heir and to which he owed a certain proportion – small though it might be – of his ideas as well (Benn 1906, II:171–172). As we have seen, the ability of Spencer to accept the latter view was due to his belief in the inheritance of acquired characteristics – a doctrine he thought applied to ideology as well as to anatomy. Accordingly, someone alive today, Spencer would argue, could be said to encapsulate within himself the accumulated experiences of untold generations of his forebears.

Despite this false notion, when Spencer’s *The Principles of Psychology* is viewed in its totality, it can be seen as playing a major role in transforming psychology from the narrow, limited discipline it had been, to a vigorous, far-ranging, and generalizing science. Foremost among his contributions to this science was the fact that, as William McDougall observed, “Herbert Spencer was the first to make a thoroughgoing attempt to describe the evolution of mind” (McDougall 1925:336–337). Spencer’s book was, in fact, a distinct forerunner of the naturalistic era in psychology. Surveying historical trends in the discipline, James Mark Baldwin declared at the end of the nineteenth century that “[i]n this matter of naturalism, our ship has had to change her course one hundred and eighty degrees,” adding that “it was Spencer who set the compass true in the new direction” (Baldwin 1897:554). Summarizing Spencer’s influence on psychology, Robert Thomason, another historian of the discipline, wrote that “Many of his original ideas have been absorbed and transformed in the general thinking of psychology” (Thomson 1968:103).

Despite the general decline suffered by many of Spencer’s views following his death in 1903, and the fact that, if remembered at all, he is known today primarily for his conservative political philosophy, his contributions to psychology have not been entirely

forgotten by that profession. Among more nearly contemporary psychologists, Gardner Murphy has pointed out that “Spencer was the first to elaborate the conception that the mind is what it is because it has had to cope with particular kinds of environment” (Murphy 1930:114–115). And the experimental psychologist Edwin G. Boring, acknowledging that the first edition of *The Principles of Psychology* (1855) “never exercised great influence,” added that “Spencer’s real influence upon psychology dates from the two volumes of the second edition published in 1870 and 1872” (Boring 1929:231), emphasizing that “the really important novelty in Spencer’s psychology,” and the one “gaining for him an undying reputation, was “his *evolutionary doctrine*” (Boring 1929:233).

Herschel, J. F. W.

DAVID L. SEIM

University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

John Frederick William Herschel, born at Slough, England, on March 7, 1792, became a British scientist of large reputation across many fields, including especially astronomy, photography, and natural philosophy. Herschel also became head of a large household, fathering 12 children with his wife, Margaret Brodie Stewart Herschel (married 1829). With respect to the history of psychology, Herschel’s main interests had to

do with human perception of brightness and color, as well as questions about whether mathematical and scientific discoveries are primarily “in nature” or “in the mind.”

Herschel was born the only son of the famous astronomer William Herschel, who was 55 at the time. Herschel’s mother, Mary Pitt Herschel, was 42 at the time. People came from distant lands to visit the Herschel estate, primarily to stand in the shadow of William Herschel’s forty-foot telescope. Though John Herschel began his formal education at Eton College (for boys up to age 18) when he was 8 years old, he was soon removed from the academy in favor of private tutoring at home. In 1809, at age 17, Herschel enrolled at St. John’s College, Cambridge, where he received the mathematical instruction for which Cambridge was famous. For his mathematics performance in 1813, Herschel won the highest academic distinction, graduating as senior wrangler. He published a mathematics paper the same year, and was also elected as a fellow in the Royal Society of London in that same year. Herschel went onward to an extraordinarily productive career in science, including the winning of many prizes; in fact twice he was named recipient of the famed Copley Medal. He performed outstanding work to improve our understanding of the orbit of Halley’s Comet, when it passed in 1835. Herschel was stunningly prolific in publishing in many fields of science over a long career. Some important books he published were *Outlines of Astronomy* (1849) and *Familiar Lectures on Scientific Subjects* (1872). Herschel died at his home at Collingwood, Kent, on May 11, 1871 (Buttmann 1970).

Major Accomplishments/Contributions

Herschel’s first researches of finer distinction were his mathematics papers of 1813 and 1814, in which he communicated new applications of mathematical analysis. Although he had some fleeting intention of being called to the bar, Herschel quickly took up the life of science. In 1820, he completed the construction of a new telescope that would be a major scientific instrument for the rest of his life.

By the 1820s Herschel was interested in a particular problem associated with the use of telescopes, which is a matter that closely intersected with the human mind – specifically, with questions about the sensation

and perception of fine differences between brightness and color. In 1819, Herschel published a short paper to clarify something he believed should be possible based on some data obtained by his father, who had attempted over 35 years to compare the brightness differences of all stars in the northern hemisphere. Herschel’s father had recognized by 1817 that (in the father’s words) “the principle of the visibility of the difference in brightness would have less influence with the gradually diminishing lustre of the stars” (Herschel 1817). William Herschel further emphasized this important empirical finding, calling it the principle of “the distinguishable difference of brightness becoming gradually less as the stars are smaller.” The son, in a short paper of 1819, looked at his father’s work and concluded how it seemed “that a single star of the first magnitude would be just lost to the naked eye if removed to 12 times its distance” (Herschel 1817; Buttmann 1970).

Fourteen years later, in a chapter on the stars in his *Treatise on Astronomy* (1833), Herschel made an explicit call for a research project when he wrote that, “by setting aside all such arbitrary subdivisions, a numerical estimate should be formed, grounded on precise photometrical experiment, of the apparent brightness of each star.” (1833, pp. 373–375) Herschel included his improved reestimation of a complete scale of six “stellar magnitudes,” based on visual empirical measurements.

Something else Herschel did, also back in 1819, was discover the solvent power of hyposulphite of soda on the otherwise insoluble salts of silver – a discovery that would, in time, help to develop a fixing agent in photography. Twenty years later, Herschel invented (simultaneously with William Henry Fox Talbot) the process of photography on sensitized paper, and in the process became the first person to apply the terms “positive” and “negative” to photographic images (Crowe 1998).

Another of Herschel’s research projects of some importance for the history of psychology is his investigations and writings on color perception and color blindness. Modern studies of color perception and color blindness trace their origin to 1794, when legendary British chemist John Dalton announced his initial efforts to carefully study his own color blindness, which he discovered while flower gardening with a friend; the phenomenon in fact became known, for a time, as “Daltonism.” But it was Herschel (soon followed by

George Wilson) who, by the 1840s, turned the study of color blindness away from anecdotal reports and toward standardized, statistical testing. The aim was to discover laws – even causes – behind the vision anomaly. In terms of methodology of science, study of color blindness was an important episode, not only because of the role of “anomalies” in science, but because studying color blindness involved movement past inductive case work and toward identification of quantitative laws. Herschel wrote about his researches on color perception in 1845, in an essay on “Light” (Musselmann 2000).

Another line of Herschel’s work with some bearing on psychological theory was his writings in natural philosophy, most notably his 1830 volume for “Dionysius Lardner’s Cabinet Cyclopaedia,” titled *A Preliminary Discourse on the Study of Natural Philosophy*. The book systematically explores the relationship between theory and observation. The reader of the book discovers Herschel describing nature as governed by laws which, though difficult to state mathematically, can be understood through the inductive power of the human mind to find a single unifying explanation for a cluster of observed phenomena. The book even begins with a section in which Herschel describes “Man regarded as a Creature of Instinct, of Reason, and Speculation.” While there is no substantial contribution to new ideas about human nature and the human mind, this short section is interesting reading for learning what a scientist of the 1830s identified as dividing lines between “bodily appetites” and “conscious wants.” Potentially noteworthy is the way in which Herschel seems to describe a point between the “instinctive” appetites and “learned” wants, which is that “the senses . . . experience these pleasures and these pains in any degree of intensity.” And there is that phrase: “degree of intensity” (Buttmann 1970).

Sir John Frederick William Herschel (knighted in 1831) was a scientific hero when he died. Great Britain decided his remains should be interred at Westminster Abbey, in close proximity to the tomb of Sir Isaac Newton.

Hilgard, Ernest R.

DARLENE B. VIGGIANO

University of Phoenix, Sacramento, CA, USA

Basic Biographical Information

Birth date/date of death – July 25, 1904/October 22, 2001

Birthplace/nationality – Belleville, IL/American

Education

Born to a doctor and his wife, Hilgard earned his own doctorate in 1930 and, in 1931, married Josephine Rohrs, who also held a doctoral degree. Hilgard went to Yale Divinity School and studied social ethics, turning to psychology for his doctoral studies with a dissertation on conditioning. Yale was where Hilgard met

Rohrs – then a budding developmental psychologist who later made her own contributions to the research and writing on hypnosis, including *Hypnosis in the Relief of Pain*, which was a husband and wife collaboration (Alexander 2001).

Professional Development

Early Career: Hilgard's post-doctoral work was also done at Yale, where he became an instructor. He joined the Psychology faculty at Stanford University in California in 1933. Hilgard developed a technique for photographically recording eyelid responses, which earned him the Warren Medal of the Society of Experimental Psychologists in 1940. He became a professor and chairman of his department by 1942. In 1946 he advised General MacArthur on changes in the Japanese educational system as a member of a mission to Japan (Bower n.d.). He published *Theories of Learning* in 1948, which described major learning theories of the century to date; analyzed shortcomings in various areas; and recommended further research. He then served as dean of Stanford's graduate division from 1951 to 1955, and became emeritus in 1969, the year he won a Distinguished Scientific Contribution Award.

Later Career: Hilgard was president of the International Society of Hypnosis from 1973 to 1976 and earned their Benjamin Franklin Gold Medal in 1980. He had won the American Psychological Foundation's Gold Medal Award in 1978 and was president of the Society for Clinical and Experimental Hypnosis from 1979 to 1981. His fourth revision of *Theories of Learning* was also published in 1981, and by the sixth edition it was co-authored with Gordon Bower. Hilgard additionally served as president of the American Psychological Association (APA). Its publication, *The American Psychologist*, recognized him in 1991 as one of the top ten most important contemporary psychologists. In 1994, the APA awarded him for his outstanding lifetime contribution to psychology. The APA further named a Division One lifetime achievement award after him for general psychology career contributions that integrate various areas of study. Hilgard was 97 when he died in Palo Alto (American Psychological Association 2010).

Major Accomplishments/Contributions

Specifically Related to the History of Psychology

Hilgard is remembered for hypnosis experimentation, medical hypnosis (i.e., children facing cancer, pain control, smoking control), co-development of the Stanford Hypnotic Susceptibility Scale, his 1977 neodissociation theory of hypnosis (allowing for both a "hidden observer" and unconscious actions to occur simultaneously), psychology and hypnosis textbooks, professorship, and organizational service (Kihlstrom 2003).

Major Publications

Hilgard's major publications are as follows: *Psychology in America: A Historical Survey* (1978), *Divided Consciousness: Multiple controls in human thought and action* (1977), *Hypnosis in the Relief of Pain* (1975, Josephine Hilgard, co-author), *Hypnotic Susceptibility* (1965), *Introduction to Psychology* (1953), *Theories of Learning* (1948), *Conditioning and Learning* (1940, Donald G. Marquis, co-author)

Impacts on History and Theory in Psychology

Hilgard's *Introduction to Psychology* was the most popular academic best-seller from the mid-1950s through the 1970s. To this day, it is the standard by which other psychology textbooks are measured. Since its fourth edition, the book took on co-authorship, and by 2003, it was in its 14th revision, now entitled *Atkinson and Hilgard's Introduction to Psychology*. The book had been so successful that the publisher agreed to publish thereafter any book of which Hilgard was an author. The resulting follow-up was *Psychology in America: A Historical Survey*, which was unique in detailing psychological subfields as Hilgard himself witnessed their development. He saw psychology as a "Hegelian synthesis" between science (particularly chemistry) and religion, thus showing his ability to connect various arenas of inquiry (Kihlstrom 2003). He helped create the Center for Advanced Study in the Behavioral Sciences at Stanford University. Hilgard contributed greatly to the understanding of learning processes and

the ability to bring under control what were once thought to be conditioned or automatic, unconscious responses – such as eye blinking. His co-authored work in this field, *Conditioning and Learning*, became a standard in classrooms, and it was in this book that the term “classical conditioning,” as opposed to operant or instrumental conditioning, was coined. Hilgard’s *Theories of Learning* anticipated the so-called “cognitive revolution” that overtook both functional and radical behaviorism as a favored psychological theory (Kihlstrom 2003). Central courses and full psychology curriculums were developed from this book in the 1950s–1960s. Hilgard also improved the usability of his textbooks’ indices, setting the standard for editorial practice in scholarly books. Late in his career, he threw out most of his previous lecture notes to focus only on courses previously untaught by him, including abnormal psychology and motivation. His hypnosis studies tested psychodynamics in the laboratory, centering on the relationship between conscious and unconscious processes. This work was a forerunner to current studies in automaticity. Thus, Hilgard became a leader in hypnosis research. His collaboration with Andre Weitzenhoffer led to the Stanford Hypnotic Susceptibility Scale and its three editions. This made a quantifiable science of hypnosis, thereby aiding replicability of experiments. The scales remain the standard today for performance-based measurement of individual differences in ability to experience hypnotic effects (Piccione et al. 1989). Hilgard also studied hypnotic analgesia extensively, making major contributions to the understanding of perception and sensation. For example, he empirically confirmed that subjective pain ratings covaried with stimulus intensity more stringently than physiological response ratings did. It was in this research that Hilgard developed his technique of using the “hidden observer” to study covert awareness of phenomena (Kihlstrom 2003). His laboratory at Stanford was funded by a grant from the National Institute of Mental Health for more than 20 years. It became a magnet for research, most particularly to replicate dissertation studies. The lab held its “valedictory year” in the 1977–1978 academic term (Kihlstrom 2003). Overall, the lab produced at least 100 papers on hypnosis plus a competing number of *Hypnosis Research Memoranda* on methodology,

data analysis, and preliminary findings. All lab work was documented in the final report entitled, *A Saga of Hypnosis: Two Decades of the Stanford Laboratory of Hypnosis Research, 1957–1979*. In 1994, *Psychological Science*, the American Philosophical Society’s journal, featured Hilgard for his 90th birthday, an honor matched by no other psychologist.

Høffding, H.

JOHN G. BENJAFIELD

Brock University, St. Catharines, ON, Canada

Basic Biographical Information

Harald Høffding (1843–1931) was professor of philosophy at the University of Copenhagen from 1883 to 1915. Høffding experienced an initial desire to be a priest, followed by a period of doubt after which he finally settled on psychology as his main interest. In this

context, Høffding (1932) described Kierkegaard as being as profound an influence on him as on the Danish people as a whole. His studies in philosophy and psychology were deeply concerned with the “mutual relations between science and religion” (p. 197). As a teacher, Høffding always “treated his students with great respect and was always ready to listen to them, react to their views, and counsel them” (Pind 2009, p. 37). Høffding became generally regarded as one of the most important figures in Danish culture, a role that was acknowledged when he was made the first resident of the Carlsberg Academy.

Major Accomplishments and Contributions

Consistent with his wide-ranging interests, Høffding (1900/1955) authored both a history of philosophy as well as a textbook in psychology (Høffding 1891/1919). The former included sagacious evaluations of the philosophical import of the work of such important figures in psychology as Herbart and Fechner. Høffding became a scholar of international repute, whose work still had a heuristic value well into the latter part of the twentieth century. Perhaps his most famous contribution was his description of what he believed to be a necessary relationship between perception and memory. He drew out the implications of the fact that the same object never presents itself to us in exactly the same way twice. For example, when you perceive someone for the second time, you may see them from a different angle and at a different distance than you ever have seen them before. All the same, you may still recognize them, and then recall their name. How is such recognition possible? To illustrate the problem, let us call the initial perception of the person “A” and the name “B.” A and B are experienced together and so must be associated in memory in order for you to be able to recall B when you see A again. However, in order to recall B, you must first recognize A. Høffding (1891/1919, p. 157) put it like this:

- ▶ [E]very association . . . presupposes . . . an immediate recognition. In order that A may excite the ideas of B, C, D, with which it usually arises simultaneously in consciousness, it must first, so to speak establish its identity.

The hypothesis that recognition precedes recall is called the *Høffding function* or *Høffding step*. For Høffding, recognition occurred on the basis of *similarity*. An event will be recognized if it is sufficiently similar to a previously experienced event. Of course, similarity had long been thought to play an important role in memory. However, before Høffding’s work, the law of similarity had not been regarded as a fundamental principle of memory.

The importance of the Høffding function was emphasized by Wolfgang Köhler (1887–1967; 1940/1960, pp. 126–130) who made it a central feature of the Gestalt theory of memory. Köhler suggested that it was necessary for a perception to be “distinctively similar” to previous experiences in order to facilitate accurate recognition. Thus, events that are highly similar to each other are unlikely to be individually recognized, although they may seem familiar. An object will elicit recognition to the extent that it is not only similar to a previously experienced event but also somewhat different from other events. For example, any one person’s face is similar in some ways to any other person’s face: They all have a mouth, nose, two eyes, and so on. However, it is the distinctive relations between the parts of a face that facilitate recognition.

Holt, E. B.

SAM PARKOVNICK

Dawson College, Westmount, QC, Canada

Basic Biographical Information

Edwin Bissell Holt was born in Winchester, Massachusetts in 1873 and died in Rockport, Maine in 1946. He received a doctorate from Harvard in 1901, remaining at Harvard until his resignation in 1918. From 1926 until 1936, Holt taught at Princeton during the spring term. Holt was both a psychologist and a philosopher and is known principally as a theorist. Significant publications include, in order of publication, “The Program and First Platform of Six Realists” (1910), *The New Realism: Cooperative Studies in Philosophy* (1912), *The Concept of Consciousness* (1914), *The Freudian Wish and Its Place in Ethics* (1915), *Animal Drive and the Learning Process: An Essay Toward Radical Empiricism* (1931), and “The Whimsical Condition of Social Psychology, and of Mankind” (1935).

Major Contributions

This entry will address *The Freudian Wish and Its Place in Ethics* (1915) and *The New Realism*, Holt’s most noteworthy theoretical contributions. It will conclude with an outline of what remains to be done regarding Holt. Looking at Holt this way leaves out a number of noteworthy aspects of Holt, including translating Hugo Munsterberg’s *The Americans* (1905) from German into English and the many years he spent running Harvard’s Psychological Laboratory.

The Freudian Wish and Its Place in Ethics

Holt’s views on psychoanalysis appeared in *The Freudian Wish and Its Place in Ethics* in 1915, an early popularization of psychoanalysis (Hale 1971). It included “Response and Cognition” which also appeared in the *Journal of Philosophy* in 1915. *The Freudian Wish* presented a mixture of psychoanalysis, behaviorism, and a naturalistic approach to ethics. Holt took from psychoanalysis what he wanted, largely the notion of the wish, and interpreted it within his

own theoretical framework (Shakow and Rapaport 1964). The wish, for Holt, meant purpose. Holt opposed introspection, proposing a methodological behaviorism which was nevertheless a purposive psychology, mind being seen as a relation (to the outside world), not a substance. Freud thought it a “strange” book (Freud 1993); for Freud, behaviorism and psychoanalysis were in conflict, behaviorism ruling out the study of mind (Freud 1935). John Watson objected to Holt’s praise of psychoanalysis; Watson wanted to do away with psychoanalysis rather than praise it. He noted that Holt’s wish was not Freud’s wish, but was, instead, compatible with behaviorism, criticizing Holt’s methodological behaviorism for not going far enough in excluding the mind from psychology (Watson 1917). Despite this, Joseph Jastrow wrote Holt that he, Jastrow, was very much in favor of Holt’s take on psychoanalysis in *The Freudian Wish* (Rieber 1998). Jastrow had just published *The House that Freud Built* (1932) which was very critical of psychoanalysis.

Holt’s praise for psychoanalysis was not uncritical or without reservations. Herbert Langfeld tells us that Holt refused to write an article on Freud for the *Psychological Review* because there were serious problems with psychoanalysis that Holt did not wish to discuss (1946). What is lacking is a thorough presentation of Holt’s beliefs regarding psychoanalysis.

Also lacking is what led Holt to psychoanalysis. Holt attended Freud’s lectures at Clark University in the summer of 1909. In a letter to Robert M. Yerkes, dated September 13, 1909 (Holt 1909), Holt wrote that he was very much in favor of psychoanalysis. Holt taught psychoanalysis in courses at Harvard (Franklin 1916; Wilbur 1943) and gave several lectures on psychoanalysis in November, 1910 (“Professor Holt” 1910). This dates Holt’s views on psychoanalysis to Freud’s lectures at Clark University in the summer of 1909, but whether those views preceded the summer of 1909 or were fully developed in the summer of 1909 and what led up to them remains to be determined.

The New Realism

The New Realism arose as a response to the idealism of Josiah Royce, specifically *The World and the Individual* (1900), by Ralph Barton Perry (1901–1902) and

William Pepperell Montague (1902). It began as a movement at the December 1909 meeting of the American Philosophical Association in New Haven, Connecticut. Originally, The New Realists included Perry from Harvard, Montague and W. B. Pitkin from Columbia, E. G. Spaulding from Princeton, and W. T. Marvin from Rutgers. They were later joined by Holt; F. J. E. Woodbridge from Columbia did not join, but gave the New Realists access to the *Journal of Philosophy*. They met over the next 4 years in New York, Cambridge, Princeton, Woods Hole, MA, and Dover, NJ. Their two publications were “The Program and First Platform of Six Realists” (1910) and *The New Realism: Cooperative Studies in Philosophy* (1912) (Perry 1954).

Methodologically, the model for The New Realism was science, particularly the emphasis on cooperation and agreement. Philosophically, The New Realism held to the independent existence of outside objects and a view of perception as direct and unmediated (Harlow 1931/1970; Heft 2001). The problem was to account for mistakes in perception such as visual illusions. Holt, in his contribution to *The New Realism* (1912), tried to do so. He held that mistakes occur, not in the perceiver, but in the interaction between the perceiver and the outside world. Visual illusions are then real, to be explained by the conditions of observation (Heft 2001).

For a few years, The New Realism had a central role in American philosophy, issues raised by the New Realism dominating the 1910 and 1911 meetings of the American Philosophical Association (Harlow 1931/1970). Then, after 1914, philosophy journals turned from discussion of The New Realism to critical realism (Werkmeister 1949).

The New Realism was successful as a critique of idealism (Schneider 1964), but much less so as a philosophical position. There were both agreements and disagreements among the six (Montague 1930/1962, 1937; Werkmeister 1949; Hill 1961; Robischon 1967; Heft 2001). “The Program and First Platform of Six Realists” (1910) and *The New Realism* (1912) included both a shared contribution with which all agreed and individual contributions with which there was both agreement and disagreement; for example, *The New Realism* (1912) had different views on mistakes in perception by Holt and Montague. And The

New Realism did not provide an adequate account of perception, not being able to explain mistakes in perception (Harlow 1931/1970; Werkmeister 1949; Robischon 1967).

What Remains to Be Done Regarding Holt

As things stand today, Holt is known for his influence on others, specifically the psychologists Floyd Henry Allport (Parkovnick 2000), James Gibson (Reed 1988; Heft 2001), and E. C. Tolman (Smith 1986), or his role in psychoanalysis gaining a foothold in America (Hale 1971), Harvard’s philosophy department (Kuklick 1977), or The New Realism. What needs to be done is, as much as possible, to rediscover Holt as a person in his own right and to regain Holt’s voice. Regarding the latter, the discussion of The New Realism is based on the reflections of Perry and Montague, not Holt. One problem in doing so is the lack of archival information. What remains of Holt’s correspondence appears not in a collection of Holt’s papers, but in the papers of others, William James, Hugo Munsterberg, R. M. Yerkes, and Ralph Barton Perry, among them. A second problem is intellectually disentangling Holt from Perry, particularly before Holt’s resignation from Harvard in 1918.

Intellectually, Holt’s positions regarding behaviorism, psychoanalysis, and The New Realism have to be fully explicated. For example, what did Holt see as problematic about psychoanalysis? This would involve dating Holt’s beliefs and indicating who influenced Holt and how. It would begin with William James. It would also involve trying to integrate Holt’s beliefs into a comprehensive philosophy (what Holt was trying to do) which would constitute a metatheory for psychology.

Regarding Holt’s life, Langfeld (1946) came close to but did not explicitly state that Holt was homosexual. Harry Heft (2001) indicated that James Gibson knew of Holt’s homosexuality at Princeton. Holt’s sexuality needs to be explored as part of the larger story of homosexuals in academia (D’Emilio 1992; Blount 2005). Of interest is whether it influenced his intellectual positions, something which seems in general to be doubtful as Holt was addressing the dominant intellectual currents of the time, though it may have been true regarding psychoanalysis where views in many cases

seem to be a matter of individual idiosyncrasy. Also of interest is whether it influenced Holt's life decisions, which seems probable. For example, Heft (2001) argues that it influenced, at least in part, his decision to leave Harvard in 1918.

Another story that should be told concerns the Wicht Club, largely composed of younger faculty at Harvard who met monthly beginning in 1902 to talk about their research. The meetings were very much social occasions and were quite irreverent. Members included Holt and Perry, the psychologist Robert M. Yerkes, the physiologist Walter B. Cannon, the neurologist Elmer Ernest Southard, the physicists George W. Pierce and Henry M. Morse, the chemist Gilbert N. Lewis, and E. V. Huntington from mathematics and Arthur O. Norton from education. There were many close friendships among members (Langfeld 1946; Hilgard 1965). Holt had members' publications bound; titled *Was Wichtiges*, volumes dated 1903 to 1911 can be found at the Harvard University Archives. Bruce Kuklick (1977) has noted the importance of male groupings to Holt, both the Wicht Club and The New Realists, something that has to be further developed. And Herbert Langfeld (1946) has argued that the intellectual influence of the Wicht Club on Holt was significant, again something that has to be further developed.

Holzkamp, Klaus

ERI PARK

Utrecht University, Middelburg, The Netherlands

Basic Biography

Klaus Holzkamp was an eminent German theoretical psychologist, born on November 30, 1927, in Berlin, where he also died on the November 1, 1995. He worked at the Freie University Berlin, where he developed in collaboration with students and colleagues the school of German Critical Psychology.

Major Contributions

Holzkamp strongly rejected the paradigmatic claim that research was supposed to be objective, neutral, and value free. Not only his idea of research but also his concept of the subject deviated from the traditional psychological approach. He opposed any objectivistic preconceived notion of humans according to which preexisting psychological functions only had to be discovered by the researcher. A concept which turns human subjects into objects, which could allegedly be understood once one had identified the forces which determine human. Instead, he stressed passionately that the so-called object of psychological research only becomes constituted through

the research process itself (1964, 1968). He was already an established professor of social psychology at the Psychological Institute at the Freie University Berlin, specialized in theoretical psychology and methodology, when he began to engage with the student movement.

And a crucial influence on German Critical Psychology can be traced back to the impact of the student movement during the 1960s. The majority of students were not only well organized but also very political. This was also due to the exceptional situation Berlin was in. The division of the city via the so-called Berlin wall was a constant reminder and a powerful symbol for the state the country was in. And it was in this political climate that first internal academic debates regarding issues such as freedom of speech and questions of democratic structures at the university came up. These political debates developed further and led to protests against the Vietnam War in 1966 and later culminated in a radical critique of the German society from a Marxist perspective.

From then on, Holzkamp's main ambition was to create concepts which would help to interrogate relations of social control and power in a society. He understood these forces to be fuelled also by ideas of the realm of social sciences and considered (mainstream) psychology to have taken on the role of collaborating with the ones in power and to help maintaining the status quo. Hence, the analysis of relations of power and control had practical implications in the sense that critical psychology would derive its power from its potential to contribute to change. And the idea of change was supposed to go beyond the academic realm. Ultimately, it was about change in the sociopolitical realm (1970).

Holzkamp positioned his critical psychological theoretization explicitly as a utopian tradition of psychology, with the goals of research and theories being explicitly linked to the aim to contribute to social and political change. He defined it as a Marxist research program working toward an egalitarian society without class difference. This utopia was based on three ideals: (a) every individual should be able to fulfill their needs, (b) every individual should be given the opportunity to develop their capabilities, and (c) the relational webs in which individuals interact should not be determined by market forces.

Driven by the wish to develop knowledge which would serve individuals' interests to improve their lives, he developed a psychology from the standpoint of the subject. And in his magnum opus, he came up with a radically new understanding of the subject. According to Holzkamp (1983) humans are neither determined by external forces in the world nor are they bare respondents of internal conflicts. But according to him, the subject holds agency or "action potency" (in German: Handlungsfähigkeit): the potential for action available to a subject according to their position in society. The subject as an agent can always choose from multiple options within their particular social context. Hence, choices to perform a particular kind of action are neither randomly done nor determined; but these choices always have to be understood as being a reasonable choice according to the subject's standpoint. This does not necessarily mean that the subjective reasons appear to be "reasonable" from an outsider's perspective nor that these reasons can be fully explained or understood by the subject themselves. But it is through action which is guided by these subjective reasons that an individual achieves autonomy. And it is this radical subject-oriented approach to look at the relation between humans and how they engage with the world, what makes Holzkamp's contribution so unique: to link his critique of academic considerations to a critique of society.

As Holzkamp was mainly concerned to engage in debates with students and colleagues in Germany only a fraction of his work is translated into English. A complete bibliography of Holzkamp's publications is given by Jaeger and Osterkamp (1987). Some original contributions by German Critical Psychologists, including some essays by Holzkamp, were published in English translation by Tolman and Maiers (1991). Teo (1998) and Papadopoulos (2009) give a chronological overview of Holzkamp's major publications and in April 2009, the journal *Theory and Psychology* dedicated a special edition to Klaus Holzkamp. Tolman (1994) was the first book-length introduction to German Critical Psychology available in English. The second one will be available soon. It is edited by two colleagues he was also personally close with: his widow and a former student of his (Osterkamp and Schraube 2012). One bibliography of up to 2,000 listings of German Critical Psychology, with several full texts (in English) available

for downloading, is available at <http://www.critical-psychology.de/publikationen.html>.

Hooker, Evelyn

AMY S. WALKER, JOHN D. HOGAN
St. John's University, Jamaica, NY, USA

Basic Biographical Information

Evelyn Hooker played a pivotal role in changing attitudes toward homosexuality primarily through a piece of research she conducted that became a classic in gender studies. Her research helped to change the view that homosexuality was – in and of itself – a form of mental illness.

Evelyn Gentry was born on September 2, 1907, on a farm in North Platte, Nebraska, the sixth of nine children. The family moved to Colorado when she was young and she was initially educated in a series of one-room school houses. Evelyn completed a bachelor's and master's degree in psychology at the University of Colorado at Boulder, and a doctorate at Johns Hopkins University (1932) in experimental psychology.

She taught briefly at the Maryland College for Women (1934–1936) when she was diagnosed with tuberculosis. During her long recuperation, her interests turned to clinical psychology and she was able to secure a fellowship to study at the Institute for Psychotherapy in Berlin for a year. When she returned to the United States, Evelyn accepted a teaching position at the University of California, Los Angeles (UCLA) where she remained for 30 years (Schneidman 1993).

Her interest in homosexuality began with a student, Sam From. Evelyn and Sam had become friendly and he was comfortable enough with her to reveal his sexual orientation. One day in 1945, Sam posed a challenge to her. He said that she must study gay men. From argued that homosexual men and lesbians were no more disturbed than the rest of the population. The problem, he argued, was that the homosexual men and lesbians usually seen by mental health professionals were a highly selective sample that often included people who were in hospitals or prisons, as well as individuals who sought professional help (Kimmel and Garnets 2000).

Evelyn made some preliminary efforts to begin a study but, in 1947, she divorced and her plans to conduct research were put on hold. She married again, in 1951, to Edward Hooker, a distinguished professor of English. The marriage lasted for 7 years until his sudden death. She never remarried, but during this period a study had begun to form in Evelyn's mind.

Major Accomplishments/ Contributions

Hooker's idea for the study had an elegant simplicity. She planned to compare a sample of "normal" homosexual men to a sample of "normal" heterosexual men on several psychological instruments. She did not argue that homosexual men were totally healthy, but rather that they were no more pathological than heterosexual men.

In 1953, she applied for a grant from the National Institute of Mental Health (NIMH). She not only

received the grant, it was renewed until 1961, at which point she was given a Research Career Award (Hooker 1993). She chose three "projective" tests to use in her research, that is, instruments designed to elicit projected feelings and thoughts from ambiguous stimuli. None of the instruments could be considered an "objective" measure of personality and this would later become one of the criticisms of Hooker's research.

Eventually, Hooker gathered a sample of 30 heterosexual men and 30 homosexual men who had been matched on such variables as IQ, age, and educational level. After the instruments were scored by experts, she pruned the data of obvious references to sexuality. Then she gave the material to three judges for their assessment. She asked two questions of the judges: (1) In each pair, which member is the better adjusted? (2) In each pair, which member is homosexual? Their answers were even more dramatic than she had hoped. The judges could not tell the difference between the two groups!

Hooker presented her findings at a meeting of the American Psychological Association in 1955 and she later published her results as an article in the *Journal of Projective Techniques* (Hooker 1957). One of the people who became convinced of the importance of her work was Judd Marmor, a psychiatrist, who would later become president of the American Psychiatric Association. Marmor argued successfully for a reclassification of homosexuality in the Diagnostic and Statistical Manual of Mental Disorders (DSM), published by the American Psychiatric Association. Before 1973, homosexuality was listed as a mental illness; after 1973, it was not.

Hooker retired from UCLA in 1970 but continued her private clinical practice. In 1989, she received a letter from a bank in Lincoln, Nebraska. One of the subjects in her original study, Wayne Placek, had established a trust fund to support research to increase the understanding of gay men and lesbians. Placek had designated Hooker to select the committee to decide how the funds should be distributed. When the fund was finalized 3 years later, it was valued at approximately a half million dollars. Today that fund is under the control and guidance of the American Psychological Foundation, and it dispenses annual grants for research related to gay and lesbian issues (Hooker 1993; Kimmel and Garnets 2000).

Hooker received many awards in her later life, including the APA Award for Distinguished Contributions

to Psychology in the Public Interest. A documentary movie was made of her life – Changing Our Minds: The Story of Dr. Evelyn Hooker (1992). The University of Chicago established an Evelyn Hooker Center for the Mental Health of Gays and Lesbians. She died on November 18, 1996, in Los Angeles at the age of 89. Most important for her, she lived to see her research help to remove the stigma associated with homosexual behavior, and have a positive impact on the individual lives of many gay men and lesbians.

Hopkins, Charles Owen

VALERIE J. GAWRON

The MITRE Corporation, McLean, VA, USA

Basic Biographical Information

Dr. Hopkins was born in Paducah, Kentucky, on November 14, 1925. He served as an Army infantryman during World War II and earned two purple hearts fighting in the Battle of the Bulge (December 16, 1944–January 25, 1945). After the war, he received a B.A. in psychology from the University of Kentucky and a Ph.D. in experimental psychology from the University of Illinois in 1952. After graduation, he accepted a position as an assistant professor at Tulane University. Three years later he joined Hughes Aircraft Company. In 1964, he moved to the McDonnell Douglas Aircraft Company in Saint Louis, Missouri where he founded its human factors department. Dr. Hopkins returned to the University of Illinois in 1970 as a professor of psychology as well as aeronautical and

astronautical engineering and a professor at the Institute of Aviation, the latter from 1971 through 1977. In addition, he headed the Aviation Research Laboratory from 1973 to 1977. In 1993, Dr. Hopkins retired and was given the title of professor emeritus of psychology. Dr. Hopkins died on December 15, 2005, in his home in Monticello, Illinois. He was 80 years old.

Major Accomplishments/Contributions

While at Hughes Aircraft Company, Dr. Hopkins was part of a multidisciplinary team, conducting research in cockpit displays for aircraft. The research resulted in recommendations for control-display direction-of-motion, vertical flight path prediction algorithms, weather display design, and pilot decision-making modeling. The team also conducted the human factors engineering for the controls and displays in the Mercury and Apollo spacecraft. While at the University of Illinois, Dr. Hopkins helped define personnel psychology as well as aviation psychology. Dr. Hopkins was part of a team of human factors experts under contract to the Nuclear Regulatory Commission tasked to recommend changes to the Three Mile Island Nuclear Power Plant in response to the partial core meltdown in March 1979.

In addition to his research and design work, Dr. Hopkins was a charter member of the Human Factors and Ergonomics Society (HFES). He coauthored the HFES (at the time the Human Factors Society) constitution and bylaws, was secretary/treasurer and Finance and Budget Committee Chair during 1970–1971, Sustaining Memberships Committee Chair during 1972–1973, President during 1973–1974, Nominations and Elections Committee Chair during 1974–1975, Fellows Selection Committee member during 1978–1979, and editor of Human Factors Journal during 1983–1988.

Hull, Clark L.

JOHN A. MILLS

University of Saskatchewan, Hornby Island,
BC, Canada

Basic Biographical Information

Clark L. Hull (24 May 1884 to 10 May 1952), son of Leander G. Hull and Florence L. Trask, was born near Akron, New York. The family moved to a farm in Michigan in 1887. Despite having to help on the farm, Hull qualified as a teacher. He worked briefly as an engineer (qualifying from Alma College) before contracting poliomyelitis, which left him permanently impaired. In 1911, he married Berth Iuzzi and graduated with an A.B. in teaching from the University of Michigan in 1913. He taught normal school in Kentucky before becoming Joseph Jastrow's teaching assistant at the University of Wisconsin, thereafter gaining his M.A. in 1915 and his Ph.D. in 1918, becoming a Professor of Psychology at Wisconsin in 1925.

Major Accomplishments/ Contributions

Hull had performed his doctoral work on concept formation, publishing his thesis as *Quantitative Aspects of the Evolution of Concepts: An Experimental Study* (1920). He then turned his attention to psychometrics (publishing his work as *Aptitude Testing* in 1925) and to hypnosis, resulting in *Hypnosis and Suggestibility: An Experimental Approach* in 1933. However, during the 1920s Hull began to think seriously about behaviorism. He found John B. Watson's version of the doctrine unconvincing and, largely as a result of a year spent

co-teaching with Kurt Koffka at Wisconsin, was equally unconvinced by the Gestalt alternative. However, reading G. V. Anrep's translation of Ivan P. Pavlov's *Conditioned Reflexes* in 1927 inspired him to create an all-embracing behaviorist theory.

He moved, as a Research Psychologist in applied psychology, to Yale's Institute of Psychology in 1929, thereafter becoming a member of its Institute of Human Relations, a highly interdisciplinary group. There Hull was introduced to anthropology, and, above all to psychoanalysis. Despite his formal commitment to applied research he succeeded in creating a cadre of experimental psychologists who carried out a series of studies designed to test Hull's growing list of behavioral postulates. Although he was not one of Hull's doctoral students, Kenneth W. Spence became the dominant member of that group. In 1935, Spence moved to Iowa and started his own graduate program that was, in effect, an extension of Hull's work. Via the very detailed Hull-Spence correspondence and Hull's voluminous entries in his diaries (the *Idea Books*) and *Research Memoranda*, we can trace the development of his theory, which culminated in the publication of *Principles of Behavior* (Hull 1943).

Hull did not just reduce all mental life (even the complex and abstract) to behavior but construed it as a mechanism driven by chains of positive and negative reinforcements (Mills 1998; Smith 1986). He presented his theory as a set of linked postulates expressed in a purpose-made mathematical language (his version of Newtonianism). That mathematical rigor was his version of operationism. His diaries tell us, however, that his theory's main function was to act as propaganda to counter the allures of Gestalt theory and psychoanalysis. Despite its intractability, Hull's theory gained wide support but his reputation did not extend beyond his death.

Human Factors Psychology

RONALD G. SHAPIRO

Independent Consultant, Providence, RI, USA

Human factors psychologists design and test products such as computer systems, medical devices, automobiles, airplanes, cell phones, and even room arrangements such as positioning of light switches so that they can be used safely, efficiently, and in an enjoyable way. In 2000 the International Ergonomics Association composed the following formal definition of the field:

- ▶ Ergonomics (or human factors) is the scientific discipline concerned with the understanding of interactions among humans and other elements of a system, and the profession that applies theory, principles, data, and methods to design in order to optimize human well-being and overall system performance.

Through the years other terms such as applied experimental psychology, engineering psychology, ergonomics, human systems engineering, human systems integration, usability, and user experience have been used to describe closely related if not identical fields as discussed below.

Helping Many People, but Anonymously

The popular notion of a psychologist is someone who helps people. Students often enter the field of psychology because they want to help people. The field of human factors provides an incredible opportunity to do this. Some human factors practitioners save thousands if not millions of lives by performing the highest quality design work. Human factors is in many ways similar to developing a vaccine for preventative medicine or a preventative mental health program. Clearly, the number of people serviced by developing a vaccine or a great human factors design is far greater than the average clinician can serve once a problem is identified. Unlike the “helping professions” physicians or psychologists who can frequently identify the patients they have helped to overcome a problem, the human factors professional and the individual developing the vaccine may not know whose lives they may have saved.

They may have saved their own life. They may have saved yours. The vaccines prevent disease from happening. Human factors professionals prevent accidents from happening. An airplane crash might be prevented or a nuclear power plant explosion might be prevented through good human factors design. When mechanical and other system failures do occur, excellent human factors work performed during the design of a product or system makes it very easy to identify, diagnose, and fix the failure before the problem escalates into being catastrophic.

While human factors is unmistakably a part of psychology, there is one critical difference between this discipline and the better known “helping professions” of applied psychology such as clinical psychology and counseling psychology. This was recognized as early as in 1947 by Paul M. Fitts when he stated: “In most fields of applied psychology, and clinical psychology in particular, the interest is in changing the individual or in placing the individual in an environment or in a work situation where he can adapt successfully. Engineering psychology is concerned with adapting one important aspect of the environment, the machines of a technological society, to man’s own requirements” (Pew 1994). Thus, there is a different working model in the “helping professions” vs. “human factors.” In the “helping professions” there is an underlying assumption that society, the environment, and the community are “normal” and the patient needs in some way to change behavior or to further their understanding of themselves and the environment. In engineering psychology quite the opposite is true. Indeed, the human factors practitioner strives to change products, systems, and processes to better suit the human operator or user. If there is an individual who needs to change, for the most part, the human factors practitioner would argue that it is the system designer or engineer who needs to change, not the operator or end user. Just On occasion the human factors practitioner will successfully change human behavior in operators or end users through selection and/or training to bring people in line with the technology (Durso et al. 2010a). Selection is by definition limiting in who can use the system. Training is often less successful than designing for the human operator. Sometimes training will not work effectively causing accidents and inefficiencies.

Oftentimes, one of the most challenging parts of the human factors practitioner's job is to overcome the desire of their clients and colleagues to try to change the person.

Good Human Factors Design

Let us look at some every day examples in which good human factors work may save lives or prevent serious injury.

- A warning signal in a nuclear reactor signifies that the cooling system is not working properly. The operator takes the appropriate corrective action. None of the people in the nearby community realize that the effective human-machine interface may have helped to save their lives.
- An airplane (perhaps the one you were riding on yesterday) lands safely in spite of bad weather. The pilot follows the flight path through instrumentation and makes no errors.
- A pharmacist properly dispenses the correct, properly labeled prescription for you.
- A professional's work involves interacting with the same tool (e.g., a computer) all day long, but the professional's workstation is properly set up so they do not develop repetitive strain injury.
- A smoke-filled building needed to be evacuated quickly using the stairwells. Everyone ended up exiting the building without getting lost.
- A computer operator receives a message about a pending computer system failure. The operator ensures that the failure is corrected. The end user, a physician looking up critical information for a pending surgery on the computer, does not even know that the problem occurred and was fixed.

Following examples are some of the ways in which good human factors work may have made life easier.

- A guest just arrived in a dark hotel room, and was able to find the light switch immediately.
- A consumer took a new electronic device out of the box, plugged it in and was able to start using it immediately.
- Potential customers visited a Web site that they had never been to before and found what they were looking for in seconds.

Poor Human Factors Design

After having positive experiences such as those described above, good human interface design may seem to be "obvious." On the other hand, people have died because of errors which could have been prevented through better design of systems for people to use. Other people have worked inefficiently, decided that they could not do a task, developed a dislike for certain tasks, and returned consumer products to the store because of poor human-system design. Reviewing a few of these examples will illustrate that proper human-system interface is far from obvious much of the time.

- A motorist who is driving an unfamiliar car (perhaps a new one, a friend's car or a rental car) enters a dark tunnel. The motorist attempts to turn on the lights and instead washes the window. Thus, in addition to not seeing well in the dark, the motorist has a stream of water approaching their window. Obviously, a serious accident could result due to obscured vision in a dark tunnel.
- A motorist is attempting to drive a hybrid car for the first time. The rental agent handed them the "keys" along with an instruction card. The motorist got to the car and tried to figure out where to put the key. No luck. So, they read the instructions. The instructions say to insert the key into the key slot. The motorist cannot find the key slot. Upon returning to the rental counter the consumer is told that the car design was improved for the new model that year. The consumer merely needed to put the keys on the center console and push the start button. There is no slot.
- A tired hotel guest is sleeping in their hotel room. It is 3:00 AM and the alarm clock goes off. A previous guest set it for 3:00 AM. The clock was not designed to reset when the guest checked out. The hotel staff was not trained or forgot to reset the clock. The unsuspecting new guest did not expect the clock would be left turned on.
- A male patient receives a prescription medication (tablets) in a pharmacy bottle. There are four yellow warnings pasted on the bottle.
 - An unreadable message followed by READ LABELS. IF A WARNING SEEN, CALL DR.
 - TAKE OR USE THIS EXACTLY AS DIRECTED. DO NOT SKIP DOSES OR DISCONTINUE.

- MAY IMPAIR ABILITY TO USE MACHINERY. USE CARE UNTIL FAMILIAR WITH EFFECTS.
- And, finally, pasted partially obscuring the other labels BECOME PREGNANT.
- Just to summarize, typed in all capital letters (implying urgency) the patient was told to become pregnant!!! The patient was also been warned to do exactly what they were told. They have further been warned that their abilities may be impaired. The patient thus concludes that they are supposed to become pregnant immediately and then call the physician after their pregnancy becomes obvious. Had the prescription been for a female teenager is there at least a minimal chance that they might have taken the instruction seriously (or at least used it as an excuse for executing certain behaviors)!!!
- Exploring the label a bit further there were at least five design or system failures:
 - The labels were in all capital letters.
 - The computer system generated a label for an adult male dealing with pregnancy.
 - The label paper was not fed into the printer properly cutting off what may have been text saying something like “Notify physician if you” prior to the words “become pregnant.”
 - The individual filling the prescription (a pharmacy technician, possibly) most likely did not read the labels (possibly due to more prescriptions coming through the system than they could properly handle).
 - The pharmacist doing the verification most likely did not read the labels either (also possibly due to more prescriptions coming through the system than they could properly handle).

- A patient received two prescriptions. Unfortunately the labels and instructions were reversed.

For numerous additional examples illustrating human–system interface failure please refer to:

- Web site <http://www.baddesigns.com> by Michael J. Darnell which provides over a hundred simple examples of bad designs such as windshield wipers, coffee machines, doors, and staplers and explanations of how they could have been designed better.

- The book *The Psychology of Everyday Things* (Norman 1988b) also known as *The Design of Everyday Things* (Norman 1988a).
- Books by Steve Casey such as *Set Phasers on Stun* (Casey 1993) and *The Atomic Chef* (Casey 2006). Each of Steve’s books illustrates numerous serious design flaws. In the *Set Phasers on Stun* (the first case in the *Set Phasers on Stun* book) case, Steve explains, for example, how a patient was given a massive radiation overdose.

Comparing Good and Bad Human Factors Design

Following this review of numerous descriptions of potentially successful and unsuccessful human–system interaction, here is the review of some of the factors which differentiate well-designed systems which result in tasks being completed safely, efficiently, and enjoyably vs. poorly designed systems which result in errors and inefficiencies.

- Well-designed systems are easy to use without instruction. Poorly designed systems rely on the end user of a product to read the directions, interpret them as the writers intended, and follow them.
- Warnings in well-designed systems point the user to the source of a problem. In poorly designed systems warning lights are ambiguous or possibly even placed in an inappropriate location.
- Well-designed systems do not rely on a single display for more than one purpose. Poorly designed systems use modal displays, that is, the same display is used for multiple purposes.
- Well-designed systems have few, if any, well-placed warning labels. Poorly designed systems have many warning labels, some of which are of no real value, arbitrarily placed on a product.
- In well-designed systems, controls are easily differentiated and clearly labeled. In poorly designed systems labels are ambiguous.
- In well-designed systems, products and systems which are to be used by the same people or in the same environment are compatible. In poorly designed systems products which are to be used together have incompatible interfaces.
- In well-designed systems, the user has an optimal workload. Not too little (which may lead to, for

example, sleepiness) and not too much (which may lead to missing critical information). In poorly designed systems the user is encouraged or permitted to do too many tasks at the same time or allowed to become bored.

Relying on the End User of a Product to Read the Directions, Interpret Them as the Writers Intended, and Follow Them

The first concern is that users may not even read product instructions. Be honest. Do you read all of the assembly instructions before attempting to do a do-it-yourself project at home or at work? Do you read all of the instructions before using a new software product?

Second, the instructions may never have been tested for readability by the intended audience (or for accuracy in some cases). Possibly the product has been updated, but updating part (or all) of the instructions was overlooked.

Third, the instructions may be interpreted differently by the person receiving them than by the person delivering them. To take a very simple example, in my *Games to Explain Human Factors: Come, Participate, Learn and Have Fun!!!* Program (Shapiro 2008) I have a simple activity in which I ask a potential participant wearing a school ring, an engagement and/or wedding ring to participate. After blindfolding them I place some lotion on the hand without a ring and ask “*What is on your hand?*” They normally correctly respond by saying “*Lotion,*” “*Something wet,*” or a similar answer. I then touch the hand with a ring on it and ask the same question. The typical responses are “*Nothing,*” “*Lotion,*” “*Skin,*” “*I don’t smell or feel anything,*” or “*You didn’t put anything on my hand.*” No one has ever answered the question correctly by saying “*My ring*” on the first try. Very few answer correctly on the second try, and some require lots of hints to answer correctly. Clearly, the participants are applying their own interpretation to my question.

Placement of a Warning Light in an Inappropriate Location

One of the primary purposes of a military reconnaissance mission is to photograph or videotape a specific area from an aircraft for later examination. Obviously, in

videotaping to have a successful mission one needs to record the scene. When video recording was done on tape a few years ago it was necessary to change the tape periodically. Pilots sometimes forgot to do this, so that part of the mission was not recorded, limiting the usefulness of the mission. According to the keynote speaker at a recent HFES meeting without instruction to the pilots a big red flashing light was placed on the pilots console right next to the hydraulic indicator to remind pilots that the tape had run out. On one of the first missions flown after the light was installed, a video recorder ran out of tape. The red light began to flash. The pilot saw the red light next to the hydraulic indicators flashing, so he proceeded to bail out of the plane.

Use of Modal Displays

A modal display involves using the same display for multiple purposes. The display content and/or response buttons change by simply pressing a button. One example of this is an IV Pump made for hospitals in which one can shift from pediatric to adult dosing and displays. Unfortunately, the only discrimination factor is the presence of a small baby illustration in pediatric mode. This has led to giving babies adult dosages of medications. The simple fix to this is never use modal displays. Of course, this may make some equipment more expensive, but it will save lives.

Overuse of Warning Labels

Please see my example on pharmacy labels above.

Nonintuitive Labeling of a Product Interface

Microsoft placed a number of “File” commands under a symbol in the upper-left corner of the display rather than under the word FILE in Powerpoint 2007. I must have spent an hour trying to figure out how to save a file the first time I used it. I assume others may have had difficulty with this also, as the word FILE has returned to the 2010 interface.

Products Which Are to Be Used Together Have Incompatible Interfaces

The telephone and the calculator both evolved almost independently. The calculator, of course, is a successor product to the old adding machine. Adding machines

were big, bulky, heavy, and expensive. Gradually, they evolved into today's calculator which is small, light, and very inexpensive. Throughout the evolution the keyboard did not change though. Almost independently, the telephone company migrated from a rotary dial to buttons for their primary interface. The telephone company prepared the best possible layout of the keys for telephone use. Presumably, they were not concerned about being compatible with the adding machine which few people owned. Now, however, both are used at the same time by the same people. Indeed, some devices are integrated telephones with calculator chips. User errors may result because of the incompatibility of the two devices. Similarly, software products or equipment made by competing manufacturers may not have compatible interfaces. These incompatibilities may lead to errors. In hospitals equipment by different manufacturers may have different noncompatible interfaces.

End User of a Product or System Tries to Do Too Many Tasks at the Same Time

A driver engages in an intense conversation on a cell phone while driving (it does not matter if the phone is hand held or not); attention may shift from the primary task of driving to the conversation. As a result the driver may not notice that they are getting too close to the car in front of them or that a child or animal has run into the road. A serious accident may result. Similar consequences may result from eating or drinking while driving, texting, becoming distracted by the DVD or radio. Alternatively, an operator is asked to watch a screen for events which occur very rarely. The operator falls asleep.

Why Are So Many Errors Permitted?

The first reason for permitting errors to escape in designing systems is relatively simple – it is the name assigned to the errors: “User error.” The name implies that the error is made by the user, not the designers. If this “user error” is really due to the “users” then how could the designers possibly prevent it? Indeed, several years ago I asked my introductory psychology classes at a community college to define user error. They stated a number of reasons. The most common was the overuse of alcohol or drugs. While it is possible that if one overused substances errors would occur, the

nomenclature used may be confusing as a large number of user errors are actually due to flaws in the design of the product or system.

John Gosbee, M.D., a respected practitioner in the area of Medical Error, has pointed out that several years ago the main objective in the medical establishment was to place blame on some practitioner whenever a “user error” occurred. More recently the blame mentality has shifted to a “sympathy” mentality. In order to really fix the problems there needs to be a paradigm shift to “It wasn't your fault, there is a systems problem. Let us fix it before someone else gets hurt.”

There is also the misperception that it is expensive to design optimize systems for use by people. Indeed, there may be minimal upfront costs to do this. However, there are also great savings in service costs, injury, etc. which do offset the minimal investment in better design. Hal Hendrick (1996) in his Human Factors and Ergonomics Society (HFES) Presidential Address “Good Ergonomics is Good Economics” provided numerous examples of investing in human factors being the wise economic decision.

An Interesting Exercise

What does the color red mean? Sometimes it means stop routinely, as in a red STOP sign or traffic signal on the road. Sometimes the use of the color red means emergency. For example, the user driving by the road is supposed to pull over and STOP so that the red fire truck with red flashing lights can pass them. In a burning building the fire alarm handle is painted red. The user in the burning building is supposed to push or pull the alarm handle to START the alarm. The elevator emergency STOP switch is also painted red. Please write a simple set of instructions explaining how to use the color RED. (Remember as you write the instructions that you do not want to be caught between floors on an elevator in a burning building).

Now, assume that you are designing a control system, what color should you make the emergency off switch? What color should you make the switch to turn on the fire alarm? What about the color of the switch to turn on the emergency generator? What about the switch to turn off the emergency generator if it catches on fire?

To make the issues a bit more complex, remember that red-green color deficiencies occur in a substantial number of people.

In reality, usability testing with real users in a real environment would be highly recommended in this case.

What Do Human Factors Practitioners Do?

In an ideal environment human factors practitioners would learn about the objective of a new product or system. They would also learn about:

- The environment in which the product will be used
- The customer set who will use the product
- The existing methods of accomplishing the tasks (if any)

The practitioner would then find appropriate psychological studies, findings, and theory as well as product standards and guidelines to help design the new product or system. They would commission studies to fill in the gaps in our knowledge. The findings from such studies would be used along with input from the engineering team and the potential users of the system to prepare a series of prototypes illustrating the potential system. The prototype would be tested in a laboratory asking potential users to execute realistic test scenarios. Later, the prototype would be tested in a realistic environment. Problems would be found and fixed. The testing would be repeated. Once our testing cycle was complete, design and development of product internals would commence. Products would then be tested as they were developed.

Unfortunately, this ideal scenario frequently does not apply because of the need to bring products to market rapidly. Thus, there are compromises made such as using the best possible judgment in lieu of scientific studies. In worst case scenarios the human factors studies do not even begin until the product is completed and human factors input is often relegated to the documentation (which may not be read), warning labels (which may be ignored), and product design changes (which are expensive).

Human factors professionals use a wide variety of techniques for accomplishing their work. Durso et al. (2010b) provide examples of use of seven methodologies in their article on human factors research. They summarize usage of:

- Knowledge mining by interviewing experts to improve detection of land mines
- Naturalistic observation to improve cockpit communications (facilitating copilots by providing

input to important decisions, even if it is inconsistent with the pilot's thinking) and safety

- Designing an automation aid to support anesthesiologists to reduce the chances of error
- Painting lines on a roadway to make it appear that cars were accelerating so that the drivers would slow down
- Surveying elderly passengers to make busses safer for them
- Observing potential contestants playing video games to adjust the level of difficulty of the games
- Studying the anthropometry (physical characteristics) of workers to design better fitting protective wear

Exciting New Developments in Human Factors

Paul Green (Walls et al. 2004) at the University of Michigan Transportation Institute (and a past president of the Human Factors and Ergonomics Society (HFES)) has served as a member of a design team developing devices to facilitate parallel parking, and reduce "bumper touching" in parking a car.

Rani Lueder and Valerie J. Berg Rice (2008) recently facilitated the expansion of the human factors/ergonomics professions to making a safer, healthier, and more enjoyable life for children from toddlers to teenagers in their new book *Ergonomics for Children: Designing Products and Places for Toddlers to Teens*. Chapters in their book focus on, for example:

- How to design toys, environments, bookbags, preschool, daycare, stairways, neighborhoods, playgrounds, museums, furniture, computer interfaces, cities, etc. for children in various cultures
- How to set up a visual environment (e.g., lighting, computer monitor) for children
- Classroom acoustics and preventing hearing loss
- Considering children's growth in product design
- Appropriate physical education programs for children
- Preventing children's cocking and other injuries
- Developing assistive technologies
- Hazard Control
- Vehicle safety
- Farm safety

What Organizations Are Available for HF Professionals?

While there are many organizations globally, here is a sample:

- American Psychological Association Division (21) of Applied Experimental and Engineering Psychology. Integrates the practical and theoretical psychological bases of the field.
- Board of Certification in Professional Ergonomics. Certifying practitioners through credentials and examination. Developed a model of what the human factors practitioner is.
- Human Factors and Ergonomics Society. The largest society representing the field of human factors and ergonomics. Headquartered in the USA. Publishes *Human Factors* journal and *Ergonomics in Design* magazine as well as an annual meeting proceedings and a monthly Bulletin.
- International Ergonomics Association. The organization which various human factors professional organizations belong to.

What Are the Specialties in Human Factors/Ergonomics?

A complete listing of all of the technical groups (which represent major areas of specialization in the human factors field) may be found on the HFES Web site (<http://www.hfes.org/web/TechnicalGroups/descriptions.html>). The groups include:

- Aerospace
- Aging
- Augmented cognition
- Cognitive engineering and decision making
- Communications
- Computer systems
- Education
- Environmental design
- Forensics
- Healthcare
- Human performance
- Individual differences
- Industrial ergonomics
- Internet
- Macroergonomics
- Perception and performance
- Product design

- Safety
- Surface transportation
- Systems development
- Test and evaluation
- Training
- Virtual environments

How Can One Become a Human Factors Professional?

Since human factors is, by nature, interdisciplinary there are a variety of scenarios which a student might follow to become a human factors practitioner. In one scenario, a student might complete a course in high school psychology. In college the student might major in psychology studying as much as possible about human physiology (return to existing text at this point) cognition, sensation, perception, learning, and memory. The student might also do some basic research as an undergraduate student and possibly an industrial internship in a human factors lab. There are graduate programs that one can attend for masters and/or Ph.D. degrees: http://www.hfes.org/web/Students/grad_programs.html. Howell et al. (1987) specified an outline for an effective academic program in the *American Psychologist* in 1987 which is relevant today. The Human Factors and Ergonomics Society also provides accreditation for academic programs.

Alternatively, one may pursue a career in human factors/ergonomics through an engineering, medical, or other technical career path.

Major Milestones in the History of the Field

Hank Taylor's (1994) *Division 21 Members Who Made Distinguished Contributions to Engineering Psychology* provides insight into the origins of the field of human factors. While one could go back to the invention of the wheel and demonstrate that the wheel improved safety and efficiency Taylor's publication traces the field back to World War I and the use of psychologists in selection of military recruits for various positions.

I would attribute the first major success in identifying system flaws which needed to be fixed to Fitts and Jones (1947) who studied 460 pilot errors and found that they were really due to problems with the human interface in the aircraft rather than to pilot behavior.

Human factors research and development in the military continued to grow and prosper. Subsequently, the human factors research expanded to other branches of government including space exploration, transportation, and labor. Even today, military and government research is a primary focal point for human factors practitioners.

As computer systems began to develop and thrive, human factors found a home in the computer industry, initially with developing individual products, and eventually expanding to produce guidelines and standards for human–system integration. The first of these guidelines may be attributed to Steve Engel and Dick Granda (1975). Classic textbooks in the field have been developed by Ernest J. McCormick in 1957 and later revised by Mark S. Sanders along with Dr. McCormick (Sanders and McCormick 1987) and well as by Chris Wickens (1984).

More recently human factors has become more established in consumer goods, the medical profession, and is also emerging in design and development of products and systems for children. In January 2010 the entire issue of the *Ergonomics in Design* magazine was dedicated to human factors in medicine.

There has been increased interest in interpreting human factors for the general public in the past quarter century. One major milestone in this effort was Don Norman's (1988b) publication of *The Psychology of Everyday Things*. The Human Factors and Ergonomics Society launched National Ergonomics Month (NEM) in 2003, and the Usability Professionals Association launched World Usability Day in 2005. The program *Games to Explain Human Factors: Come, Participate, Learn & Have Fun!!!* which is targeted to explaining the profession to students from middle school to graduate school and to professionals as well was published for limited distribution to educators and human factors professionals by HFES for National Ergonomics Month 2008. A timeline of interesting events in the history of human factors is presented in Table 1.

Clarification of Our Name

The terms human factors and ergonomics were used interchangeably in the definition at the beginning of this article. Throughout the article the term human factors has been used wherever practical, but other

Human Factors Psychology. Table 1 Background of modern human factors psychology

The primary sources for much of the following information are the 2009–2010 Directory and Yearbook of the Human Factors and Ergonomics Society and the Web site for APA Division 21.
1898 – Frederick W. Taylor in a study for Bethlehem Steel showed that the optimum weight for shoveling productivity is 21.5 lb (Schultz and Schultz 1994)
1911 – Frank Gilbreth published <i>Motion Study</i> book. In his earliest work Gilbreth showed that by eliminating unnecessary motion a worker can triple the number of bricks he could lay in an hour from 120 to 350 (Schultz and Schultz 1994)
1945 – Engineering Psychology Branch of the Army Air Force Aeromedical Laboratory established
1956 – Human Engineering Society voted into existence on October 25. This society seems to have evolved into becoming the Human Factors Society of America
1957 – Human Factors Society of America voted into existence on September 25. First Annual Meeting of Human Factors Society in Tulsa, Oklahoma. Paul M. Fitts becomes first president of American Psychological Association Division 21: The Society of Engineering Psychologists. Ernest J. McCormick publishes classic textbook <i>Human Engineering</i>
1958 – Human Factors Society of America renamed Human Factors Society, Inc. Flagship journal <i>Human Factors</i> first published
1959 – HFS Bulletin first published. International Ergonomics Association founded (April 6)
1964 – HFS permanent headquarters established in Santa Monica, CA, where HFES is headquartered today. First International Ergonomics Association Council meeting Dortmund, Germany
1975 – Guidelines for Man/Display Interfaces. Published as IBM Technical Report by Engel and Granda
1981 – APA Division 21 renamed The Society of Engineering and Applied Psychologists
1984 – I/O (& Human Factors) psychologist Lillian Gilbreth is first psychologist be honored on US Postage Stamp
1990 – Board of Certification in Professional Ergonomics (BCPE) incorporated (July)
1992 – Human Factors Society renamed Human Factors and Ergonomics Society
1993 – Ergonomics in Design applications-oriented magazine first published

Human Factors Psychology. Table 1 (continued)

1996 – APA Division 21 renamed Division of Applied Experimental and Engineering Psychology
2002 – National Ergonomics Month established by vote of HFES Executive Council
2003 – First National Ergonomics Month (October)
2008 – Games To Explain Human Factors: Come, Participate, Learn & Have Fun!!! outreach presentation published in HFES conference proceedings
2010 – Retired US Airways pilot Chesley B. “Sully” Sullenberger III, who landed Flight 1549 on the Hudson River on January 15, 2009, presents keynote address at HFES 54th Annual Meeting. HFES membership approximately 4,500. Captain Sullenberger is awarded the HFES Oliver Keith Hansen Outreach Award

terms such as engineering psychology and ergonomics have been introduced as well. Indeed, there are several different terms used to describe the human factors discipline. In addition to the terms “human factors” and ergonomics, “engineering psychology” is frequently used.

Some professionals in the field would use the various labels to refer to differences in approach and practice. In a 1987 article Howell et al. (1987) stated that engineering psychology might be viewed as emphasizing the content of psychology but that there is continuing debate about whether that distinction was meaningful. In 2010, Durso, DeLucia, and Jones wrote two articles for Corsini’s 2010 *Encyclopedia of Psychology*, one entitled *Engineering Psychology* (Durso et al. 2010a) and the second entitled *Human Factors Research* (Durso et al. 2010b) suggesting that there may be a meaningful difference.

Both Durso, DeLucia, and Jones articles do an excellent job of introducing the field and include good examples. They also describe what some professionals would identify as differences between engineering psychology and human factors research in their article. While some people would argue there is no difference between engineering psychology and human factors research even those who believe that there is a real difference in the terminology would agree that individuals may practice in multiple fields. For example, Frank Durso is a past president of the American Psychological Association Division

21 (Applied Experimental and Engineering Psychology) and is on the Executive Council of the Human Factors and Ergonomics Society (HFES). Pat DeLucia is the President of APA Division 21 and heads the accreditation committee for HFES. Numerous individuals throughout the history of the profession have served as leaders of both organizations.

In addition to potential conceptual differences between human factors and engineering psychology, there may also be geographic differences in names. The term Ergonomics has been used to refer to the entire discipline in Europe, whereas the term human factors has historically been used more frequently in the USA.

Recently, the Board of Certification in Professional Ergonomics (BCPE), one of the premiere groups for certifying human factors professionals, has added the designation “certified user experience professional” to their certifications along with “certified human factors professional (CHFP)” and “certified professional ergonomist (CPE).” The requirements and examination are identical for the various certification titles and once certified professionals are permitted to change certifications upon request (and payment of a nominal fee) suggesting that there may not be any meaningful difference. To add some complexity to the issue, various academics and employers seeking to hire professionals in the field have used other designations such as Applied Experimental Psychology and Cognitive Engineering as well. The controversy continues!!!

Acknowledgments

I would like to express my appreciation to Deborah Boehm-Davis, Haydee Cuevas, Pat DeLucia, Valerie Gawron, Krystyna Gielo-Perczak, and Paul Green for suggesting content for this article. I would also like to thank Pat DeLucia and Harold Takooshian for a helpful review of an earlier draft.

Humphrey, George

DAVID J. MURRAY

Queen's University, Kingston, ON, Canada

Basic Biographical Information

George Humphrey, who was born on July 17, 1889, in Boughton, Kent (roughly 50 miles East of London, England) played a pivotal role in the formation of academic psychology in Canada, made important contributions to learning theory and to the history of cognitive psychology, and, in 1949, essentially founded the Institute of Experimental Psychology at the University of Oxford.

After having been schooled locally in Faversham, Humphrey completed the requirements for an M.A. degree in Classics at All Saints College at Oxford. Funded by scholarships, he traveled to the University of Leipzig and to Harvard University for brief visits before taking up a tutoring position in Latin and Greek at Borough Road College in Isleworth, West London, in 1915. In 1916 he was appointed Professor of Classics at St. Francis Xavier University in Antigonish, Nova Scotia, Canada. In 1916, he married Muriel Miller, and they had one daughter.

From 1918 to 1920, Humphrey worked for a Ph.D. degree in Psychology at Harvard, following which he served as Assistant Professor of Psychology at Wesleyan University, Middletown, Connecticut. Here he was a colleague of Raymond Dodge (1871–1942), an authority on eye movements and their measurement. Humphrey then returned to Canada in 1924, having been offered the Charlton Professorship of Philosophy at Queen's University at Kingston, Ontario. Queen's had been founded in 1841, only 3 years after the first chartering of a University in Canada, namely,

Dalhousie University in Halifax, Nova Scotia. Humphrey was expressly charged by the Dean of Arts at Queen's to build up the psychological side of the Department of Philosophy.

In a small basement room in the Department of Biology, Humphrey began his classic experimentation on habituation in freshwater snails (Humphrey 1930); he also demonstrated, with human participants, that a defensive conditioned reflex movement that had been acquired to a specific tone no longer appeared when that tone was part of a well-known melody or of an arpeggiated chord based on a small sample of notes from that melody (Humphrey 1927).

A proper laboratory for psychology was provided by the University in the late 1930s, and Donald O. Hebb (1904–1985) was hired from McGill University to develop laboratory research on learning in rats. (Hebb left Queen's, however, in 1942, to do research at the Yerkes Laboratories of Primate Biology, in Orange Park, Florida.) Humphrey was one of the founding members of the Canadian Psychological Association (CPA) in 1939. During World War II, CPA organized a Test Construction Committee (War Committee) for the devising of a battery of verbal and nonverbal tests in connection with the selection of personnel for the Canadian Armed Forces; the test was administered to about a million individuals (for more on this test battery, please see Ferguson 1982). Humphrey also served as President of the CPA during the period 1942–1944.

In 1947, Humphrey spent a sabbatical year at the Experimental Psychology Laboratory at the University of Cambridge, and, in the following year, accepted an appointment to the First Chair of Experimental Psychology at the University of Oxford. His tenure at Queen's, from 1924 to 1948, had been unusual insofar as, in his role as the Chair of Philosophy, he had acted throughout by furthering the cause of experimental psychology, but a separate department of psychology was not established at Queen's until 1949, the year in which Humphrey left for Oxford. The first holder of the Chair of Psychology at Queen's was the social psychologist Julian Blackburn (1903–1974).

Following Muriel's death in 1953 and Humphrey's retirement from his Oxford post in that same year, he married Berta Wolpert in 1956 and moved to Cambridge, where he became a familiar visitor to the library

in the Experimental Psychology Laboratory prior to his death on April 24, 1966. Among his distinctions were a Fellowship in the Royal Society of Canada and the title of Emeritus Professor from Oxford. In a Presidential Address to the CPA on the occurrence of Humphrey's retirement from Oxford, Blackburn (1957) gave a valuable summary of Humphrey's achievements in learning theory, and Inglis (1982) offered a detailed account of Humphrey's accomplishments at Queen's University.

Major Contributions

At Wesleyan, Humphrey had written a book, directed at laymen as well as at professional psychologists, aimed at interpreting the ideas of behaviorism, Gestalt psychology, and psychoanalysis into a coherent narrative for viewing the psychology of everyday life. In *The Story of Man's Mind* (Humphrey 1923) can be found the kernels of several ideas on which Humphrey would elaborate in later publications. At Queen's, he wrote *The Nature of Learning in Relation to the Living System* (Humphrey 1933) and *Directed Thinking* (Humphrey 1948), as well as many articles and book chapters. In collaboration with Muriel, he translated two early nineteenth-century monographs by J.-M.-G. Itard (1775–1838); these were later incorporated into a book entitled *The Wild Boy of Aveyron* (Humphrey and Humphrey 1932). This is a key historical source showing how difficult Itard had found it to educate a feral 10-year-old boy to a level at which he could function socially.

While at Queen's, Humphrey also wrote two science fiction novels, using the pseudonym Donald Macpherson. They were entitled *Go Home Unicorn* (Macpherson 1935) and *Men are like Animals* (Macpherson 1937). Both incorporated recent discoveries in neuropsychology and both were partly set in the island scenery of the St. Lawrence river where it flows past Kingston.

At Oxford, Humphrey completed a volume entitled *Thinking: An Introduction to its Experimental Psychology* (Humphrey 1951). This historical review remains, even today, a useful account of the laboratory investigations by members of the Würzburg school into the thinking processes of intellectually gifted persons; the ideas of Otto Selz (1881–1944) on the mechanisms underlying mental problem solving; and the

experiments undertaken by members of the Gestalt School into problem solving in “hands-on” practical contexts.

The dominance in the 1930s of the three competing schools of behaviorism, Gestalt psychology and psychoanalysis was attested to in a widely read textbook by Woodworth (1931); a short evaluation of their influence upon academic psychology as seen from a present-day perspective has been offered by Murray et al. (2000). As already noted, Humphrey picked out his preferred features from each school and tried to apply these features to ongoing problems in experimental psychology. For example, in *Directed Thinking*, Humphrey (1948) confronted the problem of *what* mental representation might be consciously experienced between the presentation of a stimulus word (or a question) and the supplying of an associated word (or answer). From the writings of the Würzburg school (between about 1900 and 1910), he took the observation that, often, a participant was not capable of listing a sequence of intervening associated words or images of which he or she had been consciously aware. From Freud, Humphrey took the notion that processes, of which one is not consciously aware, nevertheless can operate in such a way as to “keep alive” the motivational state, often emotionally toned, that had been aroused by the stimulus word or question. Humphrey then combined these approaches into a hypothesis according to which the continuity of an individual’s thought is determined by motivational states, of which we are often not always aware, quite as much as it is by the semantic determinants of a chain of mental associations of which we often do happen to be aware.

In *The Nature of Learning*, Humphrey (1933) interpreted his “arpeggio effect” as being the evidence supporting the introduction of Gestalt principles into our understanding of classical conditioning. If the conditioned stimulus (a tone) be considered as a stand-alone stimulus in its own right, it follows that the tone will not necessarily continue to serve as a conditioned stimulus if the tone is embedded in a physical context of other tones such as the melody or common chord. His work on snails (Humphrey 1930) also led him to reconsider the usual schema used by instructors to describe the course of classical conditioning. At the onset of the conditioning trials, the conditioned stimulus might elicit an arousal or

defensive response (partly because of its novelty). It will be necessary for the subject to become habituated to that stimulus, that is, no longer treat the stimulus as a signal of possible danger or gratification. Only after a quiescent emotional attitude vis-à-vis the conditioned stimulus has been arrived at, will that stimulus be able to be associated with the unconditioned stimulus and come to elicit the expected conditioned response.

Perhaps the most striking of Humphrey’s innovations in learning theory was his suggestion that a chain of learned responses should not be seen only as one in which each learned response fires off the next response in the chain as a result of mere habit formation; for Humphrey, each response is also determined by the organism’s need to restore the psychological and/or physiological state of equilibrium that had been disrupted by the initial presentation of the unconditioned and conditioned stimuli. The idea that sequences of physical events involve a reaction (a disruption in equilibrium) followed by a counterreaction (a restoration of equilibrium) had been elevated into a scientific principle by Henri Louis Châtelier (1850–1936). According to Asimov (1972), the principle may be stated as: “Every change of one of the factors of an equilibrium brings about a rearrangement of the system in such a direction as to minimize the original change” (p. 460). The principle had originally been applied in the context of chemical thermodynamics, but anticipations of the principle can be seen in Herbart’s (1824/1961) theory of the statics and dynamics of mental representations concurrently being consciously experienced. In Humphrey’s own time, Cannon (1915/1929) had formulated a theory of how bodily physiological equilibrium could be attained by processes of “homeostasis,” a term Humphrey also adopted. J. von Uexküll (1926) anticipated the modern cybernetics approach when he claimed that the interaction between an organism and its environment included the growth of feedback mechanisms within the organism that were designed to ensure behavioral stability. In Humphrey’s discussion of habituation, when an unlearned defensive reaction to a disturbance in the environment gradually drops out as the organism “learns” that the disturbance, when repeated, is non-harmful, the adaptive usefulness of the habituation mechanism is that it restores

the organism to a pre-disturbance level of equilibrium. Humphrey (1930) also claimed that this argument might also apply to Pavlovian extinction mechanisms.

In short, Humphrey challenged many traditional beliefs associated with classical conditioning, and his penchant for integrating diverse currents of contemporary psychological ideas clearly bore fruit in his analysis of human thinking processes.

Hunter, Walter S.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

H

Basic Biographical Information

Born: March 22, 1889; Died: August 3, 1954.

Walter Samuel Hunter was born in Decatur, Illinois and spent his early life living and working in rural farming communities in Illinois and Texas. He studied with C. S. Yoakum at the University of Texas and received a scholarship to the University of Chicago, where he took the Ph.D. with Harvey Carr in 1912. He became a central figure in the development of academic experimental psychology and ultimately became identified with Brown University in Providence, where he worked from 1936 until his death.

Major Accomplishments/Contributions

Hunter was fascinated by animal studies, and combined this interest with refined experimental technique. His early research on the delayed reaction (Hunter 1913) is exquisitely representative of the elements that were most compelling in establishing functionalistic behaviorism as a dominant force in psychology at that time. He showed that organisms ranging upward from rats through raccoons to children were able to delay responses to a desired object, the delay proportionate to the level of complexity of the organism involved. Hunter rendered the mental state, obviously involved in maintaining readiness to respond after a delay, as a palpable negative figure surrounded by the positive ground of apparatus and measurement. Mental representation was thus a necessary fact

inferred from objective, species-comparative experimental data, rather than from trained introspection. Between 1915 and 1925, Hunter critiqued the classical psychological concepts of association (Hunter 1917) and consciousness (Hunter 1924), and then turned his attention to formulating a general theoretical position. In doing so he drew not only on his experimental expertise but also on his store of general cultural knowledge, which distinguished him from Watson and others in the field who disavowed philosophy. Hunter called his system by the old Kantian term “anthroponomy,” which he contrasted with different types of “psychology” ranging from the pure science of introspectionism of Wundt and Titchener, to blends of introspective and objective material which he saw as inextricably tangled and, to the extent that they focused on individual experience rather than objective data, sterile and barren inventories of experiences unrelated to social and physical reality. Wryly utilizing quotations from Victorian poets, Hunter, in his contribution to Murchison’s *Psychologies of 1925* (Hunter 1926), found an analogy to the nonproductive solipsism of most “psychology” in Matthew Arnold’s “To Marguerite, Continued” and challenged the choice between an objective and subjective psychology by quoting Dante Gabriel Rossetti’s “The Cloud Confined.” Hunter was most in sympathy with the reductionism of A. P. Weiss, the neural correlative approach of Karl Lashley, and the theoretical physical analysis of perception advanced by Wolfgang Köhler, though he personally favored molar analyses at the level of ordinary objects and social transactions. He was willing to admit any idea into psychology providing that it could be translated into a stimulus/language reaction form, and, like Meyer and Weiss, emphasized the necessity of language in a theoretical account of behavior (though Hunter did not pursue the study of language specifically). Hunter did not pursue his theory and other approaches to objective psychology gained ascendancy in the 1930s. His attitude toward the proper level of psychological analysis was consonant with tendencies in the field to focus psychology strictly on experimentation based on directly observable entities. One probable effect of his influence in this direction is the creation of the Psychonomic Society: one of Hunter’s students, Clarence Graham, was a founding member.

Hunter could be justly said to have “placed service to his science above all else” (Graham 1958, p.146). However, it was as a teacher, as a proponent of applied psychology, and as a developer of several infrastructural elements in psychology that Hunter had his greatest effect. He wrote a well-received general psychology textbook and fostered the careers of many significant psychologists at the University of Kansas (1916–1925), Clark University (1925–1936), and Brown University (1936–1954), mostly in the areas of sensation and perception, one of Hunter’s other experimental interests (Hunter 1914). Among these were Clarence Graham, Frank Geldard, and Lorrin Riggs. While at Clark, he gave a course in animal behavior which was attended by, among others, F. S. Keller and B. F. Skinner early in their graduate careers. He also gave an initial boost to the career of Donald G. Paterson, who began work on reliability of mazes at Kansas in 1917 and continued this work with Hunter after moving to Minnesota after the First World War. Hunter accepted responsibility for both the *Psychological Index* in 1926 and the newly developed *Psychological Abstracts* in 1927, which he edited for 19 years. He was elected President of the American Psychological Association in 1931. He also played roles in many major applied psychology initiatives, especially in military psychology. During the First World War he, like many other psychologists, served as a commissioned officer with the US Army Testing Program. During the Second World War, he was involved in several committee efforts to coordinate psychology’s response to military needs, and eventually chaired the Applied Psychology panel of the National Defense Research Committee after 1943. He continued to work on defense projects after the war and was honored with a Presidential Medal for Merit in 1948 for his defense-related work. His anthroponomy meshed with a general interest in humans as a species, recognized by his appointment as chair of the Division of Anthropology and Psychology of the National Research Council in 1936. Hunter was also among those psychologists for whom race was a consistent theoretical concept. During the First World War, Hunter actively collected nation-of-origin data for Army inductees. Also, during Army service at Camp Lee, Virginia, he came into contact with George Ferguson, author of *The Psychology of the Negro*, whose work he cited in support of the idea of differences in mental ability between races

in a chapter on social and racial psychology in his general psychology textbook. Having formed a conviction of race differences in intelligence, Hunter, assisted by Eloise Sommermeier, tested intelligence during 1920–1921 in Indian schools in Kansas and published data showing a relation between increasing “white blood” and the Otis Intelligence Score, results that persisted in the literature (Hunter and Sommermeier 1922). This pattern of activity on many different levels, though peripheral to Hunter’s main interests in theoretical psychology, is indicative of the way that race-related ideas were carried along with general experimental psychology during the first quarter of the twentieth century.

Husserl, E. G.

THOMAS F. CLOONAN
Fordham University, Bronx, NY, USA

Basic Biographical Information

Edmund Gustav Husserl, the father of phenomenology, was born on April 8, 1859, in Moravia, then part of

the Austro-Hungarian Empire and today part of the Czech Republic. His family was of Jewish heritage. He was a philosopher whose education and writings straddled the end of the nineteenth century and the first third of the twentieth century. His philosophy in parts importantly addressed psychology. Husserl died on April 29, 1938 in Freiburg im Breisgau, Germany, at the age of 79.

From 1878 through 1881, Husserl studied mathematics at the University of Berlin. In 1881, he moved to the University of Vienna where he received his Ph.D. in mathematics. At the University of Vienna, Husserl attended the lectures of Franz Brentano in 1884–1886. Husserl claimed that Brentano’s example of scholarly research influenced him in believing that philosophy could be scientific. As consequence, Husserl turned his attentions to philosophy.

Milestones in Husserl’s personal life paralleled the redirection of his professional life. In 1887, he married Malvine Steinschneider. She too was of Jewish heritage and she also had been born in the Austro-Hungarian Empire. They had three children: Elisabeth, Gerhart, and Wolfgang. The Husserl parents survived the death of their son Wolfgang, who was killed in action at Verdun in World War I. Malvine died in 1950.

Major Accomplishments/Contributions

With respect to his continuing scholarly development from 1886 and on, in 1900 Husserl (1970) published the two parts of his *Logical Investigations*. In 1901, Husserl and his family moved to the University of Göttingen. His stay at Göttingen lasted through 1916. The year 1913 saw Husserl (1998) *Ideas I* published. These two books heralded the start of Husserl’s development of philosophical phenomenology. In 1916, Husserl was appointed to the University of Freiburg. He remained in Freiburg up through 1928. World War I had been in progress already for 2 years when Husserl was appointed to Freiburg. Edith Stein worked as his assistant 1916 through 1918. Martin Heidegger became Husserl’s assistant in 1919 and later succeeded him to the Chair of Philosophy at the University of Freiburg. In what was termed the Circle of Freiburg that gathered around Husserl, there numbered Martin Heidegger (who later came to articulate his own

hermeneutic phenomenology), Hans-Georg Gadamer, and Emmanuel Levinas.

Significant as were Husserl's critiques of psychologism, they did not inhibit his addressing the issue of a valid psychology. Among the topics in philosophy that Husserl treated in his writings that were of psychological relevance were meaning, evidence, perception, imagination, and time. In 1925 and 1928, Husserl presented lecture courses on phenomenological psychology. In his Freiburg lectures, Husserl was "aiming at giving a solid foundation for all psychology through a pure psychology on philosophical grounds" (Spiegelberg 1972, p. 8). This aspiration for psychology and phenomenology was in the context of subsequent developments in Husserl's thoughts.

Amedeo Giorgi (2009), an American psychologist who has been explicit in his mediation of a phenomenological psychological method from Husserl's work, has pointed out, "at the level of psychological science what is required is what Husserl calls the psychological phenomenological reduction. . . . the acts of consciousness correlated with. . . objects [of experience] belong to a human mode of consciousness" (p. 98). Psychology is engaged.

From 1933 on, the life of Edmund Husserl and his family was subject to the anti-Semitism of the Nazi regime. In 1933, Husserl received an invitation to a position at the University of Southern California School of Philosophy. His children had already left Germany and were living in the United States and had urged their parents also to move from Germany. Husserl, nevertheless, declined the California invitation. He preferred to die in his homeland.

Although Husserl had seen the publication of a number of his important writings, he was to leave behind him a vast amount of unpublished writings – his philosophical *Nachlass*, "estate." These writings comprised approximately 40,000 pages of stenographic material in Husserl's handwriting, and about 10,000 pages of typed or handwritten transcriptions (the work of Husserl's assistants, Edith Stein, Ludwig Landgrebe, and Eugen Fink). All these pages housed the further reflections of Husserl. It was a body of vast material invaluable for the full comprehension of Husserl's thinking. All of it was in danger of destruction and the story of its rescue requires mention. The danger

was from two sources. The first was the pogroms instituted by the Adolf Hitler government. In 1886, Husserl had converted to Lutheranism. The comprehensiveness of Nazi anti-Semitism, however, encompassed all Jews – observants, non-observants, and converts. Husserl's *Nachlass* faced destruction.

The second factor contributing to the parlous situation of Husserl's writings was the geography of Freiburg in Germany, the city within which Malvine Husserl resided and within which rested the unpublished writings of Husserl in her care. The proximity of Freiburg to the border with France heightened the vulnerability of the material to war zone destruction in the quite imminent World War II.

Four months after Husserl's death, in the face of this situation Malvine Husserl entrusted the rescue of Husserl's unpublished writings to Herman L. van Breda. Van Breda was a student of Husserl's phenomenology and a Franciscan priest from Belgium. Upon accepting the task of saving Husserl's manuscripts, van Breda smuggled out of Germany the transcriptions in his luggage. The remainder of Husserl's writings was rescued by an operation involving Louvain University and the Belgian government that resulted in the final safe deposit of them as the "Husserl Archives" in Louvain University. Van Breda obtained a visa and permit for residence in Belgium for Husserl's widow.

With the subsequent invasion and occupation of Belgium in World War II, for a period of 4 years until the end of the war Husserl's writings had to be hidden. The most fortunate rescue of Husserl's manuscripts has enabled further appreciation of Husserl's phenomenology not only for philosophy but also for psychology.

Hypnosis

TRICIA CHANDLER

Butterfly Endeavors, Lakewood, CO, USA

Introduction

Hypnosis as an accepted practice has had a long and tenuous history around the world and especially in Western civilization. In some of the oldest recorded history, the use of trance has been established for self-transcendence and healing among spiritual traditions around the world. Individuals have practiced self-hypnosis through meditation techniques that either controlled breathing or focused on an object, such as a candle flame. Others have gone into trance states dancing into a frenzy of ecstasy such in the circle dancing of the Sufi religion. Still others have used natural mind-altering drugs to alter their normal perceptions to enhanced and transcendent states. Shamanic healers have been found in most indigenous cultures that have gone into trance themselves and/or produced trance states in their patients to aid in the cure of disease. In many cultures, these practices continue today.

The paranormal perspective of trance mediums, psychics, and those that have used hypnosis for its notoriety and entertainment value have at times brought the idea of hypnosis into disrepute especially in the past few hundred years in Western Civilization. During this period of time, scientists and theorists wishing to distance themselves from religion or superstition suspected any practice or concept that could not be proven through visible means. This breach in acceptance was broadened by the lack of adequate technology to properly examine many concepts. Spiritual practices that did not maintain a logical basis was considered suspect by scientists, and the schism between the two grew larger and larger.

There is a rich history beginning in the 1700s in Europe whereby a number of physicians, neurologists, and psychiatrists began to explore the mind–body connection. At that time, hypnosis began to be researched in clinical practices to develop understanding of the connection between psychological dysfunction and physical ailments. While the mechanics of hypnosis

was not understood and is still debated today, progress was made in discovering that physical and psychological health are connected through the inner workings of the mind. The contributions of those individuals developed and legitimized the study and science of psychiatry and psychology.

In the last half of the twentieth century, the schism between spirit, mind, and body has changed due to the significant advancement of research technology and theories into the abilities related to states of consciousness. Hypnosis as a tool for accessing unconscious trauma and changing self-defeating beliefs has received scientific acceptability. Hypnosis for self-regulation and healing of one's own immune system and pain is being researched and being substantiated. Other methodologies are being developed around the concept of single-pointed concentration found in hypnosis that are proving to be profoundly helpful treatment options for trauma, stress, anxiety, and pain. Fueled by all of these advances, the introduction of integrative medicine that combines both traditional medicine practices with alternative and complementary practices are opening up tremendous opportunity for hypnosis to become fully accepted in both psychology and physiological health care.

Definition

Hypnosis has been defined as an altered state of consciousness or an increased state of awareness that heightens suggestibility or responsiveness to ideas that is induced by expectation, focused attention, and suggestion (Braid 1846; Bernheim 1891/1980; Hull 1933/2002; Erickson 1980). To reach this state of susceptibility has been called a hypnotic induction, which generally follows a series of preliminary instructions and suggestions. Hypnotic suggestions may be delivered by a hypnotist or hypnotherapist in the presence of the subject, or may be self-administered through the process of self-suggestion, deep relaxation, or meditative trance.

The American Psychological Association (APA) has proposed a scientific definition of hypnosis published by Division 30 of the APA, the division for psychological hypnosis:

- ▶ Hypnosis typically involves an introduction to the procedure during which the subject is told that suggestions for imaginative experiences will be presented.

The hypnotic induction is an extended initial suggestion for using one's imagination, and may contain further elaborations of the introduction. A hypnotic procedure is used to encourage and evaluate responses to suggestions. When using hypnosis, one person (the subject) is guided by another (the hypnotist) to respond to suggestions for changes in subjective experience, alterations in perception, sensation, emotion, thought or behavior. Persons can also learn self-hypnosis, which is the act of administering hypnotic procedures on one's own. If the subject responds to hypnotic suggestions, it is generally inferred that hypnosis has been induced. Many believe that hypnotic responses and experiences are characteristic of a hypnotic state. While some think that it is not necessary to use the word "hypnosis" as part of the hypnotic induction, others view it as essential.

Details of hypnotic procedures and suggestions will differ depending on the goals of the practitioner and the purposes of the clinical or research endeavor. Procedures traditionally involve suggestions to relax, though relaxation is not necessary for hypnosis and a wide variety of suggestions can be used including those to become more alert. Suggestions that permit the extent of hypnosis to be assessed by comparing responses to standardized scales can be used in both clinical and research settings. While the majority of individuals are responsive to at least some suggestions, scores on standardized scales range from high to negligible. Traditionally, scores are grouped into low, medium, and high categories. As is the case with other positively-scaled measures of psychological constructs such as attention and awareness, the salience of evidence for having achieved hypnosis increases with the individual's score. (APA, 2010)

Historical Background

The earliest historical references to hypnosis are reflected in the trance states found within meditation practices, mystical rites, and Shamanistic healing practices within Eastern and indigenous cultures, and early world religions including Buddhism, Taoism, Hinduism, Islam, and Christianity (Braid 1846; Brennan 1998; Heinze 1988, 1991). The single-pointed concentration found within such practices as meditation, Sufi dancing, and deep breathing that move consciousness

into a heightened and diffused awareness or trance state was first noted in Persia, dating back to between 628 and 551 B.C., in the ancient spiritual teachings by the prophet Zarathustra. As ancient Persia (now known as the area around Iran) was a gateway for travel between Indian, Arabic, Hebrew, and Greek societies, many philosophical ideas have benefited from Zarathustra's teachings that focused upon spiritual transcendence within these other societies and major religions (Brennan 1998; Heinze 1988).

Spirituality and medical healing techniques were in harmony with each other throughout the ancient world and can still be found in indigenous cultures that utilize Shamanic healing (Heinze 1988). When Alexander the Great defeated Persia around 330 B.C., many of these philosophical ideas and teachings of Zarathustra migrated into Greek culture. The use of imagery and hypnosis as healing techniques was found in the ancient temples of Asclepius, a Greek physician later deified as the god of medicine, (Braid 1846; Brennan 1998; Hilgard 1987). Asclepius was reported to have treated the sick while they were in some sort of sleep (trance) state with testimonies of cures of blindness, speech disturbances, and paralysis (Veith 1965).

The spiritual connection of body–mind philosophy waned as the Age of Enlightenment and subsequently the Age of Reason took over in Europe. Hypnosis as a Western psychological and physiological study began with the experimentations and theories of German born, Franz Anton Mesmer (1734–1815). Mesmer was a physician trained in Vienna who theorized in his doctorate thesis that all animate and inanimate objects shared a natural energy (animal magnetism) that could be transferred through a process he called mesmerizing (Ellenberger 1970; Hughes and Rothovius 1996). He speculated that the magnetic waves of universal invisible fluid found in people and animals could be transferred through inducing a trance state in (mesmerizing) patients and would lead to cures for such issues as sleep walking, lethargy, catalepsy, and both maniacal and ecstatic visions (Braid 1846; Ellenberger 1970). His theories were eventually discredited by the scientific community due to his ideas about animal magnetism being deemed unscientific forays into imagination (Brennan 1998; Ellenberger 1970; Hughes and Rothovius 1996). Mesmer's techniques of staring into the eyes of his

patients to induce a state of susceptibility to suggestion intrigued others, and led to further studies of his speculations that eventually replaced his ideas about animal magnetism with concepts of suggestion, visualization, and dissociation that contributed to the development of hypnosis by other physicians and scientists.

Hypnosis fell out of favor for a time in the scientific communities due to the use of it within the spiritual movements that surged through Europe and America during the late eighteenth century. During that period, hypnosis became recognized as a combination of spiritual practice and science referred to as psychotherapy by spiritual communities in Europe and America and was used by many clergy that practiced healing techniques (Taylor 1999). Hypnosis has maintained a presence in the alternative healing and spiritual practices throughout Europe and America while its acceptance has waxed and waned in the scientific community throughout the last two centuries. Such practices as trance mediums, automatic writing, séances, and hypnotism for entertainment led to skepticism from the scientific community more than once throughout the past 200 years.

James Braid, a physician (1795–1860) born in Scotland and educated at the University of Edinburgh, became interested in the phenomenon of the physical effects that were produced by Mesmer as well as the concepts of the Marquis de Pyusegur (a French contemporary), who speculated that trance states were similar to the same state found in sleepwalking, known as somnambulism (Hughes and Rothovius 1996). Braid hypothesized that the induction technique used to facilitate a trance state was linked to brain physiology, and he coined the name of hypnosis to describe that state and induction process (Braid 1846, 1960). Braid developed a straightforward approach to the process of hypnotizing an individual through use of an object to bring forth single-minded focus that would render the individual susceptible to suggestion. He also studied Zarathustra's ancient teachings noting in his writings that the ability to induce a trance like state was not a new discovery, but had been practiced for thousands of years in spiritual traditions (Braid 1846). Braid's work ultimately legitimized the study of hypnosis in medical and scientific communities for a time, leading the way to the eventual use of hypnosis with psychological pathology.

Jean Martin Charcot (1825–1893), a neurologist, born and educated in Paris, led research at the Salpêtrière school and has been credited with reviving a scientific application of hypnosis by identifying the difference between convulsions that were associated with the physiological disorder of epilepsy and those of a psychological nature related to hysteria (Brennan 1998; Hilgard 1987; Hughes and Rothovius 1996). His work with hypnosis led to speculations of a neurological basis for the origins of hysteria and posttraumatic phenomena that were different from organic physiological symptoms found in the nervous system. While some of his later work was ultimately ridiculed and discounted, his ideas still fueled the later work of Janet, Breuer, and Freud, leading to the further developments of psychiatry and psychoanalysis (Ellenberger 1970).

Hippolyte Bernheim (1840–1919), a French physician trained in Strasbourg and a professor at the *Faculté de Médecine* at Nancy, determined that hypnotic effects were due to the power of mental suggestion and a continuum of hypnotic susceptibility in the subject (Bernheim 1891/1980; Ellenberger 1970). Bernheim was a critic of Charcot's work, disagreeing with the concept that hypnosis is a pathological nervous condition related to hysteria and completely rejecting Charcot's idea that physical symptoms could be transferred laterally with magnets. Insisting instead that hypnotism is a psychic condition that increases the susceptibility to suggestion, Bernheim used hypnosis to treat organic diseases such as menstrual disorders, gastrointestinal diseases, and rheumatism. Eventually, he and his students abandoned the use of hypnotic induction for direct suggestion using a technique they called psychotherapeutics (Bernheim 1891/1980; Ellenberger 1970).

Pierre Janet (1859–1947), another French physician at the Lyceum in Le Havre, furthered the research on clinical data of the abnormal mental states related to psychosis and hysteria using hypnosis. His studies identified the connection between traumatic origins and automatic actions. He developed an analytic framework that emphasized the relationship between consciousness and action stressing the concept of a field of consciousness, and coining the phrases dissociation and subconscious (Ellenberger 1970). Breuer and Freud, both students of Janet, published a pivotal

paper (1895/1957) discussing experiments using hypnosis on a woman, Anna O, who was able to resolve several debilitating physiological symptoms by going back in time to specific traumas she had experienced and bringing the traumas into consciousness. The paper had quite an effect on the psychiatric community at the time. Breuer demonstrated by using hypnotic induction how psychological trauma that had been repressed in the subconscious had adversely affected both psychological and physical health, and how those affects could be reversed. Freud eventually quit using hypnosis and developed psychoanalysis that he felt led to the same effect of uncovering unconscious beliefs and memories by using free association and dream analysis.

The collective research contributions on hypnosis by Mesmer, Puysegur, Braid, Charcot, Bernheim, and Breuer, along with Freud's psychoanalytic contributions to therapy led to a large body of evidence and understanding of neurological, physiological, and psychological theory over a period of about a century (Ellenberger 1970; Hughes and Rothovius 1996; Wozniak 1992). The mind–body connection was established as a concept from the evidence that trance states, mental suggestion, psychic trauma, dissociation, and catharsis, as well as the therapist's intention to cure and develop rapport does effect change in the physical body. However, the mechanisms of hypnosis continued to be questioned by the scientific and medical communities with it falling out of favor as a method to reach that cathartic state with Freud's switch to psychoanalytic psychiatry in the early twentieth century and with the acceptance of behavioral psychology and medical pharmacology as preferred methodologies of treatment.

Clinical research into the use of hypnosis for the rehabilitation of war-related disorders, such as, anxiety, obsession, depression, and reactions to posttraumatic stress such as amnesia and psychological paralyses, was sanctioned after World War II in the United States (Watkins 2009). Watkins, a professor at Auburn University in the early 1940s, studied the use of hypnosis for war propaganda prior to working at the Welch Convalescent Hospital in Florida with returning veterans. Watkins continued to work for the veteran administration as the Chief of Psychology in Oregon in the early 1950s at a VA hospital treating

posttraumatic stress in veterans with hypnosis, and he contributed substantially to academic journals on the results of his clinical research (Watkins 2009).

He became a founding member of the Society for Clinical and Experimental Hypnosis in 1949, which was an exclusive society working to establish hypnosis as a reputable contribution in the medical and psychological fields. Due to its membership standards being out of reach for most hypnotherapy practitioners, Milton Erickson established a less restrictive group for practitioners, the American Society of Clinical Hypnosis in 1958 that still produces a journal today (Watkins 2009; Weisberg 2008). By the late 1950s, the American Medical Association (AMA), the Canadian Medical Association (CMA), the British Medical Association (BMA), and the American Psychological Association (APA) all endorsed hypnosis as a valid medical practice (Weisberg 2008). Watkins has gone on to use a combination of psychoanalysis and hypnosis in clinical practice while continuing to teach at the university level and write about his clinical cases throughout the last half of the twentieth century.

Milton Erickson (1901–1980) was probably the best-known American psychiatrist that conducted research, wrote publications, lectured, and developed 3-day workshop training for hypnosis practitioners, bridging the gap between experimental laboratory experiments and clinical experience of hypnosis (Ellenberger 1970). His studies of hypnosis began in collaboration while studying with Clark Hull (1884–1952), the first major scientific researcher of hypnosis at the University of Wisconsin. Hull's contribution to behavioral psychology was to formalize laboratory methods. Hull, and his behavioral psychology followers have continued speculation that research into mechanics of hypnotizability of subjects demonstrates that suggestibility is a behavioral construct (Kirsch et al. 2007).

Initially Erickson's application of hypnotic principles worked to turn resistance in clients to advantage using paradoxical techniques that ultimately contributed to the concept of brief therapy concepts (Nichols 2010). Erickson continued to research hypnosis from the perspective of state theory and added to the literature on many areas of psychopathology that contributed to an understanding of mind–body dynamics. He suggested that the unconscious holds useful knowledge

that assists in the healing process when accessed (Erickson 1974/1980; Hilgard 1987). He also contributed to facilitating the induction process of hypnosis by suggesting that rather than using a ritualistic method, the hypnotherapist take into consideration the needs and personality of the client in any given situation, leading to a more naturalistic approach. He suggested that the naturalistic approach to trance induction was less time consuming and more effective in the long run (Erickson 2009).

Current Theories of Hypnosis

There are two dominant modern theories about hypnosis that have emerged from the original schools of thought developed from the Salpêtrière school from Charcot to Feud, and the Nancy school and Bernheim's work, which are, respectively, called state theory and nonstate theory. State theory follows a neodissociative model that emphasizes that hypnosis activates an altered state of consciousness where by cognitive functioning is no longer in control and a partial dissociative state takes over (Hilgard 1986, 1992). Nonstate theory, or sociocognitive theory, suggests that hypnotic behaviors occur due to the person's suggestibility, attitudes, and/or motivations. The nonstate theory has emerged from Bernheim's early work and the behavioral psychology perspective carried on by Hull and others (Spanos and Chaves 1991; Spanos and Coe 1992). These two opposing theories have both been supported in research with the variance in support related to the concept of degree of susceptibility of the subjects. The argument that some individuals are more susceptible to being hypnotized than others has led to considerable research into the mechanisms of susceptibility.

Modern advances in neurology and technologies that permit brain scans led to research that supports and repudiates both of these theories. Some researchers have noted physiological changes in activity in the electro cortical region of the brain using Electroencephalogram (EEG) readings that demonstrate hypnotic susceptibility (Kirsch and Council 1992; Silva and Kirsch 1992). These findings lent support to Braid's hypothesis in the 1800s of the correlation between high hypnotizability being linked to brain physiology (Braid 1960). EEG readings are a simple process that records and identifies wave patterns of

the brain's electrical activity. Some researchers have found a correlation between individuals with higher susceptibility to being hypnotized producing higher than normal alpha waves while resting (DePascalis et al. 1988; MacLeod-Morgan 1979). Other researchers have criticized those findings due to the supposedly poor empirical design and controls used in the research (Ray 1997). Research has suggested that individuals who are highly susceptible to hypnotic suggestion have more right hemisphere activity in their brains, which has been associated with intuition, imagination, and creativity (DePascalis and Penna 1990; Macleod-Morgan 1979). While other researchers found no relationship between high or low susceptibility to being hypnotized and the lateral hemispheres of the brain (DePascalis et al. 1988; Morgan et al. 1974).

There seems to be evidence that theta brain activity, which is associated with activities such as meditation and focused attention, has been correlated with high susceptibility for hypnosis using EEG outcomes (Crawford and Gruzelier 1992). More sophisticated research methods have yielded support that highly susceptible individuals for hypnotizability have greater theta output in the frontal and temporal cortex areas of the brain at baseline, which suggests a heightened state of concentration of attention (Sabourin et al. 1990). Erickson and Rossi's mind-body research have supported Braid's definition of hypnosis as a reversible amnesia or dissociation, whereby memory is dependent upon the psychophysiological state of the individual at the time of the experience (Erickson and Rossi 1974/1980). These theories have been supported in recent research into the phenomena of Posttraumatic Stress Disorder (PTSD) and Dissociative Identity Disorder (DID) associated with extreme trauma (Gauld 1992; Spanos and Chaves 1991; Bertrand and Spanos 1989). While there have been no definitive conclusions accepted into the mechanisms of hypnosis, the mind-body theories provide the best options for research that may bring more conclusive evidence into how hypnosis works in the future.

Areas of Continuing Hypnosis Research

Research into the efficacy of hypnosis has been actively ongoing in the United States and internationally for both psychological and physiological problems since

the 1950s (Watkins 2009). Due to participants being required to be actively involved in the procedures of hypnosis induction, empirical quantitative research with double-blind and/or single-blind standard procedures have been difficult to accomplish. Despite these procedural difficulties, a literature review sampling found significant studies in a variety of areas within psychological research that include the positive effects of hypnosis for treatment of anxiety and phobias, posttraumatic stress disorder, addictive issues such as smoking cessation, and weight loss. Areas of research into the physiological use of hypnosis have also produced significant efficacy as a treatment modality for such issues as an anesthetic for surgical procedures, chronic pain, gastrointestinal disorders, irritable bowel syndrome, nausea, and asthma.

Psychological and Physiological Research

In combining cognitive-behavioral therapy (CBT) with hypnosis for the treatment of posttraumatic stress disorder (PTSD), one study found a 70% greater improvement in clients' symptoms of distress, as opposed to those that just received CBT (Kirsch et al. 1995). A study treating clients with anxiety and phobias using either systemic desensitization or hypnosis found that both techniques produced significant improvement at a 1-year follow-up (Marks et al. 1968). Another study examining the effects of hypnosis, health education, or behavior modification for the treatment of smoking cessation found that each program reduced cigarette consumption equally (Rabkin et al. 1984). Three studies on the effects of hypnosis contributing to weight loss indicated that for those individuals with high hypnotizability, there was a correlation for greater sustained weight loss (Anderson 1985; Barabasz and Spiegel 1989; Cochrane, and Friesen 1986).

For psychological symptoms of preoperative anxiety, pain, and as analgesia for surgery, several studies have been conducted. Saadat et al. (2006) found a 56% decrease in preoperative anxiety; while Lang et al. (2000) found anxiety and pain decreased, and less analgesia was needed for patients experiencing conscious sedation in minimally invasive procedures during radiology with use of hypnosis. Two studies affirmed postoperative pain reduction in patients that

used hypnosis (Horton et al. 2004; Zachariae and Bjerring 1994). Four studies suggest that patients responded with improved recovery when given positive therapeutic suggestions along with anesthesia during surgery (Bonke et al. 1986; Hutchings 1961; Pearson 1961; Wolfe and Millett 1960). In addition, a critical review of 18 clinical trials that used hypnosis, suggestion, or relaxation as interventions to aide in recovery from surgery by Blankfield (1991) found that while these techniques were still generally underused in hospitals at that time, they all promoted physical recovery, shorter hospital stays, and contributed to a more positive psychological and emotional response after surgery.

Pain has been demonstrated as reduced significantly by hypnosis in a number of studies. Cancer patients with malignant tumors demonstrated significantly reduced pain symptoms in a study by Spiegel and Bloom (1983). Syrjal et al. (1992) found significant pain and nausea reduction in patients with hematological malignancies undergoing bone marrow transplants. A review by the National Institute of Health found that hypnosis was strongly effective in reducing pain in cancer patients (Hammond 2007). A study by Patterson and Ptacek (1997) also found that burn patients experienced less pain during posttreatment when using hypnosis. Two studies on hypnosis for fibromyalgia pain demonstrated relief with symptoms as well (Castle et al. 2007; Haanen et al. 1991).

In the treatment of gastric disorders, one study found relapse significantly reduced in hypnosis users with duodenal ulcers (Colgan et al. 1988), and two studies by Klein and Spiegel (1989) found that gastric acid production can be reduced with hypnosis. In the case of irritable bowel syndrome, five studies concluded that the majority of patients experienced an improvement in symptoms with just one session of hypnosis (Harvey et al. 1989; Tan et al. 2005; Whorwell et al. 1987; Whorwell et al. 1984; Whorwell 1991). A literature review by Whitehead (2006) found eleven studies demonstrating that hypnosis improved symptoms in about 87% of cases for gastrointestinal disorders.

Studies for the use of hypnosis to control nausea have been done with cancer and pregnancy patients. Two studies using hypnosis to control nausea in chemotherapy patients found the treatment to be effective (Redd et al. 1982; Walker et al. 1988). While Fuch et al. (1980)

found group hypnosis more effective than individual hypnotherapy for the relief of nausea in first trimester pregnancy patients.

Four studies found some relief in symptoms of asthma using hypnosis (Ewer and Stewart 1986; Maher-Loughnan et al. 1962; Morrison 1988; Research Committee of the British Tuberculosis Association 1968). In a study with children with asthma, Anbar (2002) concluded that 80% of the patients had improvement in their symptoms. Studies have found that children can also be effectively taught self-hypnosis to manage and improve symptoms of recurrent headaches (Kohen and Zajac 2007), insomnia (Anbar and Slothower 2006), and in lessening anxiety and pain in procedures with pediatric cancer patients (Lioffi et al. 2006).

There has been criticism of the use of hypnosis for accurate recall in a number of studies that led to hypnosis falling out of favor again for a while in the 1980s, especially in the legal system. However, the ramifications of the legal concerns over use of testimony found from hypnosis also affected its acceptability in healthcare (Watkins 2009; Weisberg 2008). Yet, the evidence of research on the efficacy of hypnosis as a viable treatment modality from the 1950s on strongly suggest its use for a variety of chronic pain syndromes, nausea, anxiety, posttraumatic stress disorder, and as a complementary treatment for addiction. Despite the overall finding of the efficacy for hypnosis it has generally been relegated to an alternative medicine status that was not endorsed by insurance carriers or used as a cost-effective alternative to hospital procedures that mandated traditional medical practices in the United States.

Self-help Movement and Integrative Medicine

The personal use of complementary and alternative therapies to promote self-healing jumped in use in the United States in the 1970s and on. Speculating on why the phenomena happened requires looking at several aspects of life at that time. In the 1960s, a large influx of Eastern philosophy, along with social unrest, and psychedelic drug experimentation found its way into some of the academic institutions, and into society at large. Trance states through a number of means were being actively explored by some prominent psychologists and

reported in scholarly journals. Self-induction of hypnotic states through progressive relaxation, guided imagery, deep breathing techniques, and meditation became more commonly practiced to de-stress and to promote self-healing. Humanistic and Transpersonal Psychology that embraced a mind–body–spirit perspective to treating psychological disorders was gaining ground in academic circles. Lay people were experimenting with alternative therapies due to being disappointed with outcomes of the medical model treatments and becoming open-minded to the influences of Eastern spiritual philosophies. This trend continued to grow across the United States through the later part of the twentieth century because alternative and complementary therapies were being demonstrated as less intrusive, less expensive, and more effective for treatment of chronic illness than many of sanctioned treatments prescribed by the medical community. Hypnosis, along with other complementary therapies again reached acceptance within the populace.

At the same time, more technological advances in psychoneuroimmunology, genetics and neuroimaging, and understanding about integrative medicine demonstrated the benefit of hypnosis as an intervention for chronic health problems and in reducing anxiety (Weisberg 2008). Research brought increased knowledge of psychoneuroimmunology and with it a general recognition that stress, anxiety, and depression adversely influence immune function was determined (Kiecolt-Glaser et al. 2001). This research led to further investigation into hypnosis as a means of intervention to activate immune system response to a variety of health challenges. With the inventions of Magnetic Resonance Imaging (MRI) and Positron Emission Tomography (PET) scans came research that suggested therapeutic interventions that were nonverbal and experiential, such as Eye Movement Desensitization and Reprocessing (EMDR) and Somatic therapies that were more helpful in treating PTSD effectively (Bryant et al. 2001; van der Kolk 1994; Levine 1997).

Integrative medicine has emerged from all of this research, which views health and illness from a new paradigm suggesting that a body–mind–spirit approach be proposed whereby the onset and exacerbation of illness can be found in a synergistic connection between all factors of the individual (Weisberg 2008). The combining of alternative healing

techniques, which includes hypnosis, with traditional medicine has been found to be more effective and less expensive in the treatment of chronic health issues such as pain, anxiety, and stress. This understanding returns to the roots of ancient thought found in Asia and the Middle East.

This new model of integrative medicine returns to an understanding of the importance of a collaborative approach between the practitioner and the patient, as well as the innate human capacity for self-healing. Integrative medicine allows for greater empowerment and participation by the patient in the healing process, thus allowing hypnosis to become part of the arsenal of treatment modalities utilized in the healing process (Weisberg 2008). Recently, there have been studies into combining acupuncture and hypnosis that found a correlation that the unity between these mind–body treatments provided low-cost and more effective treatment that assists the promotion of self-healing for a number of chronic and acute issues (Eitner et al. 2005; Samuels 2005; Lu et al. 2001; Schiff et al. 2007; Zelter et al. 2002).

Future Trends

Clearly, the advances in research that have led to a paradigm shift toward integrative medicine will continue to research and demonstrate the efficacy of hypnosis along with other complementary treatment modalities for the treatment of chronic illness. The high cost, adverse side effects, and poor rate of cure of traditional medicine for chronic pain, anxiety, addiction, and trauma indicate a need for finding more efficacious treatment modalities. Continued research into combining modalities such as hypnosis and acupuncture may prove further the efficacy of hypnotic suggestion in activating an individual's immune system and innate healing abilities. The use of self-hypnosis through such practices as progressive relaxation, guided imagery, mindfulness, and meditation can be taught to individuals to assist in self-healing. Such treatment methods as EMDR, Somatic Experiencing, and Emotional Freedom Technique (EFT) need to be further researched to determine efficacy for treatment of trauma-related disorders. All of these modalities have been noted to include aspects of hypnotic susceptibility.

At this point, even cognitive-behavioral psychologists are suggesting the use of mindfulness strategies

along with traditional psychotherapy to facilitate a wellness philosophy in mental health care (Seligman et al. 2005; 2006). As continued research demonstrates the continuum between states of consciousness and relative health or illness, there may be a wider acceptance of the ancient healing and spiritual practices of trance found in hypnotic induction. Self-hypnosis is easily teachable to even children to facilitate stimulating immune response for healing, self-regulation of pain, and chronic symptoms of psychological and physical distress. Certainly, as people learn that they have control over the functioning of their own immune systems through self-hypnosis, a renaissance of mind–body–spirit practices may occur worldwide lessening the gap between scientific reasoning and intuition found in spiritual approaches.

Indiana University, History of Psychology at

JAMES H. CAPSHEW

Clark University, Bloomington, IN, USA

The Indiana University Psychological Laboratory, organized in 1888, was the first research and teaching laboratory devoted to experimental psychology in the Midwest, and the second such facility established in the United States. This laboratory served as the matrix for the development of scientific psychology as an academic discipline at Indiana University and provided the nucleus for the Department of Psychology. The department, like American psychology generally, has evolved considerably to the present, both intellectually and institutionally. The early general-purpose laboratory has grown into several specialized laboratories that pursue investigations in a variety of fields, and the department conducts a multifaceted program of research, teaching, and service activities. Despite significant changes in scale and operation, however, laboratory research has remained the vital center of psychology at Indiana for well over a century.

In January 1888, the original laboratory, located in the Department of Philosophy, was established by William Lowe Bryan, a young philosophy professor who had been inspired to pursue the new psychology as one way to reconcile traditional religious and philosophical concerns with the increasingly powerful authority of science. In addition to an intellectual agenda, psychology provided Bryan a route for academic advancement within the university, which was entering a new era as it adapted to the demands of modern higher education. For the first few years, the psychological laboratory was as much a symbol of Bryan's commitment to the promise of science as it was a place to

perform research. In 1892, Bryan obtained a doctorate under G. Stanley Hall at Clark University. During Bryan's time at Clark, Hall was organizing the American Psychological Association, and Bryan became a charter member (and was elected, in 1903, as president). After his return to Indiana, Bryan transformed the laboratory into a scientific workshop dedicated to original research and the training of students. He wanted the laboratory to serve the practical needs of the university, and he stressed the role of experimental psychology in addressing educational issues – particularly scientific pedagogy. As a consequence, investigations of learning emerged as the key motif in the psychology program as it came to dominate the affairs of the Department of Philosophy.

Bryan and his student, Noble Harter, performed a series of groundbreaking studies on the process of learning telegraphy. In their view, the telegraphic language was ideally suited because no other human communication system could be so completely translated into precisely measureable terms that could be easily quantified. And there was much equipment in the psychological laboratory that had been directly appropriated from devices in the workplace, such as the telegraphy key and various types of electrical counters and timers. Their studies represented a strategic research choice, combining methodological rigor with practical significance. Bryan and Harter reported the results of their research in two long articles in 1897 and 1899, in the *Psychological Review*, representing acquisition of learning graphically by kymograph curves. Among the first example of "learning curves," the widely cited studies became a landmark in psychology.

Between 1888 and 1910, Bryan and his colleagues directed a host of bachelor's and master's degree students who went on to professional careers in psychology and in education (e.g., Lewis M. Terman, BA 1902, MA 1903). By 1902, when Bryan embarked on his 35-year term as president of Indiana University, he had recruited a small staff of psychologists to continue

the program, including Ernest H. Lindley, who served as head from 1902 to 1917. For the next 2 decades, undergraduate teaching and public service took much faculty time, and department members played important roles in establishing the university's School of Education. Throughout its first 30 years, the laboratory provided a focus for the ideals – if not always the activities – of Indiana psychologists.

Between the First and Second World Wars, the psychology program continued to have a strong utilitarian thrust, but the foundations of an autonomous research enterprise were also being laid. Enrollment in psychology courses was about twice as much as in philosophy courses, and in 1919, the department was renamed the Department of Psychology and Philosophy, with William F. Book as head from 1917 to 1934. After the First World War, the psychology faculty grew substantially, reaching a total of eight by the early 1930s, including noted theorist J.R. Kantor. Unlike before, many of these new faculty members did not have strong roots in Indiana. Beginning in the 1920s, the rudiments of a doctoral program were assembled, and by the end of that decade, the psychology program had attained complete administrative independence from philosophy. By 1931, the Department of Psychology included a nucleus of productive scientists on its faculty, and research and graduate education were increasingly emphasized. The department developed notable strengths in the areas of animal conditioning, clinical psychology, and psychophysiology, each of which had its own specialized laboratory facilities. Guided by department head Edmund S. Conklin since 1934, pure as well as applied research was flourishing at Indiana at the start of the Second World War, and the department was poised on the edge of far-reaching changes.

Along with the entire university, the psychology department entered a new era after the Second World War. Already in the midst of a renaissance under the administration of Herman B Wells, who had become president in 1937, Indiana University grew dramatically after the war, and research and graduate education were strongly supported. In 1945, B.F. Skinner was selected as chair, bringing a robust experimental program in operant conditioning and a new species – the pigeon – as subject. Scientific ideals came to dominate every aspect of the department's program, and applied research became less important. A host of new young

faculty members arrived, who broadened and strengthened research in both experimental and clinical areas. The topic of learning continued to provide a focus for the department, but a variety of theoretical viewpoints coexisted, all sharing an overarching commitment to methodological rigor.

In 1948, Skinner resigned and joined the Harvard University faculty, and Douglas G. Ellson succeeded him as chair of the IU department. By the early 1950s, the Indiana psychology department was one of the country's leading academic centers for experimental psychology, and for the first time in its history was a major producer of Ph.Ds. Growth continued through the 1950s and into the 1960s as the department expanded into new fields, notably mathematical modeling and sensory psychology, while also strengthening the mainstays of animal learning, physiological psychology, and clinical psychology. By the time Ellson concluded his term as department chair in 1959, faculty size was approaching two dozen, and plans were laid to construct a new facility to house the department. In 1960, psychologist William K. Estes became the first faculty member on the Bloomington campus to receive the title of Research Professor. The new Psychology Building was dedicated in 1963, and by 1964–1965, the faculty boasted 40 faculty members at the assistant professor level and above. Various national rankings of American university graduate programs in the 1960s placed Indiana among the top dozen or so institutions in the country, with high ratings for both the quality of its faculty as well as the effectiveness of its doctoral training. The department was chaired by Roger W. Russell (1959–1967) and Conrad G. Mueller (1967–1969), and Delton C. Beier served as Director of the Psychological Clinic (1945–1969).

Along with the rest of the academic community, the psychology department entered an era of limited resources in the 1970s. Faculty size reached a steady state of around 40 members, and Ph.D. production leveled off. Notable efforts to recruit women faculty members started in the early 1970s. The program came to encompass the major areas of animal behavior, cognitive/mathematical, sensory, physiological, developmental, social, and clinical. In 1969, Irving J. Saltzman began a 20-year career as department chairman. Toward the end of that period, in 1988, the department observed the centennial of the founding of the original psychology laboratory with a gala

celebration, with many of the department's 500 doctoral alumni in attendance (Capshew 1988).

Over the past 20 years, the department has changed in response to disciplinary and professional trends within the field of psychology, and has maintained its status as one of the best science departments at Indiana University. Among the important developments was the creation of an interdisciplinary graduate program in Cognitive Science in the early 1990s, directed by cognitive psychologist Richard Shiffrin. In 1997, the undergraduate psychology program was ranked 13th in the nation in the "Gourman Report of Undergraduate Programs" published by *Princeton Review*. Facilities have undergone expansion and modification as a major addition to the Psychology Building was completed in 2002. A brain-imaging research center was dedicated in 2006 in order to perform functional magnetic resonance imaging (fMRI) to indicate brain activity while subjects are engaged in various tasks. As experimental psychology turned increasingly toward neuroscience and clinical psychology renewed its claims of clinical science, the department was renamed Department of Psychological and Brain Sciences in 2005, reflecting a diversity of approaches to the field. Another department faculty member, Sharon S. Brehm, was elected President of the American Psychological Association in 2007.

Although specialization has continued, rigorous research training remained the hallmark of the graduate program for both experimental and clinical students. In 2010, students could specialize in the following Ph.D. programs: Biology, Behavior, and Neuroscience; Clinical Science; Cognitive Neuroscience; Cognitive Psychology; Developmental Psychology; or Social Psychology. Today, the department enjoys a secure reputation as an important scientific institution in psychology. Well into its second century, the legacy of the laboratory endures.

Industrial-Organizational Psychology

HAROLD TAKOOSHIAN

Fordham University, New York, NY, USA

Industrial-Organizational (I-O) Psychology is defined simply as "psychology applied to work" (APA 1971). It studies "work" in its broadest sense, including paid and unpaid effort, recreation, and any purpose-driven effort (sports, hobbies). Compared with other specialties, I-O is more "applied" – putting practice above theory, since it typically aims to solve specific problems, increase efficiency, and maximize outcomes.

For over a century, I-O psychology consists of four distinct sub-areas, each with its own history: (1) *Personnel*: fitting the individual to the current organization, using psychological tests and other methods to assess job applicants or current employees. (2) *Organizational*: fitting the organizational structure to its current individuals, through organizational development (OD) or other restructuring methods. (3) *Consumer behavior*: strengthening the organization's effective two-way communication with the outside world – both outward (advertising) and inward (market research). (4) *Human factors* (or ergonomics): adapting the physical environment to fit the worker, through diverse means – such as office architecture, equipment design, work schedules. Each specialty within I-O psychology has its own historical origins (Benjamin and Baker 2004) (see Table 1).

Personnel psychology is the oldest and once-largest specialty. It dates from 1890, when James McKeen Cattell (1860–1944) coined the term "mental tests." After raising this possibility to quantify individual mental abilities, Cattell soon devised 10 sensorimotor tests to select graduate students for his program at Columbia University; 30 years later, Cattell founded the Psychology Corporation in 1921, which still continues to apply psychological assessments to improve

Industrial-Organizational Psychology. Table 1

Background of I-O psychology

1879 – Wilhelm Wundt “founds” the science of psychology, forming the first psychology lab in Leipzig
1890 – Columbia professor J.M. Cattell coins the term “mental test” in the journal <i>Mind</i> , and suggests 10 perceptual-motor tests which, by 1894, are part of Columbia’s procedure for selecting psychology students for admission
1901 – On December 20, W.D. Scott lectures on “The psychology of selling” to a group of Chicago businessmen. This popular idea quickly grew into four books starting with <i>The Theory of Advertising</i> (1903)
1911 – “Scientific management” arrives in F.B. Gilbreth’s <i>The Brick-Laying System</i> and F.W. Taylor’s <i>The Principles of Scientific Management</i>
1913 – At Harvard’s Laboratory of Applied Psychology, Prof. Hugo Munsterberg’s popular <i>Psychology and Industrial Efficiency</i> also sells applied psychology to industry
World War I – Psychologists and their new tests are called upon for selection and training of 1,700,000 military recruits. Their efforts proved enormously successful
1927–1939 – Psychologists and engineers conducting the “Hawthorne studies” document the importance of informal social relations among workers. This 12-year study of <i>Management and the Worker</i> (Roethlisberger and Dickson 1939), led to the “human relations movement”
World War II – Again, 2000 psychologists are recruited by the US military to develop new areas of I-O expertise: training, placement, and human factors
1971 – The APA Task Force report on the practice of psychology in industry
1987 – The industrial psychology group, which joined APA as its Division 14 in 1943, incorporated in 1987 its own Society for Industrial-Organizational Psychology (SIOP), now semi-autonomous of both APA and the then-new APS
2010: SIOP members considered changing its name, then voted to keep it

industrial and other organizations. This specialty took a huge step forward in 1917–1921, when a team of military psychologists was charged to develop new group ability tests to quickly assess thousands of the 1.7 million recruits drafted into service for World War I. In the 1920s, their work developing both verbal and nonverbal tests was seen as hugely successful, to

quickly match soldiers with assignments. Over the decades, psychology in industry burgeoned, to the point where in 1971 the American Psychological Association released an APA task force report focused on the growth and special challenges of what it now re-named “I-O” psychology.

Today personnel psychologists are charged with many tasks, all assessing the individual to better fit into the organization. This includes job analysis (the duties of a specific job), performance appraisal (how well the individual or unit is performing), recruitment of new employees, selection and placement of job candidates, training, job design, safety, and personnel decisions.

Organizational psychology originated in the pioneering work on “scientific management” around 1910 by Frederick W. Taylor (1856–1915) to make US industry more competitive. Later, the classic “Hawthorne studies” conducted in the Western Electric plant in Hawthorne, Illinois, in 1927–1939 documented how workers’ feelings toward their employer impact their performance – maintaining that it is the wise employers who make their workers’ satisfaction a goal alongside productivity. These Hawthorne studies were later debunked as flawed, but not before launching a powerful “human relations movement” (HRM) in US industry. In 1960, Douglas McGregor (1906–1964) published his classic HRM manifesto entitled “The human side of enterprise” (McGregor 1960). This “O” in I-O surpassed personnel as the largest I-O specialty after the 1950s, due to many factors – the massive growth in the size and complexity of US corporations, as well as the growth of service (versus production) workers from 20% to 80% of the US work force.

Today, organizational psychologists try to adapt the organization to fit its current employees on two levels: (1) management psychology, focused on diverse ways to improve leadership; (2) human relations, focused on diverse ways to motivate employees in general. Some key topics in organizational development are: worker motivation, satisfaction, person-environment fit, employee attitudes surveys (EAS), organizational citizenship behaviors (OCB), burnout, payment/benefit systems, stress, employee assistance programs (EAP), training and development.

Consumer behavior originated back in 1901 with an immensely popular series of pre-Christmas lectures to a group of Chicago businessmen on “the psychology of

selling” by Walter Dill Scott (1869–1955), which quickly became a book *The Theory of Advertising* (Scott 1903). Starting in the 1930s, psychoanalyst Ernst Dichter (1907–1991) introduced “Motivation research,” probing the unconscious factors in consumer attitudes. After World War II, war-time research on propaganda, along with the growth of corporations in general and Madison Avenue advertising in particular, led hundreds of psychologists into consumer research and practice.

Today, psychology’s role has waned in consumer behavior, and is divisible into two specialties. (1) *Advertising* focuses on the effectiveness of the organization’s outward communication – to the public, policy-makers, and others. (2) *Market research* focuses on the accuracy of inward communication into the organization from the outside – the public, policy-makers, and others. For example, Sony Electronics conducts market research to learn what new products the public desire so that it can design them, then advertises to draw the public toward these new products. Because of their training in methodology (experiments, surveys, statistics), psychologists are now far more involved in marketing, leaving advertising more to non-scientists. Moreover, in large corporations, there is typically a healthy tension between these two functions, since the role of the marketing department is to objectively assess the impact of the advertising department.

Human factors originated in the pioneering work around 1910 by F.W. Taylor and his colorful colleagues Frank B. Gilbreth (1868–1924) and his wife Lillian Gilbreth (1878–1972). This couple pioneered “time-motion” research which revolutionized the ancient craft of brick laying, and was initially welcomed by labor unions as much as management for gains in work efficiency. The Gilbreths wrote “Cheaper by the dozen,” applying their efficiency methods to run a 12-child household, and in 1984 Lillian became the first psychologist to be honored with a US postage stamp. During World War II, ergonomics advanced apace with the need for pioneering new methods to develop “person-machine” systems, to maximize the safety of complex new equipment – airplanes, submarines, and other new devices.

Today, ergonomists are involved in diverse ways to harmonize workers with their physical environment: time-motion analysis, operator-machine systems,

workspace design, open architecture offices, safety and accident-reduction.

Compared with other fields of psychology, I-O psychology today has several features: (a) *Small*: I-O is a small specialty, including just 5% of US psychologists. (b) *High-employment*: Since I-O is in high demand in the industry; it has a negative unemployment rate below zero. (c) *Lucrative*: I-O has long had the highest salary, averaging at least 25% higher than 14 other psychology specialties. (d) *Separate*: I-O has become a very separate specialty within psychology, with its own independent association since 1987 – the Society for I-O Psychology (SIOP). (e) *Hybrid*: I-O overlaps with business and other social sciences. (f) *Credentials*: There is no one credential to define who is an I-O psychologist – be this a M.A., M.S., M.B.A., Ph.D., Psy.D., state license, APA or SIOP membership, or ABPP Diploma. (g) *Demographics*: SIOP members today are 6% ethnic minorities, 37% female, only 26% licensed, and 85% have a doctorate. I-O work settings vary greatly – employees in large firms, small “boutique” consulting firms, professors in psychology or business programs, or solo-practitioners.

Several useful volumes offer different overviews of I-O psychology. Riggio (2008) offers a textbook for students and novices. Jones et al. (1991) offer a practical handbook for managers to find research-based solutions to common questions. Dunnette and Hough (1990–1994) offer the definitive four-volume handbook of I-O psychology. There are also numerous web resources on I-O psychology (www.siop.org), *human factors* (www.hfes.org), *human resources* (www.hrny.org), and *the many divisions of psychology in general* (www.apa.org/about/divisions).

Today, I-O psychology faces several challenges – such as globalization of organizations, the increased diversity of the US workforce, increased regulation by government and labor law, and the changing nature of work. These same challenges make a science-based I-O psychology more indispensable to successful organizations.

Irwin, Orvis

HARRIS WINITZ
University of Missouri-Kansas City, Kansas City,
MO, USA

Orvis Irwin received his Ph.D. in psychology from Ohio State University in 1929, and as a professor of psychology at the Iowa Child Welfare Research Station,

beginning around 1945, he initiated a series of studies on the speech sound development of infants. This period of language development, often referred to as the babbling stage, had been given only limited attention in biographical accounts of the psychosocial development of infants. As electronic recording was not available at the time Irwin's investigations were conducted, Irwin began his research by establishing a system of examiner reliability. Large numbers of infants were included in each of his meticulously conducted investigations which reported the growth of the sounds of English-speaking infants from birth to 30 months. The results of these investigations served as the basis for descriptive and theoretical accounts of speech sound development and provided a foundation for later investigators when electronic sound recording, speech sound spectrography, and X-ray technology were available and when comparisons could be made among infants from a variety of linguistic communities and when the effect of various stimulus conditions could be assessed.

J

Jahoda, Gustav

CARL RATNER

Institute for Cultural Research and Education,
Trinidad, CA, USA

Basic Biographical Information

Birth date: October 11, 1920.

Birth place: Vienna, Austria; naturalized British subject
Educated Vienna, Paris, and London.

Major Accomplishments

Prof. Jahoda was perhaps the first modern cross-cultural psychologist. He has done pioneering research that plumbed important methodological issues.

As a young lecturer in social psychology at the University of Manchester, he went, in 1952, to what was then the Gold Coast (now Ghana). This was long before there was such a thing as cross-cultural psychology, which did not emerge until the 1960s, and IACCP was not founded till 1972.

He tried but failed to replicate some social psychology experiments, which left him with permanent reservations about that area.

At that period, the IQ of Africans were not infrequently regarded as inferior, and in particular they were said to be (in reputable publications) incapable of abstraction. In a series of experiments, the falsity of such generalizations was demonstrated.

After spending 5 years in Africa, he set up a new department at the University of Strathclyde. For the next two and a half decades, he returned regularly to Africa, and also did research in India and Hong Kong. His main research topics included susceptibility to visual illusions, space perception, and cognitive development.

Most studies administering Piagetian tasks to African children reported that they perform at a lower level than young Genevans. He suspected that the reason was the latter's greater familiarity with the materials, so that one could reverse the relationship by finding a sphere more familiar to African children. He proved this by using ecologically valid tests.

Other evidence shows that with rapid social change, the gap between the performances of African and European children is closing.

Whereas Jahoda was closely involved in the groups from which his subjects came, he laments that most cross-cultural today rarely have personal contact with participants. They typically ask colleagues in third world countries to administer questionnaires or scales for them. Jahoda finds this trend disconcerting.

He also feels that typing societies as individualistic or collectivistic is reified and misleading because it obscures the diversity within societies. Jahoda favors more concrete, situational descriptions of social conditions. This enables the researcher to explore specific processes that link culture and psychology.

Jahoda's *Crossroads between Culture and Mind* masterfully traces the history of cultural psychology, especially developments in the eighteenth century and German idealistic *Volkerpsychologie*. He addresses the crucial question of whether psychological science should/can be a universal science or a culturally specific discipline that varies in different societies.

Janet, Pierre

DAVID O. CLARK

Independent Scholar, Lincoln, NE, USA

Janet's obituary in *The Psychological Review* (1949) begins, "This year saw the death of a man whose name will be one of the great landmarks in the history of psychology." Janet was the dean of French psychology after Charcot, Binet, and Ribot died, according to Boring, *A History of Experimental Psychology* (1950). Janet stood at the threshold of all modern dynamic psychology according to Ellenberger, *The Discovery of the Unconscious* (Ellenberger 1970). Among the psychologists influenced by Janet were Eugen Bleuler, Carl Jung, Alfred Adler, Sigmund Freud, and Edwin Guthrie.

Janet was born in Paris, he was a gifted student, and he received a privileged education. He began teaching philosophy in secondary schools. He became interested in psychology and volunteered at a hospital in Le Havre where the doctors allowed him to observe patients. At that time he was looking for topic for a doctoral thesis, and there he met a woman who could be hypnotized at a distance. She became his research subject, and subsequently she provided the opportunity for Janet's area of investigation, hysteria. This research introduced Janet to scientific psychology. His approach to psychology was influenced by Theodule Ribot (1839–1916). Ribot was the first person to hold the chair of experimental and comparative psychology at the College of France, and he was a significant figure in introducing the new, scientific psychology, in France. Janet's dissertation was titled *Psychological Automatism: Experimental-Psychological Essay on the Inferior Forms of Human Activity*. Therein, his purpose was to reveal elementary automatic activity that was normally inhibited by higher mental functions.

Janet's dissertation introduced the automatism as the irreducible object of study. His dissertation was noteworthy in the history of psychology because of his treatment of automatisms (the more or less complex purposive acts of behavior) in terms of conscious versus subconscious control. Janet

introduced the "subconscious" to the status of psychological phenomena. When consciousness was the undisputed object of psychology, Janet argued that phenomena that were unconscious were also within the field of psychology. This means that psychology remained the science of the consciousness, but for Janet the observed scientific object becomes behavior made manifest in purposeful activities, activities often inaccessible by the method of introspection.

With regard to Janet's method, science required identification of elementary units followed by their individual study. For Janet, the automatism was the irreducible element, and his choice was significant when most psychologists had selected the sensation as the basic starting point from which to analyze the mind. The automatism (reoccurring organized behaviors) followed an autonomous and subconscious development: That is common habits were often learned outside of complete awareness. Historically, the discovery of the unconscious can be interpreted as a chronological chain of events where religious exorcism was linked to animal magnetism that in turn was linked to hypnotism, and hypnotism provided the important research that linked suggestion to modern dynamic theories of psychology. Janet forged the link that provided a scientific explanation of hysteria.

In 1902, Janet succeeded Ribot as the professor of experimental psychology at the College de France. Janet was perhaps the most eminent representative of French psychology at the beginning of the twentieth century. Believing that in psychology there were too many explanations on too many narrowly defined subjects, he undertook the construction a unifying model of human psychology. From approximately 1909, Janet worked on a comprehensive theory of psychology. Basing his theory upon adult psychology, psychopathology, child psychology, ethnology, and comparative psychology, Janet emphasized the analysis of "tendencies." For practical purposes, for the English speaking reader, tendencies are synonymous with habits. Janet's concept of tendency seemed to evolve from his automatisms; although similar, they were different. With the automatism the emphasis was on an internal source of action while with the tendency, the emphasis shifted to

the probability of the occurrence of the activity of interest based on the given environment.

Janet's theory was expressed in *Medecine Psychologique* (1923). He said that he was taking up his previous studies from a new perspective, and the new view gave special emphasis to the basic principles and methods of psychotherapy. Janet advanced a social-behavioral theory to describe the conditions under which learning occurred. He believed that an individual's behavior was the result of the complicated functioning of a multitude of habits that were being constantly formed and modified. The acquisition of new habits relied on the well-known trial and error paradigm and conditioned reflex theories. True to his clinical experience, Janet's approach emphasized the untoward effects that followed the failure to progress apace toward successful habit formation. He believed that adaptation, and its deficiencies, were of the greatest importance in mental medicine. Emphasizing the central role of learning, the habit was treated as the fundamental unit of analysis. He used widely received learning paradigms to organize, illustrate, and conceptualize mental phenomena. He relied on the conditioned reflex theory that was attended with the familiar physiological terms of stimulus and response for concepts in the analysis. What distinguished Janet was his concept of "mental force."

Janet argued that energy was an important factor in the analysis of habit formation. He observed that his patients often lacked the ability to initiate successful responses to meet situational demands, and he attributed this failure to a lack of what he called "mental energy." Activity, behavior, implied that learning could not be divorced from physiology. Obviously, learning required effort, and Janet pointed out that learning required energy over an extended period of time. Thus, an energizing component was a dynamic principle that could be used for analysis. Boring, *The History of Experimental Psychology* (1950), recognized Janet's psychology as dynamic by saying that life for animals and plants was built around a continuous struggle for existence, and it was obvious that psychology had to consider the activity of the organism acting in accordance with internal tensions that represented the potentialities for action. Janet gave credit for this concept of mental force to William James's, *On Vital*

Reserves (1911). Janet assumed that acquiring a new habit required excess energy with which to generate the new combinations of movements.

Janet asked, what mechanism was at work in the mobilization of this energy? He assumed that energy was necessary to support responding through the necessary number of learning trials. He assumed that the amount of energy available to acquire new habits was not the same for everyone. Energy was clearly defined: A person's energy was diminished when they could no longer do what they previously had done, and energy was restored when the person regained the ability to carry out their previous activities. However, "mental energy" was not a simple concept. Attending the concept of mental energy was the concept of "psychological tension." For Janet, psychological tension pointed to the capacity of the individual to rise to the occasion with regard to both discrimination and the appropriate organization of activity. Learning was not only constrained by physical stamina, it was also constrained by the capacity of the individual to use their resources effectively. Together, the interaction between mental energy and mental tension formed the necessary conditions for successfully learning adaptive behavior.

The goal was to understand the critical balance between the primary conditions of learning: energy and tension. And the role of the psychotherapist was to analyze the client in terms of assessing their available energy and their capacities to organize it toward their goals. Expressed in terms of economy, the goal of psychotherapy was to plan a realistic mental economy for the individual, one that used his or her resources effectively. Janet believed that the psychology of behavior that proved so useful in the study of animals should be applied to describing even higher psychic functioning in terms of behavior and that someday mental disorders would be described solely in terms of action and conduct.

Japan, History of Psychology in

MIKI TAKASUNA

Tokyo International University, Kawagoe, Japan

Introduction

Before surveying the history of psychology in Japan, it is essential to first know that psychology or science of mind, in the modern definition, was not studied until the mid-nineteenth century. Prior to then, Japanese scholars were unaware of such possibilities. However, it does not mean that Japanese literature contained no descriptions of the human mind, just that it was not studied scientifically.

Consider Zen and its effect on Japanese psychology. Zen is a religious practice and a tradition that harks back to thirteenth-century Japan. Though applying Zen to psychotherapy began in the twentieth century, the essence of Zen practice or meditation lays in the quest for an undivided state of inner experience, which rejects any theory of mind or scientific analysis. Thus, Zen has been only a marginal topic for psychological research in the history of psychology in Japan (Kato 2005).

The new science called “psychology” was introduced in Japan at a time when the country was undergoing enormous changes, both societal and political. Unlike many other countries, psychology’s beginnings in Japan are easily identified in a timeline (described below in Historical background).

Definition

The history of psychology in Japan began in the 1870s, where it was imported from Western countries (prior to this is the prehistory period) (Oyama et al. 2001; Sato and Mizoguchi 1997; Sato and Takasuna 2003). The foreign study first required a name in Japanese, and this need was met by early pioneer Amane Nishi (1829–1897), who coined the word *shinrigaku*. Literally translated, *shin* means mind, *ri* refers to reason, and *gaku* implies knowledge or science. To this day, *shinrigaku* remains the current Japanese word for psychology. In 1888, Yujiro Motora (1858–1912), the first Japanese psychologist, propelled *shinrigaku* to the next phase by presenting the first lectures on psychophysics

at Imperial University. Twentieth-century Japan brought with it a sharp rise in the number of psychologists and research institutions. Before World War I (1914–1918), psychology was applied to industry and the military. Postwar, American psychology replaced the German influence of Gestalt psychology. Each of these periods is described below.

Accounts written by Japanese psychologists before World War II (1939–1945) often describe psychology’s existence in Japan before the mid-nineteenth century in terms of its connection to Eastern thinking (i.e., Buddhism and Confucianism). One example, *shingaku* (literally, mind science), was proposed by Baigan Ishida (1685–1744) and popularized in the eighteenth century. However, this *Sekimon* school of scholars not only educated people on how to realize the nature of themselves, but how they should serve the world, demonstrating the deep influence of Eastern thought. *Shingaku* is now considered a branch of Eastern moral sciences and is not associated with anything common to modern psychology, despite it sounding close to *shinrigaku*.

Historical Background

During the Edo era (1603–1868), Japan’s government enforced a rigid closed-door policy (1641–1854) against all Western countries (except the Netherlands), which seriously restricted the import and, so, impact of foreign knowledge. Beginning in the Meiji era (1868–1912), Japanese scholars were finally introduced to the many fields of Western science, including psychology. The sea change occurred in July 1853 when Commodore Matthew Perry (1794–1858) appeared off Japan’s shores with his squadron of four American warships. Though the Japanese government reconciled one-sided treaties with its new partners (USA, Great Britain, and France), a new desire to be accepted as an equal to the West provided additional incentive for Japan to overhaul its political system and open the door to Western social customs. Consequently, the modernization or westernization of Japanese society came about rapidly and continued until the early 1870s.

Throughout the Meiji Restoration (1867–1868), the revamped Japanese government endeavored to import various knowledge and techniques from Western countries. The new way of living dramatically transformed day-to-day life for Japanese citizens, being referred to

as *bunmei-kaika* (civilization). People adopted a Western lifestyle, such as wearing Western clothes and hats and using electric lamps and solar calendars. Besides foreign material goods, Western religions were more widely accepted, whereas Christianity had been officially forbidden from the beginning of the Edo era until 1873 when both Catholic and Protestant churches were acknowledged. Because many Japanese intellectuals considered Christianity to embody the spirit of Western civilization, missionary schools welcomed these innovators with access to Western knowledge. The schools not only produced clergymen but also leading social critics and scholars, including Matora.

The Meiji government threw itself wholeheartedly into the new goal of Western acceptance by dispatching many Japanese students to Western countries – at government expense – to absorb new scientific knowledge and bring it home. Yet, this support did not include those pursuing the subjects of psychology and the humanities as these were generally not considered urgent or practical for supporting Westernized society, compared to, say, medicine or law. Hence, scholars who majored in psychology (and at that time, philosophy) did not enjoy learning abroad at national expense until much later. For years until World War II concluded, studying abroad was regarded as a prerequisite to obtaining a professorship at a national university.

Key Issues

Timeline of the History of Psychology in Japan

1870s–1888: Introductory Period

The introductory period is characterized by two landmarks: coining *shinrigaku* and introducing the new field into the modern educational system. Nishi, who went to the Netherlands from 1862 to 1865, studied economics, philosophy, and politics at Leiden University. After returning to Japan, he translated the book *Mental Philosophy* by American philosopher Joseph Haven, whose first edition was published in 1857. In 1875, Nishi published the first part of the Japanese edition, *Shinrigaku*. Though no direct connection exists between Nishi's study in the Netherlands and the birth of psychology, his claim to the term *shinrigaku* marked a turning point because many schools were

simultaneously applying the word into curricula (Kaneko 1987). Ironically, Nishi originally used the term as an abbreviation of mental (*shinri-jo-no*) philosophy (*tetsugaku*), not as an exact translation of psychology, but this is moot since the term has been used to refer to psychology ever since (Nishikawa and Takasuna 2005).

In 1877, the Meiji government established Tokyo University as the first national university in Japan. However, there was a dearth of Japanese professors to teach the new sciences including psychology. Nishi never qualified for professorship because he had not formally matriculated at a foreign university. Note that although many foreign educators were hired at various schools early in the Meiji era, virtually none specialized in teaching psychology. Add to that the limited number of visiting foreigners who presented lectures in philosophy, ethics, and psychology to Japan's university students further hamstrung the field.

Therefore, because decades came and went where the entire history of Western philosophy was unknown to Japan, it is not surprising that when knowledge from Plato to Hegel finally arrived, it did so all at once. And so it fell to the first generation of philosophers, including early psychologists, to translate Western literature into Japanese and to conceive Japanese terms that corresponded to the new concepts. Some examples of newly invented words included those that translated to “philosophy,” “consciousness,” “attention,” and “representation.”

Masakazu Toyama (1848–1900) was one of the few Japanese professors at Tokyo University. He had previously studied chemistry and philosophy at the University of Michigan (1873–1876). Toyama became the first Japanese professor to lecture on psychology, emphasizing his talks on the English writings of Alexander Bain (1818–1903) and Herbert Spencer (1820–1903) (Matsumoto 1937). Toyama did not contribute theoretically to the psychology field in terms of writing papers or textbooks, but he advanced the field in two ways. In 1888, he helped bring experimental psychology to Japan by appointing Yujiro Matora, a new lecturer of psychology at Imperial University (renamed from Tokyo University in 1886). And he helped spread the concept of evolutionary theory within Japanese academia.

Toyama secured the 2-year appointment of Edward S. Morse (1838–1925), an American zoologist who,

fortuitously, was visiting Japan in 1877 to collect samples of brachiopods (lamp shells). In September 1887, as professor at Tokyo University, Morse presented the first lecture on Darwinian evolutionary theory. His anxiety over a potential audience backlash was unfounded, as the theory of evolution became nationally accepted by the Japanese without remarkable objection. The easy approval came likely because Japanese people were familiar with wild monkeys that widely inhabited Japan, particularly Japanese macaques and their seemingly human attributes.

1888–1912: Motora's Contribution

Modern psychology that featured psychophysics and experimental psychology was not fully introduced to Japanese students until 1888 when Yujiro Motora began lecturing on psychophysics. Motora had been interested in Western knowledge since his youth and went abroad to the United States (USA) in 1883. After 2 years of studying philosophy and theology at Boston University, Motora continued on to Johns Hopkins University, mostly to study under G. Stanley Hall (1844–1924), whose psychology laboratory was founded in 1883. Motora's experimental studies on dermal sensitivity using psychophysical methods resulted in his coauthoring a paper with Hall. Published in the inaugural volume of the *American Journal of Psychology* in 1887, it became the first psychological paper by a Japanese scholar. In 1888, Motora completed his dissertation and was awarded a Ph.D. (in philosophy, not psychology).

When Motora returned to Japan, Toyama, the Dean of the College of Letters at Imperial University, invited him to teach a psychophysics course. Consequently, Motora began there as part-time lecturer beginning September 1888. This opportunity also allowed him to demonstrate a few experiments to the students. Motora achieved professorship in 1890, the year he published the textbook *Psychology*. It was Japan's first textbook of scientific psychology and included several figures of the brain and geometric optical illusions. Shortly thereafter, in 1893, Imperial University established a chair system that supported two professors in "psychology, ethics and logic" independent from the philosophy chair. Motora was appointed to one of the chairs and began lecturing not only on psychology but on ethics and logic. Rikizo Nakashima

(1858–1918), who obtained a Ph.D. in philosophy at Yale University in 1889 and specialized in ethics, was appointed to the second chair.

To enable further pursuit of psychology research, a few more implementations were necessary. First, a curriculum was needed so students could learn concepts and theories in modern psychology on a university level. Making psychology coursework available would lead to increased numbers of students majoring psychology. This in turn would ultimately make viable the publishing of a scientific journal specializing in psychology, the founding of a society of psychologists, and eventually the holding of a nationwide conference on psychology. While the burgeoning of psychology in Japan followed this path, establishing a psychological society with regular conference was not realized until the 1920s.

Motora established the first psychological laboratory in 1903 at Tokyo Imperial University (as renamed in 1897), following up in 1904 with a newly implemented course of study. Finally, undergraduates were allowed to major in psychology within the Department of Philosophy at the College of Letters (Sato and Sato 2005). This revolutionary change tacitly acknowledged the acceptance of psychology as an independent course of study within the academic curriculum, although no change was made to the bachelor's degree awarded.

The second laboratory was settled in 1908 at Kyoto Imperial University (founded in 1897) by Matataro Matsumoto (1865–1943), one of Motora's earlier students. Matsumoto received his undergraduate degree from Imperial University in 1893 and continued on as a graduate student with experiments on acoustic space. After attending a lecture by George T. Ladd (1842–1921), a professor of moral philosophy and metaphysics at Yale University who was visiting Tokyo in 1892, Ladd encouraged Matsumoto to go to Yale. In 1896, Matsumoto entered graduate school in psychology at Yale to conduct experiments under Edward W. Scripture (1864–1945), receiving his doctorate from Yale in 1899. In 1906, when a new College of Letters was established at Kyoto Imperial University, Matsumoto was appointed to the psychology chair, the first chair dedicated solely to psychology. Two years later, in 1908, Matsumoto established a second psychological laboratory in Kyoto.

Motora presented a paper, “The idea of ego in oriental philosophy,” at the fifth meeting of the International Congress of Psychology (ICP) held in Rome in 1905. Motora was not the first Japanese to present at an ICP as two Japanese scholars presented their research at the ICP’s fourth meeting in Paris in 1900: Tomeri Tanimoto (1867–1946) specialized in pedagogy, and Tongo Takebe (1871–1945) was a sociologist. However, the first for both the ICP and Japanese scholars was the appointment of Motora and a pediatrician, Yasusaburo Sakaki (1870–1929) as committee members. The ICP had never before extended the invitation to anyone outside Europe or North America (Rosenzweig et al. 2000).

Although Motora conducted experiments with Shuzo Kure (1865–1932), a professor of psychiatry at Tokyo Imperial University, no Japanese psychologist graduated from a Western-style medical school, such as that corresponding to the education of Wilhelm Wundt (1832–1920) in Germany or William James (1842–1910) in the USA. As a result of Western medicine arriving in Japan not much earlier than psychology, it did not impact the development of psychology. After Motora’s death in 1912, Matsumoto moved from Kyoto to Tokyo Imperial University to chair the psychology department. The new position included endorsement of applied research and rejection of abnormal psychology (see later section of Fukurai Affair).

1910s–1920s: Burgeoning of Psychologists

When the first volume of *Shinri Kenkyu* (literally, psychological research) was issued in January 1912, it signals Japan’s first foray into publishing periodicals specializing in psychology. Yoichi Ueno (1883–1957), one of Motora’s students, compiled virtually the entire journal. *Shinri Kenkyu* reigned as the sole psychological journal until 1919 when *Nihon Shinrigaku Zasshi* (literally Japanese psychological journal) came into print in Kyoto. The new journal was rather short lived (the final volume was published in 1922), mainly due to economics. Not long after, in 1923, *Nihon Shinrigaku Zasshi*, a new quarterly journal with the same name was published in Tokyo. Since both editorial offices were connected with the Department of Psychology at Tokyo Imperial University, in April 1926, *Shinri Kenkyu* and *Nihon Shinrigaku Zasshi* were integrated into a single,

new periodical, *Japanese Journal of Psychology* (*Shinrigaku Kenkyu*).

Meanwhile, the College Act enacted at the end of 1918 finally allowed private schools to be officially acknowledged as colleges or universities provided they met specific requirements. In due course, new psychological laboratories blossomed at various universities, totaling 15 laboratories by the beginning of World War II: six imperial universities (Tokyo, Kyoto, Tohoku, Kyushu, Keijo, and Taihoku), two national universities (Tokyo Bunrika and Hiroshima Bunrika), and seven private universities (Kwansei Gakuin, Nihon, Keio, Doshisha, Hosei, Waseda, and Rikkyo) (Japanese Psychological Association 1980).

From the late nineteenth century to the beginning of the twentieth century, many Japanese psychologists visited Wundt in Leipzig, Germany. The only Japanese psychologist to receive a doctorate from Leipzig was Umaji Kaneko (1870–1937), who earned Ph.D. in 1904 (Oizumi 2003). His dissertation, *Moralphilosophie Adam Ferguson’s*, was evaluated by Max Heinze (1835–1909) and Wundt. Motora chose to study for his Ph.D. under Hall, one of the first American students to attend Wundt’s seminars. Matsumoto’s dissertation was directed by Scripture, who also obtained his Ph.D. under Wundt. Thus, the early years of Japanese mainstream psychology were influenced by Wundtian psychology as modified by American psychologists.

Wundt’s influence was such that not even his death deterred Tanenari Chiba (1884–1972), an associate professor at Kyoto Imperial University, from traveling to Germany at the end of 1920 for additional psychology studies. While staying in Leipzig, he was nominated as the first chair of the psychology department at newly founded Tohoku Imperial University. Shortly thereafter, Chiba discovered a large collection of books and journals once owned by Wundt for sale at a bookstore in Leipzig. He promptly decided he must procure them for his new psychological laboratory. After a period of negotiation, he purchased so-called *Wundt Bunko* (the Wundt Collection consisted of 6,762 books and 9,098 reprints) and successfully shipped them to Japan. Since then, the *Wundt Bunko* has been well preserved at the Central Library of Tohoku University (Takasuna 2001).

Matriculation to a college or university did not include women in nineteenth century Japan. Around

the turn of the twentieth century, a few schools for women emerged with the word “college” attached to them (e.g., Japan Women’s College, founded in 1901 in Tokyo); none was officially acknowledged as a college or university, even after passage of the 1918 College Act. It took enacting the School Education Law in 1947 for women to realize opportunities in higher education, but some women managed to skirt the problem before then (Nishikawa and Takasuna 2005, chap. 13).

Tsuruko Haraguchi (née Arai, 1886–1915) entered Japan Women’s College in 1902, where she became intrigued by psychology lectures given by Matsumoto. As graduation time neared, she consulted Matsumoto about furthering her studies in psychology. With no access to pursuing graduate work in Japan, he encouraged her to study psychology abroad. In 1907, Haraguchi traveled to New York where she entered the graduate program at the Teachers College of Columbia University. There she conducted experiments on mental fatigue under the direction of Professor Edward L. Thorndike (1874–1949). The Ph.D. she obtained in 1912 was the first for any Japanese woman in any field. Despite her early death in 1915 at the age of 29, she inspired two more Japanese women psychologists to obtain a Ph.D. in the USA before the onset of World War II.

Tomi Kora (née Wada, 1896–1993) completed her experiments on the effects of hunger, in collaboration with Curt Richter (1894–1988). The work, carried out under the supervision of Thorndike, led to her Ph.D. from Columbia University in 1922. Sugi Mibai (1891–1969), who studied at the University of Michigan under Walter B. Pillsbury (1872–1960), received her doctorate in 1931. Of the six imperial universities mentioned above, Tohoku Imperial University was the first to matriculate female students. Further, the university’s Department of Psychology was the first to graduate a female student. Tsuyako Kubo (née Kurose, 1893–1969) not only graduated from Tohoku Imperial University in March 1926, but was in the inaugural group of students (both male and female) to major there in psychology.

By the 1920s, numerous Japanese psychologists claimed travel to Europe and the USA, enough for many among them to feel the necessity of founding a nationwide psychological society in Japan like those founded in other countries. Some societies had already

been established at the local level, but the first national psychological society in Japan, the Japanese Psychological Association, was not founded until April 1927. Its inception was announced during a session of “The First All-Japan Congress of Psychology” at Tokyo Imperial University, which was later counted as the first meeting of the Japanese Psychological Association. Matsumoto was elected its first president, and 30 psychologists were chosen as committee members. *Japanese Journal of Psychology*, which had begun publication the previous year, became the official periodical edited by the association (Nishikawa 2005).

World War I stimulated the military’s interest in applied psychology. Three major institutes prominent in this aspect of the war effort include the Institute of Aeronautics at Tokyo Imperial University, the Japanese Imperial Navy, and the Japanese Imperial Army. The Institute of Aeronautics at Tokyo Imperial University was originally established in 1918, and after consulting with Matsumoto, the Department of Aeronautic Psychology was established there in 1920 where it was conveniently arranged close to the psychological laboratory. Throughout the 1920s, Koreshige Masuda (1883–1933), Yenjiro Awaji (1895–1979), and their colleagues based at Tokyo Imperial University chiefly studied the psychological and physiological influences of aviation (Osaka 2000; Sato and Mizoguchi 1997).

Early on, naval officers conducted their own research at Tokyo Imperial University’s psychological laboratory. In April 1918, Matsumoto was appointed as an advisor to the Investigating Committee on the Navy’s Application of Experimental Psychology, a post he held until 1919. As part of his job, Matsumoto traveled to the USA to investigate the ways the military applied psychology to its servicemen. Upon return to Japan, Matsumoto wrote a report on the “army intelligence tests” used in the USA. This motivated Japan’s military to develop a similar group intelligence test to be administered by psychologists in Tokyo. In 1925, the Naval Institute of Technology established a division to evaluate aptitude, with testing carried out through 1926. In reality, intelligence tests served as aptitude tests to identify soldiers best suited to be telegraphers, artillerymen, machinists, or pilots (note that by the end of World War II, the Japanese flying corps had separate branches for the army and navy).

The Military Academy of the Army hosted psychology lectures as early as 1921. In 1924, the army conducted the first intelligence test, which consisted of nine subtests given to 4,633 subjects. The results suggested that some subjects had aptitudes for telegraphy, engineering, or combat. However, unlike the navy, the army did not carry out full-scale psychological studies until the 1940s.

1920s–1945: Prevalence of Gestalt Psychology

Psychological studies carried out in Japan during the 1920s and 1930s were distinguished by the popularity of Gestalt psychology (Misiak and Sexton 1966, chap. 16; Oyama et al. 2001). Though this branch of psychology originated at the Frankfurt/Berlin school of Gestalt psychology, it did not arrive in Japan via Germany. Instead, it was Sadaji Takagi (1893–1975), a student who had been studying psychology at Cornell University under Edward B. Titchener (1867–1927) from 1919 to 1921, who brought home the new knowledge (Matsumoto 1937). Because virtually no Japanese scholars studied psychology in Europe over the course of World War I, Takagi's report on Gestalt psychology made an impact. He talked about it at a 1921 meeting at Tokyo Imperial University after returning to Japan, which was attended by Matsumoto's past and present students. Among them was Kanae Sakuma (1888–1970), who eventually left Japan in 1923 to study Gestalt psychology in Berlin for 2 years. Later, one of Sakuma's works on visual perception was published in *Psychologische Forschung* in collaboration with Kurt Lewin (1890–1947).

From the 1920s to the early 1940s, about 30 Japanese psychologists studied abroad in Germany. These two decades comprised one of the most prolific eras for Japanese psychologists in terms of publishing in foreign journals, especially those written in German and in the field of perception. With Leipzig and Berlin corresponding to the hubs for Chiba and Sakuma, respectively, the two cities were the most frequently selected for study by Japanese psychologists by the end of World War II. Usao Onoshima (1894–1941) was another Japanese representative of Gestalt psychology. He and Sakuma boarded the same ship from Japan to Europe in 1923.

Since Onoshima and Sakuma received much assistance from Lewin during their stay in Berlin, when in 1933, arrived to lecture in Tokyo and Fukuoka, both were present to welcome him at the Port of Yokohama. Lewin's visit triggered a second boom of Gestalt psychology in Japan, so described because his first influence in the early 1930s resulted in the formation of a Gestalt study group in Tokyo. Called "*Lewin Klasse*" (Lewin's class), the name reflected Lewin's significant influence on Japanese psychologists. The group's name was later renamed the "Thursday Group" since university students were afraid of mistaking the handwritten "Lewin" for "Lenin" (Sato and Mizoguchi 1997).

Prior to and during World War II, Gestalt psychology influenced experimental studies on perception and influenced the application of holistic theory to education. Immediate impacts were seen in studies on perception, where size constancy was most popular with Japanese psychologists. "Psychophysiological induction," a unique contribution to perceptual theory in 1930s and 1940s, was proposed by Torao Obonai (1899–1968) whose theory first appeared in 1933, antedating the field theory presented by Wolfgang Köhler (1887–1967) in 1938.

Gestalt psychology also influenced the fields of educational psychology and developmental psychology, being somewhat mixed together with *Ganzheit* psychology, another holistic psychology trend in Germany. Katsujiro Iwai (1886–1937) and Ichiro Fukutomi (1891–1946) studied *Ganzheit* psychology at Leipzig in the 1930s. Although Iwai and Fukutomi understood the difference between Gestalt and *Ganzheit* schools of thought, Gestalt overshadowed *Ganzheit* for most Japanese psychologists. Nevertheless, in the 1930s and 1940s, *zentaisei* (the Japanese translation of totality or *Ganzheit*) was used more frequently in Japanese education since the German word "Gestalt" was a somewhat more difficult concept for non-psychologists to grasp (Takasuna and Sato 2008).

Japanese psychologists were interested not only in laboratory experiments, but also in practical application of such findings. Within the first decade of the twentieth century, Morota had devised a special apparatus to measure children's attention span. By the beginning of the 1910s, Japanese companies such as the Fukusuke Tabi Corporation in Osaka were attempting to apply psychology to advertising and

industrial efficiency. In 1931, the Association of Applied Psychology in Tokyo was born due to the proliferation of applied psychology. The first volume of its periodical, *Journal of Applied Psychology*, appeared in 1932. Though the Kansai Association of Applied Psychology had already been founded in 1927, because it lacked its own periodical, the Association of Applied Psychology is considered Japan's second psychological society. The two societies often convened joint meetings, then integrated after World War II in 1946, and finally emerged as the newly named Japan Association of Applied Psychology.

The Society for Animal Psychology, founded in 1933, was the third and last psychological society to function before World War II. Masuda's pioneering work at Tokyo Imperial University likely inspired other comparative psychologists to follow in his path, as evidenced by the output of more than 100 papers and articles on the subject within 35 years, beginning from the end of World War II. Although the society's first two presidents were biologists, psychologists took initiative from Takagi, the third president and one of the first Japanese psychologists to apply Gestalt laws to animals. The periodical *Animal Psychology*, issued quarterly from 1934 to 1938, was followed by *The Annual of Animal Psychology* from 1944 until 1990, after which it was renamed *Japanese Journal of Animal Psychology*.

Once there was closure on the Manchurian Incident (1931), Japan pushed forward into what historians called "the dark valley," the decade of global catastrophe. Japan dealt with its severe economic and ideological crisis by officially adopting a "General Mobilization of National Spirit" in September 1937. Established by the Japanese Cabinet, the guidelines were introduced in a national effort to promote citizen cooperation in regard to financial and national ideologies. Psychologists were influenced by the guideline touting frugality because the general meetings of academic societies were costly. Subsequently, the Japanese Psychological Association and the Association of Applied Psychology chose to meld with two smaller societies (Kansai Association of Applied Psychology and Society of Mental Technology). In July 1941, the now-unified group emerged as the Psychological Association. Both the 1942 and 1943 annual meetings of the new association convened in Tokyo; the 1944 meeting, to be convened

at Kyoto Imperial University, was cancelled due to the worsening situation of World War II (Nishikawa 2005).

The theme of "national unity" (*kyokoku-itchi*), as stated in the guidelines, was reflected in various journal and newspaper articles from the late 1930s until World War II's conclusion. By that time, education in Japan had already taken on certain aspects of totalitarianism or ultranationalism. The view that all children were equal to one another under the Japanese emperor stifled the concept of individuality. Thus, intelligence tests were more frequently evaluated as groups of data, instead of evaluating data from individuals. For example, from 1933 to 1936, Kan'ichi Tanaka (1882–1962), known for publishing the Tanaka-Binet Intelligent Scale in 1947, collaborated with the Ministry of Education to compare intelligence levels among various Asian groups (i.e., urban children from Korea, Manchuria, Taiwan, China, and Japan).

By 1941, students were mobilized to the war effort, which halted psychology lectures at the universities and colleges. Psychology research was severely hampered, particularly toward the end of war, due mainly to the shortage of paper goods – necessities for taking notes and administering and scoring tests. Professional exchange was also stunted: The *Japanese Journal of Psychology* managed only one issue of Volume 19 (appearing September 1944) before ceasing publication for 2 years.

1945–1972: Catch-up Period

After defeat in World War II (August 1945), Japan experienced a period of so-called "Occupation" (1945–1952). General Douglas MacArthur (1880–1964) was in charge of The General Headquarters of Supreme Commander for Allied Power (GHQ/SCAP) that included a division called Civil Information and Education (CIE). This department was responsible for democratizing Japan and introducing an American system of education. The GHQ/SCAP, along with the CIE, played important roles in further developing psychology in Japan.

The reform of Japan's university/college system in 1949 completely transformed Japan's half-German-style educational system into a fully American style and increased the number of 4-year universities and colleges. Private universities, including women's colleges, were now legally allowed to become universities.

Every national and public university as well as college was renamed. Each prefecture's Normal School was upgraded as was each school of teacher education, the latter being incorporated as its own department on campuses of the new national universities. Consequently, the overhauling and implementing the curriculum for national universities and resuming the international exchange of students not only changed Japan's educational system, but significantly impacted Japanese psychologists (Sato and Mizoguchi 1997).

The Law for Certification of Education Personnel, simultaneously enacted, pushed many universities into offering a teacher-training course for those wanting to instruct at junior high and high school levels. Here, "educational psychology" and "adolescent psychology" were compulsory subjects. As a result, there was a great demand both for qualifying psychologists to become teachers and psychologists qualified to teach at the newly established universities.

One of the first student exchange programs post-World War II was sponsored by the USA through the Government Appropriation for Relief in Occupied Areas Fund (GARIOA). In 1949, the GHQ/SCAP selected 50 young professors from various Japanese universities and sent them to study in the USA. Five psychologists were among the first scholars selected for the exchange program. That all five of them graduated from *bunrika* universities, whose graduates were influential in Japan's educational world, reflected the extent that GHQ/SCAP believed in the importance of reconstructing the psychology field in terms of education. The GARIOA program continued until 1952 when the Occupation ended and the Fulbright Program was initiated.

A great thirst for information about new psychological findings followed the extended drought brought on by an absence of available foreign journals during the 1940s. One fresh trend was neobehaviorism. Though a Watsonian type of behaviorism had previously been introduced in various articles during the 1910s, there was not enough interest to spark experimental study pre-World War II. However, after the war, the number of papers on learning increased rapidly, with about half of those studies directed at learning in animals. Japanese psychologists were aware of the series of studies carried out by Edward C. Tolman (1886–1959) in the 1930s because they were similarly aligned

with the popular Gestalt theory. Yet, once the war was over and Clark L. Hull's (1884–1952) papers on learning and behavior became available, Japanese psychologists were finally stirred to study this area. Hull was cited so frequently, especially from his *Principles of Behavior* (1943), that the work was eventually translated into Japanese in 1960, confirming his influence in the history of psychology in Japan.

By the mid-1960s, eight psychological societies had been founded, including three established before World War II: Japanese Psychological Association (founded in 1927), Japan Association of Applied Psychology (founded in 1931), Japanese Society for Animal Psychology (founded in 1933), Japanese Group Dynamics Association (founded in 1949), Japanese Association of Educational Psychology (founded in 1952), Japanese Society of Social Psychology (founded in 1960), Japanese Association of Criminal Psychology (founded in 1963), and Japanese Society of Clinical Psychology (founded in 1964) (Kaneko 1987). These societies indicated that psychology in Japan was proliferating and maturing. The next step would be a high-profile engagement with the international community of psychologists.

Though Japan had been elected one of 11 original charter members of the International Union of Psychological Science (organized in 1951), not until 1960 was Japanese psychologist Koji Sato (1905–1971) elected to the executive committee. Until then, regardless of a century of contact with Western psychology, international exchange of Japanese psychologists with those in other countries had been inexcusably one-sided (Iwahara 1976). Further, too few Japanese contributed to and participated in international activities. Now finally ensconced in a position of power, Sato lobbied to secure Japan as the destination for the next conference.

Catch-up time for Japanese psychologists culminated in the twentieth conference of the ICP, which was held in Tokyo from August 13 to 19, 1972. This was the first ICP conference held in Asia and was considered a first major step in the globalization of psychological science. There were 2,562 registered psychologists from over 50 countries and 1,394 from outside Japan. The program consisted of 32 long symposia, 9 short symposia, 8 review sessions, 56 paper sessions, and 4 film sessions (Japanese Psychological Association

1987; Rosenzweig et al. 2000). The conference was truly the turning point because, since then, other Japanese psychologists have been elected to the executive committee, and hundred more Japanese psychologists participate in at least some of the ICP meetings.

Although hosting an international meeting precipitated Japanese psychology going international, aims to integrate Japan's various societies into a psychological union modeled on the American Psychological Association were left unrealized. Over the decades, the political juggernaut has impacted how Japan's psychologists are qualified, a confusion that continues to this day.

Decline of Abnormal Psychology, Importing Psychoanalysis, and Rise of Clinical Psychology

Fukurai Affair and Decline of Abnormal Psychology in the Prewar Period

In the late 1880s to 1890s and 1910s, spiritualism boomed among Japanese people, an example the Japanese style of Ouija board, which had been in popular use for years. This spiritual period reflected the delayed import of overseas news on psychical research or parapsychology, whereas the second boom in the 1910s reflected an argument about science being unable to thoroughly explain psychic phenomena.

Tomokichi Fukurai (1869–1952), who earned his undergraduate degree at Tokyo Imperial University, remained there to pursue graduate work in hypnotic theory, as proposed by William James. Beginning in 1905, Fukurai lectured on abnormal psychology at his alma mater and, after practicing hypnotism and conducting experiments, he completed a dissertation of psychological research on hypnosis, earning a Ph.D. in 1906. It was one of the first cases of a Japanese psychologist obtaining a doctoral degree without having studied abroad. In 1908, Fukurai was appointed associate professor under Motora at Tokyo Imperial University.

Fukurai further pursued psychical research. Had he gone abroad to study like many of his colleagues, he would have likely cast a critical eye on psychic research. Instead, from 1910 until 1911, he began experiments on clairvoyance, aided by subjects Ms. Mifune and Ms. Nagao. These experiments, including a public experiment, caused a major dispute among academics,

including psychologists and physicists. Although Motora tried to dissuade Fukurai from further parapsychological research, Fukurai insisted on the existence of clairvoyance and “thoughtography,” the latter term he coined by finding that Ms. Nagao could project her thoughts onto photographic film in a camera.

After Motora's death in 1912, Fukurai published *Clairvoyance and Thoughtography*. Although an English version was later published in 1931, the book was criticized among academics because it lacked a valid scientific approach, which requires verification. Fukurai eventually resigned his post in 1913, fed up with his work being disparaged. Despite his choice of study, Fukurai was considered an elite psychologist and would realize professorship at Tokyo Imperial University in the future. However, Fukurai's ongoing controversy prevented his appointment at this time. Instead, in 1913, Matsumoto became the next new professor, wasting no time in declaring that psychologists in the department must focus on normal phenomena to regain the department's credibility. All future lectures on psychology given at the university were done so by “not mentioning abnormal psychology,” which had prevented the rise of clinical psychology in prewar Japan (Sato and Mizoguchi 1997; Sato and Sato 2005).

Acceptance of Psychoanalysis

While interest in abnormal psychology dwindled during the 1910s, psychoanalysis, familiar to psychologists and psychiatrists since the early 1910s, was on the rise. G. S. Hall, the president of Clark University, was one thread that connected psychoanalysis to Japanese psychologists. In 1909, Hall invited several prominent scholars, including Sigmund Freud (1856–1939), to a ceremony celebrating the school's 20th anniversary. In the audience were two of Hall's Japanese graduate students, Hikocho Kakise (1874–1944) and Sakyo Kanda (1874–1939). Although neither Kakise nor Kanda much influenced the development of psychoanalysis in Japan, another of Hall's Ph.D. students, Yoshihide Kubo (1883–1942), who graduated from Tokyo Imperial University in 1909, went on to write an introductory book, *Psychoanalysis*, in 1917. Here he revealed that he learned psychoanalytic theory during his study at Clark (Oyama et al. 2001; Sato and Mizoguchi 1997).

Psychoanalytic study and practice were mainly pursued outside of academic psychology. Kiyoyasu Marui (1886–1953) and Heisaku Kosawa (1897–1968) were early pioneers of psychoanalysis in psychiatry. During World War I, Marui learned psychoanalysis while studying psychopathology under Adolf Meyer (1866–1950) at Johns Hopkins University. From 1924, Marui lectured on psychoanalysis at Tohoku Imperial University's newly established Department of Psychology, these being the first systematic lectures on psychoanalysis presented to psychology students in Japan. Although Kosawa first studied psychiatry under Marui at Tohoku Imperial University, he continued studying psychoanalysis in Vienna. After returning home in 1933, he left the university to forge the field of psychoanalysis as a private practitioner in Japan.

Long before Kosawa organized the Japanese Psychoanalytical Association in 1955, Kenji Otsuki (1891–1977) had established the Tokyo Institute for Psychoanalytic Study in 1928, in cooperation with Seiya Hasegawa (1876–1940) and Yaekichi Yabe (1875–1945). None were psychiatrists or psychologists, but they still published the first Japanese journal of psychoanalysis (*Seishin-Bunseki*) in May 1933. Otsuki and colleagues collaborated on translating Freud's works, the series being published from 1929 to 1933. Prior to Volume 35, the final issue being disseminated in 1978, the journal had been published intermittently with a long suspension during World War II. The rivalry between Marui, the psychiatrist, and the nonpsychotherapists, Yabe and Otsuki, in terms of which Japanese psychoanalytic society was worthy of Freud's accreditation, provides insight into how psychoanalysts in prewar Japan were viewed. Interestingly, psychologists were generally not involved in developing psychoanalysis, likely because within the field of Japanese psychology, psychoanalysis was not considered an important technique in psychotherapy.

Development of Clinical Psychology After the War

Though the development of clinical psychology was hindered before World War II, several psychologists working at clinical institutions managed to make contributions, such as Yuzaburo Uchida (1894–1966) who developed the Uchida-Kraepelin Psychodiagnostic Test. In the 1950s, Hiroshi Ito (1919–2000), Fujio

Tomoda (1917–2005), and Morio Saji (1924–1996), among other psychologists, were responsible for bringing knowledge they earlier acquired from psychological counseling and applied it in the field. As early as 1953, the Japan Association of Applied Psychology proposed to the Ministry of Education that “school counselors” be introduced into elementary, junior high, and high schools. Progress was stymied by ongoing issues of how to qualify counselors. Discussions dragged on into the 1960s when the Japan Psychological Association and other societies got involved in discussing what determines a qualified “clinical psychologist.” By the late 1960s and early 1970s, a master plan emerged outlining qualifications for clinical psychologists, but it foundered during the student movement. Critics complained the program's design did not afford students rigorous enough training and education. Further criticism was directed at the rationale behind classifying and discriminating people based on their psychological assessment using psychological tests.

In spite of these obstacles, the 1970 directory of the Japanese Psychological Association showed that the field of clinical psychology had fully matured, as depicted by the various genres represented, though in different proportions: Psychologists specializing in division III (clinical, personality, criminal) occupied more than a third of the entire membership, more than those specializing in divisions I (experimental, physiological), II (developmental, educational), or IV (social, cultural, industrial) (Iwahara 1976). After the Association of Japanese Clinical Psychology was founded in 1982, the number of counselors, psychotherapists, and clinical psychologists dramatically increased. This organization established standards for what qualifies a “clinical psychologist,” which society members accepted in 1988 (Azuma and Imada 1994).

The Japanese Psychological Association may be the first psychological society established in Japan, but it is not the largest and does not speak for the majority of psychologists, namely clinical psychologists, as does the American Psychological Association. To counter the trend of emphasizing clinical psychology, the Japanese Psychological Association introduced its own standards for what qualifies a “certificated psychologist” (acknowledged in 1990). Unfortunately, dueling qualifications designated by the various societies led to a mushrooming of qualification that would be

acknowledged, which has further fragmented the psychology field in Japan. This dilemma continues into the twenty-first century because throughout the previous century, no national qualifications or licenses for psychologists were established, as was done for medical doctors and social workers.

International Perspectives

As described earlier, there was no connection between psychological knowledge in the Edo and Meiji eras. This contrasts sharply with Chinese historiography, which typically begins with Confucius. As an imported knowledge, psychology became a lecture subject at universities and colleges in the 1870s. Around that time, government officials determined that scholars teaching at the national university should specialize not in Japanese sciences (*kokugaku*), but in Western sciences (*yogaku*). Accordingly, psychology like other sciences was introduced as a novel system of knowledge that did not share anything in common with Eastern thought. Since then, Japanese psychologists were doomed to follow European and American psychological trends, at least by the end of the 1940s. After the Occupation, many Japanese psychologists struck out on their own, pursuing their own brand of psychology, which included Japanese and Oriental thought. The resulting international journal, *Psychologia*, which debuted in 1957, originated in the Orient and was edited by Sato.

Not many original themes or topics have emanated in Japanese psychology, besides those studied in cross-cultural psychology. Most themes involve either psychotherapy, such as Morita Therapy proposed by psychiatrist Masatake Morita (1874–1938) in the 1920s, or cognitive psychology, which incorporates Chinese characters (*kanji*) as well as Japanese syllabaries (*hiragana* and *katakana*) into material of memory research.

One theme, blood-type typology, proffered a unique influence to the history of psychology in Japan (Sato and Mizoguchi 1997). Originally proposed by Takeji Furukawa (1891–1940), a pedagogist, during the 1920s, he looked for a relationship between ABO blood type and children's temperament. The published theory was submitted to the *Japanese Journal of Psychology* in 1927. One aim of Furukawa's study was to warn against reading too much into the results of any

intelligence test students take for their entrance examination. No matter that Furukawa's blood-type theory was repeatedly disproved at meetings of the Japanese Society of Legal Medicine and elsewhere in the 1920s and 1930s, many army officers proposed substituting the time-intensive aptitude test for the blood test because it would be a fast and easy way to assess soldiers. The officers even imagined controlling occupied areas like Taiwan or Korea with blood-type typology based on Furukawa's belief that those with blood types A and AB had passive temperaments. Thus, the officers also proposed emigrating more Japanese with type A blood to those occupied areas to marry into the local Asian population, which would lead to many more babies with a passive temperament, a better situation for the dominating Japanese government.

Though completely refuted, the ABO theory was reborn in the 1970s as "blood-type typology," which proposed a relationship between blood-type and a person's personality. Though unscientific, it remains popular for Japanese lay people. As well, many people in China, Korea, and other parts of Eastern Asia believe the theory, likely a reflection of the influence of Japanese occupation during the wartime.

Future Directions

Since the historiography of psychology in Japan has been influenced only recently by the international progress of theories and the history of science, most studies on the subject have employed presentism and internalism (i.e., psychologists reconstructing history by substantially relying on the subjective recollections of others without validation from external sources). Thus, further studies demand more concrete evidence to verify the early views. Moreover, the subject has not been fully investigated: for example, the extent Japanese psychologists were involved in the war effort, or how American officers evaluated and censored Japanese psychological writings during the Occupation. While the impact of Western psychology has been thoroughly analyzed, the influence of Japanese psychology on other Asian countries (especially countries Japan occupied during the late nineteenth century to mid-twentieth century) has been scarcely studied. International perspectives are needed to advance such studies and gain greater knowledge of the history of psychology in Japan.

Jastrow, Joseph

PETER J. BEHRENS

The Pennsylvania State University, Lehigh Valley,
Center Valley, PA, USA

Basic Biographical Information/Major Accomplishments

Born in 1863 and died in 1944.

Within the history of psychology, a special place is reserved for Joseph Jastrow. He holds more “firsts” than perhaps any of the early American psychologists: the first to receive a doctoral degree in psychology from an American university (from The Johns Hopkins University in 1886); the first chair of the Department of Psychology at the University of Wisconsin (1888); the first secretary of the American Psychological Association (1893); the first psychologist to make a national radio address (1926); and the first English major (B.A., University of Pennsylvania, 1882) to enter a Ph.D. program in psychology(!).

Born in Warsaw, Poland, on January 30, 1863, Jastrow immigrated to America with his family in 1866. He had a long and illustrious career in psychology that spanned more than 50 years. He was first an experimental psychologist conducting studies in perception and learning, and then a promoter of psychology through public speaking, syndicated newspaper

columns, books, and radio broadcasts. Jastrow typifies the character of many early American psychologists, such as James McKean Cattell, G. Stanley Hall, and George T. Ladd, who were trained in laboratory methods of psychology and later worked to apply psychological theory and principles (Boring 1950).

Jastrow's earliest experimental studies were conducted at The Johns Hopkins with the notable and infamous logician and mathematician, Charles Sanders Peirce (Cadwallader 1974). Peirce was a major influence on Jastrow's thinking about the importance of logic and reason applied to formulating propositions and arguments. They collaborated on an important study in psychophysics, which provided a proof of sorts for the proposition that judgment at the threshold of perception (in the visual field) is affected by subconscious registration and influences correct conscious judgments (Jastrow 1930). Jastrow's doctoral dissertation was a study of the differences in perception by the senses. At Wisconsin, he began the custom of publishing experimental reports from his laboratory as "minor studies." Other universities quickly followed, such as Cornell, Michigan, and Vassar (Boring 1950).

Jastrow was led to promote the "new" psychology because much of what passed for psychology in popular culture was not based on sound science or reason. His popularizing addressed important psychological topics: spiritualism, hypnosis, psychic research, the subconscious, human character, and "mental hygiene," or what we would today call mental health (Blumenthal 1991).

For example, Jastrow led in a crusade among psychologists and other scientists from the early 1900s through the late 1920s against spiritualism, the widely held belief in psychic phenomena, such as clairvoyance and telepathy. In 1909, The Society for Psychical Research published a list of "scientists" willing to form a committee to investigate the claims of the notorious medium, Eusapia Paladino, an Italian who held claim to psychic powers of telepathy and clairvoyance. In addition to Jastrow, G. Stanley Hall, Hugo Muensterberg, and William James assented to investigate Paladino's claims, but Jastrow was the only psychologist to eventually become a member of a 3-person committee in 1910. Ten years later, when two prominent Spiritualists, the British physicist, Sir Oliver Lodge and Sir Arthur Conan Doyle, the famous mystery writer and infamous believer in psychic photography, traveled to the USA for

lecture tours, Jastrow was intent on discrediting them. He announced that he would follow Lodge on his tour around the country, and he shadowed Lodge, lecturing one week, respectively, after Lodge's visits to Toledo, Milwaukee, and Kansas City in 1920. In these efforts to discredit spiritualism, Jastrow argued that the basis for belief in scientifically discredited ideas arises out of a human propensity to accept that which is presented in the context of authority, wonder, and sensationalism. Jastrow termed this a "will to believe," even in the presence of a coherent scientific rebuttal (Jastrow 1930).

A second arena of promoting sound psychological theory and practice for Jastrow was the study of abnormal behavior and personality, particularly the subconscious and unconscious, as proposed by Sigmund Freud. Wholly consistent from his training in experimental psychology at Hopkins and the influence of Charles Peirce was Jastrow's suspicion of any purely psychical interpretation of mental phenomena that did not have, at least, a hypothesized connection to evolutionary biology. Freudian doctrines, he claimed, form but one interpretation of the unconscious, but not the only one. Any interpretation must be consistent with what is known about the neurological basis of behavior.

Jastrow's views on the role of psychology for human welfare became a matter of international consequence with the calamities that were World War I and World War II.

Yet, he saw psychology as the key for understanding the relationship between war and peace and pathology and sanity. He argued that war and aggression were the consequences of unhealthy and repressive personal and social factors. The individual could be expected to be bound by emotion, instinct, and habit on the one hand, or, if nurtured by a modern, civilized society based on reason, science, and psychology, would be free from superstition, irrationality, and incredulous beliefs. In this regard, he undertook analyses of war and militarism through psychological studies of Kaiser Wilhelm after World War I and Adolf Hitler at the outset of World War II. The public, he believed, could be persuaded that psychology offered the best hope for personal and social redemption (Jastrow 1935).

Jastrow and others of the first generation of American psychologists became known for putting psychology "on the map" for the general public. He skillfully harnessed the venues, such as public lectures,

newspaper syndication, and even broadcast radio, to educate and enlighten a curious, if not skeptical, public on the benefits offered by psychology for mental health, adjustment, and personal well-being. For all of Jastrow's "psychologizing," however, his writing often lacked substance and impact, even though he was his own best promoter. He died in Stockbridge, Massachusetts on January, 8, 1944. It would be a decade or more following Jastrow before better formulations of psychological theories of Freud, Alfred Adler, and Erik Erikson, for example, were applied to an understanding of the human condition in more convincing forms.

Jevons, W. S.

DAVID L. SEIM
University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

William Stanley Jevons was born in Liverpool, England, on September 1, 1835, the ninth child in a prosperous iron merchant family. Jevons's mother died when he was 9. When he was 12, the family lost nearly all its savings in a financial panic. Jevons gained his early education at home, then at the Liverpool Mechanics Institute, as well as at a preparatory school in London. He pursued higher education at University College,

London, a Benthamite institution where he studied chemistry, mathematics, and logic. In 1854, Jevons took time away from school to work for 5 years in Australia, at Great Britain's new Mint of Sydney. He returned to London to complete his B.A. (1860), followed by an M.A. in Logic, Philosophy and Political Economy (1862), both at University College. Jevons's decision to add economics into his education was stimulated, in part, by his interest in a local Australian dispute over railway funding.

The scholarly life of Jevons spanned from the early 1860s to the early 1880s, and blended work as a logician and as an economist. As a logician, Jevons attempted nothing less than to reform the very foundation of formalized philosophy. As an economist, he focused especially on the psychology of consumption, both at individual and societal levels. Jevons is best known for playing an essential role in the nineteenth-century debate over the "mathematization" of social and behavioral science, and he is especially recognized for cofounding a version of mathematical, behavioral economics known as the "theory of marginal value." Jevons died young, at age 46, in a drowning accident in the ocean on August 13, 1882 (Schabas 1990).

Major Accomplishments/Contributions

Jevons's chief point of fame is his publication of *The Theory of Political Economy* (1871), a work that made him (along with Leon Walras and Carl Menger) one of three independent codiscoverers of the theory of marginal utility, which is the theory that each added unit of a consumable commodity becomes less and less valuable to a consumer (Jevons 1871). This theory sometimes is called the "principle of diminishing marginal utility."

Within the well-known triumvirate who participated in a near simultaneity of scientific discovery, it is Jevons who is usually considered to have provided the clearer and more penetrating statement of the new theory. In addition to stating the core of marginal theory as being founded upon individual psychological pursuits, Jevons added a second dimension to the theory, which is his "equation of exchange." Such an equation establishes that for a consumer to maximize his or her individual utility, equality must be achieved in the ratio of the marginal utility to price for each and every

item consumed. When this equality is not met, consumption must be reallocated, since there is an incentive to redistribute one's purchases until the equation of exchange holds. Sometimes this part of Jevons's theory is called the "principle of equimarginality" (Peart 1996).

Taken altogether, Jevons's theory was able to explain relative prices of commodities in terms of a psychological principle joined with a principle of exchange – with both being represented in mathematical forms. The central theoretical problem of economics was now framed as maximizing the utility obtained from a given set of resources. Jevons described this end goal thusly: "Given, a certain population, with various needs and powers and production, in possession of certain lands and other sources of material; required, the mode of employing their labour which will maximise the utility of the produce" (1871, Ch. VIII). Such a form of economic activity is known as "constrained maximization," and the foundation of such activity is, in essence, a psychological theory.

Jevons had other important ideas, which spanned numerous fields of science and philosophy. As we stick with those ideas that are psychological theories, we should consider Jevons's work on logic and scientific method, which Jevons expounded through a series of writings.

Between 1863 and 1874, Jevons published four significant philosophical tracts, three on formalized logic and one on scientific method – titled *Pure Logic* (1863), *Substitution of Similars* (1869), *Elementary Lessons in Logic* (1870), and *The Principles of Science* (1874). Throughout these writings, today's historians can identify a system of logic in which Jevons aims to do away with an older-style scholastic classification of syllogisms and rules for conversion, by recasting the whole of formal logic into a simple and improved shape, doing so by adopting two principles: "quantification of the predicate" and "substitution of similars." The basic underlying idea throughout Jevons's work on formal logic is that all logical problems can be restated by framing them as deterministic algebraic equations, which should be done by stating the initial conditions in clean symbolic terms and then substituting elements with similar properties. Once so stated, any trained person need only repeatedly apply the same small set of simple, mechanical rules. By 1870, Jevons even

constructed a machine – described as a "logical piano" – that with keyboard, pulleys, and switches all properly manipulated would produce conclusions consistent with the given premises. Jevons believed it should be evident to any person who studied the machine that the principle of mechanism is capable of substantially replacing "the action of thought" required in the performance of logical deduction.

Taking all these philosophical books together, Jevons's logical analysis generally begins with some investigation into the nature of the "action of thought" and the "laws of thought." And, when it comes to Jevons's analysis of science in particular, science is not *in things*, but is *in the mind*. As such, the laws of scientific method ought to be presupposed, in part, as "the prior conditions of all thought and all knowledge." The laws of thought are objective laws; they are fundamental mental powers for knowledge acquisition, including the powers to discriminate, to detect, and to retain. Jevons takes these three fundamental mental powers and attempts to somehow map them upon three standard laws of formal logic: the law of identity ("Whatever is, is"); the law of contradiction ("A thing cannot both be and not be"); the law of duality, or excluded middle ("A thing must either be or not be") (Wood 1988).

With respect to Jevons's philosophy of scientific method, *Principles of Science* is a book with a wealth of examples drawn from across the physical sciences. Throughout the book, Jevons discusses probability, which he understands to be a measure of the incompleteness of knowledge; hence he introduces what we now label an "epistemological theory" of probability, since probabilities are nothing other than "measures of ignorance" or "degrees of rational belief." In an attempt to closely connect together the two most fundamental epistemological methods – deduction and induction – Jevons offered an "inverse probability" theory of induction to argue that the human mind is well suited to deducing the "most probable" cause of an event by examining all possible hypotheses and deducing all possible consequences from these hypotheses, after which these deduced consequences can then be compared against empirical facts. The basic idea is that if many observations suggest some kind of regularity, it becomes highly improbable that the observed outcome happened by chance (Schabas 1990).

Another place where we find some degree of psychological theorizing is in connection with Jevons's ideas about statistical measurement of human attributes. While Jevons is most commonly recognized for his employment of various series of aggregate price and wage statistics, Jevons was also inspired by Adolphe Quetelet's notion of an "average man." Some of this influence comes through when Jevons considers average consumption versus aggregate consumption, and he reasons that in any large community, a law of average tendencies sets into play, while at a strictly individual level of behavior there can be a strong influence of random tendencies. Jevons supposed that if all individuals have essentially the same physical and psychological features (at least of those features pertinent to consumption), then the average laws of supply and demand would be equal to the conduct of every individual. If, however, the "powers, wants, habits, and possessions" of different people were widely different, then the average would not represent "the character of any existing thing." People are recognized as not homogeneous, and so it would be wrong to create "representative agents." There are even group differences in the human ability to be rational, such as in anticipating future utility within one's mental calculations; this Jevons specifically contemplated in the second edition of *Theory of Political Economy*, when he wrote of "the intellectual standing of the race, or the character of the individual" (1879, Ch. 2), and noted an example of one particular "race" about which he did not think so highly, namely, the Irish (who he believed were innately more subject to drunkenness).

Jevons also had a psychological theory embedded within his writings about business cycles. Here he included a psychological dimension within his somewhat notorious attempt to introduce a "sunspot theory" of business booms and busts. In a series of short papers over many years (but especially some published during the mid- to late-1870s), Jevons argued through multiple steps of logic as he deduced how specific economic consequences should follow from purely meteorological data. These steps went as follows: variations in sunspots occur; these variations affect the sun's rays, which in turn affect harvest qualities on earth; times of weaker harvests send food prices higher; these higher prices impact "mood" and "confidence"; shaken confidence can alter investment decisions,

which in turn can give rise to financial panics and commercial crises. Jevons was thus among the earliest economists to argue that phases of business activity have regular and predictable periodicity, and that an aggregation of individual states of mind can play a role in causing fluctuations in a national economy (Black and Könekamp 1972–1981).

In his later years, Jevons got interested in the economic value of education. His papers "On a National Library" (1874) and "The Rationale of Free Public Libraries" (1881) were part of an argument about comparative social utility, in which Jevons argued that library impacts on the educated mind yield a higher quantity of social utility than something such as horse racing tracks, which only yield quick and intense pleasure (Inoue 1993).

Jones, Ernest

THOMAS J. MARTINEZ, III
Saratoga Springs, NY, USA

Basic Biography

Alfred Ernest Jones, renowned British psychoanalyst, physician, and author, was born on January 1, 1879, in Gowerton, Wales. He died in London, on February 11,

1958, one of the most influential psychoanalysts of the twentieth century. Ernest, as he was called by his parents, was the first born and only son of Thomas Jones and Mary Anne May-Lewis. In addition to Ernest, the couple had two daughters, Elizabeth and Sybil, each born 20 months apart. Later, Elizabeth married his professional associate and closest friend Wilfred Trotter. His youngest sister Sybil was represented in an open-ended sign for infinity and the mythological and literary *Sibyl*, a *dramatis personae*, whose name evoked divination and prophecy. Jones scribed the symbol beneath his signature, and retained this practice a good portion of his life.

This salutary symbolic gesture concealed both tender early feelings that Jones retained for his sister and family, as well as his lifelong love of fate and the mystery of time. After completing studies at University College, Cardiff, Jones received his Medical degree from University College London. Equipped with a medical degree, Jones elected to stay in London, continuing he studies, which became increasingly more psychological and psychotherapeutic in nature.

Shortly after making his decision to stay in London, he made the acquaintance of Wilfred Trotter, a physician and surgeon who made a powerful impression on Jones. Trotter possessed an extraordinary blend of scientific mastery with a philosophical temperament. He encouraged Jones in his desire to understand the psychic expression of both normal and abnormal conditions as a vital relation to material and biological facts. In 1905, Thomas Jones purchased a house on London's Harley Street, where Ernest Jones, Trotter, and Elizabeth (the oldest sister of Ernest) lived for several years. Elizabeth and Trotter were married in 1909, the year that Mary Anne May-Lewis Jones died of a massive brain hemorrhage. Jones's youngest sister Sibyl returned from America, and her study of Art, to take care of things in Gowerton. These important life events presaged the psychoanalytic transformation of Alfred Ernest Jones.

Major Contributions

In August 1907, Jones traveled to Amsterdam to attend *The International Congress of Neurology* and present a paper. While at the gathering, Jones made the acquaintance of Swiss psychiatrist, C. G. Jung, who at that time was an unabashed supporter of Freud's theory of

psychoanalytic theory. Jung was already famous for demonstrating scientifically, the efficacy of the word association method for discovering the presence of unconscious feeling-toned complexes in disturbances of memory. Jung demonstrated experimentally, with ample reference to Freud, that these complex disturbances were caused by displaced or repressed affect and emotion. The complex is the mask that conceals a painful experience or event that the individual would rather forget: evident in the inability to react appropriately or convey painfully personal self disclosures.

Favorably impressed by the presence and psychological acumen of Jones, Jung invited the young English psychiatrist to visit him in Zurich and glimpse firsthand the analytic work that Jung and his staff were conducting at the Burgholzli Psychiatric Hospital. On November 30, 1907, days after attending a rather intense seminar on psychodiagnostics with Emil Kraepelin in Munich, Jones arrived in Zurich.

Jones, accompanied by Jung and American psychiatrist A. A. Brill, made his way to the first *International Psychoanalytic Congress*, at Salzburg in April 1908. The Congress provided Jones with the opportunity to have his first face to face encounter with Sigmund Freud.

Jung had already informed Freud of Jones in a letter sent after leaving the Amsterdam Congress the previous September. From Salzburg, Jones and Brill accompanied Freud back to Vienna. Here, we recognize the beginnings of the translation and dissemination of Freud's works and vernacular into English. Given Jung's doubts and subsequent defection concerning the pansexual aspects of psychoanalytic theory, Jones, from the Vienna encounter with Freud onward, became the most loyal and influential member of Freud's inner circle. This circle consisted for the most part of Jung, A. A. Brill, Otto Rank, Ludwig Binswanger, Karl Abraham, and from Hungary, Sandor Ferenczi. Incidentally, the monumental meetings with Jung at Amsterdam and then the Burgholzli in Zurich, and with Freud at Salzburg and Vienna had the practical purpose of understanding in analytic terms, concept of *rationalization*, an original and lasting contribution by Jones to modern psychology. Together with Brill, Jones left Vienna for Budapest, and further analytical work with Ferenczi, followed by additional analysis with Otto Gross in Munich, and study in Paris, the work of Pierre Janet, and the *Salpêtrière* School of psychiatry.

The psychoanalytic transformation of Alfred Ernest Jones occurred with a cost. There were misunderstandings among the English. In fact, the medical community remained both suspicious and hostile. In the course of treating a young girl suffering from hysterical paralysis, Jones employed psychoanalytic practices and cured the girl. This infuriated both her physician and parents. An ethical complaint was lodged against him, and he was forced to resign his various posts in London, all but ruined by the public's presumption of guilt and the lingering stench of the scandalous. When an opportunity for an Academic position at a teaching hospital in Toronto came up immediately after the London intrigue, Jones quickly accepted. His stay in Canada which lasted 5 years, beginning in 1909 and ending in 1914, must be considered as a complete success. The foundation for several of his most notable publications occurred during this time period. Among them, *On the Nightmare, Hamlet and Oedipus*, and *On Symbolism*.

He also began a study of aesthetics, and gradually focused on Italian renaissance art in particular. After a torturous 7 year relationship with Loe Kahn ended, Jones married Morfydd Owen, a English pianist, composer, and singer. The marriage was a happy one but short lived, for as fate would have it, she died of appendicitis in the summer of 1918. He married his second wife Katherine in October of 1919. The couple had three children, one of whom, a daughter named Gwenda, died in February 1928. With Anna Freud now living in London conducting her pathbreaking work with children, Jones found his analytic and organizational skills very much in demand. Given the death of Karl Abraham in 1925, and with his passing, the ascent of Melanie Klein and the object-relations school of analytic thought, these skills were sorely needed. Early in 1938, amid the rise of the Nazis and the provocative innovations proposed by Jacques Lacan and the French school, Jones secured passage to London for Freud and his wife Martha. His three volume biographical study, *The Life and Work of Sigmund Freud*, began to take shape at this time. In 1948, Jones published an expanded version of *On Symbolism* and, in 1953, published the first of three volumes of his biography on Freud. Parts two and three of this study appeared in 1955 and 1957. He then returned to work on his *Memoirs*, which he began in 1944, and which remained

unfinished during his lifetime. His autobiography, titled, *Free Associations*, was published posthumously in 1959, 1 year after his death at the age of 79.

Judd, C. Hubbard

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: February 20, 1873; Died: July 18, 1946.

Judd was born in India to Methodist missionary parents and came to the United States in 1879. He graduated with the B.A. from Wesleyan University and, sponsored by a minister friend, proceeded to Leipzig where he studied with Wilhelm Wundt. After obtaining the Ph.D. there in 1896, he returned to Wesleyan and began its laboratory tradition that was carried on by Raymond Dodge after Judd left for New York University in 1898. After 3 years at New York, Judd then went to the University of Cincinnati, where he stayed for a year until he was called to Yale in 1902. There he became Professor of Psychology and director of the laboratory in 1907 after the departures of Scripture and Ladd. While at Yale, Judd contributed to the development of eye movement research. In 1909, Judd moved to Chicago where he became head of the Department of Education and Director of the School of Education. He remained at Chicago, chairing the Department of Psychology between 1920 and 1925, until his retirement in 1938.

Major Accomplishments/Contributions

Judd was probably the most personally close to Wundt of all of the Americans who studied with him: after

quickly completing the doctorate with a thesis on space perception and touch, he began a translation, authorized by and in consultation with Wundt, of the *Grundriss der Psychologie*, which appeared in English in 1897 as *Outlines of Psychology* (Wundt 1897) and in two subsequent revised editions in 1902 and 1907. While Judd said that he tried to read everything Wundt wrote (Baldwin 1921) and while he was among the most faithful to Wundt's worldview (Rieber 2001), nonetheless he developed his unique applied variation in the area of educational psychology. Judd studied pedagogy alongside psychology in Germany and attempted early in his university career to put curricular reform into practice. His first substantial publication in the area was his *Genetic Psychology for Teachers* (Judd 1903), which appeared again in 1911 and to which Judd returned for ideas and illustrations over the next 30 years. He was a member of the group that addressed the National Educational Association in 1907 on the elements necessary in the training of high school teachers. After his American Psychological Association presidential year in 1909 and his appointment at Chicago, he immersed himself entirely into the life of education, becoming involved at all levels of the process from the direct observation of schools in several areas of the country to participation in national educational affairs. He authored several books that reflected his ongoing interests in teacher preparation and practice and which identified specific points of connection between teaching and theoretical psychological principles. For an example, drawn from his *Psychology of High School Subjects* (Judd 1915), Judd advocated, based on contemporary theories of relational space perception, teaching three-dimensional geometry by using models of figures to generate spatial perceptions. Judd also advocated including vocational education in the curriculum because of the opportunities it offered for developing precise control of action in the environment. His 1918 *Introduction to the Scientific Study of Education* (Judd 1918a), informed by Judd's background as member of the APA committee on standardizing mental tests in 1911, was a clear programmatic statement for the development of an educational psychology based on measurement. In another book from that year, *The Evolution of a Democratic School*

System (Judd 1918b) Judd defined the undemocratic German educational system and its survivals in America as the object of reform, and proposed several methods of democratic involvement in reform efforts including educators' self-reflection and self-analysis. Judd saw the highest level of civilization being the achievement of ideation against instinctive behavior, and he saw that achievement in light of the Herbartian idea, also a part of the *Völkerpsychologie* of Wundt that few other psychologists remembered by that time, that the individual is nothing without society. In his *The Psychology of Social Institutions* (Judd 1926), he insisted on necessary conformity to social realities in domains ranging from language through art and music. He saw order and punctuality as fundamental to the development of accurate thinking. For the rest of his career he was a distinguished spokesman for the civilizing effects of education (e.g., Judd 1939), continuing the theme of the evolution of consciousness advanced much earlier in his work (Judd 1910).

K

Kagan, Jerome

BRITTANY SWETT, NAVA R. SILTON

Marymount Manhattan College, New York, NY, USA

Kagan, Jerome (born in 1929) was a pioneer in the area of Developmental Psychology. One of his principal areas of study centered on the stability of temperament from infancy through adolescence to adulthood.

Biographical Information

Jerome Kagan was born in Newark, New Jersey in 1929. Kagan was born to Myrtle Libermann and Joseph Kagan. Joseph was a businessman. Kagan attended Rutgers University in New Jersey and graduated in 1950 with his B.S. degree.

In 1951 Jerome married Cele Katzman. They then went on to have a daughter.

Kagan went on to earn his master's degree at Harvard University. Upon completion he began his Ph.D. at Yale University, which he completed in 1954.

Major Contributions

Kagan went on to work as a Professor of psychology at Ohio State University. He remained in this position for a year. He then spent 2 years at the US Army hospital in West Point as a psychologist. Following the completion of this venture, he became employed in Yellow Springs, Ohio where he worked for the Fels Research Institute as a research associate. By 1959, Kagan had been named chairman of the Institute's Department of Psychology.

At the Fels Research Institute, Kagan began his most renowned research. His research focus was on individual personality traits and to what extent the traits from infancy and childhood would be carried over to

adolescence and adulthood. Kagan worked with Howard Moss on his research at Fels. After completing their basic research, they reexamined the participants during adulthood. Initially, the researchers did not find strong correlations among the personality traits including traits of dominance and aggression. It was not until 19 years after the initial study was completed that Kagan was able to finally draw some conclusions on this case study.

Kagan and other researchers conducted a study at Harvard on how day care affects infants. The researchers found that more fearful and shy children tended to be Chinese. Caucasian children tended to exhibit fewer of these characteristics. This provided a solid study group for Kagan because of the very young age of the children. Their age made it clear to Kagan that these characteristics could not be a result of learned environmental situations. Kagan began to doubt the widely popular belief that environmental situations are what determine the social behavior of children. It was at this point in time that Kagan really began to find his niche within the field of psychology. He began to focus all of his professional energy on the connection between certain human behaviors and psychology.

After working at the Fels Research Institute, Kagan returned to his Alma Mater, Harvard University. He began his work at Harvard in 1964. Kagan began by spending a year in a rural portion of Guatemala. While in Guatemala, he focused on how biological influences could have an impact on the differential development of children. After an extended study, Kagan came to the conclusion that important stages of child development occurred in a specific order during the first 2 years of a child's life. The specific developmental skills that Kagan focused on included morality and self-awareness. After examining these specific areas of development, Kagan stated that children are resilient, and despite difficult challenges they may face within their living situations,

they are adaptable. Their biological makeup will allow them to progress in a standard way. Kagan published a book on this subject in 1982, which was titled *The Nature of the Child*.

Over the course of his many years as a researcher, Kagan has turned many of his research findings into popular books. Some of his published works include *Understanding Children: Behavior, Motive, and Thought* (published in 1971), *Growth of the Child* (published in 1978), *The Second Year: The Emergence of Self-Awareness* (published in 1981) and *Unstable Ideas: Temperament, Cognition, and Self* (published in 1989).

As a result of his success, Kagan has often been asked to serve on various committees and boards. He has been a member on the National Academy of Sciences committee and the Social Science Research Council. He is also on the Child Development and Developmental Psychology editorial board. Kagan also serves on the President's Science Advisory Committee.

Kagan is now viewed as one of forefront leaders in his field. He is one of the most important developmental biologists of this time period. He has allowed for the scientific community to gain a better understanding of the connection between biology, mainly relating to the brain's neurochemistry and how the activity in the brain influences behavior by building temperamental types. Kagan has been awarded the Daniel and Amy Starch Professor of Psychology at Harvard University. He was also awarded the G. Stanley Hall Award by the American Psychological Association (APA) in 1994. In 1963 he was also awarded the Hofheimer Prize by the American Psychiatric Association. Yale University awarded Kagan the Wilbur Lucius Cross Medal in 1982.

Kantor, J. R.

RUTH ANNE REHFELDT

Rehabilitation Institute, Southern Illinois University,
Carbondale, IL, USA

Basic Biographical Information

Jacob Robert Kantor was born in Harrisburg, Pennsylvania, on August 8, 1888. He died on February 2, 1984, at age 96. Kantor is known for his conceptualization of the system of psychology known as Interbehaviorism, which was influenced by Watson's behaviorism, Darwinism, and other sciences, including physics and ecology. Although Kantor conducted little experimental research, his theoretical work contributed to the philosophical assumptions underlying the discipline during the twentieth century and helped to promote psychology as a natural science.

Kantor earned his Ph.D. from the University of Chicago in 1914 and served as an instructor at the University of Minnesota from 1915 to 1917. His Ph.D. was awarded in 1917, and he served as an instructor at the University of Chicago from 1917 to 1920. J. H. Tufts was the Head of the Department of Philosophy, and J. R. Angell, who is credited with establishing The Chicago School of Functional Psychology, was the Head of the Department of Psychology at the University of Chicago during Kantor's time there, although Interbehaviorism shows little resemblance to

Functionalism. Kantor was appointed as an Assistant Professor of psychology at Indiana University in 1920 and was promoted to Associate Professor in 1921 and Professor in 1923. He served on the faculty at Indiana University for 39 years. His publication record spans 1915 through 1984, and includes 20 books, over 120 published papers, and numerous presentations.

Major Accomplishments

Kantor can be credited with establishing the first naturalistic system of psychology since Aristotle. Troubled at an early age by the dichotomy between scientific and religious explanations, he argued throughout his career that the mind was a construct invented by Descartes and Freud, and the belief in such a construct had prevented psychology from aligning itself with the natural sciences. These views were articulated in his dissertation, *The Functional Nature of the Philosophical Categories* and his first major work, *Principles of Psychology* (Kantor 1924/1926), in which Kantor described all available psychological data of the early twentieth century using only naturalistic, as opposed to mentalistic, terms. Kantor chose the name Interbehaviorism because it captured the dynamic nature of psychological events. In *Principles of Psychology* a two volume work, Kantor defined “interbehavior” as interactions between the responding organism, stimulus objects in the environment, the media of contact between them, and the setting factors in which they are embedded Kantor 1957/1959. The interaction between the organism and the environment is thus a field of interaction between a number of factors, all of which are interdependent. An organism’s physiology contributes to, but is not the cause of, the organism’s interaction with the environment.

In *Outline of Social Psychology* (Kantor 1929) Kantor provided a behavioral conceptualization of social psychology. In *Objective Psychology of Grammar* (Kantor 1936) Kantor critiqued linguistic theories of language, and *Problems of Physiological Psychology* (1947) focused upon the role of physiological factors in psychological events. The two volumes of *Psychology and Logic* (Kantor 1945/1950) and *The Logic of Modern Science* (Kantor 1953) focused upon scientific system building and the role of constructs in science. Kantor

argued that the verbal constructs used by scientists to describe events are different from the events themselves (See also Midgley and Morris 2006).

Kantor established the Principia Press around the time of World War II to support the publication of his own books. In 1937, Kantor founded *The Psychological Record*, a journal of naturalistic psychology that was intended to represent all areas of scientific psychology and is still active in the publication of articles reporting new and innovative methodologies today. From 1968 onward, he contributed a number of brief theoretical commentaries to the journal under the name “Observer.” Kantor maintained a relationship with B. F. Skinner over the course of his career, inviting Skinner to the University of Minnesota while he was on the faculty and appointing Skinner as an Associate Editor for *The Psychological Record*.

Many of Kantor’s former Ph.D. students obtained faculty positions at private 4-year liberal arts colleges, making it difficult for Interbehaviorism to be widely disseminated. Renowned behavioral psychologists whose work was very influenced by Interbehaviorism include Sidney Bijou and William S. Verplanck. A note found on Kantor’s bedside table prior to his death in 1984 read, “No spirits, wraiths, hobgoblins, spooks, noumena, superstitions, transcendental, mystics, invisible hands, supreme creator, angels, demons. (Kantor 1984).”

Keynes, John Maynard

DAVID L. SEIM

University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

John Maynard Keynes was born June 5, 1883, in Cambridge, England. His father, John Neville Keynes, was a lecturer at Cambridge University, while his mother was a social reformer. Keynes had two younger siblings. Keynes was schooled at home for a time, then attended Eton College (for boys up to 18 years old), before arriving at King's College, Cambridge, on scholarship. Keynes enjoyed studying classics and history, and he especially liked mathematics. Upon graduating in 1906, Keynes served for 3 years at Britain's India office while in the British civil service. During the 1910s and into the 1920s, Keynes mingled with members of the "Bloomsbury Group" of writers and artists (including Vanessa and Clive Bell, E.M. Forster, Duncan Grant, Lytton Strachey, and Virginia Woolf). In 1925, at age 37, Keynes married Russian dancer Lydia Lopokova. Beginning in 1909, Keynes published many dozens of papers and quite a number of books. Keynes is generally considered the "father of modern macroeconomics," by which is meant a breed of macroeconomic theory based on "micro-foundations" to describe human economic behavior. Keynes died on April 21, 1946, and was survived by his father (Skidelsky 2003).

Major Accomplishments/Contributions

Keynes's first book, *Indian Currency and Finance* (1913), was strictly an economic analysis, focused on

effects of the global economy on India's economy. His second book, *The Economic Consequences of the Peace* (1919), was an analysis of a national economy that included the factor of a collective mindset or mentality. Keynes argued that post-war reparation penalties imposed on Germany were so excessive that, upon "depriving a whole nation of happiness," the "abhorrent" scale of the penalty would likely "sow the decay of the whole civilized life of Europe" and speed along "that final war between the forces of Reaction and the despairing convulsions of Revolution, before which the horrors of the late German war will fade into nothing."

Keynes's third book, his *Treatise on Probability* (1921), is considered a breakthrough work. He described the idea of probability with both formal and philosophical discussions, and concluded that a statement of probability is a special-case truth value intermediate between complete true and complete falsity. Keynes launched what has become known as the "logical-relationist" theory of probability.

Next came Keynes's *Revision of the Treaty* (1922), where he extended his discussion from his 1919 book. Keynes's fifth book, *A Tract on Monetary Reform* (1923), introduced discussion of the psychological value of a person choosing to hold some portion of personal wealth in a highly liquid cash balance – a choice soon to be called "liquidity preference." Keynes also advocated depreciating a nation's currency so as to increase demand for the nation's exports. Keynes also began exploring the idea of strategic use of government spending on public works, with the goal of boosting jobs. It was this latter idea that, over the next dozen years, Keynes transformed into a theoretical proposition established upon psychological attributes of consumers, savers, and investors.

During the 1930s, Keynes published his sixth, seventh, and eighth books: his *Treatise on Money* (1930), which included an argument that one cause of unemployment is a combination of high interest rates and a fearful psychology that results in savings exceeding investments; his shorter essay, *The Means to Prosperity* (1933), explored an argument that increased public spending during a recession can make use of an income–expenditure "multiplier effect" (which stems in part from perceptions of confidence); and, *The General Theory of Employment, Interest and Money* (Keynes 1936), which established a unified understanding of

macroeconomics. *The General Theory*, despite its fully economic-sounding title, is largely about human-behavioral justifications for interventionist government policies. Keynes takes direct aim at the “neo-classical” point of view in economics, which (dating from 1870s and 1880s writings by W.S. Jevons, F.Y. Edgeworth, and others) advanced a belief that the best outcomes from market activity come from markets left unfettered (Leijonhufvud 1969).

What Keynes challenged in *The General Theory* was the main principle underlying neo-classical arguments about perfectly rational consumers whose minds continuously calculate marginal costs and marginal benefits. While Keynes did not outright reject the marginal principle, he rejected certain outcomes of marginal reasoning. He concluded: Rational calculative behavior by many individual consumers does not necessarily aggregate into collectively rational outcomes, but instead operates according to individual and societal “consumption functions”; calculative behavior by workers does not always result in acceptance of lowered wages during recessionary times (when such lowering of wages would likely help decrease the number of persons laid off); calculative behavior by savers does not always result in every last dollar of saved money turning into invested money; and, people can behave collectively irrational when driven by “animal spirits,” such as during financial market panics. The most psychological of the chapters in *The General Theory* (and in many ways two of the keystone chapters in the book) are Chap. 9 on “The Propensity to Consume: Subjective Factors” and Chap. 15 on “The Psychological and Business Incentives to Liquidity” (Keynes 1936).

Based on his series of brief arguments about mind and behavior, Keynes overturned three previous conventional wisdoms: (1) no longer would there stand the neo-classical notion that “supply creates its own demand,” (2) no longer would there stand the neo-classical notion that an entire economy in stable equilibrium will have full labor employment, and (3) no longer would there stand the assumption that the economy works best without government interference. Within a unified theoretical argument, Keynes established that demand is the key variable governing the overall level of economic activity, that an economy can have high labor unemployment even in a state of stable equilibrium, and that public spending is

necessary to help speed up or slow down an economy that has a low level of labor employment. The essence of the “Keynesian Revolution” is that labor employment levels are determined not by wage levels, but by aggregate spending – including both consumer spending and government spending (Fletcher 1989).

Keynes’s last book was *How to Pay for the War* (1940), and for the most part the answer was not by voluntary buying of war bonds, but by imposing higher taxation and compulsory saving requirements. Altogether Keynes provided a series of reasons, through numerous articles and books, that government’s legitimate and, indeed, necessary role is interventionist economic policy, using both fiscal and monetary measures to mitigate recessionary economic conditions and to dampen expansionary conditions.

Kinsbourne, Marcel

JACQUELINE LIEDERMAN, JUSTINE COHEN
Boston University, Boston, MA, USA

Marcel Kinsbourne was born in Austria in 1931. His family fled the Nazis in 1939, and he spent the remainder of his youth in England. He obtained his Medical degree from Oxford University and later received the British equivalent of a Ph.D. He specialized in pediatric neurology and behavioral neurology and has served on the faculties of Oxford University, Duke University Medical Center, University of Toronto, Harvard

Medical School, and Tufts University. He is currently a professor at the New School, a university in New York, where he received an award for Teaching Excellence. He is the author of more than 400 scientific papers, the author or editor of nine books, and has served on the editorial board of 26 scientific journals.

Relationship Between the Central Nervous System and the Conceptual Nervous System

Kinsbourne has spent much of his life questioning, challenging, refuting, and reconstructing several previously accepted ideas about how the brain works. He studies clinical syndromes in patients for clues about brain function and uses his knowledge and discoveries about the brain to devise treatments for neurological disorders. He is also an experimentalist who has invented many paradigms in order to test his theories. Thus, Kinsbourne is both a scientist and a philosopher of science. He moves effortlessly through two levels of neural function: the central nervous system (CNS) and the *conceptual nervous system (cns)*. Within his “cns,” Kinsbourne respects Brodmann’s cytoarchitectonic areas, but acknowledges that functional neural networks are distributed and overlapping both within and across the boundaries of these regions. In a sense, Kinsbourne is the grandfather of what is currently referred to as the cognitive neuroscience view of regional specialization. This view does not attribute functions to one specific brain location, but claims that neural networks are either recruited or inhibited on the basis of competing task demands, changes in arousal, or reaction to damage in the brain. His view of the brain is that of a dynamic organ constantly changing in response to the internal and external environments.

Development of the Notion of Overflow of Activity Between Adjacent Neural Circuits

Kinsbourne (1972, 1974a) was fascinated by the influence of activity in one neural circuit upon another seemingly independent circuit. He demonstrated that when the left hemisphere is occupied with a verbal task (such as memorizing a series of words), visual and auditory attention shifts rightward and the eyes involuntarily move to the right. When primed with

a visuospatial task, attention shifts leftward and so do the eyes. He then proved that the converse is also true: rightward orientation improves verbal processing and leftward orientation improves spatial processing.

Depending upon the task or type of stimuli, *overflow* of activity into adjacent neural circuits can facilitate or interfere with task performance. Elaboration of this novel overflow phenomenon led to the discovery that voices heard by schizophrenics can be inhibited merely by occupying some of the relevant circuits by either widely opening the mouth or humming (Green and Kinsbourne 1990).

Application of Dual Task Methodology Leads to Principle of Functional Cerebral Distance

Kinsbourne elaborated on his theory of hemispheric interaction by examining dual task performance. He created a variety of tasks requiring involvement of neural networks that are either tightly connected to one another within a single hemisphere or widely distributed between the two hemispheres. The two tasks were performed concurrently. For example, Kinsbourne and Cook (1971) asked subjects to balance a dowel rod while repeating sentences (a left hemisphere task) and found that balancing time decreased for the right finger (controlled by left hemisphere) but not the left finger (controlled by right hemisphere). With this “dual task methodology,” they found that young right-handed children already showed the adult pattern of greater disruption of right- rather than left-sided finger tapping when asked to perform oral language or verbal memory tasks (Hiscock et al. 1987). Similarly, as the phonetic difficulty of the verbalizations increase, control of the right hand is increasingly affected. In fact, hand and oral-articulatory neural structures occupy adjoining neocortical space.

These results in both adults and children led Kinsbourne to his principle of *functional cerebral distance*, which states that the degree of connectivity between two regions predicts dual task performance. For example, while speaking, the ability to simultaneously track, manually sequence, position, or maintain stabilization of the arms and hands is disrupted, particularly on the right side because both verbal ability and control of right-sided motor functions are in the

left hemisphere (Kinsbourne and Cook 1971). This paradigm was the first to offer investigators a motor test for laterality, and in various forms it continues to be used for this purpose.

There is reason to suppose that functional cerebral distance increases with age. As networks become pruned and the corpus callosum completes its maturation, incongruent simultaneous processing is able to occur in separate hemispheres better than within a single hemisphere. This makes sense since the number of interhemispheric connections is a fraction of the number of intra-hemispheric connections. This was demonstrated in the study by Merola and Liederman (1985), who showed that children can read upright and inverted letters more accurately when upright letters were presented to one hemisphere and inverted letters to the opposite hemisphere compared to when both letter types were presented to a single hemisphere.

The Developmental Invariance of Cerebral Lateralization

Kinsbourne (1974b) was an early critic of the widely accepted theory of progressive lateralization of cerebral localization of function. Progressive lateralization stated that when a child first develops a skill, it is bilaterally represented in the brain, and with further development, the representation shifts to one hemisphere or the other. Progressive lateralization claimed that the two hemispheres were equipotential at birth and that there was no intrinsic advantage for one hemisphere to predominate in a particular function, such as language, until development of that function (Lenneberg 1967). Evidence for this was based on data that there was equal recovery of language from lesions to either hemisphere in childhood. Kinsbourne (1975) critically reviewed that literature and showed that a) the lesions that were claimed to have been unilateral were secondary to infection and therefore almost certainly bilateral and b) that even at an early age left hemisphere lesions were less well compensated for in terms of language than right hemisphere lesions.

Kinsbourne's theory of the *developmental invariance of cerebral lateralization* stated that the two hemispheres have a small but important bias in the way they process inputs that is already established at birth and subsequently elaborated on by experience. Kinsbourne called attention to the rightward bias of the tonic neck

reflex in infants which consists of turning the head and eyes sideward, opening the mouth, and pointing the ipsilateral arm in the direction of the gaze. He proposed that the extended hand would develop into the preferred hand for reaching and grasping (Caplan and Kinsbourne 1976). The notion that this bias was genetically mediated was established when Liederman and Kinsbourne (1980) showed that the offspring of two right-handed parents were more likely to exhibit a rightward turning bias in the tonic neck reflex than the offspring of parents with at least one non-right-handed member. This was demonstrated in newborns between 1 and 4 days old, thereby eliminating possible effects of parental handling.

Hiscock and Kinsbourne (1980) reviewed their own and others' behavioral data and concluded that there was no time at which hemispheric activation swung from symmetry to asymmetry. For example, when right-handers are presented with competing verbal messages to both ears (referred to as dichotic stimulation), they identify more of the right-sided material. When the material is musical, the left ear has the advantage. Children as young as 3 years of age manifest such dichotic listening asymmetrical effects which are as strong as those of older children (Hiscock and Kinsbourne 1977).

The concept of invariance of lateralization with increasing age remains the standard in this field.

The Scaffolding of Circuits Mediating Basic or Reflexive Behavior Evolves into Circuits That Mediate Related Higher Order Behaviors

Kinsbourne promulgated the view that circuits mediating early onset behaviors become the scaffold upon which later onset behaviors were based. For example, he was captivated by the relationship between the onset of right-handed pointing and the onset of babbling. He posited that naming is based on a perceptual change that engages the child's attention and engenders an orienting response. First words are most often objects of contemplation rather than objects of action. Objects of contemplation are known through orienting (pointing, looking, and turning), whereas objects of action are known through grasping. Naming during the first 2 years occurs as part of an orienting response (almost always occurs with pointing) and orienting is

right-biased in right-handers and in the offspring of right-handed people. This association may reinforce the bias to the left hemisphere control of speech very early in life (Kinsbourne and Lempert 1979). More recently, he has pointed out that infant imitation foreshadows entrainment between people as they converse, similar to how a crowd entrains to a unified point of view (Kinsbourne 2005).

Kinsbourne's Theory of Cerebral Hemispheres as Opponent Systems

Kinsbourne developed a theory of cerebral processes as *opponent systems*. It is based on the notion that if there is damage to one polar element of the system, symptoms arise that do not occur when both elements are impaired. Areas of cortex that subserve specific functions inhibit other areas that are potentially capable of that same function. Destruction of primarily responsible areas releases homologous areas from inhibition and compensatory functioning is effective in proportion to the severity and extent of the lesion (Kinsbourne 1974b). For example, in left hemispherectomized patients, the right hemisphere is able to compensate for much loss of function because it is free of competitive inhibition from the (absent) left hemisphere. Extrapolating this concept to the control of attention in the normal brain, Kinsbourne suggested that reciprocal inhibition between the hemispheres mediates the balance of attention.

Reconceptualizing the Syndrome Known as Unilateral Neglect as Hemispatial Neglect

Damage to the parietal region of the right hemisphere had been claimed to cause unilateral neglect, a lack of awareness for all stimuli located in the contralateral (left) side of space. Kinsbourne (1987) showed that neglect was not for one side of space, but was actually on a gradient across space and was therefore *hemispatial* not unilateral. Thus, even when stimuli were clustered in the intact (i.e., right) side of space, the patient with right parietal lobe damage neglected the left-most stimuli (Reuter-Lorenz et al. 1985).

Kinsbourne (1977) posited that *hemispatial neglect* results in an imbalance in the opponent system that controls lateral orientation with excessive orienting toward the side of the lesion. Kinsbourne explained

why right-sided lesions induced more severe neglect than left-sided lesions. He argued that from birth, there is a strong lateral bias to turn rightward mediated by the left hemisphere. Damage to the right parietal lobe diminishes the ability of the right hemisphere to keep this left hemisphere-mediated rightward orientation bias in check.

The concept of unilateral hemispatial neglect as an imbalance of hemisphere activations remains the basis for continuing research into this syndrome.

The Corpus Callosum as an Interhemispheric Activation Equilibrator

Kinsbourne (1974b) was particularly fascinated with the experiments by Levy et al. (1972) in which patients who had surgical section of the interhemispheric commissures were presented with faces composed of two halves of two different familiar faces (chimeric faces). It struck Kinsbourne that these "split-brain" patients never noticed that the faces were odd looking. Instead, when asked to *name* the person, they spoke the name of the person on the right side of the face. When asked to *point*, they pointed to the person on the left side of the face. The common interpretation was that this is due to a lack of interhemispheric integration. However, Kinsbourne took this as a demonstration that one hemisphere can gain ascendancy over the other depending upon task demands. He conjectured that the callosum (which was absent in these patients) normally functions as an *equilibrator of interhemispheric activation* and that its absence in split-brain patients allows extreme shifts in hemispheric activation and wild swings in attention. Kinsbourne (2003) elaborated on the concept of transcallosal equilibration.

Left Hemisphere Specialization for Positive Emotion; Right Hemisphere Specialization for Negative Emotions

Kinsbourne (1986) hypothesized that the left hemisphere mediates focusing on a detail or a single point and is oblivious of everything else. This outlook promotes approach. Kinsbourne pointed out that the right hemisphere is specialized for recognizing and depicting existing relationships and is therefore responsible for establishing context and setting a framework for the

point of focal attention. The right hemisphere sees the whole picture, what is really going on, and promotes withdrawal. The approach/withdrawal dichotomy for hemispheric differences is able to accommodate laterality effects for both cognitive and affective processes. He elaborated on this idea to state that the right hemisphere is associated with negative emotions and the left with positive emotions. Kinsbourne and Bemporad (1984) reviewed the literature. They pointed out that patients with left hemisphere damage are often gloomy and depressed, whereas those with right hemisphere damage are often cheerful and elated. Conversely, overactivation of the right hemisphere during seizures causes epileptic patients to cry, whereas left hemisphere seizures induce laughing. In an experiment by Root et al. (2006), participants were presented with happy or angry faces at fixation point, and asked to identify the emotion of each with either their right or left index finger. There were faster response times for angry faces when the left finger was used, indicating right hemisphere dominance for negative emotions, and faster response times for happy faces when the right finger was used, indicating left hemisphere dominance for positive emotions. Kinsbourne's ideas have been confirmed and elaborated by Davidson in a series of papers which demonstrate that this asymmetry is readily observed specifically within the left vs. right prefrontal cortices (Davidson and Fox 1982; Davidson 2004).

The Dominant Focus of Consciousness and the Notion of Multiple Drafts of Responses

Kinsbourne's recent work has revolved around developing and refining a unique neural model of consciousness. Dennett and Kinsbourne's model (1992) rejects the notion that reaction time reflects the sum of the time required for three serial and independent processes: stimulus perception, decision analysis, and response execution. Instead, they propose that every stimulus immediately provokes a stream of responses based on increasing analysis of the situation. Thus, when encountering threatening or dangerous stimuli, an immediate response is often required (if you see a fire, run). Which of the *multiple drafts of responses* that are prepared is actually executed is influenced by threat level, amount of competing information,

competing response demands, and individual differences in what constitutes sufficient support for a response decision. Thus, the combination of interacting neural networks mediating these aspects of decision making determines how fast the response will be and from which part(s) of the brain the dominant activation pattern will emerge.

Given this notion that "the decision maker" is whatever network at a given moment (Kinsbourne 1988) has achieved sufficient activation to dampen down (by lateral inhibition) competing networks, Kinsbourne declared that there is no one seat of consciousness. He states that there is no privileged region that receives and processes information and from which information must be transported. Simultaneously perceiving multiple stimuli and at the same time preparing multiple responses relies on the "winner-takes-all" notion of lateral inhibition. The network with the greatest degree of activation inhibits surrounding networks and therefore becomes the dominant focus. This is an ephemeral process. Within milliseconds, another network can become the most active, and therefore become the *dominant focus*. The apparently single and unified stream of consciousness is actually composed of many different, largely independent, constantly reforming regional activations. These activations can conflict with or mutually support each other, thereby rapidly shifting the dominant focus, which incorporates the contents of attention.

Kinsbourne's Argument That There Are No "Multimodal Convergence Zones"

Many theorists including Damasio (1989) argue that information from various points of the brain project upon "multimodal convergence zones" and that conscious awareness emerges from such cortices. However, Kinsbourne forcefully argues that a loss of the ability to simultaneously perceive different modalities or simultaneous (but spatially distributed) stimuli has never been shown to be a consequence of damage to the association cortices. In addition, he argues that the number of meaningful ways in which modalities may be combined is astronomical and well beyond the space available for "association regions." Instead, he argues that the base state of the brain is largely multimodal and that in real life people are rarely confronted by

a single modality situation. In Kinsbourne's view, it is the simultaneous activation of representations distributed throughout the brain that leads to the unification of neural activity and conscious thought. Cross-modal integration is not accomplished by convergence, but is anchored in the shared topography and timing of its referents. Single modalities are appreciated via an abstraction from the multisensory whole. There is growing evidence that intermodality crosstalk occurs even in the primary areas of the cortices Falchier et al. (2002).

Kinsbourne's theory of consciousness rests on the idea that the brain is a self-organizing and self-stabilizing network. The brain does not wait idly for stimulation. It is a constantly active network that seeks to maintain equilibrium. Taking this one step further, Kinsbourne (2000) believes that human experience is the direct reflection of the dynamic activity of the brain or "the chatter of neurons." Subjective awareness is not a product of the brain, but the functioning of the brain itself.

Individual Differences in Criterion Setting for Decision Making

Kinsbourne (2001) theorized that there were individual differences in the amount of information processing required for readiness to make a decision. Individuals with low decision criteria are apt to be impulsive, sensation seeking, and risk taking. This tendency is exemplified by individuals with attention deficit hyperactivity disorder (ADHD). In contrast, individuals with high thresholds for decision making are those that are obsessive compulsive and seek to gather information long past the time needed to inform the decision. Such personality traits as well as their extensions into psychopathology can be seen as arising from the need to self-regulate the overall level of cortical neural activity to an unusually high or low level.

A New Subtype at the Highest Functioning Level of Autistic Spectrum Disorder

The notion that there are *individual differences in criterion setting for decision making* led Kinsbourne (1991) to identify *an apparent subtype of ADHD that he called overfocusing*. He defined this disorder in terms of his theory of the brain as a network striving to

maintain a homeostatic level of arousal. In contrast to the underfocused person with ADHD, who constantly seeks stimulation so as to raise arousal levels into a subjective comfort zone, the overfocuser's arousal system continually threatens to overshoot; overfocusers try to dampen arousal by avoiding situations and interactions that are novel or unpredictable. Overfocusers are often diagnosed with ADHD because of their inattention due to persisting concentration on some other topic of interest. Unlike the hyperactive patient who has trouble concentrating, the overfocuser has perseveration of mental set and task orientation. Indeed, overfocusing is on the cusp between the cognitive mainstream and high functioning autism, and an overfocusing factor describes significant properties of autistic behavior (Liss et al. 2006).

Early Contributions

In an early collaboration, Marcel Kinsbourne and Elizabeth Warrington set a new standard of experimentation in the analysis of neuropsychological deficits, which ushered in the cognitive neuropsychology movement. They also discovered visual masking by pattern, which is widely used in experiments in which visual stimuli are briefly presented (Kinsbourne and Warrington 1963). Kinsbourne was the first to describe two neurological disorders (Kinsbourne and Warrington 1962; Kinsbourne 1964), the former of which is often called Kinsbourne disease.

In conclusion, Marcel Kinsbourne is truly a man with a protean mind. He has strived throughout his career to think beyond the constraints of popular opinion and accepted theories and has succeeded in restructuring our ideas about the brain to an extent that knows no bounds. What can be a better example than a recent paper titled "Morality without God: Is human brain biology enough?" (Kinsbourne 2000).

Klein, Melanie

GAIL DONALDSON

Union College, Schenectady, NY, USA

Basic Biography

The British child psychoanalyst Melanie Klein was born Melanie Reizes on March 30th, 1882, in Vienna, Austria, and died in London, England, on September 22nd, 1960. Klein's family was of the Jewish middle-class and they ensured that she received a grammar school education, but her father's death in 1900 left the family in financial difficulties and prevented Melanie from pursuing the medical training she desired. Instead, she married her second cousin, Arthur Klein, and had three children before moving to Budapest in 1910. In 1914, she began treatment for depression with the Hungarian psychoanalyst Sandor Ferenczi, who encouraged her intellectual interest in psychoanalysis (Grosskurth 1986).

Major Contributions

Klein began by psychoanalyzing her own children, and presented one of the earliest papers on child analysis to the Budapest Psychoanalytic Society in July 1919 when she became a member. In 1921, Klein left her husband and took the children to Berlin where she joined the Berlin Psychoanalytic Society and, with the support of its president, Karl Abraham, developed her method of child analysis: the psychoanalytic play technique, which treated children's play activity as symbolic of unconscious phantasies (this British spelling is preferred in Kleinian theory to emphasize the unconscious nature of the phantasies, in contrast to conscious fantasies, or daydreams). When Abraham died suddenly in 1926, Klein lacked support in Berlin for her new approach, so she moved to London to join the British Psychoanalytical Society which was enthusiastic about her play technique.

Meanwhile, Anna Freud in Vienna was also developing a method of child analysis and disagreed with Klein about theory and methodology. In a 1927 debate between the Kleinians and Freudians, Klein and her followers advocated a deep analysis of oedipal phantasies because they believed that a young child

has a rudimentary superego and is capable of transference, while Anna Freud argued that analysis should seek to strengthen the child's ego, with the analyst serving as an external superego for the young child who, in her view, lacked a superego in any form. Klein's psychoanalysis of children led her to develop theories challenging the Freudian account of child development, for example, she proposed the existence of aggressive phantasies in the infant psyche derived from the death instinct, but her most important contribution was the idea that the infant has a primary object relationship with the mother. In Freud's view, the infant feels love for the mother only because she satisfies its basic physiological needs, but Klein argued in her first book *The Psychoanalysis of Children* (1932) that the infant is predisposed to seek a relationship with a caregiver independent of any other needs. In other words, the relationship to a love object is primary.

In Klein's view, this relationship is represented within the psyche in the form of a complex world of mental representations called internal objects. Klein and her followers developed this idea into object relations theory, which emphasizes the importance of the mother-infant bond in shaping the adult personality (Segal 1979). Object relations theory also proposes the existence of two fundamental phases in development: the paranoid-schizoid and the depressive positions. In the paranoid-schizoid position, the infant mind is dominated by psychotic defense mechanisms such as projective identification and splitting of objects into good and bad, and by phantasies of attacking and destroying the bad objects. This leads into the later depressive position in which the child's psyche is dominated by feelings of unconscious guilt for having attacked the objects in phantasy. The child works through the depressive position by making successful reparations toward the object, i.e., the mother, and develops a healthy personality based on a mature internal object world (Hinshelwood 1989).

Klein's innovations in psychoanalytic theory sparked a second debate with Anna Freud in the early 1940s, soon after the Freuds moved to London, fleeing from the Nazi invasion of Austria. Anna Freud quickly became a powerful member of the British Society and, with the support of a few British analysts and other émigrés, she argued that Klein's ideas were incompatible with traditional psychoanalysis. The goal of the

Freudians in these so-called Controversial Discussions was to throw Klein and her supporters out of the Society, and the debate went on for several years. The situation was eventually resolved when the Freudians and Kleinians agreed to disagree and instituted separate training programs for their groups (King and Steiner 1991). Klein's famous case-study Narrative of a Child Analysis (1961) was published shortly after her death from cancer. Her papers were placed in the Wellcome Institute for the History of Medicine in London. Kleinian theory is still practiced by a strong Kleinian group in London and is popular among South American psychoanalysts, but it is largely rejected by American psychoanalysts, primarily because they disagree with the notion of the death instinct. However, Klein's ideas have had a much larger, although indirect, influence on academic developmental psychology through the work of the psychoanalyst John Bowlby, who trained with Klein and who formed his theory of infant attachment out of object relations theory.

Klemm, Otto

PETER J. BEHRENS

The Pennsylvania State University, Lehigh Valley,
Center Valley, PA, USA

Basic Biographical Information

The career of Otto Klemm, born on March 8, 1884 in Leipzig, Germany, shows the transformation of an experimental, laboratory psychologist to one of the most important psychologists engaged in a multitude of applied psychological investigations in the period between the First and Second World Wars. His research was deemed important to agriculture, education, transportation, sporting competition, and even radio broadcasting (Klemm 1936).

Klemm's scientific career began when he constructed a homemade telescope to study sunspots. He published his findings in a popular journal of astronomy when he was 15 years old (Klemm 1936). From 1903–1904, Klemm studied philosophy, mathematics, physics, and philosophical psychology at the University of Munich, Germany. In the Fall of 1904, he returned to his native Leipzig and enrolled in Wilhelm Wundt's Institute of Experimental Psychology. He conducted archival research that compared the writings of the Italian philosopher Giovanni Battista Vico (1668–1744) with Wundt's psychological system published in his *Voelkerpsychologie (Folk Psychology)*. This work won him an award and a doctoral degree from the university, as well as a position as a senior assistant to Wundt at the Institute. After completing an experimental dissertation in Wundt's laboratory, Klemm became an untenured and unsalaried lecturer at Leipzig, until 1923, when he was at last appointed a tenured professor of applied and educational psychology. Klemm divided his time among teaching, conducting research, and consulting with government bureaus (Hartmann 1939). He was forced by the National Socialist government in Germany to retire from the university at the end of 1938 at the age of 54, and he died of his own hand on January 5, 1939. His eulogy was delivered by Wilhelm Wirth, the first director of Leipzig's Psychophysical Seminar. Wirth referred to Klemm in the context of Klemm's own *History of Psychology (Geschichte der Psychologie)* of 1911 and said: "Now we must become accustomed to the painful thought that he belongs to the history of psychology, in which he will always have a place of honor" (Wirth 1939, p. xi).

Major Accomplishments/ Contributions

Klemm's earliest experiments at the Institute were concerned, quite understandably, with the traditional psychological problems that occupied the early years of experimental psychology, such as the study of attention, sensation, and perception. In a major work in 1910, for example, Klemm examined the ability to localize sound with various ancillary stimuli. His techniques determined constant errors, and, importantly for some of his later applied work, compared localization of sound with and without the simultaneous

presentation of nearby visual stimuli (Klemm 1910). On the basis of this kind of work, he was promoted to a salaried professorship, but remained untenured. Klemm's studies in these years on sound localization and related auditory illusions were classic experiments of human perception and had an unexpected application to targeting and sound localization. During the First World War, he conducted investigations as a training officer and field observer with a German artillery unit (Klemm 1936).

When Wundt retired from Leipzig in 1917, the role of Director of the Institute passed to one of his able assistants, Felix Krueger (1874–1948), with Klemm remaining on as Krueger's assistant. Following the death of Wundt, Krueger and Klemm led the Institute in important new directions based on a psychological and philosophical orientation known as holistic psychology (*Ganzheitspsychologie*). Klemm explained holistic psychology as distinct from the Gestalt approach in this way at the International Congress of Psychology at Yale University in 1929: "All experience of meaning is an awareness of belonging to a whole" (Hartmann 1939). Krueger and Klemm adapted holistic psychology to the work at the Institute, to the difficult social, economic, and political conditions that confronted Germany following the First World War. New sections of the Institute were created and devoted to applied psychology, developmental psychology, Gestalt psychology, and character psychology (Hammer 1993).

Klemm pursued a variety of practical applications holistic psychology that promised to support German redevelopment. His research related to social, economic, and educational concerns that faced the German state in the areas we now know as industrial psychology, sports psychology, forensic psychology, and mental abilities and testing. Klemm himself had trouble with the logical organization of his research, and upon reflection admitted to the "motely conglomeration" of published studies that had thus far characterized his career (Klemm 1936). In all, he produced 15 books and more than 80 articles, mostly in areas of applied psychology.

Several examples of Klemm's research will illustrate the breadth of his interests. Just after assuming his tenured position at the university in 1923, he began a series of studies on human work and equipment control design, which represented a very practical

direction of economic benefit in postwar Germany. These studies included, for example, an analysis of handle designs with both male and female subjects. Largely, the studies and reports were published in journals specifically devoted to applied psychology.

An area of research in forensic psychology focused on the selection of police detectives for the purpose, among others, of enhancing the interrogation process. He devised a series of tests to measure recruits' cognitive abilities, such as sentence completion and immediate recall, but also included measures of judgment, such as with handwriting, the comparison of photographs, and with observation of slight-of-hand performances. Within sports psychology, Klemm studied the benefit of physical exercise (knee bends, pull-ups, diving, and running) and school performance among girls. One group received 1 hr of physical exercise per week, and the second group received 5 hrs. Klemm noted that the intellectually weakest students, tested by standard ability measures, generally benefited more from the intensive physical training than the intellectually stronger students. Finally, the area of greatest productivity for Klemm and his students in applied psychology concerned human mental functioning, or what we may call today *cognitive psychology*. He demonstrated the superiority of logical prompts, or cues, for learning sequences of numbers and studied the role of verbal prompting in learning. Altogether, Klemm published 21 papers investigating mental functioning.

Klineberg, Otto

EDWIN P. HOLLANDER

City University of New York, New York, NY, USA

Prof. Klineberg, Paris, In his 70s Frieman (Photo courtesy of Richard Frieman) (Nov 2, 1899–March 6, 1992)

Basic Biographical Information

American social psychologist, born in Quebec City, he was raised and educated initially in the multilingual, multi-ethnic milieu of Montreal, and became an American citizen in 1938. He credited his parents, brought to Canada as youngsters from central Europe and modestly educated, for stressing education's importance to all of their eight children, four of whom went on to graduate degrees. Though they did not have much money, "We were brought up in a friendly and warm atmosphere and conservative Jewish tradition, with a strong emphasis on education and scholarship" (1974, p. 164).

Klineberg graduated from McGill University in 1919, with a major in psychology and philosophy, receiving a first-class honors bachelor's degree. He was awarded the Prince of Wales Gold Medal with a tuition scholarship to study for an M.A. in philosophy at Harvard. There he encountered what he called "eye-openers" about psychology, by hearing Floyd Allport's social psychology lectures and attending a psychology seminar with H.S. Langfeld. After earning

his M.A. in 1920, he intended to obtain a Ph.D. in psychology, but was advised instead to get a professional degree because of poor academic job prospects in Canada. He then entered McGill's medical school thinking of becoming a psychiatrist, but on earning his M.D. in 1925 was still drawn to an academic career in psychology.

Klineberg took the major step in 1925 of studying for a psychology Ph.D. at Columbia. There he was influenced by the teachings of Robert Woodworth, who said that all psychology may be social psychology, and who later encouraged him to write his eminent text, stressing culture. This emphasis came from working with Franz Boas, a founder of anthropology, who also was very Frieman influential in Klineberg's development. He was the first chair of Columbia's Anthropology Department, and began the field's first U.S. Ph.D. program there. Klineberg's peers, such notable anthropologists as Ruth Benedict and Margaret Mead, with a master's degree in psychology, furthered Boas's views of culture's importance in their doctoral work. Pickren (2010) says, this was at a time when "culture became a boundary object" in the emerging identities of psychology and anthropology as scientific disciplines.

Others with whom Klineberg studied were Gardner Murphy, who became a close friend; Edward Sapir in anthropology; and the psychologist of learning, Edward Thorndike at Teachers College. Klineberg brought these latter streams together in his doctoral dissertation by studying the speed of reaction on performance tests among Yakima children in Washington State. He found that they were less concerned with speed than with accuracy, compared with white children there, which raised significant issues about culture's effects on tests of learning.

On completing his Ph.D. at Columbia in 1927, Klineberg went to Europe on a 2-year fellowship to study national differences among children. His results showed greater similarities than differences between nations. Returning in 1929, he took up a position as research associate in anthropology offered him by Boas. In 1931 he was appointed to the first of his psychology faculty positions at Columbia, where he remained until his retirement in 1962. He was the first chairman of a short-lived social psychology department, with Richard Christie, Stanley Schachter, and William

McGuire, among others. It followed Columbia's interdepartmental doctoral program, codirected by Paul Lazarsfeld in sociology and Goodwin Watson at Teachers College, joining Klineberg. This program was where the writer received a Ph.D. in 1952 in social psychology, with the latter two on his dissertation committee and Robert L. Thorndike, eminent psychometrician son of Edward L.

Major Contributions

A much admired figure in the social sciences internationally, Klineberg brought social psychology to the world, and the world to social psychology, by his influential books and far-reaching research on race and intelligence, international relations, and cultural comparisons (Hollander 1993, 1998).

The headline on Klineberg's obituary in *The New York Times* featured his study that contributed to the Supreme Court's 1954 *Brown v. Board of Education* decision overturning "separate but equal" schools. He found that children from all-Black schools in the South who migrated to integrated schools in the North had improved their intelligence test scores to a level equaling Northernborn Blacks. This work played a significant part in his long-time challenges to racial superiority theories. His seminal books in 1935 on *Race Differences* (Klineberg 1935a, b) and *Negro Intelligence and Selective Migration* (Klineberg 1935a, b) placed him at the center of a continuing controversy about beliefs in racial superiority, from which he did not flinch, even when faced with a reviewer's statement that his work was "hidden dynamite" (Klineberg 1990, p. 39).

In his talk to the New York Academy of Sciences in 1984 (published as Klineberg 1990), he considered his major contributions to be in cross-cultural studies, race differences, international relations, and mental health and illness. At home in New York, Paris, Rome, or São Paulo, he was fluent in most Romance languages, in addition to English, German, and Chinese, which he had acquired on his Guggenheim fellowship to China in 1935–1936. He later learned Portuguese to lecture as a visiting professor at the University of São Paulo in 1945–1947, receiving an award from Brazil for his contributions to the development of psychology there. Among his other influential roles on the international scene, he was president of the World

Federation for Mental Health, the International Union of Scientific Psychology, and the Inter-American Society of Psychology. He also authored a widely used and translated text, *Social Psychology* (1940, 2nd ed., 1954), and credited his wife, Selma, for helping him write it.

Invited by Jean Stoetzel to join him in teaching social psychology as a visiting professor at the University of Paris in 1960, Klineberg took up full-time residence there in 1962 to continue his research at the International Center for the Study of Intergroup Relations, which he established, with Marissa Zavalloni, a Columbia Ph.D. who had studied with him there, as Assistant Director. Among their publications together was *Nationalism and Tribalism Among African Students* (1969; Paris, Mouton), commissioned by UNESCO. During his year in China researching the emotional expression of the Chinese, he found traditional views of their non-expression were stereotypes. As Director of his Center, he and his students studied race problems, minorities, immigrants, national characteristics, the effect on student attitudes of study abroad, and other issues of culture and personality.

After teaching and doing research for two decades in Paris, he returned to New York in 1982 and was appointed to the adjunct faculty of the then called City University Graduate School and University Center. Harold Proshansky, its president at the time, had been a doctoral student of his, as were others of us, and we established a lecture series there to honor him in his 90th year. He and his wife were present for the Inaugural Klineberg Lecture on racial prejudice by John Dovidio, then at Colgate, in September 1990. The second lecture, on evaluation apprehension, was given in May of 1992 by Claude Steele, then at Stanford. Among subsequent lecturers in the series were Rupert Brown of the University of Kent and Marilyn Brewer of Ohio State University. Two doctoral dissertations in ethnic relations were also supported with these funds, contributed in honor of Klineberg.

The impact of Klineberg's international leadership extended also to his two appointments at UNESCO in Paris. He was Director of the Applied Social Science Research Division in 1953–1955, after serving there in 1948–1949, when he headed the "tensions project," from which he produced his book *Tensions Affecting International Understanding* (1950). As Director, he

took pride in having supported the funding of research by Gardner and Lois Barclay Murphy on the partition of India, leading to the book, *In the Minds of Men* (Murphy, 1953). He also authored the integrative book on persisting cross-national problems, *The Human Dimension in International Relations* (1964). In the early 1960s, he worked on these issues with Ralph White, Morton Deutsch, Charles Osgood, Herbert Kelman, Irving Janis, Urie Bronfenbrenner, and myself, all members of the Committee on Psychology in National and International Affairs at APA. Klineberg made the initial contact for us to perform research for the United Nations, set up during our 1963 visit with him to UN Undersecretary General Ralph Bunche, who hugged him as a dear friend.

Klineberg served in several US government roles, including with the Office of War Information in World War II and the US Strategic Bombing Survey in Germany afterward. APA gave him its award for Contributions to Psychology in the Public Interest in 1979, and posthumously in 1992 APA's first award for Distinguished Contributions to the International Advancement of Psychology.

His other honors include the Kurt Lewin Award in 1956 from the Society for the Psychological Study of Social Issues (SPSSI), for which he was seventh (1942–1943) president. He was the first recipient of the Klineberg Award for Intercultural and International Relations created by SPSSI in 1989 to recognize the significance of his work and encourage others to perpetuate it. Awards have been given yearly for research and publications on these topics, of such meaning to him. At its inception, he said, “[W]hat a wonderful, heartwarming experience it is for me to find toward the end of a long career that the kind of research I have been doing is considered worthy of being continued by others. I can no longer do it properly myself. . . . This is a very precious gift you have given me, and I thank you for it” (Quoted in Hollander 1992, p.20).

Among Klineberg's overriding achievements was the legacy he left of his inspirational values and character. His inexhaustible optimism was expressed by his son, Stephen, professor of sociology at Rice University, who spoke at the centennial honor of his father's birth held by the psychology section of the New York Academy of Sciences, saying, “He supported the decision to raise his children as Quakers, the religion my mother

joined but he did not, remaining an agnostic ‘humanist,’ as he often described himself. His philosophy of life was marked by a deep faith in human beings, in the power of reason and evidence to solve disputes and to move humanity forward. . . . [H]is belief in their essential goodness more than anything made him so beloved by so many. Life is filled, he used to say, with self-fulfilling prophecies: If you treat people in the firm belief that they are essentially good people who mean well, they will be likely to act in ways that confirm those expectations. And the most important and enduring body of his scholarly research was predicated on his deep conviction about the essential equality of all peoples, his absolute confidence, long before it became generally accepted, that the evidence would disprove any and all theories of ethnic or racial superiority” (S. Klineberg 1999).

A devoted family, Otto and Selma Klineberg's three children are Rosemary Coffey, a freelance editor and former teacher in Pittsburgh, PA, Stephen at Rice in Houston, and John, an aeronautical engineer, whose last NASA position was as Director of the Goddard Space Flight Center in Maryland.

Klüver, H.

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Klüver (1897–1979) was born in Schleswig-Holstein, Germany, and he died in Oak Lawn, Illinois. He immigrated to the USA in 1923, and became a naturalized US citizen in 1934. Before immigrating in 1923, Klüver had studied at the University of Berlin and had 3 years of graduate study at the University of Hamburg where his principal mentor was Max Wertheimer. Klüver received the Ph.D. degree at Stanford University in 1924. Klüver's first academic position was at the University of Minnesota where he became a friend and research colleague of Karl Lashley. From 1926 to 1928, Klüver was at Columbia University. He rejoined Lashley in 1928 at the Chicago Institute for Juvenile Research. Both joined the faculty at the University of Chicago in 1928 where Klüver remained until his death (Nahm and Pribram 1979).

Major Accomplishments/Contributions

Initially, Klüver gained notice for his research comparing eidetic imagery with perceptual experiences under the influence of mescal where Klüver mostly experimented upon himself. Subsequently, and to some extent influenced by Lashley, Klüver began the research that culminated in his best-known book, *Behavior Mechanisms in Monkeys* (Klüver 1933). The

book is well remembered for Klüver's behavioral methods applied to sensory, perceptual, and learning mechanisms. Klüver did not work in the era after it became both acceptable and fashionable to speak of "animal cognition," but had he done so, he might have been one of its ablest innovators and severest critics. A subject of overriding interest to Klüver was that of stimulus equivalence. His interest in equivalence is not easily summarized, but Klüver's view corresponded well with Henry Nissen's who wrote, "... all reasoning reduces to three processes, responsiveness to identity ... [and] ... difference, and, ... the balance, or relative weight given to each. ..." Substitute equivalence for identity and it summarizes what Klüver deemed important about equivalence.

Klüver's work with monkeys led to the theoretical contribution for which he is best known, the Klüver-Bucy syndrome. Before discussing that, when Stephen Polyak died (1955), the research for his monumental *The Vertebrate Visual System* was complete but the book was not ready for publication. Taking 2 years away from his own research, Klüver saw it through to publication. Klüver also provided some of the research that established that the striate cortex serves as the primary visual cortex, and he is remembered for developing neuro-histological methods, including an effective stain for white matter and the Klüver-Barrera method that combines in a single brain section one stain for the gray matter and another for the white matter.

Working with Paul Bucy, a neurosurgeon, and in a quest to understand the role of the temporal cortex in visual perception, temporal lobotomies were done on rhesus monkeys. Unanticipated, what became known as the Klüver-Bucy syndrome resulted (Nahm 1997). The syndrome, which it may be noted has also been reported to occur fully in humans, added significantly to understanding the neural substrates of emotion. The syndrome had been observed earlier (1888) by Brown and Shafer who apparently failed to realize its significance. Most striking following the temporal lobotomies was a behavioral tameness rarely seen in these feral monkeys. Eventually, this tameness was attributed to the removal of amygdala, and some of the other syndrome components were eventually attributed to structures in the temporal lobe other than the cerebral cortex. Nevertheless, a significant perceptual deficit

was attributable to the temporal cortex. It has been said that Klüver's research on striate cortex showed its role in the visual identification of objects, and his research on temporal cortex showed its role in knowing what the objects meant to the observer.

Klüver received so many high honors during his lifetime that only a select few can be mentioned here. He was a member of the American Academy of Arts and Sciences and of the National Academy of Sciences. He received the Gold Medal Award from the American Psychological Association in recognition of his scientific contributions, and he received an honorary Ph.D. degree from the University of Hamburg and honorary M.D. degrees from the University of Basel and the University of Kiel. Klüver also received the Karl Spencer Lashley Award in Neurobiology from the American Philosophical Association.

Koffka, Kurt

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: March 18, 1886; Died: November 22, 1941.

Koffka's first encounter with philosophy and psychology was via Alois Riehl at the University of Berlin. After a year in Edinburgh, which confirmed Koffka in his Anglophilia, he returned and concentrated on psychology, obtaining the doctorate in 1908 under Carl Stumpf with a dissertation on auditory and

visual rhythm. Koffka then moved to Freiburg and Würzburg for short stays, and then to Frankfurt in 1910, where he encountered both Wolfgang Köhler and Max Wertheimer. Together they formed the “big three” of the emergent psychological movement *Gestalttheorie* (Gestalt Theory or Gestalt psychology). Many philosophical and psychological insights were blended in this movement, which rapidly gained adherents in Europe and soon also in America as an alternative to established psychologies, structuralism on the one hand with its narrow and atheoretical stance, and behaviorism on the other with its exclusion of mind. Koffka moved to the University of Giessen in 1911 and, while maintaining contact with the Frankfurt psychologists, began a diverse independent program of research including work on brain injury and aphasia in conjunction with Robert Sommer parallel to the work of Gelb and Goldstein at Frankfurt. His appointment also covered education, which directed Koffka's toward developmental ideas that led to his most significant work, *Die Grundlagen der Psychischen Entwicklung*, published in 1921. Postwar privation in Germany limited Koffka's future, and Gestalt ideas had become very attractive to Americans. Ogden, R. M. at Cornell, who had taken his Ph.D. with Külpe in 1903 and was the head of the Department of Education, encouraged Koffka to publish a summary of Gestalt psychology in English in 1922, which is often acknowledged as essential to the growth of the movement in America (Koffka 1922). Ogden translated Koffka's developmental book, titled in English *The Growth of the Mind*, which was widely read, and also arranged the first of Koffka's American visits, to Cornell in 1924. Koffka, attracted by the economic opportunities in America, accepted, after several subsequent stays in America, a research professorship at Smith College in Massachusetts in 1927, where he remained until his death. Although Koffka had one Jewish parent, he did not directly experience the persecution that drove many of the rest of the Gestaltists into exile after 1933. At Smith, with freedom to work on his interests, he took advantage of opportunities to travel, to Uzbekistan in 1932 under the aegis of the Soviet government, where he conducted perceptual studies along with his required work in educational testing, and to Britain in 1939 to study head trauma.

Major Accomplishments/ Contributions

The essence of Gestalt theory as conveyed by Koffka was its focus on the perception of objects as meaningful within a context, its emphasis on the constructive and creative character of the mind, actively taking a role in organizing its understanding of the environment, and its wholism and molar point of view. In place of laws of stimulus and response, Gestalt offered laws of perceptual organization that conditioned all transactions between organism and environment. In 1935, Koffka published *Principles of Gestalt Psychology*, which became the central reference of its time for Gestalt ideas (Koffka 1935). By this time, however, Gestalt had another generation of adherents and practitioners who had themselves become well established in the USA, and also it had broadened to include other related streams of thought, for instance Lewin's field theory, R. M. Wheeler's idiosyncratic Gestalt-related laws, and younger psychologists such as Karl Duncker, Hans Wallach, and Rudolf Arnheim. So in a way the original Gestalt psychology was swallowed up in the stream of its successful derivations. Even so, Koffka had a profound influence on psychology. His accessible writing and his early and easy adaptation to America made him an excellent representative of the movement. Even though he worked at a smaller institution away from the American mainstream and died prematurely, he did have influential students and colleagues there, including Molly Harrower, Eugenia Hanfmann, Mary Henle, and Fritz and Grace Heider. He was also an undergraduate teacher of Bettye Goldstein (later the eminent feminist Betty Friedan) and Eleanor Jack (later Eleanor Gibson, James J. Gibson's wife). Probably his greatest influence was through his contacts with major psychologists who either adopted or resisted his ideas. Of these the two most significant in American psychology were E. C. Tolman and ► [Gibson, James J.](#) Tolman was one of the first Americans to have contact with Koffka when, after Herbert Langfeld suggested it, Tolman traveled to Giessen in 1912. Tolman continued this relationship after the war and eventually produced a hybridized psychology that had strong Gestalt influences. Gibson had written a dissertation at Princeton arguing against a Gestalt interpretation of perception

and then found himself on the Smith faculty with Koffka. Though he emphasized the primacy of environment and was even considered a perceptual behaviorist, much of what Gibson thought about the readiness of the organism for information pickup was anticipated in Koffka's *Growth of the Mind*. Gibson himself acknowledged a great debt to Koffka as well as attesting to his paramount importance in setting the direction for perceptual studies in the USA (Gibson 1971).

Kohlberg, Lawrence

NAVA R. SILTON¹, ARIEL BRANDWEIN²

¹Marymount Manhattan College, New York, NY, USA

²Long Island Jewish Medical Center, New York, NY, USA

Kohlberg, Lawrence (October 15, 1927–January 19, 1987) was a professor of Education and Social Psychology at Harvard University and is most renowned for his work in moral development and moral education.

Biographical Information

Lawrence Kohlberg was born on October 15, 1927, in Bronxville, NY to Alfred Kohlberg, an importer of Asian merchandise and to Charlotte Albrecht, a chemist. Charlotte was Alfred's second wife and

Lawrence was the youngest of four children. While Kohlberg was born into an affluent family, his parents separated while Kohlberg was still a child. Lawrence's Jewish family roots inspired his later interest in justice as well as his interest in putting his theories into practice. For instance, Kohlberg demonstrated an early concern for the welfare of others when he volunteered as a Merchant Marine in World War II and later when he smuggled Jews through the Jewish blockade into Palestine as a member of the Haganah, the Israeli defense force.

Kohlberg completed his secondary education at Phillips Academy in Andover, Massachusetts, a private boarding school. Following his service to the Merchant Marines, he attended The University of Chicago where he received a bachelor's degree in 1 year (he had been excused from many of his requirements due to outstanding scores on admissions exams). He then went on to complete a doctorate in developmental psychology at Chicago. It was during the writing of his dissertation and through the influence of Jean Piaget that Kohlberg began to develop his stages of moral development for which he is renowned today.

In 1955 Kohlberg married Lucille Stigberg. They had two sons, David and Steven, but later divorced. He was later linked with Ann Higgins, who is currently a professor of Applied Developmental Psychology at Fordham University.

Major Contributions

Following completion of his graduate studies, Kohlberg went on to teach psychology first at Yale University from 1961 to 1962 and then at the University of Chicago from 1962 to 1967. He then moved east to Harvard University where he taught social psychology and education for 10 years. It was at Harvard where Kohlberg met Carol Gilligan, who would later challenge his work and amend his theory to incorporate a woman's voice and a feminist ethic. Gilligan noted that Lawrence Kohlberg's conventional stage theory was limited by the fact that his sample primarily included 72 Caucasian male youths, who were largely lower and middle class. She suggested that women may express morality more from a care and relationship

perspective than a solely male-oriented justice perspective. Later, he improved upon another criticism, that his theory dealt more with moral reasoning than moral action, by introducing the notion of a "just community approach." This idea was initially inspired by a trip to Israel in 1969 where he observed children's interactions on a Kibbutz. Kohlberg believed that children on a Kibbutz demonstrated greater moral development than those living off a Kibbutz. Upon returning to the USA he tried to create "just communities," mostly in school environments, where students and faculty would work in a democratic fashion to create moral school policy. The first of these schools, the Cluster School located in Cambridge, Massachusetts, opened in September 1974. Unfortunately, many of these schools disbanded following Kohlberg's death.

In 1971, while conducting cross-cultural research in Belize, Kohlberg contracted a rare parasitic illness that affected him both physically and mentally for 16 years. On January 17, 1987 he requested a day of leave from the Mount Auburn Hospital in Cambridge, Massachusetts wherein he was being treated for his illness. After missing for a few days, his car was found abandoned on a residential street in Winthrop, Massachusetts on January 21. Although controversial, it is speculated that he committed suicide in the Boston Harbor at the age of 59. One year later, the Harvard Graduate School of Education declared April 15th as Lawrence Kohlberg Day.

Kohlberg's greatest influence on the field of psychology came from his conventional stages of moral development. He first began to identify these stages while writing his doctoral dissertation. By expanding upon ideas originally described by Piaget, Kohlberg analyzed the moral decision making of individuals at various ages to specific moral dilemmas. One of the most well-known dilemmas presented by Kohlberg is the "Heinz Dilemma." In this scenario, a man named Heinz is faced with the decision of whether or not to steal a drug to save the life of his sick wife (which he cannot afford) or to let his wife die. The pharmacist, who is selling the drug for ten times its cost will not allow Heinz to purchase the drug cheaper or to pay him the remainder of money later. Kohlberg presented

numerous other scenarios, including a scenario involving a boy working to afford camp, a girl working to afford a special rock concert, and other relevant moral dilemmas as well. Based upon his findings, he was able to classify moral development into three levels, with each level featuring two stages. The first level, Preconventional Morality (including Stage 1 [Obedience and Punishment Orientation] and Stage 2 [Instrumental-Relativist Orientation]) extends from ages 4–10 years. The second level, Conventional Morality (including Stage 3 [“Good Boy/Nice Girl” Orientation], and Stage 4 [Law and Order Orientation]) spans the ages of 10–13. His final level, Postconventional Morality (including Stage 5 [Legalistic Orientation] and Stage 6 [Universal, Ethical Orientation]), begins in adolescence and lasts through adulthood.

Köhler, W.

PATRICK DRUMM

Ohio University, Lancaster, OH, USA

Basic Biographical Information

Wolfgang Köhler (1887–1967) was born in Tallinn, Estonia, where his father worked as headmaster in a school for German citizens living there. The Köhlers returned to Germany when Wolfgang was 6 years old. In a family that valued educational achievement, Wolfgang’s older brother became an academic and his sisters became either teachers or nurses. The German university system was arguably the best in the world as the twentieth century began, and Köhler followed the common practice of selecting professors from different schools. He attended classes at Tübingen and Bonn before studying physics at the University of Berlin under Max Planck. He earned his Ph.D. in psychology there with Carl Stumpf in 1909.

Major Accomplishments/Contributions

Köhler’s professional career began at the University of Frankfurt’s Psychological Institute. There, in the summer of 1910, Max Wertheimer (1880–1943) enlisted Köhler’s aid in studies of illusory movement. By varying the intervals between successive presentations of static images, Wertheimer created perceptions of movement whenever an interval was sufficiently brief. Wertheimer’s participants, Köhler, Kurt Koffka (1886–1941), and Koffka’s wife, all reported seeing illusory movement (Köhler 1967/1971a; Sekuler 1996). Wertheimer, Koffka, and Köhler became convinced that such findings could neither be predicted nor explained by any theory proposing that the conscious mind constructs perceptions out of constituent sensory elements. Instead they concluded that the mind organizes incoming discrete sensations and gives them meaning beyond the sensations themselves. Thus, Gestalt Psychology was born. In emphasizing the top-down role of higher mental processes, it opposed the reductionism of Wundt’s voluntarism, Titchener’s structuralism, and varieties of behaviorism that later arose in the United States (Köhler 1929).

During World War I Köhler conducted seminal research on cognitive processes in apes. The Prussian Academy of Science appointed him director of the anthropoid research station on Tenerife, one of the Canary Islands off the west coast of Africa. Beginning in 1914, he conducted a series of studies of human and nonhuman problem solving that supported the construct of *insight learning* (Köhler 1925, 1967/1971a). The studies included *Umwege*, or detour problems, presented to a child, a dog, and several hens – the child and the dog found their way around barriers to reach desired objectives after brief periods of reflection, which were marked by a discontinuity between their behavior before and after the problem's solution was initiated. The hens did not perform well and many kept butting up against the wire fence barrier obstructing their path until the problem was simplified by shortening the barrier. Chimpanzees solved these simple problems so easily and quickly that Köhler felt no conclusions could be drawn from their behavior. Therefore, he created more complicated problems for them. He suspended a weighted basket containing bananas set to swinging back and forth from their enclosure's wire roof. When their attempts to jump to the basket failed, several chimpanzees independently solved the problem by climbing a nearby scaffold and catching the basket when it swung within their reach. One chimpanzee even learned by observing another's successful solution and then imitating her. In another test a banana was suspended from the top of the enclosure. One chimpanzee tried unsuccessfully to knock it down with a stick but then succeeded when he dragged a box over, climbed up on it and used the stick to knock down the fruit. In variations of this test problem, chimpanzees built towers of up to four boxes to retrieve the fruit. Köhler documented chimpanzees' insightful use of implements in several different problem situations, and by designing novel problems demonstrated their intelligence and insight. Some controversy surrounds Köhler's activities on Tenerife, which the Allies blockaded during the war. Ley (1990) alleged that Köhler illegally sent intelligence information about offshore naval traffic to the Germans via wireless radio. Teuber (1994) challenged that allegation, asserting that Köhler's activities on Tenerife were purely research, not espionage.

In 1920, Köhler returned to Berlin to become acting director of the Psychological Institute, and

within 2 years was appointed professor at the University of Berlin. His *Physical Gestalten* (Arnheim 1998; Köhler 1920/1997) extended Gestalt psychology and tied it to other sciences. Köhler's former teacher, Max Planck, the originator of quantum theory, clearly influenced him and *Physical Gestalten* remains a noteworthy attempt to integrate ideas from physics into psychology. Köhler applied concepts from field physics and proposed that force fields in the brain accounted for the Gestalt phenomena of perception (see also Köhler 1967/1971a).

Although Germany endured years of hardship following its defeat in World War I, Gestalt psychology flourished at the University of Berlin. But, when the National Socialists assumed control of the government in 1933, the acclaimed German university system could not sustain the depredations imposed almost immediately by the Nazis. The Nazis fired Jewish professors and expelled Jewish students. Books unacceptable to Nazi ideology were banned and public book burnings soon followed. Reacting to these developments, Köhler wrote in April of 1933 what was to be the last anti-Nazi article published openly in Germany during Hitler's regime. Expecting to be arrested for this act, Köhler and some close associates at the Psychological Institute spent the night playing chamber music (Henle 1968/1971). The Gestapo never arrived, and Köhler, who had twice accepted brief teaching assignments in the United States, emigrated to accept a position at Swarthmore College thereby joining the other founders of Gestalt psychology who likewise had emigrated to America.

Köhler's later work explored *isomorphism*, a form of psychophysical parallelism in which the dynamics of brain processes should correspond with conscious experience (Köhler 1960/1971b). Based on the thesis originally formulated in *Physical Gestalten*, it proposes that two events adhere together as one if brain excitation associated with these events overlaps, but separation between fields of brain excitation embodies two events subjectively perceived as separate in space and time. Although some evidence supported the construct (Köhler et al. 1952), other research ultimately led to isomorphism's abandonment (Hilgard 1987).

Köhler's acceptance of the position at Swarthmore in 1935 placed him in the minority of American

psychologists who held an explicitly cognitive perspective during the mid-century heyday of American behaviorism. In 1956 he became a research professor at Dartmouth College, and in 1959 he was elected president of the American Psychological Association. Near the end of his professional career, Köhler saw the dominance enjoyed by behaviorism begin to decline as perspectives opposing it became increasingly popular. Structural linguistics provided convincing alternatives for behaviorist accounts of language acquisition, and Piaget's cognitive stage theory gained acceptance in American developmental psychology (Hilgard 1987). Thus, Gestalt psychology's critiques of behaviorism were joined by others as American psychology once again recognized the study of cognitive phenomena as legitimate. Köhler died in New Hampshire on June 11 in 1967.

Krippner, Stanley

RIVKA BERTISCH MEIR

Mental Health Counselor, New York, NY, USA

Basic Biographical Information

Stanley C. Krippner, an American psychologist, was born on October 4, 1932 in Edgerton, Wisconsin, of Norwegian, German, and Irish ancestry. In 1954, he received his B.S. in speech education at the University of Wisconsin, Madison, and worked as a public school speech therapist before attending graduate school, receiving his M.A. and Ph.D. degrees from Northwestern University in 1957 (in counseling and guidance) and 1961 (in educational psychology) where he was the graduate assistant for Paul A. Witty, the first of his distinguished mentors. While at Northwestern University, he met Dr. Martin Luther King, Jr., attended all of his on-campus seminars, then personally guided him on a tour of the campus; he credits King for stimulating his interest in social activism, a theme that was to characterize Krippner's later work on behalf of children with special needs, combat veterans, Native Americans, and other marginalized groups. In his earlier years, he spent his summer vacations working as a program director at YMCA youth camps and in 1959 he received the YMCA Service to Youth Award, the first of many awards he was to receive during his career.

Currently, Krippner is the Alan Watts Professor of Psychology in the College of Psychology and Humanistic Studies at Saybrook University in San Francisco. Formerly, he was director of the Kent State University Child Study Center (Kent, Ohio), which houses his archives in the Special Collections department of its library. From 1964 to 1973, Krippner was the director of the Maimonides Medical Center's Dream Research Laboratory (in Brooklyn, New York), having been suggested for this position by Gardner Murphy, a long-time mentor for whom he had served as teaching assistant during Murphy's guest professorship at the University of Hawaii. For 36 years he was married to Lelie Harris, and retained a friendly association with her after their divorce.

Major Accomplishments and Contributions

At Kent State University, Krippner's classes for graduate students in the School of Education emphasized the neuropsychology of learning disabilities. As early as 1967, he published a pioneering paper on the role played by central nervous system dysfunction in reading problems, at a time when many specialists in the field were emphasizing emotional difficulties and poor schooling as the primary etiological factors. He continued to contribute articles on this topic after leaving Kent State for Brooklyn, New York, where he and his colleagues studied anomalous effects in dreams for 10 years. This was the first long-term laboratory study of the topic and is described in the 1974 book *Dream Telepathy* coauthored with the renowned psychiatrist Montague Ullman, the founder and director of the Maimonides Community Mental Health Center. This work was the basis for career achievement awards that Krippner received from the International Association for the Study of Dreams (in 2006) and the Parapsychological Association (in 1998). In 2002, he received Andrah University's Award for Life-Time Achievement in Parapsychology, named after J.B. Rhine, another of Krippner's long-time mentors. In 2010, he co-edited *Debating Psychic Experience: Human Potential or Human Illusion* an historic volume in which parapsychologists and their critics confront each other in the form of presentations and rebuttals.

Krippner's next position was at the Humanistic Psychology Institute in San Francisco, later renamed

Saybrook University, where he designed a series of courses focusing on the study of consciousness. Krippner was an early leader in Division 32 of the American Psychological Association (APA), the Society for Humanistic Psychology, serving as the president of the society from 1980 to 1981. He received the Charlotte and Karl Buhler Award from this society in 1992; Charlotte Buhler had been an early mentor, introducing him to the basic principles of humanistic psychology. Krippner was given the Pathfinder Award by the Association for Humanistic Psychology (AHP) in 1998, "for enduring contributions to the exploration and expansion of human consciousness." Krippner served as the president of AHP in 1992. Krippner has written many articles about humanistic and existential psychology, linking them with chaos theory, Jungian thought, and postmodern perspectives. He has served as the president of the National Association for Gifted Children, the International Association for the Study of Dreams, and APA's Division 30 (the Society for Psychological Hypnosis) from which he received its Award for Distinguished Contributions to Professional Hypnosis in 2002, the same year that he received APA's Award for Distinguished Contributions to the International Advancement of Psychology. In 2003, he received the Ashley Montagu Peace Award from a Russian-American consortium for his "service toward the advancement of an international culture of peace." In 1996 the First Church of Humanism, New York City, named him "Humanist of the Year" for his years of social activism.

For 4 decades, Krippner had a close association with the celebrated psychologist Albert Ellis, attending many of his seminars on Rational-Emotive Behavior Therapy. Krippner drew on the principles of REBT (especially his distinction between rational and irrational beliefs) to conceptualize, with the psychotherapist David Feinstein, "personal mythology," the life narrative and worldview that impact one's attitudes and behaviors. Their book, *Personal Mythology* served as the basis for several doctoral dissertations at Saybrook University and Krippner and Feinstein conducted personal mythology workshops and seminars jointly or separately in a dozen different countries. It also served as a theme for Krippner's co-edited anthology *The Psychological Impact of War Trauma on Civilians* (2003) and coauthored book *Haunted by Combat:*

Understanding PTSD in War Veterans (2007). Another pioneering co-edited anthology was *Varieties of Anomalous Experience: Examining the Scientific Evidence* published by APA in 2000, becoming one of their best-sellers. Krippner became a Charter Member of the International Society for the Study of Dissociation, a Charter Fellow of the Association for Psychological Science, and a Founding Fellow of the American Academy of Clinical Sexologists, having published the first studies of the dreams of pregnant women and, in a separate study, the dreams of male-to-female transsexuals.

His co-edited book, *Broken Images, Broken Selves: Dissociative Narratives in Clinical Practice* (1997), reflects his long-standing investigation of dissociation, a phenomenon that he encountered in visits and field research with shamans and other indigenous practitioners from six continents, among them the Mazatec shaman Maria Sabina and the intertribal medicine man Rolling Thunder. Krippner regards one of his greatest honors as being the Lakota Sioux name, *Wicasa Waste*, given him by a Native American elder, which can be roughly translated as “*mensh*.” Krippner met Rolling Thunder through his association with the Grateful Dead musical group, and is a member of the Grateful Dead Scholars, having published the first scholarly article in 1973 about this legendary rock band. Krippner was the first recipient of the Ruth-Inge Heinze Memorial Lecture Award (2008) named after

his colleague, Dr. Heinze, who founded an annual shamanism conference, held at Dominican University, San Rafael, California, where Krippner currently lives. Krippner published the first article on shamanism to appear in APA's flagship journal, *The American Psychologist* taking the position that shamans served many psychological functions for their communities and that their contributions to health care, the expressive arts, mental imagery, ritual and mythology, and even the placebo response are worthy of academic investigation. In 2007, Krippner received the Woodfish Award for his collaborative work with Native Americans.

L

La Mettrie, J. O. de

PATRICK DRUMM

Ohio University, Lancaster, OH, USA

Julien Offray de La Mettrie. Public domain image.

Basic Biographical Information

Julien Offray de La Mettrie (1709–1751) was born on December 25, 1709 in Saint-Malo, a city in Brittany along the English Channel whose inhabitants championed independence. In fact, in the last decade of the fifteenth century, Saint-Malo attempted to establish itself as an independent republic. They adopted the motto, “not French, not Breton, but Malouins.” La Mettrie’s independent-mindedness represented well the reputation of the city of his birth. His father’s successful merchant business made a good education possible for the young La Mettrie. At the age of 15, he wrote in support of Jansenism, a heretical theology formulated during the Roman Catholic Counter-Reformation. In 1725, he entered the College d’Harcourt, which pioneered a Cartesian curriculum of philosophy and natural science. After 5 years studying medicine at the University of Paris, he avoided the steep graduation fees

there by finishing his degree at the University of Rheims. Convinced his training was inadequate to actually practice medicine, La Mettrie undertook 2 years of additional study under Hermann Boerhaave (1668–1738), the highly respected physiologist and clinical practitioner at the University of Leiden, before returning to practice medicine in Saint-Malo. There La Mettrie translated several of Boerhaave’s works, emphasizing the mechanistic perspective expressed in them. He also wrote treatises on specific diseases and medical satires that ridiculed Parisian physicians. The satires antagonized the medical establishment in Paris. Further outrage provoked by his subsequent philosophical works drove him from France to Holland, then to the Berlin court of Frederick the Great (1740–1786) who appointed him to the Royal Academy of Sciences. La Mettrie remained in Prussia until his death on November 11, 1751. Most of the biographical information on La Mettrie comes from the eulogy given by Frederick the Great. Although La Mettrie’s published works survive, no personal papers and little of his correspondence remain (Wellman 1992).

Major Accomplishments/Contributions

La Mettrie was considered radical during the French Enlightenment but much of what he wrote is uncontroversial for twenty-first century psychology. His first major philosophical work was inspired by a bout of fever while he was on a military campaign serving as a physician in 1744. He observed within himself changes in his thinking that he attributed to the physiological effects of his fever. Published in 1745, *L’histoire naturelle de l’âme* (*Natural History of the Soul*) proposed an empirically based understanding of thought as a product of activity within the human body. The reaction in France was banning the book and exiling La Mettrie to Holland. In 1748 he published his most famous work, *L’Homme Machine* (*Man a Machine or Machine Man*) which described

mechanistic effects of the body on the mind, and also pointed out similarities between humans and animals. La Mettrie argued that conscious, volitional activity differs from reflexive, instinctive activity only in the complexity of the mechanistic substrate that supports it. Most introductory treatments of modern neuroscience agree with this assertion, correlating working memory and volition with activity in the cerebral cortex, especially the frontal lobes, whereas reflexes are associated with the hindbrain or spinal cord. Regarding the similarities between humans and animals, one of La Mettrie's assertions seemed remarkably prescient of twentieth century comparative psychological research. He proposed that an ape could learn a language via the methods of Jean Coenrad Amman, a Swiss teacher of the deaf. If Amman's pedagogical techniques were applied, an ape should learn a language just as a deaf person can. (The use of sign language in twentieth century research with apes was more successful than the use of spoken language, but confusion remains about La Mettrie's prediction. The seemingly simple question of whether he thought an ape could learn a spoken or a signed language has much to do with the history of deaf education. Two pedagogical approaches have divided educators of the deaf for centuries. One approach emphasizes the use of signs or manual gestures whereas the other oralist approach emphasizes speaking and lip-reading. It is noteworthy that France in the eighteenth century accorded sign language education unprecedented legitimacy – the abbé de L'Epée, used signs in his deaf education program in the 1760s, not long after La Mettrie's death. La Mettrie's use of the phrase "*faire des signes*" (La Mettrie, 1912/1748, p. 29) clearly refers to gestural communication. Still, Amman (1972/1694) was undisputably an oralist whose goal was to teach his deaf students to read lips and speak. Thus, it remains unclear whether La Mettrie truly anticipated attempts to teach signs to apes.)

In February of 1748, La Mettrie took refuge in Berlin after publication of *L'Homme Machine* triggered a public outcry and the burning of his books in Holland. There he continued to write and practice medicine until his untimely death. At a feast held in his honor, he consumed pheasant pate, fell ill, became delirious and died (Vartanian 1960).

La Mettrie is significant in psychology's history as a thinker who espoused a biological basis for mental

phenomena. He carried forward Descartes' ideas of a mechanistic body but rejected the corresponding notion that an immaterial soul exists separately within the human body. Thus, he connects Descartes with the mechanism that emerged in European physiology of the nineteenth century and that characterizes significant areas within psychology to the present day.

Langfeld, Herbert Sidney

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: July 24, 1879; Died: February 25, 1958

Langfeld's early education was gained in Philadelphia schools and Haverford College. His first career was as a secretary to the US Naval attaché in Germany. There, in 1903, he decided to pursue advanced studies in psychology under Carl Stumpf in Berlin, receiving the doctorate in 1909. One of the last Americans to study psychology in Germany, he returned to America and taught at Harvard until 1924, mentoring Floyd Allport whose dissertation he supervised. Langfeld also counseled Gordon Allport. When E. B. Titchener complained about Allport's choice of personality traits as a subject for research, Allport said that Langfeld remarked "You don't care what Titchener thinks," confirming him in his vocation (Allport 1967). In 1924, after the arrival of E. G. Boring at Harvard, Langfeld became Howard C. Warren's colleague at Princeton University, bringing

with him Leonard Carmichael and also enticing E. B. Holt out of retirement for 10 years. Together Holt, Warren, and Langfeld had a hand in the education of James J. Gibson, who revolutionized perception. Langfeld became department chair in 1932, retiring in 1947.

Major Achievements/Contributions

Although very capable as a laboratory psychologist, Langfeld proved to have his greatest influence through his ubiquitous activity as an editor, collaborator, teacher, and committeeperson. Langfeld was well versed in knowledge of the range and content of textbooks (he was the regular reviewer, during the early 1910s, of textbooks for the *Psychological Bulletin*) and a close colleague of psychologists preeminent in establishing the working vocabulary of the field, Howard C. Warren and E. G. Boring. During the 1930s and 1940s, He co-edited, along with Boring and Harry Porter Weld, the multiauthored *Psychology: A Factual Textbook* (1935) and participated in its several revisions. He also was part of the team that produced the widely read *Psychology for the Fighting Man* (1943), an outline of psychology that was widely disseminated among the US Armed Forces. His most significant publishing contributions were, however, his journal editorships, especially of the *Psychological Review* from 1934 through 1947, where he directed the publication of many of main articles of psychology's era of grand behavioristic systems. The most important of his contributions there was his organization, following the suggestion of E. G. Boring, of a *Review* symposium on operationism in 1945 (Langfeld 1945). Multilingual and with a background in practical diplomacy, he was acknowledged as an important facilitator of international cooperation among psychologists in the inter- and postwar eras, and served for a time in the late 1940s as Secretary-General of the International Union of Scientific Psychology. Theoretically he was strongly influenced by E. B. Holt who was a close friend and frequent correspondent, and he reflected many of Holt's ideas, especially those relating to a motor theory of consciousness (Langfeld 1931). While his commitment to a generally physicalistic psychology is reflected in his association with Boring, Langfeld's most comprehensive theoretical statement is found in his 1920 monograph *The Aesthetic Attitude* (Langfeld 1920). There he expressed not only his agreement with Lipps's

theory of *Einfühlung* (empathy) as well as with many of the ideas advanced by the Gestalt school on the influence of structure and form on perception, but also embodied a wide-ranging integration of various other areas including social and developmental considerations, which imbued his later contributions as well. Langfeld was also a highly cultured individual and was as comfortable referring to artists, playwrights, or poets as to scientific psychologists, and helped continue an interest in psychological aesthetics during a particularly nonaesthetic interregnum. It is unfortunate that few of Langfeld's papers have survived, as he was a major facilitator of the emergence of eclectic modern psychology.

Lashley, Carl

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Basic Biographical Information/Major Accomplishments

American psychologist. Born in Davis, West Virginia. June 7, 1890. Studied at the University of West Virginia. Morgantown. B.A. 1910; University of Pittsburgh, Pennsylvania, M.S. 1911; Johns Hopkins University, Baltimore, Ph.D. 1914. Married Ann Baker in 1919; married Claire Schiller in 1957. Instructor, 1917–1918, Assistant Professor, 1920–1921, Associate

Professor, 1921–1924, and Professor of Psychology, 1924–1926, University of Minnesota, Minneapolis; Research Psychologist, Behavior Research Fund, Institute for Juvenile Research, Chicago, 1927–1929; Professor of Psychology, University of Chicago, 1929–1935; Professor of Psychology, 1935–1937, Research Professor in Neuropsychology, 1937–1955, and Professor Emeritus, 1955–1958, Harvard University, Cambridge, Massachusetts. Hughlings Jackson Memorial Lecturer, Montreal Neurological Clinic, 1937; Vanuxem Lecturer, Princeton University, New Jersey, 1952. Investigator, United States Interdepartmental Hygiene Board, 1919–1920. Director, 1937–1955, and Director Emeritus, 1955–1958, Yerkes Laboratories of Primate Behavior, Orange Park, Florida. Associate Editor, *Journal of Genetic Psychology*, *Quarterly Review of Biology*, *Genetic Psychology Monographs*, and *Journal of Psychology*, President, American Psychological Association, 1929, and Society of American Naturalists, 1947. Recipient: Howard Crosby Warren Medal, Society of Experimental Psychologists, 1937; Daniel Giraud Elliot Medal, National Academy of Sciences, 1943; William Baly Medal, Royal College of Physicians, London, 1953. Honorary M.A.: Harvard University, 1942. Honorary doctorate: University of Pittsburgh, 1936; University of Chicago, 1941; Western Reserve University, Cleveland, 1951; Johns Hopkins University, 1953; University of Pennsylvania, Philadelphia, 1954. Member, National Academy of Sciences; American Academy of Arts and Sciences. Foreign Member, British Psychological Association; Royal Society. *Died August 7, 1958.*

After completing his doctorate on cortical learning in rats, K.S. Lashley worked with Shepherd Franz at the Government Hospital for the Insane in Washington, DC. In 1917, the two of them published work on the effects of cerebral destruction on habit-formation and retention in rats. Lashley soon took over this work from Franz and produced an important series of studies on the effects of cortical lesions on sensory discrimination and speed and ability in learning mazes in rats. It was during this time that Lashley created the jump stand, an apparatus used in studying operant conditioning. A rat is placed on a small stand and forced to jump through one of two doors, each of which is marked with a stimuli, such as vertical and horizontal lines. If he jumps through the correct door, the rat finds some

food or other reinforcement behind it. If he attempts to jump through the incorrect door, he finds it locked, bumps his nose, and falls down into a net. In order to avoid the possibility that the rat is learning a position preference – that is, jumping through the right or left door – Lashley switched the doors back and forth at random.

Lashley summed up his general conclusions in a monograph entitled *Brain Mechanisms and Intelligence* in 1929. In this work, Lashley plotted the number of errors rats made in learning a maze against the amount of destruction of cortical tissue and against the difficulty of the maze. Lashley found that the more difficult the maze and the more extensive the cortical destruction, the more rapid was the increase in the number of errors the rats made. From this work, Lashley laid down his principle of mass action, which stated that the more cortical area available the more rapid and accurate the rat's learning. Lashley was unable to discover whether any specific area of the cortex was responsible for any specific function, and he determined that in general it was the size of the lesion, rather than its location, which impaired the rat's learning abilities. Although all of the lesions had some effect, none of them completely obliterated the rat's capabilities. Some years later, surveying the work he had done over the years, Lashley said facetiously that he was tempted to conclude that learning was impossible.

Lashley developed the principle of equipotentiality from this work. Equipotentiality stresses the complexity of habit-formation. According to this principle, which is an extension of the principle of mass action, the cortex is able to substitute new areas for control in performing a task when the old areas are destroyed. Nonetheless, Lashley concluded that there were certain tasks where specific areas of the cortex were responsible for learning. For instance, the visual area is necessary for the rat to discriminate visual patterns; they are not, however, necessary to discriminate brightness. Thus, while more difficult learning tasks may indeed require extensive cortical use, simpler tasks, such as pattern discrimination, may after all have only one specific area of control available for use.

As early as 1929, Lashley raised a number of questions involving this matter of specific versus general areas of control. How do you put a relationship

between two stimuli on a common path which carries the report of what is discriminated? How especially can this be done when the two stimuli are simultaneous? When they are successive? And how do you get temporal organizations within the cortex which take account of order? Lashley's research shows just how it is possible for a physiological psychologist to study the neural bases of learning and discrimination, both of which can be measured through behavioral techniques, without resorting to the concept of consciousness.

⁵Facultad de Psicología, Universidad de Buenos Aires and Hospital Infanto-Juvenil Dra. Carolina Tobar García

The history of psychology in Latin America and the Caribbean has followed a diverse path, strongly influenced by philosophical and the scientific movements of the time, while attempting to develop an autonomous psychology that reflects the uniqueness of the specific countries. Since this can only be a brief synopsis of some of this history, we will only present

three sampled countries (namely, Argentina, Dominican Republic, and Mexico) so as to give the reader a sense of how the psychology movement operated differently in different Latin-American countries. Early accounts of the history of psychology in other Latin-American Countries, such as Cuba, Colombia, Nicaragua, Puerto Rico, Venezuela, and Brazil, were chronicled by Sexton and Hogan (1992) and by Whitford (1985) for Uruguay. Some of the history of psychology in Mexico can be seen in the biographical entry for Rogelio Diaz-Guerrero, one of the most prominent psychologists in Mexico, prepared by Rolando Diaz-Loving.

A History of Psychology in Argentina: Its Theories, Research, Contribution, and Future

The media frequently comments about the large number of psychologists practicing in Argentina and the strong psychoanalytic bend that many of these psychologists tend to maintain. The Argentinean philosopher and physician Mario Bunge (2010) provided an interesting analysis regarding the state of psychology in Argentina. According to him, of the 50,000 psychology graduates, 38,000 practice in Buenos Aires (or 150 professionals per 100,000 inhabitants), with 800 in the Federal Capital. His analysis has psychology as the third most popular degree in La Universidad de Buenos Aires, which has several departments, all with a strong psychoanalytic orientation.

Current programs in psychology at the *Universidad de Buenos Aires* are characterized by a variety of training programs which, in addition to psychoanalysis, also include different psychological schools of thoughts. However, the problem has been the issue of disconnect of the focus of psychology training in Argentina and the rest of the world. According to the Historian Lucia Rossi (1994), when one looks at the national and international arena, we can see clearly the endemic absence of contributions of the Faculty at the University of Buenos Aires (UBA) in international psychology congresses. This absence is due to the clear incompatibility of the training model in Argentinean universities with the emphasis on the cognitive-behavioral theme predominant in these events. The over-reliance on psychoanalytic principles to explain the range of psychopathological formations sets Argentina apart from other countries.

Thus, explaining the history of psychology in Argentina inevitably also implies the need to articulate the role of psychoanalysis in this regard, its influence in the field of mental health to which it belongs, and in the area of philosophy and psychiatry. This is the case because, before becoming an independent program, psychology programs at the University of Buenos Aires were originally housed in the Faculty of Philosophy and Liberal Arts, and were strongly influenced by theories on positivism, phenomenology, existentialism, materialism, and idealism. As we will see later, the formation of psychologists, psychiatrists, and psychoanalysts was strongly influenced by the contribution of various thinkers with these intellectual foci.

Critical Moments in the Development of Psychology in Argentina

The importance of the philosophical influence in Argentinean psychology can be clearly seen in the International Philosophy Conference in Mendoza in 1949. At this conference, attended by world-renowned authors, such as Jean Hyppolite, Julián Marías, Karl Jaspers, and Bertrand Russell, among others, we see that of the 30 plenary sessions, 6 were from psychology and of the 90 papers presented, 22 were of psychological nature (Rossi 1994). We can also see the influence of psychiatry in the training of psychology, where many of the faculty involved in Argentina's psychology degree programs came from a medical background; an example of the affinity between the two disciplines can be seen in the numerous papers written by psychologists that were presented at several psychiatry congresses in Argentina.

But the history of psychology in Argentina goes back to the colonial times when psychology focused its attention to the study of the soul, from the point of view of Aristotle and St. Thomas Aquinas. According to Nidia Georgina De Andrea (2009), this movement was predominant in Europe and to a lesser extent in the United States and had an impact on the intellectual and scientific community in Latin America, including in Argentina, with its main proponents being Juan Crisóstomo Lafinur and Diego Alcorta. It is in this context that at the end of the nineteenth century, psychology as a science was born in Argentina. Thus, formally, the beginning of psychology as discipline can be said to have started with the establishment of

the first chairs of psychology toward the end of the nineteenth century, with a strong positivistic influence. Soon after, the first experimental psychology laboratory was created and, in 1908, the Argentinean Psychology Society was established, founded by José Ingenieros, Horacio Piñero, Víctor Mercante, and Francisco de Veyga, the first of its kind to be created in Latin America (Alonso and Eagly 1999; Klappenbach 1987, 1998, 2000). It is in the *Colegio Nacional Buenos Aires*, institution dependent of the *Universidad de Buenos Aires*, where the first experimental research is performed by Víctor Mercante, framed in the physiological tradition. A year later, Dr. Rodríguez Etchart introduced in this same college, Wilhelm Wundt's experimental psychology which had a strong psychophysiological basis. Dr. Horacio Piñero also organized there the first experimental psychology laboratory in 1900 and which made possible for him to be appointed as Professor of Experimental Psychology in the Philosophy Faculty in 1902, creating the first ever experimental psychology laboratory there. These events demonstrate that the first inclusion of psychology as a discipline was influenced by the European wave, which itself was influenced by the German wave. Additionally, authors, such as Janet, Charcot, and Binet from the French tradition and later on Charles Darwin, William James, and Herbert Spencer, with biological bases, were introduced in Argentina by José Ingenieros.

With regard to psychiatric influence, it is important to note that from 1880 to 1910, psychiatry in Argentina was dominated by the French psychiatric tradition and positivism (Alienism). It is at this time when not only the first psychiatric hospitals were built but that the first academic psychiatry departments were created. A few years earlier, the Women's Hospice (1854) and the Men's Hospice (1863) were inaugurated. These hospices are now the "Braulio Moyano" and "José T. Borda" hospitals, which are the largest psychiatry hospitals for men and women in Argentina and where the psychiatry and psychology residents of the *Universidad de Buenos Aires* do their practicum.

Thus, the first psychiatry chair of the Faculty of Medicine of the *Universidad de Buenos Aires* was created in 1886 and headed by Dr. Lucio Melendez, who was also the Director of the Men's Hospice. Its model for curing mental illnesses was to isolate the patients in locked inpatient wards where they were treated with

physical and social interventions. A departure from this model was the creation in 1899 by Domingo Cabred of the *Colonia Nacional de Alienados Open Door* (a hospital for mental patients), which was to pave the way for one of the entrance points for psychologists in the mental health field. As its name indicates, Cabred's intention was to break away from the traditional culture and view of mental health patient, which emphasized more a view of mental illness as incurable and hence as requiring an isolation from society. His proposed "open door" alternative introduced a series of reforms which highlighted the role of the environment and external organizations in the treatment of the patients and clearly showed the influence of the North American Mental Hygiene movement, thus cementing psychotherapy as a treatment for mental illnesses.

Another important development in this regard was the creation of the Argentinean League for Mental Hygiene, founded in 1929 by a psychologist from Rosario, Gonzalo Bosch, the Director of the *Hospicio (Hospice) de las Mercedes* and psychiatrist Mauricio Goldemberg's teacher, who would become an influential figure in the field of Mental Health in Argentina. During this time, different institutions were created to address the problems of mental illness from two different perspectives: One based on treatment given as solidarity (such as the *Sociedades de Socorros Mutuos* or *Mutuales* and *Asociaciones de Colectividades*) which highlighted the work of José Ingenieros in the treatment of mental patients. Ingenieros saw these patients in his private office and in the local *Centro Socialista Femenino* (Feminine Socialist Center), as well as institutions that followed the hygienists' traditions, such as the *Patronato de la Infancia* (Children's Welfare), *Liga Argentina contra la Tuberculosis* (the Argentinean League against Tuberculosis), *Sociedad de Asistencia a Domicilio de Enfermos Pobres* (Society to Assist the Poor at Home), and *La Liga Argentina de Higiene Mental* (the Argentinean League for Mental Health). Gonzalo Bosch became its first president.

In 1931, Bosch published a book entitled *El pavoroso aspecto de la locura en la República Argentina* (The Horrific Aspect of Madness in the Argentinean Republic) in which he criticized the state for failing to solve the problem of psychiatry in Argentina (Carpintero and Vainer 2005). Around the same time, in 1936, Gregorio Bermann, a psychiatrist from

Cordoba, founded the magazine *Psicoterapia* (Psychotherapy) and, in spite of only publishing four issues, it was of great relevance in that it emphasized the importance of using 'words' as a means for the treatment of mental illnesses. With this emphasis, the field of psychology went on to progress as an important clinical force in the understanding and treatment of mental illnesses. These events coincided with the advancement of psychoanalysis in Europe, which engendered a great deal of interest among young psychiatrists first, and then psychologists, in Argentina.

A Critical Figure in Argentinean Psychology

Jose Ingenieros is considered one of the most fundamental figures in the history of psychology in Argentina. A philosopher and political activist, he was the first psychologist who tried to establish an integral psychological system in South America. His long list of publications includes 484 articles and 47 books, which are generally classified in two time periods: studies of mental and criminal pathology (1897–1908) and studies of philosophy, psychology, and sociology (1908–1925).

At the beginning of his studies in biological psychology, he analyzed the development, evolution, and social context of mental functions. Being the first in South America to try to establish an integral psychological system, his work has a special emphasis on the biological basis of mental phenomena. In 1904, he was offered a temporary position as the Chair of Psychology, a position which was made permanent in 1906 when he was named professor. Ingenieros, whose prestige transcended borders, in addition to having written the first history of psychology in Argentina, wrote the first two most recognized publications in Argentina. In 1904, he published a study of hysterical phenomena and their relationship with art and, particularly, music. The study was honored by the Medical Academy in Paris. Ingenieros based his critical studies on the works of Charcot and Janet, with some additional references to the works of Breuer and Freud. Ingenieros was first introduced to Freud through French authors, especially Pierre Janet's critical work on Freud in 1913. His 1919 book on hysteria and suggestion sold various editions at a time when many Argentine intellectuals were back and forth from Europe, especially Paris, and with an increasingly growing interest in the

subconscious and dream interpretation (Vezzetti 1988, 1998, 1999). Ingenieros later abandoned psychotherapy and wrote his influential book *Madness in Argentina* which centered on his interest in dementia as a social phenomenon (Triarhou and del Cerro 2006).

Development of Psychology Departments

In 1910, the First Psychology Congress of South America, presided by Dr. Piñero, took place and in 1954 the First Argentinean Psychology Congress opened. In this latter congress, there is a recommendation to establish psychology as a profession, something that started to occur almost immediately in 1956 in Rosario and the following year at the *Universidad de Buenos Aires*; in 1958, psychology programs were established in Cordoba, La Plata, and San Luis, in 1959 in Tucuman and in Mar del Plata in 1966. At that time, there was no clear delineation of what psychology as a profession was all about and there were no graduates of the discipline, something which propelled the discussion about the role and identity of the psychologist and the practice of the profession (De Andrea 2009). Those teaching psychology were professionals who came from a medical and philosophical background and, in general, lacked training in psychology.

During the following decades, it was not unusual to have psychologists treat patients in public hospitals and private practices, but they were only considered psychiatry assistants legally who had to follow the orders of and under the direct supervision of psychiatrists. The law prohibited psychologists to exercise psychotherapy although in public hospitals they were the principal backbone of the mental health staff. At the same time, group treatment started to take place which included family and institutional treatment, psychodrama, social psychology, children's psychoanalysis, and schools for parents (Carpintero and Vainer 2005). The new profile of the psychologists was first and foremost as clinicians, who put empirical research on the backburner in terms of its relevance to clinical practice (De Andrea 2009). According to Carpintero and Vainer (2005), it is in the city of Rosario that an important movement in psychiatric practice takes place and moves the practice of psychology away from its exclusively medical environment. Gonzalo Bosch and Lanfranco Ciampi's professorships produced a set of

medical, sociological, and psychological concepts which had as its core the prevention of mental health problems. The ideological foundation of this work was based on a mental hygiene movement, which allowed the acknowledgment of nonmedical specialists in the treatment of mental illnesses, such as specialized teaching staff, psychopedagogical professionals, educators with psychological backgrounds, and visiting social workers. Between 1945 and 1955, mental hygiene was part of a health bill which was consolidated in 1949 with a proposal by the Health Minister Ramón Carrillo. In this way, psychology left the field of medicine and experimental psychology to enter the field of "human sciences."

Psychology Comes of Age in the Argentina Society

Following the International Psychology Conference in Tucuman in 1954, clinical specialization started to take supremacy and the practice was no longer dictated by medical doctors from Rosario but was replaced by psychoanalysts of *Psychoanalytical Association of Argentina* (APA). José Bleger was one of its more notable figures who, among other psychoanalysts, began to teach psychoanalysis at the university. This expansion of psychological culture which had started in Rosario was determined by two fundamental facts which consolidated it: (1) The creation of a specific editorial house, *Paidós*, founded by Jaime Bernstein and Enrique Butelman; and (2) the so-called Rosario experience, created by Enrique Pichón Riviere, from which the "operative groups" and social psychology emerged (Carpintero and Vainer 2005). The influence of the psychology degree in Rosario extended to the one in Buenos Aires. Enrique Pichón Riviere and José Bleger are two scholars with great standing in generations of psychologists in Argentina.

Bleger is unique in that, while he was still a young man, he reached notoriety in the psychological field with the publication of his emblematic book entitled *Psychoanalysis and Materialistic Dialectic*, which provoked intense controversy within the *Communist Party* to which he belonged. His intentions were to link psychoanalysis and Marxism, taking inspiration from George Politzer. His membership of both APA and PC created a conflict which culminated in his expulsion from the party in 1961, because the dominant ideology

of this political party considered psychoanalysis to be bourgeois. The dominant position of psychiatrists of the *PC* usually followed the line of thought of reflexology which discredited its position by denouncing that “in psychology, dialectic materialism is Pavlovism” (Lertora 1959).

Bi6n and Balint’s contributions in England were to reach Argentinean shores soon after and added to the enrichment of group studies, whether with patients or with the professionals themselves. For instance, Pichon Riviere suggested the idea to Gonzalo Bosch, the Director of the hospice, to introduce group courses to train the nursing staff, so as to prepare them to deal more effectively with conflicts involving the patients and their families. The idea for this practice emerged when, due to a nurses’ strike, the patients had to be trained in nursing care in order to be able to provide the necessary services. The application of group therapy showed a notable amelioration in the patients. The year 1954 saw the creation of the Argentinean Foundation for Group Psychology and Psychotherapy. With this development, it began the institutional phase of group therapy in Argentina.

Among other precedents for the change in the role of the psychologists in their practice of psychotherapy, we found that in the 1960s, in addition to the creation of the majority of psychology degrees, two other important events took place: The National Institute for Mental Health was created (based on the English model of National Mental Health Care and the Social Psychiatry Model predominant in the United States) and one of the first psychopathology services was established in a general hospital. The first mental health residencies, the intern rooms in general hospitals, day clinics, and therapeutic communities were created during these years. The importance of the creation of the Mental Health Institute (INSM) is that since its creation, there has been an active participation by the state in problems related to the mental health field which, until its formation, had been only part of the psychiatry domain.

The 1960s represented a change in psychoanalytical influences. Until that time, the predominant influence was the English School. In Buenos Aires, the ideas of Melanie Klein found fertile ground and came to be dominant for many years. Many based their works on the *kleinian* theory but in a creative way; among these

we find Pichon who applied it consistently in psychosis, Garma y Rascovsky to psychosomatic medicine, to dreams, and to child development, and Heinrich Racker to technique with its transference and counter-transference theory, which later enriched Grinberg’s concept of projective counter-identification. The Barangers, Willy and Mad6, also applied Klein’s ideas to the psychoanalytical process and its field theory, Bleger to the study of personality, and Resnik to psychosis and culture. Others, like Cesio, used Melanie Klein to construct his lethargy theory, while Liberman used it to explain the psychoanalytical dialogue and to support his linguistic theory of interpretive styles. In this context, we should also mention Rebe Alvarez de Toledo who used Klein’s formulations to demonstrate the effect of the “Word” and its free association in psychoanalytic dialogue. Finally, we should also mention in this regard Marie Langer who applied Klein’s theories to her exploration of femininity, Joel Zac to understand separation anxiety and “acting out,” and Benito L6pez to the study of addictions and of borderline patients (Etchegoyen 2001).

Another important influence in the development of the Argentina psychology was that of Lac6n. According to the history, Pich6n Riviere invited Oscar Masotta to give a conference in the Social and Psychological Institute. Masotta’s speech entitled “Jacques Lac6n or the subconscious in philosophy” was published the following year in the magazine *Pasado y Presente* (Past and Present), the first article in Spanish to be dedicated to the French psychoanalyst. Indeed, Masotta is recognized worldwide for introducing Lacan’s teachings and practices to the Spanish language. His introduction of Lacan’s works to Argentina produced in time a change in the psychoanalytic hegemony of the English School to that of the French School. In 1969, the *First Lacanian Congress* in Monte Grande took place. In October of the same year, the *Second Lac6n Congress* was organized in the Center of Medicine in Buenos Aires. In 1970, *An Introduction to the Reading of Jacques Lac6n* was published and in 1971 the first issue of the magazine *Cuadernos Sigmund Freud*, with the title “Themes about Jacques Lac6n.” In 1974, Buenos Aires Freudian School was founded by Masotta together with 18 others, the first Lacanian psychoanalytic institution which would later be succeeded by many more.

In 1975, Masotta traveled to Paris where he was invited to present in the *Ecole Freudienne de Paris* and where he was given the title of Practicing Analyst for his contribution to the cause of Freudian psychoanalysis. The political situation in Argentina took him to London where he settled and taught in the Arbous Association and the Henderson Hospital in Surrey, later moving to Barcelona which was to become his last home and where he founded the Freudian Library of Barcelona.

In Search of a Scientific Foundation

In an interesting study entitled “Scientific psychology and behavioral analysis in Argentina,” Alba Mustaca (2006) explores the different non-psychoanalytic investigations that have taken place in Argentina. In her study, she examines the creation in 1969 in Buenos Aires of the *Centro Interdisciplinario de Investigaciones en Psicología Matemática y Experimental* (Interdisciplinary Center for Research in Mathematical and Experimental Psychology), directed first by Horacio Rimoldi and, since 2001, by María Cristina Richaud de Minzi, of the *Facultad de Ciencias Exactas y Naturales* (on the faculty of the Exact and Natural Science Department).

Professor María del Rosario Lores Arnáiz of the Psychology Faculty in the UBA should be mentioned in this regard for her work with rats on memory and environmental enrichment and with humans on treatment for hypertension and the treatment of social abilities with patients who suffer from mental illness. The General Psychology Department is also notable for its program of cognitive studies, dedicated to the research of cognitive processes.

Current State of Affair and Future of Psychology in Argentina

There are two innovative approaches, which speaks well about the current and future state of psychology in Argentina: One is the “*Cuidar Cuidando Program*” (Care by Caring) (Massei et al. 1990), which is part of “the Dra. Carolina Tobar Garcia Hospital”, a psychiatric children’s hospital in Buenos Aires. The other is the Communication Rehabilitation Program (Orlievsky et al. 1997) in the same hospital.

The *Cuidar Cuidando Program* aims to treat children with problems such as autism, psychosis, and other illnesses in a nonhospitalized setting, working

closely with other outside institutions. This program works closely in partnership with the local zoo in Buenos Aires so as to provide more community-based treatment to these patients. This is not a cure in itself, but the reinsertion into society through a means which allows them to move from the condition of dependency normally associated with institutionalization, to being able to care for others. Thus, through working closely with the zoo staff to care for animals, it is assumed that patients’ pathology becomes less controlling of their lives. The types of tasks performed by each child are defined according to his or her condition. Later, they are assigned a companion or partner who is the link between the hospital and the zoo. At some point, this companion is trained to progressively distance himself or herself from the child as he or she begins to develop ties with the caretaker who works in his or her area. Under the mentorship and the supervision of the professional staff at Tobar García, the children learn to acquire the necessary skills which will help them to face society and integrate into the workplace. This program has the support of UNICEF and was declared of National Interest. It was recognized by the Episcopate through the San Martín of Tours Prize and the S.O.S- VIDA prize. This program has been successful for many of these patients; some even have found permanent jobs at the zoo.

The other innovative program focuses more specifically on working with autistic children. This is still a pilot communicational rehabilitation program that was created in 1997 to stimulate language and communication skills in autistic patients through the use of writing. In 1999, through Resolution number 23, the Director of Education of the Health Secretary from the City Council of Buenos Aires, Dr. Nestor Perez Baliño, appointed Daniel Orlievsky and Susana Massun de Orlievsky as Educational Coordinators of the program.

Since 2001, three research projects have been developed with UBACyT funding, according to an agreement between the *Dra. Carolina Tobar García Hospital* and the *Universidad de Buenos Aires*, particularly, the *II Cátedra psicología Evolutiva: Niñez* (Under the great contribution of Professor Juan José Calzetta). The findings have already contributed a great deal to helping us understand more about language function, the communication process, and the psychological structure of people with severe developmental problems. It has

already been recognized in a 2005 award by the *Universidad de Buenos Aires* for its “Contributions to the Psychology of Childhood Problems.”

The findings of this innovated program has not only encouraged research interest in Argentina but also resulted in a growing interest abroad, including the *Universidad Autónoma de Madrid*, the *Universidad de Barcelona*, the *Universidad de Gerona*, St. John’s University, etc., to name a few. The program has also attracted the attention of the Massachusetts Institute of Technology (MIT) in Boston, United States. The program is currently in collaboration with the Media Lab at MIT which is interested in using their technology to augment further the work of the Communicational Rehabilitation Program. They are interested in finding a biological correlate that can explain the effect of the program with regard to the language aptitude mechanism. Since May 2010, Drs. Daniel Orlievsky and Sebastián Cukier have been using this technology to record physiological stress patterns (cardiac rhythm, external behavior, temperature) without any cables: usable movement sensors which record stereotypic behaviors, flapping, and rocking. It is too early to tell, but it is expected that data collected will help us enrich/increase our understanding of the autistic spectrum with regard to specific mechanism responsible for the phenomenon and which we hope will lead to more targeted interventions in support of the capabilities of people affected by different types of autism.

Development of Psychology in Dominican Republic: A Brief History

A Look at the Early Development: On Describing the Dominican Character

In August 2009, the journal *Psicología para América Latina* published a brief history of psychology in the Dominican Republic by Enerio Rodríguez Arias which provided an important account of that history beginning with early attempts by various intellectuals, and the development of early departments of psychology in the country. The brief history by Angel Enrique Pacheco published in 1992 by Sexton and Hogan also provided important information about that history. According to these accounts, although the history of psychology proper in the Dominican Republic did not start as a discipline until 1967 with the establishment of

the first psychology departments, there were a number of early attempts by Dominican intellectuals, not trained in psychology, who tried to provide early descriptions of the Dominican character in terms of its unique characteristic. One of these descriptions was provided by José Ramón Lopez (1866–1922), a journalist with a strong sociological intuition. In his essay “La Alimentación de las Razas,” Lopez saw good nutrition and balanced diet as having a crucial role on the proper psychological development of the Dominican individuals, the lack of which was thought to result in the development of poor character, poor cognitive ability, proneness to violence, gambling, intellectual laziness, naïveté, etc. In Lopez’ formulation, mental disorders were seen as deriving directly from this condition. Since the poor and disenfranchised individuals from the countryside were most affected by poor nutrition, these individuals were most likely to be considered at risk for the poor psychological conditions described by Lopez.

Between 1945 and 1950 a number of interesting publications began to emerge which attempted to elucidate further the nature of the Dominican Character. The first one in 1945 was by Fernando Sáinz, an exiled Spaniard writer; the second one in 1946 was by Antonio Román Durán, also a Spaniard exiled with a degree in psychiatry, and Rafael Fco. González. Finally, in 1950 Enrique Patín published a series of essays about the Dominican character. These different publications generated a variety of reactions in the psychological discourse in the Dominican Republic. For instance, Professor Sáinz (1945, as cited by Rodríguez Arias 2009) compiled in a book form a number of newspaper publications about the psychology of the Dominican personality that had been published earlier in *El Diario La Nación*, one of the leading newspapers in the nation. Sáinz viewed the Dominican as much more complex in its appearance. His thinking was considered more theoretical and opinionated. He was described as courteous and kind, generous, and as someone who likes to be of service to others; he is given to conformism, is stoic, and traditional. With regards to action, he is pragmatic and positivist but without much concern about what science has to offer.

Both of these descriptions of the Dominican character were found to be very problematic at their basic

foundation. Lopez' conceptualization was strongly criticized at the time as lacking any empirical validation for the thesis and as relying mainly on inferences and the prejudices of that time. It was also alleged by Rafael Castillo, one of his contemporaries, as fraught with reductionism and unilateralism, and of intellectually poor explanatory paradigm (cited by Rodríguez Arias 2009). Similarly, Rodríguez Arias (Op. cit.) found Sáinz' description of the Dominican personality as based on anecdotal information and too general to be useful. He found Sáinz's thesis as lacking the scientific rigor necessary for a more accurate and valid description of the Dominican identity. It was Rodríguez Arias' view (Op. cit.) that we cannot speak about people as if they have a homogenous reality since there are differences due to cultural expectations that are linked to gender, age, social class, and educational level. Nevertheless, he thought that Sáinz's thesis was a good foundation for the beginning of a productive dialogue as to what constituted the unique characteristics of the Dominican character. This is particularly the case because Sáinz's thesis had a solid philosophical and cultural merit and showed great familiarity with the psychological theories of the time, prevalent in Europe in the first half of the twentieth century.

More clearly psychological formulations on issues affecting the Dominican society are seen in publications by Dr. Antonio Román Durán in the *Diario la Nación* who in 1946 attempted to elucidate specific psychological subjects, such as stuttering from a psychodynamic perspective, the gambling behavior, the instincts, masculinity and femininity, alcoholism, and issues of taxonomy. In the same year, Rafael Fco. González published an article in the *Revista Jurídica Dominicana* about psychoanalysis and the penal laws. Finally, Enrique Patín's publications ("Los Complejos del Pensamiento Dominicano" and "El Alma de Nuestra Plebe") provided an important analysis of the sources or reasons behind, what he called, the inferiority complex in the Dominican thinking. He posited that the source can be found in the lack of a clear notion and appreciation of the uniqueness of the Dominican self-definition, in the poor appreciation of its value, the poor knowledge of its history, etc. (Rodríguez Arias 2009). According to Patín, this quality of the Dominican thinking is responsible for the tendency to look at the outside for affirmation of the national identity,

where the foreign is seen as more valued than the local, and where there is a tendency to understand everything that happens in the country as the result of its colonial history. It is in this context that Dominican costumes become supplanted by North American ideals and costumes, both seen as more desirable. Again, Rodríguez Arias' criticism on this formulation is that Patín's descriptions about the Dominican identity, particularly of individuals living in the slums, are fraught with negative stereotypes about these inhabitants and with a strong class prejudice already promulgated by the ruling class at the time. He suggests again that only descriptors that are based on comparative studies, those which follow clear scientific methods of observation, will make it possible for us to arrive at more valid descriptions of the Dominicans in general and particularly of the underclass living in the slums.

Critical Moments in the Development of Psychology in the Dominican Republic

It was not until 1940 when the study of psychology began to appear in the Dominican Republic in any meaningful way with the inclusion of the first course in psychology at the *Universidad Autónoma de Santo Domingo* or UASD (Autonomous University of Santo Domingo), as part of the Philosophy Department. Thus, the first course in abnormal psychology was taught to students of philosophy by Fabio Mota, a medical doctor with solid philosophical knowledge and who was professor of psychiatry at the university. Similarly, Professor Salvador Iglesias, who had a degree in philosophy from Rome and who has taken several courses in psychology from various American universities, taught a course in general and applied psychology and education at the same university (Rodríguez Arias 2009).

Nevertheless, according to Rodríguez Arias (2009), the impetus for the establishment of the first psychology department did not occur until the first Interamerican Congress of Psychology that was held in the Dominican Republic in December of 1953. This congress provided a unique opportunity for the Dominican intellectuals to become part of an important dialogue about psychology as a discipline that was taking place already in many parts of the world. Presenters in that congress featured intellectuals that presented the state of psychology in Latin-American and Caribbean

countries (including, Ecuador, Venezuela, Chile, Mexico, etc.), as well as in the United States and Canada. What became clear from the synopsis of that congress (Rodríguez Arias 2009) is that psychology all over of the world was a discipline in search of a more defined identity as a science and profession. Thus, questions such as what types of curriculum should be taught to those interested in pursuing the profession of psychology and whether training in scientific methodology should also be emphasized dominated the intellectual dialogue in the field.

Two of the most important concerns of the Dominican psychologists were the application of psychological knowledge and the philosophical and theoretical problems that were afflicting the discipline throughout the world. In this context, Rodríguez Arias (2009) referred to two critical contributions: The first is the work of G. Lockward (1955), which looked at the problem of applied mathematics to psychological phenomenon; and the second, the important work of the Dominican philosopher Andres Avelino García (1955), which challenged the scientifically based psychological paradigm in its ability to provide answers to important and complex questions about the human condition. According to Avelino García, part of the problem was the strong tendency of empirical psychology to simplify the complex phenomenon in order to be able to submit it to so-called scientific investigation. Avelino García was interested in the study of the existence of “consciousness” and “psyche.” From his perspective, one can only have relative evidence of the existence of these aspects of mental functioning as fluid categories, while empirical psychology treats these as absolute phenomena based on absolute evidence. According to Rodríguez Arias, Avelino García’s view is in keeping with the argument put forward by Edmond Husserl (1859–1938), the father of phenomenology, in his eidetic psychology where he claimed for the importance of a logical investigation of a phenomenon and the interrelation of truth, intuition, and cognition (Stanford Encyclopedia of Philosophy 2007). It calls for scientists to seek a clearer definition of the subject of study prior to venturing into scientific investigations. This can only be accomplished through the utilization of what he calls “the eidetic reflective paradigm” or the necessary theoretical framework which allows for clearer elaboration of the definitions

of the notions/phenomena under consideration prior to engaging in scientific investigation. This process can then elucidate more clearly the nature of the findings that emerge from the scientific enterprise.

The Birth of Psychology as a Discipline in the Dominican Republic

According to Rodríguez Arias (2009), what became clear in the first congress was the distinct difference between the theoretical and scientific influences guiding psychology in Latin-American and in North America. In the Dominican Republic, psychology was much more influenced by philosophical conceptualizations while in North America there was a much more intense influence of operationalism and logical positivism. As more Dominican psychologists received training in American universities, these influences began to take hold in Dominican Republic as well. This became evident in the first psychology department created on July 14, 1967, at the *Universidad Autónoma de Santo Domingo* (UASD) within the Faculty of Humanities. The same year a psychology department was also established at the *Universidad Nacional Pedro Enriquez Ureña* (UNPHU) (Pacheco 1992; Rodríguez Arias 2009). The UASD program was founded by Dr. Tirso Mejía-Ricard (1936–), a medical doctor with training in psychiatry and psychology from Bonn University in Germany, who also became its first director. A Dominican born intellectual, he published a series of books and textbooks on general psychology, social and forensic psychology, as well as on personality. Dr. Enerio Rodríguez (1939–), a graduate in psychology of the *Universidad Nacional Autónoma of México* who also possesses a doctorate in philosophy, followed from 1970 to 1981 and was influential in the teaching of functional analysis of behavior and cognitive psychology. He was also involved in disseminating the main issues that fueled the debate between phenomenology and behaviorism, which he translated into Spanish. Throughout the years, the psychology department in the UASD remained focused on a more scientific basis in its curriculum, with a strong view that applied psychology should be guided by scientific findings. Psychology was seen as a science and a profession and hence the emphasis of its training has these qualities. This emphasis is in keeping with the Boulder model followed by many universities in the United States.

The UASD is the first university that introduced a course in cognitive psychology but also included in its curriculum courses in the theories of personality, Freud's theories and the work of Allport, as well as the work of Karl Rogers in psychological interviewing. Students obtained a professional degree as *Licenciado* in psychology, originally a 4-year program and then a 5-year program. In 1991, the program was extended to include training with emphasis in clinical, organizational, school, social, and developmental psychology. It also required a period of supervised training and hence the length of training was extended to nine semesters. The prerequisite for admissions to these programs, as it was the case with any university in the Dominican Republic, was the completion of a *Bachillerato* or a high school with more college level requirements than most high schools in the United States.

As indicated earlier, another psychology department (*Departamento de Psicología y Orientación*) emerged also on October 16 of the same year 1967, within the School of Education, at the *Universidad Nacional Pedro Henríquez Ureña* (UNPHU), a private university. Its focus was initially on counseling and guidance, and courses in methodology were added much later. Dr. Jose Cruz was one of its early directors and became instrumental in the changes that took place in 1978 that gave birth to the current Mental Health Division, by separating it from the Division of Psychiatry and Mental Hygiene of the Secretary of Public Health and Social Assistance. In this context, he initiated community-based mental health services and started a joint master's level training program in community psychology with the Psychology Department of the UASD. It also required completion of a thesis. UNPHU, on the other hand, followed a humanistic focus with a strong philosophical and applied basis (or scholar-practitioner model). It was not until 1983 when courses in animal psychology, behaviorism, training in therapy in behavior modification, as well as courses on investigation and methodology and statistics were added to the curriculum. In 2008, the program was discontinued for financial reasons.

Current State of Affairs of Psychology Training and Profession

According to Rodríguez Arias (2009), as of 2005, there were 14 programs at the level of *Licenciatura* and

several others at the master's level in clinical, organization, school, family therapy, and sexual therapy at various private institutions in the Dominican Republic, with about 15,000 professional psychologists and 16,000 students of psychology. This was an increase from the 1992 estimate of 900 professional psychologists (Pacheco 1992). These programs were also offered by the *Instituto Tecnológico de Santo Domingo* (or INTEC) and the *Universidad APEC*, among others. Rodríguez Arias expressed great concern with this proliferation of programs and the difficulty in assuring comparable quality of education across the different programs, something that he reaffirmed recently in a personal communication (January, 2011). He also raised great concern with (1) the flexibility of admission criteria held by many of these institutions, particularly in the master's programs; (2) the consequence that most students attend on a part-time basis, a situation that we see in many Latin-American Universities today; and (3) the lack of adequately trained professionals to provide the teaching and supervision of the clinical practices of psychology students. All of these issues make the overall training of psychologists quite problematic and challenging, a situation that is expected to improve with more qualified psychologists becoming involved in training and supervision.

It is clear that psychology as a discipline and profession has grown in respectability among the Dominican Society (Pacheco 1992; Rodríguez Arias 2009). More and more psychologists are now working and contributing their knowledge to society within a broader range of occupational practice, such as in public health, education, industries, etc. In 1975, the *Asociación Dominicana de Psicología, Inc* (ADOPSI) was founded and in 1978 the *Asociación Conductista Dominicana, Inc.* (Dominican Behaviorist Association) was founded but became inactive in 1982 (Pacheco 1992). These associations attempted to take a leadership role to guide the practice of psychology. Nevertheless, the practice of psychology was poorly regulated until recently, with few professionals even applying for the official permission (*exequatur*) from the executive branch of the government to practice the discipline, a permit that was given by just asking (Pacheco 1992). It was not until the creation of the *Colegio Dominicano de Psicólogos* (CODOPSI), through the passing of Law no. 22-01 on January 9, 2001, that

the profession became more clearly regulated. The law standardized specific requirements in the different areas of practice that all institutions involved in training of psychologists are expected to follow.

Current Status of the Dominican Psychology as a Scientific Enterprise

In 1999, the Psychology Institute was created under the leadership of Dr. Mayra Brea as a way to encourage more psychological investigation. This development had only limited success, due to the few numbers of students attending the institute. Nevertheless, the institute has reportedly published several volumes of the journal *Perspectivas Psicológicas*, which is the main venue for dissemination of scientific contributions made by Dominican scientists.

We also see new Dominican intellectuals, many graduated from foreign universities and returning to the country to become involved in the dialogues about the psychology of the Dominican individual. Of significance is the work of Huberto Bogaet García, who published *Enfermedad Mental, Psicoterapia y Cultura* (Mental illness, psychotherapy and culture, 1992) and *Los Enigmas de la Sexualidad Femenina* (The enigmas of female sexuality, 1993).

Other Dominicans of merit are Josefina Zaiter, for her work on the social and national Dominican identity (Zaiter 1987, 1996, 1999) and Antonio de Moya, for his numerous publications and investigations on the Dominican sexuality and the role that it played in the spread of AIDS (De Moya and García 1996, 1999; Garris et al. 1991).

According to Rodríguez Arias, the UASD has attempted to provide opportunities for the study of psychology as a science and practice with the initiation of a postgraduate training program in investigation to train investigators.

Enerio Rodríguez Arias: His Contributions to the Development of Psychology in Dominican Republic

Professor Enerio Rodríguez Arias (1939–) can be considered the first and one of the most influential psychologists in the Dominican Republic. He graduated from the *Universidad Nacional Autónoma de México* on December 11, 1968, although he previously had studied philosophy for 6 years at the *Universidad Autónoma de*

Santo Domingo, where he obtained his doctorate in philosophy after his return from Mexico. Dr. Rodríguez Arias then became an important and influential force in the Dominican psychology, helping to shape the future of psychology. In fact, he became director of the psychology department at the *Universidad Autónoma de Santo Domingo* from 1970 to 1981 and hence became intimately involved in the preparation of future psychologists. He is credited with introducing to the Dominican Republic one of the most important theoretical debates in the psychology of the twentieth century between behaviorism and phenomenology, which started in 1963 during the *Symposium of Rice* and extended for several decades. He was the first in introducing to the Dominican Republic Thomas S. Kuhn's ideas about the development of scientific knowledge and the first to teach a course on behavior analysis in 1970. He was also the first to make the concepts of Chomsky's generative grammar and its impact on the psychology of language familiar to Dominican students, as well as the central ideas from cognitive science. The first course on the psychology of reasoning was also introduced by him in the 1980s.

In terms of his intellectual legacy more specifically, we can distinguish five distinctive areas: (1) issues related to the philosophy of science; (2) elucidation of the problems in statistical analysis and inference procedures in psychological research; (3) metapsychology considerations; (4) relevance or irrelevance of learning research for educational practice and research on human reasoning; and finally (5) notions about behavior analysis and its applications.

Concerning scientific epistemology and research methods in psychology, Rodríguez Arias has been concerned throughout his life with the "relative character of the method." Over the years, he has emphasized the importance of first asking what the research problem is and to then determine what methods may be most appropriate to answer that research question, warning us about the danger of taking the inverse process.

With regard to statistics, he has emphasized the importance of reestablishing the supplementary and subordinated character of the statistical analysis in psychological research. By so doing, he is trying to bring to our attention the danger of confusing the inductive quality of statistical inference as a magical

instrument to determine “the truth” or certainty of a phenomenon, as if coming from a deductive process.

In looking at the philosophy of science, some of Rodríguez Arias’s recent works on the impact of the evolutionary theory on epistemology and philosophy of science call to task the “Popperian falsificationism” approach of Karl Popper to evolution and exposes the way this philosopher applies the natural selection mechanisms to the development of human knowledge. In this context, he was particularly concerned with the problem of demarcation between science and metaphysics.

The same (philosophical) analysis is seen consistently in his dealing with any aspect of psychology. Indeed, he is considered one of the most influential authorities in the Dominican Republic as a metapsychologist. His focus was on analyzing the history of psychology, establishing comparisons between its theories, deliberating over the validity of the arguments from these theories, and examining their relation to the efficacy of the professional practice. His strict loyalty to the scientific method has gained him tremendous respect among the Dominican scholars. He has brought to the psychological community of the Dominican Republic the only account on what may represent the history of the origins of the psychological studies in this country. Dr. Rodríguez Arias has been acknowledged (Ardila 1986) as the most prestigious Dominican psychologist for his scientific contributions. In February 2010, the Department of Psychology at the *Universidad Autónoma de Santo Domingo* published a special issue of its journal, *Perspectivas Psicológicas*, and included 24 Rodríguez Arias’s selected papers.

Dr. Enerio Rodríguez Arias is a member of Philosophy of Science Association (PSA) and an International Affiliate of American Psychological Association (APA).

Mexican Psychology Through Its Most Influential Pioneer, Rogelio Diaz-Guerrero

Diaz-Guerrero’s psychological thinking and research runs over with originality, accuracy, consistency, culture, and longevity. It is through his work and his leadership that he becomes the pioneer and guide of Mexican psychology, an icon to Latin-American

psychology and a referent of cross-cultural psychology decade after decade. As a researcher, he published abundantly and is the most cited Spanish speaking psychologist. As a mentor, he formed generation after generation of Latin Americas finest psychological minds. As a colleague, he championed international psychology and introduced indigenous psychologies into the main stream and carried universal psychology to majority countries.

Rogelio Diaz-Guerrero was born in 1918 in Guadaluajara, Mexico. His quest to understand human behavior begins at the National Autonomous University of Mexico where he studied medicine and psychology with a series of distinguished and prominent Mexican professors and thinkers: Enrique Aragon, Ezequiel Chavez, Guillermo Davila, Oswaldo Robles, Antonio Caso, Samuel Ramos, and Jose Gaos. Finishing his years in medical school, he received a scholarship for postgraduate studies at the University of Iowa, where he completed his master’s and doctoral studies in neuropsychiatry and psychology, being lectured by renowned psychiatrists such as Jacques Gottlieb and Paul Huston, eminent neurologists like Van Epps and Adolph Saks, and pioneers in psychology such as Kenneth Spence, Kurt Lewin, and Robert Sears.

His medical background became apparent in his first publications in the 1940s, where he shows his interest in the relationship between biological variables and behavior. Moving into the 1950s, his professional practice and the Mexican ecosystem sets the basis for his inclusion of culture in the understanding of mental health, which he developed with Abraham Maslow. At this stage, his research centered on the conceptualization and operationalization of psychological variables rooted in culture; such is the case of his work on anthropo-cultural values, which served as the immediate successors of the historic-socio-cultural premises, which he postulates a decade later as the operationalization of culture through norms and believes.

In the 1960s, Diaz-Guerrero’s interest in the socio-cultural basis of behavior flourishes and crystallizes in research with Wayne Holtzman, with whom he authors “Personality development in two cultures”; with Charles Osgood with whom he works on the pan-cultural study of meaning with the semantic differential; and with Herman Witkin in regards to cognitive development. Among his major contributions of

this decade is the clear, empirical, and theoretical definition of cultural concepts, the valid, reliable, and culturally appropriate manner of operationalizing universal psychological constructs, and the rules to adapt, change, and construct objective measuring instruments. He further indicates that the culture in which an individual develops will specify the foundations, structure, and acceptable and desirable norms of behavior. Hence, socio-culture becomes a system of thoughts, interrelated ideas, norms, and roles that offer a hierarchy of acceptable and desirable behaviors, habits, needs, and values for each cultural group. His work on the psychology of the Mexican conceptually solidifies the aspiration toward a scientific and cultural psychology, and additionally offers valid and reliable operationalizations that result in culturally relevant and interpretable data.

The center stone of his work is the historic-psychosocio-cultural premises. The norms and beliefs that compose them, regulate the formation of national character, and delimit the acceptable behavior in human interaction, depending of the level in which each person adopts and believes their cultural dictates. Thus, the socio-cultural ecosystem serves as the ontological ground on which individuals learn the correct ways of interaction with their world. A historic-socio-cultural premise is a simple or complex statement that provides a group the logic of understanding and guiding their world. Diaz-Guerrero extracted premises from proverbs, sayings, and other ways of popular communication. After carrying out careful content analysis based on the obtained representations, the crucial role of the family in traditional Mexican culture became evident. In sum, three prepositions describing the traditional Mexican family appear: the power and supremacy of the father, the love and absolute and necessary sacrifice of the mother, and the obedience of children. In other words, children and youngsters must always obey their parents and everyone should love their mother and respect their father. This means, that children must always show their regard to their parents, who in return must protect and care for them. The traditional factor is complemented with a gender dimension, with "machismo" and abnegation-virginity at the axis. In sum, it is considered that traditional Mexican society is built upon a hierarchical structure based on the respect for others, particularly parents and kin. The internalization of these premises produces

abnegation, a cardinal trait in Mexican culture, which is sustained as true by Mexican men and women who believe that satisfying others' needs is more important than satisfying their own.

In the 1970s, the ideal of integrating cross-cultural psychological perspectives into mainstream psychology began to consolidate. Keeping in mind the need of the majority of countries to work out solutions to substantial problems related with educational, social, economic, and individual development, Diaz-Guerrero, Harry Triandis, Martin Fishbein, and other collaborators research and publish profusely in applied areas. A few examples of these lines of study are the "Study in eight countries on occupational values in children and young adults when faced with violence." Other projects dwelled on the pertinence and effect of educational programs in general, such as "Sexual differences in the development of the Mexican student's personality," or specifically, through television, like the case of the *Formative Evaluation of Sesame Street*. As an epilogue to the 1970s, he coordinated a series of projects from which he postulated a transdisciplinary and cultural conception termed "Towards a historic-bio-psychosocio-cultural theory on human behavior."

The 1980s found Diaz-Guerrero in charge of several decades of solid and robust intercultural and intracultural findings. In addition to constructing a theory on the psychology of the Mexican, he added the study of masses, health, and led research toward understanding psychology from a socio-cultural perspective. The synthesis gave way to some of the first gender studies in psychology from a structural perspective depicted in "Roles, personality and the status of women." Continuing the task of integrating behavioral and cultural psychology, he stressed the need of incorporating the effect of contextual and cultural niches in which human beings develop into psychological studies, as is evident in his "The cultural ecosystem and life quality," and "The culture counter culture approach." In summary, his conjectures were summarized in the theoretical and methodological creation and delimitation of a new branch in psychology, *ethnopsychology*.

Diaz-Guerrero's accumulation of work by the 1990s showed three new clear tendencies. He continues his work characterizing and differentiating the effect of culture on visible psychological variables in "The subjective worlds of Mexicans and North Americans" with

Szalay, and “The effects of culture on national identity.” He established the basic precepts of “Mexican Ethnopsychology,” and he revises the work on coping styles due to the effects of time in “The new philosophy of life” and in the study and measurement of “abnegation.” A third line of inquiry relates to the roots of values where he shows that their expressions depend on the degree of satisfaction, difficulty and intensity of needs, described in “Human values and needs: the missing link.”

The seminal work of Diaz-Guerrero is culminated in the new millennium in the book *Under the Claws of Culture*. In it, he reports longitudinal and cross-sectional data spanning 50 years on the processes of socialization and enculturation responsible for the maintenance of structures that work for the permanency of the socio-cultural premises. In fact, he expands on the small effects that political, economic, and social changes have had on the way Mexicans think and act when it comes to the realms of family, male-female interactions, and the interaction of parents and their children. The book consolidates a life’s work dedicated to understanding human behavior from a historic-bio-psycho-socio-cultural perspective.

Brief Biography of Rolando Díaz-Loving

It is a complex task to describe a great human being, an extraordinary scientist, and a superb teacher. With his 56 years of age and a life that manifests the mixture of cultures of his parents – Mexican and Australian – as well as his innate intelligence and talent, regarded as one of the pioneers of social psychology in Mexico, there can be no doubt today that the career of Rolando Díaz-Loving reflects an equilibrium between lecturing, divulgation of science, training of students, and the exercise of strategic administrative responsibilities.

To describe Díaz-Loving as a university professor is to bring to mind the image of a teacher of vocation, an expert and authority in his area, committed, untiring, punctual to a fault, accessible, and close to his students and for whom teaching and the transmission of knowledge is an indispensable task in the advance of science. The primary beneficiary of these qualities is the UNAM’s faculty of psychology in Ciudad Universitaria, where he has taught since 1982 to the present day; this period – with the sole interruption of his four

sabbaticals – adds up to a total of 28 years devoted to teaching, during which he has imparted a total of 215 courses both at bachelor’s and higher-degree level. This is without taking into account the courses given as a visiting lecturer at 11 different institutions, including in Mexico the Universidad de Chapingo, the Universidad Autónoma de Yucatán, and the Universidad Autónoma del Estado de México; and abroad the Universities of Texas, Manitoba, and Palermo.

As regards the training of groups of students, his extraordinary capacity for leadership and considerable skill in the management of human relations stands out. These qualities yield fruit in his working groups, which have been open to both first-degree and higher-degree students and have also enjoyed the participation of colleagues from other universities in Mexico City and other parts of the Republic, as well as foreign researchers. It is worth emphasizing that most of those who are today his colleagues were at one time his students and tutees. In keeping with his interest in the consolidation of groups, in 1986 he became a founding member of the *Asociación Mexicana de Psicología Social*.

In his role as a disseminator of science, Dr. Díaz might be described as an academic globetrotter. He has visited the 31 states of the Mexican Republic, whether as a visiting lecturer or as a speaker at conferences – his visits to Yucatán, Puebla, Chihuahua, and the Estado de México being particularly numerous. Beyond Mexico’s borders, he has been a frequent visitor to Austin, Texas, and has also visited the Universities of California, Chicago, Indiana, Washington, Oklahoma, Wisconsin, Orlando, and New York; further afield he has visited universities in Puerto Rico, Canada, Japan, Greece, China, Australia, Belgium, France, Sweden, Poland, Great Britain, Spain, Cuba, Chile, Colombia, Guatemala, Brazil, Venezuela, Argentina, Costa Rica, and Peru.

As regards his publications, his first article was published in 1981 with Dr. Richard Archer (who also directed his doctoral dissertation at the University of Texas) under the title: “The role of dispositional empathy and social evaluation in the empathic mediation of helping.” In the same year he published the article “Comparación transcultural y análisis psicométrico de una medida de rasgos masculinos (instrumentales) y femeninos expresivos” with Rogelio Díaz-Guerrero,

Lazarus, Richard S.

NOACH MILGRAM

Ariel University Center of Samaria

Tel Aviv University, Kochav Yair, Israel

Basic Biographical Information

Richard Lazarus was born on March 2, 1922, in New York City and died on November 24, 2002, at Walnut Creek, California. After graduating from City College of New York in 1942, he served in the United States Army for three and a half years, completed his doctorate at Pittsburgh University in 1948, and served in the psychology departments of Johns Hopkins University and Clark University before going to the University of California Berkeley where he conducted pioneer work on a variety of controversial issues until his retirement in 1990. In the decade that followed retirement, as professor emeritus, he published five books and numerous chapters and articles.

Major Accomplishments/Contributions

In a scientific sense, Lazarus was a revolutionary. He left a legacy of scientific inquiry, investigation, and theory that challenged the dominant theoretical framework of the time, Skinnerian behaviorism. He was ahead of his time in emphasizing the role of cognitive appraisal in affecting the individual's emotional and behavioral response to stressful situations. His book, *Stress, Appraisal and Coping* (Lazarus and Folkman 1984), coauthored with Susan Folkman, a former doctoral student, became the most widely read and cited academic book and text in the field.

His cautiously articulated defense of denial was a direct attack on the prevalent theoretical and professional view at the time that denial was self-deception and, therefore, tantamount to a mental disorder, while accurate reality testing was an indication of mental health. His defense of denial would appear to run counter to his overarching concept of cognitive appraisal, a cognitive activity that is presumably realistic. He was, however, consistent in promoting realistic appraisal in dealing with potentially solvable problems and in advocating denial of reality in situations that were not. On a universal philosophical level, Lazarus was comfortable with self-serving illusions and beliefs that sustain meaning, purpose, and vitality in face of the inevitability of death for all, and the frustrations, disappointments that many experience at some time in their lives. On a psychological level, he cited studies that show (1) optimists are happier and live more productive lives than pessimists, although the latter may be more realistic in their appraisals of events; (2) patients who avoid hearing details of imminent surgery enjoy more rapid postsurgical recovery than those who request and receive these details; (3) patients following stroke who deny the realistic consequences of their condition are more calm and relaxed than those who become sensitized to their limitations. Denial has positive benefits according to Lazarus, when people have done all that they can to achieve positive outcomes, and when eventual outcomes are beyond their control.

He demonstrated, contrary to conventional wisdom at the time, that the little irritations that occur daily may cause more damage than large sources of distress that occur once in a while or even just once. In psychological terms, daily hassles may exercise greater deleterious effects on one's physical and psychological well-being than major life stresses.

He was the recipient of many awards in recognition of his seminal work. Nationally, he received one of the highest awards of the American Psychological Association, the award in 1989 for Distinguished Scientific Contribution to Psychology. Internationally he received a Guggenheim Fellowship in 1969–1970, honorary doctorates from the Johannes Gutenberg University in Mainz, Germany in 1988 and the University of Haifa in 1995, and was invited to lecture at many other universities outside the United States (Australia, Denmark, Japan, and Sweden).

His comprehensive analysis of goal-congruent (positive) emotions as well as goal-incongruent (negative) emotions marked him as a pioneer in positive psychology long before the field achieved prominence. In this analysis, he cited happiness/joy, pride, love/affection, and relief/change for the better as the former, and anger, fright/anxiety, guilt/shame, sadness, envy/jealousy, disgust as the latter. He also created a separate category for hope, compassion/empathy, and aesthetic and religious emotions, because these emotional experiences have multiple meanings on the one hand, unique meaning for individuals on the other, and their valence (positive versus negative) is less clearly defined (Lazarus 1991).

He made many visits to Israel, the first of these in January 1975 when he was a keynote speaker at the First International Conference on Psychological Stress and Coping in Time of War and Peace. The conference took place in the aftermath of the Yom Kippur War, when Israelis were coping with the specter of near defeat on the battlefield, the loss of life, and the shattering of long-held beliefs about military supremacy. In an invited chapter based on the conference, Lazarus responded to these postwar crises at two levels. "first, as that of a psychologist whose theoretical and research commitment is stress, emotion and coping; second, that of middle-aged American Jew who keenly identified with the national struggle of Israel to establish and preserve a place in the world for Jews in a viable and humane society" (Lazarus 1982, p. 23).

He maintained scientific objectivity and theoretical consistency in analyzing Israeli society's appraisal and response to the war and to the challenge of reformulating its national coping strategy. He distinguished between active (problem-focused) mastery and passive (emotion-focused) mastery, and suggested that extreme reliance on either the one or the other is unwise for the individual or for any society in handling stresses and crises.

Richard Lazarus was a man for all seasons and intellectual pursuits. He was a scholar, a gentleman, and a generous mentor to all who knew him; a person whose extraordinary erudition was manifest not only in his command of the psychological theories extant during his lifetime, but also in his ability to glean from philosophy, history, and literature, insights that were relevant to whatever argument, assertion, or proof he

was demonstrating; he was an indefatigable thinker and writer who was wholly engaged in relating aging to emotion at age 80 until an untimely fall ended his productive life. He was a devoted husband to Bernice, his wife of 57 years, and a caring father to his children and grandchildren.

Levitt, Harry

ARLENE C. NEUMAN

New York University School of Medicine, New York, NY, USA

Basic Biographical Information

Harry Levitt was born in Johannesburg, South Africa, in 1937. He received his Ph.D. in Electrical Engineering from the Imperial College of Science and Technology, London, where he studied with Colin Cherry. From 1964 to 1969, Levitt was a member of the Speech and Auditory Research Department of Bell Labs. He then joined the faculty of the Doctoral Program in Speech and Hearing Sciences at the Graduate School, City University of New York where he taught and mentored students for over 30 years. He is currently Distinguished Professor Emeritus at the Graduate School, City University of New York.

Major Accomplishments/Contributions

Levitt's areas of research include methodological issues in psychophysics, speech perception, and aural

rehabilitation. With substantial contributions in all three areas, Levitt is best known for his work on adaptive testing in psychophysics. His seminal paper on transformed up-down procedures for psychophysical testing (Levitt 1971) continues to influence the methodology used in psychophysical research to this day. According to Levitt, all measurements are adaptive in that they form a key link in the iterative cycle of measurement and theory. One does not measure without having some idea (theory) of the variables that are likely to affect the measurements. This philosophy, inherent to scientific method, has been much refined in the development of adaptive methods of measurement, in which data obtained in preceding observations are used to determine how to make the next observation. Levitt's transformed adaptive procedures emphasize simplicity, efficiency, and robustness of measurement. The simplicity and efficiency of measurement make these among the most widely used methods of measurements in psychophysics.

Another of Levitt's early research efforts has led to a better understanding of binaural hearing of speech in noise (Levitt and Rabiner 1967). He and Rabiner developed a model that combines information about masking level differences for pure tones in narrow bands of noise with the articulation index. The model predicts increases in speech recognition performance under several competing noise conditions. This model has been expanded by later researchers to explain binaural advantages for understanding speech in complex listening environments with noise at various azimuths.

Levitt's research has contributed substantially to an understanding of the relationship between hearing loss and speech production in deaf children and the nature of the speech production errors that negatively affect the intelligibility of deaf speech. It has also influenced approaches to aural rehabilitation of persons with hearing loss. His scientific contributions are data-rich, with important conclusions either supporting key assumptions of underlying theories or pointing the way to new, more general theories. His monograph on the development of language and communication skills in hearing-impaired children (with Nancy McGarr and Donna Geffner) is a good example of his

approach (Levitt et al. 1987). Rather than select a subset of children with characteristics likely to be supportive of a theory to be tested, his research team evaluated, with few exceptions, every child of a given age at schools for the deaf in the State of New York. The children were tracked over a 4-year period. The resulting data provided powerful tests of key assumptions. It was the first study to show a significant statistical correlation between early intervention and improved speech and language development 10–15 years later. Another finding, new at the time, was that speech and language development in children with hearing loss is neither delayed nor deviant. Rather, children with hearing loss develop their own phonology that is determined in large measure by the limitations imposed by the hearing loss. One outcome of this observation was the development of a general theory for predicting, in quantitative terms, how the speech of a child with hearing loss is likely to differ from that of a hearing child, given information on the child's hearing skills.

Levitt has been a leader in applying computer technology to the study of speech and hearing problems, as well as to the development of better sensory aids for people with hearing loss. He developed the first digital master hearing aid and has been a leader in investigating digital signal processing strategies that differ fundamentally from the signal processing approaches implemented in analog aids. These studies directly influenced the noise reduction and feedback reduction algorithms used in current hearing aids.

Harry Levitt has been and continues to be a prolific researcher. He has been honored for his work by the Acoustical Society of America, the American Speech, Language and Hearing Association, the American Auditory Society, and the American Academy of Audiology.

Lewin, Kurt

MOSHE L. MILLER

Touro College, Queens, NY, USA

Basic Biography

Lewin, Kurt (September 9, 1890–February 1, 1947) was a revolutionary figure in the field of experimental psychology, a mentor to many, and an innovative theoretician. He developed *Topological Psychology*, and *Field Theory*, but is most remembered as the father of *Social Psychology*.

Kurt Lewin was born in 1890 to a small, Jewish, middleclass family in the village of Mogilno, Prussia, which is in modern-day Poland. In 1905 his family moved to Berlin, and in 1910 he began studying psychology at the University of Berlin. At the outbreak of WWI, in the year 1914, Lewin joined the army and received his doctorate from the University of Berlin in 1916. In 1918 Lewin was wounded and awarded the Iron Cross (Marrow 1969, p. 10). Subsequently, he returned to the University of Berlin and joined the remarkable circle of the three founders of Gestalt psychology: Max Wertheimer, Wolfgang Kohler, and Kurt Koffka. Although Lewin appreciated the principles of Gestalt psychology, he did not continue with the standard Gestalt methods but expanded the idea of looking at the Gestalt, or whole, of an issue and applied it to the experimental study of practical psychology questions. In 1921 Lewin was appointed *Privatdozent* (a professor that is paid based on student attendance) at the University of Berlin (Hothersall 1995, p. 239–241).

The reputation of Lewin and his ideas soon spread beyond the continent of his birth. A paper written by JF Brown in 1929, and Lewin's own contribution to the *Handbook of Child Psychology*, published in 1931, introduced Lewin's work to the United States. In 1932 Lewin was invited to teach at Stanford University for 6 months. The following year, due to the rise of Nazism in Germany, Lewin resigned from University of Berlin and immigrated to the United States taking a 2-year nonrenewable teaching position at Cornell University. He was placed in the School of

Home Economics and used his position to study the eating habits of adolescents (Hothersall 1995, p. 246).

After 2 years at Cornell, Lewin joined the University of Iowa's Child Welfare Research Station. There he carried out some of his most famous experiments, which demonstrated the efficacy of democratically led systems over autocratic and laissez-faire ones (Boring 1957, p. 727). He remained in Iowa from 1935 until 1944, when he returned to the east coast and founded the Research Center for Group Dynamics at the Massachusetts Institute of Technology. Lewin was serving as the director of his new research center when he suffered a heart attack and died on February 1, 1947 (Marrow 1969, p. 226; Hothersall 1995, p. 251).

Accomplishments

Kurt Lewin's contribution to psychology was more profound than is clearly discernable from his current reputation. Lewin's theories and experiments deeply affected the field of psychological research and the way psychologists think about human behavior and interaction. In contrast to the psychoanalysts, structuralists, and behaviorists of his time, Lewin brought psychological experimentation into the practical world in order to study the human psyche, with the hope of making society better as a whole. This approach to experimentation spawned the field of Social Psychology and dramatically changed the way experimental research is carried out.

Lewin was a strong proponent of working within a theoretical framework, as well as studying human dynamics through experimentation (Marrow 1969, p. 30). He wanted to solidify psychology as a science and felt the way to do that was by using certain mathematical language to create a unifying system of concepts and laws which would encompass the entire field of psychology (Marrow 1969, p. 116). Early in his career, while still in Germany, Lewin developed *Field Theory*. This theory postulates that every person is made up of complex fields of energy. Each person's field contains a unique and dynamic system of tensions and needs that interacts with the environment. Lewin used a specialized jargon with words such as *energy*, *tension*, *need*, *valence*, and *vector*, some borrowed from topology while others useful neologisms (Marrow 1969, p. 33). In this theory Lewin termed the interaction between the person and the environment *Life*

Space. *Field Theory* posits that behavior is the function of *Life Space*, which can be written as a formula; behavior (B) is a function of an individual's (P) interaction with environment (E) [$B = f(P, E)$] (Ash 1992; Marrow 1969, p. 38). This theory is now accepted as a basic premise in the field of Social Psychology. Lewin used an oval shape, called a *Jordan curve*, borrowed from geometric topology to demonstrate the positive and negative valences, or forces, between an individual and the outside environment, which results in behavior. For this reason Lewin called his approach *Topological Psychology* (Marrow 1969, p. 34–39).

Lewin was not only a theoretician but he also tested and applied his theories in many practical experiments involving seemingly disparate fields of psychology throughout his life including *Action Research*, child development, personality, group dynamics, and racism. The results of these experiments helped formulate certain principles of psychology including *levels of aspiration*, *approach-approach conflicts*, *approach-avoidance conflicts*, *avoidance-avoidance conflicts*, the *dedifferentiation hypothesis*, the benefit of conversation over rhetoric, the understanding of the dynamics of social interaction, and the *unfreeze-change-refreeze model* (Marrow 1969; Hothersall 1995). Lewin carried out these experiments with a number of his students in Germany, Iowa, and MIT. In both the University of Berlin and Iowa, Lewin was famous for forming groups of students who would meet regularly to hold free-flowing conversation style meetings from which a wide range of research ideas emerged. Lewin's democratic, accepting, and enthusiastic style drew many students to follow in his footsteps (Marrow 1969, p. 26–27). Included among the ranks of his students are some of the most famous social psychologists of the twentieth century (Hothersall 1995, p. 252).

In addition to his many papers on a variety of topics, Lewin also wrote two books describing his theories: *A Dynamic Theory of Personality* (1935) and *Principles of Topological Psychology* (1936). Compilations of his papers were also reprinted in *Resolving Social Conflicts and Field Theory in Social Science* (1997) and *The Complete Social Scientist: A Kurt Lewin Reader* (1999).

Lewin was instrumental in founding the Commission on Community Interrelations (CCI) as well as the Society for Psychological Study of Social Issues (SPSSI)

in which he served as the president of from 1942 to 1943 (Hothersall 1995, p. 249–251).

In 1945 Lewin founded the Research Center for Group Dynamics at MIT where he and his students studied a variety of issues important to social psychology including leadership. His leadership training research led to the formation of the National Training Laboratories and T-groups (Hothersall 1995, p. 249–251).

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: July 28, 1851; Died: October 15, 1914.

Lipps was broadly trained for a philosophical career on which he embarked first at Bonn, then at Breslau, and finally after 1894 at Munich, where he succeeded Stumpf and remained for the rest of his life, and with which institution and environment he was most often identified.

Major Achievements/Contributions

Lipps was the most prominent of the “psychologistic” philosophers of his generation. He fell to the philosophical side of the divide between philosophy and psychology, but just barely: He styled himself a philosopher but saw philosophy as the study of inner experience, grounded mainly in psychology.

His influence on psychology proper came in three chronologically ordered stages. The first of these was effected by his monumental *Grundtatsachen des Seelenlebens* (Basic Facts of Mental Life) from 1883. This was a compendious collection of all the various ways that the conscious world could be experienced. Lipps’s primary focus was on feeling and the *Grundtatsachen* can be read as a catalog of possible feelings. Another important principle embodied in the *Grundtatsachen* as well as in Lipps’s later works is mirroring, which Lipps employed to understand the problem of other minds and activities and also adapted to understand the way in which internal communication was managed in the mind. This emphasis on mirroring has gotten new life over the past quarter century in theories of mirror neurons and their function in imitation and the understanding of others’ actions (Semin and Caccioppo 2009). Among the many psychologists who were influenced by the *Grundtatsachen* were James Sully and William James. James’s *Principles of Psychology* contains nearly as many references to Lipps as to Wundt, all from the *Grundtatsachen*. In order, in the *Principles*, James cites Lipps on the following: “unconscious” sensations, theory of ideas, time-perception, muscular feeling, distance, visual illusions, space-perception, reality, and effort. Lipps’s ideas play an important role for James in his discussion of the perception of reality, which includes the following direct quote: “Mein Jetzt und Hier,” as Prof. Lipps says, “ist der letzte Angelpunkt für all Wirklichkeit, also alle Erkenntnis.” (Lipps (1883) p. 400, in James (1890), p. 926). And later, James supports a phenomenology of will by again quoting Lipps: “Professor Lipps, in his admirably clear deterministic statement, so far from admitting that the feeling of effort testifies to an increment of force exerted, explains it as a sign that force is lost. We speak of effort, according to him, whenever a force expends itself (wholly or partly) in neutralizing another force, and so fails of its own possible outward effect.” (Lipps 1883, pp. 594–595, in James (1890), p. 1178.) Another stream of Lipps’s influence runs toward Freud (Sigmund Freud) (Devonis 2000; Kanzer 1981). Freud, much more biological at base, was moving away from a biological psychology and saw in Lipps, who was far more conceptual than the biological and mathematical psychologists who were his contemporaries, a kindred

spirit. Freud was impressed by the parallels between Lipps's version of the unconscious and his own developing ideas. Lipps's conception of the unconscious as a fundamental ground of experience accessible by consciousness was key to Freud's thinking that led to the conception of the "System Pcpt-Cs," which allowed for communication between the conscious and unconscious worlds. Freud also turned to Lipps's theories of the comic in the creation of *Jokes and Their Relation to the Unconscious*. The last of Lipps's large contributions to psychology is his recasting of the term "Einfühlung" from its origins in Lotze and in the philosophical aesthetics of Robert Vischer, itself an extension of ideas about ideality in art dating back through Herder. Lipps broadened and extended the term to incorporate all aspects of projective, imitative, and analogical understanding of art by reference to conscious emotional life. The term was rendered into English by Edward B. Titchener as "empathy" in 1910 and it had continuing influence as a point of reference in psychological aesthetics from Herbert S. Langfeld through Rudolf Arnheim and Daniel Berlyne. Modern variants of empathy are found in clinical and counseling psychology as well as other areas including social psychology and the comparative psychology of the emotions (Gladstein 1984; Preston and DeWaal 2002). Beyond his influence on psychology, Lipps had substantial effects on philosophy. The genesis of Husserlian phenomenology involves reactions against Lipps's positions and Edith Stein's dissertation on empathy was originally conceived as a critique of Lipps (Farber 1967). Lipps also impacted the development of modernist art theories, influencing some of the main figures of art theory and criticism in the era of Jugendstil and Secession including Wilhelm Worringer, August Endell, Wassily Kandinsky, and Paul Klee (Poli 1997).

Localization of Function, Outline of

J. WAYNE LAZAR

Neuropsychological Services, Garden City South, NY, USA

Background

This chapter will be an outline of the last 200 years of history of localization of psychological functions. Two hundred years allows a nice overview of modern history. It allows continuity with a more philosophical, even religious, approach to science than is currently popular. To understand modern localization attempts, one must understand that these antecedents are, to some extent, still with us. This period also allows comments about attempts to move away from these early roots to a more scientific approach. It allows comments about the development of laboratory methods that support such inquiries. It allows a snapshot of our modern view. Basically, this chapter is a story about growth: a growth of sophistication of questions, answers, and methods in the quest to understand brain related sources of intelligence.

Clearly, this is a complicated story that would best be covered in a monograph. This chapter, as its title acknowledges, is an "outline" of these developments. Detailed information on various topics can be found in Finger (2011), Harrington (1989), Jacyna (2000),

Lazar (2009b), Tizard (1959), Tyler and Malessa (2000), Walker (1957), and Young (1970).

First, as an orientation, the history of localization of psychological functions in the brain fits nicely in the history of science because it illustrates how scientific ideas develop. Science is a human endeavor thus influenced by religious and political motives as well as scientific ones. Think of James' "great blooming, buzzing confusion" (James 1890). There is a lot of information to be sifted through and interpreted. How is this done? In science, perhaps in all enquiries, straightforward observables, such as, objects or simple actions are recorded first. Many things are observable: the movement of the sun, specific animals, gross body parts or even activities, such as, seeing or problem solving. These observables eventually get systematized by various schemes whether natural (e.g., types of animals) or speculative (e.g., powers or faculties of mind that account for them). In the former case, observables are *organized* according to various categories that are common or found useful. In the latter case, the observables may be *integrated* into folklore or speculative schemes that relate to why such ideas occur. This was particularly evident in earlier explorations of localization of psychological functions in the brain, but may be seen even now.

There is a long history to localization of cognition. Psychology and philosophy tell us that cognition has to do with the process of knowing, which includes awareness, perception, reasoning, judgment, volition, and memory. These several cognitive functions carry philosophical implications that determine how they are related to brain anatomy and physiology.

Cognitive functions have their origin in human activities and in concepts like soul and mind. They have an incredibly long history, measured in millennia. Their meanings have changed over time to reflect cultural values. Plato, for example, understands the meaning of soul or psyche in terms of moral qualities of man and his activities, like thinking and reasoning – observable activities not mental activities. Not until the time of the Roman Empire and the developing Christian influence does the meaning of soul begin to accrue transcendental properties.

- ▶ Generally speaking, soul in this period was regarded as a spaceless and timeless substance with which the

creator endowed human organisms. Soul was the source of knowledge and feeling, as well as the enduring entity which underwent the punitive and purifying sufferings in the afterlife. Another, special trait of the soul was the link it provided with the creator. By sharing this spiritistic essence with God man gained in dignity and provided himself an avenue of escape into a secure eternal life. (Kantor 1963, p. 225)

It is this meaning of soul that Descartes considered when he contemplated its indivisibility and the "soul–flesh" or "mind–body" relationship. This meaning of soul is the source of the modern meanings of "mind," "consciousness," and "mental processes." The importance of this for our consideration is that during the nineteenth century, anti-localization arguments were based, either explicitly or implicitly, on Descartes analyses rather than on naturalistic or experimental based arguments.

Over the years, the nervous system has taken on the role of soul. This may sound astounding, but from at least the time of Homer, that is, possibly about 900 BC, there has been debate about whether the brain or the heart was the seat of what has been variously called emotions, intellect, soul, mental processes, and cognition (Rose 2009). For example, was the seat in the blood, the chest, or was it in the head, the meninges, or ventricles? Notice the cerebral cortex was not among these candidates in early times. In fact, the ventricles, not brain parenchyma, stand out as the most popular area for localization throughout the medieval era by both European and Islamic scholars (Green 2003). There were many "ventricular theories," during this era and they differed from time to time and place to place. They surfaced regularly over the two millennia ending as late as 1800. Generally, the "inner" or "internal" senses (As opposed to the "outer" or "external" senses, namely, touch, taste, smell, hearing, and sight.) of perception, imagination, estimation (meaning something like innate knowledge), cognition, memory, and volition were located in the various known ventricles, more or less those from front to back and top to bottom of the brain in the order listed. As the older soul doctrines were naturalized, the rational powers and functions of the soul, such as allowing cognitive abilities, were attributed to the bodily functions (Kantor 1969). As these bodily places were shuffled among body

parts, the solid parts of the brain or nervous system became the prime locations and this accounts for the exalted position the nervous system has in the explanation of complex behavior and cognition in particular. To put it generally, instead of having the nervous system participating in a cognitive activity, it takes on the role of originating it and a place where it occurs.

The Organology of Gall

With this background, we step into the stream of history at the time of Gall because the theory that the cerebral cortex can be divided into functional parts is largely a nineteenth century development. The work of Franz Joseph Gall (1758–1828) appeared just after about a half century of anti-localization sentiment in the eighteenth century (Karenberg 2009). He is best known for the localization system known as phrenology. Unfortunately for his legacy, phrenology is the name applied to a popularized version of his ideas more appropriately attributed to Johann Spurzheim (1776–1832) and George Combe (1788–1858). Gall preferred “Organology” and did not use the term phrenology in his writings. Spurzheim began working with Gall in 1804. Their collaboration ended 9 years later over disagreements about Gall’s system. Once on his own, Spurzheim increased the number of faculties, reclassified the faculties, and popularized the theory showing, for example, how useful it could be for choosing a mate, educating children, and selecting leaders, (Finger 2009; Spurzheim 1825, 1832). Gall could not be induced to write a popular version of his theory although his work was motivated by explaining the behavior and morals of people. In 1816, Combe (1788–1858), a Scotsman, was impressed with phrenology after hearing Spurzheim lecture. He became a leading spokesman for phrenology after Spurzheim’s death (Combe 1835). Spurzheim and Combe lectured extensively in Europe, Britain, and USA.

Gall’s organology taught that the cerebrum is composed of different functional regions each associated with different moral and intellectual faculties. These faculties are innate and their exercise or manifestation depends on their organization (Gall 1835b). Organology also taught that the size of a region directly reflects its influence on a person’s personality. The size of a region also directly affects the topography of the skull. Extreme personality characteristics based on

exceptional mental faculties were related, at least to Gall’s satisfaction, to bumps and depressions on the individual’s skull. He was struck by relationships between facial characteristics and mental characteristics even as early as among his boyhood friends. Later, Gall documented these relationships by observing individuals with outstanding talents in literature, science, politics, crime, etc. He interviewed a myriad of individuals and observed the contours of their heads. He collected and analyzed well over 600 skulls of eminent men. Surprisingly, for an accomplished anatomist, he did not systematically study their brains.

Gall was a respected anatomist, for example, he discovered the decussation of fibers at the pyramids. What is not as well known about him is that he can be described as a physiologically oriented philosopher, and this is where his organology comes from. He developed organology to predict personality characteristics based on the localization of mental faculties. Fundamentally, his theory was a grand scheme to find the laws of organization of the nervous system in general and of the brain in particular. His theory was paramount; the bumpy road to personality seemed to follow.

- ▶ The moral and intellectual dispositions are innate; their manifestation depends on organization; the brain is exclusively the organ of the mind; the brain is composed of as many particular and independent organs, as there are fundamental powers of the mind; – these four incontestable principles form the basis of the whole physiology of the brain. [Once he established these principle he went on to] . . . inquire, how far the inspection of the form of the head, or cranium, presents a means of ascertaining the existence or absence, and the degree of development, of certain cerebral parts. (Gall 1835a, p. 308)

Each cerebral part, that is, each cerebral organ, was related to a mental trait. How did he come by these traits? Gall got them from the “language of common society” not from philosophers (Gall 1835b, p. 84) because he believes that philosophical faculties of the soul were too abstract to work with. He was well versed in philosophy, for example, he was aware that Francis Bacon distinguishes the rational soul and the sensitive soul. That Descartes recognizes four principal faculties, namely, will, understanding, imagination, and sensibility. That Condillac admits six faculties of understanding.

Kant's system has primitive faculties or functions, pure conceptions, and a priori ideas amounting to 25 elements. Gall wrote,

- ▶ Whether we admit, one, two, three, four, five, six, or seven faculties of the soul, we shall see, in the sequel, that the error is always essentially the same, since all these faculties are mere abstractions. None of the faculties mentioned, describes either an instinct, a propensity, a talent, nor any other determinate faculty, moral or intellectual. How are we to explain, by sensation in general, by attention, by comparison, by reasoning, by desire, by preference, and by freedom, the origin and exercise of the principle of propagation; that of the love of offspring, of the instinct of attachment? How explain, by all these generalities, the talents for music, for mechanics, for a sense of the relations of space, for painting, poetry, &c.? (Gall 1835b, p. 84)

His theory is a practical theory; one related to functioning people in everyday life. His faculties of common society came from interviews of common people about themselves and their children, for example, they are ashamed and they despise. They came from descriptions by biographers of remarkable men, for example, courageous warrior, cruel, and talent for language. They also came from characteristics of animals. Gall believes that humans share many characteristics with animals, for example, gentle, affectionate, and docile. Gall felt it necessary to compare man with animals in order to acquire a complete understanding of man's nature, moral, and intellect. His final list of faculties of the mind totals 27, 19 of which are shared with animals.

Gall's work drew considerable attention among researchers and laymen. The positive attention peaked decades earlier among researchers than it did for laymen. His ideas also caused quite a stir among those in charge of public morals. In Vienna in 1805, after his lectures were becoming more and more popular, he was directed by the conservative Hapsburg rulers of Austria and the Catholic clergy to have his lectures approved before continuing, not because he correlated cranial bumps with personality, but because they felt his ideas were atheistic and materialistic. His thinking was dangerously materialistic and soulless (Finger 2009). The city fathers were against his philosophical system not his practical application (Hollander 1901). Instead of having his lectures censored, he with

Spurzheim left Vienna in 1805 and traveled and lectured in northern Europe where his lectures were well received. The lectures included numerous anatomical and physiological facts and they were accompanied by dissections and the exhibition of skulls, heads, and casts. He eventually settled in Paris at the end of 1807 and lived there until the end of his life in 1828. As soon as 1808, Gall began writing his four volume *Magnum Opus, Anatomie et Physiologie du Système Nerveux en Général et du Cerveau en Particulier*. The first two volumes, coauthored with Spurzheim, were published in 1810 along with an Atlas. The second two volumes appeared in 1819. The second edition, a six volume work, called *Sur le Fonctions du Cerveau* was published from 1822 to 1826 solely under Gall's authorship. These volumes were translated into English in 1835 and entitled *On the Origin of the Moral Qualities and Intellectual Faculties of Man*.

Apropos of the notoriety of Gall, controversy followed him to Paris. He was refused membership in Académie des Sciences in 1808 even though his entrance application included a straight anatomical paper that did not mention his controversial theory. How could this happen to an eminent anatomist? Unfortunately, his theory was discussed during the review process and his application was rejected (Finger 2000). Later, like the city fathers of Vienna, Napoleon and the scientific elite considered Gall a threat to French culture and science. This gave impetus to the experimental research of Gall's most powerful scientific adversary (Finger 2000; Olmsted 1953). The French Academy in 1822 commissioned Jean Pierre Flourens (1794–1867) to investigate Gall's localization claims.

Flourens and the Indivisibility of the Soul

Flourens was a protégé of Georges Cuvier and he was beginning to make a reputation in 1822 when he began the experimental brain research directed to evaluate the claims of Gall. In 1824, Flourens read his results to the Academy and published them in a book called *Recherches Expérimentales sur les Propriétés et les Fonctions du Système Nerveux dans les Animalux Vertébrés*. The second edition of this book, *Examen de la Phrénologie*, first published in 1842 was translated into English in 1846 and called *Phrenology Examined*. He dedicated these books to Descartes. This work and

his subsequent research attracted considerable attention. He went on to professorships and at Cuvier's dying request became the perpetual secretary of the Academy of Sciences in 1833. Flourens clearly epitomized the French academician. He came to be known as the founder of experimental brain research.

Flourens concluded that Gall was wrong. Flourens' analysis went to the heart of Gall's system. Gall has a physiology, an anatomy, and a psychology. His physiology is that the brain is the organ of the mind. Of this Flourens found nothing new and nothing disagreeable. His anatomy is about the localization of organs. Gall used the expression "individual intelligences" where each individual intelligence has its own proper organ. Flourens wrote, "Of all Gall's writings, his anatomy is that which has been most talked of, and yet it is the part least known" (Flourens 1846, p. 69). Flourens observed that Gall's lectures on anatomy in 1808 were of ordinary anatomy, that is, not giving special insight into locations of faculties. His psychology is about multiple faculties. Of this, Flourens felt, there is, "perhaps," nothing true. Flourens wrote that Gall's faculties are merely words created to explain behavior. "Gall's philosophy consists wholly in the substitution of *multiplicity* for *unity*. In place of one general and single brain [cerebral hemispheres], he substitutes a number of small brains: instead of one general sole understanding, he substitutes several individual understandings. These pretended *individual understandings* are *the faculties*" (Flourens 1846).

For Flourens, criticism of Gall's theory was based on more than anatomy and experimental observations. After all, he dedicated his book to Descartes. He was fundamentally against multiple organs of intelligence. He believed in the unity of the intellect because introspection informed him of it. "The unity of the *me* ['moi,' better translated here as 'self'], is a fact of the conscious sense, and the conscious sense is more powerful than all the philosophies together" (Flourens 1846, p. 40). The seat for this unity of intelligence resides in the cerebral hemispheres. When the hemispheres were damaged, intelligence dwindled as a unity might. The reduction in intelligence was proportional to the amount of brain tissue removed. Intelligence "grows gradually less; and certain limits being passed, is wholly extinguished" (Flourens 1846, p. 34). He attributed this to a mass effect and called it

"equipotentiality." "When one faculty disappears, all the faculties disappear" (Flourens 1846, p. 35). Unlike Gall then, according to Flourens, the cerebral hemispheres cannot be partitioned into separate mental functions. It must be said that Flourens was aware that other gross parts of the brain were associated with different functions. Beside the cerebral hemispheres subserving intelligence, the cerebellum controls motor functions, the quadrigemina are associated with sight, and part of the medulla oblongata is associated with respiration.

It is now understood that Flourens' failure to find any differences following ablations of different parts of the cerebral cortex was due to his choice of experimental animals (e.g., ducks, hens, pigeon, and frogs), his crude assessment techniques, and his interpretations. He primarily experimented with birds and amphibians without appreciating the relatively little cortical control over subcortical structures in these groups. His assessment technique, standard for the time, was simply to observe the animal and record possible ablation effects. There is nothing subtle about this and much was missed. Flourens' role within the French academic community and his Cartesian bias must have been overwhelming. For him, Gall's theories would not only undermine the unity of the soul, but it would undermine free will, human immortality, and the very existence of God (Harrington 1989). The aphorism that you look for what you know and you find what you look for certainly weighed heavily in his conclusions.

But what of Flourens' own conclusion of equipotentiality in cerebral hemispheres. It made perfect sense according to contemporary philosophical beliefs, namely, the mind acted through the brain, but the mind and the brain were independent. An altered brain would alter the actions of the mind, but only "diminish the brightness and clearness of conceptions generally" (Attributed to Johannes Muller, 1838; Tizard 1959). Where Descartes emphasized the indivisibility of intelligence and will and the unity of the mind, Flourens emphasized the indivisibility of intelligence. Where Descartes chose the pineal, Flourens chose the entire mass of the cerebral hemispheres. Thus, Flourens doctrines came into sharp contrast with the more materialistically colored ideas of the phrenologists.

Flourens' conclusions were initially convincing because they were a reasonable reflection of his

experimental results, yet it was not realized at the time that the same “psychological difficulties attach to them as to the phrenological theory of organs” (Wundt 1904). Intelligence and will are complex processes just as Gall’s faculties are. That Flourens’ intelligence and will should have their seat in any or even a small fragment of the cerebral lobes is just as difficult to comprehend as is a special organ for Gall’s “love of one’s offspring.” The field was left placated, but unsettled.

Clinical Pathology and Language Localization

Jean-Baptiste Bouillaud (1796–1881) was a central figure in the Parisian academic society and he was an admirer of Gall’s localization thesis. He had been a founding member of the Société Phrénologique. Bouillaud was a physician in Paris, which at that time was the center for clinical teaching and pathological anatomy in Europe (La Berge and Hannaway 1998). Instead of depending on Gall’s technique of craniotomy to localize brain functions, Bouillaud used the “clinical method” of correlating clinical signs and symptoms to autopsy data. By 1825, he implicated the anterior lobes – either lobe – with the “legislative organ of speech” and felt that he confirmed the opinion of Gall that language was located in the frontal lobes. Even though he accumulated hundreds of clinical cases over subsequent decades to support his contention, his claims were strongly disputed by other pathologists and attracted more criticism than support. By the 1840s Bouillaud’s opinion in these matters, as was Gall’s, held little sway (Jacyna 2000).

Paul Broca (1824–1880) formally entered the language localization debate in 1861. At that point he was a respected, liberal minded scientist with interests in physical anthropology and neuroanatomy. He had founded the Société d’Anthropologie 2 years before and was disposed to Bouillaud’s localization ideas. The society was known for its members’ dislike of metaphysical intrusions on science. Localization theory was compatible with this idea because localization would serve to give brain science a firm material base by partitioning the soul (partitioning would contradict the soul’s traditional unity; it would diminish its exalted position and be a step toward its naturalization) and distributing it in different parts of the cortex.

A pro-localization vs. anti-localization debate occurred over several days at the Society in 1861. On the surface, the debate was about the localization of speech, but underlying this was an implicit emphasis on a naturalistic approach to brain functions. Neither side won the debate, but it was a milestone. It was part of the reduction of language that occurred at that time from a vehicle for reasoning and thinking to a bodily function. Language had been identified with thought itself, a quasi-divine attribute. Although a higher, complex function to be sure, language became more like any other form of muscular movement. More generally, metaphysics had lost ground. “Metaphysics might have its place; but it had no use in understanding man conceived as a distinct, observable and measureable object” (Jacyna 2000, p. 77).

It was soon afterward and in this milieu that Broca delivered his landmark paper that was later published as *Remarques sur le siege del la faculté articulé; suivies d’une observation d’aphémie* (Remarks on the seat of the faculty of articulated language, following an observation of aphemia) (Broca 1960). He defined aphemia, later called aphasia, as loss of speech without loss of intellect and illustrated it with the case study of his now famous patient, “Tan” (“Tan” was the name eventually given to his patient, named Loborgne, because he often uttered a word that sounded like “tan” when asked a question). His observations confirmed Bouillaud’s claim that the center of articulated language, that is, speech, was located in the anterior lobe and, he added, “probably” in the third frontal convolution. The much maligned Bouillaud called Broca’s adoption of his views “the Conversion of St. Paul” (Sanders 1866, p. 816). Broca was not definite about the left hemisphere until about 4 years later (Finger 2011). His location of articulated language disconfirmed Gall’s suggestion that it was located not far from the eyebrow above the orbital arch. Broca’s proposal did not suffer the same fate as Bouillaud’s (Sondhaus and Finger 1988). It was accepted. Broca distanced himself from Gall and his proposal came at a time and place when language was more easily accepted as a bodily function and when metaphysical and religious ideas had less control over ideas in medical science. Remember, in contrast, that at the beginning of the century Gall had been run out of Vienna and ostracized by the Parisian academic community for similar ideas.

Was articulated language, motor language, really located at that spot? Carl Wernicke (1848–1904) thought not. Wernicke made a variety of contributions to clinical medicine including a three volume *Lehrbuch der Gehirnerkrankheiten (Textbook on Diseases of the Brain)* published in 1881–1883, which Kurt Goldstein wrote was “an astounding accomplishment for so young a man” (Goldstein 1953). Yet, the ideas for which he was most remembered came out, even earlier in 1874, in his monograph, *Der Aphasische Symptomencomplex (The symptom complex of aphasia)* (Wernicke 1874). This monograph did more than introduce receptive aphasia or sensory aphasia and link it to the posterior section of the superior temporal gyrus, a region now called Wernicke’s area. It argued that aphasia, like other mental functions, is a symptom complex composed of primitive “memories” of past sensory and motor experiences, which are associated and combined according to an associationist–connectionist brain model (Harrington 1989). Wernicke did not organize the brain according to psychological functions as did Gall. Wernicke rejected the notion of faculties of the mind as advocated by Gall and to a certain extent by Broca. He reversed the emphasis. Sensorimotor functions (that is, brain functions) were associated and became the basis of psychological functions. From this followed the classical disorders of aphasia, agnosia, and apraxia. These form the bases of the modern symptom complex for neuropsychology. The connectionist model was revived recently by Norman Geschwin (1926–1984) (Geschwin 1965a, b).

Laboratory Studies and Motor Localization

Before 1870, the focus of attention was on whether or not the hemispheres were the seat of a unified intelligence, a single function. This issue continued, but in the period 1870–1873 another concern surfaced, namely, whether or not the cerebral cortices of the hemispheres could be artificially stimulated (Lazar 2009b). This specific concern was prompted by the work of two young Prussian physicians, Gustav Fritsch (1838–1927) and Eduard Hitzig (1838–1907). They demonstrated that weak electric current applied to certain parts of the cerebral cortical surface consistently elicited specific movements in dogs. If these movements were, in fact, elicited by stimulating the

cerebral cortex then motor functions would be located there and the unity of function of the hemispheres would fall.

Flourens had assumed without fear of serious contradiction that the cerebral cortex was not artificially excitable. That is, it did not respond to electrical, mechanical, chemical, or thermal stimulation. It is excitable only by the will. Stimulate the cortex by whatever method and nothing happens; there is not even evidence of pain. Yet, both Fritsch and Hitzig were convinced of a connection between the cerebral hemispheres and motor movements before their famous experiment. Fritsch, when a physician during the Prusso–Danish War, noticed twitches of the opposite side of the body when cleansing and dressing an exposed brain of a soldier. Hitzig became interested when he found that electrical stimulation of the back of the head or the ears caused eye movements in humans. He subsequently undertook experiments with rabbits that were also suggestive. Neither Fritsch nor Hitzig were associated with a laboratory at the time of their experiments. In the spring of 1870, they started their famous studies on a dressing room table in Hitzig’s house in Berlin.

Fritsch and Hitzig recognized they were contradicting traditional doctrine (Fritsch and Hitzig 1963). Their 1870 article reviewed anti-localization history. They were respectful and not condescending toward earlier experimenters like Flourens. They were careful not to exaggerate their findings. They were cautious and admitted they were only certain that their experiments showed that structures in the central nervous system responded to electrical stimulation with visible responses and that a considerable part of the hemispheres was in direct connection with specific muscular movements while the other part was not. They were also careful to acknowledge the limitation of their study. For example, they admitted uncertainty and lack of proof to whether their stimulation was on gray substance or white substance and that there was more ambiguity as to whether nerve cells or nerve fibers were stimulated (The neuron was not formally identified until 1891 by Waldeyer. At this point in history, nerve cells or ganglia (gray matter) were separate, but interacting, nervous elements with nerve fibers (white matter)). They even suggested why earlier researchers had not found what they had. Their answer was “the

method creates the results” (Fritsch and Hitzig 1963, p. 913). Others did not search the entire convexity or they would have found it too. After a search over a limited area and “based upon the still widespread assumption that all the psychic functions were omnipresent in all the parts of the cerebral cortex” (p. 913), they probably stopped searching and did not trephine the entire region.

These reservations did not deter them from concluding that motor functions were localized in the cerebral cortex and, thus, the cerebral hemispheres did not represent a functional unity. Despite this tradition breaking conclusion, they were not young iconoclasts out to “right” all traditional ideas. They were firmly within the dualistic mind–body tradition of interactionism when suggesting they found an experimental approach to the mind. They were very much interested in knowing if they were stimulating the cortical place where volition originated, but even if it were admitted that they were stimulating the gray substance, they would be uncertain as to where in the chain from sense impression to intentional response they were impinging. This approach and goal contrasts with Ferrier’s position, which will be discussed below in relation to John Hughlings Jackson.

During the 1860s coincident in time, but not space, John Hughlings Jackson (1835–1911) in London was accumulating clinical cases and thinking about neurology. Although a clinician, it will be seen that his conclusions affected laboratory studies. He was assistant physician to the National Hospital for the Paralyzed and Epileptic in 1862, and in 1863 he became assistant physician to the London Hospital. During this period, he learned about the recent work of French physiologists from Charles Édouard Brown-Séquard (1817–1894) and he learned neuroanatomy from Jacob Augustus Lockhart Clarke (1817–1880). In clinical lectures between 1864 and 1868 Jackson informed that according to his clinical findings loss of speech is associated with right sided paralysis. This corroborated Broca’s findings that are essentially based on anatomical observations. In 1866, Jackson demonstrated cases of apraxia. In 1868, he recognized that aphasic patients, which in agreement with Broca he thought had left sided lesions, performed reasonable well on perceptual tasks. He, therefore, reasoned that spatial impairments are more likely associated with right hemisphere

damage than anywhere else. Jackson’s clinical work with epileptic seizures – mainly those starting unilaterally called focal motor seizures – began in 1862. He reasoned that there is a focal irritation in a voluntary system of the cerebral cortex that initiated the seizures. He also recognized that a somatotopic organization of the cortex of the hemispheres is the only way to account for the progression of seizures (Finger 2009). Jackson was able to watch epilepsy up close. His wife, from 1865 to 1876 when she died, had a seizure disorder. Unfortunately, at that time the French school of physiology led by Flourens dominated and Jackson’s idea that convulsions arise from some change in the cerebrum and usually from a focus within the territory of the Sylvian artery was passed over in contemptuous silence. But after Fritsch and Hitzig showed that stimulation of the cortex could produce movements, “Jackson’s views came to the front, and local convulsions are now called by his name” (H.H. 1911, p. 524).

The story of Jackson’s vindication involves a young colleague named David Ferrier (1843–1928) even more than Fritsch and Hitzig. Ferrier was a Scottish physician of great intellectual promise. He graduated from the University of Aberdeen in 1863 with the highest honors and won a scholarship in classics and philosophy. He studied psychology, anatomy, physiology, and chemistry at the University of Heidelberg. He studied medicine at the University of Edinburgh from 1865 to 1868, where he graduated after winning several medals. Ferrier was aware of the research of Fritsch and Hitzig soon after its publication (Brunton and Ferrier 1871). Jackson and Ferrier were encouraged that the Prussians’ approach might validate Jackson’s theories. In 1873, Ferrier had an opportunity to find out. He obtained monies for research and laboratory space at the West Riding Lunatic Asylum. Ferrier confirmed Fritsch and Hitzig’s results and demonstrated localized motor responses in a variety of animals. His research identified the motor region as a strip along the Rolandic fissure and suggested medical implications of it. Ferrier’s initial work was surprisingly important in spreading the word about localization of motor functions across Britain, USA, and even France (Lazar 2009a). He became the foremost advocate for localization of function during the last quarter of the nineteenth century (Ferrier 1876, 1886).

Ferrier's stimulating current was faradic (alternating) rather than galvanic (direct) like the current of Fritsch and Hitzig. His current was also somewhat stronger, which resulted in elicitation of more complex movements than Fritsch and Hitzig's flexions and extensions (Ferrier elicited behaviors that might be called "molar" or psychological today, whereas Fritsch and Hitzig elicited behaviors that might be called "molecular" or physiological). He interpreted them as purposive because he, like his contemporaries, interpreted hemispheric functions in terms of consciousness and higher functions, like intelligence and purpose. He, like Fritsch and Hitzig, was keenly aware of the main issue to be proved.

- ▶ Though it is by means of the cerebrum that we feel and think and will, the question is whether, by physiological or pathological investigation, we can throw any light on psychological manifestations; whether the cerebrum, as a whole and in each and every part, contains within itself, in some mysterious manner inexplicable by experimental research, the possibilities of every variety of mental activity, or whether certain parts of the brain have determinate functions. (Ferrier 1876, p. 124)

Unlike Fritsch and Hitzig, Ferrier's answer is in sensorimotor terms. For example, with respect to aphasia, "it is the cohesion between sound and articulation which is broken . . ." (Ferrier 1876, p. 276)

After initial criticisms, cerebral stimulation was generally accepted. Students of Flourens, like Brown-Séquard and Vulpian and their students, particularly Eugene Dupuy, did not accept Fritsch and Hitzig's results. They were persistent and clear in their criticism. Although movements consistently followed stimulation, it was their view that it was not the cortex that was stimulated. Dupuy proposed that electrical current diffused through the brain to subcortical structures, which incited the movement (Lazar 2009b). Eventually, this criticism was not accepted as crucial. By the end of the decade, or certainly by the end of the next, cerebral cortical localization of motor functions and to some extent sensory functions were generally accepted. The study of the brain and its functions had become an experimental science. The mind was no longer associated with the soul and studied only by metaphysicians. It too, was an object of scientific study both by neurophysiologists and by psychologists (Young 1970).

But, many questions were left unanswered. The case for cerebral localization of function was made and accepted before the how, what, and where of localization were understood (Phillips et al. 1984; Lazar 2009b). The hard questions were not answered. "What exactly was localized in these regions?" "How was each function actually accomplished?" "What about complex mental functions; were they localizable like sensory and motor functions?" Answers to these questions were not known and basically inconceivable. Arguably, research had gone as far as it could with these and other questions within the confines of contemporary knowledge. The fact is nineteenth century physiologists were naïve about neuroanatomy, about surgical techniques, and about assessment of behavior. With their level of expertise, they could be expected to find only the grossest of effects, particularly when lesions were involved. For example, Broca emphasized centers in convolutions themselves. Ferrier did his initial studies without antiseptics. Lesion effects were assessed by recording common laboratory behaviors, such as, whether or not the animal ate, whether or not the animal was friendly, and whether the animal flinched when a pistol was shot-off next to it. Bianchi reported data about a baboon that did not salute anymore after a frontal lesion. Theirs was a boot strapping process. Lesion first; ask questions later. Fortunately, this resulted in sort of a positive feedback loop. The answer to each question resulted in other questions. Each question required a more subtle lesion, which required a more subtle technique, which forced a more subtle understanding of the nervous system (Franz 1902).

The Twentieth Century and Complex Systems

By about the beginning of the twentieth century, the reality of the neuron had been established; the reflex was extended as a hierarchically based, explanatory concept; experimental methods of psychology were established; new experimental techniques for assessing behavior of animals were invented; and more demanding experimental designs were developed. Unexplained old findings and new findings caused a reinterpretation of classical localization ideas. For example, recoveries of the functions lost after lesions were difficult to explain and fostered new ideas. Recovery made no sense if, in fact, the center for that function had been

destroyed. Initially, the only conclusion was that the destroyed area was not the center and another place in the nervous system must play that role. Research on this subject was plentiful over the years, but no definitive answer was reached. Questions were raised, for example, “Can a mechanical system operating according to the laws of reflex and association even accomplish such a feat?” There was little agreement that it could or even that it was necessary since most still had thought the mind accomplished these functions. Nevertheless, mechanical explanations were invented, like von Monakow’s “diaschisis,” which emphasized complex interactions with systems far from the lesion site (Finger et al. 2004). Other research findings also pointed to a more complicated and more dynamic nervous system (Harrington 1987; Finger et al. 2004).

Shepherd Ivory Franz (1874–1933) took the lead in the early twentieth century among psychologists dealing with the physiological basis of learning and meaning of localization of function. Franz’ research on the role of the frontal lobes in learning and retention is the first application of Thorndike’s puzzle box to brain localization research (Franz 1902). (Franz received his Ph.D. from Columbia University in 1899 at the time when Edward Lee Thorndike (1874–1949) (Columbia Ph.D., 1898) was there developing his puzzle box technique.) Franz’ best known article about localization called “New Phrenology” was published in 1912 (Franz 1912). In it he tried to make sense out of research on brain physiology and the meaning of what is localized when brain localization of function is discussed. He felt that the conception of brain centers for particular mental acts grew out of simplistic theories of the nineteenth century. The brain does have diverse functions, but specific parts of the brain do not have *specific full-fledged functions*. Various parts of the brain do not act independently; they act together to accomplish complex mental processes.

- ▶ The physical and chemical activities of the cells can not be believed to be equivalents of the mental processes which may be concomitant with or the result of these activities. Since for practical purposes we may need some general principle of localization, we may say that mental processes are not due to the independent activities of individual parts of the brain, but to the activities of the brain as a whole. (Franz 1912, p. 327)

These theories of the nineteenth century and activities of the brain as a whole were put to the test by the research and theories of Karl Spencer Lashley (1890–1958). Lashley’s work, not Franz’ challenged American physiological psychologists for most of the first half of the twentieth century.

It should not surprise that Lashley was a young protégé of Franz. In fact, Lashley started his research career into brain mechanisms of learning because of his association with Franz (Bruce 1986). In 1916, they collaborated on a project exploring frontal lobe involvement in maze learning. At their earliest collaboration, Franz did the surgery and Lashley ran the animals. Lashley was well prepared for what Franz had to offer. He came to Franz after completing his Ph.D. at Johns Hopkins in 1914 with Herbert Spencer Jennings (1868–1947). From Jennings, Lashley learned an aversion to vitalism and an interest in “internal, sensorimotor, physiological explanations of behavior” (Bruce 1991). Also while at Hopkins, as graduate student and later as a post doctoral student, Lashley collaborated with John Broadus Watson (1878–1958) when Watson was approaching the peak of his fame. His work with Watson converted him to psychology (Lashley was a zoology major at the University of West Virginia. His Master’s degree from the University of Pittsburg was in bacteriology. His Ph.D. at Johns Hopkins was in zoology.) and “laid the foundation for many of his later scientific interests in development, primatology, sensory capacities of animals, comparative psychology, and psychology of learning” (Bruce 1991, p. 310). It gave him a strong respect for materialistic monism and an objective explanation of behavior.

Lashley came to psychology from zoology so he had interests that did not fully match any of the prominent schools of psychology active at that time. His hunt for the physiological basis of brain mechanisms was unusual. Read how he introduced one of his first papers, which was influenced by Franz and published in 1917. The “psychology” he refers to is probably Titchener’s structuralism.

- ▶ For psychology the problem of motor activity has been largely one of the perception of movement. Discussion has centered about the questions of the receptors which are excited differentially by changes in extent

and force of movement, about the psycho-physics of the constant error, the influence of the emotions upon the perception of movement, the relation of the “will impulse” to the perception of movement; with the result that the equally important questions of the nervous mechanism of initiation, continuation and cessation of adaptive movements have been dealt with only incidentally as throwing light upon this perception. (Lashley 1960b)

Through his research, Lashley explored basic assumptions of physiological and psychological theories. Localization of function was one of them. For example, he found that frontal lobes are necessary for intelligent behavior, but only in a limited way. No particular part of them is necessary for learning. Retention of new learning is lost after a frontal lesion, but the lesioned animal is capable of new learning and that new learning is retained unless the animal suffers another frontal lesion. Furthermore, retention is affected by the complexity of the task learned and by the extent of the lesion. He concluded that the seat of learning is not in the frontal lobes although they are relevant to it. Another research probe attempted to trace connections of reflexes through the cortex, but his findings would not fit such a scheme (Pavlov and Watson wanted to explain links between perceptions and motor responses with anatomical connections between sensory and motor centers in the brain. A behavioral link between perception A and action B implied activation of axonal connections from A to B. Lashley failed to find such connections). Disruptive lesions could be anywhere in the frontal lobes. They did not seem to be interrupting specific stimulus–response connections. His findings emphasized “the unitary character of every habit, the impossibility of stating any learning as a concatenation of reflexes, and the participation of large masses of nervous tissue in the functions rather than the development of restricted conduction-paths” (Lashley 1963).

Lashley was aware that “functional differentiation of various parts” of the cerebral cortex was well established (Lashley 1931), but he believed that the classical concept of cerebral localization was of limited value because it was of static character. It failed to suggest how the specialized parts of the cortex interacted. In 1941, Lashley observed that the relation

of mind and body still underlay all neurological and psychological investigations, but he saw movement from the old conceptualization of the nervous system to a new one. The old one, for him, was about an integration of reflexes with nervous impulses transmitted over limited paths in one direction only from sense organ to muscle (Lashley 1941). He would substitute a gestalt inspired “diffuse spread of excitation through nervous tissue, almost as through a continuous network,” but with a “recurrent or reverberatory circuit” (Lashley 1941, p. 463). The latter he credited to Lorente de Nó as early as 1934.

His interpretation was a gestalt-like field approach with such concepts as “equipotentiality” and “mass action.” Equipotentiality is his term to account for any part of a functional area being able to preserve “with or without reduction in efficiency” the function of the whole. Mass action is his term for the finding that within a functional area the more tissue lost the greater the reduction in efficiency of function. Equipotentiality is a function of mass action.

Lashley’s approach is reminiscent of Flourens’, but there were significant differences. Lashley was careful to admit the limitations of these “laws.” They applied to association regions of the brain not to the entire cerebrum. They applied to complex functions like learning and memory, but not to mental functions in general. Lashley published these and other findings in tens of papers over 5 decades until his death in 1958. The best anthology of his writings is in *The Neuropsychology of Lashley* published as a memorial by several of his students (Beach et al. 1960).

Lashley had no way of knowing how complicated vision was. When he studied the role of vision in learning, the striate cortex was that part of the occipital lobe known as the seat of vision. Rats with lesions of the striate retained preoperative discriminations and were able to learn new ones. Blindness due to enucleation did not affect retention of a maze habit. Surprisingly, lesions of the striate area affect retention in blinded animals (Lashley 1960a). The role of the striate in vision was obviously more complex than commonly understood. For Lashley, these results confirmed a previous conclusion that the striate had some important function in maze learning beyond reception and integration of visual impulses. What accounted for these results, Lashley had no way of knowing. He had

no way of knowing that later research would show that the striate was only one part of the visual system. It had connections with subcortical structures (the pulvinar of the thalami and the superior coliculi), adjacent cortical structures, and other hemispheric areas in the inferior temporal lobes. When all of the connections were interrupted, there was a severe impairment of visual learning (Mishkin 1966).

The neurophysiology of vision was a primary area of study during the last half of the twentieth century. Two researchers, David H. Hubel and Torsten Wiesel, led in this endeavor. Their research led to an unprecedented depth of understanding of any neurophysiological or neuropsychological system thus far. Vision is a system scattered over the breadth of the occipital lobe and parts of the temporal and parietal lobes. The classic theory of localization of brain functions was eliminated in favor of a complex interactive system approach.

A complex interactive system approach dominates current neurophysiology and neuropsychology. Damasio and Damasio (1997) discussed the importance of dissociating lesions from the quest for “brain centers [and faculties] capable of performing complex psychological functions with relative independence” (Damasio and Damasio 1997). Instead, the lesioned region had to be “conceptualized as part of a large-scale network of cortical and subcortical sites that operate in concert, by virtue of their interlocking connectivity to produce a particular function” (p. 69). The work of Sherrington (1906), perhaps, is the culmination of the old way while Adrian, McCulloch, and de N6 as cited by Lashley (1941) led in the new direction (Sherrington 1906; Abraham 2003; Finger 2000; Abraham 2003). Mesulam (2000), Damasio and Damasio (1997), and McIntosh (2004) discuss new experimental, anatomical, and physiological techniques as well as the broad interactive view (Mesulam 2000; McIntosh 2004). Network analysis promises the ability to explore connections among complex networks including connections among neurons (Butts 2009).

Concluding Overview

Over the last 200 years, the main question has remained the same, namely, how is a person or animal capable of intelligent behavior? At various times, the answer laid with the soul, the mind, and the brain. Over this time,

there has been movement in conceptual understanding and much progress in research techniques, but no clear answer. Tables 1 and 2 offer thumbnail summaries of these changes. Conceptual changes include changes in the capacities of the body (during the following discussion the terms body, person, brain, and cerebral hemispheres will be used interchangeably; “body” is used because of its historical meaning in this context even though the discussion is about the cerebral hemispheres or, sometimes, the brain in general), changes in the origin of mind, and, in consequence, changes in how the mind and body relate to one another. These are summarized in Table 1.

At the beginning of the 1800s it was conceived that a person or animal required a soul to be intelligent, that is, the person acts purposefully or intentionally only because of the action of the soul. The body by itself would be an automaton, a zombie. The cerebral hemispheres played a crucial role in intelligent behavior because somewhere and somehow within them the soul imparted the capacity for this behavior. The loss of spontaneity when animals are decorticated is interpreted as dramatic evidence of this. A decorticated frog sits without moving unless prodded. Once moving it continues to move until it meets an obstacle. The soul and the mind were inextricably mixed, but eventually the mind replaced the soul as the scientific source of intelligence. Arguably, the mind functioned as the soul without religious implications. Only comparatively, recently, was it conceived that the nervous system was complex enough to allow intelligent behavior without external help. It could, in effect, create a mind of its own. The four middle columns of Table 1 show these trends.

The important points of this period are (1) the mind lost its association with the soul; (2) the mind was conceived as an epiphenomenon of the brain; (3) discoveries about the complexity and computational nature of the brain made conceivable that the brain could take on the functions of the mind; and (4) although the mind lost its soul, it was still associated with consciousness and cognition. Consciousness and intelligent (purposive and intentional) behavior are still recognized as the *sine qua non* of humans and “higher” animals.

The mind–body relationship necessarily changed to reflect the conceptual changes in the body and the

Localization of Function, Outline of. Table 1 Shows prominent men discussed in the entry along with several of their attitudes about how the soul and the mind relate to intelligence, how the soul and the mind relate to one another, and how the mind and the brain relate to one another

Major researchers	Does a person require a soul to be intelligent?	Does a person require a mind to be intelligent?	Are the mind and the soul the same?	Is the mind a product of the brain?	Mind – brain relationship in philosophical terms
Gall	Yes	Yes	Yes	No	Dualistic interactionism
Flourens	Yes	Yes	Yes	No	Dualistic interactionism
Bouillaud	Yes	Yes	Yes	No	Dualistic interactionism
Broca	No	Yes	No	No	Dualistic parallelism ^a
Wernicke	No	Yes	No	No	Dualistic parallelism
Jackson	No	Yes	No	No	Dualistic parallelism ^b
Hitzig	No	Yes	No	No	Dualistic interactionism ^c
Ferrier	No	Yes	No	No	Dualistic parallelism ^d
Franz	No	Yes	No	Yes	Monistic materialism
Lashley	No	Yes	No	Yes	Monistic materialism

^aOn the strength of Broca's founding of the *Société de Anthropologie*, which had strong anti-metaphysical leanings and yet Broca's insistence that articulated language was a faculty of language, i.e., more than just a motor function, I put Broca in the dualist and parallelist camps

^bAccording to Young (1970), Jackson followed Bain and Spencer. "I do not concern myself with mental states at all, except indirectly in seeking their anatomical substrata. I do not trouble myself about the mode of connection between mind and matter. It is enough to assume a parallelism" (Jackson, 1931 from Young 1970, p. 208)

^cFritsch and Hitzig are ontological dualist and interactionists (Young 1970). They and the Germans in general were not in the Bain–Spencer tradition

^dYoung (1970) says that Ferrier is in the line from Bain, Spencer, and Jackson, accepting psycho-physical parallelism. "No purely physiological investigation can explain the phenomena of consciousness" (Ferrier 1876, p. 255)

mind. In broad terms, the change went through three stages: (1) a dualistic interactionism where an immaterial and transcendental mind interacted with a corporal body; (2) a dualistic parallelism where activities of the immaterial mind and the corporal body were correlated in time, but ran parallel to one another; and (3) a *monistic materialism* where the mind (or its surrogates, consciousness, and cognitive processes) were somehow associated with bodily functions. See the last column of Table 1.

Philosophers continue to interpret the mind–body relationship. Currently, the general philosophical question seems to be, "Can neurosciences reveal the physical basis of awareness or consciousness?" Are these

capacities of the human mind the capacities of the human brain? Current philosophers look at this question from a variety of perspectives even though none apparently take the classical dualistic approach (Churchland 1995). McGinn even argues that the question is beyond the capacity of the human intellect to answer (McGinn 1999). McGinn's, monograph-long, argument is sophisticated and astute and based, at least in part, on failures for multiple millennia to explain consciousness. The position of Daniel Dennett is based on human linguistic abilities and states that neuroscience has nothing to say about the mind (Dennett 1991). For him, consciousness is a virtual program running on the brain, much like "Flight Simulator" is

Localization of Function, Outline of. Table 2 Shows prominent men discussed in the entry along with several of their orientations to data including the general type of behavior observed, the setting in which the behavior occurred, and the way their observations were reported

Major researchers	Type of observed behavior	Setting of observations	Data presentation
Gall	Unsystematic	Naturalistic	Prose
Flourens	Unsystematic	Laboratory	Prose
Bouillaud	Clinical signs and symptoms	Clinical	Prose with case studies
Broca	Clinical signs and symptoms	Clinical	Prose with case studies
Wernicke	Clinical signs and symptoms	Clinical	Prose with case studies
Jackson	Clinical signs and symptoms	Clinical	Prose with case studies
Hitzig	Molecular ^a movements	Laboratory	Prose with illustrations
Ferrier	Molar ^b movements	Laboratory	Prose with illustrations
Franz	Test measures	Laboratory	Prose with graphs
Lashley	Test measures	Laboratory	Prose with graphs and statistical tests

^aHitzig used a relatively weak galvanic current which tended to elicit fine movements like the extension of the fingers and the rotation of the wrist

^bFerrier used a relatively strong faradic current which tended to elicit grosser movements that he perceived as functional and purposive, like the foot drawn to the midline of the body as when the animal grasps something or scratches its chest

a virtual program running on a computer. John Searle, according to Churchland, argues that the brain causes conscious states and that neuroscience can reveal quite a lot about consciousness, but he does not accept the identification of brain states with conscious states (Searle 1992). Patricia Churchland writes that consciousness, in fact, can be reduced to brain states (Churchland 1995).

Progressive changes can be seen in Table 2. The Table shows for each of the prominent researchers the type of data collected, the place where observations were made, and the way they reported their findings. Progress is reflected in the type of observed behavior. See the second column of Table 2. Generally, it changed from the unsystematic, anecdotal observations of Gall through carefully defined clinical signs and symptoms of clinicians Bouillaud, Broca, Wernicke, and Jackson, to the relatively fine observations of discrete movements of Hitzig and Ferrier, to the test measures and, thus, rigidly defined behaviors of Franz and Lashley. The third column of Table 2 implies the absence of clinical data since about the time of Hitzig and Ferrier. Although clinical subject may be used as subjects, data are typically derived experimentally not from

case studies. The way observations were reported progressed as well. See the last column of Table 2. There were descriptions of results by Gall and Flourens; systematic presentations of case studies by the clinicians; systematic presentations of observations accompanied by brain cartoons by Hitzig and Ferrier; and finally data presentations using graphs by Franz and using graphs and statistical tests by Lashley.

Test measures not only allow more systematic and more precise observations, but various devices were invented that extend and supplement human sensory capacity much like infrared or gamma ray detectors have increased our knowledge of stellar objects. For example, over the last 50 years there have been remarkable technical innovations based on computer, computational, and biophysical advances. These devices allow non-invasive, real time measures in vivo of shifts of hydrogen atoms allowing a view of anatomical structure (MRI, magnetic resonance imaging); blood dynamics, thus the functional connectivity rather than anatomical structure (fMRI, functional magnetic resonance imaging); gamma rays associated with a biologically active molecule like glucose, again allowing functional connectivity (PET, positron

emission tomography); and water diffusion, which allows a view of white matter activation during psychological tasks (DTI, diffusion tensor imaging). These promote an interactive view because they show associated activity in multiple brain areas as psychological tasks are accomplished.

Technical advances in miniaturization allow tens of electrodes to be implanted and recorded from at one time. Transcranial magnetic stimulation (TMS), which takes advantage of rapidly changing magnetic fields, allows temporary focal lesions. Lesion studies with animals advanced through both technical and theoretical stages. The subtlety of the lesioning technique advanced from arbitrary partitioning of the brain to lesions of circumscribed areas. It improved with antiseptics and ability to locate brain areas from scalp locations (Finger 1994). It also improved in parallel with advances in anatomical and histological techniques.

Understanding the complexities of functional areas grew at a remarkable rate during the twentieth century when compared to its growth during previous centuries. In the nineteenth century, psychologists were far more sophisticated than neurophysiologists. They informed the fledgling neurophysiologists how to interpret research data. By the late twentieth century, neurophysiology was able to inform psychologists. This new reciprocity promises to advance the next stage of research in localization of psychological function in the brain.

Loftus, Elizabeth

KAREN M. ZABRUCKY, REBECCA B. BAYS
Georgia State University, Atlanta, GA, USA

Basic Biographical Information

Dr. Elizabeth F. Loftus was born on October 16, 1944, in Bel Air, California, to Sidney and Rebecca Fishman. She attended UCLA for her undergraduate studies and majored in Mathematics and Psychology. In 1966, Loftus was admitted to Stanford's Ph.D. program in Psychology. She was the only woman in her class. She received her Master's degree in 1967 and her Ph.D. in 1970.

Loftus took her first job in 1970 at the New School University in New York City as an Assistant Professor of Psychology, Graduate Faculty. She then served as an Assistant, Associate, and Full Professor of Psychology and an Adjunct Professor of Law at the University of Washington for 29 years, where she remains an Affiliate Professor. Currently, Loftus is a Distinguished Professor at the University of California, Irvine, holding

appointments in the Departments of Psychology and Social Behavior, Criminology, Law and Society, Cognitive Sciences, and the Center for the Neurobiology of Learning and Memory.

Major Accomplishments/Contributions

For much of her career, Loftus has focused on the malleability of human memory and the implications of memory vulnerability on eyewitness testimony. She began studying eyewitness memory at a time when other researchers were still concerned with the recall of discrete bits of information such as letters, numbers, and nonsense syllables. In the 1970s she began to explore the idea that postevent information could interfere with memory of an event. Loftus and colleagues were among the first to demonstrate that the nature of the questions asked about an event often led to changes in research participants' accounts of the event. This "misinformation effect" paved the way for a wealth of memory research related to the constructive nature of memory and to research on the development of false memories.

Loftus' research on human memory has strongly influenced numerous researchers and lines of research. As a result of her pioneering work much research has been conducted on the misinformation effect, the suggestibility of memory, false memories, source monitoring errors, imagination inflation, and more. Perhaps one of her largest contributions, and also the most controversial, is the idea that memories for traumatic events in childhood are not necessarily "repressed" until adulthood, but are often false memories for events that never occurred. Loftus's productivity during her career is extraordinary with 19 books and approximately 200 articles published.

Because of the implications of Loftus's work on eyewitness testimony, she has spent much of her career in the courtroom providing testimony on the malleability of memory. She has been called as an expert witness in hundreds of trials including those of accused child killer George Franklin, mass murderer Ted Bundy, and the Hillside Strangler, as well as litigation involving Michael Jackson, Scooter Libby, the Duke University lacrosse players, and the Oklahoma bombing case.

Loftus has won countless prestigious awards including the Grawemeyer Award in 2005, the APA Award for Distinguished Scientific Applications of

Psychology in 2003, the Inaugural Henry and Byrna David Lectureship from the National Academy of Sciences in 2002, and the Distinguished Contribution Award from the American Academy of Forensic Psychology in 1995. A study by Haggbloom and Monte (2002), published in the *Review of General Psychology*, named Loftus one of the top 100 most distinguished psychologists of the twentieth century. At number 58, she was the top-ranked female on the list appearing alongside fellow psychologists such as Skinner, Freud, and Piaget.

Luria, A. R.

ELKHONON GOLDBERG

New York University School of Medicine, New York, NY, USA

Basic Biographical Information

Alexandr Romanovich Luria (1902–1977) is a Jewish-Russian psychologist and neuropsychologist. He was born in Kazan, Russia but spent most of his career in Moscow. Early in his career, Luria was exploring diverse approaches to the studies of mental life and corresponded with Sigmund Freud, but was concerned with the dearth of rigorous methods available to psychology at the time and set out to develop such methods (Luria 1932, 1961). A. R. Luria's close collaboration with his mentor and friend L. S. Vygotsky

culminated in a range of important contributions to cultural-historical, developmental and cross-cultural psychology. A psychologist by training, later in life Luria also earned a medical degree while already a professor of psychology.

Major Accomplishments/Contributions

Luria's most fundamental work is in the field of neuropsychology, of which he is considered a founding father and one of the most influential framers in the twentieth century. Luria's contributions cover virtually every aspect of neuropsychology, particularly language and aphasias, memory and amnesias, as well as the functions of the frontal lobes and their disturbances (Luria 1966, 1970, 1976). Most of this work was conducted at the Lomonosov Moscow State University, where Luria had a chair in neuropsychology, and at the Burdenko Institute of Neurosurgery where he founded and directed a neuropsychology laboratory. Luria's work is characterized by a unique blend of theoretical insight and experimental ingenuity, and his endeavor to formulate a comprehensive theory of neural basis of higher-order cognition was pioneering, and arguably one of a kind, for its time; it remains influential to this day. Some of the theoretical constructs and research directions introduced by Luria foreshadowed certain central themes of contemporary cognitive neuroscience. These include his concept of the "functional system," the role of the frontal lobes in metacognition, and the dynamic, developmental approach to functional cortical organization.

In addition to his fundamental contributions to neuropsychology, Luria is known for the development of ingenious procedures for the diagnosis and rehabilitation of various types of brain damage. No neuroimaging technologies existed in Luria's time, and neuropsychology was the main tool of neuroanatomical lesion diagnosis. In that capacity, Luria's laboratory provided important diagnostic input into neurosurgical decisions at the Burdenko Institute, which was the foremost neurosurgical center in the then Soviet Union

and remains so in Russia. His approaches to neuropsychological diagnosis were very different from those practiced at the time in North America, and they foreshadowed the more recent interest in a "process approach." Luria's interest in cognitive neurorehabilitation was prompted by the needs of World War II with its numerous wounded soldiers, and it evolved into an important aspect of his subsequent work at the Burdenko Institute of Neurosurgery.

In addition to his scientific and clinical work, Luria was the originator of what he called "romantic science," whereby he rendered topics of central scientific importance through poignant individual case studies. While ancillary to his more formal research and clinical work, Luria's "romantic science" inspired the emergence of a whole genre in later years, most prominently represented in the writings of Oliver Sacks.

Luria was a prolific and generous teacher and the founder of an influential school of neuropsychology at Moscow State University. He also directly trained, or indirectly helped shape the careers of, a number of neuropsychologists, cognitive neuroscientists, developmental and cross-cultural psychologists, many of whom have become prominent scientists in their own right and who conduct research and clinical work in Russia, North America, several European countries, Israel, and elsewhere around the world (Christensen et al. 2009, Goldberg 1990, 2009).

M

Mach, Ernst

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: February 18, 1838; Died: February 19, 1916.

Mach was born in Moravia, educated at the University of Vienna, and became one of the most eminent physicists of his era. His sheer brilliance, which led him to his many discoveries in acoustics, supersonic phenomena, and aerodynamics, coupled with the effects of his philosophical approach to physics through perception and sensation, which had portentous results when adopted by Albert Einstein early in the process of creation of the relativistic worldview, led to Mach becoming a central figure in the intellectual milieu of the late nineteenth century (Blakemore et al. 2001). Indeed, Lord Haldane included him alongside Mozart, Beethoven, and Freud as exemplars of the contributions of Vienna to the world (Szasz 1960). Alongside these, his specific connections to psychology are considerable.

Major Accomplishments/ Contributions

Though Mach's status in science feeds the mythology of a psychology modeled mainly on physics, psychologists should remember that Mach was equally at home in mathematics, physiology, medicine, and the root of scientific psychology, Fechnerian psychophysics, with which he had early direct acquaintance and which was the basis of his earliest writing. His main contribution to psychology was the same as his essential contribution to physical science generally: making dynamic phenomena elegantly visible. Within 10 years of his doctorate, Mach had devised an apparatus to demonstrate the phenomena now eponymously termed

“Mach Bands” and had constructed a theory to account for their appearance based on statistical averaging of responses, a theory that led to the modern theory of lateral inhibition, an essential tenet of perceptual science. He also devised an apparatus to study the Doppler effect and the effects of rotation on perception of orientation and space, which culminated in a theory of the operation of the semicircular canals (shared eventually with the independent work of Breuer, one of Freud's great teachers). And he advanced theories of form perception that eventually were elaborated into the essential theoretical basis of Gestalt theory (Mulligan and Smith 1988). He generalized his perceptual work into a theory of knowledge based on sensory data, elegantly expressed in his *Analysis of Sensations* in 1886, which had many ramifications in science and philosophy beyond its fundamental basis in sensory perception, to the extent that Mach is said to have founded the modern philosophy of science.

In physics, Mach's sensationalism led to a confrontation with Max Planck over atomic theory, in which Mach maintained skepticism with integrity and asserted the right to value psychological data over abstract physical law. Besides this assertion of the primacy of psychology in scientific thinking, Mach's analytic and statistical approaches led to the development of later positivisms with a strong probabilistic component such as those of Reichenbach and Neurath, which impacted the development of probabilistic thinking in psychology generally. Mach saw science as evolutionary at base and truth as provisional, arrived at by approximation and experiment and subject to revision. This point of view was congenial to many psychologists who counted Mach as an influence, chief among whom were William James, for whom Mach's skepticism and iconoclasm meshed with James's distaste for idealism and formalism, and B. F. Skinner, who came as close as anyone in psychology to a completely selectionist and antitheoretical account of the development of the

forms of human behavior. In perception, besides his contributions to the theory of lateral inhibition and to Gestalt theory already noted, there are profound similarities between Mach's conception of perception as the analysis of sensations received at a particular viewpoint and J. J. Gibson's (► [Gibson, James J.](#)) expansion of this idea into the theory of information pickup in a teeming world of sensory possibilities (Walker-Andrews 1992). Overall, Mach's psychology anticipates the view of an organism moving through an environment subject to selection pressures and dependent on rapid sensory analysis to survive. On this view, it is not hard to conclude that Mach may have provided for psychology the sort of basic theory that modern psychology imbibed, to echo what Einstein said about Mach's effect on generations of physical scientists, with their mother's milk.

There are, beyond these towering achievements, some other contributions of Mach that though they are not as often remarked are important to the enrichment of modern scientific psychology. Psychology as science rises and falls with the popular idea of science and Mach was a tireless promoter of science both in textbooks and in popular articles which reached wide audiences. His writing style was universally admired and his *Analysis of Sensations*, especially, was widely read in translation. Mach also had an activist side and potentiated the development of a modern socially responsible psychology with a progressive focus (Winston 2001). Lastly, Mach was an important influence on culture generally and in the arts in particular (Weibel 2005). One persisting presence of Mach is in the ironies and indeterminacies of *The Man Without Qualities*, Robert Musil's unfinished masterwork, which can be read not only as a catalog of experimental psychological ideas of the time, but also as an artistic realization of a Machian worldview (Sebastian 2005).

Malthus, T. R.

DAVID L. SEIM

University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

Thomas Robert Malthus played an important role in the Enlightenment-era debate between the dangers of “passions” and the virtues of “reason.” Malthus was born February 13, 1766, at his family's country home near Wotton, Surrey, England – just south of London. He was the second son and sixth of seven children born to Daniel and Henrietta Malthus. Malthus's father was a landowner and an Enlightenment enthusiast, who was personally acquainted with the likes of David Hume and Jean-Jacques Rousseau. From 1776 to 1782, young Robert – often known as “Bob,” and never as “Thomas” – was schooled at the small family mansion dubbed “The Rookery,” and then at Claverton Rectory, near Bath. In 1788 he earned an undergraduate degree from Jesus College, Cambridge, with awards earned in Latin and English – this despite a serious speech defect due to a cleft palate and harelip.

In 1789 Malthus was ordained by the Church of England and was appointed as curate at Okewood Chapel, a country parish resting in a quaint valley a short distance up a country lane from the village of Ockley, in Surrey. In 1793 Malthus was made a nonresident fellow of Jesus College, Cambridge, a position he would relinquish 11 years later to marry Harriet Eckersall, his first cousin once removed, with

whom he had three children. From 1805 to the end of his life, Malthus was Professor of History and Political Economy at the East India Company College in Hertfordshire, an appointment that made him England's first academic economist. In his later years, Malthus's students – civil servants of the East India Company – took to calling him “Pop,” short for “Population Malthus.” Malthus took ill on Christmas and died on December 29, 1834 at Bath. He is buried at Bath Abbey. He has no living descendants (James 1979).

Major Accomplishments/Contributions

Malthus's chief claim to fame is his authorship of *An Essay on the Principle of Population* (Malthus 1798). One story goes that while in parochial duties at Okewood, Malthus noticed a phenomenon about which he would soon write, that “It cannot fail to be remarked by those who live much in the country, that the sons of laborers are very apt to be stunted in their growth, and are a long time arriving at maturity. Boys that you would guess to be fourteen or fifteen are, upon enquiry, frequently found to be eighteen or nineteen” (1798, Ch. V).

Indeed, in Malthus's day the English poor, especially in rural areas, were numerous and generally in bad shape. During the 1790s, Malthus amply discussed the condition of the poor as a key point in some spirited debate with his father over the Enlightenment notion of the “perfectibility of society.” Malthus came to a decision to write his famous book, which in 1798 he published anonymously. In *Principle of Population*, Malthus responded to recent utopian idealism with a bit of harsh realism, including his well-known calculation: that whereas human populations increase geometrically (1, 2, 4, 8, 16, 32, 64, 128, etc.), food supply and means of subsistence increase arithmetically (1, 2, 3, 4, 5, 6, 7, 8, etc.). An unchecked population will, all else equal, quickly expand far beyond a society's ability to organize and distribute resources, resulting in much poverty, suffering, and starvation. It was this “Malthusian analysis” that prompted Thomas Carlyle, in 1849, to dub economics “the dismal science.”

Malthus's real argument was not the famous calculation designed to compare geometrical and arithmetical growth, but was his search for what humankind might do to avoid the problem. In the first edition of *Principle of Population*, Malthus began a lifetime of

analyzing what he believed is within human nature. He introduced two major categories of “checks,” which were “preventive” ones and “positive” ones. Five years later, in an expanded and revised edition of the book, Malthus added “moral restraint” as a third fundamental category of population checks. Preventive checks work by lowering the birth rate, and include delayed marriage, sexual intercourse not for procreation, contraception, and abortion. Positive checks raise the death rate, and include “crime, disease, war, and vice,” along with famine and infanticide. Moral checks include postponement of marriage, practice of celibacy, inculcation of “prudential motives,” and a general “sense of duty.”

Malthus built his system of social analysis upon a psychological scheme based on principal drives, called “hungers.” Two preeminent hungers that God instilled in humankind are hungers for food and for sex. Neither of these hungers can be completely controlled or quelled; in humans, as in other animals, “passions” and “appetites” can tend to be stronger than “reason.” In connection with his analysis of population growth coming to exceed the limits of the means of subsistence, Malthus reached something of a psychological conclusion: “The race of plants and the race of animals shrink under this great restrictive law; and man cannot by any efforts of reason escape it.” Among humankind will arise much misery and vice, and in the end “the voice of reason will be unheard; the passions only will bear sway” (Malthus 1798, Ch. I).

Malthus's system of analysis resulted in some policy implication, including advocacy for abolition of Poor Laws and implementation of Corn Laws. The former were national assistance programs for the needy, which had been in existence since the 1600s, and which Malthus believed encouraged idleness and provided “a check to productive industry.” Malthus suggested of the poor, “that they are themselves the cause of their own poverty; that the means of redress are in their own hands, and in the hands of no other persons whatsoever; that the society in which they live, and the government which presides over it, are totally without power in this respect” (Malthus 1798, Ch. 3). Hence Malthus opposed the Poor Laws. His goal in supporting the Corn Laws (which placed taxes on imported wheat) was to promote domestic grain production and long-term economic progress. Malthus also advocated policies to favor universal suffrage, education for the

poor, and establishment of unfettered labor markets. He believed that carefully enacted policies could play into the moral powers of a socialized mind, such as when the mind of a poor person gains a taste for luxury and proceeds to seek a higher standard of living – which, Malthus reasoned, can in turn be a sufficient incentive to reduce fertility.

Psychological foundations and policy implications are closely interconnected in Malthus's thought. Because he believed human nature is not easily changed, he wondered about the heritability of intellect in humans as well as in other animals. He wrote in 1798: "It does not . . . by any means seem impossible that by an attention to breed, a certain degree of improvement, similar to that among animals, might take place among men. Whether intellect could be communicated may be a matter of doubt; but size, strength, beauty, complexion, and perhaps longevity are in a degree transmissible. . . . As the human race however could not be improved in this way without condemning all the bad specimens to celibacy, it is not probable, that an attention to breed should ever become general" (Malthus 1798, Ch. IX).

Following publication of the first edition of *Population*, Malthus spent time in Germany, Russia and Scandinavia, and recorded a travel diary (published in 1966). He used his new discoveries to rebuild a better and vastly expanded version on his argument, which he published as a second edition of *Principles of Population*, in 1803. A frequent interpretation is that Malthus's new ideas and findings enabled him to transform a 1798 product that (in phrasing from Lionel Robbins) was "a brilliant a priori polemic" into an 1803 edition that became "a weighty empirical treatise."

Malthus's other major book came in 1820 (Malthus 1820). This work, *Principles of Political Economy Considered with a View to Their Practical Application*, dealt with various economic problems, including – if only briefly – the notion of psychic measurement of economic value. Malthus began by introducing some of the established theories of economic value, particularly those in which value comes from accumulating more gold and silver through commercial trade (known as "Mercantilist Theories of Value") and those in which value comes from the accumulated labor input into the making of a product (known as "Labor Theories of Value"). Malthus responded that he

generally favored the labor approach but believed another factor that could help account for value might be a psychological "will to purchase," meaning that the greater a person's will to obtain the item, "the greater or more intense may be said to be the demand for it." Malthus added that, "as long as the means and competition of sellers continue to bring the quantity wanted to market at a low price, the whole intensity of the demand will not show itself" (Malthus 1820). Malthus receives some credit from historians for being an early expositor of a principle that just hints at being a behavioral principle of marginal utility. Closely related to the idea of intensity of demand, Malthus introduced, at least verbally, the idea of a demand schedule, which has since come to be defined as the conceptual relationship between prices of goods and the quantity desired by buyers (Hollander 1997).

Between the years of his two major books, Malthus also receives credit for a few other important ideas. In 1815 he published a pamphlet containing the first analysis of a "differential theory" of rent. In other writings he developed an idea that economic crises are characterized by insufficient consumption which renders a general excess of supply; this is known as Malthus's theory of a "general glut" of goods, and it is a theory that foreshadowed ideas of J.M. Keynes during the 1930s (Dupaquier 2001).

Today's overall assessment of Malthus's system of analysis, particularly in its 1803 version, concludes that the system stands as the first careful study of the condition and welfare of lower classes.

Maslow, A. H.

PEGGY BRADY-AMOON

Seton Hall University, South Orange, NJ, USA

Basic Biography

Abraham H. Maslow was born on April 1, 1908, in Brooklyn, New York, the eldest of seven children. His parents were Russian Jewish immigrants who valued education. Abraham Maslow began his undergraduate studies at the City College of New York (CCNY), transferred to Cornell University, and returned to CCNY.

He married his childhood sweetheart, Bertha Goodman, on December 31, 1928 and moved, with his new wife, to Wisconsin to study psychology with Harry Harlow at the University of Wisconsin.

Dr. Maslow earned three degrees in Psychology from the University of Wisconsin at Madison: His BA in 1930, his MA in 1930, and his Ph.D. in 1934, while teaching and pursuing his research.

Shortly after earning his doctorate, he secured a postdoctoral position at Columbia University where, with the support of E. L. Thorndike, he was able to pursue his own research agenda. In this position and his next, as a member of the faculty at Brooklyn College from 1937 through 1951, Dr. Maslow met and learned from and with many prominent people from psychology and allied fields, including Max Wertheimer, Erich Fromm, Karen Horney, Alfred Adler, Kurt Goldstein, Margaret Mead, and Ruth Benedict. Mead and Benedict encouraged Abraham Maslow to consider the influence of culture and society on human experience. He later adapted the concept of self-actualization from Goldstein.

In 1951, Abraham Maslow accepted an invitation to become Professor of Psychology and the Inaugural Chair of the Psychology Department at the newly opened Brandeis University, a position he held through 1969. He subsequently accepted a fellowship at the Saga Institute in Menlo Park, California.

Having suffered from poor health for many years, Abraham H. Maslow died on June 8, 1970, at 62 years of age, in Menlo Park, California. His archives are maintained at the University of Akron's Archives of the History of American Psychology (AHAP).

Accomplishments

In many ways, Abraham Maslow's contributions to psychology defy categorization. He was one of the first to systematically study the fullness of normal and optimal human functioning and he did so from an interdisciplinary perspective. While exploring the highest ideals of psychological wellness, Dr. Maslow began to explore *peak experiences*, those mystical or transcendent experiences that touch on awe, mystery, and human possibility. He was a trailblazer in humanistic psychology, the human potential movement, existential, and transpersonal psychology. His work continues to influence psychology and allied fields, including education and business management.

Abraham H. Maslow is best known for his *Theory of Motivation*, originally published in 1943 when he was 35. This theory includes Maslow's *hierarchy of human needs*, in which basic physiological needs form the necessary foundation for people to meet their psychological needs that, in turn, are prerequisites for *self-actualization*, originally conceptualized as the pinnacle of the hierarchy. Throughout his career, Maslow continued to refine this theory, particularly self-actualization, ultimately arguing that *self-transcendence* is a more evolved state of being than simply meeting one's own goals (Koltko-Rivera 2006).

In his quest to understand optimal functioning by studying self-actualizing people, Maslow began to further explore *peak experiences*. His writing at that time, particularly *Religions, Values, and Peak-Experiences*, published in 1964, shows that his thinking about human potential, values, spirituality, and religion had evolved.

Abraham H. Maslow was a prolific author. Many of his books and articles are regularly re-printed and remain easily accessible. *Toward a Psychology of Being* (1968) and *The Further Reaches of Human Nature* (1971) are among his most famous books. Other contributions include the publication of *Motivation and Personality* in 1954, one of the first books to emphasize normal and optimal human development; the inclusion of a full chapter on Maslow's theories in Betty Friedan's *The Feminine Mystique*, a catalyst for the second wave feminist movement, and *Theory Z*, the application of Maslow's hierarchy of needs to business management and consultation.

Notwithstanding his interdisciplinary approach, Abraham H. Maslow was among the founders of

humanistic psychology, establishing many of the principles that guide humanistic psychology and counseling today. He is also recognized as a co-founder of the *Journal of Humanistic Psychology*.

Abraham H. Maslow served as President of the American Psychological Association (APA) in 1968, building on his service as President of APA's Division of Personality and Social Psychology, and of the Massachusetts Psychological Association.

Among his many awards and honors, some of which were received posthumously, Abraham H. Maslow was honored by APA for his creativity and named 1967 Humanist of the Year by the American Humanist Society.

McClelland, David C.

JOSÉ M. PRIETO, GLORIA CASTAÑO
School of Psychology, Complutense University,
Madrid, Spain

Basic Biography

David C. McClelland was an American psychologist, with a background in psychoanalysis. His first university degree was in foreign languages: he wrote a play in Latin and translated Emily Dickinson poems into German. The first wife, Mary Sharpless (1918–1980), set up a painting studio in the basement and became art

teacher. Together they attested multilingual expertise in science, culture, and the arts, that is, they were intellectuals, a rather endangered species in the university milieu throughout the twentieth century and almost eccentrics after twenty-first century standards, genuine academic monolingualism. Their huge Victorian house emerged as a meeting point of highly educated university graduates in Cambridge. They used to travel together to foreign countries every year, and they took a world tour in every sabbatical leave. In 1941, he obtained the Ph.D. degree in Experimental Psychology from Yale University. In 1946, he was chairman of the department of Psychology at Wesleyan University; in 1950, staff consultant for the Social Science Research Council; in 1952, Deputy Director of the Behavioral Science division of the Ford Foundation, member of the Fullbright Award Committee in 1953; and in 1956, Professor of Psychology in the Department of Social Relations at Harvard University, and Chairman in 1962. In 1963, he founded McBer Consulting Co with Henry Murray (1893–1988) and several doctoral students such as David Berlew, Lyle Spencer, and Richard E. Boyatzis. The focus was on psychological assessment and training programs to increase satisfaction and performance among employees. In 2011, it is a part of the Hay Group, a global management consulting firm operating in 49 countries.

Major Contributions

In 1968, McClelland started to act as consultant to the Peace Corps Volunteers and, in 1972, to the United States Information Agency, that is, proactive involvement in international educational and cultural exchanges, broadcasting, and information exchanges congruent with foreign policy and national interests abroad. Widower, he married to Marian Adams in 1981. In 1986, he retired as emeritus professor of Harvard University and became distinguished research professor of Psychology at Boston University. In 1987, he obtained the award for Distinguished Scientific Contribution from the APA and, postmortem, the Henry A. Murray Award from Division 8 of APA. A little bit surrealistic. Murray had been the key figure to understand research and development projects led by McClelland and all his associates in what are known in the twenty-first century as the competency-based models of management effectiveness. A good example

is the Bologna Declaration on the European Space for Higher Education: competence is mentioned only once in the policy making text but evolved as the magic formula to generate comparable and compatible academic degrees and quality assurance standards across universities and countries in the European Union. In 1973, McClelland published a seminal article in *American Psychologist* stating that IQ and personality tests were poor indicators of a person's competence. This is a typical example of how a psychological finding generated changes in the world of business and consultancy the next decade and in the university milieu three decades afterward.

The initial phase was experimental research on motivation by identifying core psychological needs such as Achievement, Affiliation, and Power, and by developing a valid and reliable method for scoring responses to the Thematic Apperception Test to measure the strength of the motive. The subject is not neutral taking into consideration that the initial sample was students at Harvard University, the aim advancing what kind of psychological variables were involved in success, benefits, and progress in organizational settings. Many of the doctoral students he supervised became intellectual leaders of the next cohort of Industrial and Organizational Psychologists. His book on the *Achievement Motive* in 1953 and that on *The Achieving Society* in 1961 provided the theoretical and methodological foundation.

During his term in office as head of the Department of Social Relation (1962–1967), a silenced case or a well-known scandal did occur. Officially, he was in sabbatical leave in India and Tunisia supervising research groups on entrepreneurial motivation. In the laboratory, his avant-garde researchers came to be troublemakers. Timothy F. Leary (1920–1996) accepted in 1959 a permanent position of Lecturer in Clinical Psychology at Harvard University under McClelland's surveillance and was fired in 1963 by Nathan M. Pusey (1907–2001), then President of Harvard University. Leary had been singled out a few weeks before as "the most dangerous man in America" by Richard Nixon (1913–1994), then past Vice-president of the USA and loser in his confrontation with John F. Kennedy (1917–1963) in the 1960 Presidential election. Another professor of Clinical Psychology was also fired in 1963, Richard Alpert (later known as Ram Dass), that was

employed in 1958 under the auspices of McClelland, director of the doctoral program in clinical psychology in Harvard since 1956. All three were good friends, and once jobless, the McClelland's house came to be a landing place for students returning from India and fond of spiritual journeys. There were spare bedrooms available. Leary and Alpert were doing experimental research in the laboratory of Psychology, and the enigma was the nexus between human brain and consciousness, normal and abnormal states of consciousness with or without meditation, psychological and spiritual well-being in the context of Health Psychology. What was the independent variable? Psychedelic substances to find out the proper dosage under controlled conditions; the design also included several scales of the California Personality Inventory and one of the MMPI. The dependent variable was recidivism rate among alcoholic patients and reforming criminals. They combined psychotherapy and drugs as well as observed changes in behavioral ratings. The turmoil came because about 300 university professors, students, writers, and philosophers did participate as volunteers. They tested the psychological effects of LSD, psilocybin, Mexican mushrooms, and so on. Further details may be found under wordings, such as "the Concord Prison Experiment," "Psychedelic experiments and experiences." Initially, it was only under the umbrella of McClelland's department, but it evolved as an open field study in the campus of Harvard and surroundings. Research participants reported profound mystical experiences. Lemle (2001) has produced a documentary film based on recordings of that time, and Epstein (2002) in his autobiography summarizes accounts at the Harvard Medical School. Doblin (1998) reviewed data and highlighted statistical errors in findings published.

In the background, there was a political confrontation always in Harvard University between behaviorism and psychoanalysis, behavior therapy versus psychotherapy, Burrhus F. Skinner (1904–1990) in the department of Education (devoted then to devising teaching machines for IBM and programmed instruction in the campus) and McClelland's associates. Another confrontation was between Skinner and Noam Chomsky on the subject of verbal behavior (1957–1959). Chomsky emphasized the role of language competence, and McClelland reworked the term competence as a key

concept in his reaction to the controversy raised by another professor of Psychology at Harvard University, Richard J. Herrnstein (1930–1994), and his 1973's book on the nexus between IQ and meritocracy. McClelland insisted in the already mentioned paper of 1973, the key is how to measure competence and not intelligence, the key is achievement as an attitude toward success and not meritocracy, the key is intrinsic motivation and not extrinsic motivation as highlighted by another psychologist, Frederick Herzberg (1923–2000), who, in *Harvard Business Review* and in 1968, pointed out that his two-factors theory of job satisfaction had been replicated in 16 studies in a wide variety of occupational settings across countries, including Communist countries. McClelland trips during his sabbatical leaves may be framed in this kind of cross-cultural research in companies. The outcome was consultancy, recognition, and leadership in Applied Psychology. The origin of Positive Psychology may be traced back to this group of scholars in the domain of Industrial and Organizational Psychology. The background was the Psychology of Ego and Self-awareness, as well as development.

McCormick, Earnest

MARK S. SANDERS

California State University, Northridge, CA, USA

Basic Biographical Information

Dr. McCormick was born on August 22, 1911 in Indianapolis, Indiana, USA. He died on February 9, 1990. After obtaining a bachelor's degree from Ohio Wesleyan University in 1933, he secured a position at the Cotton Garment Code Authority in New York City. After 2 years, he took the position as Chief of the

Planning Unit in the Job Analysis and Information Section of the U.S. Employment Service (1935–1939). During his tenure there, he coordinated an ongoing nationwide job analysis program and developed a system for coding and classifying jobs. That coding system became the basis for the first edition of the *Dictionary of Occupational Titles*. It was during his time with the Employment Service that his lifelong interest in job analysis was established.

His employment history in the area of job analysis included jobs at the Population Division of the Bureau of the Census (1939–1941), the Occupational Statistics Section of the Selective Service System (1941–1943), and, having been Commissioned in the U.S. Navy in 1943, he took the position as Chief of the Classification Analysis Unit in the Enlisted Classification Section of the Bureau of Naval Personnel (1943–1945).

After being stricken with polio in 1945, he decided to pursue graduate work in industrial psychology at Purdue University, Lafayette, Indiana, USA in 1946. He quickly earned a Master's (1947) and Ph.D. (1948) degrees. In recognition of his work history and academic performance, Purdue University offered Dr. McCormick a position as Assistant Professor. He quickly moved through the ranks to Associate and then Full Professor. He remained at Purdue for 29 years, teaching, being a mentor to students, and publishing in the areas of job analysis, industrial psychology, and human factors. He retired in 1977 as Professor Emeritus.

Major Accomplishments/Contributions

Dr. McCormick authored/coauthored numerous articles, book chapters, and technical reports dealing with the theory and methods of job and task analysis. He authored/coauthored textbooks on job analysis, industrial and organizational psychology, and human factors.

His most significant contribution to the field was the co-development, validation, and co-publication of the *Position Analysis Questionnaire (PAQ)* in 1969. The PAQ approaches job analysis from a behavioral perspective where job elements are rated in terms of psychological and contextual factors. It is a widely used instrument still in use today. He cofounded and

served as President of PAQ Services Inc, Bellingham, WA. The PAQ has been applied to a wide range of jobs and has been used as a basis for salary scales and selection, placement and training programs among other important applications.

Dr. McCormick has received numerous awards, including Distinguished Scientific Contribution Award (1986) and the James McKeen Cattell Award (1964), both from the Society of Industrial and Organizational Psychologist (Division 14, American Psychological Association); the Paul M. Fitts Award (1972) from, and Fellow status in, the Human Factors and Ergonomics Society; and the Franklin V. Taylor Award (1966) from the Society of Engineering Psychologists (Division 21, American Psychological Association). Dr. McCormick served on many national panels, including the Army Scientific Panel, the Naval Advisory Board for Human Resources, and the National Academy of Sciences Committee on Occupational Classification and Analysis. He was a Fulbright Lecturer at Catholic University in Milan, Italy (1964–1965) and a Ford Foundation consultant in New Delhi, India (1969–1970). In recognition of his contributions to the field, the Society of Industrial and Organizational Psychology established the annual Ernest J. McCormick Award for Distinguished Early Career Contributions.

In addition to all of the above accomplishments and recognitions, probably his most lasting contributions are the more than 100 graduate students he advised and to which he served as a mentor over the years.

McCosh, James

ELISSA N. RODKEY

York University, Toronto, ON, Canada

Basic Biographical Information

Born: April 1, 1811, Died: November 16, 1894

James McCosh was born April 1, 1811, in Carskeoch, a farmhouse in the Scottish lowlands. The only surviving son of a well respected and pious covenanting farmer, McCosh was encouraged in his early interest in the ministry, and departed for Glasgow University at age 13, under the supervision of an older cousin. At Glasgow, where the aftereffects of the Scottish Enlightenment were still strong, McCosh found that he was interested in philosophy and began reading the Scottish Realists. After graduating from Glasgow in 1829, McCosh began his studies at Edinburgh University, where philosophical greats such as William Hamilton resided (Sloane 1896).

McCosh wrote his thesis on Stoicism under Hamilton, but in 1834, he set his interest in mental philosophy aside to become a Presbyterian minister. After spending some time as an inerrant preacher, he was appointed to the village of Arbroath and then Brechin, where he sided with the Free Church during the Disruption of 1843. In 1850, McCosh published a book, *The Method of Divine Government, Physical and Moral*, which resulted in his appointment to the chair of logic and metaphysics at the newly established Queen's College in Belfast. There he published several philosophical works, such as *Typical Forms and Special Ends in Creation*, in 1855 and *The Intuitions of the Mind Inductively Investigated*, in 1860 (McCosh 1860). The former laid out McCosh's theistic interpretation of evolutionary science and the latter represented his first contribution to mental philosophy in which he attempted to categorize the intuitive principles of the mind.

McCosh's books were also published in America, so when he visited the states in 1866, he found himself a popular and sought-after speaker there. This trip brought McCosh to the attention of the trustees of the College of New Jersey (later Princeton University)

who were looking for a theologically orthodox yet pro-science president who could integrate traditional Presbyterian doctrine with new scientific findings. Previously disappointed in his loss of the University of Aberdeen chair of logic to Alexander Bain, McCosh was favorable to their invitation and arrived at Princeton in 1868. McCosh quickly set about reforming the school, inaugurating an elective program of studies, launching an energetic building campaign, and strengthening the faculty. These reforms were well received, and McCosh remained a popular figure throughout his presidency (Hoeveler 1981).

Major Contributions

As was common at that time, as president McCosh taught mental and moral philosophy classes at Princeton and published mental philosophy textbooks based on these classes. McCosh's preferred method for discovery of mental phenomena was inductive introspection, the discovery of mental laws through the careful observation of mental actions by the conscious self. McCosh was optimistic about the accuracy of introspection because of one of the central tenets of Scottish Realism: direct perception of reality. This core belief, which was in opposition to both Kantian idealism and Humean skepticism, meant that observation of the mind was just as possible and reliable as observation of matter (Maier 2006). In McCosh's view, the new physiological psychology was useful but best used to supplement and enhance the insights of mental philosophy, not do away with it, since a purely physiological perspective was in danger of being reductionistic and materialistic (McCosh 1871). This more traditional perspective meant that McCosh's books tended to center on philosophical categorizations of mental functions consistent with Scottish Realism rather than original theorizing. However, McCosh's 1880 book *The Emotions* covered new ground – it included material which anticipated the James–Lange theory (McCosh 1880).

Although McCosh's Scottish Realist approach to psychology at times put him at odds with New Psychology's aims, he intentionally fostered an environment at Princeton where the new discipline would flourish. McCosh instituted a number of psychology electives, including a physiological psychology class that he team taught with two Princeton graduates

who had been trained in science in Europe. According to James Mark Baldwin, who was mentored by McCosh, the course included physiological demonstrations by the young professors and reading Wilhelm Wundt. McCosh also created the Mental Science Fellowship, a \$600 award which allowed students to pursue graduate studies abroad to receive the latest the new psychology had to offer. Baldwin used the award to visit Wundt and study under Friedrich Paulsen in Germany.

McCosh supported the Wundt Club, a weekly gathering started in 1881 by several young Princeton professors intended to help them keep up with the latest psychological advances. McCosh was quite proud of the Wundt Club, asking, during Baldwin's time abroad, that Baldwin mention the club to Wundt. McCosh also became involved with Henry Fairfield Osborn's research on memory imagery, which is generally regarded as the first psychological questionnaire research in North America. Although Osborn carried out the actual research, the results were published jointly by McCosh and Osborn in 1884 as *A Study of the Mind's Chambers of Imagery* (McCosh and Osborne 1884), and McCosh promoted it in his 1886 textbook *Psychology: The Cognitive Powers* (McCosh 1886).

Even though McCosh had hired Baldwin to help him integrate the latest in physiological research into *The Cognitive Powers*, it received a scathing critique from G. Stanley Hall in the first issue of *The American Journal of Psychology*. Hall saw it as scientifically sloppy and philosophically outdated – Scottish Realism was strongly associated with the old school of psychology from which the New Psychologists were eager to distance themselves. As a result of this New Psychology attitude, McCosh is missing from many histories of psychology, or else, along with other early American mental philosophers, stereotyped as antiscience and dogmatic (Rodkey 2011).

However, McCosh is an important transitional figure in psychology, a staunch Scottish Realist who wrestled with the challenges of evolutionary science and physiological psychology. He was extraordinarily open to both, embracing and promoting theistic evolution at a time when most Protestants were wary of Darwinism and providing a hospitable environment for the New Psychology at Princeton despite the challenges it represented to his views.

Mead, G. H.

VINCENT W. HEVERN

Le Moyne College, Syracuse, NY, USA

Basic Biographical Information

George Herbert Mead was born on February 27, 1863, in South Hadley, Massachusetts, to a Congregationalist minister, Hiran, and his wife Elizabeth. The family moved to Oberlin, Ohio, in 1870 when his father began to teach homiletics at the Oberlin Theological Seminary. In 1879, Mead entered Oberlin College and graduated with a B.A. in 1883. After a series of jobs, Mead began graduate studies in philosophy at Harvard University in 1887 and earned an M.A. degree. He studied at Harvard under **Josiah Royce** and served as tutor to **William James'** children. Mead pursued but did not complete a doctoral degree in Germany between 1888 and 1891. He studied philosophy and physiological psychology at the University of Leipzig and then physiological psychology and economic theory at the University of Berlin. In Germany, he attended lectures courses by **Wundt**, **Ebbinghaus**, and Dilthey. After marrying Helen Castle in Berlin in 1891, he

returned immediately to teach philosophy at the University of Michigan. There he became a close friend of **John Dewey**. In 1892, he followed Dewey to the University of Chicago where Mead taught philosophy and engaged in a range of progressive educational and social initiatives along with Dewey and Jane Addams. Though Dewey moved to Columbia University in 1904, Mead remained in Chicago where he taught social psychology for more than 30 years. Mead's wife died on December 25, 1929. That same year Robert Maynard Hutchins arrived at Chicago as president and, with Mortimer J. Adler, reorganized the curriculum of the university along more traditional lines. These changes led to conflict with Mead who resigned in 1931 to accept a post at Columbia University. However, after four months of illness, Mead died in Chicago on April 26, 1931 before he could assume his new position (Cook 1993).

Contributions

Mead never published a book in his lifetime. Yet, as one of the most important figures among the American Pragmatists and arguably the seminal theorist for the school of Symbolic Interactionism in the social sciences, Mead's journal articles, mentorship of graduate students, and class lectures were enormously influential. Following his death, his students gathered notes transcribed during those lectures. These posthumously published texts (Mead 1934, 1936, 1938) made Mead's general ideas available to a wider audience than that found within the precincts of the University of Chicago itself. His ideas continue to echo among cultural, social, and personality psychologists to this day (Joas 1985).

At the core of his thinking, Mead believed that the human person is the product of social processes. Rejecting Cartesian Dualism and the individualism of psychological behaviorists, he elaborated a theory of the social genesis of human mind and individuality. Mead argued that all living organisms engage in two forms of "conversation." The first of these conversational modes consists of behavioral gestures. A second organism is affected by the gesture of a first organism which, in turn, responds with a gesture to that of the second organism and so on. These organisms converse by means of gestures. Over the course of human evolution, the form of this conversation changed with the

emergence of language, i.e., conversation that uses “significant symbols.” Humans interact by the exchange of meaningful vocal and nonvocal gestures. Communicative meaning arises out of the interaction of the two (or more) participants and is not independent of the social processes between them.

For Mead, the social world is primary and the basic matrix from which each human person develops – first as a body and, subsequently, as a mind. How does the mind develop? Mead answers: in the process of social experience and activity. This process involves symbolic exchange in three forms: language, play, and games. The most pervasive and earliest activity involves language. Individuals are immersed in the linguistic world of others from the moment of their birth and eventually come to understand the other, particularly the other’s mind in *its* social world, through the use of vocal symbols, i.e., language. This ability to engage in a form of social “role taking” – comprehending what the other is thinking – is elaborated by play when children (and adults) use the dress, mannerisms, bodily movements, and emotions of the character’s role they occupy (police officer, teacher, parent, etc.). Finally, individuals enter into a third and more complex form of symbolic communication by means of games. These involve an understanding of and acquiescence to a broad set of roles, rules, and symbolic relations among all the game’s participants.

Mead is perhaps most famous for his proposal that the self must be viewed as a kind of polar entity comprised of the “Me” and the “I.” The “Me” consists of the judgments, comments, and conduct directed toward a particular individual by the many social partners who populate that individual’s world or what Mead calls “the generalized Other.” In this fashion, the “Me” is constituted by the world of others who create situations toward which the individual must offer a response. The “Me” represents a kind of socially constructed identity. However, the other pole of the self is the “I” and involves the active appraisal and response to the “Me” by the individual. In the act of responding to others, persons can assume novel or different stances than that represented by the “Me” and, in so doing, alter the processes of social interchange. The response of the “I” is adaptive and allows individuals to affect their own environment while still being affected by it in return.

Meehl, Paul E.

DONNA-MARIA MAYNARD

The University of the West Indies, Cave Hill Campus,
Bridgetown, Barbados

Basic Biography

Paul E. Meehl was born on January 3, 1920, in Minneapolis, Minnesota, to Otto and Blanche Swedal. He lost both of his parents during his childhood; his father an intelligent man who valued education, committed suicide in 1931; his mother remarried (Meehl used his stepfather’s name) in 1934 and died soon afterward in 1936 from ether pneumonia following surgery for a brain tumor (Meehl 1989).

Meehl was married to Alyce Roworth Meehl who died in 1972, and was later married to Dr. Leslie Jane Yonce for nearly 30 years. Dr. Yonce was very involved, helping Meehl in his research and writing (Yonce 2006), and she continues to maintain his Web site which houses Meehl’s complete bibliography and links to many of his papers.

Dr. Meehl earned his B.A. (psychology major with a minor in Biometry) from the University of Minnesota in 1941, and in 1945 he was awarded his doctorate in clinical psychology from the same institution, he was hired as a faculty member and remained at the University of Minnesota throughout his entire professional career (Meehl 2008).

As a graduate student, Meehl had such teachers and mentors as B. F. Skinner and Donald Paterson. He also was an assistant to Starke Hathaway, when Hathaway was refining the assessment instrument that

became the Minnesota Multiphasic Personality Inventory (MMPI). Meehl developed the K scale, a measure of subtle defensiveness, for the MMPI. While on the faculty, he held concurrent appointments in psychology, psychiatry, philosophy, and law. He was trained as a psychoanalyst and kept a couch with a chair at its head in his office, where he practiced traditional Freudian psychoanalysis, alongside Albert Ellis's rational-emotive therapy. He retired in 1990 but continued to teach at the University until 2002 (Peterson 2005b).

Paul E. Meehl died on Friday February 14, 2003, at his home in Minneapolis. He was 83. The cause was chronic myelomonocytic leukemia (Goode 2003).

Accomplishments

Paul E. Meehl is renowned for his insistence on precise thinking and scientific tough-mindedness (Goode 2003). He has made a number of important contributions to diverse domains of psychology, including the clinical judgment versus actuarial prediction debate; theory of diagnosis; the cognitive activity of the clinician; objective personality assessment and trait theory; behavior genetics; the etiology of schizophrenia, psychoanalysis, and psychotherapy; the shortcomings of statistical significance testing; and the use of metascientific methods to evaluate competing models of human nature. Meehl played a pivotal role in forcing clinical psychologists to think more clearly and incisively about their subject matter (Lilienfeld and Waller 2005).

In the early 1960s, Dr. Meehl argued that counter to popular belief, schizophrenia was not caused by bad parenting, but rather that it had a strong genetic component. He discussed the subject in his 1962 presidential address to the American Psychological Association (APA 2011). Now, some 50 years later, the genetic basis of schizophrenia is widely accepted (Goode 2003). In his 1990 paper, *Toward an Integrated Theory of Schizotaxia, Schizotypy, and Schizophrenia*, (Meehl 1990) developed an extended analysis of the relation between genes, brain function, and psychopathology (Thompson 2005).

Dr. Meehl in his 1954 book, *Clinical Versus Statistical Prediction: A Theoretical Analysis and Review of the Evidence*, infuriated many colleagues by meticulously pointing out the limitations of clinical judgment. He

argued that clinicians were not very good at predicting people's behavior and proposed that a far more reliable method was to analyze the information gained from personality tests, psychiatric interviews, and other sources using mathematical formulas.

Meehl's effectiveness as a critic of slipshod thinking in psychology was aptly characterized by his conversational writing style and ability for coining phrases. In his classic paper, "Why I Do Not Attend Case Conferences," Dr. Meehl listed the logical sins routinely committed by psychologists when they gathered to discuss patients. Which ranged from the "Me too" fallacy where psychologists, upon hearing of a patient's odd behavior, insist that it is normal because "anyone would do that" to the "Uncle George's pancakes fallacy" exemplified by the clinician who, told that a patient stored leftover pancakes in the attic, declares, "Why, there is nothing so terrible about that – I remember good old Uncle George from my childhood, he used to store pancakes in the attic" (Peterson 2005a).

In the latter part of his career, Meehl played a central role in developing taxometrics, a field concerned with using mathematical formulas to determine the natural groupings of biological or psychological variables (Peterson 2005a).

Paul Meehl served as president of the APA in 1962, the second youngest person to ever serve. He was active in several key APA governance groups, including the Committee on Test Standards and the APA Task Force on Statistical Inference.

Meehl received many awards for his contributions. He received a number of APA awards: the Distinguished Scientific Contributor Award (1958), the Award for Distinguished Professional Contributions to Knowledge (1993), and the Award for Outstanding Lifetime Contribution to Psychology (1996). Paul was also honored by the American Psychological Society (now Association for Psychological Science), for his contributions, they made him both a James McKeen Cattell Fellow and a William James Fellow. He was also a member of the National Academy of Sciences (American Psychological Association 2011).

Meehl's papers are cataloged on his Web site, "Paul E. Meehl, 1920–2003," available from <http://www.tc.umn.edu/~pemeehl/> Regularly updated by his wife, Leslie J. Yonce.

Mesmer, Franz Anton

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Mesmer (1734–1815) was born in Iznang on the German shore of Lake Constance. Mesmer's secondary education was in Jesuit schools, and his post-secondary education continued at the Jesuit universities in Dilligen and Ingolstadt. Pursuing a theological degree, Mesmer was exposed to rationalism which led him to question Catholicism and away from theology. The years 1755–1759 are unaccounted for in Mesmer's life, and some sources report that he earned a doctorate in philosophy

in 1759. That claim was included in the title page of his medical dissertation (see facsimile in Pattie 2004, p. 14). However, Pattie, a reliable Mesmerian scholar, concluded that it was likely “self-conferred” (p. 15).

In 1759, Mesmer began studying law in Vienna, but he soon abandoned law to study medicine. He earned a medical doctorate in Vienna in 1766, and his medical dissertation was *Dissertatio physico-medica de planetarum influx*. The dissertation presented a theoretical argument that gravitation could influence the body and that gravitational tides in the body could be manipulated to treat disease. Pattie argued convincingly that Mesmer plagiarized Richard Mead's *On the Influence of the Sun and Moon upon Human Bodies and the Diseases Arising Therefrom* (Pattie's translation from Latin) although others have said that Mesmer was merely guilty of following the poor rules of citation that prevailed at that time.

Little did it matter whether Mesmer plagiarized Mead, because Mesmer soon shifted his emphasis to animal magnetism. Poor magnetic conditions in the body were believed to be the sole cause of disease, and for many patients such conditions could be manipulated to the patient's benefit. Initially Mesmer used strong magnets to treat his clients, but he soon realized that the magnets were unnecessary and that he, especially, and any suitably trained physician could manipulate a patient's animal magnetism. Mesmer believed that he could charge substances, including water, with magnetism and that he could treat several patients concurrently by having them hold metal rods placed in containers of magnetized water; his famous *baquet* was a variation on this kind of group therapy device.

It is unclear what Mesmer thought the material basis for animal magnetism might be, but he sincerely believed that it had one. While Mesmer's notion of animal magnetism seems farfetched today, it must be recalled that this was an era when legitimate scientists believed electricity to be a “subtle fluid,” neural conduction was attributed to the flow of “animal spirits” (there was experimentation to determine whether animal spirits were gaseous or liquid), and that life resulted from a supernatural “vital spirit.”

Mesmer had some early successes and failures, and he soon learned to sort his patients into those who might benefit from his treatment and those who might not, and he referred the latter to other

physicians. He enjoyed several years of success in Paris, until King Louis XVI appointed a commission to test the validity of animal magnetism. A distinguished committee headed by Benjamin Franklin, the American statesman and member of the Royal Academy of Sciences for his expertise in electricity, conducted several sophisticated control tests. They concluded that animal magnetism did not exist and that any so-called beneficial effects were due to the patient's "imagination." The 1784 report has only recently been translated from French to English (Franklin et al. 1996 [1784]).

Depending upon whom you read, Mesmer was either a charlatan (e.g., Zilboorg 1941) or a genius ahead of his time (e.g., Alexander and Selesnick 1966). Confirming the former is that Mesmer could be petty, greedy, vindictive, secretive, and, for example, he refused to submit his ideas about animal magnetism to control tests. Supporting the latter was that he was a conscientious scientist in his beliefs and a sincere and compassionate medical man who treated the poor for free.

Eventually, much medical, psychiatric, and psychological good would come from "mesmerism," a name suggested by Karl Wolfhart who was a friend and the editor for Mesmer's final published work. Later, to improve the legitimacy of "mesmerism" for medical use (anesthesia), James Braid gave it a new name (neurypnology) that soon evolved to "hypnosis" and he gave it a physiological explanation. However, Pattie (2004) whose concluding chapter is titled "Genius or Charlatan," gave Mesmer little or no credit for anticipating the psychological uses of hypnosis which is where mesmerism's ultimate redemption occurred.

Major Accomplishments/Contributions

Many of Mesmer's medical and scientific writings are available in English translation (Bloch 1980). As indicated above, it is difficult to know how much to attribute to Mesmer for mesmerism's (hypnosis) ultimate contributions. After Mesmer's disgrace at the hands of the Royal Commission's report in 1784, serious consideration of mesmerism by the medical establishment was dismissed. Despite strong resistance by his medical colleagues at University College, London, John Elliotson carried the banner for mesmerism as surgical anesthesia and to treat mental illness, and James Esdaile, a Scottish surgeon in India, had great success

using mesmerism as anesthesia including a drastic reduction in mortality rates for some medical conditions. Braid's contribution mentioned above was invaluable. The successful use of ether for surgical anesthesia in 1842 by Crawford W. Long of Georgia opened the way for chemical anesthetics to replace mesmerism as anesthesia, but mesmerism continued to be advanced in the treatment of the mentally ill. Psychiatrists such as Hippolyte-Marie Bernheim and Jean-Martin Charcot in France led the way. Today, there are numerous organizations and medical and psychological practitioners devoted to the advancement of medical and psychological hypnosis.

Meyer, Max F.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: June 15, 1873; Died: March 14, 1967.

Max Meyer was one of the most distinctive voices in psychology throughout his long career. He was born in Danzig and was motivated toward psychology by reading the work of Lazarus Geiger on thought as inner speech (Wozniak 1993). He began formal psychological studies at Berlin where, after an unsuccessful time with

Ebbinghaus which did not leave a permanent mark, as he later translated and edited Ebbinghaus's *Psychology: An Elementary Text-book*, he was introduced to the study of auditory perception, his lifelong work, by Carl Stumpf. His dissertation subject in 1896, sponsored by Stumpf, was combination tones. A further sponsor was Max Planck, which presaged Meyer's development as the major exponent of a thoroughgoing physical reductionist psychology. In 1898, he had a public and acrimonious falling-out with Stumpf (not a hard thing to do, as E.G. Boring (1929) noted in "The Psychology of Controversy") over the interpretation of musical consonance and dissonance, and was compelled to search widely for a new academic position. He had to go as far as Columbia, Missouri, to the University of Missouri, where from 1901 until 1930 he directed the psychology department from his office in the Jesse Hall cupola.

Major Achievements/Contributions

During the first decade of the 1900s, he focused on hearing and completed two versions of his theory of hearing, which was, as Boring classified it in his 1942 *Sensation and Perception in the History of Experimental Psychology* (where he also termed Meyer's theory the best-publicized theory after Helmholtz's) as a frequency-non-resonance theory in which the basilar membrane is considered inelastic. Sound is represented by a frequency pattern assembled from the interleaving of punctate depressions and elevations of the basilar membrane corresponding to vibrations transmitted by the media of the middle ear. Though Meyer's theory became obsolete in light of advancing physiological knowledge, he continued to advocate for his view for the next 60 years. Meyer generalized his mechanistic approach to audition into a comprehensive psychological system in which all "mental" activity would be translated and discussed in terms of neural function, as much as that was possible at the time. This theory, presented in his major book *The Fundamental Laws of Human Behavior* (Meyer 1911), was one of several versions of behaviorism that precipitated from the functionalisms of the era. While most contemporary histories of psychology did not accord Meyer priority as the originator of American behaviorism (W. B. Pillsbury was an exception), more recent accounts have recognized how many aspects of later

behaviorism were represented in Meyer's work. Meyer, avidly self-promoting, wrote two successor texts, *Psychology of the Other-One* (1921) and *Abnormal Psychology: When the Other One Astonishes Us* (1927), both of which were based on the idea that behavior is observable in others rather than in the self and which were based on his neural learning theory. Meyer anticipated, among other things, adaptation-level theory, but the prescient parts of his work were lost as it was translated into the strident denials of internal processes and introspection of his more popularly accessible acolyte, his only Ph.D. student, Albert P. Weiss. Personally, Meyer could be caustic and he did not shrink from negative evaluations: Reviews he wrote during the 1920s allow no mistake to be made about his preference for objective versus subjective terminology and conceptions in psychological science and was peremptorily direct in consigning most contemporary textbooks and most practicing psychologists to a lesser status than science. He frequently referred to William James's work as "literary" and he saw much current psychology instruction as instruction in "English." On the other hand, his writing was crisp and sharp and he had a fine sense of the comic: His essay "That Whale Among The Fishes – The Theory of Emotions" (Meyer 1933) is still a provocative challenge to psychologists to provide a definition that clearly demarcates what is, and what is not, an emotion. Though difficult and at times prickly, he attracted several eminent colleagues and students. With R. M. Ogden, he translated *The Problem of Form in Painting and Sculpture* by Adolf von Hildebrand in 1907, and among his students were, as mentioned, Weiss, as well as Paul Farnsworth and O. H. Mowrer. Meyer is often remembered for an academic political dustup between several intransigents – Meyer and the University of Missouri's president and Curators – which centered around a survey of student sexual mores conducted by Mowrer in 1929. This resulted in the firing of the president, Mowrer's removal to Johns Hopkins where he was mentored by Knight Dunlap, and Meyer's dismissal from his position in 1930, an action deplored by his colleagues nationwide. In exile in Florida, Meyer continued to write on audition and also on historical issues for 30 more years. His mathematical observations on Tartini tones and other difference tone phenomena are still cited in discussions of the subject.

Microgenetic Theory: Brain and Mind in Time

MARIA PAŁCHALSKA^{1,2}, BRUCE DUNCAN MACQUEEN¹,
JASON W. BROWN³

¹University of Gdansk, Gdańsk, Poland

²Frycz Modrzewski Krakow University, Kraków, Poland

³Center for Cognition and Communication, New York, NY, USA

The term “microgenesis” refers to the process by which a mental state unfolds through qualitatively different stages to form the present moment. The temporal extent of this unfolding extends from the onset or genesis of the mental state in phylogenetically older structures, through more recent systems in the evolution of the brain, to the final representation of the content in consciousness or behavior (Brown 2002).

The Antecedents of Microgenetic Theory

Würzburg Studies

The work of the Würzburg group (see also Kragh and Smith 1970; Hanlon 1990) toward the end of the nineteenth and beginning of the twentieth century provided an early conceptual framework for microgenetic theory. The experiments designed by this group typically

involved introspection, that is, the examiner observed his own mental operations at the onset of the response to a particular verbal task. Thus, task performance was less important to the investigators than the initial state and the immediately ensuing phases preceding the overt response. These experiments (see Humphrey 1963) led to the postulation of a non-sensory (or “imageless”) stage that arises in consciousness immediately following the presentation of a stimulus, corresponding to the “birth” of a thought in consciousness. This stage was presumed to give rise to a second stage of imageless knowing, in which the relatively amorphous developing thought takes on a particular shape, due to the operation of will and direction, that is, intentionality. The importance of the Würzburg school lies not so much in its contribution to a then-raging debate over imageless thought, which has long since tailed off (cf. arguments over the propositional basis of mental imagery), as in their attempt to describe the microstructure of the cognitive process. The relation between this approach and the theories of the pioneer English neurologist, J. Hughlings Jackson (Taylor 1958), as well as its conceptual links to the theory of Gestalt formation (even though many details of the transformational process still remained to be explained and elaborated) provided a foundation for the notion that a microtemporal transition underlies cognition, and provided a basis for continuing research in normal and brain-damaged individuals.

The Term “Microgenesis”

What is microgenesis? According to Hanlon (1990, p. 17), the term itself has a tangled history. Sander (1930, cited by Catán), a Leipzig psychologist, used the German term *Aktualgenese* in the context of his studies on the temporal evolution of percepts. He presumed that the realization of a percept developed according to a logical process that perhaps could be demonstrated experimentally by exposing a subject to suboptimal stimuli, for example, by showing a picture tachistoscopically or in dim light. Heinz Werner, in connection with his interest in the comparative psychology of mental development (Werner 1948), sought to derive laws that would be applicable to the unfolding of psychological experience, which occurs not only in a matter of seconds, but also over prolonged periods of time (see Catán 1986, p. 254). Improvising on methods

used by Sander and others of the Leipzig school, he devised for experimental purposes a “micromusical scale” as one of several means to “actualize . . . the development of internal representations and the mechanism whereby they were constructed” (see Catán 1986, p. 256).

It was Werner, then, who first used the word microgenesis in English as an approximate translation of the German *Aktualgenese*, referring to the process by which a mental state is formed in the present moment (Werner 1956, 1957; Werner and Kaplan 1956, 1963). In Catán’s view, he failed to explain why the prefix *Aktual* – in German should be rendered *micro* – in English, proceeding as though both terms “were familiar items of [the reader’s] conceptual equipment” (see Catán 1986, p. 253). Indeed, Suzanne Langer, an American philosopher, in translating Sander’s 1930 paper into English, had interpreted the rarely used German word *Aktual* to mean *realize* (see Catán 1986, p. 254), with the whole term *Aktualgenese* rendered as “the origin of realization.” This is a reasonable enough inference from the point of view of a native speaker of English, given the meaning of “actual” in English, but the German adjective *aktual* has a different meaning, more like “current” or “present,” so that *Aktualgenese* in German means rather literally “the origin of the present moment.” There being no English word that would both correspond precisely to the meaning of *aktual* in German, and would be philologically suitable as a prefix to “–genesis,” Werner’s “microgenesis” is perhaps the best available candidate, though it leaves some readers confused, and others dissatisfied. The confusion over the formation of the word “microgenesis” itself (English “micro-” vs. German “actual-,” along with the problematic relation between “genesis” and “genetics”) has undoubtedly been a factor in making microgenetic theory less accessible to both psychologists and philosophers of mind, who may be unaware that “microgenesis” could have anything at all to do with the problems in which they are interested. This is regrettable, but it is hard to know how it could be avoided.

The term *microgenesis*, then, has come to mean “the microtemporal unfolding of object representation, conceived as a more or less instantaneous recapitulation in cognition of patterns laid down in phylogeny and ontogeny” (Brown 1988, p. 3). In Werner’s formulation, phylo-ontogeny was thought “to leave a track

that was retraced each moment in the process of object formation.” As opposed to this regressive view, current theory sees microgenesis as a unidirectional forward flow from “archaic” to “recent” structures in a matter of milliseconds. Microgenesis is evolution taking place in an instant (Brown 1988, p. 6), rather than the eons of phylogeny or the years of ontogeny. In the work of the third author of the present study, microgenetic theory began to be important as a useful approach for clarifying the development of different kinds of aphasia, while at the same time suggesting very necessary changes in older interpretations of brain and language (Brown 1988). This has developed over the years from a strictly clinical problem to a multifaceted effort to make sense of the mental state itself, a subject of interest far beyond the confines of the neurology clinics where the initial work was done.

Early Studies in Brain Pathology

Following Herbert Spencer and Hughlings Jackson, and Freud’s early work (topographic theory), Arnold Pick (1913) studied the hierarchic aspects of language organization in relation to the symptoms of brain damage. Pick (1931/1973) described the different forms of language breakdown (aphasia) from the standpoint of a microtemporal sequence, which was thought to lead from the initial formulation of a thought as a loose, structural assembly, through a stage of prediction and word choice, and finally to articulation (Brown 2002). Pick retained the Jacksonian idea of an inhibition or restraint of lower centers by higher ones, but was vague on the neurological correlates of the system (see introduction in Brown 1972). This approach was continued in neurology by Henry Head (1920, 1963), Klaus Conrad (1947), Kurt Goldstein (1948, 1995), and Alexander R. Luria (1966), but still without a concerted effort to correlate the psychological structure inferred from the aphasia with brain organization.

An exceptional contribution, however, and one of the most important contributions to this topic in neurology, was a paper by Paul Yakovlev (1948), in which the different forms of motility and action space were mapped to patterns of structuration in the evolution of the forebrain. Arguably, the most creative studies from a microgenetic standpoint, however, were those of Paul Schilder (1951), whose work covers an extraordinary

range, from social theory and psychopathology to brain damage and child development. Schilder viewed thought disorders as “abortive formations produced in the course of the differentiation-process of thought.” In his view, the content passes to consciousness and reality orientation through a stage of dreamwork mechanisms, in which similarity and contiguity played a role. Symbolic images were not transitional structures, but aids in the comprehension of meaning. A similar formulation was employed for the disorders of language and perception (agnosia). The symptoms of aphasia and agnosia, the various impairment of language and object recognition, were thought to reflect an uncovering of earlier stages in their microgeny. This idea was picked up and developed further in the third author’s book, *Aphasia, Apraxia and Agnosia* (Brown 1972).

Whereas the microgenetic theory of aphasia and related disorders developed by Pick (1913), Schilder (1951), and others has not been refuted, it has not achieved a wide acceptance among specialists in this field, who, mirroring trends in behavioral neurophysiology and experimental cognition, have shown greater interest in localization and modularity than process models (Brown 2002, p. 3). It is only the incipient collapse of the modular paradigm (cognitivism) that has opened the field for a different approach. The studies discussed above, from many different perspectives, have provided documentation for the insights of the Würzburger school and others as to the existence of a microtemporal process underlying object and thought development. Some of the major conclusions of this research are as follows:

- The demonstration that the symptoms of brain damage and psychopathology refer to “buried” normal stages that are exposed prematurely. These normal stages can be tapped, or accessed, by certain experimental methods.
- The finding that symbolic operations, imagery, and other aspects of subconscious cognition are entrained at preliminary stages in the object development.
- The finding that meaning is extracted prior to conscious awareness of the stimulus.
- The demonstration that affective states occur in association with preliminary cognition. These

studies did not succeed in clarifying the brain mechanisms or processes involved in cognitive microgenesis, nor in specifying the stages, or sequence of stages, both neural and psychological, in the progression to a final content.

Developmental Psychology

Werner (1948, 1956) (see also Flavell et al. 1997; Catán 1986) argued that “functions underlying abnormal behavior are in their essence not different from those underlying normal behavior . . . and human activity such as perceiving, thinking, acting, etc., is an unfolding process, and this unfolding of microgenesis, whether it takes seconds or hours or days, occurs in developmental sequence.”

An important element in Werner’s thinking, and indeed the entire microgenetic approach, is that the unfolding of cognition retraces levels or stages in evolution and ontogeny. Werner compared patterns of thought formation and behavior over the evolutionary series to maturational patterns in children and in cases of delayed or aberrant development. The pattern of thought and percept development in phylo-ontogeny was assumed to be related to that of cognitive processing in ongoing behavior. The conflation of phylo-ontogeny with the microtemporal unfolding of thoughts led to a rather dubious parallel being drawn between the cognition of young children and that of “savages,” the brain-damaged, and cases of psychiatric decompensation. Another unfortunate effect was the so-called regression hypothesis (This hypothesis, usually associated with Hughlings Jackson in neurology and Roman Jakobson in linguistics, was the focus of a critical discussion in a collection edited by Caramazza and Zurif 1978.), which held that brain pathology unpeels cognition in the reverse order in which skills or capacities are acquired. These byproducts of microgenetic theory became targets for criticism, and the concept was largely abandoned.

Although critical in some respects of the Würzburg school and too broadly biosocial in its formulation, the work of Lev Vygotski (1934–1962) also had a microgenetic dimension, especially in studies of the development of inner speech. Vygotsky argued that the role of language was mediation, through the internalization of egocentric speech as verbal thought (Brown 2002, p. 3). The laws of thinking, of concept

formation, and the transformation of word meanings were studied over the course of development and during the performance of a specific task.

The implications of these studies for microgenetic theory and their exploration in adult aphasia were described by Alexander Luria (e.g., 1962–1966). Luria tended to think of inner speech as subvocal speech, the “preverbitum,” almost speech, or speech that was just not verbalized. This differed from Vygotsky, who felt that the linguistic structure of inner speech was different from that of ordinary speech (Brown 2009).

Much of Luria’s work was published in English; much of it is repetitive and has been largely forgotten in the West – except for his idea of “functional system,” which he said he borrowed from Anokhin, and which has not been interpreted as he would have liked. In the usual interpretation, a functional system is a circuit board or network of components. For Luria, there was a dynamic element, while pathology in the system led to a qualitative reorganization.

Luria also had a hierarchical theory, which he took from Vygotsky. In his view, the right hemisphere was concerned with space in and around the body, the left with action and speech in a space “out there” in the world; thus, the right hemisphere had a cognition that was older or earlier than that of the left. His view of action was of a system of oscillatory levels, an idea which he got from Bernshtein. This idea has been further developed in microgenetic theory (Brown 2005). From Pavlov, Luria took the idea of primary and secondary analyzers, which figured more in his work on aphasia. From Vygotsky’s work on egocentric speech in children, he took the idea of verbal regulation of motor activity. According to this view, egocentric speech in children internalizes as inner speech in adults. Luria felt that motor aphasia was a defect of inner speech (and regulation of action by speech, which produces apraxia), but more recent microgenetic work sees inner speech as a preverbal phase (Brown 2009).

To some extent, Luria also had a microgenetic idea, in that there was an unfolding from older to newer systems, and that cognition was hierarchically organized. The problem with his writing is that he had so many different – and largely borrowed – theories that it is difficult to know what his interpretation of any one condition actually was. For example, in the frontal (dynamic) aphasias, did Luria see the problem in

hierarchy? in regulation? in rhythmic motor function? as a node in a distributed network? in primary/secondary analyzers? All of these and more can be found in different works in different places, with no effort to reconcile them into a single theory (see also: Pachalska 2002, 2007).

Luria’s testing was bedside rather than standardized, so a problem, for example, in repeating a series of sounds, *ba, pa, ba*, could be due to comprehension, production, serial ordering, memory, perseveration, etc., so it was only in the context of a total examination that one could interpret an isolated symptom. In this respect, his approach was consistent with microgenetic theory, but in the West, his approach has been translated into yet another quantitative battery, known as “Luria-Nebraska,” which he would never have approved.

Studies in Genetic Psychology

Genetic psychology, properly understood, is the study of micro- or macro-trends in the development of the mind, not the tracing of behavior to genes. This approach provides a background for microgenetic theory. Piaget (e.g., 1969) described the growth of knowledge in a transition of developmental stages, each an obligatory transit in the growth of mind. For example, around the age of 7–11, there is a shift from the egocentric to the concrete-operational view of the relation of self to world. The child is able to incorporate the perspective of the other into his own point of view. There is also a shift from a syncretic and intuitive phase to one of deduction and reasoning. Judgments of value have more influence on the earlier egocentric phase than on the later one of communicable thought (Piaget 1955). Such stages in the growth of mind or intelligence form the bases for the investigation of the maturation of specific functional domains, such as perception, language, logic, etc. When a novel response appears, its underlying operations are studied. When the response diminishes in importance with age, antagonistic factors are assumed to have intervened. A response that is invariant across age is said to reflect innate factors, though the sequence of stages must itself be governed by innate forces, even if there is considerable variation according to learning and experience.

Piaget conceived intelligence as a continuation of perception, or obeying the same laws as perception.

While he accepted the genetic notion of a progression from whole to part and the priority of process over substance, he did not resolve the problem of reconciling process theory with substantive modes of thought. Nor was there a coherent account of objects and relations. He wrote, “elements are not given from the beginning because they do not exist independently of the relations which unite them. . . (the relational method is a) striving towards the construction or composition of a whole, not starting with elements but with the relations between them, which is not the same thing” (Piaget 1972). Nor did problems of internal and external relations, or wholes and parts, achieve an adequate analysis. Piaget distinguished causal explanation in physiological science from psychological explanation, which deals with “systems of significations” or of significant actions that are inter-related by “implications” in the broad sense of the term.

There have been attempts to relate Piagetian stages to the pattern of myelinogenesis (e.g., Lecours 1975), but the correlations are imprecise. The brain matures as a whole, and specific functions cannot be related to the development of anatomical systems with great accuracy. The relation to pathological breakdown (e.g., Ajuriaguerra et al. 1963) supposes that functional stages are stacked in the acquisitional sequence and unpeel in the reverse order in pathology. In cases with posterior brain damage, an attempt was made many years ago without success to demonstrate a deconstruction according to the Piagetian stage theory. Such an effect, were it to be confirmed, as postulated by Heinz Werner, Hughlings Jackson, Roman Jakobson, and many others, is referred to as the regression hypothesis. This concept was for many years a mainstay in the study of development, but it has been called into question (Caramazza and Zurif 1978), at least in its simple form (Brown 1996).

In contrast to Piagetian accounts, which deal with the whole child and its relation to the world, perceptgenetic research (e.g., Smith 2001) has focused on the fine microtemporal processing of a perceptual object. Smith and his colleagues have employed a host of innovative methods, many involving rapid tachistoscopic exposure, to explore otherwise concealed stages in the perceptual process. These techniques are thought to expose early stages of affect and meaning that are ordinarily buried in the final object. The implication is

that phases of meaning, emotion, and memory are conjoined early in object formation, with the final object being the outcome of a rapid traversal over layers in cognition, which, in some way, correspond with the maturational history of the individual. The percept genetic approach has close affinities with microgenesis, in which the symptoms of focal brain lesion are used to reconstruct the neural and psychological process of percept formation.

A third approach to genetic psychology places emphasis on the relation of developmental stages in maturation and perceptgenesis to its attenuation in mental retardation, in pathology, and in primitive thought. Heinz Werner (e.g., 1945, 1957) is most closely associated with this school. As with other genetic thinkers, Werner asserted the primacy of process over substance. He argued that development proceeds in an orderly manner from a state of globality and lack of specification to one of increasing differentiation, articulation, and hierarchical integration or “genetic” stratification. Werner disclaimed an association with evolutionary psychology, for the latter deals with the history of mankind and what is early and late in the historical scale, while developmental psychology deals with the pattern from low to high mentality. He listed several features characteristic of developmental psychology, specifically, the progression from the syncretic to the discrete, the diffuse to the articulated, the indefinite to the definite, the rigid to the flexible, and the labile to the stable. Werner’s importance has receded with the cognitive shift in psychology, but there has also been a caricature of his thesis, which comes of taking too literally the comparison across different populations. The savage, the child, the psychotic, and the brain-damaged are not equivalent in terms of thought content. A child with an imaginary playmate, the native with his crocodile gods, or the schizophrenic with his visions cannot be compared to performance errors in persons who have incurred brain damage. The similarity is not in preliminary contents as end points, or those that surface, or remain submerged or transformed in normative cognition, nor do such phenomena reappear in pathological breakdown. What these diverse populations do have in common, in some if not all respects, is a pattern or mode of thought, one that is pre-rational, paralogical, or syncretic. The prominence of metaphor and symbol, and magical or

animistic thinking, points to a phase traversed in every rational thought. The commonalities in patterns of mental process are guides to regularities in the process of self-realization. They help us to understand the fundamental “laws” of thought, irrespective of the particular contents, which the process deposits at any given moment in any given case.

In sum, these varied approaches – over different time scales – share the concept of an action or perception as a derivation over levels or stages in cognition. The derivation is the intra-psychic phase of object formation, the object being the end point of a formative (micro- or macro-developmental) process. The progression is unidirectional, like growth, and obligatory. It leads from antecedent phases in conceptual, affective, and memorial experience to the presentational immediacy of acts and objects in the world. It goes from the wholeness and largely undifferentiated potential that originate the process to the multiplicity of world objects and conscious images in which it eventuates, that is, from self to world, and from ego- to object-centeredness. The momentary “growth” of a perception from an intra- to extra-psychic locus is a microcosm of the maturation of the mind, in that it resembles process across other domains of cognition. The microgenetic contribution to genetic psychology is a more precise formulation of the phase-transitions underlying this process, and their correlates in evolutionary brain structure. Microgenesis distills the different time scales into repeatable epochs in the relation of patterns of forebrain evolution to patterns in object-generation.

Microgenetic theory has demonstrated that too great a focus on the content of a performance is detrimental to the understanding of the process through which the content is deposited. The content of an action, an utterance, or a perception is “thing-like” and of a different order than the process through which it develops. Genetic psychology gives a description of cognitive development over the long- or short-term-based on epochs that recur, but it only provides a limited explanation of the contents that develop out of this process. This is its strength and its weakness. For example, such a psychology can account for the process of form or meaning development in a perceptual or linguistic object, or the relation to stages in memory, but not the content of what is actually said or remembered.

Psychoanalysis has in common with microgenetic theory the fact that it takes the actual (or latent) content of an act of cognition and attempts to explain its origins in unconscious process. However, the theory is not fully process-based, since explanation is in terms of the interaction or conflict of logical or mental solids, with the dynamic of feeling (cathexis) injected as the glue of the varied elements. Psychoanalysis is also problematic in that its constructs have not been successfully related to those of other fields of psychology, much less process thought. Some writers have tried to extract from psychoanalysis a theory of perception or memory (e.g., Schilder 1950; Rapaport, cited by Gill 1967), but these innovations have succumbed to orthodox interpretations.

A psychology that begins with mental content takes for its starting point an object that has completed its development. The object is assumed to be the product of parts/functions inferred from the putative structure of the object itself. Additional elements, that is, rules, operations, mechanisms, strategies, buffers, representations, and so on, are postulated to explain the content. These are eventually reduced to the atomic elements from which the part-functions, and from them the final contents are assembled. The entire process is content-like, with process inserted to string the contents together like beads on a chain. The linguistic and analytic schools of philosophy have generated, in cognitive psychology, a veritable industry to support this paradigm. In contrast, process philosophy has not sought connections to genetic or process approaches in psychology, veering toward theology and metaphysics instead of empirical science. The conceptual overlap of process philosophy and genetic psychology is such that a dialogue between the fields should be mutually enriching. Genetic psychology provides a direction and brake on philosophical speculation, which in turn provides novel or renewed insights for psychological study.

Perceptgenesis

Perceptgenesis, influenced by gestalt theory, concerns the microtemporal process underlying the development of percepts. This approach was initiated inter alia by Sander in 1928, who, as previously noted, referred to the process of object formation as *Aktualgenese*, or “moment genesis.” Sander developed techniques for studying the process of perceptgenesis,

including the use of poor illumination, peripheral location, obscuration, and brief (tachistoscopic) exposure. Sander maintained that a perceived object developed from an initial stage of a diffuse percept through progressive differentiation and discrimination to a distinct configuration. The early diffuse pre-object first achieves coarse figure: ground properties, then passes to a labile pre-gestalt, and then is derived to a veridical object. There is a corresponding microgeny to affect, such that a stage of anxiety is associated with the pre-gestalt, giving way to relaxation when the figure is resolved.

In cases of perceptual disorder (agnosia) with brain damage, Pötzl (1917, 1960) (see Brown 1988b for a translation of several of Pötzl's papers) noted the recurrence (intrusion) of unreported elements in subsequent object descriptions. For example, a green asparagus stalk that was not reported on one task recurred a few moments later in the description of a person as having a (nonexistent) green tie. Pötzl confirmed this effect in normal subjects with tachistoscopic methods. He presented scenes to subjects, and later found that unreported fragments were integrated into dreams that could be recovered in morning reports. For example, a waking subject shown very quickly a house with a picket fence, and able to describe only the house, might report in the morning a dream about a cage. This was an experimental confirmation of Freud's observation that dreams often concerned the least noticed fragments of daytime perception. Fisher (1960) subsequently confirmed and extended these findings. The work stirred interest in the advertising potential of these (subliminal) effects. The implication of these findings, that subconscious residues are linked to early stages in object perception and that the symptoms of object breakdown can be reproduced through experiments in percept formation, were a major theme in the work of Pötzl (1917, 1960), and had a great influence on later studies in perceptgenesis.

Such work has used modifications of these same experimental methods to study personality structure and development. For example, Froehlich (1984) has utilized procedures that elicit imaginal activity, guessing, and hypothesis formation in relation to progressive changes in the energy level (luminosity, clarity, etc.) of an intact stimulus presentation. Kragh and Smith (1970) have described changes in the thematic content of percepts from a psychodynamic standpoint.

These authors noted a progression in the resolution of the stimulus from ambiguity to stabilization and reality orientation. Various psychiatric populations have been shown to be distinguishable by this method. Smith and Danielsson (1982) used a Meta-Contrast technique, in which incongruent or threatening subliminal stimuli are presented with a tachistoscope to evoke anxiety. They described the series of transitions in the manifestation of anxiety and in defensive strategies from early childhood to adolescence. Smith and Carlson (1990) have used tachistoscopic methods to study creativity, in relation to personality development, the subjective pre-stages of a perceptual act, and the progression of these stages to the final correct meaning. These studies confirm the verbal reconstruction of a perceptual process, with increasing stability and automation of the process in the course of maturation.

Perceptgenetic studies assume that increments in the microdevelopment of a behavior in maturation predict or determine the response to the experimental probe. Such an interpretation conflates, however, several different levels of analysis:

- The longitudinal series in the acquisition of a behavior;
- The probe sequence at successive series in the acquisitional points;
- The on-line entrainment in the generation of a behavior once it is acquired.

These issues need to be resolved in order to distinguish whether or not the behavior that is being explained is the set of capacities needed for its description, or the operation enlisted for its elaboration.

The perceptgenetic data do not map to brain anatomy and neurological disorder (Brown 2002, p. 5). As mentioned earlier, pathology is not "ontogeny in reverse." Furthermore, the correlation of brain maturation with patterns of language or cognitive development is fraught with difficulties. Gradation in developmental sequence (e.g., myelination patterns) can provide insight regarding structural organization, but they do not correlate in a clear-cut manner with patterns of acquisition.

Time, Change, and Stability

Microgenetic theory developed as a clinical model, but gradually became a theory of time and process.

The central argument is that the subjective present, about which past and future seem to orbit, originates in the arising of a mind-independent passage from before to after. The past is less tangible, less real than the present, but it is more durable, absorbing the present as it fades into memory so that the future can become actual. Experience seems to go from the present of existence to revival in personal or collective memory, but this is the reverse of the passage of nature, which goes from earlier to later or, in subjective life, from the past to the future. Put differently, psychology assumes a direction going from present to past in the shift from perception to memory, while nature moves in the opposite direction, from past to future. A theory of mind consistent with the process of nature would have the future becoming the present out of the past, rather than having the past deposited by the present.

Temporal order in perception and memory has been conceived as realized within a given mind/brain state, or over a succession of states. Serial order might then involve a concatenation of states with a blurring of the boundaries between them. However, succession alone cannot map directly to passage, that is, perceived succession in the world does not give the succession in the mind, since objects and entities perish on actualization. The perception of temporal order requires that past and no-longer existent objects recur in memory. However, to attribute serial recall to short-term, working, or episodic memory merely restates the problem without explaining it. A succession of perceptual states may be necessary for serial order, but this is not a solution to the consciousness of succession.

Succession is as essential to change as to stability. Object stability occurs when replacements are similar, change when recurrences are novel. Serial order is required both to see a tree and hear a sonata. For epochal theory, events arise within nontemporal spatial wholes, with the simultaneity within a state replaced by its successor. The perception develops out of memory through the effects of sensory constraints on an infrastructure of memory. The state lapses to its precursors in the incomplete revival (decay) of perception in a series of replacements. The transition from simultaneity to succession within a state and the layering of the state in the graded revival of past states, that is, the orderly regress from a prior object to a present image, transposed to a temporal series within the

virtual present, is the basis of serial order in memory and perception.

Conscious and Unconscious

Change in the motion from one event to another in the observer's world reflects the temporal order of events as they actualize in the mind. From the lag in perceiving an object or from the image that results from binocular disparity, we know, *inter alia*, that perception is not *on-line* with physical nature. What we really perceive is a mental image that models a physical event, not the physical event itself, which is inferred from the image. Object and space are the outcome of the sculpting and externalization of phases underlying image formation. The transition from the intra-psychic and unconscious to the conscious and external in the formation of objects is so obvious and so often stated that it can be taken as the starting point for speculation. Let us begin with the transition in the mental state from depth to surface or onset to termination in relation to time and change.

Many thinkers since von Hartmann (1868/1931) and Freud have posited a transition from timelessness to temporal order. Since timelessness is nonexistence, and the unconscious does not have the instantaneity of a durationless slice, it is preferable to speak of simultaneity, which has extension or thickness. If unconscious process in a conscious person is conceived as a subliminal transition, that is, if the *psychic* unconscious is beneath or outside consciousness though essential to it, and if the unconscious exists when the mental state actualizes, what would be the form of an unconscious transition that actualized without becoming conscious? On the microgenetic account, consciousness is always preceded by, and enfolds, an unconscious transition, so that an attenuated mental state could exist without reaching the stage of consciousness. For most psychologists, it is the other way around, that is, experience first passes through consciousness in order to be revived in the unconscious. A memory is the record of a perception, as the imagery of a dream is a memory (true or distorted) of prior conscious experience. On this view (which is not uncommon among those hostile to psychoanalytic excess, in which content in the *un-conscious* is dependent on, is a copy of and secondary to consciousness, without which, *qua* unconscious, it would not exist), the unconscious is

merely a physiological storehouse of past conscious experience.

For microgenetic theory, unconscious memory underlies *and is antecedent to* conscious experience (see Fig. 1). Consciousness is an end point of unconscious process – actually, a relation of early to late phases in this process (Brown 1988a; Pachalska et al. 2010). An image develops out of memory to externalize as an object, while a perception sinks or decays beneath consciousness. Microgenetic theory holds that the perceptual rim is uncovered to reveal underlying memory or dream, as preterminal phases re-actualize to varying degrees of completeness and in conformity with immediate experience. In brief, *instead of perception laying down memory, memory lays down perception*. Further, it is essential to avoid a preoccupation with the *contents* of the unconscious – memories, images, dreams – for it is the *process* of unconscious mentation, not the content into which the process deposits, that is common to organisms lacking human consciousness. Content varies, process is uniform.

The Perception of Change

The shift from cause to effect has usually been postulated as simultaneous, though for some it is successive.

Microgenetic Theory: Brain and Mind in Time. Fig. 1 The transition, or process of becoming, from core (self) to perception (world) frames a mind/brain state.

Consciousness is the relation of early to late or depth to surface in this process. Visual and verbal imagery, including conceptual or intentional feeling, arise at intermediate phases, so long as an external world is realized. The *arrow* represents sensation acting on the phase of imagery to externalize and adapt the state to the physical world. The phase-transition is nontemporal until it terminates. The mind/brain state and immediate present develop in a fraction of a second, replaced by overlapping states

Causal sequence in the world is perceived as a transition of a continuous event or event series. If the process account of this shift is correct, that is, as the appearance of a transition from one conscious end point to another, with change occurring in the derivation of the end point in an epoch of consciousness, the causal shift would be simultaneous if occurring within an epoch and successive if occurring across epochs.

Not just the simultaneity of the unconscious can be posited, but that of the mind/brain state as a whole, which is simultaneous over the epoch of its existence. Entities have a temporal extensibility over which they become what they are. In mind, late phases are not the outputs of early ones which, having been traversed, disappear, but rather early phases are embedded in late ones and all phases actualize together on completion of the final phase. There are conditions in which the core might be the end point of the state, say when processes mediating subsequent phases are inactive or destroyed, as perhaps in coma or dreamless sleep. There are cases in which an intermediate phase actualizes briefly as a pathological symptom, but a phase *in transition* does not exist in isolation. A phase is not a temporal object. An object is the minimal cycle of phases that constitutes one epoch. Thus, a hypothetical atom is not a collection of slices in the orbit of an electron or the sum of its positions at every slice, but is one complete revolution. Existence is all or nothing, and the existence of the all is simultaneous when an entity becomes the being that it is.

If serial order in consciousness is coupled to the phase-transition leading to consciousness, as deduced from the state on completion, with memories of recent events revived in the order of their occurrence – the transition activating earlier, then later phases in memory up to the final perception – the sequence of activation could provide the basis for *a line in time* from the immediate past to the present end point. When we listen to speech or music, the words and tones continue to resonate for some period of time as each new sound is perceived. This is explained by the strength (degree) of revival – usually cast as decay – of preceding states in novel ones. The earlier events are incompletely revived in relation to their pastness or, perhaps, the feeling of the relative pastness owes to the degree of revival. A transition leading through memory to perception that is apprehended as a *horizontal* sequence from

past to present would explain sequencing in action, music, language, in the world, and in the mind (see Fig. 2). Since the duration laid down by the phase-transition enfolds the memorial remnants of prior states that provide the posterior boundary of the now, both perceived and remembered event-series fall within the present duration. In that, this account explains order in both memory and perception, it has a parsimony not found in rival theories.

As mentioned, the mental state lays down serial order, yet has a spatial character, actualizing as an epochal whole. The simultaneity or spatial totality of the present epoch distributes into the order it realizes. Regardless of whether temporal order in a mental state develops from the totality of an epoch or an iteration of totalities, in the transition from initial simultaneity (core), through the before and after of the phase-transition, to the now that arises with a conscious end point, the state incorporates three modes of time discourse:

1. Simultaneity, which entails temporal thickness or extensibility.
2. Physical passage in the becoming of the mind/brain state, which gives mind but is itself mind-independent.
3. A subjective present (past, future) that gives being or existence to the transition.

The simultaneity (1) that is the spatial whole of the core, or the epoch it generates, leads to and embraces a transition over phase (2) that is the bridge to temporal order. This transition, and the duration of the present that is its outcome (3), corresponds to the two series of McTaggart (1927). Since the transition does not exist until it is complete, at which point the entire transition actualizes, every temporal moment or mind/brain state – whether a static picture or an event-sequence – occurs against a backdrop of simultaneity.

Ordering depends not on perceived succession but the implicit role of succession in the layering of memory and the *replacement* of one state by the next. But is it possible that serial order is just the perception of linkage made fluid by the rapidity of shifts? This assumes that a mental state, as an epochal whole, is simultaneous through its phases, with change in the causal shift from one epoch to the next, that is, in the linkage of states, not their replacement or overlap. We

are conscious of the final contents of a state, not the transition from state to state or depth to surface, nor are we aware of interstices in the linkage. Even if temporal order is not dissociable from oncoming and antecedent states, any account based on rapid succession must return to events *within* the state itself.

Consider the phase-transition *within* the state in relation to replacement *across* states. If order is laid down in the distribution of spatial objects, or if it is derived serially from the outpouring of the core, the array of objects in the world would be a static grouping with a leading edge of change, that is, micro-events fused to an event-sequence in the overlap. An object would then be an incipient event that becomes continuous when the next state appears. The perishing of the state would support the anticipation of the next and avoid reality appearing to the mind as a stroboscopic succession of pictures. If the clock duration of a mental state (say, 50–100 ms) is insufficient to generate serial order within the state, like the flash of a tachystoscope (stroboscope), it might permit a perception of forward momentum. Order and continuity would then depend on the overlap of recurrences.

Is conscious succession – the sequence of events in observation, or the motion of the world in perception – an illusion of causal transition? Is it like the *phi* phenomenon, in which illusory change results from the rapid replacement of static images? A series of causal pairs may explain fusion from one state to the next, but not memory of preceding pairs to give a continuous event or narrative. In a motion picture, the impression of continuity in the viewer's mind requires a frequency of around 40 ms per frame, which is close to the estimated duration of a mental state, thus the rate postulated for the replacement. This rate is likely governed by a pacemaker and is relatively constant, but there are individuals with brain damage in whom events appear to be speeded up or slowed down. The acceleration and deceleration of events in pathological cases, as in the speed of a film projector, might reflect the frequency of replacement.

The conclusion of this line of thought is that states are not concatenations of stochastic images, but rather superimpositions on the remnants of predecessors that are embedded as memorial residues (Fig. 2). The graded decay of memory is its graded revival in conformance with the occurrent state.

Microgenetic Theory: Brain and Mind in Time. Fig. 2 The perception (P) at T_n is replaced at T_{n+1} by another perception (Q), which may resemble or differ from that at T_n . Perceptual stability depends on resemblance; change depends on difference. Within the perception (arrow, R), the mind/brain state at T_{n+2} revives T_{n+1} almost completely, such that the image of P at T_{n+2} is prior to the object (Q), and so on. Over a brief succession of mental states, P, Q, and R represent images of past perceptions revived to a decreasing extent in the oncoming present, and graded according to this revival. An eidetic image is a near-complete revival. A memory image is a vague recurrence at some psychic distance from a present object. At T_{n+3} , the series of images, P, Q, and R, form an order antecedent to the perception (S). The perception and memory of serial order depend on the perception developing out of memory. Serial order occurs within the present, but depends on succession for the layering of prior experience

Perception and Memory

In order to understand temporal order in perception, it is essential to understand the relation of perception to memory. An incomplete perception has the character of a memory. The decay of perception to short-term memory, which is dogma in psychology, is ordinarily conceived as the transfer of perception to a store that retains many of the physical features of the original stimulus. One problem with this theory is that it posits a trace that is degraded rather than one that is incompletely revived. The persistence of a dead past is the heart of the problem under study. As soon as an object is past, it no longer exists except as an echo in memory. The concept of perception as externalized memory, or forgetting as incomplete revival, puts the relation of memory and perception in a different light. On this view, the transition is *from* long-term *to* short-term memory *to* perception. The trajectory is the opposite of that assumed in psychology. A perception grows out of phases in memory uncovered as incomplete recurrences within a momentary actuality.

The claim here is that serial order in memory underlies serial order in perception. The recall of the order of past events, the so-called episodic memory, develops in a setting (some would say out of a store) that is simultaneous until it partitions. Whether memories are conceived as associative chains, circuits, networks, or configural potentials, whether they are localized or distributed, until they are activated they are dormant possibilities, not actualities or existents.

An event in memory is a potential for activation. The search for the memory *store*, *trace*, or *engram*, has a long and disappointing history. This is because the accuracy of recall is determined by the extent to which the phase-sequence of the initial encounter is revived. In what other sense can we even write of the existence or temporal location of the memory of a long-forgotten face that is suddenly revived in a chance encounter? *In what sense is a memory in the brain waiting to be activated?* On the other hand, how does something come into existence from nonexistence?

A difference between episodic memory, in which an event is ordered in time, and semantic memory, which is for knowledge rather than events, that is, for thought or language rather than perceptual experience, is that episodes become parts of categories, shifting their allegiance from occurrence to family resemblance. An event absorbed in a category, say by repeated exposure, loses its exceptionality. The recurrence strips the event of episodic context for the relational system of thought. If we travel a certain route only once, we may remember it as an event in time. If we travel the same route every day, it becomes part of our knowledge, and is recalled as a specific occasion only if something unexpected happens. The unexpected creates novelty by decontextualizing an event from a family of like-occurrences.

The temporal locus of a memory can be accurate in immediate recall, as in hearing and recalling a telephone number, but even here it is imperfect, and it

becomes more fallible over time. In amnesia, with shrinkage of past (and present) duration, the inability to revive events, even implicitly, fails to articulate and expand past duration. Empty duration collapses on itself.

Do events in episodic memory have markers or relational indices of the perceptual history of their occurrence? To assign a temporal tag to events, or postulate a scanning device (Lashley 1951), offers a mechanism as much in need of explanation as what it purports to explain. In citing the Würzburg school, Lashley implied a hierarchic system of unconscious schemata or constructs out of which serial order develops. His example of the final word of a lengthy sentence disambiguating the meaning evoked the problem of languages such as German, in which a sentence may not be understood until the final verb. This suggests that an episodic sequence in memory, that is, the temporal order of past events in a mental state, or the basis on which we say A came before B, and B before C *in the past*, is the same problem as the temporal order – A, B, C – of ongoing experience (Fig. 2).

William James (1890) was the first to postulate overlap in the succession of mental states, which he termed pulses of cognitive consciousness. If the overlap is for early phases, later ones will perish before the tip of the oncoming state arrives (Fig. 3). More precisely, the

early unconscious phases associated with long-term memory, character, and the self are revived in the oncoming state before the present state concludes. Since the epoch does not exist until the transition is complete, phases trailing in the derivation would recur in the forward edge of the overlap, indeed, these phases would be continuously modified by ensuing states before they become actual. This is a solution to the nonexistence of the unconscious, for while unconscious phases never exist, they are constantly being replaced before existence is possible, while conscious phases exist but are continuously perishing. The paradox is that the nonexistent survives and is perpetually transformed, while existents are novelties that do not mutate, for they are replaced as they arise.

Emotion

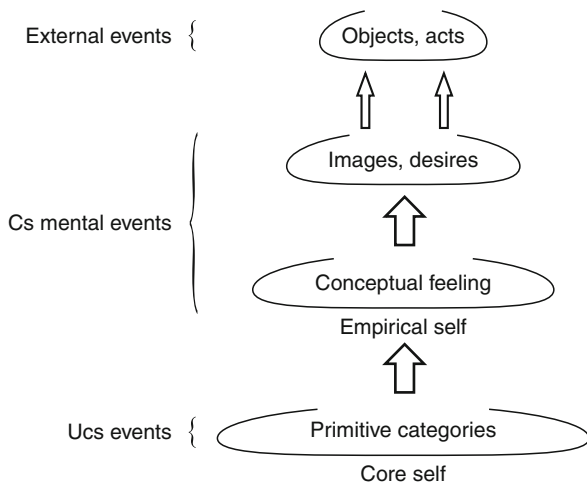

The problem of how emotion relates to thinking, the “heart” to the “head,” is a perennial one in psychology. Freud promoted the view that conflict arises within the psyche between that which one wants to do (drive, feeling) and that which one thinks or knows one should do (conscious thought, moral values). In many ways, one might even say, his “discovery” of the unconscious was an attempt to solve this old problem rather than to pose a new one. More recent psychological theories, by reducing the phenomenal field down to behavior or

Microgenetic Theory: Brain and Mind in Time. Fig. 3 Phases in short-term or working memory are generally revived in ensuing states in the order of their registration, that is, in relation to their resemblance to the oncoming state and, thus, their capacity for revival. Images closer to the current perception, that is, those in short-term memory that almost achieve re-perception, are most likely to be revived in the current state. The mind/brain state at T-1 is replaced by an overlapping state at T-2. The core of T-1 is overlapped at T-2 before T-1 terminates, that is, before the epoch exists. This explains the recurrence of early phases in T-1 associated with individuality, self, character, dispositions, long term, and experiential memory, and the “persistence” of core beliefs, values, and personality. Later phases perish on completion of the entire state to make way for novel perceptions. The reactivation of earlier phases by the overlapping state explains the sustained personhood behind succession. Early phases are ingredient across states, later ones are malleable to a greater extent as endogenous process is shaped by sensation

information processing have submerged or marginalized the problem of emotion, which is left to more psychotherapeutic theories and humanistic psychology. The latter, in turn, implicitly or explicitly view thinking as a barrier to (healthy) feeling, and we are back to where we started, with the valences reversed. Microgenetic theory – and this has been implicit in much of the foregoing discussion – places emotion almost literally in the center of the process by which drive articulates into objects and acts. The role of emotions is illustrated in Fig. 4.

First, there is pure subjectivity: a core self that wants to survive and strives to avoid pain and discomfort. Then, at the instinctual core, a core or unconscious (Ucs) self forms, and gradually there is opposition between the subject and the objectified portion of the subjective field, that is, a core subject at one pole, and at the other the object world, but the object world is not the world of outer events but the objectified segment of a subjective field. Then out of the Ucs core, a Cs self

Microgenetic Theory: Brain and Mind in Time. Fig. 4 The fine structure of the mental state. The core self is derived to the empirical self, which in turn leads to objects in the world. Corresponding with the object development there is a transition from drive through desire (emotion) to object value. The affect-charged category of the core self is the initial drive-representation. This is derived to conceptual feeling, then to object value. The transition from core to world is a continuum; the entire sequence constitutes a momentary mental state or an act of cognition

develops, with an articulation of inner and outer space. Inner space partitions to the Cs self and images. Outer space (i.e., the objectified part of the subject’s field) also undergoes partition to objects and their affective tone.

An emotion, from the microgenetic perspective, is an inner or subjective feeling, generated by the same process that deposits or actualizes an act or object, namely, the microtemporal process that leads from the archaic core of the mind/brain state to its outcome at the neocortical surface. The development of an object, action, or thought creates feeling within the developmental process. This process, along with the feeling that is its manifestation, constitutes the *becoming* of the object, while the final object, idea, or memory that “contains” the process leading to it is its *being*, that is, the epoch or category that enfolds the feeling. The process that generates a mental content, including perception, creates an internal feeling that with intense emotion can spill over to external physiology. The relation of feeling to the final object depends on the phase in the process that receives the major emphasis in the transition. The quality and the intensity of an emotion are determined by an emphasis at a given level and the context at a phase within the actualization process. According to the phase that is dominant for a given cognition, there is a different emotion and a different intensity. In general, enhancement at a deep or early phase gives strong emotions in relation to core needs, while enhancement at a terminal or surface phase gives emotions referred to the object, such as value or worth. At intermediate phases, one has emotions within the category of desire (want, wish, like, dislike, hope, fear, etc.). At an early phase, emotion discharges in the body. At an intermediate phase, the emotion, though internal, is directed to a pre-object or image. At a distal phase, the emotion is referred to *is ingredient* in the external object.

The Initial State

Drive arises through upper brainstem and diencephalon or hypothalamus to generate the initial manifestations of emotion. The foundational drive is for self-replication, that is, to sustain the life of the organism. The drive is organized about the bodily needs for the organism to “reproduce” itself. Hunger (thirst) is the feeling tone of drive, food (water) the object of the drive-category. The combination of drive as intense

feeling, hunger as drive expression, and food as the drive object constitutes the drive-representation. (Freud used this term for the activation of a trace to an idea by libidinal drive energy. Here, the drive and the category (feeling and pre-object) are a unitary entity.) Hunger, feeding, and satiation are felt within the body. The drive-representation is bound up with rhythms, with feeding cycles, nursing, orality, and the older axial motor system. Drive states have the characteristic of increasing pressure with arousal by gestalt-like patterns leading to consummation and satisfaction.

In the normal, waking human mind, the categorical primitives of drive may discharge in the body space or, more typically, are derived to successive phases (below). The drive-representation is ordinarily embedded as an initial phase in the mind/brain state, which goes on to the completion of the full microgenetic sequence leading to an object. The drive is at the core of every act of cognition, though the derivation to successive phases mitigates its impact except in extreme cases of need, for example, severe hunger or starvation.

Vectors of Action

Soon after birth, drive takes on a direction. With hunger, there is predation and food selection, which is the active or aggressive vector in the expression of the drive. The passive or defensive vector is in the avoidance of predators, that is, not being the food for other organisms. These two directions of behavior have been discussed extensively by other theorists, particularly Schneirla (1966), who claimed that approach and avoidance are the basic responses in all organisms. Even in paramecia, there is approach to a weak light and avoidance of a strong one. The concept was expanded by Denny-Brown (1967) in the interpretation of a range of motor and cognitive responses. For example, even the Parkinson's tremor was interpreted as a rhythmic alternation of positive/negative, or approach/avoidance behavior. This was also the basis of his description of pallidal and striatal syndromes, and was extended to psychological attitudes in the account of frontal and parietal lobes (and lesions) in relation to grasping (approach) and denial (withdrawal).

In this context the approach/avoidance dichotomy is thematic throughout the derivational structure of the emotions, and plays out in complex ways in the

pain/pleasure opposition in a variety of behaviors. With respect to the present theory, we argue that approach and avoidance or aggression and defense are less the manifestations of drive than vectors for drive implementation. On this view, hunger entails aggression in search of satisfaction and defense in the avoidance of other aggressors.

Sexual Drive

The next derivation of the instinctual drive-representation of hunger is to sexual drive. When this transition occurs is a topic of controversy. For the psychoanalysts, it is quite early. For others, it appears later. In any event, while the sexual drive appears at an early stage in cognition, it is not primary as Freud thought. Hunger sustains the individual, sexuality is for the species. First, the individual is replicated or recurs through the satisfaction of hunger; then the species is replicated or recurs through the satisfaction of the sexual drive. As with hunger, at the level of the drive, there is appetitive behavior that leads to arousal, capture, and satiation. The drive expression also involves the body axis, in rhythmic cycles of need, estrous, satisfaction and recurrence, and discharges in the axial motor system in the rhythmic movements of coitus.

The transition from hunger to sexuality is marked by the exploitation of attributes of the initial drive state, such as oral behavior and aggression to sexual activity. As with hunger, the approach/avoidance vectors determine the relation of capture, control, dominance, and acquisition to submission and dependency. Whereas hunger does not have a defined object – it is still at a pre-object phase – sexual drive narrows the drive-category to members of the other gender. For hunger, food is essential, while for sexuality, in humans, satisfaction can be postponed, diverted, or arrested. The implementation of the sexual drive is more optional than that of hunger, though there is a more limited range of satisfactions within the general category. This marks the delimitation of the force of hunger to the narrower scope of the sexual drive.

The phase of the drive-category is purposeful but non-intentional. There is no imaginary object, though the tracking of prey and mating appear to have some *proto-intentional* features. The inner feeling of a drive is that of an intense urge or pressure for discharge.

In human behavior, this urge or need is felt as a pressure for release, though it remains unconscious. In animals that are fully drive oriented, at late stages in mammalian evolution there appear the first marks of individuality or personality, expressed in shyness, aggression, tenderness, indifference, and other social behaviors. These marks of individuality signal the appearance, in the human mind/brain, of a core or unconscious self (see below).

The Transition to Desire

With learning and maturation, drive-categories and the core self become the repositories of the implicit or unconscious beliefs and values that make up individual character. These serve as dispositions or presuppositions that guide the core self as it partitions to the ensuing phase of the explicit or conscious self of desire. The transition from instinctual drive to conscious desire is from category to concept as objects resolve along with their affective tonalities. The pre-object categories of drive enfold the core self, entrained by implicit beliefs and values. The construct is organized within or about the axis of the body (with an orientation bias) to constitute a potential that underlies and gives rise to the multiplicity of part objects and refined feelings in desire.

As this subliminal construct is derived from the threshold of consciousness, it gives rise to the explicit self and conceptual feelings. As the core self develops, it comes to stand behind the drives, empowering them as Will while the conscious self that issues out of this background is the agent of desire. The Will is the forward surge that passes from need to want. Agency is the transition from the want of the conscious self to the valence of desire that is related to pain and pleasure, to like and dislike, to tastes and preferences.

The feeling of desire can weaken as it distributes over many objects or is indecisive for the one, and it strengthens as it concentrates in a single object or image. Desire is strongest for the image, which unlike the object that is settled in the world, can grow in thought. Desire is organized about, and may arise from, the conscious self, as drive does from the core. While drive has no inner space of pre-object growth, desire appears in the inner space of introspection and imagination. The intensity of desire increases with a reduction in its range of potential objects, as

a failure of one image to resolve with clarity creates uncertainty and an inability to go forward. We all see people who think too much on what is possible and are paralyzed in action, while others go directly into action with little reflection. These extremes find pleasure at a temperate zone where action is postponed and one object or goal is savored.

The core self of Will, drive, and need goes out to an object without deliberation, while the conscious self of desire can choose which object to pursue (avoid, etc.). Desire (fear, wish, etc.) is the bridge of the intentional from the conscious self to the object (act, image, thought, etc.). With desire, there is the choice and possibility of inaction. Desire mitigates the urge of drive in the delay before action, and the optional character of its objects, except for a state of passionate longing for one object as in love. Moreover, as drive is felt in the body, desire is felt in the mind. This degree of separation from bodily discharge is transitional to the ensuing phase (below) of the feeling of value out there in the world as the object detaches.

The tree-like structure of the emotions leads from the root and trunk of the core, to desire and its innumerable branching to the leaves of value that populate the world of perception. The shift from necessity to possibility and choice, then to externality and independence, is replicated at each moment as the mental state recurs. At one moment, the emphasis may be on the proximal segment of the transition, and need is foremost. At another moment, the distal segment is emphatic with attention and interest on objects in the world. Desire is the transitional segment that adapts the needs of the body to the exigencies of the world. The transition also carries a different feeling tone at each phase, from the drive-categories through the object concept to the object itself, as the process leads from generality through choice to definiteness.

The end point of the object development is, naturally, an object or action in the derivation of a concept to an adaptive resolution. As the object migrates outward, the antecedent drive-categories and conceptual feelings remain embedded in the external object as its identification, meaning, and value. The object is the surface appearance of a momentary epoch – the mind/brain state – that includes the precursor phases as part of its structure.

Self and Consciousness

As microgenetic theory has evolved and matured as a psychological theory, the point of emphasis has shifted from developmental and acquired pathologies to the nature of conscious experience and the self. In the heyday of behaviorism, the rejection of psychoanalysis turned the attention of academic psychology in a different direction, and such problems as “consciousness” or “self” were simply dropped. Cognitivism arose as a revolt against behaviorism but has implicitly followed the lead of its predecessor by, at least in its early stages, relegating consciousness, the unconscious, emotion, and the self to the margins of scientific discourse. It has become increasingly apparent, however, that a psychology that cannot account for awareness, consciousness, the feeling of being oneself or possessing an identity has failed to provide what one expects from psychological theory.

For the present purposes, *awareness* is defined as the *relation of a subject to external objects and bodily states*. A *subject* is the subjective whole of the organism, excluding its external portion. An *object* is the external portion of that whole, perceived as outside the organism, a perceived event. An *entity* is a physical event postulated to exist outside perception. The *external or objective world* is defined as a segment of the subjective that has objectified. In contrast, the *physical world* is the world of physical entities.

A subject is antecedent to the object. The *relation* is the unidirectional process of becoming through that subject and then object actualize. *Awareness* is the waking state of small children, not unknown to animals and the foundation of *consciousness*. One can have awareness without consciousness, since the former, from an evolutionary, maturational, and microgenetic standpoint is the earlier state. But one cannot have consciousness without an implicit state of awareness, since consciousness arises on this foundation.

Conscious perception differs from object-awareness. In the latter, the subject-as-a-whole is aware of external objects. In the former, a self is conscious of objects. The self is a segment in the stream of outgoing subjectivity, aware of its own priority and subjectivity. *Consciousness, then, consists in the relation of a self to inner and outer objects*. (The original meaning of consciousness was self-consciousness Ward 1933. Locke wrote, “consciousness is the perception of what passes in a man’s

own mind” [Essay II, I, 19].) The relation arises in the process through which images and objects objectify. The relation of the self to inner objects is introspection or reflection. The relation of the self to outer objects is exteroception or perception.

A perception by a subject differs from a perception by a self, even if the “same” object is perceived. Objects carve out the boundary of a subject. There are no inner objects, only different states of subjectivity, for example, anger, hunger, etc. The subject is what is left after its world is subtracted. In contrast, the self is buffered from the world by a subjective field. The self withdraws into this field in reflection, or remembrance. This field can be a private hell, or it can offer respite and sanctuary. Because the self is in relation to its own subjectivity, it does not have the immediacy of action that occurs in a subject. The self, along with images, thoughts, feelings, etc., is most emphatic when a delay in behavior dilates the automaticity of direct awareness; otherwise, all human behavior would be reflex.

An image or idea is a segment *en route* to a perception or an utterance. In a rapid traversal, action and perception dominate consciousness. If I am not thinking of anything in particular, I am still conscious of the world as the circumference of my point of view. When a thought or image comes into prominence as the dominant focus of attention, external space recedes to an ambient field that grounds the inner figural content. (Consistent with Cobb and Sherburne 1973, who wrote, “conscious attention shades off by degrees into unconscious inattention, the latter constituting by far the larger part of the experience of the dominant occasion . . . (and that) backgrounds that are vaguely discriminated consciously have as their backgrounds others that are completely unconscious but which are also capable of so developing as to become conscious.”)

We “think up” the world we perceive. This thought-up world is a model of an inferred physical world that impacts on the brain. The accuracy of our model of the world can be tested, but it is still a model. Walking, touching, chasing are kinds of tests. The model of reality depends on the type of organism and the adequacy of sensory data. The world may be thought-up, but without the constraints of sensation, thought alone cannot sustain the world. The rationality of thought depends on its proximity to the world, that is, to the accuracy of the model. The approximation to an

objective world determines the content of the state, for example, daydream, reverie, fantasy, hallucination, delusion, etc., phenomena that actualize at different points in the object formation. Without an objective world, thinking is dreaming; psychosis is an intermediate phase.

The Intuition of the Self

We all have a sense of our self as the center of gravity of character, along with a feeling of its continuity and repeatability over time. We do not feel that the existence of a self is problematic, or that it is an illusion or mix of momentary impressions. The self cannot be isolated on introspection, yet it grows and endures as a relatively stable entity over all the changing acts, thoughts, and desires of a life. While we have many modes of self-expression according to the occasion, each momentary self is felt to be a manifestation of the one genuine self. The inability to identify or define the self as it fluctuates with the situation does not persuade us of an absence or lack of personal identity. Experience is “taken in” and responded to by a self that stands behind as observer or agent. A feeling of identity, individuality, or personhood, binds successive states of consciousness together, or rather, the feeling of self-identity is the ground for the succession, providing unity to perceptions in the observer’s field. According to the modality, the self feels “situated” at the center of its experience, as in pain, or at the circumference, as in vision. The visual world is not a jumble of objects but a coherent picture. This is less so in dream, but then, the dream-self differs from that of wakefulness. The self is host and source of the varied thoughts and acts of a life, and except for illness, in which it is threatened with loss, has a development that is more or less continuous.

The self’s experiences are not felt as *impersonal* events that occur at the same time or in the same brain, in each waking moment and over intervals, such as sleep, intoxication, or altered states. Events in the mind and acts in the world, as well as external objects, are felt as *my events*, or as happening *in or to me*. Even events that are distinct from the self impact in a way that has consistency and organization. We recognize the randomness of events and, to an extent, their unpredictability, but at the same time we acknowledge a lawfulness and causal order, even if it is obscured by

contingency. We say that the self, through interpretation, gives meaning to randomness. However, meaning is not applied to events that impinge from outside; events arise through planes of meaning-laden images. All objects arise in this way, some felt as part of the observer, others as its possessions, still others as extrinsic. Thought is an activity that issues from the self, even as thought thinks up the thinker. The same process that lays down the core and empirical self continues into thought, act, and object, the latter being a part of the self that thinks them up.

Inner events and outer perceptions are generated with the self of that occasion. This does not mean that a perception of a green object evokes a green self, though severe pain is identified with a self in which pain is pervasive. In perceiving an object, the self, indeed the entire perception, is generated with the object. Some phenomena seem to be produced by a self that voluntarily summons them up, others confront the self or coalesce with it. A feared or loved object can be identified with a fearful or loving self. With intense feeling in pain, fear, panic, love, with a relaxation of boundaries, the self can become one with its perceptions. Feeling may so dominate a self that it is replaced by the object that seems to induce it. Severe pain fills the mind to the point that other objects are scarcely noticed. Intense fear or love focuses on the object or situation at the expense of other feelings, thoughts, or objects in the field. Feeling flows out of the self to concentrate in the object, replacing other lines of development. When feeling overwhelms the partition of the core to the empirical self, the mental state may recede to foundational drive-categories.

All acts and objects develop out of a self that is laid down prior to conscious action and perception. The priority is the antecedence of earlier to later in the mental state. Objects are necessary for the self to actualize; they depend on the self as their source. Equally, the self degrades when objects disappear. We assume, falsely, that the self, as observer, is an adjunct to an object, or that perception is an accessory to the self. This entails that the self and its objects are separate entities with discrete brain loci or networks. To study perception, language, or action without including the observer (or agent) leaves out the essential aspect, namely, the guiding or organizing substrate and origin.

For a self to attend to its derivations is quite natural and remote from attending to itself, which requires the agent to be the object of the same mental state. This turns the initial phase of the mental state into its terminus, or involves a regress from distal to proximal that occurs chiefly in meditative or mystical states, in which the self is more intuited than examined. The bundle of percepts accessible to Hume's intuition is a manifestation of the earliest phase in partition. The self that Hume could not describe is a category prior to the images that were accessible to his introspection. (An attempt to describe an imageless phase in thought was the program of the Würzburg school of psychology.) Moreover, such inner percepts or images are not random assortments; they assume a direction and coherence by virtue of the self that precedes them. Deeper than its implementations, the self fractionates to images that then pass (are transformed) to acts and objects.

The self feels it is an agent to objects that are its own ramifications, even an "owner" or possessor at the center of a personal universe. Some states of mind and body are felt to *belong* to a self that suffers or enjoys them. There is a powerful sense that all personal images, even occasions in the world, belong *ab origo* to the self, even if they are shared with others. The sense of ownership – my house, my car – expresses the value that flows distally into inanimate objects as an accrual through an economic vetting of what flows naturally into animate ones, such as in a person that is loved. To attempt to possess an object is to affirm its belongingness. The impression of a self as the owner of acts and images is reinforced in the variance of the world and mental contents in the face of the self's relative stability.

In a normal brain, all mental phenomena or bodily events are experienced as belonging to the self, a dependency seen in pathological disorders. In psychosis, thought-possession and delusion occur in an individual frightened by and subordinate to his own image-productions. Thoughts seem to come from outside, like alien intrusions, or they objectify, like objects, while objects become thought-like. The once-sharp transition from concept to object, or mind to world, is indistinct. The unity of self, image, and object is on display, in that change in one entails change in the other. Such disorders are not to be dismissed as meaningless perturbations. The inner relations of phases in

mental process are observed in the terror that is experienced when the illusory separation of mind and world is ruptured.

The sense of ownership is confirmed when the self feels detached from its own thoughts. The voices that speak to the schizophrenic, the thoughts that come to him from outside, the objects that take on psychic properties all reinforce the observation that inner and outer are outcomes of psychic process. In phantom limb, as in some forms of body agnosia, or stimulation of brain areas for movement and vocalization, bodily and psychic events may seem detached. Limb movement on excitation of motor cortex does not have volitional feeling. We have some idea of this experience from nocturnal jerks of the legs, when we are uncertain if movement is voluntary or spontaneous, that is, self generated or extrinsically induced. Such movements are like objects in relation to the self. The intermediate position of such phenomena – clearly endogenous but neither image nor object – accounts for their unreality, or the uncertainty of their psychic origin.

Dreams can be experienced in this way, as images inserted into the mind with the self a spectator. The passivity to dream and to certain forms of imagery results from the lack of self-image separation due to incomplete actualization and a loss of volitional feeling. The sense of agency is the link from self to image in visual and auditory imagery, as in the verbal imagery of inner speech. The loss of agency in dream or hallucination deprives the self of the feeling that it generates the image. The self is then assaulted or possessed by the image instead of producing it. The agency of inner speech or the *preverbitum* is transformed outward into a hallucinatory voice. A subtle interplay of such attitudes and feelings occurs in relation to image type and degree of objectification. In the controversial state of multiple personality, which is probably a factitious condition, personalities are neither distinct nor uncoupled from the core self.

There are two categories of the self, a deep core or unconscious self aligned with values, implicit beliefs and character, and a liminal, conscious, or empirical self that adapts to momentary needs and future expectations. One hears a person say, "I was not myself," by which is meant the "I" or ego of a given situation did not reflect the underlying beliefs and values of the "me" or the core. That many search for the genuine self or

sense of identity speaks to the intuition of an abiding core that underlies its varied manifestations. The distinction is embodied in the unconscious and timeless self of the “me,” and the conditional or temporal self of the “I,” one constant and authentic, another transient and adaptive; one that endures changing events, another, hostage to the passing scene. Yet, there is no accepted account of core and empirical self, how they develop, their relation to mind or brain, and the basis of identity.

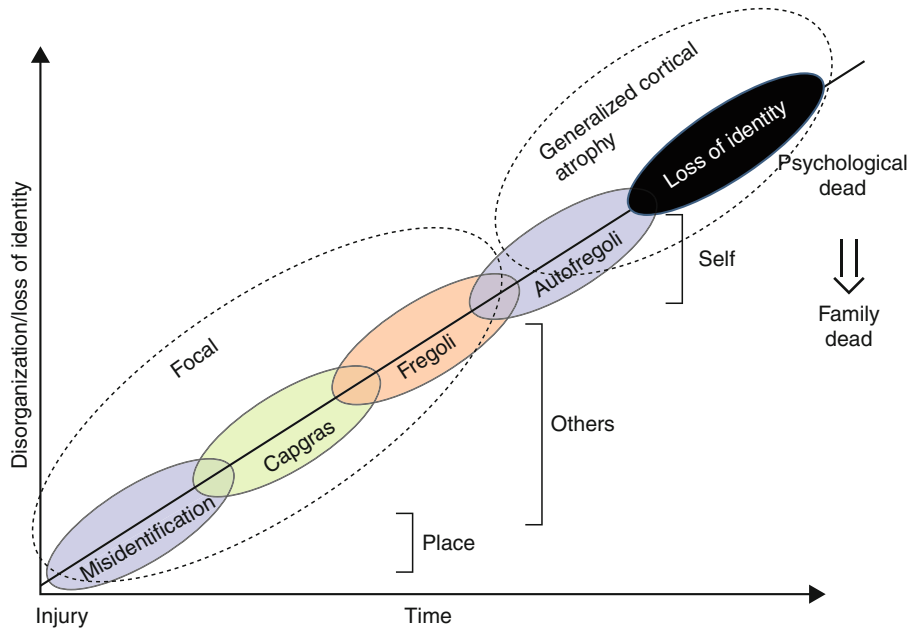

A significant link between the early neuropsychological studies inspired by microgenetic theory and the further development of the theory in psychology and the philosophy of the mind can be found in a recent paper written by the first and second authors of the present study (Pachalska and MacQueen 2002). Mainstream psychological theory, under the influence of cognitivism, tends to see language as primarily, or even exclusively, a system for processing information that is presumably created elsewhere, either within the organism (the “cognitive module,” or perhaps a group of modules responsible for mentation) or outside it, in the form of external stimuli. This approach relegates language to a distinctly ancillary role in relation to other mental processes and functions. In the microgenetic approach, however, language, cognition, and feeling are all closely intertwined in the upward-and-outward flow of thinking (MacQueen 2008).

The system of personal pronouns used in European (and many other) languages is the trace of a psychological process, whereby the child in the primordial symbiosis experiences world and self as an indivisible US, which later breaks down into the I-Thou dyad. It is at this point that consciousness can be said to emerge. When the child becomes aware that there are other centers of experience outside the I-Thou dyad, the third person emerges as a way of referring to that which is absent, and, later, to that which is present but not capable of entering into a dyad (N.B. the child typically personalizes and animates his toys at an early stage, and sees an object on which he has banged his head as having attacked him, i.e., he attributes agency to inanimate objects, thus making them “Thou’s.”). When the ability to manipulate grammatical persons breaks down in aphasia, then, what we are hearing is not merely or essentially the loss of a certain

morphological skill, but primarily the breakdown of a mental world broken down into discrete persons. Brain-damaged individuals frequently exhibit an inability to use grammatical persons correctly, which can be shown to reflect a loss of personal identity – that is, the first-person-singular pronoun is incorrectly used because the “I” no longer has a clear referent (Pachalska 2009). This symptom can easily be interpreted as an inability to re-actualize, at the moment of speaking, the development road from the symbiotic US, through the I-Thou dyad, to the fully developed world of three grammatical persons and two numbers. What surfaces, then, is the substrate, a dream-like/child-like state of consciousness in which the boundaries between inner and outer, self and other, animate and inanimate are blurred or nonexistent.

It follows from the foregoing that the problem of personality and the self-concept can be approached from the standpoint of pathology, in terms of patterns of transition from one symptom-complex to another in the same individual, and not as isolated defects. Disorders of the self cannot be localized to separate brain areas, but constitute a spectrum in the process through which personality is preserved and sustained. Clinical observation (Pachalska et al. 2010) has provided convincing evidence that the stability and identity of the self depends, not on the association of discrete components but on a recurrent process that maintains the self-concept over time, in aging, through sleep, and in the course of changing life events (see also Pachalska et al. 2010). This is illustrated by Fig. 5.

A brain-damaged patient may initially be unable to identify familiar persons (prosopagnosia), and in rare instances may not recognize him or herself in a mirror (the “mirror sign”). Over time, the ability to associate another person’s name and face may return, along with onset of the Capgras syndrome, that is, the delusional belief that a person with whom the patient is highly familiar (often a spouse) has been replaced by a double, who, though closely resembling the person, is merely acting the role. The patient will claim to be able to discern subtle differences that supposedly distinguish the alleged double from the actual person. Instances of a kind of self-oriented Capgras are reported in clinical studies, in which case the patient says or implies that he himself is a double, that he is not “himself” in a quite literal sense (Pachalska 2007).

Microgenetic Theory: Brain and Mind in Time. Fig. 5 The transition from misidentification through Capgras to auto-Fregoli and Cotard's delusion (psychological death) (Pachalska et al. 2010)

The Capgras syndrome may give way to the Fregoli syndrome, in which the patient is convinced that a complete stranger is someone he knows very well. In Capgras, a familiar is misidentified as another (usually with malevolent intent); in Fregoli, a stranger is misidentified as a familiar. The transition from Capgras to Fregoli may further evolve into “auto-Fregoli” symptoms in which the patient appropriates an identity that belongs to someone else (a casual acquaintance, a complete stranger). This is an episodic occurrence that may pass within a few hours or last for several days. Though phenomenologically distinct, the Capgras and the Fregoli syndromes lie on a single continuum of deterioration, which begins with Capgras, evolves into Fregoli, and comes near to close with auto-Fregoli symptoms (D. T. Bradford 2009, How the symptom evolves in neuropsychiatry, personal communication). The three stages represent, in reverse fashion, the microgenesis of self, which follows a path of increasing differentiation from the subliminal “core,” to a partially subliminal “self-concept,” to an “empirical self” actively engaged with others and the greater world.

In a case studied by the first and second authors of the present study (Pachalska et al. 2010), the

“auto-Fregoli” at some point gave way to a Cotard delusion – that is, the patient began to maintain that he was dead (this point is marked on Fig. 5 as “psychologically dead”). At least one other case of the Cotard delusion succeeding Capgras syndrome has been reported (Wright et al. 1993), in which the authors suggest that patients with Capgras syndrome project changes in themselves onto others, while in the Cotard delusion, the patient correctly attributes the change to him- or herself, but exaggerates its extent. The final stage in this progression, then, is a complete loss of identity, as most commonly seen in advanced stages of neurodegenerative diseases, such as (but not limited to) Alzheimer’s disease. We usually say then (colloquially) that “his mind is gone,” though few can be found who can give a coherent explanation of exactly what that expression means. Even if we find it inexact, naïve, or even offensive, the feeling that underlies it is clear enough: there no longer seems to be a self within this body, with which we could enter into an I-Thou relation. Thus, the ultimate psychic consequence of memory loss is not merely the loss of a certain kind or amount of information, but the disintegration of the self.

Not every patient, of course, exhibits all the syndromes in Fig. 5: a given patient may emerge from

pathology at any stage, or may persist in a given stage without moving on to the next. (Two patients described by the first author of the present study Pachalska et al. 2010 passed through most of the stages described in Fig. 5, and it is possible to see the whole sequence in the deterioration of self in the course of the middle and late stages of Alzheimer's disease.) The important point here for the present purposes is the sequence of qualitatively different stages by which one syndrome becomes another, differing from the previous one but reflecting the same process and leading in the same general direction. This "general direction," in turn, is clearly related to the development of the self in ontogeny: as the outer layers are destroyed or disorganized, or decay, the nature of the underlying layers becomes manifest, no longer buried under the products of later stages in the microgenesis of the self. This can be seen as the "microgenetic variant" of the regression hypothesis mentioned above. Although the regression hypothesis in its original form is untenable and has been rightly marginalized, the phenomenon that both Jackson and Jacobsen observed does exist, and can be explained, if microgenetic theory is applied.

Further Theoretical Implications

Microgenesis, like ontogeny and evolution, is a theory on the origins of present events, not a predictive theory as to future outcomes. The origins of events – whether over evolutionary, maturational, or psychological time – are inferred from present occurrences. In this respect, they deviate from the scientific paradigm in which effects are postulated from causes. This does not necessarily make genetic theory noncausal or nonscientific. The prediction of effect from cause is not logically so different from the retrodiction of cause from effect, though there are important psychological differences. In the first instance, the future effect does not yet, and may never, exist; in the latter, the putative cause is past; it has occurred but no longer exists. Predictive theories branch outward from causes to multiple possible effects, whereas in retrodictive theory causes converge to the present effect.

Predictive theories tend to be tightly controlled and limited to immediate data, as in a scientific experiment. One can forecast a future vacation, or predict that a strong hurricane will cause flooding on the coast, but the temporal window must be relatively narrow

for one to predict with accuracy. The greater the duration between cause and effect, the weaker the cause and/or the more contingent the effect. In contrast, retrodictive theories look to a more distant past in which an attempt is made to isolate a specific event or a more complex prehistory. The effect in question, that is, the present state, is the outcome of a convergence of prior causes – accidents, contingencies – distributed over a greater duration. There is also the question of how and why a particular state developed out of past states, especially with a lengthy series of intervening events. For these reasons, because complexity devolves to specificity, or proclivity becomes actuality, the past of a retrospective theory is often conceived less as a cause than as a potential that gives one of a multiplicity of possible actualities.

The shift to a theory in which a specific cause has many possible antecedents to one in which a specific cause has many possible consequents is the shift from a hermeneutic of coherence to a science of correspondence. The transition from potential and actual to cause and effect collapses the past into the present as possibility becomes fact. The specification of potential to a given actuality replaces the branching of a given cause to some future possibility. Put differently, the shift from unknown possibility to known fact in retrodictive theories is the opposite of predictive ones that go from known fact to unknown but hypothesized possibility. In contrast to ordinary causation, where a cause causes an effect, in retrospective theories the rumination on duration instead of immediate consequence conceives an effect not as the result of a cause but its replacement over a series of intervening states. We see this strikingly in ontogeny, where an organism changes each moment imperceptibly, causing itself to become the next moment in its existence. The same phenomenon appears in the replacement of mental states. The causal factor in genetic theories is that of *causal persistence*, that is, replacement, which is not a linear sequence of cause-effect pairs.

First, we will consider some further aspects of the relation of causality and potential that impact both fields of inquiry with the hope that deeper study will lead to a more precise formulation of basic principles that can ground a theory of becoming in psyche and nature, one that if not scientific in the usual sense, is concordant with the data of experience. However,

if process philosophy is to truly be an “adventure of ideas,” it must invite the novelty that was the creed of its founder even if this entails a revision of principles that have become almost axiomatic. It should also, where it can, seek empirical grounds without succumbing to the simplistic agenda of mechanical psychology. On the other hand, genetic psychology is a diverse field with little cross-talk among its members. The field is in some disarray and lacks an essential, that is, unitary, philosophical framework.

Subjectivist claims in philosophy can begin with either physical or psychological universals. Whitehead (1929/1978) approached psychology from the world of physics. Microgenesis began with psychology and reached a limit in fractal mathematics (Paul MacLean; in Hanlon 1990). A subjectivity of the inorganic that is continuous with human mind is a theory of mind continuous with physical nature. A coherent philosophy that begins with nature or human mind builds on the theory of cognition or nature, whether mechanical or subjective. A “mechanical” nature leaves quantum features unexplained, not to mention psychic states, while subjectivism grapples with the theory of substance and causation. The path that leads from nature to mind can import causal objects to the mind, or export duration and potential to nature. The appeal to process thinking of a genetic psychology rooted in subjectivity is that patterns in the actualization or becoming of the mental state can be mapped to features in the concrescence of physical entities that would otherwise be opaque to causal science.

Causation is accepted for the most part unquestioningly as the basis of all scientific work. The causal relation inheres in the objects of the science, as well as in their relation to the observer. For process theory, causation is a fundamental difficulty that must be confronted, no less for philosophical speculation than for genetic psychology. The growth of the child cannot be easily formulated in a causal discourse; mechanisms come into play at successive stages or are occluded or vanish as new ones appear. In the growth process, the child gradually becomes an adult by continuously replacing itself with a novel version of what it was a moment earlier. The causality most appropriate to the genetic model is that of “causal persistence,” defined as replication with minimal novelty between replicates.

Whitehead’s understanding of causality is relevant here. In a human psyche, each momentary occasion prehends or absorbs preceding occasions. What a person becomes moment by moment is largely conformal to the personal past. However, the new occasion also prehends other events in the ever-changing environment and integrates these prehensions with those of the personal past.

Causation

The two basic ways that causation is understood are object and agent causation. The doctrine of cause and effect between objects that is fundamental to much of science, for example, billiard-ball causation, has given the philosophy of mechanism. The causal interaction of solids in the world is imported to the mind in the interaction of brain areas or mental components. This notion of causality is deeply rooted and felt to be intuitively true but it has proved difficult to pin down.

One strategy for resolving the difference between object and agent causation entails a distinction of acts of will as “eventuations” or conclusions of thought that are preceded by deliberation, dissociated from prior states, and discontinuous with a causal continuation in nature. Rescher (2006) writes that “acts of will are mental eventuations that mark the completion of a process of which they do not constitute a part. . .,” though the force of the distinction is mitigated in that it is labeled as conceptual, not ontological. The approach uses object causation as a model for agent causation, even in distinguishing the latter as leading to a stoppage independent of its predecessors and not part of an ensuing series. However, a different picture emerges if instead of taking object causation as a model of the mind one begins with a theory of agency as foundational. On this view, physical events are like mental states in that they have a subjective (intrinsic) aim to completion, with the final effectuation conceived as internal to the process through which it unfolds. The “eventuation” is not, as Rescher would have it, the end product of a production line. An act that is the outcome of a period of deliberation is one in a series of mind/brain states that a self or observer takes to be a termination. Since events have no clear boundaries and states overlap, the point of termination is arbitrary.

One can say the froth of a fountain cannot exist, or can only exist artificially, without the surge of which it

is part. The ending is part of the story, the last word part of a sentence, and that part of a thought. Closing the cover is an act of cognition just as reading the last word. Every act or object – and every physical entity – is part of the whole of its development. This is not so clear when events are stretched out over time such as positing that deliberation is separate from the decision it leads to. But each outcome has a genetic undersurface, states develop and are replaced. An end point does not differ from a prior state, since every entity is an epoch replaced by another epoch, including inaction and silence. What is fractured is a logical, not ontological sequence. Physical events or mental eventuations are surface appearances of a microtemporal process, phase-transitions of internal relations of which outcomes are superficial marks.

Consistent with this view, the psychic precursor of (the feeling of) object causation is an ingrained sense of agent causation that precedes the feeling of transition in object causation. The agent causation that embraces the microtemporal structure of the mind/brain state should be the basis of a theory of object causation, not the reverse. The infant's control of its limbs and action on objects gives the feeling of causal power. The infant seizes a moving object or one that is displaced. To follow a trajectory is to anticipate. The primitive motion is to the future. The sense of causal power in the infant who reaches for a rubber ball is perhaps no more than the behavior of a cat that reaches for a rolling ball of wool, but with the individuation of the self, consciousness of this power develops to awareness of agency, or self-initiation, with its roots in organic process. The *necessity* in causation (Hume) that arises in infancy recurs as a psychic residue that informs and empowers agency in mature cognition. The grasp and control of an object that is the seed of agency is less a projection of human thought onto nature than a delimitation of unconscious potential into conscious actuality, just as indeterminateness in physical nature resolves into material fact. The momentary genesis of an act of cognition – or genetic process in general – is a model for the actualization of a physical entity. Mental state and physical entity develop over and actualize a temporal extensibility or minimal duration of existence.

The importation of simple causation to the mind is a classical instance of explaining complexity as

a compounding of the simple. This is, for example, the strategy of those who argue that mind is a collection of reflex operations, basically cause-effect pairs. But one does not easily go from the simple to the complex. The simple is never as simple as it seems, and the assumed simplicity obscures the process through which complexity develops. A reconstruction of the complex after it has been reduced to its elements – or from elements postulated to be constituent – is usually not possible. A pile of bricks is no more or less complex than one brick, though an artwork of a pile of bricks, or a wall, is a conceptual pattern distinct from an arbitrary assortment. The artwork or wall is a unitary whole in which separate elements are bound together contextually by the intrinsic relations of the mental state. The assumption of elements in the psyche bound by external relations in the mind as in the world generates and severs those elements in the distinction of cause and effect, a strategy that cannot regain the complexity lost when the elements were dismembered. In revealing the fundamental properties of the stage out of which it evolved, the complex better informs a theory of the simple than the reverse.

Further individuation of self and object leads to greater autonomy and a feeling of a self opposed to inner and outer contents. The direction of this relation promotes intentional feeling. Purposefulness achieves its aim when it terminates. The aim, not given beforehand, incorporates the potential it actualizes. As feeling takes on direction, what is implicit in drive becomes explicit in desire. In human thought, the derivation of affects and ideas out of conceptual feeling gives intention its direction. The immediate action of simple purposefulness transforms to conscious intention when an idea individuates in the self, and the external world abides in the background. The interposition of conscious ideas, verbal images, and feelings when the outgoing stream is abbreviated is obligatory for a conscious self. Unthinking action on objects involves a subject-object relation, not a self. Intention is awareness of goal or the “aboutness” of this direction, an attempt to mark off a closure that was satisfied in the immediacy of direct action. In sum, agency in organism is the basis of object causation. Intentionality in organism is the basis of a theory of (conscious, but incipient) agent causation. In all these matters, natural process insinuates itself into human thought.

As the self individuates, it perceives a world of particulars distributed in space and time, and interprets the particulars as a succession of causes and effects when, in fact, temporal order individuates in consciousness from unconscious simultaneity. The distinction of cause and effect in object causation complements the distinction of self and world in agent causation. Each mode of thought reflects a different metaphysic, one of mechanism, the other, of organism. In the latter, objects are categories of “events-with-meanings,” in the former, demarcations to which meanings are added. It is an error to dismiss the latter as prescientific, for it displays psychic qualities not evident to scientific thought.

Consider Piaget’s demonstration to Einstein that relativity theory is closer to the common space-time of young children rather than the separate space and time of the adult. Similarly, the felt curvature of dream space that differs from the open expanse and extension of waking perception foreshadows theory in modern physics.

The irrational, even mystical, has a significance in its proximity to organism. The need for an awareness of the unconscious structure of mature theory was expressed by Dewey (1926, p. 317): “as long as our own fundamental psycho-physical attitudes in dealing with external things are subconscious, or attention going only to the relations of external things, so long will our perception of the external situations be subject at its root to perversion and vitiation.”

Nevertheless, there are acute difficulties with both object and agent causation; in the former, the demarcation of cause, the doctrine of external relations, the transition to effect, or the role of contingency and accidental causation. These problems resist solution because they are analyzed by the very methods of the theory they subtend. A theory that cannot explain its core assumptions is vacuous, not merely incomplete. Persistent incoherence is close to unacknowledged refutation. Similar problems bedevil agent causation but here contingency embraces freedom, and the relation of cause and effect is still more obscure.

Object causation and agent causation give priority to the cause, whether going from cause to effect, or inferring effect from cause. In the conventional account, specific causes bring about specific effects. In medical science, a certain disease is caused by virus X,

or by X in combination with gene Y, or by X and Y with a preexisting constitution Z. The specificity of the cause is taken as equivalent to the specificity of the effect, especially if one begins with the effect and moves backward to the cause, since the effect is evident and can be identified. Another way of saying this is that an actual object, an actuality, entails a cause, and that even if the cause is multifactorial (XYZ in the above example), its components are as discrete as the effect, so that the transition from cause to effect is like that from one actual object to another.

The Actualization of Potential

When potential is thought of as the “cause” of the actual, no such precision of antecedent cause is forthcoming. This way of thinking entails that definite effects are not the outcomes of discriminable causes. Definiteness is in the effect, not the cause. In the transition from potential to actual, the presumed specificity of a present object is exchanged for the uncertainty of the potential in past ones. The efficacy of potential coincides with the priority of whole to part, or on a larger scale, in the relation of community to individual or of nature to individual organism. However, the doctrine of potential has its own difficulties, chiefly that potential is unspecifiable. In the mental life, potential corresponds (after Dewey) to the fringe of feeling-qualities, premonitions, and inchoate meanings – the stuff of intuitions – that guide the selection of acts. Those processes in the natural world that are the antecedents of these unconscious phenomena are no less inscrutable. For Whitehead, the “cause” as the real potential for the new actual occasion is the entire “actual world.” But cause in this sense does not determine what the effect will be, since the effect is also *causa sui*.

Genetic psychology is a subjective record of individual self-realization generalized to and across others. For genetic psychology, the past is revived in the present, which is felt as the outward crust of an inward history. The future is not what the present moves into, it is another present that the past deposits. There is a natural inclusion of the past, which makes up the major portion of the present, a past that is as important for the present as what the present holds for the future. An orientation to the past gives an inward focus on genuine change as reflection and retrospection take

precedence over anticipation and prediction. Each approach involves an implicit theory of (subjective) time. The excavation of the antecedents of known effects, or the consequents of known causes, takes the present as an actual datum in relation to an anterior or posterior extension. There is an infinite regress in the uncovering of earlier causes that are more like possibilities or probabilities than discrete occurrences. The retrospective approach is linked to the *transition from potential to actual*, the prospective approach to a *transition from cause to effect*.

Effects are the concrete facts we actually know, while causes are their anticipations or the potentials behind them inferred or vaguely sensed. The actual is describable, but its antecedents are uncertain unless viewed as collections of outcomes. If an actuality were the cause of a subsequent actuality as in linear or chain theory, it would be ingredient in the potential for the next round of actualization.

In some forms of process thought, such as for Whitehead, an actual object, on perishing, becomes part of the real potentiality for the next round of actualization. The world at state B actualizes out of the world at state A. This view entails that the actual occasion in one moment – with all other actualities at that moment – constitutes a potential for the ensuing occasion. On this interpretation, potential consists of perishing actualities and the actual has causal efficacy. A potential comprised of perished actualities gives new actualities that integrate elements of real potentiality in diverse ways. If the potential for a new occasion were exhausted by the real potential provided by past occasions, the novelty in new actualities would be limited to the reordering of elements in the past. Whitehead did not think this accounted for novelty in the world. In his view, every entity actualizes by its own “decision” out of the inclusive potentiality, which includes pure potentials not derived from its actual world.

A past entity can be considered a causal point. Microgenesis is a theory of becoming in which the final phase is not prepackaged or forecast at its onset. Actualities do not provide surface templates for ensuing actualizations but are cleared away (perish) for novel objects, while the entire process traversed in the actualization, but especially the initial segments, provides the ground for the next traversal. I look to one side and see a house, then the other side and see a tree.

The actual object has changed. The perception must be erased so a novel one can ensue. What recurs is the conceptual and experiential ground common to the series of actualities. This ground is part of the potential of the state as of the actuality. Since the scope of potential is wider than that of the actual, the actual object as an end point, that is, the *world as perceived*, delimits possibility and cannot form a comprehensive ground for the ensuing potential.

A consideration of the causal role of constraints on the actualization or concrescence of the mental state suggests the need for a different way to think about potential and actual in relation to cause and effect, namely, that the former are *phases in a single existent*, as opposed to elements in causal succession, in which *cause and effect are distinct existents*. Potential does not exist until it becomes actual, and it is then not causal but ingredient. The transition from potential to actual can be construed as causal if it is divisible into intervening phases, but this would not apply if potential and actual are part of a single entity. Potential perishes in actuality, not successively at each phase in a path to the actual. At each phase, potential is part of the actuality it leads to, that is, part of the epoch of actualization, or successive phases in a single momentary existence.

Development

The paradigm for mental development is mitosis, division within a membrane. In mind, the first division is subject and object, which is a psychological mitosis within the subjective field of the organism. The object, or objective world, does not so much confront the subject as it draws outward and objectifies a portion of a subjective ground. This creates an objective and subjective segment within the same subjective field. The subject apprehends and responds to an outside world that is an extension of its subjectivity. This is likely the mode of cognition in animals and young children.

The individuation of subject and object in a subjective ground is the initial phase. Gradually, within the subject portion, a self individuates in opposition to the world and in relation to its own subjective content. At the same time, the object-portion undergoes further articulation. The appearance of proto-intentional, then intentional, goals still remain within the mind’s outer garment. The separation of object from subject is

a transition from mind to world over a continuous sheet of mentation. This occurs in a recurrent sequence from a subjective core to an objective surface that is constrained by sensation at successive points. It leads to an objectified image that represents or models a world that results from the pruning of maladaptive form driven by the impact of sensory data on an endogenous process of image formation.

The Impact of Sense Data

After activation to a phase of vigilance or arousal, a construct of the act- and object-to-be that is organized about the body sets the process in motion, keeps it on track, and shapes unconscious precursors to their outcomes. Sensory data orient the incipient act-object at archaic formations in brain to an outcome in rational thought, veridical perception, and adaptive behavior. After the initial phase, there is a relative suspension of sense data as the construct passes to a space of dream, symbolic imagery, and thought. This phase is then propelled to conscious reason and adaptation. The gaining of reality, or the detachment of perception from the mind, requires sensory data at the end point of this microtemporal development.

When sensory constraints are in abeyance and the world is still present, say when we close our eyes and the visual data that impinge on the brain are reduced, earlier phases in thought development come to the fore. So long as there are auditory or other sense data to maintain an external world, these phases are rational and adaptive, as in contemplation, deliberation, or sustained concentration. With a persistent relaxation of constraints, thought can range from creative imagination to daydream and fantasy. With sensory data markedly reduced or eliminated, as in sleep or sensory deprivation, there is dream, hallucination, or psychosis. Sensation at the neocortical phase of the traversal is the final constraint on the emerging pre-object. Sensation is essential to the analysis and externalization of the pre-object. Otherwise, there is premature termination or an improbable route of actualization. Personal need must adapt to impersonal reality.

The final effect on primary neocortex is to model cognition to mirror the outer world. In pathological conditions, a veridical object can be achieved while preliminary phases are derailed. In normal perception, the application of sensation through the geniculostriate

pathways partitions the holistic pre-object and its space to a fully objectified image that appears distinct from its antecedent process in the mind of the observer. The foreshortened, palpable subject-centered space of imagery that underlies a proximate space of object relations – the perimeter of limb action or the world of the infant – becomes the open-ended, infinite expanse of waking perception. The transition is so abrupt, the model so accurate, the passivity and detachment so complete that we believe the outer world to be the source, not the product, of the perception. The restriction of the analysis and exteriorization to the distal segment of the mental state cleaves the object from the self, from private thought and feeling, to create an external rim of mind filled with seemingly extra-psychic objects. But all it takes is a brief spell of vertigo as the world spins around the observer to remind one that the world before us is an image in the mind.

Stages in Memory and Perception

The initial phases of the mental state arise out of an instinctual core – the inherited repertoire of drive-categories – then pass through a phase of affective and experiential memories that shape conceptual feeling in the direction of perception. Early phases are felt as memorial, later ones as perceptual, but a memory is an incomplete perception, and a perception is a memory specified to an object. The image transports the experiential past to the occurrent present. The same transition occurs in all domains of cognition, for example, when a word individuates a semantic category. At successive phases and with sensory guidance, whole-part shifts eliminate the potential irrelevance or maladaptation of possible objects to outer conditions. The transition from a perception that is like a memory to a memory that is like a perception delivers the present of ongoing experience out of the past of its own infrastructure.

The traversal of a pre-perception from phases of distant to recent memory embeds conceptual, experiential, and affective knowledge within what appears to be a naked object. The conventional belief that perception precedes memory merely translates common sense to theory of mind. The natural impulse is to ask, how can we recall something before we perceive it? But if object formation is parsed to a model of reality over an

endogenous phase-transition, the object incorporates as its trace the memorial sequence through which the world is realized. In forgetting, earlier phases in the object are recaptured. Memory is thinking to the extent it departs from perception, and perception is memory to the extent it fails to reach a veridical end point.

Feeling in Opposition to Objects

We seem to attach and direct feelings to an object. The feeling is felt inside the person as an interior phenomenon communicated in speech and action but largely inaccessible to others, as their feelings are to us. Most people believe that feeling is associated with objects, or derives from them, or that there is an external connection from self to object or other, but feeling in the object is part of what the object is, part of its becoming, or the process through which it is realized. The impression of an external relation to objects comes from their outward movement and loss. This splits the object off as something external, leaving its affective tonality behind. The effect is to reinforce the separation of mind and object and support the belief that the world is not ours to create but is out there to observe, react to, and experience, which of course it is, but not in the manner most people believe it to be. If we ponder how object worth or value is generated – the feelings we have for others, for animals, for things, possessions, memories – we come to understand that feeling is not applied to objects but *develops into them*. The intensity of feeling for memory, dream, the savoring of the past, the concept of memory as incomplete perception, all conform to the idea that as the memorial becomes the perceptual, the affect that accompanies the image distributes as value into objects.

Generally, feeling is more intense at early phases of drive and desire, less so at distal ones of object and word production. Moreover, feeling is felt as a pressure behind or directed to the object, not in it. In states of love or fear, emotion concentrates in one object that fills attention rather than being distributed evenly over the field. The process that leads outward from categories to objects accompanies a specification of drive to desire, to affect ideas, feelings of interest, and then outward in the externalization of the object, as value or worth. The qualitative change over successive phases is continuous from activation to termination. Feeling is the vitality and becoming of the object and the mark of its realness.

Mind Arises in Experience of the World

The mind is not a *tabula rasa*, but to the extent it is so conceived, it is a tablet on which letters are carved in relief by chipping away at maladaptation or redundancy. Mind is endowed with instincts and other primitive categories of knowledge that form part of the animal endowment. The enrichment of mind through instruction and experience seems inserted from outside. The diversity of the world is not felt to be created by the observer but exists for enjoyment or suffering, in any event, to be perceived, absorbed, felt, stored, and digested. There is a powerful impression of mind as a container filled by experience rather than sensation shaping the mind to conform or adapt to what is experienced. The reflection of the physical world is taken for the real. The creativity trimmed away in each cycle of world creation is attributed to the internal portion of mind before the world appears. The incessant novelty that is the work of nature – the astonishing creativity of life – in the novelty of each perception is a tributary of creativity in the mind.

Extension and Causality: Space and Time

One of the earliest objections to a conflation of the mental and physical concerns the extension of external space. We know there are levels of space formation in the mental state, such as the space of dream, the space of the body, that of the newborn and congenitally blind, so that an extended three-dimensional space, along with its objects, is achieved out of earlier space forms. External space is elaborated over a transition in which an initial nonspatial field of insubstantial mind is set in opposition to the extensive space of a substantial world.

Subjective time, duration, and the virtual present, which preclude instantaneity, differ from objective time order and the causal sequence of world events (Bohm 1980). The causal interaction of external objects is observed but not felt, unless there is impact by an external cause, while in agent causation, an action willed by the self is strongly felt but not observed. Specifically, we perceive the cause–effect relation in the world and we feel it in the mind. If we act on a decision, it is not the decision that instigates the action, but the self that makes the decision and feels an agent to the act. A decision is not the cause of an

action, no more than options that are blocked, abandoned, or exhausted are the cause of inaction. In conscious thought, we are informed of acts that are instigated at unconscious phases.

For the most part, the direction of world events is from cause to effect, that of mental events is from possibility to commitment. In the world, fact is primary and mind-independent, though influenced by probability and contingency. In the mind, possibility is the ground of freedom and fact is the final stage of belief. In mind, the progression is from potential to actual, in the world, from cause to effect. Consciousness involves a trajectory from self to object, and thus mediates a transition from the simultaneity of the unconscious to the temporal order of world events. The discovery of transitional phases in the *creation* of temporal order undermines a sharp opposition of these two frames of time experience.

Transience and Permanence

The inner perception of time and the outer perception of space, the feeling of transience in the mind, the coming and going of mental phenomena, the evanescence of life generally, the passing of things mental and the endurance of things physical, the stability of objects, the insubstantiality of thought, all combine to set one world against the other. All things are in change, indeed, it is intrinsic to them, but the tree in my garden will outlast my thoughts about it, the telephone will be there long after my conversation is over, and the generic cows in the meadow will replicate themselves long after my individuality is lost. Stability is the iteration of like-objects; impermanence is the iteration of dissimilar ones. It is a matter of the perceptibility of change and the repeatability of occasions. But, the tendency of mind to apprehend the extremes rather than the gradations accentuates these distinctions and makes overcoming them all the more difficult.

Evolution and Cognition

The pillars of evolutionary thought are abundance of form and elimination of the unfit as the environment trims away and prevents the reproduction of less-fit organisms. Adaptation entails a pruning of organism so only those best-fitted to the environment will survive. The population dynamic of evolution is realized in the micro-transition of the mental state. The

environment in the form of sensation trims away irrelevant or maladaptive possibilities, so what survives – an act, a thought, an object – is best suited to its social or physical habitat. The world of the organism, like that of object formation, is a limiting point on degrees of freedom. The aim of evolution to produce and reproduce an organism best adapted to some niche in the physical world is the same as the aim of thought to produce and reproduce (replicate) an object best adapted to a momentary niche in the physical world. Both processes lead to an objectification and a continual retesting of fitness.

Agency and Recipience

An essential aspect of the indifference of the world to individual mind, and the feeling that the objects that grow out of us are, like the children we bear, independent of their conception is the transition from agency to recipience in the outward-going flow. The feeling of agency is that of the self willing an action. This feeling is conveyed into an action to give it a volitional character. This is because agentive feeling deposits in the body, not the world. I do not raise the glass – that would be telekinesis – rather, I move my hand which then raises the glass. An action belongs to the agent because it remains in the body and does not fully externalize. In object development, intermediate phases prior to detachment may have a volitional quality. I can will a mental image to occur and *manipulate* it as I like. The image is *my* image. It has not fully separated. In instances of incomplete object development, agency can be carried outward with the image, as in hallucinatory voices that command actions by the percipient observer.

As the endogenous phases that actualize an image are guided by sensory data to veridical objects, there is a progressive loss of voluntary control, which is ceded to terminal sensory constraints, finally to the world. As the image detaches and is felt to be independent of the perceiver, the agent becomes passive to the outcomes of his own image formation. The feeling of passivity to objects is an essential element in the detachment, but agency is dependent on the nature and the phase of the content it accompanies. Agency can be lost or regained in pathology, as when an individual feels that objectified thoughts are transmitted to others. The differing modes of agency in various forms of mental

imagery – after-images, eidetic images, memory images, and so on – illustrate a transition from the voluntary to the involuntary in the passage outward to objects.

Knowledge and Insight

We are constantly guided by knowledge of the world, especially the pragmatics of life, much of which is attributed to the cumulative wisdom of common sense. Common sense draws its considerable authority as a tactic for coping and survival that, by genetic or cultural transmission, has passed down over the ages. The perils attached to ignoring common sense have, no doubt, eradicated most of the outliers who raised questions about it or acted in a way as to deny what seem to be obvious truths. When applied to behavior in the world, common sense is a reasonable strategy. The difficulty arises when such beliefs are transferred to a theory of the mind, or become a standard against which theory is judged.

Much of microgenetic theory is a challenge to common sense beliefs, though the theory can explicate their origins. The problem occurs when a common sense theory of the world is interiorized as a theory of mind, or of antecedent phases in the mental state, or when early phases or constituents in perception are described in terms of final ones, or the flux of brain activity is depicted from the standpoint of external solids, or when memorial or unconscious contents are held to be copies of what is selected by consciousness. That a model of the real should grow out of fantasy, that objects are recognized before they are consciously perceived, that the world is an extension of the mind, that succession in time is generated out of simultaneity, or that the pathology of cognition displays preliminary normal phases is not common sense dogma.

Prospects

Implications of Microgenetic Theory for Psychology and Philosophy of Mind

Science and psychology take an objectivist or externalist view of the same material as the subjectivism of microgenesis. Externalism imports objects into the mind and isolates them from their spatial and

temporal context, achieving an account of mind at the cost of its most essential features. For direct realism, which extracts the subjective from nature, then mind, objects of perception are the constituents of reality. Internalism, of which microgenesis is an example, works with the same data but leads to an account that retains more of the richness of its topic even if it seems untestable and speculative. Both accounts have ontological implications. For externalism, it is simply that objects, mental or external, are substance-like, either physical or logical solids. For the internalism of microgenesis, a *becoming* over the temporal extensibility of an object or an entity – a rock or a mental state – deposits the *being* that the thing becomes. There is much truth in the comment of William James that the basic problems of psychology – mind and brain, thought and nature, knowledge and reality – are ultimately metaphysical.

There is one reality but many doors through which it is apprehended, and each doorway is a perspective that takes the reality it perceives as the true one. Some of these perspectives, especially those shared by many observers, are taken for a direct view of the one, others are dismissed as perspectival. For most people, the world of perception is the real world. For some, the question is the degree to which mind encroaches on the physical or the degree to which the physical is installed in the mind. The debate is whether the perspective is a direct, subjective appearance, a model or representation, an illusion or false belief.

In our view, knowledge of reality is inferred from its copy or representation. This takes the subjective to its limits. A long tradition of such thinking includes a negation of the real by denying its existence, creating an alternate reality in art or mystical contemplation, or retreating to dream and fantasy, even psychosis. An intuition of the primacy of the subjective is the starting point of philosophy. In an echo of Descartes, Schelling (1800/1978, p. 31) wrote that “the science of knowledge cannot proceed from anything *objective*, since it actually begins with a general doubt about the reality of the objective.”

Transitional phenomena help us to understand that the division of mind and world is not as stark as at first it appears. There was a time before the universe was purged of subjectivity or divinity and mind was pervasive that nature was replete with spirit and mentality.

This animistic mode of thinking is still found in dreams, primitive cultures, and pathological states. In our view, it is embedded in preliminary stages of waking thought. At present, except for symptoms or experiences that display a continuum from inner to outer, there is a bifurcation of nature into two portions, one mental, one physical, a way of thinking that derives from, and in turn supports, the distinction of self and other, past and present, feeling and mechanism. The bifurcation dissolves in all-mind or all-nature by eliminating one of its limbs, the physical in idealism, the mental in materialism, the replacement of nature by mind, or the gradual removal of mind from nature and brain, restricting subjectivity to pains, after-images, and other *qualia*, or assuming that consciousness is the last remaining problem before mind can be fully reduced to material brain function.

Current Work in Neuroscience and Microgenetic Theory

The relative neglect of microgenetic theory in the “mainstream” of current neuropsychology and other sciences has perhaps already been adequately explained and lamented. The theory challenges so many and such basic assumptions in the largely cognitivist establishment of academic psychology and neuroscience that accepting it or even acknowledging it would bring a great deal of contemporary research (“normal science” in Thomas Kuhn’s sense; cf. Kuhn 1996) into serious question. Nevertheless, it is of some interest (and no small gratification to the present authors) to note that many predictions made by microgenetic theory and passed over in silence for 10, 20, or 30 years can be verified by recent developments. The emergence of new brain-imaging techniques has brought us results that in fact undercut the old assumptions, and can be much better explained by microgenetic theory. In a recent paper, Talis Bachman (2009) has listed a number of such studies, detailing their relation to microgenetic theory – even though, in many cases, the authors who have published their results are baffled by them, and unaware that they had previously been predicted by microgenetic theory.

Examples of this phenomenon include the back-propagation theory of visual awareness (Lamme et al. 2004) or the neurobiological framework for

consciousness proposed by Crick and Koch (2003). These new developments have reversed the conventional view about how perception evolves (which sees the percept as the result of the gradual accumulation of “bits” of “raw” information that the brain subsequently synthesizes into an image), but the authors themselves do not seem to be aware that similar views have already been expressed, several decades before the imaging technology was available to confirm them (Brown 1988). An increasing number of neuroscientists now understand that the perceptual essence of the object (the feeling that there is an object and its assignment to a primitive functional category) precedes the awareness of fine perceptual details in percept formation. In microgenetic theory, this has been understood and substantiated already by Nikolai Lange, Felix Krueger, Friedrich Sander, Heinz Werner, and, especially, the third author of the present study. Although attempts have indeed been made to import the central concepts of microgenesis into mainstream cognitive neuroscience, experimental psychology (e.g., Bachmann 2008), psychophysics (e.g., Tucker 2008), and neurophysiology (e.g., Kropotov and Mueller 2009), additional research is needed to further demonstrate the theory’s empirical validity. Otherwise, the microgenetic school may acquire a status somewhat similar to psychoanalysis, with a still receptive audience in philosophy, therapy, and fine arts, but with no foundation in mainstream empirical research to keep the theory alive. A merger of scientific data, philosophical vision, and the art of thinking is in the making.

The further development of approaches to neural systems that are not fully deterministic may lend further support to microgenetic theory. Mental states, like weather systems, change in ways that are neither fully linear nor entirely random, a fact that brings to mind the application of chaos theory to evolutionary biology. The appearance of novelty in the course of replication, as previously mentioned, does not allow either for a strict determinism or a roll-of-the-dice randomness. Microgenetic theory stresses the evanescence of each phase in the unfolding of a mental state, but it is never the case that, literally, anything can happen from one moment to the next. The advantage of microgenetic theory here over other current psychological paradigms is that it is not inordinately dependent on a

deterministic certainty of the cause–effect relation, but neither does it deny the possibility of rigorous scientific inquiry.

Another advantage of microgenetic theory (by no means the least, in our opinion) is that it provides a workable, reasonable alternative to the currently fashionable, highly reductionist, and naively materialistic models of the brain. Philosophical dualism of mind (soul, spirit, psyche) and body is not the only viable alternative to a theory that reduces mind to brain and brain to neurons or genes. As contemporary physics forces us to rethink the nature of matter itself and the ways by which information is transmitted, models of the mind/brain built on the assumptions of classical mechanics and information theory also need to be rethought. Experimental work has confirmed theories that have been circulating among physicists since Einstein's day, that two quantum particles, which once belonged to the same physical system can continue to resonate together even when they are far separated in space, as though they were still parts of the same system ("quantum entanglement," cf. Schrödinger 1935). It may be that the entanglement effect, once thought to be limited to the microscale, may be observable in macro-objects (Musser 2009). The implications of this discovery far outside the bounds of theoretical physics may be profound. For the present purposes, it may be enough to point out that the very existence of bonds independent of space-time suggests that matter is not what we thought it was. And what is true of photons in a physics laboratory may well prove to be true also, *mutatis mutandis*, of neurons in a living brain.

Conclusion

This discussion reviews some phenomena that account for our experience of reality and the bases for believing, indeed, rarely questioning the naive view that the real world is just as it appears before us. We have learned that fact in the world is appearance in the mind – "irreducible values" as Dewey wrote – and that the phase-transition in the actualization of the world, as revealed by pathological conditions and altered states, is a continuum over neural substrates and psychic phases, not a sudden break from mind to nature. As in object formation, feeling goes into objects as interest,

value, or worth, seeks reciprocity in friendship or in love, and suffers grief in loss. Love is a feeling that is sequestered in one object of inestimable value, the loss of that object being an excision of its conceptual precursors in the self. The notion of the unconscious and the perceptible world as *physical* spheres surrounding a psychic arena of consciousness is refuted by the perturbations of neuropsychology that expose phases that fill the process from unconscious to conscious and from consciousness to the world. (For recent studies in neuropsychology from a microgenetic perspective, see Pachalska and MacQueen 2008.)

The psychic landscape before us is not a hallucinatory vision, but a representation of reality, though not the reality it represents. This changes little unless, like a schizophrenic, we *feel* the phenomenal basis of conscious experience in which case the model, in its distortion or incompleteness, is exposed for what it is and life becomes intolerable. To know the real is inaccessible is an intellectual challenge or limitation, but to *feel* it is unreal is to live in the transition from dream to wakefulness.

Apart from an entrapment in the mind, the temporal extensibility of physical entities, as inferred from that of the mental state, entails that knowledge of a thing is knowledge of the change by which the thing exists. This means that being is not a frozen substance or slice but a becoming, a before and an after, that brings the thing into existence. It is probable that uncertainties at the quantum level in physics, or ambiguities that cannot be resolved by calculation, or do not obey some of the laws that underlie prediction, can be attributed to the temporal extensibility of nature, compounded in the mind, and the inability to escape the psyche regardless of the instrumentalities that are employed. A slight but significant error will occur owing to the approximation of mind to reality, or to the psychic process through which reality is encountered. We study the reality in the mind, not what a reality mind can perfectly measure, for even in the most accurate representation there is inevitably some immeasurable disparity.

Miles, Walter R.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: March 29, 1885; Died: May 15, 1978.

Walter Miles was born in Dakota Territory and then moved to Oregon, beginning his study of Psychology at Pacific College in Oregon and Earlham College in Indiana. He was invited to the graduate program at the University of Iowa by Carl Seashore, who on a tour of Iowa colleges in 1909 visited William Penn College in Oskaloosa where Miles, a devout Quaker, was a new instructor. Miles supplanted his graduate funds by serving as a Quaker pastor in Iowa. He obtained the Ph.D. in 1913 and moved to Wesleyan University where he replaced, for a year, Raymond Dodge on leave for his

work with F. G. Benedict with the Carnegie Institution of Washington on the effects of alcohol. Dodge and Miles formed a close friendship and Miles, through Dodge, became associated with the Carnegie Nutrition Laboratory in Boston in 1914. There he conducted research on the effect of alcohol on basic psychomotor and physiological functions (Miles 1918) and worked with F. G. Benedict and other staff members on an extensive research project undertaken during the First World War on the effect of restricted diet on human performance (Benedict et al. 1919). He remained at Carnegie until 1922 when he moved to Stanford University for 10 years. He moved permanently to Yale in 1932 and remained there until retiring in 1953. He then spent 3 years in Turkey and after that took up another career at the Medical Research Laboratory for the naval submarine base at New London, Connecticut, echoing the activity of his mentor Dodge 40 years earlier. There he remained until finally retiring in 1965.

Major Accomplishments/Contributions

Miles was a scientist's scientist and an experimenter's experimenter, confirmed in his interests in measurement and instrumentation by both Seashore and Dodge. Like them, he was not particularly theoretical; rather, he saw experimentation as a method that could be turned to practical advantage in any area, and this is reflected in the range of his interests. Represented in his published work, starting with his work on the accuracy of pitch in singing (Miles 1914), are studies on honey-bee olfaction, alcohol and its effects on driving, interpretation of shadow movement, ocular dominance, elevation of the eyeball in winking, reaction time and football linemen's charging, methods of using binoculars, and the metabolic changes associated with several yoga techniques. These last he studied with Kovoov Behanan, a graduate student at Yale who authored *Yoga: A Scientific Explanation* in 1937 for which Miles wrote the foreword (Behanan 1937). Miles created and refined apparatus including the pursuitmeter and the elevated maze, which became a standard device in rat laboratories in the 1920s, and is also credited with the introduction of the use of the old darkroom technique of safe red light to maintain pilots' dark adaptation during the Second World War (Miller 1980). He also wrote on the relation of psychology to other

professions (Miles 1932; Miles 1934) and edited a substantial collection of studies on human variability, a homage to Dodge on his retirement (Miles 1936). In 1927, 2 years after the death of his first wife, he married Catherine Cox, another devout Quaker, the author of a study of intelligence in historical geniuses and a student of Lewis Terman. He collaborated with her on a series of studies of the maintenance of intellectual capacity in old age: Their work was instrumental in changing psychological and public views of ability and its relation to aging (Miles 1933). He was also a meticulous diarist and note writer, and left a very extensive collection of not only the usual manuscripts and papers but also of records of conversation, trip diaries, home movies, and personal documents. This is one of the most complete collections of personal data and material artifacts of any American psychologist of that time and is a primary source for the “fine texture” of psychology’s history (Goodwin 2003).

Military Psychology

GERALD P. KRUEGER

Krueger Ergonomics Consultants, Alexandria, VA, USA

Introduction

Military Psychology: Yesterday, Today, and Tomorrow

Military psychology, a special discipline of work psychology, focuses on research and application of psychological methods and principles to unique job facets in innumerable military settings. In various countries, military research psychologists, both uniformed officers and civilians, work in government and university settings, or with defense contract groups, where they conduct laboratory and field research on topics important to soldiers, sailors, airmen, marines, and coastguardsmen, to their families, and to their leaders. Military psychologists design screening tests for aptitude and mental ability in recruits. They are involved in placement of large numbers of personnel into appropriate job categories or in selection of individuals based upon abilities to fulfill specialized jobs and mission assignments. Psychologists do research on improved techniques used in training tens of thousands of military personnel per year; they provide advice to training officers and, occasionally, conduct training themselves. Psychologists supply guidance to military leaders and decision makers on behavioral issues regarding individual combatant or team performance, on human engineering design of developmental weapon systems, and on operational procedural matters to prevent or reduce physical and psychological casualties that accompany battlefield exigencies of war. Occasionally, psychologists serve as behavioral science advisors at staff headquarters or on governmental legislative committees with oversight of a broad range of national personnel policies impacting millions of military personnel.

Military psychologists also work in military medical centers, schools of medicine, and at outpatient mental health or family counseling clinics. Clinical psychology teams provide mental health services and

psychological treatment to military populations, striving to improve the lives of armed services personnel and their families, especially important work when military members are separated from loved ones while deployed to other countries with unfamiliar cultures and surroundings. Uniformed psychologists work in troop units on field assignments and, occasionally, they accompany combatants on dangerous military missions. In newer military venues, psychologists analyze and advise on humanitarian and peacekeeping missions to determine procedures for saving military and civilian lives.

Across the millennia, military leaders have been interested in the *psychology* and *behavior* of their own warriors in combat, as well as that of the adversary leaders against whom they fight. From the great captains of war, Alexander the Great, Caesar, Napoleon, and others, to today's combatant leaders, they all have searched for ways to motivate troops to put their lives on the line, to fight for political, philosophic, or economic ideals, for the security of their fellow countrymen, and due to the special camaraderie they share with fellow soldiers in arms – first and foremost to fight for one another. Military planners seek answers to such questions as: Can we select the best individuals for leadership positions; are leaders born or are they made? How best to train military competency into military forces? How to develop stress hardiness and resilience in individual combatants and military teams? How do we prepare military forces psychologically for the fog, the shock, and the exigencies of war? To gain tactical advantage in combat, military strategists gather intelligence information about an enemy's vulnerabilities and then employ psychological warfare targeted at enemy soldiers and the indigenous local populace. The list of issues military psychologists address is extensive. Such work invokes numerous psychological theories and principles, and pushes the envelope for new psychological constructs to resolve the constantly changing issues that arise.

Military Psychology in World War I

Late in the nineteenth century, university-based study and research on predicting human behavior formally established *Psychology* as a scientific discipline and profession. One of psychology's predominant academic pursuits was to demonstrate measurement of mental

abilities of individuals. Alfred Binet's work on the measurement of intelligence helped form the basis for employment testing for industry, whose leaders were interested in systematic selection of the right man for the right job so as to net more efficient management of personnel. *Psychological theory* received a huge boost as did the relatively new profession of being a *psychologist* when US academic psychologists took on the challenge in World War I of assisting the military to gain better understanding of people's mental abilities and prediction of their performance at work.

Immediately after the United States declared war on Germany on April 6, 1917, Robert M. Yerkes, a Harvard University professor, and then President of the American Psychological Association (the APA was established in 1892) convened fellow psychologists into a number of committees to assist in the war effort. The influx of millions of conscripted men into the US Army required an economical and efficient method of classifying new soldiers and identifying potential officer candidates. In August 1917, the US Army Medical Department appointed Yerkes to the rank of Major and assigned him to organize and direct psychological examinations for selecting and classifying recruits on the basis of intellectual ability. In keeping with the emphasis of testing for feeble-mindedness at the time, the Army planned to use such tests to eliminate the unfit and to identify the exceptionally superior. To perform this and other work, in January 1918, the US Army Surgeon General's Division of Psychology was authorized 132 psychology officers – many of whom played prominent roles in development of American psychology.

The Army Alpha test designed for literate recruits had eight parts covering grammar, vocabulary, arithmetic, analogies, common sense, filling in next numbers in a sequence, and unscrambling sentences. The pictorial Army Beta test for illiterates included mazes, block counting, number similarities, what is missing in this drawing, and figure similarities. During WWI, 1.7 million US military recruits were rapidly tested, screened, and identified for their intellectual levels. Test scores were made available to commanding officers for use in assigning individuals to specific duties, selecting officers and "balancing the intelligence" of military units. The Division's tests helped select 42,000 recruits for admission to officer training.

The Army Alpha and Beta tests, Psychology's first mass-produced written tests of intelligence, gained respect because they could be administered to groups, and they represented a convenient means for ranking everyone for nearly every purpose. The US military adopted mental measurement and psychometric screening tests as important aids in manpower management, giving credence to applied psychology within the academically based APA (Gal and Mangelsdorff 1991). Experiences with Army intelligence testing during WW I gave impetus to personnel testing and selection screening by psychologists in other venues – for children's placement in school, for entrance into universities, for professional certification and licensing, and for a variety of other endeavors. The Army testing spurred industry into administering tests for both employment and educational purposes.

In the USA, civilian and uniformed military psychologists serving during WW I performed many other functions, including lecturing on training methods, and advising training officers, planners, and program directors in development battalions and special training companies. They measured troop morale and assimilation into the military and developed methods and procedures to improve combat effectiveness. In 1918, the U.S. Army Surgeon General authorized the first duty assignments of psychologists to assist in evaluation of neuropsychiatric patients at the Walter Reed Army Hospital in Washington, DC – thus giving a boost to the clinical practice role of professional psychologists in the military.

The WW I Committee on Psychological Problems in Aviation developed mental, physical, visual, and physiological tests predictive of flying ability. Edward Thorndike studied records of over 2,000 fliers to determine the relation between actual success as a military aviator and predictors based on age, social status, intellectual ability, business achievement, athletic ability, and a number of other characteristics – an effort that informed psychological testing in the selection of aviators. Such work became the precursor to the numerous aerospace medicine and psychological research laboratories that sprang up after WW II.

After WW I, the military forces of most countries demobilized. Psychologists returned to their academic pursuits where they applied their wartime lessons to advancing the science of psychology. Between the two

World Wars, the military continued to make minor improvements in psychological testing; but most areas of military psychology were relatively inactive. In professional practice, rendering psychological decisions regarding selection and placement of US naval personnel, even for aviators and submariners, was largely delegated to general medical officers, and to line officers and, therefore, not to psychologists (McGuire 1990).

World War II and Military Psychology

In the early 1940s, military forces resumed interest in psychological applications for selection, classification and placement of military personnel. During WW II, over 2,000 civilian and uniformed psychologists in the USA addressed military problems, firmly establishing the role of psychology in the military. To replace the Army Alpha test, US Army psychologists developed the new Army General Classification Test (AGCT). It was administered to 12 million men during WW II. Instead of striving to eliminate those who were not good risks, the newer psychometric screening tools sought to identify individuals who could effectively acquire certain military skills or to perform specific tasks. These tests evolved into the widely used Armed Forces Vocational Aptitude Battery (ASVAB). At the time, several European countries established military behavioral science activities and research groups. Psychologists used psychomotor tests of coordination and physical ability for the selection of pilot candidates, and employed specialized tests for navigators and other military specialties. Psychological assessment centers were formed to develop performance-oriented tests and to select and train military operators for the British Special Operations Executive (SOE) and for the US Office of Strategic Services (OSS) – the predecessor to the US Central Intelligence Agency (CIA).

The rapid buildup of military forces again gave impetus to developing psychological tests to identify individuals possessing innate characteristics and abilities desirable in leaders. Other psychologists downplayed innate qualities and insisted instead that leadership skills could be developed through training. Both views were supported by studies of officers' leadership performance, and instructional innovations. Since the early days of psychological testing, military psychologists have been in the midst of controversy about both the structure and nature of intelligence

and about how to select and train good leaders (Zeidner and Drucker 1988; McGuire 1990).

During WW II, hundreds of experimental psychologists teamed with military weapon system design engineers to conduct laboratory and simulation research, assessing abilities of men to effectively operate complex equipment systems. The advent of radar, sonar, high-performance aircraft, submarines, large naval vessels, command and control centers, and other military hardware challenged the cognitive capabilities of military personnel. Studies assessed sensory and perceptual demands, cognitive skills of sonar and radar operators, visual search techniques, aviator visual capabilities, psychomotor skills of equipment operators, design and location of controls and displays in vehicles and aircraft, other man-machine interfaces, and work-rest schedules. Important military research included studies of human performance in extreme heat, cold, high altitude, and the effects of environmental factors such as acoustical noise, vibration, and toxic fumes on military performance (Krueger in Gal and Mangelsdorff 1991; Krueger 2008).

In aiding weapon system designers to understand human capabilities and limitations in operation of complex equipment and jobs, these military psychologists became known as *engineering psychologists* as they strove to optimize integration of human operators into “total system designs.” These psychologists developed analytical tools such as functional-, task-, and time-line analyses, as well as simulation testing techniques for examining operational procedures, information flow, and soldier decision making (Parsons 1972). After WW II, in Europe, engineering psychology became embedded into ergonomics with more emphasis on biomechanics and physiology (Zinchenko and Munipov 1989), whereas in the USA, it was called human factors psychology, or human engineering because of its focus on cognitive processing. The principles of military engineering psychology developed in WW II were integrated into system engineering’s military equipment design centers in industrialized countries (Krueger 2011).

Military social psychologists conducted attitude surveys, examined soldier/sailor morale and motivation, developed small group performance assessment techniques, expanded psychological warfare techniques, added new psychosocial perspectives to

enemy intelligence analyses, and did studies of prisoners of war. Their applied research solidified generalizable social psychological findings. Many important social psychological findings, documented in “The American Soldier” (Stouffer et al. 1949), described the importance of: (a) cultural and personality influences in understanding and predicting behavior, (b) the role of attitudes in predicting and controlling behavior, and (c) the role of the primary group in determining the morale and motivation of soldiers (Gal and Mangelsdorff 1991). The social psychological studies in several countries informed WW II personnel policy makers and thereby established the use of the social survey as a military personnel management tool.

Military Psychology Since 1950

After WW II, during the so-called “cold war” era (1946–1990), several victorious countries did not want ever again to be caught unprepared for large-scale war. They recognized the importance of maintaining in-house engineering development and human-related research laboratory capabilities to continually push the state of the art, and to stay abreast of new technologies, advances in weapon system developments, and so on. With these notions, there was an accompanying need to fully understand the human variables associated with managing or operating modern warfare systems, and also to shape and manage manpower and personnel systems for large standing armies, navies, and air forces. Accordingly, a collection of military research laboratories was retained, and some were developed anew, to conduct multidisciplinary work in such topics as human engineering of materiel systems, aviation and submarine medicine, psychological assessment of military personnel for use in selection, placement, training, and retention. They also conducted training studies to continually prepare rotating military forces for battle. With these needs, there was employment of large numbers of both research and applications psychologists, assigned to work in government laboratories or at universities on defense grants and contracts, and at industrial research firms (Mangelsdorff 2006).

Since the 1950s, military psychologists have studied extensively psychological and performance effects of highly stressful military environments. Diverse stressors not commonly found in civilian life include

conditions of fear, sensory overload, sensory deprivation, social isolation, sleep deprivation, sustained operations, operating while wearing bulky chemical warfare protective uniforms, working at high mountain altitudes, climatic temperature extremes of deserts and tropics, enduring severe winters, living under the sea, on remote stark land masses, and in outer space. Military personnel are exposed to extreme heat in combat vehicles, to high rates of vehicle acceleration, vibration, high acoustical noise, high levels of toxic gases, air pollutants in the work station, and even to unusual dietary and nutritional mixes (Krueger in Hancock and Szalma 2008).

Today's Military Psychology Morphs into Tomorrow

Between major global wars, government cost-cutting measures winnowed down the number of military research laboratories and decreased the number of psychologists working in them. However, among the NATO nations and several other westernized countries at least, there has been a sufficient continuity of labs to promote longitudinal research and development programs. Based upon collaboration across international boundaries, some of these labs participate in regular sharing of research instrumentation, expertise, and research data, technical reports, and published articles (Bartone et al. 2010a). Frequent exchanges and dialogue among military psychologists and operational military agencies ensure adaptation of psychological research results (Bartone et al. 2010b; Krueger 2011; the journal of the Society of Military Psychologists – the Division 19 of APA, 1988–2011).

Forward looking topics in military psychology research labs include determining: (a) how battlefield soldiers are to cope with an inundation of computer systems and digital data streams in the face of rapid decision making; (b) what the role and treatment regimen should be for prescribed ingestion of psychoactive chemical and nutritional substances proposed as human performance enhancers; (c) how best to integrate large numbers of women, ethnic minorities, and gays and lesbian soldiers into the workforce; (d) how changing paradigms of leadership will affect future military operations; and (e) how military leadership must change to accommodate intercultural and international alliances.

Since 2001 military forces of NATO and in particular of the United States have conducted repeated extended deployments to the mid-East (e.g., Iraq, Afghanistan, and surrounding neighboring countries). Combatants there undergo many traditional, but now also many new stressors such as being exposed to bomb blasts on an individual level (i.e., from Improvised Explosive Devices: IEDs), wherein the devastating injuries of those conflicts are limb loss, traumatic brain injuries, and post-traumatic stress disorders (PTSD). Extensive post-injury medical and psychological rehabilitation programs are in place; and numerous psychologists and other medical specialists are making tremendous advances in both individual treatments and by pushing the state of the art in neuroscience.

In terms of newer psychological advances for the troops, today military psychologists are constructing tomorrow's comprehensive soldier fitness (CSF) programs to include preventive medicine, training to attain developing psychological hardiness, and increasing an individual's and a unit's resilience to cope with multiple stressors in order to preserve health and performance. Recent developments include developing a Global Assessment Tool (GAT) as a self-report inventory to measure psychological strengths, assets and problems of each soldier, by tapping into emotional, social, family, and spiritual fitness. GAT provides soldiers with immediate feedback as to their individual strengths and needs and can be used to assign soldiers to appropriate training protocols for each. In WWI, psychological assessment focused on *abilities*; assessment in WW II focused on *attitudes*. In the new millennium, the Comprehensive Soldier Fitness program focuses on *assets* – on what people do well, and then cultivates excellence on a larger scale. While experiences with this approach are new, such a comprehensive soldier fitness program could eventually be a model for psychological fitness training in other large organizations (Seligman and Matthews 2011).

For almost 100 years, military psychology has continued to contribute meaningfully to national defense in countries that maintain military forces. Military psychologists bring psychological principles to bear in tackling “real world problems,” including operational military personnel performance-related issues, as well

as addressing issues confronting individual military service personnel, their families, and their leaders. Military psychologists are pacesetters in numerous topical matters of critical importance to military organizations. Their work often has far-reaching implications for the civilian populace. In that process, military psychologists continue to make significant contributions to psychology as a whole.

Miller, George A.

IVAN MANCINELLI-FRANCONI

Saybrook University, San Francisco, CA, USA

Basic Biography

George Armitage Miller (February 3, 1920–) Charleston, West Virginia, United States. American psychologist and innovator in the study of language and cognition. Helped establish psycholinguistics as an independent field of research in psychology. Married to Katherine James.

George Miller was born on February 3, 1920, in Charleston, Virginia. Miller, was raised a Christian Scientist and lived with his parents until they divorced in 1927. In 1937, after graduating from Charleston High School, Miller moved to Washington D.C., with his mother and stepfather and enrolled in George Washington University for one year.

In 1938, Miller transferred to the University of Alabama where he met Katherine James, whom he married in 1939. Katherine introduced him to

psychological science and to Donald A. Ramsdell, head of Alabama's psychology department. Miller earned his master's degree in 1941 from the Department of Speech. After graduation, Ramsdell offered him a position as a psychology instructor, and helped him get into graduate school at Harvard University in 1942.

At Harvard University, Miller met Gordon Allport, Wendell Garner, and J.C.R. Licklider with whom he worked extensively on war-related research throughout World War II. Miller's research, based on his knowledge of speech and hearing, focused on psychological operations, primarily psychoacoustics and the impact of sounds on auditory reception. He also taught in the Army Specialized Training Program. In 1944, he became a member of the Psycho-Acoustic Laboratory at Harvard, where his research focused on evaluation of radio-telephonic systems for the armed services. J.C.R. Licklider had worked with Miller at Harvard in 1942 on cold war psychological operations, worked again with Miller in 1951 at Massachusetts Institute of Technology (MIT) on Cold War radar engineering. Their research led to the opening of a speech perception lab focusing on phonetics. Miller's first book, *Language and Communication* (1951) helped to establish psycholinguistics as an independent field of study.

On September 1956, Miller met Noam Chomsky at MIT. Chomsky exposed Miller to the phonetic differences between languages. With Chomsky's help, Miller was able to formalize his theories, and together they began their study of semantics, which eventually resulted in the creation of the TOTE concept.

In 1960, Miller founded the *Center for Cognitive Studies* at Harvard with *Jerome Bruner*. His book *Language and Perception* (1976), coauthored with Philip Johnson-Laird, was the basis for the discipline of cognitive psychology.

In 1985, Miller founded *WordNet*, a *lexical database* for the *English language* operating out of the *Cognitive Science Laboratory* at *Princeton University*, which he help found in 1986. Miller also created commercial applications based on *WordNet*, the most popular being *Simpli*, an Internet search and marketing engine. *Google AdSense* and *WordNet* were based on the *WordNet* lexicon.

Dr. Miller is the author of more than 160 publications, the recipient of numerous honors including honorary doctorates from the University of Sussex (1984), Columbia University (1980), Yale University (1979),

and the Catholic University of Louvain (1978) and the recipient several awards. He is the recipient of the Distinguished Scientific Contribution Award of the American Psychological Association (1963), Distinguished Service Award of the American Speech and Hearing Association (1976), and the Warren Medal from the Society of Experimental Psychologists (1972). In 1991, Dr. Miller received the National Medal of Science, the highest scientific honor awarded by the United States, and in 2003, the American Psychological Association awarded him with the Outstanding Lifetime Contribution to Psychology Award.

In 1992, Dr. Miller was elected to the National Academy of Sciences and was president of the American Psychological Association in 1969 and Eastern Psychological Association in 1962.

Accomplishments

The behaviorists led by B.F. Skinner, whose work in operant conditioning had dominated psychological research, did not seriously acknowledge the mind, and believed that consciousness, introspection, and other mental activities could not be subjected to scientific study because they could not be observed. However, with the "Cognitive Revolution" of the 1950s, spurred by a series of events, including the convergence of various scientific disciplines, which sought the understanding of human mental activity, put cognitive psychology on the forefront of psychological science. In 1956, George Miller's research on the limitations of human thought, especially memory, challenged their dominant position, stressing that learning was a change in knowledge stored in memory and governed by internal processes rather than by external circumstances, as the behaviorists believed. His research proposed a series of representations and processes for the coding and decoding of information at a time when computers were in their infancy and were no more than calculating machines.

Miller contributed two major theoretical concepts considered fundamental to the information-processing framework and cognitive psychology, in general.

His first theoretical concept known as "chunking" and the capacity of short-term memory first appeared in his landmark article *"The magical number seven, plus or minus two: Some limits on our capacity for processing information,"* published in 1956 in *The Psychological*

Review. His article presented the idea that human short-term memory could only record seven (seven plus or minus two) pieces of information at any given time. These bits of information he called “chunks,” and they characterized people’s memory performance on random lists of words, numbers, or any kind of meaningful familiar items. The phenomenon of chunking and the limited capacity of short-term memory has become a basic element of all subsequent theories of memory. However, recent research has revealed that span does depend on the category of chunks used, and even on features of the chunks within a category. Cowan (2001) proposed that working memory has a capacity of about four chunks in young adults (and less in children and old adults).

The second concept is known as the Information Processing Theory of Learning (IP). Information processing posits the idea that the human mind functions much like a computer. The human mind takes in information (input), changes its form and content (processing), stores and locates it (storage), and generates responses (output). This theory also states that there are three kinds of memory: sensory registers (the area of memory responsible for receiving information through the senses); short-term memory (STM) or working memory, the area of memory where new information is temporarily stored, either placed into long-term memory or erased; and long-term memory (LTM) which has unlimited capacity and can hold information indefinitely.

Dr. Miller is currently professor emeritus and senior research psychologist at Princeton University as well as the director of the McDonnell-Pew Program in Cognitive Science.

Miller, Neal E.

THOMAS J. MARTINEZ, III
Saratoga Springs, NY, USA

Basic Biography

Neal Miller noted American psychologist, who together with colleague John Dollard advanced a theory of

behavioral analysis based on the combined scientific insights from learning theory and findings from psychoanalysis, was born in Milwaukee on August 3, 1909. His father, an educational psychologist, and mother, a schoolteacher, moved the family to Bellingham, Washington when Miller was still a boy. He received a BS from University of Washington, an M.A. from Stanford, and a Ph.D. from Yale. In 1935, Miller traveled to Vienna to study psychoanalysis with psychoanalyst, Heinz Hartman. Miller had hoped to study with Freud himself, but could not afford his fees. Upon returning to America, Miller became a faculty member at Yale and a research psychologist at *The Institute for Human Relations*. It was during this period that Miller and fellow researcher John Dollard began to advance their ideas on psychology, social theory, and culture. Miller died in New York on March 23, 2002, at the age of 92.

Major Contributions

In 1939, Miller and Dollard, together with several fellow colleagues at Yale, most notably, O. Hobart Mowrer and Robert R. Sears, published *Frustration and Aggression*. This powerful exposition on the etiology of conflict and violence includes, as one of its many accomplishments, a cautious validation of the psychoanalytic concepts of displacement and repression. Yet, Miller, Dollard, and associates, approach aggression and frustration, not from the theoretical standpoint that is specific to psychoanalysis, or any other theoretical affiliation. On the contrary, their exposition transcends any exclusive paradigmatic claims that imply an exclusive paradigmatic affiliation, or theoretical hegemony. Psychology's well-known frustration–aggression hypothesis was developed from the findings that Miller, Dollard, and associates advance, in this pioneering work.

Following the appearance of *Frustration and Aggression*, a cross-disciplinary *tour de force*, Miller and Dollard published in July 1941, *Social Learning and Imitation*. This publication, like their previous collaboration with colleagues, Mowrer and Sears, conveyed the *Institute's* expressed intention of combining the various facts obtained from the social sciences into a comprehensive social theory. The book was dedicated to Mark May, the *Institute for Human Relations* founder, and drive psychologist and scientist Clark Hull,

the pair's mentor at Yale. The primary goal of Miller and Dollard's text was to present a scientifically nuanced account of the principles and conditions of learning and then examine the various behavioral contexts by which imitation manifests as a social fact. Another goal concerned Miller and Dollard's desire to reformulate the psychoanalytic concept of identification in terms of learning theory, and further *differentiate between imitation as a function of socialization and learning*, and *imitation as a function of heredity*.

After serving as a research psychologist and intelligence analyst for the Office of Strategic Services during the Second World War, Miller returned to Yale to teach and continue his collaboration with Dollard. Miller's return was heralded by his prestigious appointment to the James Rowland Angell chair of psychology at Yale. Their second book, *Personality and Psychotherapy*, published in September 1950, replete with a dedication to Freud and Pavlov and their students, reveals like their previous collaboration, the pronounced influence of Clark Hull. The structure, dynamics, and development of the personality is outlined by employing a relatively small but effective collection of concepts derived from learning theory, including drive, cue (or discriminate stimulus), response, and reward. The principles of psychology and learning are set forth amidst a discussion of behavior, the formation of the personality, and the practice of psychotherapy. It is worth noting, that the elaboration of the relationship between experiences of frustration and aggression, is carried out with the goal of ameliorating and integrating stimulus and response differences, arriving at a new scientific understanding of the conditions that facilitate learning. *Personality and Psychotherapy* is now considered by many historians of behavioral science, to be foundational for understanding the principles of learning theory and for anticipating the ascendancy of the neo-behaviorist psychotherapeutic perspective.

In the years following his second and last book with Dollard, Miller began to focus increasingly in his research upon the neurological, biochemical, and physiological components that accompany the activation of drives, related behaviors, and challenges to learning. The question that asks, what happens in the body during drive activation was addressed almost

immediately. One year after the publication of *Personality and Psychotherapy*, Miller published independently of Dollard, a highly influential chapter titled, "Learnable Drives and Rewards" in *The Handbook of Experimental Psychology*. For Miller, the concept of drive may be understood most simply, but not exclusively, as an expression of the organism's basic physiological needs for survival. Learning theory acknowledges these basic physiological needs but goes farther in the application of drives to behavior and learning. Miller borrowed from the work of drive psychologist Clark Hull, and understood drive broadly, to indicate *any stimulus forceful enough to evince action*. *Drives are primary*, when they are an expression of physiological need. Drives are *acquired* when their origin is environmental, or owe their origin to other sources than the body's basic needs for survival. *Acquired drives* are learned, and include, the need for power, approval, money, affiliation, and achievement, just to name a few. With the activation of a drive, there is then the potential recognition of the various *intrapyschic* (awareness of bodily psychic stimuli) and *extrapsychic* (environmental) impressions, or *cues*. *Discriminatory stimuli, or cues*, are thus distinguished from other stimuli by virtue of their recognition. Learning consists of strengthening, or rewarding specific behaviors (i.e., responses) and accompanying cues (stimuli awareness, or discriminate stimuli), when and where this action is desirable. Hence, any drive reinforcement must speak to the variety of contexts of the drive[s] manifestations: the biophysiological, social, and psychological needs of the organism. The problem of understanding the nature of drives, antedates Miller's inquiry into the *voluntary and involuntary* aspects of the body, and the limits of mind or consciousness.

In 1957, Miller was awarded the prestigious *Warren medal from the Society of Experimental Psychologists*, and in 1959, elected President of the *American Psychological Association*. Several years before, Miller's contributions to psychology garnered him membership in the *National Academy of the Sciences*. He became a strong defendant of the use of animals in scientific research, a position that was periodically assailed by animal rights organizations. Miller had been experimenting with animals since the 1930s at Yale, testing for neurological changes and biophysiological

reactions to anxiety, conflict, and fear, in a variety of motivational settings. Much of the research that led Miller to formulate the concepts of *behavioral modification and biofeedback*, involved animals. The tendency, for example, to approach or avoid, a parcel of food, given the imposition of an aversive element, such as the presence of another more aggressive animal, or the lingering memory of a painful jolt of electricity, tells us something about the strength of the drive mechanisms activated and the animal's decision, to *approach and feed*, or in decisions of *avoidance, to take flight*. The need for food, corresponding to the primary drive of hunger, is confounded by the possibility of *conflict*, or the *anxiety* associated with a violent shock, or deafening noise. At the same time, Miller noted the acceleration of heart activity, production of gastrointestinal fluid, breathing, as well as changes in other vital organs. Miller kept a record of the fluctuations that occurred with the physiology of the animals. When learning had been achieved (i.e., in life enhancing decisions, or the acquisition of new behaviors), the animal was rewarded. Miller's practice of rewarding learning and life-enhancing behavior in animals, including the optimum performance of the vital organs, led to his belief that the autonomic nervous system could be educated. The implication for human beings was even more impressive. Virtually, every aspect of *voluntary behavior* and many aspects of the *involuntary functions of the body*, respond to conditioning. Miller suggested behavioral modification founded on principles of learning to correct maladaptive behaviors. He also suggested biofeedback training in cases where a lifestyle change was desirable, or necessary. In biofeedback training, individuals are taught to monitor their own physiological processes (heart rate, blood pressure, breathing), toward the goal of increased *awareness of the involuntary aspects of the body*.

In 1966, Miller left Yale, to work as the director of the *Laboratory of Physiological Psychology at Rockefeller University* in New York. A year earlier, he was awarded the President's *Medal of Science*. In 1969, he began to test his ideas on behavioral modification and biofeedback. Miller retired from Rockefeller University in 1981, retaining the title of Professor Emeritus. When *The American Psychological Association*, honored him in 1992 with the *Citation for Outstanding Lifetime*

Achievement in Psychology, he was still conducting research on potential learning applications in the autonomic nervous system.

Mills, T. Wesley

DAVID J. MURRAY

Queen's University, Kingston, ON, Canada

Basic Biographical Information

Wesley Mills was born in a small Ontario town, Brockville, on February 22, 1847. While he was a medical student at the University of Toronto, he formed a congenial friendship with William Osler (1849–1919), who would go on to become one of the best-known doctors in North American history. Osler early became a popular professor of medicine at McGill University in Montreal, and in that capacity offered strong support to Wesley Mills when the latter was attracted there in 1881 to teach physiology at McGill alongside Osler. Both Osler and Mills complemented their studies by experiences in Europe, notably with Sir John Burdon-Sanderson in England; Burdon-Sanderson had written a widely used textbook, and this must have inspired Mills (1886, 1889) to write his textbooks on comparative physiology, which Murray (1990, p. 206) praised because of their usefulness to present-day historians of psychology who can learn from them what black and yellow bile are and to what anatomical structure Galen's *rete mirabile* refers. Osler (1892) went on to write what would become the dominant medical textbook in the English-speaking world.

When Osler (1915) came to write Mills's obituary, he described Mills, who had achieved an excellent reputation at McGill as a teacher and researcher on comparative physiology, as being somber in outlook, and wrote:

- ▶ Upon men obviously striving to be taken at their own valuation the world has no mercy; now and again one wins out, but the majority form a battered band whose work and worth never receive a due mead of appreciation. It is the careless sinner who goes a-whistling and working through life, caring not for what the world thinks, who gets more than his due (Osler 1915, p. 339)

The last years of Mills's life were spent in England, where he gave time to his hobby of violin-playing, amassing a collection of books on teaching violin performance and on the manufacture of violins; he bequeathed this collection to McGill University (Cyr 1990). He also wrote a well-informed and highly regarded book (Mills 1906) on the physiology underlying the singing voice (his second wife was an opera singer). In 1910, Mills underwent a prostatectomy, remaining ill for months until his passing on February 13, 1915. His old friend William Osler (1915) praised him for his first-person account of what he felt like to be a patient during those months.

Major Contributions

Mills did more for the propagation of comparative psychology as a subdiscipline than is generally realized. At McGill, he spent time involved not only with the Physiology Department, but also with the School of Veterinary Medicine. He founded an Association for the Study of Comparative Psychology; he started private kennels that allowed him to make protracted scientific studies of dog behavior (Mills 1891, 1892); and he published research articles on the behavior of both wild animals native to the Montreal region (e.g., beavers, squirrels, and chipmunks) and domesticated animals and birds (e.g., guinea pigs, hens, and rabbits). His best-known work consists of his meticulously kept diaries of the behavior of kittens, puppies, and the young of the above-named fauna. These diaries were collected in a single volume (Mills 1898) and are full of facts that still strike us as relevant. For example, he reported a case of “one-trial

avoidance learning” in a pedigree St. Bernard puppy aged 45 days. A cat's first purr was recorded when it was aged 54 days.

Apart from his book, he courted controversy with an article (Mills 1899) in the widely read *Psychological Review* in which he took E. L. Thorndike (1898) to task for what Mills thought were inadequacies in Thorndike's otherwise highly regarded studies of how cats escape from puzzle boxes. Mills considered Thorndike's emphasis on reinforcement to be simplistic and Thorndike's rejection of cognition in his animal subjects to have been founded on ignorance. Thorndike had written that “cognition, inference, judgment, memory, self-consciousness, social consciousness, imagination, association and perceptions, in the common acceptance of the terms, are all absent from the animal mind” (quoted by Mills 1899, p. 264). Mills's riposte to Thorndike's rejection of imitation as a feature of animal behavior was to write: “So obvious an example of imitation as the talking parrot is set aside or twisted out of recognition” (Mills 1899, p. 267). Mills added that it can often be adaptive for an animal to desist from imitating another; it cannot be assumed, therefore, that, when an animal shows no evidence of imitation, that animal is not capable of imitation.

Thorndike's rejection of memory as a determinant of animal behavior was disputed by Mills, who reported the following experimental result with one of his dogs:

- ▶ I had a greyhound that was very prone to chase cats, a habit which became with him more and more pronounced, I presume, from his success in consequence of his speed. On the occasion I wish to emphasize I had taken the dog in a certain direction, and, as a result, a cat crossing the street was so highly pursued by him that she took to a tree. Many months after I brought the dog along this same way, but approached the scene of the exciting chase from the opposite direction. Long before the exact spot was reached the dog was all attention. It was perfectly plain that he remembered the long-past incident, and that certain feelings (which accompanying feelings Dr. Thorndike denies to animals) were also aroused; but great was my astonishment when the dog stopped at a certain tree, looked up and behaved otherwise in such a manner as left no doubt in my mind that he remembered the

identical tree and every detail of the whole incident. This cannot be explained by the sort of consecutive association that Dr. Thorndike would substitute for “memory” as ordinarily understood, for the locality was approached from the opposite direction. (Mills 1899, p. 269)

Finally, Mills thought that the puzzle boxes were so small as to submit the cat to a state of entrapment, and its behavior would be as “unnatural” as that of a human likewise confined. Mills also became embroiled in a polemic with Conwy Lloyd Morgan (1852–1936) and others on whether newly hatched chickens and other birds know “instinctively” how to drink water. Mills established that the bird’s beak had to be dipped in water before a “drinking” response (gulping, swallowing) would ensue. This exchange of scientific communications was also reprinted in *The Nature and Development of Animal Intelligence* (Mills 1898).

Mischel, Walter

VERONICA DI BELLO

Marymount Manhattan College, New York, NY, USA

Mischel, Walter (22 February 1930–) is an American psychologist specializing in social psychology and personality theory. His research interests focus on: personality development, structure, and processes as well as self-/emotional regulation (control). Since 1994, Mischel has held the Niven Professor of Humane Letters position at Columbia University, while continuing his research in personality psychology.

Basic Biographical Information

Walter Mischel was born in 1930 in Vienna, Austria. Shortly after the Nazi invasion of Austria, in 1938, Mischel and his family fled to the United States where they began living in Brooklyn, New York. Years later, he would attend New York University, where he studied poetry under Delmore Schwartz and Allen Tate. While attending, Mischel became fascinated by psychoanalysis, furthering his interest in personality measures at Ohio State University.

After receiving his Ph.D. in clinical psychology at Ohio State University in 1956, Mischel began teaching at the University of Colorado in Boulder until 1958, at Harvard University from 1958 to 1962, and then at Stanford University from 1962 to 1983. Since then, Mischel has been in the Department of Psychology at Columbia University, and has served as the Robert Johnston Niven Professor of Humane Letters since 1994.

In 1955, Mischel was given the opportunity to observe the Orisha religious ceremonies in Trinidad. Living on a part of the island split between people of African and of East Indian descent, Mischel was fascinated with the opposing lifestyles and beliefs held by

each group. The people of East Indian descent saw the Africans as hedonists, who lived their lives without any concern for the future, while the Africans felt the East Indians were unreasonably disciplined and left no room for themselves to enjoy the pleasures of life. Mischel wanted to reveal opposing attitudes through an experiment with indulgence. Mischel offered children of both ethnic groups a choice to receive a small chocolate bar immediately or, if they were willing to wait, receive a larger chocolate bar later. With his experiment, Mischel intended to demonstrate the groups' opposing mentalities with how quickly they submitted to their desires. However, the children's ability to wait or not corresponded with social and economic backgrounds, rather than their ethnic group. Although the experiment did not produce the anticipated results, they revealed a correlation between self-control and other variables, prompting Mischel to become interested in the concept of "delayed gratification" (Mischel 1974). What enabled some of these children to withstand temptation? What cognitive mechanisms did these young children use to do this? These questions led Mischel to continue his research, determined to answer them.

Major Contributions

From 1968 to 1974, Mischel and his colleagues conducted a series of experiments at the Bing School located on Stanford's campus. The experiment, often referred to as "The Marshmallow Test," analyzed "cognitive-attentional" processes and mechanisms that allowed children to defer gratification. In these studies, children were placed individually into a room with an experimenter. Each child was given a single marshmallow (or another appropriate reward) and told they would receive an additional marshmallow if they could resist eating the first one before the experimenter returned to the room. The preschool delay-of-gratification situations revealed cognitive processes that allowed young children to delay when given the choice between two different outcomes: an immediate but less desirable reward, or a delayed but more desirable reward. The preschoolers who succeeded were able to withstand temptation using cognitive-attentional processes that allowed them to orient their delay toward the reward (the more desirable outcome) by minimizing the less desirable reward

in front of them using mental manipulation. In an interview conducted by author Jonah Lehrer, Mischel says, "What we're really measuring with the marshmallows isn't will power or self-control," adding, "It's much more important than that. This task forces kids to find a way to make the situation work for them. They want the second marshmallow, but how can they get it? We can't control the world, but we can control how we think about it" (Lehrer 2009). Presently, Mischel and his team continue following up on those preschoolers. Now in adulthood, the "Marshmallow Test" has provided direct correlations between the ability to delay gratification with vast successes in life. From the ability to cope in stressful situations to higher Scholastic Aptitude Test (SAT) scores, the delay situations have shown strong connections with cognitive adolescent and outcomes later in life (Mischel 1974, 1996 and Shoda et al. 1990).

When Mischel published his monograph, "Personality and Assessment" in 1968, he challenged traditional principles of personality theory. Mischel proposed that conventional theory suggested that personality (qualities and traits) stood constant in individuals even across a wide range of diverse situations. Mischel claimed the existing data, evaluation, and measurement techniques failed to demonstrate that notion. The techniques being used at the time were created on the basis of an unchangeable personality, which Mischel argued was sensitive and fluctuated from situation to situation. This meant that the field of personality psychology was looking for stability where it should not be; The human mind was actually changeable to circumstance (Mischel 1996). His claim meant personality theory placed human social behavior within a "nonsocial," even "nonhuman" context and was therefore unreliable – stirring considerable conflict within the field. At the time his book produced a paradigm crisis in psychology. Today, it is recognized for having transformed the field of personality psychology to how we understand it today.

Since then, Mischel has been a prominent figure in the field playing an extensive role in its advancement. His insight to the human psyche has earned him a professional reputation in the field of psychology. Mischel served as President of the American Psychological Association Division of Social and Personality Psychology and of the Association for Research in

Personality, earning such honors as: the Distinguished Scientific Contribution Award from the American Psychological Association, the Distinguished Scientist Award of American Psychological Association's Division of Clinical Psychology, the Distinguished Contributions to Personality Award of the Society of Social and Personality Psychologists, and the Distinguished Scientist Award of the Society of Experimental Social Psychologists.

Mischel has made incredible contributions to both personality theory and social psychology. There has been significant progress in the field of psychology and in its ability to access the human personality in a more relevant direction. His concepts and theories have enabled psychologists and researchers to assess the human mind more objectively and with greater success.

Montessori, Maria

AMY S. WALKER, JOHN D. HOGAN
St. John's University, Jamaica, NY, USA

Basic Biographical Information

Maria Montessori is best known as the creator of an educational system that emphasizes the interaction of a structured environment and the inner timetable of a child's development. Her system experienced an enormous popularity soon after its introduction, ultimately having an impact on early childhood education around the world. After a period of decline in the USA, her

method has gone through a revival, along with the recognition that she was a developmental theorist of substance.

Maria Montessori was born in Chiaravalle, Italy on August 31, 1870. A precocious child, she ignored occupational gender stereotypes of her time and originally intended to be an engineer. She eventually graduated from the University of Rome in 1896 with an MD degree, the first woman in Italy to receive a medical degree (Kramer 1976).

Her early work in a psychiatric clinic affiliated with the University of Rome sparked her interest in working with retarded and emotionally disturbed children. She was particularly influenced by the writing of Jean-Marc Itard (1774–1838) and Edouard Séguin (1812–1880). Itard, a French physician who was noted for his work with Victor, the Wild Boy of Aveyron, developed an approach to learning whose elements can be found in Montessori schools even today. Séguin, a student and follower of Itard, continued and extended Itard's beliefs while working with retarded children.

In 1907, Montessori was offered the opportunity to run a children's school in a slum section of Rome. She accepted and dubbed the school *Casa dei Bambini* (Children's House). It became the first Montessori School and it is still in existence. It was here that she developed many of the principles that would guide her educational and developmental theory (Standing 1984).

The success of Montessori's *Casa dei Bambini* was immediate, and within a few years she had achieved an international reputation. Schools around the world began to adopt her approach and she traveled to other parts of the world to discuss her method. Later, she was forced to leave Italy because of pressure from Mussolini to make her teaching more consistent with his political goals. She spent the period of World War II in India. At the end of the war, she returned to Europe to live in the Netherlands where the International Montessori Society had its headquarters. Greatly honored in her lifetime – she was nominated for the Nobel Prize three times – she died in the Netherlands on May 6, 1952.

Major Accomplishments/Contributions

Although highly regarded as an educator, it is not often appreciated that Montessori was an important

developmental theorist. While some of her language and ideas are outdated, many of her principles retain their usefulness and explanatory power today. For example, her use of naturalistic observation as a primary method for understanding the child as well as her child-centered approach are considered important elements of contemporary child care and research.

Montessori's ideas fall squarely in the tradition of classical developmental theory, informed by Rousseau, with an emphasis on maturation and stages of development. Her observation of children in the Casa dei Bambini led her to posit many natural needs and abilities in them that were largely independent of the environment. Among her primary beliefs, Montessori argued that children experience genetically derived *sensitive periods*, similar in concept to critical periods. During a sensitive period, the child is at his or her greatest potential for learning. If the child does not have the appropriate experience during this period, the child's ability in that particular domain may suffer. Montessori believed in a host of sensitive periods ranging from the need for order to the development of language.

Montessori believed that young children learned differently from adults, and were possessed of an *absorbent mind*. Consequently, the role of the parent or teacher was not to direct the child to particular activities, but rather to make available opportunities to the child. It was up to the children to select those activities that would best fulfill their current need. As a result, Montessori classrooms are very child-centered, with the children displaying a great deal of independence in choosing activities. Montessori spoke of the intense concentration that her children would often exhibit, as if they were fulfilling some great inner need (Montessori 1964).

At the same time, Montessori did not ignore more traditional goals of early education. In fact, it was probably her success in teaching reading and writing that was a major reason for her fame. Montessori made available to her original group of children cutout letters for which she would supply the sounds. She also prepared them with related motor activities and with moveable letters. As Montessori later explained, the children did not understand the connection between the preparation and the act. Suddenly, they burst into writing as if it were a natural ability that came with age.

She referred to these "explosions" as commonplace among her students, and they were not confined to writing. They included other basic abilities as well (Shephard 1996).

Montessori's method was not accepted by everyone. Criticisms of her work included her ambivalent attitude toward fantasy and some aspects of creativity. She judged them to be immature and unrealistic behaviors. Additionally, material that was prepared for her classrooms was to be used in a prescribed way only. Some critics found this a significant limitation on the child. Montessori also seemed to downplay the importance of social development of children while emphasizing cognitive development. Despite the criticism, her work represents a major contribution to developmental theory and education (Lillard 1996).

Morgan, C. Lloyd

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: February 6, 1852 Died: March 6, 1936.

Conwy Lloyd Morgan trained as mining engineer but lost interest in that in proportion to his fascination with biological science. However, his first love was philosophy and he conceived of his career as

a continual search for evidence to bring to bear on the Berkeleian conception of direct conscious perception and the question of knowing other minds (Morgan 1930). He came to study under T. H. Huxley and immersed himself in Darwin. He evolved, after some time as a teacher in South Africa and after his return to the University of Bristol where he spent the rest of his career, a systematic approach to the understanding of consciousness both through self-directed introspection and through the relation of the insights gained through such introspection to minds in other species.

Major Accomplishments/ Contributions

Within psychology Morgan is properly classified as a comparative psychologist – indeed, one of the founders of comparative psychology – who bridged the era in which the Darwinian postulates of mental evolution supported by organized bodies of anecdotal reports of animals in the field gave way to the laboratory study of elements of behavior situated in experimental paradigms. Morgan was far more interested in incorporating the wealth of observational (if anecdotal) data gained by his contemporaries such as George Romanes and St. George Jackson Mivart into a framework of an evolutionary psychology of consciousness. Morgan was more interested in incorporating Mivart's conception of "consentience" as the essential level at which cats, Mivart's special study, interacted with the environment rather than fullblown consciousness, and this he did on the basis of a scheme of levels of consciousness theoretically derived from philosophical writings and from introspection. Morgan sometimes is known only for a statement made in *An Introduction to Comparative Psychology* which he termed a "basal principle" and which has since come to be known as his "canon": "In no case may we interpret an action as the outcome of the exercise of a higher psychical faculty, if it can be interpreted as the outcome of the exercise of one which stands lower in the psychological scale" (Morgan 1894, p. 53). Morgan advanced this principle in order to counteract a tendency to offer simple explanations of animal behavior in terms of Lamarckian inheritance or by analogies to human capabilities. However, in practical effect it placed mind on a sliding scale with the canon as a cursor: while Morgan and others of his generation

were generous in including varieties of consciousness throughout the scale, others who came later adjusted it to exclude consciousness from most of the forms of animal life, and at least between 1910 and 1945, from humans themselves in the most radical behaviorist interpretations. Many modern commentators have noted that interpretations of Morgan's canon which make a direct analogy between it and Occam's Razor misinterpret both the intent of Morgan's proposal and the evidence for substantial amounts of thoughtlike behavior at many levels of brain complexity and organismic development. But this was known comparatively early: Donald K. Adams, a progenitor of the study of insight and of animal cognition in naturalistic environments, identified the problems and potential distortions inherent in Morgan's canon in 1928 (Adams 1928). Morgan's several books on animal intelligence stressed an evolutionary model, suggesting levels of consciousness that represented different degrees or directions of evolution in different species: this idea was formative in the development of Robert Yerkes's even earlier approach to comparative cognition (Yerkes 1905). It is in the context of this hierarchical model of mentation that his "canon" should be properly understood (Wozniak 1997). Morgan's academic title evolved as well, from zoology in the 1880s to psychology and philosophy at the end of his distinguished academic career. In 1921–1922, he was invited to give the Gifford Lectures in Natural Theology at St. Andrews on the subject of emergent evolution (Morgan 1923), wherein he speculated on the potential intuitive awareness of unity with God at the highest evolutionary levels of consciousness.

Morgan, T. H.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: September 25, 1866; Died: December 4, 1945.

The zoologist Thomas Hunt Morgan was born in Kentucky and attended the State College of Kentucky, then went to Johns Hopkins where he obtained the MS in 1888 and the Ph.D. in 1890. His early influences were Jacques Loeb and Hans Driesch. He began his lifelong interests in morphology, embryology, and development in sojourns at Woods Hole between 1888 and 1890. He taught at Bryn Mawr between 1891 and 1904, at Columbia from 1904 until 1928, and then at the California Institute of Technology for the rest of his life.

Major Accomplishments/Contributions

Morgan's great contribution, for which he won the Nobel Prize in Medicine in 1933, was the elucidation of the chromosomal mechanism of heredity. Starting around 1908, Morgan and his colleagues isolated the chromosomes of *Drosophila*, the fruit fly, and made visible the principles on which the Mendelian theory was predicated – the elements of modern genetics. Morgan's magnum opus was actually in two parts. The first, authored with his Columbia colleagues Sturtevant, Bridges, and Muller in 1915, *The Mechanisms of Mendelian Heredity* (Morgan et al. 1915) was a masterpiece of lucid expository prose and perfectly matched illustrations of chromosomal activity, which presented the new science of genetics to a wide

readership inside and outside of the biological sciences. The second was a work of several years' gestation, *A Critique of the Theory of Evolution* (Morgan 1916), revised as *Evolution and Genetics* (Morgan 1925). This work was essential to forging the link between Darwinian theory and Mendelian genetics, which was further developed into the "modern synthesis" by Morgan's colleagues and students, especially Theodosius Dobzhansky.

One might expect that Morgan's work would have had a substantial effect on psychology, especially at a period of its development where hereditarian explanations of behavior were widespread. However, this was not the case, for many reasons. Mainstream American psychology was decidedly British and pre-genetic in its choice of contemporary biological theories. Thus, most psychologists' thinking about heredity was more likely to be couched in terms connected with selective breeding and to rely on statistical analysis of the results of crosses as well as the inspection of pedigree charts rather than on explanations at the cellular level. Among biologically oriented psychologists, there was a preference for the analysis of molar behavior and, secondarily, for referring behavior to putative brain mechanisms which themselves were conceptually comparatively primitive. Theorizing in terms of brain chemistry and neurological microstructure was still in the future, and genetics at the chromosomal level, as practiced by Morgan and his colleagues, was not in psychologists' field of vision. Also, genetics as a specialized science was quite new, as Morgan himself observed: There was no tradition to emulate and the inertia of older approaches based in embryology and physiology determined the direction of psychobiological research. During the 1930s, the new evolutionary synthesis became more accessible due in part to Morgan's effective popularizing, and psychologists began to speculate about specific connections between genetics and behavior, one of the prime areas for future research identified by Morgan at the time of his Nobel Award (Morgan 1933). Finally, the prevalence of eugenic theories in psychology worked against the inclusion of Morgan's theories, which were sober, laboratory-bound, and only rarely connected with any hint of their importance for a eugenic program, although this occasionally surfaced (Morgan 1938).

Morgan may serve as an example of psychology's reaction to a new science and also as a gauge of the boundaries of biopsychological "normal science" in that era. It may be, too, that Morgan's work is a touchstone for the level of explanatory detail to which psychologists have aspired and fallen short. Morgan's isolation of a physical element of heredity points up the difficulty, for psychology, of identifying a comparably specific element of mind. For all these reasons, Morgan's presence in psychology is not great. He did publish an early contribution in the *American Journal of Psychology* on a rudimentary sense organ (Morgan 1889). Insofar as psychologists noticed genetics between 1910 and 1930, Morgan was the source to which they turned: E. G. Boring cited *A Critique of the Theory of Evolution* as the definitive view of evolution in a single note in *A History of Experimental Psychology*. There may have been a connection between Boring and Morgan via Boring's sister Alice, who was a student of Morgan's at Bryn Mawr and who collaborated with him on research for several years thereafter. Morgan contributed chapters to Murchison's edited volume *The Foundations of Experimental Psychology* (Morgan 1929) and in its subsequent handbook version in 1934. There is also a distant conceptual relation between Morgan and the work of Roger Sperry. Sperry's experiments involving regeneration, which led him to his theories of brain functional organization, were presaged by Morgan's regeneration studies which were among his main interests before he turned to genetics.

Mowrer, O. H.

R. W. RIEBER

Fordham University, New York, NY, USA

Basic Biographical Information/Major Accomplishments

American psychologist. Born in Unionville, Missouri, June 23, 1907. Studied at the University of Missouri, Columbia, B.A. 1929; Johns Hopkins University, Baltimore, Ph.D. 1932. Served as a clinical psychologist. Office of Strategic Services, 1944–1945. Married Willa Mae Cook in 1931; three children. National Research Council Fellow, Northwestern University, Evanston, Illinois, 1932–1933, and Princeton University, New Jersey, 1933–34; Sterling Fellow, 1934–1936, and Instructor in Psychology and Member of Research Staff, Institute of Human Relations, Yale University, New Haven, Connecticut, 1936–1940; Assistant Professor, 1940–1943, and Associate Professor, 1943–1948, Harvard University, Cambridge, Massachusetts; Research Professor, 1948–1975, and since 1975 Professor Emeritus, University of Illinois, Urbana. President, American Psychological Association, 1954, and American Psychological Foundation, 1959–1960. Recipient: Certificate of Merit, University of Missouri, 1956; Distinguished Contribution Award, Illinois Psychological Association, 1975. Fellow, American Psychological Association. *Died in June 1982*.

O. Hobart Mowrer was in many ways a psychologist of all seasons. One of the factors that made Mowrer such a maverick in the field is that he managed to bridge the gap between experimental psychology and applied psychology without detriment to either field. He is among the five psychologists most often cited in the literature for their scientific contributions. From the time he retired until his recent death, Mowrer remained an active author and speaker within the fields he worked in. Mowrer studied as an undergraduate at the University of Missouri, graduating in 1929. Following this, he began his graduate work at Johns Hopkins University. During this time, Mowrer became interested in vestibulo-ocular functions and spatial orientation, and he published extensively on this subject between 1929 and 1934 when he joined the Yale Institute of Human Relations.

In the mid-1940s, Mowrer's work led him into the field of language and learning. One of the results of these studies was one of his most important contributions to the field of language and thought, the Autism Theory of Speech Development. This theory arose out of Mowrer's work with talking birds (as opposed to laboratory animals such as rats) such as the mynah bird. In this theory, Mowrer developed the idea of subjective utility as secondary reinforcement in the process of the bird's learning to "talk."

According to Mowrer, the use of certain words or phrases in intimate connection with the process of caring for the bird results in a positive conditioning of the bird; that is, the bird comes to consider them *good sounds*. In the course of its own, at first random, vocalizations, the bird will make somewhat similar sounds. Writing in the *Journal of Speech and Hearing Disorder*, Mowrer had this to say: "By the principle of generalization, some of the derived satisfaction of pleasure which has become attached to the trainer's sounds will now be experienced when the bird itself makes and hears like sounds: and when this begins to happen the stage is set for the bird's learning to 'talk.'" Essentially this means that when the bird hears itself making sounds like the trainer's, it is encouraged to continue making the same sounds. Further, the bird soon learns that he can use these sounds instrumentally as a means of indicating some need or simply to attract an admiring crowd. Mowrer ascribes such an action to a desire in the bird to be like its trainer, which results from the development of a positive relationship between the bird and the human being.

From this Mowrer extrapolated a theory of language development in human infants. The child first identifies certain sounds as being good because his parents use them in connection with actions that provide the child with pleasure. He begins imitating them and perfecting his imitations; this provides him with a sense of gratification and attracts attention from his parents, which encourages him to continue. Finally he discovers the use of words in communicating by learning to use them to control his parents and other people, and to get what he wants. In his 1952 paper, Mowrer concludes that:

- By the procedures indicated, the response is, so to speak, *baited* in advance with secondary reinforcement

so that whenever a closely related response occurs, a satisfying experience is assured, without our necessarily being present to reward it. The autistic satisfaction is, of course, likely to be relatively weak and ephemeral but it is often strong enough to carry the desired response along until it can occur in the presence of another organism and thus elicit a more powerful external reinforcement. Then its stability can be assured.

In the early 1960s, Mowrer became interested in psychopathology, and this led him through the "back door" as he describes it to become interested in deception and its effects on personality. One of the first pieces he wrote on deception was for the Alcoholics Anonymous newsletter, *The Grapevine*, in 1962. Mowrer was impressed at the time with the axiom among members of AA that every alcoholic is a "liar" and that he cannot get sober until he gets honest. While Mowrer recognizes the role heredity plays in causing mental illness, he feels that the stress created by deception can play an enormous part in triggering otherwise inert physiological troubles. In his paper for *The Grapevine*, Mowrer quotes Sir Walter Scott, who says in "Lochinvar," "Oh what a tangled web we weave, when first we practice to deceive." It is the stress caused by becoming tangled in this web of deception that Mowrer believes is responsible for much of the mental anguish that people suffer. It is not just the deception of others that Mowrer cites too; it is also self-deception. Few psychologists have contributed more to the advancement of psychology, and particularly the psychology of language and thought, than Mowrer. His work has been both imaginative and practical, as well as very often being candid and outspoken in its direction.

Münsterberg, Hugo

ERWIN V. JOHANNINGMEIER
University of South Florida, Tampa, FL, USA

Basic Biographical Information

Münsterberg, chiefly known for his pioneering work in applied psychology, especially industrial psychology, and as one who successfully argued for the utility of psychology, after his arrival in the United States, was born on June 1, 1863, in Danzig Germany and died on December 16, 1916, of a cerebral hemorrhage while presenting a lecture on introductory psychology at Radcliffe College. In 1882, he began his university studies at Leipzig and planned on studying medicine. During his first year, he studied with the biochemist Karl Friedrich Wilhelm Ludwig (1816–1895) and the anatomists Karl George Friedrich Rudolf Leuckart (1822–1898) and Wilhelm His, Sr. (1831–1904) from whom he gained a mechanistic approach to natural science.

During his second year, Münsterberg began attending the lectures of Wilhelm Wundt (1832–1920) who a few years earlier founded what is often considered the

first true psychological laboratory and secured a position as a research assistant. However, Wundt was not pleased with his conclusion that “‘will’ is not represented in consciousness” and assigned him other work (Hothersall 2004, p. 156). Still, he was able to complete his dissertation, “The Doctrine of Natural Adaptation,” a critical study of the biological doctrine of natural adaptation that was neither an experimental study nor a study based on Wundtian methods of introspection, and was awarded his doctorate in 1885. In 1887, based on his study of the visual perception of space, the university at Heidelberg awarded him an M.D.

In 1887, Münsterberg secured a position as a *Privatdozent* (a private lecturer who received no salary from the university but received fees from students who attended his lectures) at the University of Freiberg. There in his own house he established what is considered to be the second psychological laboratory in Germany. In 1888, he returned to the work on will and voluntary activities that had earlier earned him a new assignment from Wundt and in 1899 published *Die Willenshandlung* (translated as *Voluntary Action*), a work critical of Wundt. Wundt attacked the work. However, William James (1842–1910), impressed by it and by Münsterberg’s experimental work, made arrangements to meet Münsterberg in 1899 at the First International Congress of Psychology in Paris. The quality of the studies that issued from Münsterberg’s home-based laboratory earned him a promotion to assistant professor at Freiberg. He then received a salary from the university and was able to move his laboratory to the university in 1891.

Major Accomplishments/Contributions

In 1892, James offered Münsterberg a 3-year appointment to take charge of Harvard’s psychological laboratory. He accepted the offer and by 1899 was chair of Harvard’s Philosophy Department. Except for a 1-year return to Freiberg after 2 years at Harvard and a year as a representative of the Harvard-Berlin-Exchange-a-Professor Program in 1910–1911, he remained at Harvard until his death. Under his direction the Harvard laboratory was recognized as one of the most important psychological laboratories in the nation. However, by 1908, when he began to publish a great variety of articles on applied subjects, including articles

in the popular media (for example, *Harper's*, *The Atlantic Monthly*, and the *New York Times*), it was clear that he was more interested in applied psychology than in laboratory work and left the laboratory duties to his assistant, Herbert Sidney Langfeld (1879–1958), who arrived at Harvard in 1910.

For Münsterberg the psychological expert, armed with the techniques of the new science of the mind, was to be the surrogate for the displaced or absent monarchy. Individuals could not be trusted either to know their own minds or to perceive reality objectively. The psychologist was to do that for individuals and assign them to their proper stations. In that way social order and social efficiency would be maintained and promoted. He held that applied psychology promised to be beneficial to society and set out to prove his claim by showing how psychology had practical principles for education, industry, law, and medicine. Mental illness was among his many applied interests. Believing that mental illness had a physiological basis, he began to offer treatment to patients in his laboratory in Germany and pursued that work after arriving at Harvard. He claimed to have had success with patients who suffered from a wide variety of problems, ranging from various addictions to sexual disorders. He described his methods and how he achieved his successes in *Psychotherapy* (1909).

In 1908, he showed how psychology could be applied to law in *On the Witness Stand* in which he argued social conditions were largely responsible for criminal activity. For educators, he published *Psychology and the Teacher* in 1910. In 1913, he published *Psychology and Industrial Efficiency*, the first such book on industrial psychology in which he advised employers on how to select appropriate workers and on the methods that could be employed to improve their efficiency and productivity. In 1914, he published *Psychology: General and Applied*, the first textbook on applied psychology and *Psychology and Social Sanity*.

Münsterberg was a productive scientist, having published over 30 books, over 60 papers, and numerous magazine articles, and was widely recognized for this work and contributions. A charter member of the American Psychological Association, he was elected its president in 1898. He served as a vice president of the 1900 International Psychological Congress in Paris and as a vice president and an organizer of the International

Congress of Arts and Sciences for the 1904 World's Fair in St. Louis. He was elected to the presidency of the American Psychological Association in 1907. However, his decision to act as a self-appointed ambassador of Kaiser Wilhelm's Germany cost him dearly. All the while he was away from *der Vaterland* he tried to serve it, endlessly trying to promote German *Kultur* and German *Wissenschaft* in the United States. He failed to win the Americans to the German cause of *Kultur*, and a popular press that did not appreciate his defense of Germany policies on the eve of World War I attached the ignominious sobriquet "Prof Monsterwork" to him. His efforts to win the approbation of the authorities in *der Vaterland* have overshadowed his scientific accomplishments.

Murphy, Gardner

DAVID C. DEVONIS
Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: 8 July 1895; Died: 18 March 1979.

Murphy came from a literary and socially progressive family in New England which had deep roots in the local transcendental tradition. He began his university career at Yale and took an M.A. at Harvard in 1917 and the Ph.D. at Columbia in 1923. He taught at Columbia until 1940. He then moved to New York University and taught there until 1952, when he became director of research for the Menninger Clinic in Topeka, Kansas, a post he held until 1968. He then moved back east and taught for a few years at George Washington University until his health failed.

Major Accomplishments/ Contributions

Murphy was one of psychology's great syncretizers. He exemplified the idea that nothing in the world is unconnected and his primary aim was to envision the future. Beginning with his editorship of *An Outline of Abnormal Psychology* in 1929 (Murphy 1929a), he authored or coauthored books distinguished by their lucid style and wide scope. Among these were *Historical Introduction to Modern Psychology* (Murphy 1929b), *Experimental Social Psychology: An Interpretation of Research Upon the Socialization of the Individual* (Murphy et al. 1937), and *Personality, A Biosocial Approach to Origins and Structure* (Murphy 1947), each of which was widely read and used as a textbook. Murphy's approach to history blended classical sources with modern developments: it went into three editions over the next 43 years. His synthesizing approach can be seen in the way he constructed his *Personality*. There, Murphy chose a case study, the life of William James, to begin the book, and then wove together theories of canalization of response synthesized from E. B. Holt, Troland's theories of hedonism, Milton Erickson's theories of hypnosis, and many others in successive chapters. Recent commentary places Murphy in the tradition of a dual-aspect psychology (Barta 1999) stemming from Spencer and James: Murphy also gave much attention to an interactionist interpretation of heredity and environment. However, most of what Murphy wanted from and for psychology transcended the boundaries set by standard biopsychological research. He had some short experience in mainstream laboratory research as a doctoral student with ► Wells, Frederic Lyman in the early 1920s, but after that his career was driven by two passions, the first to understand how peace and disarmament might be achieved, and the second, his intense and lasting commitment to psychical research. Murphy's experiences in the First World War led him to develop a practical pacifism that resulted in theoretical consideration of conflict (Guthrie and Murphy 1938) and also to an appointment with UNESCO to study conflict in the field in India in 1950. Murphy was one of the primary forces in the development of cross-cultural psychology with books such as *Asian Psychology* (Murphy and Murphy 1968) written, as were many of his works, in collaboration with his wife, Lois Barclay Murphy. Murphy

cannot be truly estimated until it is seen how deeply his commitment to parapsychological research informed his thought. He was one of the few mainstream psychologists (he was President of the APA in 1944) to overtly identify with psychic research: He was associated with it throughout his career, from the time he assisted with Leonard Troland's (► Troland, Leonard T.) researches at Harvard in 1917. Murphy was supported by the Hodgson funds from 1922 to 1925 and he worked under MacDougall at Harvard in close connection with the Boston Society for Psychic Research. In 1925, illness and a disagreement within the psychic research community caused Murphy to retreat from psychic research to writing generalist books, but he returned as research director for the reconstituted American Psychical Research Society in 1941. Murphy believed that psychical research was necessary in order to continue to search for dimensions beyond conventional reality (Murphy 1967). Murphy's lasting effect on psychology was to bring many diverse voices together in the field: he argued successfully for including the phrase "human welfare" into the APA mission in 1945. He was a major contributor to the development of humanistic psychology's program in the 1950s and his *Human Potentialities* (Murphy, 1958) as well as his article *The Psychology of 1975* (Murphy 1963) capture his vision of psychology's future in a dynamically changing world. Commenting on the 'space race' in 1961, Murphy observed that we have always been in space, and we are only beginning to understand the implications of that (Murphy 1961).

Murray, Henry A.

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Basic Biographical Information/Major Accomplishments

American psychologist. Born in New York City, May 13, 1893. Studied at Harvard University, Cambridge, Massachusetts, B.A. 1915; Columbia University College of Physicians and Surgeons, M.D. 1919; Cambridge University, Ph.D. in biochemistry, 1927. Served in the Office of Strategic Services, 1942–1946: Lieutenant Colonel. Married Josephine Rantoul in 1916, one daughter; married Caroline C. Fish in 1969. Surgical Intern, Presbyterian Hospital, New York, 1924–1926; did research work in embryology at the Rockefeller Institute for Medical Research, New York, 1926–1927; Instructor, 1927–1929. Assistant Professor, 1929–1937. Associate Professor, 1937–1948. Professor of Clinical Psychology, 1948–1962, and since 1962 Professor Emeritus. Harvard University (after 1929, Director of the Psychological Clinic). Recipient: Distinguished Science Contribution Award. American Psychological Association, 1961. Honorary doctorate: Lawrence College, Appleton, Wisconsin, 1964; University of Louvain, Belgium, 1966. Member, American Academy of Arts and Sciences. Address: 22 Francis Avenue, Cambridge, Massachusetts 02138, USA.

The focus of Henry A. Murray's work has been the study of human personality for which he has coined the word "personology," defining it as "the branch of

psychology which principally concerns itself with the study of human lives and the factors that influence their course." The ultimate aim of the personologist is threefold: to construct a theory of personality, to devise suitable techniques for studying its more important attributes, and to discover its basic facts through careful and extensive studies of actual human lives. Since personology is the science of men, Murray considers it the most inclusive field of psychology, other branches being essentially special areas within it.

Murray has always been an advocate of interdisciplinary personality studies accepting a wide range of approaches as useful in personology. Biological, historical, cultural, social, and evolutionary concepts, as well as those in all areas of psychology, are important to personality as Murray sees it. He is concerned with interpersonal, intrapersonal, and impersonal psychological forces, and, while recognizing the value of subjective material, he does not neglect objective observation. He has formulated a number of special evaluation techniques to study both conscious and unconscious psychological processes. Among the most well known of these are the Thematic Apperception Test, a projective technique through which data can be analyzed to permit inferences about the dominant psychological forces affecting the subject's thought and behavior. This is done through the intermediary device of heroes or central figures in the TAT pictures, about which the subject is asked to make up stories. The ways he handles the issues he projects into the pictures are assumed to indicate his own characteristic problem-solving approaches, and the endings he envisions are assumed to embody the endings he desires for his own conflicts.

Murray defines personality as "the hypothetical structure of the mind, the consistent establishments and processes of which are manifested over and over again. . . in the internal and external proceedings which constitute a person's life." In speaking of personality, Murray uses a number of terms. The term "proceedings" refers to the units of time during which the person attends to either the internal or external circumstances of his life. Serials, a series of proceedings, are related to each other but separate in time and permit the pursuit of long-range goals. Murray sees the person as continually planning schedules for achieving these goals by setting up serial programs, sequences of subgoals, which serve as steps along the

way. All of these processes constantly arise, shift, and give way to others as circumstances change, and personality changes with them. He sees the person as constantly under pressure by conflicting internal and external demands so that throughout his life he must give up things as well as take for himself.

Murray's views on personality contain a strong Freudian Emphasis, stressing the role of the past as the seed of the present. At the same time, however, he does not neglect either present or future states and their influence on personality. Murray uses Freudian concepts to describe the stages of childhood. The id, as he conceives it, remains the source of energy and the reservoir of unacceptable impulses as it was for Freud. However, Murray also sees the id as containing positive and constructive impulses. The ego is not merely a repressor and inhibitor for him; it has energies of its own which direct id drives toward a suitable expression. The superego, although still the internal regulator of behavior derived from early experiences, can be significantly changed later by peer-group and other influences, including those associated with literary, historical, and mythological characters with whom the person identifies. Murray's concept of the ego ideal, which is associated with the superego, consists of the various self-images representing the person at his very best, helping him to maintain goal-directed living.

Murray also identifies certain temporal sequences in childhood that represent their Freudian counterparts, although they are a bit more widely interpreted: to the oral, anal, and phallic stages. Murray introduces two further stages, the claustral and the urethral. The claustral involved the tranquil state of prenatal existence, while the urethral, falling between the oral and anal stages, involves the pleasurable sensations associated with urethral erotism. In Murray's view, these can naturally lead to complexes of their own, the claustral producing a passive, dependent personality with prominent withdrawal tendencies, and the urethral complex producing an overly ambitious, strongly narcissistic adult with a prominent concern for achieving immortality and a strong attachment to fire. The urethral complex is also known as the Icarus complex. The extremely detailed case history called "An American Icarus" is one of Murray's best-known works. Murray has also developed a theory of motivation, one of the main concepts of which is that of "need," which he

regards as a force in the brain which can be aroused by either internal or external stimulation. Once stimulated, it produces continued activity until it is reduced or satisfied. Murray has worked out a number of classifications of needs in a continuing effort at greater precision. In one such system, he distinguishes between activity and effect needs, activity needs being directed toward activity for its own sake and effect needs being directed toward some goal. Another of his classifications involves mental, viscerogenic, and sociorelational needs. These arise respectively from the character of the human mind, from properties of physiological tissues, and from man's inherent social nature. He also adds creative needs that promote novel and productive activities, as opposed to negative needs, which induce avoidance of the undesirable. Another distinction he makes is between proactive needs, which arise from within the person, and reactive needs, those induced by environment. This emphasis on proactive needs removes man from being merely acted on and gives him some control of his destiny.

Although he has insisted that he has never made more than a beginning in the work which he set out to do, Henry Murray's contribution to personality study has been described in a book of essays published in his honor as "a unique and inexhaustible house of treasures."

Myers, Charles S.

SHARLENE D. WALBAUM, BETHANY S. HUARD
Quinnipiac University, Hamden, CT, USA

Basic Biography

Charles Samuel Myers was born in London on March 13, 1873, just before Wundt established his lab and as the industrial revolution was transforming work. Myers' work was multifaceted, reflecting the interaction of anthropology, experimental psychology, and applied psychology. As a scientific psychologist with an enduring commitment to the "human factor" in work, Myers made his mark (Myers 1920).

Myers was the firstborn son of a successful businessman, Wolf Myers, making him aware of workplace issues from the start. His mother, Esther Eugenie Moses, an avid supporter of the arts, influenced him to become an accomplished violinist (Bartlett 1948).

Myers attended college at the City of London and Cambridge University. Although he worked toward a medical degree at St. Bartholomew's Hospital from 1895 to 1898, he would not become a physician (Obituary 1946). At 25, Myers had his first of two transformative experiences, the first taking him from medicine to experimental psychology and the second from the lab to pioneering work in industrial psychology.

Major Accomplishments and Contributions

In 1898, Myers joined Alfred C. Haddon, William MacDougall, W.H.R. Rivers, and others on the Cambridge Anthropological Expedition to Torres Straits and Sarawak (Bartlett 1948). He went to study psychophysical responses of indigenous peoples, but culture that caught his attention. He became interested in what would now be called cross-cultural psychology.

Myers assumed that "primitive" or indigenous people would perform differently because they differed from him geographically, socially, and physically. But, his study of music, color, and taste perception revealed differences best understood in terms of language or cultural practice (Pear 1947). Myers' curiosity

compelled him to continue his study of cultural differences in language and perception after expedition, eventually passing on his fascination with culture and cognition to students such as F. C. Bartlett.

Myers completed his medical thesis in 1901, but, by 1903, was assisting W.H.R. Rivers as University Demonstrator in Experimental Psychology at Cambridge. He also became a lecturer on Psychology for Kings College London (Obituary 1946).

By 1909, Myers became the first full-time lecturer in Experimental Psychology at Cambridge and was soon directing a new Psychology Lab (Obituary 1946). In that same year, he published *Textbook of Experimental Psychology* (1911), the first English survey text. These accomplishments completed his transition from medicine to psychology.

For Myers, psychology was the study of experience, versus behavior (Pear 1947). His research topics ranged from synesthesia (1914) to the role of handedness in letter reversal (Fildes and Myers 1921), but his primary interest was in the psychology of music (cf. Myers and Valentine 1914). Myers inspired a generation to think about research questions relating to individual differences, cognition, culture, and applied psychology; many, such as Bartlett, R. H. Thouless, and C. W. Valentine, became important British psychologists (Bartlett 1948).

During World War I, Myers volunteered for the Royal Army Medical Corp in France (Obituary 1946). Witnessing the physical and psychological costs of war strongly motivated Myers to apply scientific psychology to the relief of soldiers and in support of England's war effort.

In Myers' war diary (1940), *Shell Shock in France 1914–18*, he coined the term "Shell Shock" and described its symptoms. Neurological damage from proximity to explosions was the presumed cause; however, Myers noticed the symptoms in soldiers who had not been near exploding shells and reasoned that the disorder must be psychological. Myers recommended immediate psychotherapy, administered away from the battlefield, that focused on restoring memory, a sense of safety, and self-esteem.

Myers was one of the first to join the War Office's Advisory Committee on Personnel Selection (Obituary 1946). He developed a test battery for identifying effective "hydrophonists," evaluating perceptual acuity,

the ability to follow complicated directions, and memory for pitch, rhythm, and sound quality.

In 1917, Myers returned to England to coordinate the training of medical officers for their psychological work with returning soldiers.

Given his transformative war experience, Myers directed his energy toward the psychology of work (Bartlett 1948). He asserted that the psychological dimension of work was the most fundamental to efficiency (Myers 1920). Myers inspired H. J. Welch, businessman, to join him in founding the nonprofit National Institute of Industrial Psychology (NIIP) in 1921. It became a research, resource, and training center for the application of scientific knowledge to occupational life (Welch and Myers 1932).

Myers left academia in 1922 to devote his time to the NIIP and study the “human factor.” Myers examined various types of fatigue, conducted time and motion studies, and worked to improve workspace design (cf. Myers 1919). To match workers with jobs, Myers developed tests for individual differences in, for example, reaction time, auditory discrimination, visual acuity, signal detection, figure memory, and manual dexterity (Welch and Myers 1932). Myers work anticipated current interest in components of cognitive processing and, for example, learning disabilities (Welch and Myers 1932).

Myers (1920) was a strong advocate of vocational guidance programs and studied the effect of training, promotion, and incentives on productivity. His goal was to help young people make better work choices and teach managers to be more equitable and effective.

Myers’ intellectual curiosity and rigor were recognized early; they served his profession well (Bartlett 1948). In addition to winning scholarships and honors, he was named the Arnold Gerstenberg Student at Cambridge for his promise in natural science and philosophy. In 1915, Myers was one of the first psychologists to be elected Fellow of the Royal Society (Obituary 1946). In 1933, he gave the prestigious Bradshaw Lecture on *A Psychological Regard of Medical Education* (Pear 1947).

Myers, along with W. H. R. Rivers and others, established the *British Journal of Psychology* in 1904. He served as Associate Editor for 3 years and was Editor from 1913 to 1923 (Pear 1947). In 1924, he became first president of the British Psychological

Society, the preeminent society for professional psychologists in the UK (Bartlett 1948). Under the auspices of the NIIP, he founded and edited *Occupational Psychology*. Myers presided over the Seventh International Congress of Psychology at Oxford in 1923 (Pear 1947).

Myers’ clear writing style and editorial work widened his impact and solidified his legacy (Pear 1947). *Shell Shock in France 1914–18* (1940) is valuable both as a first person account of war and a detailed description of shell shock. His survey text of experimental psychology (1911) went into multiple editions, proof of its staying power. Myers repeatedly published in *Lancet*, arguing for the psychological origin and treatment of “war neuroses.” Seeing great promise in industrial psychology, he wrote four well-received books, including *Mind and Work* (Myers 1920).

The National Institute of Industrial Psychology turned 25 just before Charles S. Myers passed away at 73 on October 13, 1946 (Obituary 1946). In the *British Journal of Psychology*, Pear (1947) observed, “psychology in Britain owes to none more than it owes to C. S. Myers.” In fact, Myers’ impact was global; his motivation and methods formed the bedrock for modern industrial/organizational psychology.

N

Neisser, Ulric

KAREN M. ZABRUCKY, REBECCA B. BAYS
Georgia State University, Atlanta, GA, USA

Basic Biographical Information

Ulric Neisser was born on December 8, 1928, in Kiel, Germany, and his family moved to the USA when he was 4 years old. Once in the USA, Neisser's father, a professor of economics, took teaching positions at The University of Pennsylvania and the New School for Social Research. Thus, Neisser grew up in the suburbs of Philadelphia and New York City.

Neisser attended Harvard University as an undergraduate and conducted his senior thesis in George Miller's laboratory. After receiving his Bachelor's degree in 1950, Neisser went to Swarthmore to study Gestalt psychology and received his Master's degree at Swarthmore. After receiving his Master's degree, he studied briefly at MIT before returning to Harvard and receiving his Ph.D. in 1956, under the direction of S.S. Stevens. Neisser's first teaching position was at Brandies University. He would later teach at both Emory University and Cornell University. He is currently a Professor Emeritus at Cornell.

Major Contributions/ Accomplishments

Ulric Neisser has made an impressive and lasting contribution to the field of psychology. He was named the 32nd most influential psychologist in history, based on a study published in the *Review of Psychology*. There is no doubt that his contributions place him among the most influential psychologists of all time, particularly in helping develop the emerging subfield of cognitive psychology within the broader domain of psychology. During the first half of the last century, American

psychology was decidedly behavioristic in approach and there was little interest or tolerance in looking inside the behaviorist's view of the mind and mental processes, the so-called black box. Neisser paved the way for the development of the cognitive revolution in psychology.

In 1967, Neisser published the first real book attempting to integrate the newly emerging cognitive literature. This book, simply titled *Cognitive Psychology*, is generally considered the first real textbook for studying cognition, with chapters on The Cognitive Approach, Iconic Storage and Verbal Coding, Pattern Recognition, Focal Attention and Figural Synthesis, Words as Visual Patterns, Visual Memory, Speech Perception, Echoic Memory and Auditory Attention, Active Verbal Memory, Sentences, and the closing chapter, A Cognitive Approach to Memory and Thought, in a final section on higher mental processes. In this important work, Neisser also produced what has been a very insightful definition of cognition, referring to "all the processes by which the sensory input is transformed, reduced, elaborated, stored, recovered and used" (p. 4). His definition still appropriately reflects the emphasis on the organism as an active processor of information and our increasing understanding of the role of constructive and reconstructive processes in interpreting the world around us. Indeed, he indicated that his approach was "more closely related to that of Bartlett . . . than to any other contemporary psychologist" (p. 10) and that Bartlett's influence on his thinking would "become obvious in later chapters" (p. 8). Bartlett's influence on Neisser would only seem to become more pronounced throughout Neisser's career.

Following the publication *Cognitive Psychology*, Neisser wrote *Cognition and Reality* in 1976. In his second book, Neisser openly discussed his dissatisfaction with the typical laboratory research and lack of ecological validity that had often come to characterize the "new" cognitive approach. He became quite

influential in helping develop an interest in everyday memory and the study of cognition in the real world. Many of his articles, books, and edited books following the publication of *Cognition and Reality* involved the issues of ecological validity and remembering in natural contexts (e.g., *Memory Observed: Remembering in Natural Consequences*).

Neisser has also had a long-standing interest in the nature of “intelligence” tests and their significance in society. He has written about these topics in works such as *The Rising Curve: Long-Term gains in IQ and Related Measures* and headed a task force that wrote a consensus statement on the state of intelligence research for the American Psychological Association surrounding controversial claims involving IQ at the time. He also chaired a conference at Emory focusing on changes in intelligence test scores. Neisser has won numerous awards for his work over the years including the Emory University Scholar/Teacher Award, and has been both a Guggenheim and Sloan Fellow.

New School for Social Research, History of Psychology at

HARMON M. HOSCH
University of Texas at El Paso, El Paso, TX, USA

Basic History of the Department

Max Wertheimer, a seminal contributor to the theory of Gestalt Psychology, was listening to a radio broadcast

in 1933 in which Adolph Hitler, the newly appointed chancellor of Germany, was speaking. After a few minutes of the speech, Wertheimer abruptly turned the radio off and brought his family together. He announced that they would leave Germany that day. The Wertheimers moved to Marienbad, Czechoslovakia, where they were contacted by Alvin Johnson, Director of the New School. Thus began a journey from Frankfurt, Germany, to New York City. Wertheimer became one of the original faculty in what was called the University in Exile (Rutkoff and Scott 1986).

To understand the University in Exile one must understand the context in which it was founded. In brief, in 1917, the President of Columbia University announced to the faculty that they were expected to support the war policies of the US Congress and the President of the United States. Those who opposed the government policies would be dismissed from Columbia. Two faculty members, James McKeen Cattell, Professor and founder of the Psychology Laboratory at Columbia, and Henry W. L. Dana, Assistant Professor of comparative literature, were soon terminated because they publically opposed the US entry into World War I. Noted historian and political scientist Charles A. Beard and distinguished historian James Harvey Robinson resigned from Columbia as well and joined with Alvin Johnson, economist and humanitarian, and philosopher John Dewey, economist Wesley Mitchell, Thorstein Veblen, a sociologist said to be “the last man who knew everything” (Henle 1979), and a group of liberal philanthropists to discuss the need for a new educational institution that was “honestly free.” The New School opened for the Spring term of 1919. According to its catalog, the standard of all work in the school will be “post graduate” in character, although an academic degree will not be required for admission. Students were presumed to be pursuing their education for its own sake. No degrees were to be granted by the New School.

The first course in psychology was offered in 1919, followed in 1921–1922 by a series of lectures on mental hygiene by distinguished psychologists Morton Prince, Adolph Meyer, and William Alanson White. The following year, John B. Watson came to the New School and gave courses in behavioral psychology. He brought such leading scholars as Sandor Ferenczi, E.B. Holt,

John Dewey, W.G. Cannon, and Alfred Adler to lecture in a Modern Viewpoints in Psychology course (Henle 1979). The New School became the focal location for the early teaching of psychoanalysis and the evolving psychodynamic theories of personality with Karen Horney, Ernst Kris, and Eric Fromm teaching in addition to Ferenczi and Adler.

Hitler rose to power in January of 1933. The Nazis were intent upon destroying the German University system, and distinguished university professors, Jewish scholars in particular, were at risk. Alvin Johnson saw the opportunity to rescue scholars and to provide a world-renowned graduate faculty for the New School. He raised money to bring faculty to New York. The University in Exile was born with ten German scholars. The faculty adopted a constitution in 1935, and the catalog stated that the Master of Social Science (MSSc) and Doctorate of Social Science (DSSc) could be earned with the Graduate Faculty. The first masters degree was awarded in 1936 and the first doctorate in 1937.

Among the original members of the Graduate Faculty was Wertheimer. He taught philosophy and psychology courses. In 1938, Kurt Koffka offered a seminar. Wolfgang Köhler commuted from Swarthmore to offer courses for the Graduate Faculty. Solomon Asch was appointed to the faculty and Mary Henle joined the department in 1946. Not long thereafter, Asch took a position at Swarthmore, Tamara Dembo who had been a student of Kurt Lewin, Irvin Rock, and Ulrich Sonneman joined the department for short periods. The department essentially remained as a two- or three-member department using visiting faculty to provide much of the course offerings. Notable names of faculty during this period were Hans Wallach, Kurt Goldstein, Rudolf Arnheim, William Sheldon, and Köhler. The department appears to have hit a nadir in 1953–1954 when the New School Catalog only listed 16 courses offered by the faculty.

The department grew in the late 1950s and early 1960s. Joseph Greenbaum joined the faculty in 1958. The 1964–1965 Catalog listed Nathan Brody, Arthur Gladstone, Howard Gruber, Mary Henle, Robert Terwilliger, John van Laer, and Bernard Weitzman as tenure/tenure track faculty. Rudolph Arnheim, Molly Harrower, Goldie Ruth Kaback, Ausma Rabe, Michael Studdert-Kennedy were listed as visiting faculty. Some 52 courses were listed in the Catalog offerings, although

it appears that only 41 were actually offered. In any case, this menu of courses was greatly expanded from what was available during the 1953–1954 term.

By the late 1960s, Leon Festinger had joined the faculty. By then, Festinger's research had shifted from social psychology (e.g., cognitive dissonance theory) to visual perception (e.g., efference theory), and he headed a semiautonomous program in consortial arrangement with Columbia University and New York University. Stanley Coren joined Festinger in this effort in 1969. In addition, the Department was offering a Ph.D. in Personality and Social Psychology and one in Experimental Psychology.

The 1970s saw Nathan Kogan (individual differences in cognition) in the role of Department Chair, and Sarnoff A. Mednick (schizophrenia), Elizabeth F. Loftus (cognitive psychology generally and memory and eyewitness identification more specifically), and Arien Mack (perception) had joined the faculty. Visiting faculty included Louise Erlenmeyer-Kimling (behavior genetics), Serge Moscovici (minority group influence), Michael Lewis (cognitive developmental psychology), and Donald Rock (regression and multivariate statistical methods).

The department changed considerably in the 1980s with the addition of a full-fledged clinical psychology program. Arien Mack took the department Chair. The department gave degrees in four fields: Clinical, Developmental, Experimental, and Personality/Social Psychology. Jerome Bruner joined the faculty. Mary Henle retired and was appointed as Professor Emerita by 1983.

The number of full-time faculty who were tenured or on the tenure track remains relatively stable ranging from 15 to 19 since the early 1980s until today. With the notable exceptions of Professors Henle, Kogan, Terwilliger, and Weitzman, the turnover among faculty has been consistent. It now awards the Ph.D. in Cognitive, Social, and Developmental Psychology and in Clinical Psychology. The number of graduates from clinical is about four times those in CSD per year (see New School for Social Research Catalog, various).

Significance

The Psychology Department played its part in the original mission of the University in Exile. It provided a home for German and other European scholars to

continue their work and escape the Nazis through the University in Exile. The founding psychologist, Max Wertheimer, who along with Koffka, Köhler, and others, provided the explication of Gestalt principles in the fundamental domains of experimental psychology: thinking, perception, memory, and the like. Other like-minded thinkers, such as Asch (social psychology) and Arnheim (psychology of art) and the students of these important historical figures were all connected with the University in Exile/Graduate Faculty of the New School for Social Research. Mary Henle, who studied with Koffka and Köhler, made lasting contributions by translating the original works of the founders from German to English and kept the Gestalt School alive in her courses.

As Gestalt principles became accepted fundamental components at the core of experimental psychology and with the passing of the founders and their students, the focus of the courses offered by the department aligned with the offerings of other major departments throughout the United States. It has been the home for periods of time to many others outside of the founding Gestalt tradition. Some have come for a relatively short period and then moved on to distinguished careers elsewhere. Examples would be Elizabeth Loftus and Stanley Coren. Others (e.g., Nathan Brody) rose through the academic ranks at the New School and then moved to other institutions where they completed their careers. On the other hand, many made important contributions to psychology before joining the Graduate Faculty. Examples would be Jerome Bruner, Leon Festinger, and Molly Harrower.

Noble, Daniel

TORY HOFF

Psychologist, Toronto, ON, Canada

Basic Biographical Information

Born on January 14, 1810, in Preston, England, of Catholic parentage, Daniel Noble received medical training at Guy's Hospital, London. He became a member of the Royal College of Surgeons, and in 1834 moved to Manchester to become a physician at the Clifton Hall Retreat for the insane. Eventually he also became a lecturer in psychological medicine at the nearby Chatham School of Medicine, and was elected a Fellow of the Royal College of Physicians in 1867. Regarding personal life, in 1840 Noble married Frances Mary Louisa Ward, of Dublin, and they fostered eight children. He died on January 12, 1885.

Major Contributions

Noble began his career heavily influenced by Franz Josef Gall, whose theory became known as phrenology, and Noble remained always appreciative of him. In the late 1830s, he became a president of the Manchester Phrenological Society, and he wrote a few articles in the *Phrenological Journal*. His book, *The Brain and Its Physiology* (1846), is likely the last articulate case for the phrenological system written in the English language to receive respectful discussion from colleagues within the established British medical community. Throughout this book, Noble juxtaposed “mechanical” structure and “organic” structure in a manner that reflected his vitalistic physiology. A “mechanical” structure, Noble conceived, is a “mere” physical object of the kind first identified by Galileo, Descartes, and Newton, and is thus available to the scientific investigation of the observable. The skull qualifies as this kind of object (Noble 1839).

By contrast, Noble believed that “organic” structures, especially the cerebral organs of humans, are hidden, as they having an “intimate quality” that is not entirely open to public observation. To a great extent Noble retained Gall's belief that the cerebral organs are each incarnations of specific internal essences known as the faculties of the mind (Gall 1935, vol. 2, p. 30),

and therefore cannot be directly observed as discreet objects (Noble 1846, p. 237). Unlike all other “organic” structures, they operate as the nonmechanical instruments of these faculties. Noble followed Gall when he imagined that the cerebral organs have a hidden, “sympathetic” kind of communication, an “association of function” among themselves (Noble 1846, pp. 19f, 80, 270).

Noble held to Gall’s theory of expression whereby these internal faculties via their powerful organs reveal themselves in behavior but also influence the shape of that adjacent “mere” structure, the skull. As incarnations of the faculties, the cerebral organs themselves act as *quasi-psychological forces*, ones which obtain expression at the exterior skull as well as through behavior.

Noble later wrote that an anonymous review of considerable length, which appeared in the esteemed *British and Foreign Medical Review* a few months later, precipitated his rejection of phrenology as a cohesive system of thought (Noble 1858, p. 33, note). It had been written by his colleague and friend, William Carpenter (1813–1885). Carpenter (1846) was already becoming a spokesperson for the new British psychophysiology with its dualistic juxtaposition of physical body and human consciousness.

Among other things, Noble took seriously Carpenter’s legitimate points that phrenologists failed to take into consideration the actual convolutions of the brain and had little to say about brain mass *not* located adjacent to the skull. When realizing that the parts of the brain are not hidden in principle but are more observable than previously thought, Noble became disillusioned with the vitalistic concepts of orthodox phrenology and its related methods. He concluded that no scientific method could be found for determining the “quality” of the cerebral organs. A reading of Noble’s subsequent two books, *Elements of Psychological Medicine* (1853, 2nd edition, 1855) and *The Human Mind* (1858), indicates that he became committed to the belief that the size of nervous tissue is the primary means for determining the power of a mental function.

Noble also came to accept Carpenter’s argument that the physiognomical tradition was not relevant to a scientific theory of brain function. The phrenological concept of expression from the internal to the external

was no longer a central part of the medical thought of Noble. He did, however, retain the belief that the shape of the skull is reflective of general endowment regarding the intellectual, moral, and instinctual modes of consciousness (Noble 1858, pp. 25, 85).

Although Noble distanced himself from phrenology, more so the system of Johann Gaspar Spurzheim than the theories of Gall, the pursuit of the relation between brain and mental processes remained his passion. By the 1850s, this endeavor occurred within a more dualistic “physiological psychology” in which the operations of brain structures *correlate* with mental processes. Likewise, Noble abandoned the phrenological search for a set of psychological categories for understanding individual differences, and instead focused on states or modes of consciousness (Noble 1855, p. 65). He described a set of brain–mind correspondences similar to what Carpenter posited.

Noble contributed to ongoing discussion regarding the nature, causes, classification, and treatment of insanity. He remained skeptical about the ability of brain anatomy to provide knowledge about the physical and moral causes of insanity. His classification was consistent with the common distinctions made in his day between mania, monomanias, and moral insanity. He emphasized that many cases of insanity are likely due to some kind of disordered sympathetic communication between unknown parts of the brain. Sober about the limits of the medical means of treatment including bloodletting and physical restraint, he was a proponent of the moral management of insanity in that he was aware of various ways that “striking derangement of the functions of the nervous system can be produced by impressions purely mental” (1855, p. 305). He held to the common opinion that “deprivation of personal liberty as secured in a lunatic institution constitutes a positively curative agency” (1855, p. 343). But he also took the novel position that the afflicted person in detention not only needs a “relation-like regard” from the physicians but in short-term cases also a family-appointed person who periodically visits.

Daniel Noble was a prominent medical theorist of brain–mind relations and psychopathology in a transitional era when scientists were beginning to understand localization of brain function and to reformulate notions about insanity. More specifically, his ideas exemplified the way that a liberalized phrenological

perspective influenced psychiatry and social reform in the middle of the nineteenth century. Although he never attained the eminence of a few of his colleagues, he was a strong supporting member of a community that advanced our knowledge about the human mind and brain.

Nutting, Perley G.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: August 22, 1873; Died: August 7, 1949.

Nutting is a good example of an individual who created practical and enduring bridges between physical science and sensory and perceptual psychology in the early twentieth century. Born at Randolph, Wisconsin, he attended Carleton College in Minnesota and then Stanford (BA 1897) and the University of California (BA 1899). He then moved to Cornell where, after a year at Göttingen, he obtained the Ph. D. in physics in 1903 under Edward Nichol. From 1903 through 1912 he progressed from assistant to associate physicist at the US Bureau of Standards in Washington, DC.

Major Accomplishments/Contributions

His earliest physical work, at California, involved the photographic photometry of ultraviolet reflection from various metallic and nonmetallic surfaces. While at the Bureau of Standards he published on gas spectra, spectrophotometry, and colorimetry, and also on psychophysical questions including Fechner's Law (Nutting 1908) and human spectral sensitivity. Interested as a spectrophotometric specialist in the differential visibility of light at different wavelengths, he extended the work of Langley and Koenig and synthesized a "visibility function" relating energy flux and visual effectiveness which led to the establishment of the lumen, a fundamental quantitative term in both vision science and illuminating engineering. By 1910 Nutting moved toward applications, publishing in 1912 *Outlines of Applied Optics* (Nutting 1912), and in 1913 he moved to the Eastman Kodak Company in Rochester, NY, where he was the director of the research laboratories through 1916. While there he convened a group of professionals representing both scientific and commercial interests in optics, which became the American Optical Society, of which he was, in 1916–1917, the first president (Kingslake et al. 1966). He then went to Westinghouse where he was director of the research laboratory until 1921 and a consulting engineer until 1924. During this period he published several technical and theoretical articles in the new *Journal of the American Optical Society* and also wrote lucidly on practical social questions such as scientific education and highway safety (Nutting 1923). He then returned to government service with the US Geological Survey and concluded his career studying the physical properties of minerals and clays.

O

O'Connell, Daniel C.

SABINE KOWAL

Technical University of Berlin, Berlin, Germany

Basic Biographical Information

Daniel C. O'Connell was born on May 20, 1928, in Sand Springs, Oklahoma. He received an undergraduate classics degree in 1951, a master's level degree in philosophy (Ph.L.) in 1952, a master's degree in psychology (A.M.) in 1953, and a master's level degree in theology (S. T. L.) in 1960, all from Saint Louis University. He earned his Ph.D. in experimental psychology at the University of Illinois (Urbana) in 1963 with a dissertation on verbal operant conditioning. Two NSF postdoctoral fellowships (1963–1964 and 1965–1966) allowed him to pursue his research interest in experimental psycholinguistics at the Harvard Center for Cognitive Studies. There he began to develop his critical engagement of mainstream psycholinguistics – and specifically to the then current fad of Chomsky's transformational grammar – which over the years eventuated in his own approach to the psychology of language use. During the 1968–1969 academic year, a Humboldt Fellowship allowed him to work with Professor Hans Hörmann at the Free University in Berlin. Hörmann's genuinely psychological approach to the study of language use remained a fundamental guideline for him in his own subsequent language research. And throughout the ensuing years, the Humboldt Foundation remained his major source of occasional support, especially through two major grants in the 1990s with Sabine Kowal as transatlantic partner in Germany.

Due to his education as a Roman Catholic priest in the Jesuit Order, with its emphasis on history, theology, and philosophy, O'Connell developed, from the very beginning of his academic career in psychology, an

interest in language, a respect for the historical roots of scientific ideas, and a critical attitude toward psychology in general and psycholinguistics in particular. In the course of more than 50 years of research on language use from a psychological perspective, this orientation led him over time to four basic shifts in his research: from Anglo-American to European psychology, from experimental to field research, from monolog to dialog, and from written to spoken language use. Along with these developments went his increasing preoccupation with a variety of verbal and nonverbal phenomena characteristic of spontaneous dialogical discourse.

Major Accomplishments/Contributions

All through his scientific career, O'Connell has made it one of his main concerns to fight publicly, in his teaching and his public lecturing as well as in his publications, against the zeitgeist, the mainstream, and an a-historical approach to research in psychology; this clearly has made him an outsider in the field of psychology. In 1957, he began with a critical rejection of O. Hobart Mowrer's notion of mental illness as human sinfulness, continued in 1958 with a critical analysis of Gordon Allport's idiographic use of personal documents, added in 1962 an article rejecting Charles E. Osgood's theory of meaning, followed by a critical replication of an experiment by William Verplanck on verbal operant conditioning (Dulany and O'Connell 1963), broadened the scope of his critical approach in his O'Connell 1988 book *Critical Essays on Language Use and Psychology*, and finally crystallized a theory of spontaneous spoken discourse in his recent critique of mainstream psycholinguistics from its historical beginnings to the present day in his 2008 book (co-authored with Sabine Kowal) *Communicating with One Another: Toward a Psychology of Spontaneous Spoken Discourse*.

His methodological developments in the study of spontaneous spoken discourse in dialog led O'Connell stepwise to the inclusion of physically measured pauses and hesitation phenomena, and to the analysis of interjections, personal pronouns, laughter, turn-taking, and applause in his empirical research. The field approach to the study of language concentrated his attention on corpora of public speeches and interviews, mostly of politicians, as well as on corpora of artistic performances of actors reading literature or playing their roles in films and plays. This field approach also resulted in critical analyses of the methodologies involved in the transcription of language data (O'Connell and Kowal 2009). For summaries of this empirical research, see O'Connell and Kowal (2008).

In many of his publications, O'Connell's concern about historical landmarks in psychology, often forgotten in mainstream research, is evident. This concern has gone along with a basic interest in the European roots of modern psychology (e.g., Wilhelm Wundt, Karl Bühler) and his persistent attempt to acknowledge the contributions of contemporary European colleagues engaged in language research (e.g., Carl Friedrich Graumann, Hans Hörmann, Per Linell, and Ragnar Rommetveit). His work with Sabine Kowal on the recent history of mainstream psycholinguistics as a monologically (rather than dialogically) oriented discipline is an example of this orientation (O'Connell and Kowal 2003).

With her too, he has concentrated on explicating concepts which they both consider necessary bases for a psychological (rather than linguistic or sociological) theory of spontaneous spoken discourse – concepts which at the same time are usually neglected in modern psychology as a general discipline as well as in mainstream psycholinguistics: *intersubjectivity*, *perspectivity*, *open-endedness*, and *verbal integrity*. None of the four concepts are empirical insofar as they logically precede empirical engagement of data. Intersubjectivity, as a prerequisite, focuses on the mutual and reciprocal consciousness of one another on the part of interlocutors before they even begin to speak or listen to one another; failing this prerequisite, spontaneous spoken discourse ceases or fails to commence. Perspectivity asserts that every utterance necessarily carries with it a perspective of the speakers and listeners involved in the discourse: Both have their own reasons, intentions,

and goals that are always relevant in research on language use. Open-endedness emphasizes the fact that spontaneous spoken discourse exists in an open, creative, and learning setting. It always moves forward in real time, and the direction and pace of this movement are essentially unpredictable. Finally, verbal integrity takes into account that an adequate analysis and understanding of spontaneous spoken discourse from a psychological point of view is impossible without regard for the moral responsibility of both speakers and listeners. And although American mainstream psycholinguistics has largely ignored these concepts, they have a rich history in the European tradition. This theoretical re-orientation has also required methodological shifts regarding measurement, transcription, and field observation. And in a much broader sense, it has inevitably involved an expansion to interdisciplinary cooperation with other social sciences (e.g., anthropology and sociology) and an openness to research traditions in other native languages.

In summary, O'Connell's professional career has extended from behaviorism through cognitivism and beyond. His involvement in the history of psychology has been twofold: By both penchant and discipline, he has returned in his research to the nineteenth-century sources of a psychology of language use; and due to this lifelong engagement, his work has spanned from the mid-twentieth to the twenty-first century – as commentator, contributor, and critic.

Ogden, R. M.

JOHN G. BENJAFIELD

Brock University, St. Catharines, ON, Canada

Basic Biographical Information

Robert Morris Ogden (1877–1959) was born in Binghamton, New York, and received his primary and secondary education there. As an undergraduate at Cornell, Ogden was primarily interested in “construction and design” (Dallenbach 1959, p. 472), an intimation of his subsequent interest in aesthetics. However he subsequently shifted to psychology, and graduated in 1901 with a major in that subject and a minor in aesthetics. He remained passionately interested in aesthetics throughout his career. Titchener arranged for him to study with Oswald Külpe at Würzburg, where he received his Ph.D. in 1903. Ogden served at the universities of Missouri, Tennessee, and Kansas, before returning to Cornell in 1916, where he became Professor and Chair of Education in 1916 and Dean of Arts and Sciences from 1923 to 1945.

Major Accomplishments/Contributions

Ogden demonstrated a breadth of interest that is remarkable in a psychologist of his time or of any time. He published dozens of articles and reviews in areas as diverse as aesthetics, education, hearing, Gestalt psychology, imagery, intelligence, learning, and philosophy. He also produced a textbook of psychology, as well as books on hearing, education, and a translation of Kurt Koffka’s *The Growth of the Mind*. However, in some ways his crowning achievement was his book on the *Psychology of Art* (Ogden 1938).

Ever since his undergraduate days, Ogden had been as interested in aesthetics as in any other discipline including psychology. He routinely taught the subject, and his book was an interdisciplinary effort, dealing as much with art history as with psychology. The chapters not only dealt with topics that are the staples of the

psychology of art, such as music, color, and design, but also covered topics that were and still are seldom adequately dealt with in psychology, including poetry, sculpture, architecture, and dance. Ogden was particularly intrigued by the aesthetic properties of the *golden section*, a proportion that has intrigued many psychologists ever since Fechner’s pioneering work in aesthetics.

Ogden did not describe many experiments in his accounts of the various aspects of art. Rather he relied on what would now be called ecologically valid demonstrations of aesthetic phenomena. He presented the reader with examples of real music and actual poems, as well as photographs and drawings of famous art objects, and attempted to show how they achieved their aesthetic effects. Although not wedded to a single approach, Ogden (1938, p. 190) made extensive use of Gestalt principles in order to show that we find art objects beautiful when we can perceive how their parts “find their just positions as partial patterns of the whole.”

Reflecting on his experiences with his teacher Külpe, Ogden (1951, p. 6) described him as an “impressive and lovable character” and regarded Külpe as a prime source of “inspiration and knowledge” (Ogden 1938, p. vii). Dallenbach (1959) observed that, like Külpe, Ogden was also held in high esteem by his peers.

- ▶ His place in the history of psychology would doubtless have been higher had he been more aggressive and self-assertive, but that would have put him out of character and he would not have been held so high in the hearts of his students and his fellow men. The choice between these alternatives was not hard for him to make. (Dallenbach 1959, p. 477)

Osgood, Charles

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Basic Biographical Information/Major Accomplishments

American psychologist. Born in Somerville, Massachusetts, November 20, 1916. Studied at Dartmouth College, Hanover, New Hampshire, B.A. 1939; Yale University, New Haven, Connecticut, Ph.D. 1945. Married Cynthia Thornton in 1939; two children. Research Associate, Yale University, 1945–1946; Assistant Professor of Psychology, University of Connecticut, Storrs, 1946–1949; Associate Professor, 1949–1952, and since 1952 Professor of Psychology and Communications. University of Illinois, Urbana (Director of the Institute of Communications Research. 1957–1965; since 1965, Director of the Center for Advanced Study). Fellow, Institute for Advanced Study in the Behavioral Sciences, Stanford, California, 1958. Visiting Professor. University of Hawaii, Honolulu, 1964–1965. President, American Psychological Association, 1962–1963. Recipient: Guggenheim Fellowship, 1955; Distinguished Science Contribution Award. American Psychological Association, 1961; Kurt Lewin Award. Society for the Psychological Study of Social Issues, 1971. Honorary doctorate: Dartmouth College, 1962. Member, National Academy of Sciences and the American Academy of Arts and Sciences. Address: 304 East Mumford Drive, Urbana, Illinois 61801, USA.

Charles E. Osgood has, during his life, developed three major “themes” in psychology. The unifying strain in these themes has been the idea of “meaning.” The tentative title of Osgood’s autobiography. *Focus on Meaning: In individual Humans, Across Human Cultures, and for Survival of the Human Species* gives a good overview of the areas in which he has made a major effort.

The first theme Osgood engaged was a behavioral theory of meaning. Osgood disagreed with the Hullian two-stage behaviorism and formulated his own theory of three-stage behaviorism which postulated an extra

integration level to account for more complex levels of behavioral organization. By simply changing one component at the integration level, entirely new “meanings” could be recognized by the organism. In order to analyze this theory, Osgood developed the “semantic differential technique” for measuring meaning. Subjects are asked to rate a number of concepts on several different scales, indicating the intensity of meaning. According to Osgood: “all three major factor analyses yielded nearly identical evidence for three massive factors easily identifiable as Evaluation (good, nice, beautiful, honest, etc.), Potency (strong, big, thick, tough, etc.) and Activity (active, quick, excitable, hot, etc.)” Thus Osgood has developed a method to evaluate and compare the meanings of various words. This work was published in 1957 in *The Measurement of Meaning*.

Osgood’s second theme is in reality an extension of the first. In order to evaluate more fully his theory of meaning (also now extending into the field of psycholinguistics), Osgood believed it was necessary to use his semantic differential technique (SD) to evaluate meaning in other cultures. Using teenage males and many colleagues in the cultures to be studied, he generated a list of qualifier types, and the subjects rated 100 nouns against 50 scales. Analysis of this led to the selection of 620 concepts for the development of an Atlas of Affective Meaning. These concepts were then rated (again using teenage males) against the SD and evaluation potency activity (EPA) structure. An analysis was also made of familiarity meaningfulness polarization and cultural instability. Osgood is also developing a “semantic interaction technique” (SI) in order to evaluate more exactly the usage and meaning of certain words. The aim of these methods of meaning and evaluation is the formulation of an Abstract Performance Grammar (APG) which would differentiate the way in which the mind innately expresses meaning from the “competence grammar” which is the structure of a language. Data has been collected for the Atlas of Affective Meaning from 30 different language culture groups with the hope that it will provide insight into the “dynamics of human societies.” A final “theme” of Osgood’s work has been in the area of “meaning and survival of the human species.” His interest in this area was stimulated by the McCarthy era and the

development of the atomic bomb. He has studied psychological factors in human relations and developed the GRIT (Graduated and Reciprocated Initiatives in Tension-reduction) strategy with regard to disarmament. The book *An Alternative to War or Surrender* (1962) gives an explanation of Osgood's GRIT strategy. Osgood believes that: "the gap between word and thing increases with the remoteness of things from immediate experience. that the words of international politics are typically analogic, that the power of words lies in the way they abstract from reality . . . and that we are being led by old men using antiquated semantic maps to guide us through the wonderland of the twentieth century." Osgood has propounded this theory at many levels, to scientists and members of the government, in an effort to promote de-escalation of the military. Osgood, in addition to his work in psychology, has also made many contributions to the field of psycholinguistics. In connection with this Osgood, in an address entitled "A Dinosaur Caper" given at the New York Academy of Sciences, spoke of the nature of scientific revolutions and their relation to modern psycholinguistics. In his book *The Structure of Scientific Revolutions*, Thomas Kuhn argued that a scientific revolution occurs when anomalies or "counterinstances" accumulate that resist attempts at explanation in terms of the prevailing paradigm of "normal science." Does this description of paradigm clash fit the recent or current circumstances in psycholinguistics? Osgood does not believe it does. Although he acknowledges the revolutionary impact of Noam Chomsky's work on the field of psycholinguistics, he questions whether we are witnessing in psycholinguistics a true Kuhnian "crisis" or merely a pendulum swing between visible paradigms. As Osgood sees it, the effect of Chomsky's contributions upon psycholinguistics fails to meet the criteria that distinguish a true scientific revolution because: (1) There has been no attempt to incorporate solutions to problems handled successfully by the old paradigm. (2) The old paradigm has not been shown to be insufficient in *principle*. (3) There has been no new paradigm to shift *to* – *in* the sense of a well-motivated, internally coherent alternative theory of language performance. There has been a shift *away from* behaviorism in any form, but in the absence of any alternative

paradigm this would be better termed "revulsion" than "revolution." At any rate, having ruled out the probability of an imminent revolution in psycholinguistics, Osgood concludes "A Dinosaur Caper" by venturing a few predictions concerning the future of psycholinguistic theory and research as we approach the year 2000: (1) There will be a complete shift away from emphasis on Competence to emphasis on Performance. (2) As part of this shift, there will be an increasing avoidance of dealing with sentences-in-isolation (whether in linguistic or psychological methodologies) and increasing dependence upon sentence-in-context (in discourse, in ordinary conversation, and so on). (3) Semantics will be moving into the foreground as syntax moves, reciprocally, into the background. (4) As already hinted, logical, rationalist models of language will be shown to be inappropriate for ordinary speakers and will be superseded by more gutsy, dynamic psychological models. (5) There will be a shift from ethno-linguo-centrism toward what might be called anthropolinguo-centrism.

Charles E. Osgood has made many varied contributions both to psychology (and psycholinguistics) and to the effort for world peace. In his own words, the old dinosaur is now "trying to drive a balanced three-theme wagon into the 1980s."

P

Pace University, History of Psychology at

STEPHEN SALBOD

Pace University, New York, NY, USA

Basic History of the Department

This is a brief history of the emergence of psychology at Pace University during the twentieth century and its subsequent development into one of Pace University's leading academic departments. Two distinct time periods can readily be delineated in considering this history.

Pace University began when two brothers, Homer St. Clair Pace and Charles Ashford Pace, in 1906, formed the partnership of Pace & Pace to help prepare candidates for the difficult New York State CPA examination. They rented an office and one classroom in Horace Greeley's Tribune Building, on Publishers Row, at 154 Nassau Street. There they taught accounting principles that were necessary to become a CPA (Weigold 1991).

In the early part of the century, Pace Institute was seen as a professional school that offered scientific instruction in Accountancy and Business Administration. With increased enrollment, the Institute leased two entire floors and part of a third floor in the Transportation Building at 225 Broadway. There it started to organize itself into six schools: Accountancy Practice; Accountancy and Business Administration; Marketing, Advertising and Selling; Secretarial Practice; Shorthand Reporting; and Credit Science. Within the school of Marketing, Advertising and Selling (in *General Bulletin 1933–1934*) personality development first appears in course titles: specifically, Business Speaking and Personality Development, Selling Technic[sic] and Personality Development – Part I and Part II, and Executive

Technic[sic] and Personality Development. Thus, before there were direct courses in the field of psychology, the psychology of personality was incorporated in business-related courses.

The first two psychology courses appeared in the *Pace Institute General Bulletin 1934–1935*, listed under the School of Marketing, Advertising, and Selling: specifically, Psychology, Part I (Elementary) and Psychology, Part II (Applied). The first course was to develop “on the part of the student an understanding of mental reactions to appeals made to human emotions, to reason, to will, to desire, to habit, to imagination, to vanity, and the like.” While, the second course applies concepts from Part I to developing “a practical working tool in the solution of problems encountered in advertising and selling that are the result of the human element as contrasted with mere mechanical and technical difficulties.” The person who taught these courses is found in the Bulletin under Faculty (name, degree, courses): “J. Stephen Bloore, M. A. . . English, Public Speaking, Psychology.”

In 1935, Pace Institute received its first charter from the New York State Education Department, and as such began operating as a not-for-profit educational institution. In 1948, Pace Institute became a college and its name was Pace College. In the new *Pace College General Bulletin 1948–1949*, George W. Fraser (Rutgers) is listed as the Psychology Chairman.

Since few records survived George Fraser's tenure, little is known of his role as Psychology Chairman. There was no space devoted just to the Psychology Department at that time. Faculty shared a large room in the Transportation Building. Considering that there were other faculty teaching Psychology at time, he was, in addition, to teaching, administratively responsible for all Psychology courses and faculty.

Mention of a Psychology Major appears in the *Pace College General Bulletin 1950–1951*. Course requirements listed included: Principles of Psychology I-II,

Test and Measurements, Child Psychology, Applied Psychology, Industrial Psychology, Social Psychology, Abnormal Psychology, Human Relations, and Mental Hygiene. The Psychology faculty listed were George W. Fraser (Litt.B., Ph.D.), Associate Professor of Psychology, Psychology Chairman; Robert H. DeJorio (B.B.S.) Psychology; Paul Echandia (B.S., M.S., M.A.), Assistant Professor of English, Speech, Psychology; Seymour Levy (B.S.S.) lecturer in Psychology; and Joseph P. Searing, Jr. (B.A.) Psychology. It was at this time that the Psychology Chairman, George W. Fraser, resigned from his position at Pace College. Administrative responsibilities were then taken over by the Social Science Department. This ended the first period of Psychology at Pace University.

In 1951, Pace College purchased the New York Times Building at 41 Park Row. In the spring of 1959, students and faculty began using all 16 floors of the building. This space was not sufficient, and in the early 1960s Pace College bought 150 Nassau Street (Weigold 1991).

In 1962 Dr. Thomas J. McShane (Fordham) was designated chairman of a newly formed Department of Education and Psychology. He had served as an adjunct faculty member from 1953 to 1958. His background included work with the FBI, from 1941 to 1961, as a polygraphist. Under his leadership, the Psychology major became a B.A. degree program in 1963 and produced its first three graduates in 1966: Jerrold Norman Stevens, Allen David Warmbrand, and Edward Jerome Zarow. At this point in time the School of Education was established, the Psychology Department remained under the School of Arts and Sciences, and had its faculty offices located on the ninth floor at 150 Nassau Street.

The *Pace College General Bulletin 1963–1965* gives a glimpse of Psychology as it started in the 1960s. The courses offered were: Principles of Psychology, Abnormal Psychology, Psychology of Business and Industry, Psychology of Personal Adjustment, Child Psychology, Psychology of Adolescence, Advertising Psychology (2 points), and Psychology of Learning I and II (2 points each). The faculty who taught them were Thomas J. McShane (Ph.D., Fordham), Professor of Education and Psychology, Chairman, Education and Psychology; Paul Echandia (M.S.Ed, Fordham, M.A., Columbia), Associate Professor of Psychology; Melvin

B. Swartz (Ph.D., NYU), Associate Professor of Psychology. Adjunct faculty were Raymond F. Levee (Ph.D., Fordham), Adjunct Assistant Professor of Psychology and Robert C. Oliver (M.A., NYU), Adjunct Assistant Professor of Psychology.

In 1969, a chapter of Psi Chi, the National Honor Society in Psychology was established. Faculty advisors for the society have been Drs. Carmine Casella (start date: February 1969); Thomas McShane (start date: July 1981), Janice Jackson (start date: April 1982), and Mercedes McCormick and Florence Denmark (start date: April 2008).

Specialized Psychology Laboratories were created on the 13th floor of 41 Park Row to meet the needs of the nascent department. The Experimental Laboratory was based on the Fordham University model (Dr. Frances Delahanty (Fordham) personal communication, January 31, 2002). The laboratory consisted of five rooms and 12 cubicles. In addition, a “Rat” Laboratory was created from an unused animal laboratory in the elevator room on the 17th floor (Dr. John J. Mitchell (Catholic U) personal communication, May 11, 2010). In order to analyze data, there was a calculator laboratory, using Merchant calculators, located on the 11th floor at 41 Park Row.

A Psychology Newsletter, *Psych Eye*, was created and first published in November 1972. Dr. Paul Echandia (NYU) was the editor. Upon Dr. Echandia’s retirement in 2005, Dr. Richard Velayo (University of Michigan) assumed the helm. The latest issue was Volume 21, no 2.

In 1972, a 60-credit M.S.Ed. degree featuring state certification as a school psychologist became part of the curriculum. This program was initiated September 1973, the year Pace College became Pace University, and graduated its first students in June 1975.

In 1979, Pace University became the first university in New York State to get approval to offer the Doctor of Psychology (Psy.D.) degree. This new degree was implemented during Dr. Thomas McShane’s tenure as Department Chairman and represented the hard work and dedication of the full-time faculty: Dr. L. Bart (St. John’s), Dr. C. Casella (Michigan State U), Dr. P. Echandia, Dr. J. Herman (NYU), Dr. J. Jackson (Fordham), Dr. J. Mitchell (Catholic U), Mr. R. Oliver, Dr. M. Swartz, and Dr. I Wentworth-Rohr (NYU). The first two Doctoral Projects were completed in 1982

under the direction of Dr. John J. Mitchell and Dr. Jack Herman: Diane W. Bauman and Daniel B. Dunn

In the early 1980s, the 13th floor was renovated to create office space for psychology faculty and staff. This is the final move of the department at the end of the twentieth century: from the 9th floor at 150 Nassau Street to the 13th floor at 41 Park Row.

The Psychological Service Center (Clinic) was established in 1984 on the first floor at 41 Park Row. It was later dedicated to Thomas J. McShane and renamed The Thomas J. McShane Center for Psychological Services. In 2002 it was moved to the fifth floor at 156 William Street.

In 1988, Florence Denmark (University of Pennsylvania) became the first Robert Scott Pace Professor and Chair of the Psychology Department. She is best known for her research on women's leadership and leadership styles and the interplay between status and gender. She has been active in APA leadership for more than 30 years. She served as president of APA, ICP, EPA, and NYSPA. It was under her leadership that the Psy.D. program received its first accreditation status from the American Psychological Association.

In 2001, Dr. Herbert Krauss (Northwestern University) became Chair of the New York City Psychology Department. Just as his role as Chair was beginning, the nearby World Trade Center was attacked on September 11, 2001. He led the department through December of 2009.

Today, the New York City Psychology Department is part of Dyson College of Arts & Sciences. The department has 13 full-time faculty, 2 part-time faculty, 4 full-time staff, and adjuncts who support 2 undergraduate programs: Psychology and Applied Psychology/Human Relations, and 4 graduate programs: Master of Arts (M.A.) in Psychology, the Master of Science in Education (M.S.Ed.) in School Psychology, the Master of Science in Education (M.S.Ed.) in Bilingual School Psychology, and Doctor of Psychology (Psy.D.) in School-Clinical Child Psychology. In addition, the department offers a BA/MA degree in Psychology.

Significance

On March 1979, Pace University became the first university in New York State to offer a Doctor of Psychology degree (Psy.D.; Peterson 1992). On November 4, 1988 American Psychological Association (APA) gave

full accreditation to the Psy.D. with a specialization in School-Community Psychology (APA 1989). In 2000, 12 years later, the specialization was changed to a combined School-Clinical Child Psychology program and it too was fully accredited by APA as a Combined Professional-Scientific Psychology Program (APA 2000).

Pace, Edward

JOHN D. HOGAN

St. John's University, Jamaica, NY, USA

P

Basic Biographical Information

Born: July 3, 1861; Died: April 23, 1938.

Edward A. Pace was an American theologian and philosopher who studied with Wilhelm Wundt at Leipzig and returned to the USA to establish a psychology laboratory at the Catholic University of America, the first at any Catholic university in the country. A Catholic priest, Pace was also a member of the American Psychological Association in its first year of existence. Although active as a researcher early in his career, he is best remembered for opening doors to the study of psychology by fellow Catholics and for the work of his students, notably Thomas Verner Moore, who was also a Catholic priest.

Pace was born in Starke, Florida on July 3, 1861. He studied at the Propaganda University in Rome from

which he received a bachelor's degree in sacred theology (1883). He was ordained a priest in Rome in 1885, and the following year he received a doctorate in sacred theology, also from Propaganda University. On his return to the USA, he became the pastor of a church in St. Augustine, Florida.

Pace did not remain as a pastor for long. In 1888, he was invited to occupy a chair in philosophy at the recently founded Catholic University of America in Washington, DC. While studying in Rome, he had impressed his superiors with his quick and agile mind and they remembered him when the new position became available. As preparation for assuming his new position, he planned to spend 3 years in additional studies at the University of Louvain and in Paris. However, while in Paris, he happened to pick up a book by Wundt and was so impressed, he decided he would have to study in Leipzig as well. He entered the program at Leipzig in 1889 and graduated with a doctorate in philosophy in 1891. His thesis was on the evolutionary theory of Herbert Spencer. Pace died on April 23, 1938 (Misiak and Staudt 1954).

Major Accomplishments/ Contributions

Pace introduced a wide array of psychology-related courses to Catholic University, from traditional laboratory courses to courses in abnormal psychology. At the time, these courses were viewed as part of the philosophy curriculum by the administration. Eventually, however, a separate department of psychology was created. In addition to his work at Catholic University, Pace was active in research. He was one of only 13 Americans to publish articles in *Philosophische Studien*, the journal begun by Wilhelm Wundt. In addition to his doctoral dissertation, Pace published two articles on the fluctuation of attention there. Other publications included research on pain perception and binocular vision (Boring 1929).

Pace was an ardent supporter of the value of professional meetings. At the very first meeting of the American Psychological Association in 1892, he presented a paper on "tactile estimates of thickness." Much of his research underscored his belief in the close connection between psychology and physiology. He also made an important contribution by defending the new scientific psychology against attack by other

Catholics, frequently writing articles for Catholic publications. In fact, his greatest contribution may have been to promote psychology and interpret it for his fellow Catholics (Gillespie 2001).

Despite his love for psychology, Pace was active in several other areas. In 1893, he was a cofounder of the American Philosophical Association, and later became an editor of the 15-volume *Catholic Encyclopedia*. He also became increasingly drawn to education. In addition, his administrative duties took him further away from psychology. He received many honors during his lifetime. In 1914, he received a papal award from Pope Pius X, and in 1920, he was elevated to the rank of Right Reverend Monsignor. A testimonial dinner was held in his honor in 1931, and the presentations were bound into a book to honor him (Ryan 1932).

Pagès, Robert

MOHAMED ELHAMMOUMI

College of Social Sciences Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/ Major Accomplishments

Robert Pagès was a long-standing pillar of the intellectual fabric of social psychology at Sorbonne University. He published dozens of books and monographs and over 670 scientific papers. He was affiliated with the Trotskyite movement and holding egalitarian, anarchist realist ideas which cost him violent reactions from colleagues and state officials. Pagès was the father of French social psychology. He promoted social psychology and his influence around the world was

significantly outstanding. He devoted a large space of his time to education and mentoring students from Africa, South America, and Asia. He believed that education could raise consciousness and overcome social, political, and economical problems that faced developed and developing societies. He was the first to apply experimental methods systematically to the study of group processes, social relationships, and power. His extensive contributions in form of theory and research marked and shaped the major avenues in which French social psychology was to head in later decades. Pagès was both a distinguished creative methodologist and innovative theorist. He was heavily influenced by Marx's writings which affected him throughout his career as researcher, instructor, and mentor. His career was interrupted by World War II during which he was commissioned as a liaison officer. He was a revolutionary leader; during the war he got to know progressive thinkers. He was the founding father of the Laboratory of Social Psychology in the Faculty of Social Sciences at Sorbonne University which he directed from 1952 until his retirement in 1986. Pagès was given the title of professor of social psychology, taught the first courses ever offered in psychology, and headed the laboratory after Danielle Lagache. Pagès' experimental work first appeared in 1950 in *Bulletin de Psychologie*. Social psychology provided a useful set of concepts for research and teaching. In his seminars which I attended for 9 years, he stimulated discussions with such conceptions as *emprise* (power/control), group processes, social influence, higher mental functions, and macro-social factors.

From scratch, he gradually organized his laboratory based on the following ideas: (1) a rich library and strong documentation services; (2) teamwork and collaboration between researchers; (3) toward an appropriate social psychology grounded within the cultural historical social context of French society; (4) autonomy of social psychology from North American hegemony; (5) the laboratory was the only one of its specialty in France; and (6) the laboratory attracted the most brilliant scholars in the field of social psychology. He elaborated a well-defined theory in social psychology known as "*Theorie d'emprise* or *Power/control theory*" in which he articulated the biological, psychological, and sociological in a unified whole. He developed new concepts such as noeuds (humans) characterized by

strong external connections, quasi-noeuds (animals) characterized by strong internal connections, innoeuds (materials or organics), anoeuds (technical or practical), and enoeuds (ideological or religious). He stated that emprise relations can be possible only between noeuds (humans), causal relations between innoeuds (materials or organics). His theory is rich, complex, and promising; due to limited space it is very difficult to do justice to Pagès' intellectual achievements. His theory did not make its way to American mainstream psychology, but it has been well received in Spain, Italy, North Africa, Greece, Switzerland, Canada, Africa, Brazil, and United Kingdom.

Paranjpe, Anand

CARL RATNER
Institute for Cultural Research and Education,
Trinidad, CA, USA

Biographical Information

Birthdate: 1936;

Birthplace: Chiplun, Maharashtra, India.

Prof. Paranjpe is a leading expert on Indian philosophy and psychology. His journey into the area of

psychology began in 1955 after studying physics and cosmology. He also studied philosophy which was taught as Western philosophy. After graduating, he joined an Indian nationalist volunteer organization and spent a year away living in small villages, spending time with people of the lowest socioeconomic strata. The plight of the poor witnessed by living amongst them was a moving experience that deepened the spirit of nationalism.

Paranjpe met Eric Erickson on a visit to India and was subsequently invited to a postdoc at Harvard under him. There he met Gordon Allport and Stanley Milgram.

Paranjpe next took a position at Simon Fraser University. At first, he conducted research on intergroup conflict. Then his interests turned to elucidating Indian philosophy and psychology. He studied Yoga as psychology. He also sought to compare and bridge Indian and Western psychological constructs. In 1998, he published *Self and Identity in Western Psychology and Indian Thought*.

Major Accomplishments

Paranjpe was quite critical of positivism in psychology, especially as practiced by the faculty at Simon Fraser. He joined forces with theoretical psychologists who emphasized philosophical issues and non-positivistic psychology. He was also unhappy with the positivism that dominated cross-cultural psychology (and continues to do so).

Paranjpe rejects reducing culture to a variable because it obscures the living diversity of culture. In addition, he criticized positivist methodology for using superficial behavioral measures that do not capture the reality of psychological activity. Nor can personality be reduced to a dependent variable.

Paranjpe followed Prof. David Bakan's writings to look at ideas in their historical and sociocultural context. He is writing prolifically about the psychological constructs that are embodied in Indian philosophy. He compares these to Western psychological concepts.

He is currently Professor Emeritus, Psychology and Humanities, at Simon Fraser University, Canada.

Parapsychology

ADAM CRABTREE

Centre for Training in Psychotherapy,
Toronto, ON, Canada

Introduction

The evolution of theory in parapsychology is inextricably bound up with a complex history of ideas in philosophy, psychology, physical science, and social science. That history has developed through several distinguishable phases. Although it may rightly be said that parapsychology entered its scientific phase in the latter half of the nineteenth century, it will be necessary to say something about the prescientific developments relating to the phenomena investigated. To prepare for that discussion, it will be useful to examine the terminologies that have arisen in the evolution of parapsychological thought.

Definitions

Parapsychology may be defined as the scientific study of paranormal phenomena. The elements of this definition require some elaboration.

Psychical Research and Parapsychology

Parapsychology entered into its fully scientific phase with the founding of the Society for Psychical Research in Britain in 1882. In this phase the investigation of paranormal psychic was commonly called "psychical research," and in some quarters that term has been preferred to the present day. In the beginning, psychical research was defined as the systematic investigation of "an important body of remarkable phenomena of

human experience, which are *prima facie* inexplicable on any generally recognised hypothesis, and which, if incontestably established, would be of the highest possible value” (Society for Psychological Research 1882, p. 3).

Paranormal Phenomena

The term “parapsychology” was coined by Max Dessoir (1867–1947) in 1889. The terms “parapsychology” and “psychical research” indicate connections with the field of psychology, yet many of the phenomena studied could fittingly be categorized as physical or physiological. For that reason philosopher C. J. Ducasse coined the adjective “paranormal” to describe a data domain embracing all inexplicable phenomena. He defined a paranormal phenomenon as: “Any occurrence whose cause is neither that from which it ordinarily results, nor any other yet known to natural science as capable of causing it” (Ducasse 1951, p. 2).

Presumably, had Ducasse’s new term been fully accepted, this entry would read “Paranormology” rather than “Parapsychology.” Although that word was never adopted, reference to “paranormal” phenomena has become commonplace, so that C.D. Broad would some years later define “psychical research” as “the scientific investigation of ostensibly paranormal phenomena” (Broad 1962, p. 3), and this has become the accepted definition of “parapsychology.”

By Ducasse’s definition, a “paranormal” phenomenon was one not brought about by ordinary causes, but by a cause not yet known to the natural sciences. That definition has been altered and refined since 1951, and probably the best version is that of philosopher Stephen Braude, consisting of three elements: (1) the phenomenon cannot be explained in terms of current scientific theory, (2) it cannot be given a scientific explanation without major revisions elsewhere in scientific theory, and (3) it contradicts our usual expectations of the kinds of things that can happen to the objects involved (Braude 2002, p. 211). The present discussion is about the theories that have been devised to explain paranormal phenomena defined in these terms, and uses the term “parapsychology” to refer to the systematic study of those phenomena.

Problems with the term “parapsychology” as descriptive of the whole field of paranormal

phenomena have long been recognized. For that reason some researchers employ the word “parapsychology” to designate the investigation of paranormal phenomena that require some kind of psychological explanation, and “paraphysics” for phenomena that require a physical explanation.

Experimental investigation of paranormal phenomena brought about the introduction of the terms “extrasensory perception” (ESP) to designate telepathy, clairvoyance, and precognition, and “psychokinesis” (PK) to denote influence of physical objects produced by the mind. The more neutral term “psi” was coined by Bertold Wiesner and first used by Robert Thouless (Thouless 1942) to refer to both extrasensory perception and psychokinesis, and remains in common use today.

Range of Paranormal Phenomena

In the treatment that follows, a wide range of phenomena will be discussed, but for now it will be sufficient to say that today the data are said to include telepathy, clairvoyance, precognition and retrocognition, psychokinesis, and the effects of the mind on living systems. In addition, mystical experiences, survival of consciousness or the personality after death, and reincarnation are often discussed as related issues, along with out-of-body and near-death experiences.

Over the decades those who write and research in the field have rejected certain types of phenomena as serious candidates for parapsychological research. Some are considered too complex, making it almost impossible to discover what in the experience might be a paranormal effect capable of being extracted and studied as such. Others are judged not to be well enough attested to, to warrant investigation; thus, phenomena ranging from purported cases of human combustion to experiences of purported alien abduction tend to be excluded from consideration. (For more on the classification of paranormal phenomena, see Carr 2008, pp. 16–20).

As a science, parapsychology is both observational and experimental. As an observational science, parapsychology functions as natural history: it observes, collects, makes judgments about authenticity, collates and compares ostensibly paranormal phenomena, and then forms hypotheses and devises theories to explain these data. As an experimental science, it uses

information acquired from the natural history of the phenomena to construct experiments to test hypotheses proposed to explain the data. It is required of parapsychological theories that they not only conform to the paranormal data provided, but also not contradict the data and well-established theories of other data domains – particularly those of psychology, neuroscience, and physics.

Historical Background

The history of theories of parapsychology is long and complex. However, to understand parapsychological theories it is essential to know something about that history, at least in its broad outlines.

Proto-Parapsychology

As mentioned, scientific parapsychology had its beginning in the nineteenth century with the founding of the Society for Psychical Research in England. Before that time, however, there were significant attempts to come to terms with paranormal phenomena by devising explanations that were based on natural factors rather than the usual religious or theological ones. These early attempts make up what might be called proto-parapsychology.

The earliest attempts to explain paranormal phenomena as facts of nature occurred in the sixteenth and seventeenth centuries. There were three men in particular who made the point that paranormal phenomena must not be considered the province of theology or theologically oriented philosophy, but be subject to investigation by the methods of the newly emerging scientific paradigm. These three, Francis Bacon (1561–1626), Henry More (1614–1687), and Joseph Glanvil (1636–1680), insisted that the data of science should not be limited, but embrace all natural phenomena, including the unusual.

In the eighteenth century, the development of a healing theory called “animal magnetism” by Franz Anton Mesmer (1734–1815) had as one of its offshoots a variety of phenomena with paranormal aspects. Mesmer claimed that animal magnetic passes (sweeping movements of the hands over the body) induced physical healing in the ill. Other paranormal phenomena were in large part made possible by the discovery of “magnetic sleep” or “magnetic somnambulism” (later terms were “artificial somnambulism” and “hypnotic

somnambulism”) by Mesmer’s pupil, the Marquis de Puységur (1751–1825). Some people, when placed in this state through application of the passes, would show indications of clairvoyant knowledge, both about the nature of their own illnesses and those of others with whom they were placed in “rapport.” In addition, there were reports that magnetic somnambulism could be induced at a distance, that magnetizer and somnambulist sometimes experienced inexplicable communication of sensations or of thoughts, that a magnetic somnambulist could mentally travel to another location and describe what was occurring there (travelling clairvoyance), and that somnambulists could communicate with spirits of the dead. In the early nineteenth century, experiments were conducted to attempt to verify the genuineness of the phenomena, and a large literature dealing with these experiments came into being (Dingwall 1967; Crabtree 1988, 1993).

The nineteenth century movements called “Spiritism” in France and “Spiritualism” in the United States and England were largely fuelled by the experiences of individuals who, in the state of magnetic sleep, claimed to communicate with departed spirits and have other paranormal experiences. Some spiritualists, often in a state of somnambulist trance, had a particular knack for apparently contacting spirits in the other world and producing unusual phenomena, such as table levitations and materializations; these individuals were called “mediums.” In 1852, American Spiritualism gave birth to a new, ostensibly psychokinetic, phenomenon called “table turning” or “table tipping,” by means of which, it was believed, spirits of the dead could communicate with the living. Among those mediums who claimed to have messages from the dead, conveyed through trance speaking or automatic writing, a few were closely studied over lengthy periods of time; probably the most striking of these was the Boston housewife, Leonora Piper (1859–1950), discovered by William James. As the somnambulist state, which was often the platform for paranormal manifestations, became more thoroughly investigated, and as Spiritualism spread throughout the world, a variety of paranormal phenomena were reported in large numbers, and by the 1870s some called for a more unified and systematic study of these manifestations (Crabtree 1993).

Psychical Research

At the same time in England there came into being an academically based group associated with Cambridge University, who were concerned about what they considered the failure of traditional Christianity to come to terms with issues raised by paranormal phenomena, and especially the question of survival of bodily death. Science had weakened religion, not so much by direct attack as by creating an atmosphere of honest doubt that called the basic tenets of the Christianity into question (Gauld 1967, p. 45). In this tumultuous climate, a small group of friends at Cambridge came together to try to work out these issues in a different way from that manifested in the then current clashes between religious believers and proponents of materialism. Three leaders emerged from this group: Henry Sidgwick (1838–1900), Frederic Myers (1843–1901), and Edmund Gurney (1847–1888) (see Gauld 1967).

During the same period, a group of spiritualists in England began experiments on phenomena such as thought-transference and the exercise of the influence of will at a distance. This group had difficulty attracting outside support and approached the Cambridge group with the idea of forming a society to carry out psychical research. The Cambridge group was reluctant, but Myers and Gurney eventually agreed to be involved if the new society would be presided over by Sidgwick. The spiritualists agreed. Sidgwick accepted the invitation to be president and in February 1882 the Society for Psychical Research was launched. In the early phases, the spiritualist faction was in the majority, but as time went on, the agenda for the Society was increasingly influenced by the Cambridge group; some spiritualists became disillusioned with the project, and in 1886 and 1887 many resigned from the Society. Over the first few years of the SPR, Myers and Gurney emerged as the guiding lights of the enterprise and its most prolific researchers and writers. With the untimely death of Gurney in 1888, Myers's influence became central to the group.

The disillusionment of many of the spiritualist faction is not difficult to understand. The ideas of the Cambridge group dominated the vision and expressed aims of the Society, and the spiritualists' hope of using psychical research to gain adherents to spiritistic beliefs were thwarted. The intentions of the Society were stated in these terms:

1. An examination of the nature and extent of any influence that may be exerted by one mind upon another, apart from any generally recognized mode of perception.
2. The study of hypnotism, and the forms of so-called mesmeric trance, with its alleged insensibility to pain; clairvoyance and other allied phenomena.
3. A critical revision of Reichenbach's researches with certain organizations called "sensitive," and an inquiry whether such organizations possess any power of perception beyond a highly exalted sensibility of the recognized sensory organs.
4. A careful investigation of any reports, resting on strong testimony, regarding apparitions at the moment of death, or otherwise, or regarding disturbances in houses reputed to be haunted.
5. An inquiry into the various physical phenomena commonly called Spiritualistic, with an attempt to discover their causes and general laws.
6. The collection and collating of existing materials bearing on the history of these subjects.
 - ▶ The aim of the Society will be to approach these various problems without prejudice or prepossession of any kind, and in the same spirit of exact and unimpassioned inquiry which has enabled Science to solve so many problems, once not less obscure nor less hotly debated... To prevent misconception, it is here expressly stated that Membership of this Society does not imply the acceptance of any particular explanation of the phenomena investigated, nor any belief as to the operation, in the physical world, of forces other than those recognised by Physical Science. (Society for Psychical Research 1882, pp. 3–5)

The aim of the SPR's scientific exploration of the paranormal was formulated in terms of finding a "*tertium quid*" (a third something) that underlies both phenomena that have already received an adequate scientific explanation and paranormal phenomena. The concept of a *tertium quid* (proposed by Gurney and developed by Myers) presumes that *all* phenomena are natural and subject to scientific inquiry and theorizing, and that neither religious nor materialistic explanations of paranormal phenomena are adequate. This initial formulation of scientific intention remains

foundational for approaches to theory-making in parapsychology.

One of the first projects for the newly formed Society was the establishment of reliable criteria for collection of reports on spontaneous paranormal experiences. A significant outcome was the publication of *Phantasms of the Living* (1886), one of the most influential works of the early decades of the Society. Another project was the design of carefully devised experiments relating to ostensibly paranormal experiences to determine whether the phenomena in question were real, and if so, the nature of their operation. The “collation of existing materials,” mentioned above, enabled, among other things, the critical examination of previous investigations of paranormal phenomena. Work on these projects has continued in the years since the Society’s foundation; it has published some 60 volumes of its *Proceedings* and more than 70 volumes of its *Journal*, together containing more than 50,000 pages of research and critical evaluations relating to paranormal phenomena.

Frederic Myers

Myers was considered by his contemporaries to be a psychologist of great capacity and ingenuity. In attempting to transcend the conundrum of human duality bequeathed by Descartes, Myers insisted that we must look to a deeply empirical and scientific psychology for a solution. To do that, he said, we must expand the scope of the data of psychology to include those experiences that occur within the sphere that remains largely outside our conscious or ordinary awareness. He began exploring that region before Janet, who gave us the term “subconscious,” and Freud, who preferred “unconscious,” had begun their pioneering work. Myers initiated his investigations in the early 1880s and by the early 1890s had decided to subsume the phenomena he was identifying under the term “subliminal.” Myers’s “subliminal consciousness” included a much broader spectrum of human experience than the systems of Freud and Janet, and his treatment of the subliminal regions of human personality gave an opportunity to expand at one and the same time both the psychological and parapsychological dimensions of the psyche (Emily Kelly 2007, pp. 59–68).

The subliminal of Myers was that aspect of the human psyche that included all that is normally out

of reach of our direct knowledge. Within the subliminal were to be found not only the “disintegrations of consciousness” that were the main concerns of Janet and Freud, but also the manifestations of sleep, the phenomena of hypnotism, the uprushes of creative genius, and the “supernormal” faculties of the psyche, which included telepathy (a word coined by Myers), clairvoyance, and precognition. For Myers, the subliminal self was also the source of what he called sensory and motor automatism, spontaneous manifestations within normal consciousness of activities originating in the subliminal.

The “subliminal consciousness” or “subliminal self” of Myers was so named because the dynamic region he was describing was below the threshold (“limen”) of consciousness. The subliminal self had as its counterpart the “supraliminal self,” that aspect of the psyche that operates above the threshold of consciousness, engaging with all that is normally directly available to us. The supraliminal consciousness is our normal, everyday self, dealing with the “mundane” concerns of daily life.

Myers believed that this hidden environment, the subliminal, must be fundamentally continuous with, and interrelated to, the one that is directly available to the supraliminal. This indicates that all of its phenomena and processes are legitimate objects of scientific investigation. This novel vision was the basis for the inclusion of psychical research among the sciences. The coexistence and profound continuity of the subliminal with the supraliminal was axiomatic with Myers, and the basis for his call for a scientific, empirically based psychology of the total human being. It was also the foundation for the scientific study of the paranormal.

Myers’s development of a vision of a broad scientific psychology based on his model of the subliminal self was laid out in a series of articles in the *Proceedings* of the Society for Psychical Research published over the course of 4 years (Emily Kelly 2007, p. 61n). The overall exposition of Myers’s vision was published posthumously in a two volume treatise *Human Personality and Its Survival of Bodily Death* (Myers 1903). This work had a profound effect on the course of the subsequent development of parapsychological theory.

Myers died in 1901, and the SPR published a number of tributes to the man and his work in its *Proceedings* (Society for Psychical Research 1901).

Among those who contributed was American philosopher and psychologist William James. James was a close friend of Myers (he was present at his death) and had long been active in psychical research (James 1986). In writing about Myers's contributions to psychical research, he emphasized the importance of his doctrine of *continuity*:

- ▶ One cannot help admiring the great originality with which Myers wove such an extraordinarily detached and discontinuous series of phenomena together. Unconscious cerebration, dreams, hypnotism, hysteria, inspirations of genius, the willing game, planchette, crystal-gazing, hallucinatory voices, apparitions of the dying, medium-trances, demoniacal possession, clairvoyance, thought-transference, even ghosts and other facts more doubtful – these things form a chaos at first sight most discouraging. No wonder that scientists can think of no other principle of unity among them than their common appeal to men's perverse propensity to superstition. Yet Myers has actually made a system of them, stringing them continuously upon a perfectly legitimate objective hypothesis. (James 1901, p. 18)

For Myers, there is only one reality, not two: there are not natural and supernatural, as the theologians would have it, nor mind and matter, as the followers of Descartes believed. All reality is one, all reality is interrelated, and there are no unbridgeable gaps between its elements. For that reason, Myers insisted, psychical research was, and had to be, a science, exactly like all other sciences, and its data and methods were in essence the same as those of all other sciences, adding one more scientific data domain to the many that already existed. Through Myers's work this has become the bedrock theoretical position of the majority of psychical researchers and parapsychologists to the present time.

Laboratory Phase

Although experimentation was a part of psychical research from its earliest days in the 1880s, with simple, relatively easy to evaluate tests, such as card guessing and telepathic communication, and although Charles Richet had developed an early form of probability calculation in connection with mental suggestion (Richet 1884), the experimental dimension of parapsychology received its true initiation with the laboratory work of Joseph Banks Rhine (1895–1980). By the time

Rhine had begun his experiments in the 1930s, the statistical apparatus needed to evaluate his data had greatly improved from its beginnings with Richet. According to Beloff (1993, p. 127), Rhine's work had three main objectives: (1) to introduce into the study of the paranormal an experimental program based on a sound methodology, (2) to gain academic status and scientific recognition for parapsychology, and (3) to show, if possible, that psychic ability was not the preserve of exceptional subjects, but a widespread phenomenon.

Rhine established his program at Duke University in Durham, North Carolina in 1930. The object was to study ESP, a term coined earlier by Rudolph Tischner, denoting the acquisition of information not obtained through the physical senses and not inferred through experience, and, later, psychokinesis (PK). His best known work involved the guessing of "Zener cards" (designed with a variety of special symbols) invented by a fellow member of the Duke faculty, Karl Zener, and attempts to influence the fall of dice. Careful records of successes and failures in guessing were kept and subjected to statistical analysis. The results over time showed significant above-chance success, and were offered as evidence for the existence of ESP and PK. Rhine wrote of his findings and their significance, in journal articles and books that became classics in the field (Rhine 1934, 1937, 1947, 1953).

Although the three objectives Rhine set for himself were not fully realized, and although many in the field of parapsychology found the laboratory approach too restrictive to give a real sense of the richness of the phenomena, Rhine's pioneering work was influential and important to subsequent developments in parapsychology.

Rhine's wife and laboratory partner, Louisa, took up collecting spontaneous cases, a project she believed had value in its own right. She made the point that "instead of isolated and concrete suggestions for experiment, the continued study of the [spontaneous] material permitted a more fundamental concept of the psi process than I could have anticipated" (Rhine 1970, p. 150.). Examination of spontaneous cases complemented the experimental approach, which tended to stress the separation of categories of paranormal phenomena (telepathy, clairvoyance, etc.), by allowing the phenomena to be examined in their contextual richness.

Skepticism

Skepticism is part of every healthy scientific process. Accuracy of observation may be questioned, sources of artifact and error detected, cogency of hypotheses put to the test, and adequacy of theories critically evaluated. Such skepticism has always been evident in parapsychology, voiced both from within and without the field. But another kind of skepticism has existed throughout the history of parapsychology. It is a skepticism based on an assumption or presupposition about paranormal phenomena in parapsychological research. That assumption might be stated: paranormal phenomena are contrary to both common sense and scientific findings (taking current scientific positions as final) and therefore not worthy of serious consideration. In some cases this skeptical attitude is based explicitly on a metaphysical position that holds such phenomena are in principle impossible. It is this presupposition, stated or implicit, that has been the outlook of a number of commentators who consider themselves skeptics about the paranormal and see themselves guardians of orthodoxy.

William James, who was always prepared to engage in dialogue with those who held seriously considered doubts about psychical research, expressed dismay at how far unthinking prejudice could take even some who called themselves men of science. His disgust was barely concealed when he described this example:

- ▶ Why do so few “scientists” even look at the evidence for telepathy, so called? Because they think, as a leading biologist, now dead, once said to me, that even if such a thing were true, scientists ought to band together to keep it suppressed and concealed. It would undo the uniformity of Nature and all sorts of other things without which scientists cannot carry on their pursuits. (James 1899, p. 10)

Here the issues of continuity and uniformity once again come to the fore. Parapsychologists hold, as presumably all scientists do, that reality *is* one, uniform, continuous, and totally interrelated. They believe that there can be no place for prejudgment of the issues. What needs to be discussed and placed under critical scrutiny is the validity of the data, on the one hand, and the cogency of the theories on the other. Analyses and criticisms of these kinds are vital to progress in the field, while a priori dismissal obstructs legitimate inquiry and promotes an antiscientific position.

Many parapsychological investigators contend that the existence of paranormal phenomena has been conclusively established, and that the chief task of parapsychology now is to look into the nature of psi phenomena and the conditions that promote or inhibit their production. Skeptics say that, on the contrary, the phenomena have not been established conclusively, and that all purported paranormal phenomena can be explained away. Skeptical commentators on parapsychology have tended to concentrate on the issue of data validity. The most frequently mentioned reasons for having doubts about the reliability of the data involve the possibility of: fraud, poor observation, selective reporting, memory distortion, defective experimental design, statistical flaws, and sensory leakage. It is not possible to enter into a discussion of the disputes that have occurred over the past century and a half, but for further information the following skeptical writings can be consulted: Alcock 1981; Hansel 1980; Hyman 1985; Kurtz 1985; Leahey and Leahey 1983; Zusne and Jones 1982.

Key Issues

In the evolution of parapsychological theories, two kinds of issues emerge: those relating to the handling of data and those that concern the theory-making process itself.

Data Issues

Over the past century, five major data domains have been distilled out of the mass of reported paranormal phenomena: telepathy, clairvoyance, precognition and retrocognition, psychokinesis, and the effect of the mind on living systems. The “big five” lend themselves fairly well to scientific inquiry and experimental testing in that they seem to have reasonably well marked boundaries. Recent investigators of the psi point out that the phenomena cannot be neatly divided into strongly distinct categories, and, this being the case, it is important to work out a theory of the paranormal that transcends this rigid classification and allows for the complexity of the data as it actually occurs.

In this connection, Robert Morris (Morris 1986) has published a description of a model for parapsychological experimentation that avoids the problematic strict categorization of the modalities of psi, and treats all paranormal events as instances of a single

configuration. His model describes what occurs when an investigator interprets a set of events indicating psi. The psychic or psi subject has as target some external situation or event from which he or she is separated by a barrier that both prevents the subject from receiving any information from the target, and the target from being influenced by the subject, through any ordinary means. The analysis of the event is then made in terms of the conditions in which the barrier is breached and psi occurs. This model, focussing investigation on how information is mediated in either direction between the environment and the individual, applies to the modalities ordinarily categorized as ESP and PK, and at the same time can be used in regard to both case reports of spontaneous experiences and experimental data.

Theory Issues

Rex Stanford points out that theories perform several functions: provide explanations by which facts can be deduced from laws; produce predictions of as yet undiscovered observations; encourage new incisive experimentation; make explicit unrecognized assumptions; clarify what is known and not known in a particular area of research. Specifically in regard to parapsychology, he states that real theory building should lead to the development of central concepts about psi functioning that subsume prior observations and suggest new ones. It is Stanford's belief that parapsychology is at present in the process of developing a conceptual framework for its research (Stanford 1977, pp. 823–825).

In the past 100 years many parapsychological theories have been proposed to explain all or some psi phenomena. Myers's theory of the subliminal self provided a broad basis for considering paranormal phenomena on a continuum with normal phenomena and subject to the same kind of scientific investigation. Myers, William James, and Henri Bergson presented theories of the relation of mind to brain, summarized as the "filter" or "transmission" theory, by which the mind is not generated by the brain, but limited and focussed by it in order to reduce what would otherwise be an overwhelming cacophony of perceptions, to a filtered input that would allow the individual to live and act effectively in the world (Edward Kelly 2007, pp. 603–639). This is still regarded as a viable explanation, especially given what modern neuroscience has

revealed about the tiny trickle of information available to consciousness awareness.

In the 1970s, Stanford developed what he calls the PMIR (psi-mediated instrumental response) model for extrasensory events. The model posits that in the presence of a particular need, an organism uses ESP as well as sensory means to scan its environment for objects and events relevant to that need, and for information crucially related to such objects or events. Where sensory information is about need, relevant objects or events, a disposition toward psi-mediated instrumental response occurs. Here psi happens because it is needed. This mobilization of psi occurs below the level of conscious awareness (Stanford 1977). Also, C. T. K. Chari produced a thorough-going analysis of psi theories, models, and paradigms (Chari 1977). He pointed out the daunting challenges inherent in any attempt to construct a psi theory that is broad enough to embrace all the phenomena usually classified as paranormal: "Any full-dress explanation in parapsychology seems to need the whole gamut of the social, psychological, biological, and physical sciences" (p. 805). He points out that there is a large gap between methodology and theory in parapsychology. Theories that lack a methodological schema for verification remain metaphysical constructs. On the other hand, experimental work carried out on a sound methodological basis may produce many interesting correlations but lead to no compelling theory that indicates why those correlations exist. Chari talks about a crying need in parapsychology for a meta-theory setting out the criteria and the limits for theories about psi phenomena and the universe, and admits that the development of such a meta-theory is "a stupendous task for which few parapsychologists or even teams of parapsychologists are equipped" (p. 810). This remains true today.

Theories since Myers, particularly those of the last half of the twentieth century, fall into several categories. Electromagnetic theories of psi explain both ESP and PK in terms of the operation of some type of electromagnetic radiation. Other theories posit new forms of undiscovered energy or new types of particles conceived specifically for the purpose of explaining psi interactions, most of which have proved completely untestable. For a comprehensive review of psi theories consult Carr (2008, pp. 23–35) and Stokes (1987, 1997, 2007).

A Meta-theory

Theories give explanations for data encountered in particular areas of observation. For practical reasons and from our evolutionary and social constitution, we delineate objects of experience and areas of investigation that isolate certain combinations of perceptual input. These areas of investigation are carved out from the plenum of experience, and we can call these areas “data domains.” Each of the sciences deals with its own data domain, and general theories meant to account for the data within that domain might be called domain theories. The science may also generate less general theories within its domain, dealing with limited aspects of the data.

Because the reality investigated by science, referred to as nature, is characterized by uniformity and continuity, domain theories must not only be consistent with the data of their domains of origin, they also must not contradict established findings of other domains, and parapsychology, as the scientific investigation of the domain of paranormal phenomena is subject to the same rules of compatibility.

Survival of Death and Reincarnation

Given the necessarily broad nature of a parapsychological meta-theory, it may well be called upon to explain data relating to human survival of death and reincarnation. Some parapsychologists believe that the accumulated evidence of survival is convincing (see Kelly et al. 2007) and that the evidence for reincarnation is even more impressive (see Stevenson 1966, 1975–1983, 1997). If indeed arguments for the reality of survival and reincarnation are compelling, it would seem that any general parapsychological theory would have to provide the means for understanding how the constitution of a human being, and the nature of identity and continuity in human personality, would make survival following separation from the physical body possible. Such a theory would have to have the backing of a philosophical framework that deals adequately with the mind-body problem and the question of the ultimate constituents of reality. The making of such a meta-theory is a daunting task indeed.

Future Directions

Although a parapsychological meta-theory has not yet been developed, certain scientific and philosophical

directions are emerging that may contribute to its eventual creation.

Because the mind is involved in paranormal phenomena, a general theory must address the mind-body problem and talk about issues that are normally considered the province of ontology and epistemology. In this regard it should be noted that among philosophers of mind, the issue of panpsychism has recently been moving into greater prominence. Panpsychism (or panexperientialism) is a theory that posits mind as a constituent element in the makeup of all reality. This approach does not necessarily imply the action of an omnipresent God, but often takes the form of the involvement of mind at a fundamental level in the original formation of the universe. If mind is basic to the very existence of all things, then the mind-body problem, which posits the complete separation of mind and matter, can be solved. Two important recent discussions of this issue are those by David Skrbina (2005) and Galen Strawson (2006).

Another philosophic position makes use of “process philosophy” to construct a framework that is compatible with the existence of paranormal phenomena in general. Prominent philosophers, whose ideas are considered to have contributed to the development of process philosophy, are Charles Sanders Peirce, William James, and Henri Bergson. The philosopher who developed the concept of process philosophy as a system is Alfred North Whitehead. Process philosophy holds that the basic realities are not substances, but passing experiences that arise out of the past and create the future. This involves the notion that everything in some way has experience, and at each present moment takes part in the creation of the next moment to come. This means that every existing thing is involved in the evolution of our universe. An essential element of process philosophy is that our perceptual knowledge of the world beyond ourselves is not dependent solely on sense experience, but involves another way of being in touch with and experiencing our environment. It should be clear that this philosophic approach has many elements that are friendly to the existence of the paranormal (see Griffin et al. 1993 and Griffin 1997). Eric Weiss has recently used Whitehead’s formulation of process philosophy, in combination with the ideas of the Indian philosopher Sri Aurobindo, to develop a model of reality that is not only compatible with,

but in some way requires the existence of, paranormal phenomena, panexperientialism, and survival of death (see Weiss, www.ericweiss.com/the-long-trajectory).

Another stream of input into a possible meta-theory flows from theoretical physics, both from quantum mechanics and from multidimensional speculations.

Mathematician and cosmologist Bernard Carr has developed a hyperdimensional theory that attempts to show that higher dimensions are fundamentally associated with mind. He believes this model bridges the gap between mind and matter and makes sense of paranormal phenomena. In his model, the material world becomes mind-like and the mental world becomes matter-like. This allows for the unification, in a higher dimension, of objects and percepts that seem to be totally separate. Carr states that his view allows for the possibility of nonphysical perceptions of the world (Carr 2008).

On another front, theoretical physicist Henry Stapp of Lawrence Berkeley National Laboratory, who studied under both Wolfgang Pauli and Werner Heisenberg, has developed an understanding of quantum mechanics that is an elaboration of the Copenhagen interpretation, as it was modified by the work of John von Neumann. This view sees the reduction or “collapse” of events in the physical world as involving consciousness in an essential way, so that the world is inherently psychophysical. The part played by consciousness is the making of a choice of an experimental question or probing action, a choice not determined by any known law or rule, and as such considered a “free choice.” This solves the problem that had plagued classical physics since the time of Newton: the fact that in a world completely explainable in physicalistic deterministic terms, a causally closed world, there is no possible role for consciousness and freedom. It creates the vision of a world no longer dynamically closed, but open to the meaningful participation of the mind (Stapp 2007). Of interest to the parapsychological theoretician is the fact that, in contrast to classical physics, Stapp’s version of Copenhagen quantum mechanics, while not proving the existence of paranormal phenomena, at least makes room for the possibility of not only psi events, but even such things as human survival of death and reincarnation. This opens the door for new avenues of parapsychological research and creates serious difficulties for fundamentalist skeptics.

Dean Radin, research scientist at the Institute of Noetic Studies, emphasizes another significant aspect of quantum theory: “One of the most surprising discoveries of modern physics is that objects aren’t as separate as they may seem. When you drill down into the core of even the most solid-looking material, separateness dissolves” (Radin 2006, p. 1). For a long time quantum theorists believed that this “entanglement” was fleeting, and operative only on the microscopic level of reality, but, says Radin, scientists are now finding that these entanglements “scale up” into our macroscopic world. He states that reality is woven from strange “holistic” threads, and “Tug on a dangling loose end from this fabric of reality and the whole cloth twitches, instantly through all space and time” (p. 3). Radin makes the case that paranormal phenomena turn out to be not bizarre at all, but the kinds of things one would expect in an entangled universe, and that what is today the study of parapsychology will tomorrow be just part of the science curriculum: “History shows that as the scientific frontiers continue to expand, the supernatural evolves into paranormal, and then into normal. During the transitional periods there is much gnashing of teeth. But with determination and courage, progress is relentless” (Radin 2006, p. 296).

Prospects for Theory Development

Today parapsychology is increasingly characterized by a “grounded” approach to theory-making. “Grounded theory” is a method for generating theories which, although first formulated in sociological research, can be applied to every science. It is an inductive approach that keeps the researcher going back and forth between data collection and categorization and producing theoretical constructs that embrace the evolving mass of data. The purpose is to stay close to the empirical data and yet allow theory and inspirational thinking an early place in the process (see Glaser and Strauss 1967).

There are several current projects that apply this approach to parapsychological theory-making. Dean Radin, investigates paranormal phenomena in this spirit. His research involves both experimental work and the statistical analysis of paranormal data, collected from the beginnings of psychical research to the present time. He writes about the importance of “meta-analysis” for psi research: “For psi experiments, we can

ask questions not only about how an individual performed, or how a group of individuals performed in a given experiment, but how people perform *in general* across many experiments” (Radin 2009, p. 49). This is accomplished through a method of statistical analysis, wherein the units of analysis are the results of independent studies, rather than the responses of individual subjects. This approach provides a significant insight into the reality of the paranormal as it has been observed over many decades of research. Radin’s experimental, theoretical, and statistical work has done a great deal to establish IONS as one of the most important centers of psi research and theorizing about psi at the present time.

Another research project that aims to advance parapsychological theory-making is a combined undertaking of the Division of Perceptual Studies (DOPS) in the Department of Psychiatry and Neurobehavioral Sciences at the University of Virginia, and the Cedar Creek Institute (CCI), also located in Charlottesville, Virginia. Under the direction of Edward Kelly, the Cedar Creek Institute undertakes psychophysiological studies of subjects using state-of-the-art neuroimaging techniques. These techniques are applied to advanced meditators, out-of-body subjects, trance mediums, hypnotic virtuosos, and high-level psi subjects. At the same time the Institute undertakes the collection and systematic analysis of all forms of evidence relating to human survival of death. The CCI has a close working association with DOPS, founded by Ian Stevenson in 1968, which has accumulated a large store of data relating to reincarnation, near-death experiences, and other phenomena occurring around the dying process. DOPS continues a 40-year project of data collection and analysis, offering insights into the nature of these phenomena and the constitution of the human psyche.

Another project with relevance to theory-making in parapsychology is the Seminar on Human Survival of Death sponsored by the Esalen Centre for Theory and Research. Originally formed in 1998 by Michael Murphy, the Seminar brings together experts from a broad spectrum of disciplines to investigate phenomena relating to the possibility of survival of death. The expertise of the seminar’s members includes: psychology, neuroscience, quantum mechanics and astrophysics, philosophy, anthropology, studies of Eastern and Western esoteric traditions, comparative religion, and

parapsychology. One of the principal aims of the Seminar is the development of a scientific meta-theory of paranormal phenomena, which will take into account the “rogue” phenomena of parapsychology, be compatible with findings of all the relevant sciences, and cast light on the possibility of survival of death and reincarnation.

Conclusion

The development of theory in parapsychology has had a long, complex history. The majority of parapsychologists believe that the validity of the phenomena has been well established by the mass of data that have accumulated since the foundation of the SPR, and there is now a push to theory development and to process-oriented empirical research. Currently, the gathering of new experimental and spontaneous case data tends to be oriented to the development of theories that are adequate to the broadest spectrum of data, and to the exploration of the implications of that data to related issues of survival of death and reincarnation. This task is conceived as both benefiting from and contributing to recent developments in the other sciences, particularly psychology, neuroscience, and physics.

Parrish, C. S.

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Parrish (1853–1918) who preferred, Celeste, was born in Pittsylvania County, Virginia Thomas (2006). She died in Clayton, Georgia, where her grave monument bears the epitaph, “Georgia’s Greatest Woman,” an honor bestowed upon her by the State Superintendent

of Georgia's public schools. Orphaned at age 10, by age 15 and largely self-taught, it became necessary for her to teach in a rural Virginia school to support herself and her siblings. In 1893, after years of considerable sacrifice, hard work, and further education, Parrish was offered the chair in mathematics at Randolph-Macon Woman's College (R-MWC) in Lynchburg, Virginia (R-MWC began admitting males in 2007 and was renamed Randolph College). Being responsible also for philosophy, pedagogy, and psychology, Parrish volunteered to learn psychology. Working around her obligations at R-MWC, she earned a bachelor's degree (Ph.B.) in psychology at Cornell University in 1896. Her supervisor was the well-known experimental psychologist, E. B. Titchener (Parrish 1925).

Major Accomplishments/ Contributions

Modeled on Titchener's laboratory, Parrish established the psychological research laboratory at R-MWC in 1894, which is widely recognized to have been the first such laboratory in southern USA. In 1901, she was appointed Director of the "Practice School" and Chair of Psychology and Pedagogy at the Georgia State Normal School in Athens, Georgia ("normal schools" specialized in teaching post-secondary students to become teachers). In 1902, Parrish obtained funds from the philanthropist, George Foster Peabody, to establish a first-rate psychological research laboratory and to build a practice school building at the Normal School. Parrish also taught child psychology during summers at the University of Georgia (Athens, GA), and circumstantial evidence suggests she was instrumental in establishing the first psychological research laboratory there in 1902.

Following her Ph.B. degree, Parrish spent three summers at the University of Chicago studying with John Dewey. She became a tireless advocate for progressive educational reform based on Dewey's pedagogical theories. Her advocacy was multiplied when her Normal School students began to teach, and Parrish obtained even wider results after she became a State School Supervisor (1911) responsible for the public schools in Georgia's 48 northernmost counties. In 1914, she evaluated the Atlanta Public School System,

and the Board of Education enthusiastically adopted the progressive recommendations in her 33-page report.

Parrish's passion for implementing progressive education in Georgia also had deleterious effects on her career. She was a strong advocate for equal educational and employment opportunity, especially in education, for women. However, her advocacy of education for Negroes, despite how necessarily muted it had to be in the south in the early 1900s, was far less well received. Early in her tenure at the Georgia State Normal School, a bitter and enduring conflict arose between Parrish and the school's president, E. C. Branson, initially due to her refusal to behave subserviently toward him and to her insistence that she was his academic peer. Branson declared very early that one of them would have to go, but that the separation was delayed until 1911 (Montgomery 2008).

An early crisis for Parrish arose at the Normal School when in a class discussion about what interests whites should have in the Negroes, a student asked Parrish for her views about teaching them. Parrish replied that she had been glad to teach Negro teachers in their normal schools and would do so again. When the student replied that she would never teach Negroes, Parrish told her that if that was true, then she should get out of teaching. The student complained inaccurately to her politically influential father, and efforts were made in 1902 and in 1903 to have Parrish fired. She was exonerated on both occasions, but in 1911 Branson succeeded in getting the Board of Trustees to dismiss Parrish.

Parrish still had considerable influence and, as noted earlier, was appointed to be a State Supervisor responsible for public schools in Georgia's 48 northern counties. At that time she relocated her residency to Clayton, Georgia, where she remained until her death.

Parrish's theoretical contributions were best expressed as an innovative founder and advocate. Founding the first psychological laboratory in the south (and two others) contributed to psychology's development as a science. Equally important were her advocacies for Dewey's ideas for progressive education, women's rights, and for equal educational opportunities for Negroes.

Paterson, Donald G.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: January 18, 1892; Died: October 4, 1961.

Donald Paterson, child of deaf parents, developed his interest in psychology in the context of applying it for individual and social improvement. While an undergraduate, he was influenced by Frank Parsons, an early proponent of vocational guidance, and then came into contact with two of the most realistic and practical psychologists in America when he went to Ohio State University for his graduate work, A. P. Weiss and ▶ [Pintner, Rudolf](#). Paterson formed a close working relationship with Pintner, and they published several papers and a well-regarded set of tests to measure intelligence nonverbally, the Pintner–Paterson Scale of Performance Tests (Pintner and Paterson 1917). In connection with his work with Paterson, Pintner developed a career interest in issues connected with education of the deaf. At this point, Paterson went to Kansas to begin an academic career, and began working with Walter S. Hunter. Paterson’s observations about the unknown reliability of the measurement of maze performance led Hunter to propose that Paterson should carry out doctoral studies in this area, but marriage and the First World War intervened and that project was not done. In fact, Paterson never obtained a Ph.D. and was awarded an honorary LL.D. by The Ohio State University only in 1952. After the war, he spent

2 years with the Scott Corporation and then was invited to Minnesota by Richard Elliot in 1921, remaining there for the rest of his career.

Major Accomplishments/Contributions

Paterson became one of the leading applied psychologists in the USA: His main contributions were to the development of systems of vocational guidance and employment statistics. He is often considered to be the originator of modern vocational guidance within universities: Several of his graduate students became prominent in the testing field. He also continued his interests in testing and measurement. His contribution to the 1928 Sigma Xi symposium at Minnesota, in collaboration with several other specialists on the measurement of physical growth, was a model of skeptical psychometric analysis, demolishing the alleged relation between physique and intellect (Paterson 1930). He also coauthored, with Elliott (▶ [Elliott, Richard M.](#)) and several other Minnesota colleagues, the Minnesota Mechanical Ability Tests (Paterson et al. 1930). Also in 1930, he began a long collaboration with his new colleague Miles A. Tinker on the legibility of type, which resulted in a well-respected manual for typographers and other print communicators (Paterson and Tinker 1940). Paterson was a productive teacher and sponsored, according to several sources, 88 doctoral dissertations and over 300 master’s theses at the University of Minnesota. He was Secretary of the American Psychological Association for several years and held many offices and editorships in the area of applied psychology: He was a charter member of the American Board of Professional Psychology in 1947. Paterson’s service extended outward into the surrounding community: He was a founding member of the ACLU in Minneapolis and active in his neighborhood association, and even provided vocational guidance to neighbors’ children when necessary (Fraser 1992). Paterson’s career has become a focus of interest both in industrial/organizational psychology (Erheim, Zickar and Yankelevich 2007) and in the history of psychology (Baker 2006) because of its many connections to important infrastructural relations between applied psychology and the surrounding society.

manifestation of human nature. Following World War II, the impact of the threat of nuclear war and conflict resolution emerged as central concerns. Subsequently, since the end of the post-Cold War period, the study of forms of violence, both individual and institutional, has taken center stage. In the twenty-first century, peace psychology has become a highly contextualized, global discipline as theorists across countries, cultures, and genders have become active contributors to the study of war and peace and to the promotion of social justice.

Historical Background

Peace psychology has been defined as the study of mental processes that produce and prevent violence, as well as facilitates nonviolence. Peace psychology is also interested in healing the effects of violence and promoting human rights (MacNair 2003). Peace psychology pursues theories and practices that promote social justice via the study of direct and structural forms of violence (Christie et al. 2001). While social psychology and political psychology share some common contents, peace psychology as a discipline differentiates itself by placing greater emphasis on understanding how broad institutions such as governmental structures, economies and cultures, and their influences shape constructive approaches to conflict management (Deutsch 1973).

The early philosophical origins of perspectives on war and peace have been traced back to Pythagoras in 570 BC, whose teachings emphasized the universality and equality of humans and opposed violence and war (Rudmin 1991). The first modern peace psychologist has been identified as William James. This philosopher-psychologist was well known for his views on war and peace, publicly expressing his opposition to imperialism and military passion. In “The Moral Equivalent of War,” James addressed the psychological, political, and economic functions of war, asserting that an alternative to war was possible and that war was not a necessary consequence of human nature (Deutsch 1995).

The question of the inevitability of war was the central issue in the exchange of letters between Albert Einstein and Sigmund Freud in 1932. Following the failure of the League of Nations, and at the request of the Institute for Intellectual Cooperation, Einstein, a noted pacifist, proposed a dialogue with Freud on

Peace Psychology, History of

NEAL S. RUBIN, MICHELLE A. NELJAK
Argosy University, Chicago, IL, USA

Introduction

The history of the contributions of psychology to the study of war and peace includes both early, philosophical origins, as well as modern and postmodern social science perspectives. Psychology’s fundamental search for understanding human behavior, motivation, and meaning has generated research on a variety of topics that inform our understandings of violence and nonviolence.

Early peace psychologists viewed human nature in terms of drives and impulses that are innate and shaped by the environment with aggression having both the potential for destructive as well as constructive outcomes. Given this conceptual framework, a key question that followed was whether war was an inevitable

the question of “Why War?” Freud’s response largely supported the idea of inevitability, referencing his concept of the “death instinct” as a part of human nature difficult, though possible, to overcome (Isaacson 2007).

Following World War II, psychologists also became advocates for peace. A noteworthy document, “The Psychologists’ Manifesto: Human Nature and the Peace: A Statement by Psychologists,” held the signatures of its creators (e.g., Gordon Allport, E.R. Hilgard, Otto Klineberg, and Edward Tolman) as well as the signatures of 4,000 other American psychologists (reprinted in Jacobs 1989, and in Murphy 1945). The manifesto affirms the position of these psychologists on the prevention of war and the promotion of peace and human rights.

Throughout the second half of the twentieth century, as psychology was growing in relevance as a social science and as a profession, peace psychology also transitioned into a more coherent and cohesive area of inquiry. This transition included a shift from individual theorists working independently to the emergence of peace psychology as a field. Following World War II and during the Cold War period, psychological research began to address the behavioral dimensions of the threat of nuclear war (Russell 1961). Psychologists contributed to knowledge regarding the impact of the risks of nuclear annihilation, strategies for deterrence of this threat, and processes of conflict resolution on individuals and societies.

American peace psychologists evolved from an aligned relationship with the military in the USA that facilitated nationalist Cold War goals amid the superpower standoff, to promoting peace and conflict resolution through the study of a wider set of national security issues. Initially, psychologists investigated the question of how the population might anticipate and adjust to the threat of nuclear confrontation. Subsequently, the voices of psychologists became increasingly independent of the political aims of a nation and focused more broadly on studying systems that contribute to war and other forms of violence worldwide. The scope of concerns, then, for the field of peace psychology, developed from an exclusive study of dyadic super power relations between the USA and the Soviet Union into a multidimensional study of all structures of societies that threaten the security of individuals, communities, and nations (Christie et al. 2001).

The interests of peace psychologists became progressively more organized via publications and conferences. Sentinel events in this new emerging field were the publication of *Psychology and the Prevention of Nuclear War* (White 1986) and the recognition of the study of peace psychology by the American Psychological Association that established the Division of Peace Psychology (Division 48) in 1990 (Wessells 1996). These developments followed from research published in the *Journal of Social Issues* and the *Journal of Conflict Resolution* that transitioned from Cold War concerns with the risk of war to a focus on conflict resolution and the promotion of peace. Clearly, the field of peace psychology initially coalesced around visions for promoting a more secure world in terms of reducing frigid super power relations.

By shifting from this twentieth century, exclusive focus on the prevention of nuclear war, peace psychology forged a new vision as a more multifaceted, globally inclusive field that addressed issues of violence and conflict resolution that affect individuals and nations worldwide. While nuclear war and tensions between nations remain a significant global threat, peace psychologists recognized that there has been a trend away from wars between nations to intrastate conflicts and asymmetrical war, including terrorism. One manifestation has been the changing structure of and the increase in the number of United Nations peacekeeping operations since the end of the Cold War (Langholtz 1998). Though the first U.N. peacekeeping mission began in Palestine in 1948, the Department of Peacekeeping Operations (DPKO) at the United Nations was not established until 1992. Sixty-three peacekeeping operations have been conducted, the majority since the end of the Cold War.

The successes and failures of U.N. peacekeeping missions led to the recognition that peacekeeping without supportive diplomacy, clear rules of engagement, and the follow-up building of societal infrastructure rendered fragile peace agreements vulnerable. Peacekeeping is now viewed as having three interrelated components: peacemaking, peacekeeping, and peacebuilding. Peacemaking involves utilizing the principles of negotiation and conflict resolution to facilitate quiet diplomacy in order to ameliorate the early stages of rising tensions; peacekeeping stabilizes conflict zones implementing peace agreements, reducing the suffering of affected populations and limiting the

potential for conflicts to spread across entire regions; peacebuilding follows conflicts and addresses the structural components of society that have provoked conflict and may undermine a peaceful future, for example, providing medical care, policing, and holding democratic elections (Rubin 2010). Psychologists representing a number of professional affiliations have achieved consultative status at the U.N. as nongovernmental organizations (NGOs) and apply psychological science to the behavioral dimensions of a range of global human rights issues (Takooshian and Shahinian 2008). The reconceptualization of the field of peace psychology, then, appears to be in concert with these changing threats to human security in the world at the turn of the twenty-first century.

Twenty-First Century Perspectives

A conceptual underpinning of twenty-first century peace psychology has been the distinction between the meaning and significance of different types of violence: direct and structural violence (Christie 1997). Direct violence kills or harms individuals and tends to occur episodically; structural violence refers to social inequality in the form of institutional structures that also harm individuals by depriving them of the basic necessities fundamental to human security (Galtung 1969, 1996). Scholarship on the theme of social justice as it relates to human security and practices that promote peacemaking and peacebuilding by embedding programs that address social inequalities into societal structures have been central to the new peace psychology agenda (Wessells 1998).

The field of peace psychology, then, has moved from a somewhat disparate group of peace psychologists in need of defining a cohesive field of inquiry to an established discipline now in the process of broadening the scope of theoretical inquiry and application. While violence and conflict resolution between nations continues to receive attention, the psychological dimensions of violence that are direct and/or structural that involve individuals, groups, and nation states are now the subject of scholarship in the field. Both traditional topics of war and conflict resolution and novel subjects such as intergroup violence, institutional forms of discrimination and oppression, intimate partner violence, gender violence, social injustice, and globalization have become subjects of inquiry (Christie 2011).

Peace psychologists have also become concerned with criticisms of the hegemony of American or westernized psychology and the significance of listening to the voices around the world often marginalized or absent from the psychological literature. Increasingly, contextualizing peace psychology culturally and historically is appearing in scholarly publications. Processes of truth and reconciliation have been prominent in the recent histories of apartheid South Africa (Goboda-Madikizela 2003) and in the revelations regarding the “Lost Generations” of Aboriginal children in Australia (Bretherton *in press*). In sub-Saharan Africa, issues related to ethnic conflict, intrastate rivalry for resources and power, gender violence, and the forced soldiering of children have received attention (Wessells 2007). Asian peace psychologists are concerned with South Asian nuclear tensions between India and Pakistan, in the East between North and South Korea (Leung 2003), as well as the cultural and religious orientations of Asians, their differences from the West, and their influence on peacemaking processes. A history of colonialism and liberation from authoritarian regimes is another key theme (Montiel 2003). These are just a few examples of the perspectives of psychologists across cultures regarding studies of their own histories and societies that now inform contemporary theory building and conceptual formation.

The roles of women in the history of peace movements worldwide and feminist scholarship on a range of issues related to forms of violence have also been identified as important contributors to understanding how exclusivity of perspectives limits knowledge (McKay 1996). Finally, there is also recognition that the field is diminished when indigenous psychologies are not articulated. For example, the conversation about topics such as conflict resolution is compromised when the wisdom that traditional, collectivist cultural practice might contribute is lost (Wessells and Montiero 2000). Societies and individuals under stress are not without their own resources to address dangers to the peaceful resolution of crises. Peace psychologists promote the integration of the resourcefulness of local populations to developing strategic responses to challenges to their societies.

Future Directions

As the field of peace psychology broadens, what are the implications for the future? It would appear that

increasingly multidimensional models of complex systems will need to characterize how peace psychologists will address the challenges of peace and violence in the world. Such models will represent the interconnectedness of systems and histories as they emerge. For example, with human security redefined as comprised not only of physical safety, but the human right to health and well-being as well, issues such as globalization, climate change, gender equality, and the information revolution will require the attention of peace psychologists, as these issues are highly interrelated and their outcomes are likely to potentiate either conflict or conflict resolution. Just as the industrial revolution resulted in inequities between those that have and have not in the past, access to information technology and the impact of global markets today will either add to or ameliorate social inequality and the conditions that promote violence. Climate change and environmental degradation already threaten the existence of island nations and the way of life of millions in the developing world. Addressing these issues on the United Nations' human rights agenda today embodies the commitment of peace psychologists to the study of and advocacy for social justice. Therefore, twenty-first century scholars and practitioners of peace psychology, across social and cultural contexts, will be contributing to understanding and engaging these threats to human security and well-being worldwide.

Pêcheux, Michel

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/ Major Accomplishments

Michael Pêcheux was a French Marxist social psychologist, psycholinguist, and philosopher. He developed a formal, potentially automatic instrument, which he called *Automatic Discourse Analysis*. He studied at *École Normale Supérieure*, where Louis Althusser and Georges Canguilhem were among his teachers. He was an active member of the left Communist movements. At his tragic death in 1983, at the age of 45 years, he was professor and researcher in the Laboratory of Experimental Social Psychology at Sorbonne University Paris 7 as well as research director at the National Center for Scientific Research. He published many papers and books in the field of social psychology, psycholinguistics, language, philosophy, and the history of human and social sciences.

Pêcheux conceived the constitution of psychology as a result of theoretical rather than empirical breakthroughs, a view he shared with Gaston Bachelard. In a series of articles, he developed the conceptual foundations for a dialectical materialist social psychology. Much of the concepts used in his theoretical framework have been recast, of course, in the light of insights drawn from the works of Marx, Engels, Lenin, Gramsci, and Lukacs and most importantly, in my view, of Soviet psychologists and linguists such as Vygotsky, Bakhtin, and Volovsinov among others. It was Pêcheux who brought to the fore power and ideology concepts in the discourse field. The makeup of language is conditioned by social forces such as social classes, gender, race, ethnicity, etc. Language for Pêcheux is an expression of the ideology of the hegemonic class domination.

Pêcheux summarized his project stating that: "All my work finds its definition here, in this linking of

the question of the *constitution of meaning* to that of the *constitution of the subject*, a linking which is not marginal (for example the special case of the ideological 'rituals' of reading and writing), but located inside the 'central thesis' itself, in the figure of *interpellation*" (1982, p. 105). Pêcheux had elaborated systematically a theory of the materiality of language or a materialist theory of language.

Pêcheux's research framework is of continuing relevance to experimental social psychology, psycholinguistics, possessing as it does much potential for analyzing concrete instances of human higher mental functions, rule-governed behavior, language, disidentification, ideology, and discursive speech analysis.

Pêcheux developed two theses to illustrate the connections between language and ideological formations. In the first he stated that "*words, expressions, propositions, etc., change their meaning according to the [ideological] positions held by those who use them, which signifies that they find their meaning by reference to those positions; that is, by reference to the ideological formations in which those positions are inscribed*" (1982, p. 111). The second thesis Pêcheux stated that "*every discursive formation, by the transparency of the meaning constituted in it, conceals its dependence on the 'complex whole in dominance' of discursive formations, itself imbricates with the complex of ideological formations*" (1982, p. 113).

Perception

NICHOLAS J. WADE

University of Dundee, Dundee, UK

Introduction

In his spiral of the history of sensation and perception, Edwin Boring (1889–1968; 1942) commenced with Johannes Kepler (1571–1630) and concluded with Raymond Dodge (1871–1942); they are all shown in Fig. 1. Another implicit feature of Boring's spiral is that one sense – vision – dominated all the others. Accordingly, it is little surprise that his book was dedicated to Hermann Ludwig Ferdinand von Helmholtz (1821–1874) – a towering figure in the history of vision. A preoccupation with the sense of sight was evident throughout the period surveyed by Boring and it remains so to this day.

Boring was aware that establishing an origin for the study of the senses was problematical since the history of perception is as long as that of description itself. Nonetheless, commencing with Kepler could be justified on several grounds, as he was instrumental in initiating a revolution in the study of vision. Kepler proposed that the eye operated like an optical instrument in which an image is focused on the retina. He also conducted experiments with a water-filled glass globe in order to examine the clarity of images passing through it and projected onto screens at different distances, thereby introducing the issue of accommodation (although that term was not then used in this context). Others, like Christoph Scheiner (1573–1650) and René Descartes (1596–1650), shown in Fig. 2, forged a closer union between the optics and anatomy of the eye, and interpretations of vision took a totally different path thereafter. While the interpretations changed, the phenomena that were scrutinized did not. It is to these that

Perception. Fig. 1 *The spiral of the senses.* The diagram of the spiral is from the inside cover of Boring's book and his portrait is dimly discernable within it. Boring's spiral of history commences with Kepler (*left*) and concludes with Dodge (*right*) (Illustration © Nicholas Wade)

Perception. Fig. 2 *Left: Scheiner's eye.* Scheiner was an astronomer who is enclosed in his accurate diagram from 1619 of the gross anatomy of the mammalian eye; he also observed the inverted and reversed retinal image on the exposed retina of an ox's eye. *Right: Descartes' brain.* Descartes continued Scheiner's integration of optics and anatomy and not only repeated the experiment with an ox's eye, but also illustrated it. He is represented in the engraving of the brain taken from *De Homine*, the title page of which is also shown (Illustration © Nicholas Wade)

we will first turn and to the general problem of what constitutes perception.

What we call “perception” is an experience that results from stimulation of the senses. It can be examined by verbal description and by psychophysical experiment, or it can be related to the processes in the nervous system that accompany the experience. Historically, the only records of action of the senses were provided by behavior but now a wide range of indirect physiological measures can augment them. In humans, the range of behaviors is broad and includes describing the experiences initiated by sensory stimulation and the links it might have with previous stimulations (Wade 2005). We refer to these as observations and we associate them with verbal descriptions. Records of observation precede records of their verbal descriptions; that is, the products of art precede those of writing. Relatively little is known about the origins of visual art: examples of marks made on tools and cave walls have been dated to tens of thousands of years ago, but we do not know when such activities began. Writing had its origins around 5,000 years ago. Verbal descriptions of observations were refined by Greek philosophers, who also introduced theories to account for the characteristics of perception (Symons and Calvo 2009).

Aristotle (ca. 384–322 BC) provided descriptions of numerous natural phenomena amongst which were those following stimulation of the senses (Ross 1931). He can be thought of as setting in train the observational tradition: perceptual experience is confined to naturally occurring events and interpreted within the theory of the day. The adoption of experimental methods to record observations developed somewhat later. An early example can be found in the work of Claudius Ptolemy (ca. 100–170) on optics (Smith 1996), but it was more widely adopted after the investigations of Isaac Newton (1642–1727; 1704) on color phenomena.

Classification of the Senses

Aristotle described the five senses of sight, hearing, smell, taste, and touch, and they are rooted in our culture despite clear evidence of the inadequacy of the ancient classification. The prominence of eyes, ears, nose, and tongue on the head, and the specific experiences associated with them, has acted in the past, as well as in the present, to fix these four senses. Touch was problematical because its sensitivity is not localized to a particular sense organ, and the experiences derived from the skin are diverse. Pain was missing altogether.

Pain and touch both presented problems for classifying the senses, although the ways they were treated differed radically. Touch was taken as the exemplar of all senses whereas pain was given less prominence; it was not included in the list of Aristotle's "common sensibles" which were defined by properties of the stimulus rather than of sensation. For Aristotle, no obvious stimulus could be assigned to pain, other than over-stimulation or damage to the other senses, and so it was placed in opposition to pleasure rather than associated with sense. Neither touch nor pain could be localized in a particular sense organ. Aristotle confronted the particular problems in the context of touch but not of pain. The other encumbrance to advance was ignorance of both the anatomy and physiology of the senses, let alone of the brain. Indeed, for Aristotle, sensation was housed in the heart, although he was later taken to task for this by Galen (ca. 130–200) who argued that all the senses have connections with the brain.

The sources of evidence available to Aristotle for distinguishing between the senses were phenomenology and gross anatomy. The situation was radically revised in the nineteenth century, with developments in physics, anatomy, and physiology. New techniques for stimulating and recording from the senses and for tracing nerve pathways to the brain changed the ways in which the senses could be classified. The criteria that emerged from the new techniques are the quality of the experience, the nature of the stimulus, the gross and microanatomy of the receptor system, and the pathways to and representation on the cortex. The psychological dimension is the oldest of these, and yet less attention has been paid to behavioral evidence for distinguishing and adding to the senses than to that derived from anatomy and physiology.

Thus, the senses were at the center of many of the dramatic departures in nineteenth century psychology, and the experimental advances in turn influenced theories of perception (Gordon 2004; Wade 1998). The color mixing experiments by Thomas Young (1773–1829) found that all colors could be produced by appropriately compounding three primaries. He suggested that the eye was selectively sensitive to each and James Clerk Maxwell (1831–1879) provided experimental support for this trichromatic theory. In the domain of motion, Michael Faraday (1791–1867) suggested how successive images presented in close

temporal sequence could result in the perception of movement and Joseph Plateau (1801–1883) devised a contrivance for synthesizing visual motion. Spatial vision also yielded to the power of this experimental approach: Charles Wheatstone (1802–1875) demonstrated that depth could be synthesized from two slightly disparate images presented to separate eyes, dissociating depth perception from its object base. In the 1830s, Ernst Heinrich Weber (1795–1878) demonstrated that the nuances of sensory discrimination could be measured, by applying what became called psychophysical methods; these were extended to demonstrate lawful relationships between stimulus intensity and sensory magnitude by Gustav Fechner (1801–1887; 1860). By mid-nineteenth century, the study of perception had moved from the natural environment into the laboratory.

Early Theories of Perception

Philosophy has played a central role in the study of perception because the senses and their functions have been of focal importance to philosophy. Most of the basic ideas were initially expounded by Greek thinkers, and they have been elaborated upon by more modern philosophers. Moreover, it was essentially the unusual aspects of visual experience that elicited most early interest (Wade 2005). Of these, three were of particular significance and they influenced theories of light as well as sight. The first concerned the experience of light following pressure or a blow to the eye and the second related to the visibility of a reflected image in the eye. The idea of light being emitted from the eye was founded on the first of these, and the notion of an image being carried back to the eye was the source of the second. A third feature of sight, which distinguished it from the other senses, was that the experience could be terminated by closing the eyelids during daytime.

Plato (427–347 BC, Fig. 3) distrusted the senses because the evidence they furnished about external objects could change; moreover, the objects themselves could change, as in the process of growth. Accordingly, he believed that the world of appearances was one of illusion, as opposed to the world of thought in which ideal forms existed. The forms reflected the universal qualities of objects rather than the particular features which can be sensed. The abstract forms could be

Perception. Fig. 3 *Left: Ideal form*; Plato argued for ideal forms in the mind and these were accessible by rational thought rather than by observation. *Right: Received wisdom*. Aristotle on the other hand embraced observation and added enormously to the range of phenomena that could be studied. In the context of perception, he argued for light being received by the eye rather than emitted from it (Illustration © Nicholas Wade)

investigated by reasoning rather than observation, and this resulted in a preference for rational rather than empirical enquiry. Plato's position demonstrates the influence that language has had on philosophical thought: particular members of a category that are given a single name (e.g., horse) do not reflect their universal characteristics. These ideal forms are permanent and inaccessible to perception because the senses are concerned with particulars rather than universals. Plato distinguished between the body and the soul: the body was part of the material world whereas the soul was immaterial. He likened the rational soul to a charioteer steering the competing horses of emotion and appetite; the rational soul was considered to be morally superior to the others and should guide their actions. These distinctions were to have considerable significance because they later permeated both philosophy and Christian theology. Mind–body dualism was at the heart of Descartes's philosophy as well as a constant current in Christian theology. The latter also placed great emphasis on the moral superiority of reason over irrational feelings and passions.

Aristotle (Fig. 3) adopted more naturalistic explanations of phenomena which did not denigrate the senses. He criticized Plato's theory of ideal forms arguing that the features that distinguish a horse, say, do not have an existence independently of horses; these

distinctive features could best be studied by examining actual horses rather than their ideal forms. Therefore Aristotle preferred an empirical approach to a rational one. He is often considered to be the first psychologist because of his emphasis on observation and because he tried to order phenomena in a systematic manner.

Rationalism

The contrast between the philosophies of Plato and Aristotle can be thought of as that between rationalism and empiricism, and both approaches have been applied to the analysis of perception. The differences between them were brought into sharper focus after the scientific Renaissance in the seventeenth century, when a wider range of perceptual phenomena was scrutinized. Descartes applied mechanistic interpretations to bodily processes while maintaining that the mind was immaterial, thus retaining the Platonic distinction between body and soul. Communion between mind and body was achieved via structures in the brain, particularly the unpaired pineal body (the pear-shaped structure labeled H in Fig. 2).

Descartes's mechanistic approach to the senses clarified many issues in perception, but he had the thorny problem of accounting for the interaction of the rational mind with the mechanistic body. This was a task attempted later by Immanuel Kant (1724–1804).

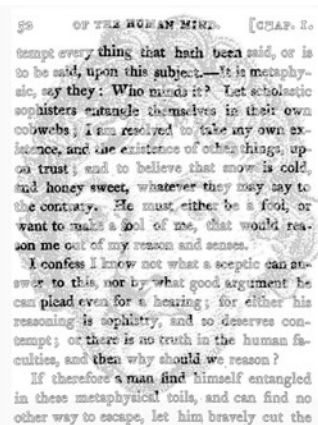

Kant did not deny that all knowledge begins with experience, but he did not believe that it all arises out of experience either. He considered that certain aspects of knowledge were innate, most particularly the ideas of space and time. That is, Kant suggested that the individual is born with the ability to organize experience in both space and time. Perception is then an active organizing rather than a passive receptive process. Kant's influence on Continental philosophy was vast, but it also had numerous repercussions in related disciplines like physiology and psychology. The distinction between innate and learned processes in perception became enshrined in nativist and empiricist philosophies, respectively. The nativists believed that we are born with the ability to perceive space, whereas the empiricists argued that we have no such knowledge of the world at birth, but we need to learn to see the spatial attributes like size, shape, and distance. For Kant our conscious, phenomenal world is a cognitive construction. He made a distinction between the world of things and that of appearances, and was pessimistic about whether the latter (and hence psychology) was open to scientific enquiry. That is, he did not consider that the inner world was open to precise measurement, and therefore its study could not be classified as a science.

Empiricism

Modern empiricist philosophy was expounded by John Locke (1632–1704; Fig. 4) at the end of the seventeenth

century. For Locke the mental element is the idea, which is based upon sensory experience. Ideas could be simple (like whiteness) or compound (like snow), and compound ideas are made up from associations between simple ones, by a process like “mental chemistry.” Similar associative links can account for our ability to generalize across stimuli: for instance, to form a general idea of a triangle from many different specific instances. Thus, Locke was an empiricist and an associationist: knowledge derives from the senses and we learn to perceive the objects in the world by association.

Locke charted the course for empiricism, but many of the details were provided by later philosophers, two of whom will be mentioned briefly here. George Berkeley (1685–1753; Fig. 4) argued that we learn to perceive the dimensions of space by associating muscular sensations with those of vision. In order to perceive distance visually, we learn the relationship between the visual stimulation and the states of the muscles controlling the eyes. The muscular and touch systems were considered to provide direct and undistorted spatial information that could be used to teach vision the dimensions of space. Berkeley (1709) refined the empiricist philosophy of Locke by arguing that appearances are all: to be is to be perceived – *esse est percipi*. That is, the matter from which materialism is constructed is itself open to question. If all we have are our perceptions, how can we prove the existence of

Perception. Fig. 4 Left: *Tabula rasa*; a portrait of Locke with a blank sheet covering his senses. Center: *Berkeley's Esse*, in which Berkeley's face exists if it can be perceived. an external world? A problem with this position is that if perceptions are transitory so is existence. Does an object cease to exist when the eyes are closed? Berkeley sought to salvage this slide into solipsism (that nothing other than one's own ideas exists) by arguing that God alone perceived an external reality. Despite this idealist stance, Berkeley made important steps toward understanding how we perceive space, and how the different spatial senses are integrated.

Thomas Reid (1710–1796; Fig. 4) reacted to Berkeley's idealism by arguing that the evidence of external reality is provided by the common activities of the senses and is supported by common sense intuition. Reid founded the Scottish common sense school of philosophy, whose ideas were to be influential in the development of psychology in America in the nineteenth century. The school was opposed to associationism, particularly when it was couched in physiological language. Reid also proposed a faculty psychology; faculties were innate properties of the mind which exerted control over habits, or behavior. His descriptive psychology could be studied by reflection on mental activity, by an analysis of the use of language, and by observations of behavior. He provided a bridge between the extreme rationalists and empiricists. His belief in the power of reason was tempered by a desire to accumulate evidence empirically. Reid is perhaps best remembered because of the clear distinction he made between sensation and perception. Thus, redness and roundness may be sensations produced by an apple, but its perception includes an appreciation of the object itself. Perceptions also involve projective aspects that are not present in sensations: the apple is perceived as being out there, but the sensations can be internal. Reid's distinction has had far-reaching consequences, and it has persisted to the present; it has pervaded our language and it even defines the categories of our enquiries.

Empiricist philosophy was initially confined to Britain, but its widest influence has probably been through its adoption beyond Britain's shores – particularly by Helmholtz in Germany and John Watson (1878–1936) in America. Boring (1942) remarked that Helmholtz carried the torch for philosophical empiricism in a hostile Kantian climate, as did his erstwhile assistant Wilhelm Wundt (1832–1920). However, their brands of empiricism were quite

different. Helmholtz developed the notion of unconscious inference to account for characteristics of color and space perception, and the concept is still active in some theories. Wundt (1874) was more ambitious and applied empiricist and associationist ideas to account for consciousness itself. His ideas were carried to America by the likes of Edward Titchener (1867–1927), whose structuralist theory was not widely followed and opposed by the theories of both Gestalt and behaviorism.

Nineteenth Century Influences

Discussions of space and time continued to be grist to the philosophers' mill throughout the nineteenth century, but they were afforded instrumental and experimental assistance that extended their scope. It can be argued that the evolution of psychology as an independent discipline was in a large part a consequence of addressing philosophical questions concerning the perception of space and time by recourse to experiment rather than exposition.

Phenomenology

Perceptual experience has always been described in words, when possible, but this has not been the only way of assessing it. Language reflects the nuances that can be applied to the richness of perception, and it has been considered by some, like Johann Goethe (1749–1832; Fig. 5), to be the most appropriate vehicle for conveying experience. Goethe (1810/1970), in line with many Romantic philosophers, rejected the experimental approach to the study of nature because it was too constrained. In its place he proposed the astute and intuitive observation of natural phenomena, setting in train the method of phenomenology. This is best seen in his 1810 book *Zur Farbenlehre*, which contrasted his observational approach to color with what he considered to be the physicalism of Newton. The purity of white light was taken to be fundamental and indivisible, rather than white being a mixture of different colored lights. Goethe chose to observe and describe instead of experiment on color vision. He distinguished between what he called physiological colors (the experience of color) and physical colors produced by optical refraction. Goethe's theory of color was never taken seriously by the scientific community, but his observations have rarely been challenged. He described many

Perception. Fig. 5 Left: *Romantic eye*; a silhouette of Goethe encompassing his observant eye. Right: *Sehen in subjektiver Hinsicht*; Purkinje's features are dimly discernible within the pattern of concentric circles, the distortions of which he described (Illustration © Nicholas Wade)

phenomena like positive and negative color afterimages, irradiation, color shadows, and color blindness, in addition to contrast effects – both in the chromatic and achromatic domains.

Phenomenology was given a more methodological twist by Jan Purkinje (1787–1869; Fig. 5), whose interests in vision were stimulated by reading Goethe's analysis of color. Purkinje was encouraged in his researches by Goethe because of his use of the phenomenological description. As a medical student Purkinje investigated subjective visual phenomena in part because he did not have access to any physiological apparatus, but also because he believed that visual illusions revealed visual truths. Most of his experimental research in both physiology and histology was conducted in Germany, but at the age of 63 he was called to the chair of physiology in Prague. He was followed in that chair by Ewald Hering (1834–1918; Fig. 6), who also embraced phenomenology.

Nativism Versus Empiricism

The contributions made by Helmholtz (Fig. 6) to visual science are legion, but his most lasting impact was his theory of perception (Cahan 1993; Helmholtz 2000). For Helmholtz, the brain only had indirect access to the external world, via the senses, and it could only process messages in the language of nerve impulses. This realization made any equation of the retinal image with

perception unnecessary, and it removed a problem that had frequently been raised earlier, and was to return later: if the image on the retina is inverted and left–right reversed, why is our perception not so? Helmholtz argued that this only created a problem if there was a picture in the retina that required further perception. If all that is available are nerve impulses then the brain can analyze them and make the appropriate inferences independently of the orientation of stimulation with respect to the retina.

Helmholtz acknowledged that little he wrote on theories of vision was novel, but he marshaled the arguments over a wider range of phenomena than others had done before. By adopting a starkly empiricist interpretation of perception, and by contrasting it so sharply with nativism, he reopened a debate that has reverberated throughout perception ever since. The debate was personified in the conflict between Helmholtz and Hering, and the main battle-grounds were color vision and stereoscopic depth perception (Turner 1994). Hering was a physiologist whose psychology was in the tradition of Goethe. He represented the phenomenological and nativist position in studying perception. Like Goethe, Hering stressed the subjective dimension of color, and he based his opponent-process theory on color appearances rather than on mixing lights of different wavelengths after the manner of Helmholtz. He also examined simultaneous and successive color

Perception. Fig. 6 *Visual opposites.* Helmholtz (*left*) and Hering (*right*) presented opposing interpretations of a range of phenomena, from color perception to binocular vision. Helmholtz also described the differences in the apparent sizes of squares comprised of vertical and horizontal lines (Illustration © Nicholas Wade)

contrast phenomena. Together, these led him to propose a theory of color vision based on three oppositional pairs: red-green, blue-yellow, and white-black. He speculated that there are three retinal pigments that are either built up or broken down by light to yield the six elements.

The psychology of the senses led Helmholtz into the metaphysical domain he had assiduously avoided in his physical and physiological endeavors. The philosophical problems remain a matter of constant revision and reanalysis, but many of the issues concerned with the senses that were debated in Helmholtz's day became the topics of experimental enquiry in the then new discipline of psychology.

Wundt and Structuralism

Psychology, as an independent discipline, is considered to have been founded in 1879, when Wundt (Fig. 7) opened his Psychological Institute at Leipzig University. Prior to this, psychology was allied principally to philosophy, although perception was often the province of sensory physiologists (Müller 2003). Wundt saw the task of his new institute as that of studying conscious experience. What distinguished his approach from the many earlier ones addressing the same issues were the methods employed. Psychology came of age when it developed its own methodology: the problems of consciousness and perception were examined in novel ways using novel instruments, and psychology

became an experimental discipline rather than just an observational one (James 1890). Perception has followed the theoretical fashions of psychology generally, ebbing and flowing as the subjective dimension waned and waxed in importance.

Wundt rejected phenomenology and introduced a technique that is now called analytic introspection – the controlled analysis of mental events. He distinguished between the mediated experience available to the physical sciences and the immediate experience investigated by psychology. His use of introspection to study the latter resulted in the proposal that sensations and feelings were the elements of consciousness. Sensations could be combined to yield perceptions, but for these to influence behavior they required attention: the voluntary control of attention to focus on aspects of perception was termed *apperception*. It was the active role played by attention that could rearrange perceptions to form a creative synthesis. Wundt was an empiricist and an associationist interested in the universal aspects of conscious experience; the application of psychology to real-world issues held little appeal for him.

Observers had to undergo extensive training before they were considered to be skilled at analytic introspection. By using this method, Wundt believed that he could determine the elements from which perceptions and thoughts were constructed and he was greatly influenced by Locke's ideas about mental chemistry. Wundt was trying to isolate the basic elements and to

Perception. Fig. 7 Left: *The Institution of Psychology*. Wundt is shown framed by the building that housed the original Institut für experimentelle Psychologie in Leipzig. Right: *Structuralist*. Titchener can be seen in circles that constitute his eponymous contrast illusion: the two central circles are the same physical size but the lower one appears larger (Illustration © Nicholas Wade)

determine the rules for their combination into more complex perceptions and thought, and this approach was later called structuralism. The basic elements were taken to be the sensory attributes (like quality and extension), and these could be combined to make the molecules of perception; the combination was achieved by a process of association. Perception represented a synthesis or building up of the sensory attributes via learning by association, whereas the method analyzed or broke down complex perceptions into their component sensory attributes.

Wundt attracted many graduate students from the USA, where psychology was forging a strong foothold. One of his students, Titchener (Fig. 7), was from Britain but carried Wundt's method and theory to America. Titchener employed introspection to uncover the structures of human consciousness, thereby giving structuralism its name. The elements of consciousness were said to be sensations, images, and affections. These elements could be isolated by a method of introspection that excluded the use of object names, because describing the meaning of objects introduced "stimulus error." Most of his experimental work was directed at the analysis of sensations, which had the attributes of

quality, duration, intensity, extensity, and clearness. Ideas and emotions derived from associations of images and affections, respectively.

Twentieth Century Developments

The advances in the experimental psychology of perception throughout the nineteenth century were driven by the invention of novel instruments that could be used within the laboratory. That is, the study of perception moved from the natural environment into the laboratory where the well-tried methods of physics could be applied to the examination of perception. However, toward the end of the twentieth century, the armory of instruments was replaced by a single device—the computer. The implications of this technological revolution were enormous but they did not play a part in the theories that were formulated in response to the impact of Wundt at the beginning of the century.

Gestalt Psychology

By the early twentieth century, there was widespread disaffection with Wundt's method and its attendant theory, and alternatives were sought. Two major reactions that appeared in the second decade were Gestalt

psychology and Behaviorism. Gestalt is a German word that can be translated approximately as configuration, but the German term is retained because of the difficulty of capturing its nuances with a single English word. Gestalt psychology had its origins in perception but its ambit extended throughout the whole of psychology (Ash 1995). Its precursors were to be found in Kant's innate categories of space and time, and in Goethe's phenomenology. The Gestaltists main opposition to Wundt's structuralism was theoretical – they did not accept that unitary perceptions could be analyzed into smaller parts. Indeed, the cliché associated with Gestalt psychology is that “the whole is different from the sum of its parts” – thus, the perception of a square is different from the separate effects of its four constituent sides.

Max Wertheimer (1880–1943; Fig. 8) redefined psychology as the study of configurations or *Gestalten*. He conducted a series of experiments on apparent movement – motion seen between two stationary and separated stimuli when presented in rapid succession. The inability to distinguish between real and apparent motion was taken as damning any approach that explained perception in terms of its successive sensations. Not only was it said that the whole is different from the sum of its parts, but the perception of the whole is prior to that of its parts. Publication of Wertheimer's thesis on the phi phenomenon, in 1912, is taken as the origin of Gestalt psychology; it was principally concerned with perception, and a range of robust phenomena was devised to support its holistic

nature. Much of its attraction lay in the power of the perceptual demonstrations.

Kurt Koffka (1886–1941; Fig. 8) was the second member of the Gestalt triumvirate. He used Gestalt concepts in studies of development and thinking, and he made American psychologists aware of the new movement in his writings and lectures on Gestalt psychology in the USA. Koffka did pose the fundamental question of “Why do things look as they do?” He also emphasized that visual perception is three-dimensional and that our perception is in terms of the object properties (the distal stimulus) rather than those at the receptor surface (the proximal stimulus). The third member, Wolfgang Köhler (1887–1967; Fig. 8), introduced the concept of field forces operating in both perception and in its underlying neurophysiology: brain processes were considered to be isomorphic (having the same form) with the percept, so that principles of brain function could be inferred from perceptual phenomena (Köhler 1930). He developed a speculative neurophysiology based mainly on the principles of perceptual grouping and on his experiments with figural aftereffects. His speculations probably did more to hasten the demise of Gestalt theory than any other factor: neurophysiologists failed to find any evidence for such fields of electrical activity in the brain, and so tended to dismiss Gestalt theory in general rather than Köhler's unsuccessful attempt at neuroreductionism in particular.

The Gestalt psychologists formulated some descriptive rules for perceptual organization and produced

Perception. Fig. 8 *Good figures*. The portraits of Wertheimer (left), Koffka (center), and Köhler (right) are all composed of small circles. It is from combinations of filled and unfilled circles that Wertheimer demonstrated his principles of perceptual organization in 1923 (Illustration © Nicholas Wade)

a wide range of demonstrations that could be used to support them. The principles were described by Wertheimer in two papers published in 1923; they appeared in the journal *Psychologische Forschung* (later renamed *Psychological Research*) which the Gestalt psychologists founded to propagate their theory.

Cognitive Approaches

In the second quarter of the twentieth century, most research in perception was conducted by Gestalt psychologists, initially in Germany and later in America, where it challenged the prevailing climate of behaviorism. At the same time, an alternative approach was being developed in relative isolation in Britain, and it has had a profound effect on the shape of modern perceptual research. Frederic Bartlett (1886–1969; Fig. 9) examined perception in realistic and dynamic situations and he represents a continuation of the British empiricist tradition with his analysis of perception as a skilled activity (Bartlett 1932). He rejected the application of stimulus–response interpretations of complex tasks (like playing cricket or tennis) because the actions were highly organized and initiated in advance of any contact with the ball. Indeed, the actions were made with respect to the position the ball would be predicted to occupy at some short time in the future. Complex activities of this type indicated

that behavioral sequences had to be programmed in advance and coordinated with predictions based on perception. This led Bartlett to a cognitive theory of perception, one in which the division between perception and thought was difficult to draw. Like Helmholtz, Bartlett considered that perception was like problem solving, incorporating processes of inference but also of prediction. Bartlett rejected associationist models of perception and memory and his cognitive theory provided a middle road between those of the molecular behaviorists and molar Gestaltists. He can be seen as ushering in the cognitive revolution that was eventually to replace behaviorism, although his work was neglected in America until the 1950s (Gardner 1987). In order to make predictions that involve action we need to have some mental representation of the environment in which the action will take place. This concept of forming a mental model of the world in which we behave was proposed by Kenneth Craik (1914–1945; Fig. 9), and it is one of the ideas that has proved important in the development of both cognitive and computational theories of vision. The machine metaphor has proved to be particularly attractive to experimental psychologists. Craik (1943) was only able to enlist relatively simple machines, but his insight lies at the heart of the cognitive revolution that was to sweep through psychology. His concern with prediction rather than reaction (shared with Bartlett) reflected

mass results of past changes of position and posture are actively doing something all the time; are, so to speak, carried along with us, complete, though developing from moment to moment. Yet it is certainly very difficult to think of any 'better' single descriptive word to cover the facts involved. It would probably be best to speak of 'active, developing schemes' but the word 'schemes', too, being now very widely and variously employed, has its own difficulties; and it, like 'scheme', suggests a greater articulation of detail than is normally found. I think probably the term 'organized setting' approximates most closely and clearly to the notion required. I shall, however, continue to use the term 'schemes' when it seems best to do so, but I will attempt to define its application more narrowly. 'Scheme' refers to an active organisation of past reactions, or of past experiences, which must always be supposed to be operating in any well-adjusted organic response. That is, whenever there is any order or regularity of behaviour, a particular response is possible only because it is related to other similar responses which have been serially organised, yet which operate, not simply as individual members coming one after another, but as a unitary mass. Determination by scheme is the most fundamental of all the ways in which we can be influenced by reactions and experiences which occurred some time in the past. All incoming impulses of a certain kind, or mode, go together to build up an active, organised setting; visual, auditory, various types of cutaneous impulses and the like, at a relatively low level; all the experiences concerned by a common interest; in sport, in literature, history, art, religion, philosophy and so on, on a higher level. There is not the slightest reason, however, to suppose that each set of incoming impulses, each new group of experiences persists as an isolated member of some passive patchwork. They have to be regarded as constituents

of the organized mass; one of the characteristics of memory and perception is the recognition of identity or of similarity. To designate a thing is hardly to state so in internally or objectively as the 'same thing' to which we attend on a perceptual occasion. In the above sense mechanical devices can show some degree of recognitional ability. A photocell can respond in the same way to spots having the same colour, a penny-in-the-slot machine to similar coins, and so forth. Men and animals are capable of much, but of much more. The progressive stages of recognitional ability may be classified as: (1) Those in which all the conditions of stimulation are identical, within the limits of discrimination sensibility; (2) Those in which there are differences in the perceptual dimension, some in which these may be 'corrected' by other sensory data so as to lead to the production of an identical pattern of central stimulation; (3) Those in which such correction is inadequate, so that there are points of difference between stimulation on two occasions, each point of difference being perceptible by the organism, yet the things being used as the same in certain important aspects; and (4) Those in which the differences extend to all dimensions of quality and physical constraints, to such an extent that the two objects is confined to some abstract characteristic such as triangularity, number, and other aspects of temporal relations or vague qualities such as intellectual difficulty.

PERCEPTION AND COMMUNICATION
Monitoring of several channels with response to one at a time.—The situation which we will now consider is much closer to real life than those which I have gone before. In the present case the listener hears speech from a number of different sources, but ignores any messages which are not for him. He is therefore carrying out a combination of the two simpler tasks; he may listen to two call-signs simultaneously, but then call to ignore one message and deal only with the other. As before, he is interested largely in central processes which may apply to psychology in general rather than to hearing alone. It is more difficult to be sure of the relative roles of sensory and central processes in this case than it was in the simpler ones, but some such distinction can be made by considering the types of noise and the effect of intensity. The results are comparatively few from this type of stimulation on the effect of varying the amount of information presented to the subject. Many data are to be found, however, on the familiar question of the physical methods used to present the messages; and in addition there are results on the effectiveness of certain types of message in learning responses. The spatial arrangement of the sound sources is again important. It will be remembered that spatial separation is highly beneficial only if one message is to be answered, but not when both are to receive a response. In the monitoring situation, which combines both the other tasks, separation is on the whole desirable but not altogether so. Webster and Thompson found that six channels were handled better when fed through six loudspeakers rather than through a single one, and that the provision of 'pull-down' facilities was helpful. Sperry, Curtis and Webster found that three loudspeakers were better than one.

Perception. Fig. 9 Left: Schema; Bartlett emphasized the constructive aspects of memory and perception as well as introducing the concept of “schemas” into psychology. Center: Recognition of identity; Craik was one of Bartlett’s students who developed the machine metaphor in analyzing pattern recognition. Right: Channel capacity shows Broadbent who analyzed dichotic listening and linked perception more closely with communication (Illustration © Nicholas Wade)

his dissatisfaction with behaviorism. Perception is considered to be a process in which information regarding aspects of the world is analyzed and utilized to plan behavior. This information-processing approach has become widely accepted as perception can then be considered as a sequence of representations that are initially crude and become increasingly appropriate to the three-dimensional environment.

Information in visual patterns could be quantified, and it resided at the boundaries between areas (contours) and where the contours changed direction abruptly (corners). However, it was the qualitative concept of information processing rather than quantitative information measures that was to have lasting appeal. The perceiver was conceived of as a limited-capacity information processor, and the information could be filtered, filed, or reformulated on the basis of stored events. Donald Broadbent (1926–1993; Fig. 9), a student of Bartlett, presented a model that formalized and represented pictorially the putative processing stages in perception, memory, and learning, and it was addressed to the realistic activity of communication (Broadbent 1958). Thus, Broadbent combined Bartlett's approach of examining skilled tasks with Craik's modeling metaphor.

When Bartlett and Craik proposed their theories of perception relatively little was known about the brain mechanisms that mediate perception. This is one of the reasons why the Gestalt psychologists were able to propose their speculative neurophysiology of vision. Craik, as well as Alan Turing (1912–1954), anticipated that the computer would be a powerful tool to simulate theories of perception, as well as providing a metaphor for the processes of perception and cognition themselves. Since the late 1960s, the study of visual perception had been profoundly influenced by computers. As well as allowing scientists to collect or to analyze data more quickly, the digital computer provided a tool for the laboratory scientist to develop new ways of testing the visual system with novel kinds of visual displays.

A similar cognitive revolution took place in America, but a little later. The approach to perception adopted by Bartlett was applied to human operators of complex systems. The experimental research on perception in the 1940s harmonized with developments in cybernetics. Information theory was developed in the context of telecommunications, and the mathematical

measurement of information was formalized in the late 1940s; its powerful impact on perception was felt in the 1950s. George Miller (b. 1920; Fig. 10) linked the concept of limited information capacity to absolute perceptual judgments (Miller et al. 1960). He also allied the processes of perception more closely to those of language, and this was amplified by Noam Chomsky (b. 1928; Fig. 10), a linguist who has introduced a wide range of novel terms into the analysis of language. In Chomsky's transformational grammar, one of the principal distinctions is between the surface and deep structures of a sentence: the surface structure corresponds to the sequence of words as written or spoken, whereas the deep structure refers to their underlying meaning.

During the 1970s, David Marr (1945–1980; Fig. 10) set out to develop a complete framework for vision, spanning the very lowest level processes within the retina up to the process of visual object recognition (Marr 1982). The key feature of Marr's theory was that vision can be understood at different levels. The first "computational" level is a theory of the task that the visual system is to solve, and an understanding of the constraints that can enable solution of that task. The second level, of "representation and algorithm," is a means of achieving the task, and the final "hardware implementation" level describes how the brain, or a computer, actually implements these algorithms in neural tissue or silicon.

In addition to presenting a unified approach to different topics within vision, Marr and his colleagues also presented a theory of the different stages of representation involved in the interpretation of a retinal image. In so doing, Marr distinguished a stage which made explicit the three-dimensional layout of the world with respect to the viewer (the 2½ D sketch), potentially useful for action in the world from the more abstract 3D models which allowed object recognition.

Indirect and Direct Perception

All theories of perception considered so far are what can be called indirect; some mediation between the pattern of stimulation, its effects on the visual system and perceptual experience was implicit – some mode of representation. The term often applied to this was that perception went beyond the information given. This is at the heart of empiricist approaches to perception and is in the organizational principles of Gestalt

psychology. An alternative approach was advocated by James Gibson (1904–1979; Fig. 11). He sought to stem the cognitive current and developed a novel theory. Rather than considering the senses as independent of one another he integrated them into perceptual systems

in which time was an essential component. That is, the distinction between sensation and perception was abandoned, and perceptual systems afforded useful information for interaction with the external world. Moreover, there was considered to be a perfect

Perception. Fig. 10 The languages of perception. *Left: The magical number seven, plus or minus two*; Miller is defined by his magical number and surrounded by its neighbors. *Center: Deep structure*; Chomsky is enclosed within terms he coined; the surface structure of the list is not punctuated, but the terms can be suitably segmented with respect to its deep structure: although the individual words are not alphabetically arranged, the novel terms are. *Right: 2½ D sketch*; Marr is outlined as differences of Gaussians and encapsulated within tokens of a cube (Illustration © Nicholas Wade)

Perception. Fig. 11 *Left: Texture gradients* shows the facial features of Gibson within a texture gradient of dots; superimposed on both patterns is a further, ecologically sound, texture gradient – the planks of a pier receding into waters near those lapping Cornell University, where he worked for over 30 years. *Center: Hidden units*; Hebb’s face can be seen in the middle (hidden) layer of a three-level network: each cell in the middle layer is connected to every other one in the levels above and below it. *Right: Schematic face*; Brunswik conducted studies on the perception of schematic faces and is portrayed with a one that reflects his own soft, sad, and intellectual features (Illustration © Nicholas Wade)

correlation between the pattern of stimulation and its perception; no stages of representation were involved in perception. Gibson (1966) retained separate perceptual systems which he called orienting, auditory, haptic-somatic, tasting and smelling, and visual. Gibson's ideas established a new field of "ecological" optics which has been tilled by many in recent years.

Gibson called for neither physiological nor computational support for his theory, but one of his contemporaries, Donald Hebb (1904–1985; Fig. 11), was integrating both of these. Hebb (1949), in his speculative synthesis of perception and learning, wove patterns with networks of neurons connecting perception to its underlying physiology. He proposed that perceptual learning takes place when assemblies of cells fire together; their reverberating activity resulted in synaptic changes which further increased the probability of the nerves firing together. The functions of cell-assemblies and phase sequences were based on his neurophysiological postulate: "When an axon of cell A is near enough to excite cell B and repeatedly or persistently takes part in firing it, some growth process or metabolic change takes place in one or both cells such that A's efficiency, as one of the cells firing B, is increased." Hebb later applied the concepts to account for a wide range of phenomena, from stabilized retinal images to sensory deprivation.

Another indirect theory was proposed by Egon Brunswik (1903–1955; Fig. 11) who introduced probabilistic functionalism into psychology. His was a functionalist theory because it emphasized the adaptive nature of behavior with respect to objects in the environment; it was probabilistic because behavior in an unpredictable environment must be based on the statistical regularities that occur within it (Brunswik 1934). He was influenced by the Vienna circle of logical positivist philosophers and believed that the probabilistic methods applied to the physical sciences were appropriate to psychology, too. He applied probabilistic functionalism principally in the area of perception. He was concerned with how we derive veridical information about objects; how the distal stimulus is perceived as constant despite wide variations in the proximal stimulus. Accordingly, he examined perceptual constancy and devised a formula for assessing it, now known as the Brunswik ratio. Veridical perception was based on the use of a family of cues that differ in

their ecological validity – the correlation between proximal cues and distal stimulus. By experience, greater statistical weight was placed on the cues with high ecological validity.

The Physiological Dimension

Most historical investigations of eyes have been addressed to the image-forming variety of vertebrates. This was so despite the knowledge of many other evolutionary adaptations for transducing light energy. Until the neuron doctrine was firmly established in the 1890s, examination of invertebrate eyes was not considered to offer insights into vertebrate visual processing. The situation was transformed with Haldan Keffer Hartline (1903–1983; Fig. 12) with his studies of responses to light in the horseshoe crab, *Limulus polyphemus*. His pioneering neurophysiological experiments, together with allied investigations of vertebrate visual responses, resulted in the emergence of a new conception of retinal processing: lateral and recurrent interactions, occurring in a complex network of neuronal circuits, were considered fundamental mechanisms for visual information processing.

In the last decades, there have been major strides in furthering our understanding of neural processes in the visual system. These discoveries have been taken to support the view that vision involves a sequence of stages in which different aspects of the stimulus, like color, contour, or motion, are extracted. Research on patterned stimulation at the receptor level had proceeded throughout the first half of the century, but its pace quickened thereafter. The glimmerings of pattern processing beyond the receptors emerged in the 1950s, and were amplified in the 1960s. When recordings of nerve impulses could be made from individual cells in the visual pathway, their adequate stimuli could be determined. It came as something of a surprise that retinal ganglion cells of frog responded to quite complex features of stimulation (like moving dark regions of a specific visual angle, resembling a bug), and stimulus properties that excited or inhibited neurons were generally called "trigger features." Retinal ganglion cells of cat, on the other hand, were excited by rather simpler stimulus arrangements. It was found that they were concentrically and antagonistically organized; if the center was excited by light, the surround was inhibited, and vice versa. Such an arrangement served the

Perception. Fig. 12 *Left: Hartline's Limulus* presents a portrait of Hartline within the carapace of the crab that he claimed for neuroscience and surrounded by the facets of a compound eye. *Right: Feature detectives* shows Hubel and Wiesel enclosed within the pattern of ocular dominance columns that they disclosed in monkey cortex using autoradiography. Hartline was awarded the Nobel Prize in Physiology or Medicine in 1967 and Hubel and Wiesel were accorded the same honor in 1981 (Illustration © Nicholas Wade)

detection of differences in luminance well, but steady states would have little effect, since excitation nullified inhibition. This pattern of neural activity was retained in the lateral geniculate body, but it underwent a radical change at the level of the visual cortex. From the 1960s, David Hunter Hubel (b. 1926) and Torsten Nils Wiesel (b. 1924), who are both shown in Fig. 12, found that single cells in primary visual cortex (V1), first of cat then of monkey, responded to specifically oriented edges; they had different receptive field properties which were called simple, complex, and hypercomplex.

Physiologists refined the stimulus characteristics of trigger features while psychologists sought their phenomenal counterparts. Almost any experiment involving contours paid lip service to Hubel and Wiesel, despite the tenuousness of the links between particular phenomena and their underlying physiology. At least an appeal to trigger features was considered preferable to reliance on the speculative neurophysiology advanced by Gestalt psychologists. The concept of channels or spatial filters emerged during the 1960s, and it was applied with particular rigor by Fergus Campbell (1924–1993) and his colleagues to the detection of and adaptation to sine-wave gratings. The attraction of gratings was that they provided at one and the same time a definition of the stimulus and theory of the response to it.

The 1960s saw the beginnings of a split between a “cognitive” approach, where the goal of vision could

be seen as an abstract categorization of the objects of vision, and an “action” approach, where vision was part of an integrated system allowing manipulation of and navigation through the world. This distinction has matured in contemporary approaches to vision, both through the influence of Marr, and through further developments in neuroscience and neuropsychology.

Future Directions

Perceptual theory in the twenty-first century is developing along many lines. Perhaps the two most prominent are the trends toward mathematics and mental modelling. The first is expressed in several strands. On the one hand, emphasis on inferential processes in perception, exemplified by Brunswik's probabilistic functionalism, finds more concrete expression in Bayesian approaches to perception. On the other, neo-Gibsonians apply increasingly sophisticated analyses of stimuli that change over time (events), particularly in naturalistic settings. Mental modelling is reflected in the imaging and computational strands. Advances in brain imaging, and the computer software associated with it, have resulted in proposals for localizing perceptual functions at more specific brain sites. Computational models of both pattern recognition and robotic control inform perceptual theory as well as being driven by it. Perception, particularly visual perception, will increasingly be integrated with motor activity and this will be reflected in both theory and experiment.

Pestalozzi, J. H.

ANGELA H. PFAFFENBERGER
Innerhealth, Salem, OR, USA

Johann Heinrich Pestalozzi (January 12, 1746–February 17, 1827) was born on January 12, 1746, in Zurich, the German-speaking part of Switzerland. He made contributions as a social critic, political reformer, and teacher and is widely regarded as a forerunner of humanistic education.

Biography

Pestalozzi was born as one of four children of a physician, who died early, and subsequently Pestalozzi was raised by his mother. Pestalozzi aspired to study protestant theology and step into his paternal grandfather's footsteps to become a pastor. In his late adolescence, Pestalozzi connected with his ability to write, and at age 19 he published for the first time and remained a productive writer for more than 60 years (Pestalozzi, 1804/1912; Pestalozzi, 1951). During his educational years he was strongly influenced by the Romanticist philosopher Jean-Jacques Rousseau and decided to reorient his career toward the study of law and politics. Rousseau's romantic idealizations of the rural life inspired Pestalozzi, and a few years after entering the path of an administrative professional, he left his position. In 1769, aged 23, he acquired *Neuhof*, a farm house and some land and tried his hand at agricultural pursuits, which failed due to his lack of training and experience in that area. He married his wife, Anna, the same year and their only child, a son, was born shortly thereafter. Pestalozzi attempted to start a school for neglected and impoverished children at Neuhof; however, the funds that his friends initially provided dried up, and he had to close the orphanage (Hunziker 1887). Pestalozzi was living with his family in poverty when he started to write his first principal volume *Leonard and Gertrude* (Pestalozzi 1781/1896),

which was published on 1781 and was well received, especially in Germany. Through the ensuing 40 years, Pestalozzi became a famous advocate for emancipatory education throughout Europe. He devoted himself to practicing in various educational settings in Switzerland and integrating his practical experience with a maturing theory of education. Pestalozzi published his most important book *How Gertrude Teaches Her Children* (Pestalozzi 1801/1898) in 1801 before retiring to Neuhof in 1825, where he died 2 years later remaining active until his 80s.

Pestalozzi's Theory of Development and Education

Pestalozzi's most important contribution is that he not only embraced the ideas of Romanticism and applied them to education, but he also was consistently striving toward practical applications. His methods evolved out of the ongoing interaction between real-life education and humanistic ideals.

Pestalozzi's personal experience of poverty following his father's death shaped his concerns with providing for the needy and offering them respect and education as a tool to provide for themselves (Silber 1960). He was a dedicated humanist, and many of the ideas Pestalozzi presented seem self-evident today; however, they were revolutionary in his days, such as offering schooling free of charge to all children. Pestalozzi also emphasized love and respect for children, and in opposition to his contemporaries, he opposed severe and corporal forms of punishment.

The so-called Pestalozzi method stressed the need to educate the whole person, including emotional, moral, social, and intellectual aspects. The method encourages direct exploration and observation. Children need to learn through their activity, and it was seen as counterproductive to present them with theories and books early, and offer ready-made answers that stifled their natural curiosity. Pestalozzi's approach to education placed emphasis on individual differences, and that children need to find out what is right for themselves. Love and emotional support are the means of helping them actualize their innate potentials. Education is the unfolding of the natural powers and faculties latent in every human being.

Pestalozzi saw the education of the child as the means to achieve social change. The goal was to attain

the ideals of the enlightenment and establish a morally superior society, where poverty can be eradicated because the citizens acquire wage earning skills and moral aspiration early in life. In Pestalozzi's utopist vision, the family, the school, the community, and the state are nestled, concentric circles that mutually support each other and provide the social and emotional supports that human beings need to thrive and make meaningful contributions through their work.

Pestalozzi's ideas influenced the educational system in Prussia, and later translations of his works lead to the adoption of his methods in some Canadian and American schools.

Phenomenological Psychology in The Netherlands

HENDERIKUS J. STAM¹, RENÉ VAN HEZEWIJK²

¹University of Calgary, Calgary, AB, Canada

²Open University of the Netherlands, The Netherlands

Phenomenological philosophy, as formulated by the German philosopher Edmund Husserl, was immediately relevant to psychology because Edmund Husserl

made a point of distinguishing phenomenological philosophy from a phenomenological psychology. Husserl, the most important founding figure of modern phenomenology, in turn distinguished phenomenological psychology from experimental or scientific psychology. Hence, the interrelationship between phenomenology and psychology was on the table from the very beginning of phenomenological philosophy's emergence in German universities. Scholars in the Netherlands were among the most receptive in exploring the possibility of a phenomenological psychology as an adjunct or addition or even replacement for experimental psychology. The Dutch role in the history of phenomenological psychology was unique and relevant to the spread of phenomenological psychology to the United States.

Phenomenology or phenomenological philosophy in Husserl's (1900–01) sense of the *Logical Investigations* was a thesis about the nature of consciousness that eventually was meant to be a grounding for all of philosophy. In that work, Husserl called phenomenology a “descriptive psychology” of consciousness. This was an attempt to create a distinction between the foundations of logic and the foundations of knowing in thought. This could not be a psychological foundation but had to be a foundation independent of any psychological considerations. This would develop by the time of Husserl's 1913 book *Ideas* into a “pure phenomenology” or a “transcendental phenomenology” which suspends all transcendental claims (Spiegelberg 1965). In addition to this pure phenomenology there was also a phenomenological psychology. This continual clarification of the relationship between psychology as conceived by the new scientific psychology of the early twentieth century and a phenomenological psychology would continue to occupy Husserl until the very end of his life. In his last work, *The Crisis of European Sciences and Transcendental Phenomenology*, published in 1936 Husserl once again differentiates the two kinds of psychology (Husserl 1954 (1970)). Transcendental philosophy differentiates itself from psychology because the latter is merely the realm of the human ego, of mundane knowledge, whereas the former is the location for investigating the intentional structure of meaning. Hence, phenomenology is the foundation of psychology and goes beyond it to locate the human ego in the transcendental realm.

Although Husserl discussed the shortcomings of psychology, he left open the possibility of a phenomenological psychology without ever specifying how it actually might be constituted in practice. After World War II a number of scholars, almost all of whom were located in the Netherlands, began to articulate a movement that would form a new phenomenological psychology based on Husserl's phenomenological philosophy. This movement took place in the 1950s and preceded the later interest in a phenomenological psychology in English speaking parts of the world, which did not reach fruition until the 1960s and 1970s. This latter movement, however, was much more diverse, concerned itself with “experience” broadly speaking and was less concerned with a phenomenological psychology, properly speaking, and hence will not concern us here.

The Institutional Context

The unique appearance of a phenomenological psychology in mid-twentieth century Europe has been well documented (see van Hezewijk and Stam 2008). From the perspective of the creation and consolidation of academic disciplines, it marks a period of transition in the development of modern psychology, characterized by shifting intellectual boundaries as well as national and international competition following the upheavals of World War II. Given the vacuum created by the radical shift in German universities, first beginning in 1933 and then with the end of the war and the partition of Germany, psychology was a rather ambiguous enterprise in European nations. Unlike the Anglo and North American context, where psychology not only continued without interruption but had, at least by its own account, contributed to the conduct and outcome of the war, European psychologists were fewer and less well established. This was as true in the Netherlands as it was elsewhere. The gradual training of Dutch psychologists in American universities and their incorporation of the standard literatures would, by the 1960s, lead to the beginning of an integration of Dutch psychology with an internationally oriented, American dominated version of experimental psychology. Prior to this time, however, there was a brief period wherein various versions of psychology competed openly, including a phenomenological psychology that was inspired by French and German phenomenological and existential philosophies.

The so-called school of phenomenology in the Netherlands included such prominent figures as the physiologist and psychologist Frederik Buytendijk, pedagogue Martinus Langeveld, psychologist David Van Lennep, jurist Willem Pompe, criminologist G.Th. (Gerard) Kempe, psychiatrists H.C. Rümke and J.H. Van den Berg, and the sociologist J.P. Kruijt. Along with Johannes Linschoten and Benjamin Kouwer (representing the younger generation of psychologists) these scholars set out to do psychology in a deliberately different fashion from the natural scientific or, what they called, the positivist standpoint. They loosely defined themselves in relation to the traditions of philosophical phenomenology in Germany such as those of Edmund Husserl (the famous “founder” of phenomenology as a philosophical approach), Karl Jaspers (the phenomenologically oriented psychiatrist), Max Scheler (the Catholic philosopher who emphasized personalism in phenomenology), and the existentialists in France such as Jean Paul Sartre, Gabriel Marcel, and Simone de Beauvoir.

Frederik Buytendijk

The Dutch tradition of phenomenological psychology originated largely with the work of Frederik Buytendijk (1950, 1953, 1967). Although phenomenologically inspired work could be found in psychiatry, criminology, pedagogy, and philosophy, psychology’s importance in the creation and propagation of phenomenological research took on international importance because of Buytendijk’s status and influence. This was due in large measure to his prewar activities in biology, medicine, and philosophical anthropology. Indeed, Buytendijk had no formal training in psychology at all, which was in some ways an advantage for creating the conditions for a phenomenological psychology. The fact that he outlived his most famous pupil, Johannes Linschoten, further added to his dominance over one stream of Dutch psychology after World War II.

Frederik Buytendijk was born in 1887 as the only child to a professional officer who taught in the Royal Military Academy in Breda. In 1904 he began his studies at the University of Amsterdam, in 1909 he wrote his exam for medical doctor, and then began 4 years of research in physiology. He traveled throughout Europe to visit the foremost laboratories of the day including those of Sherrington in Liverpool, Langley and Hill in Cambridge, Engelmann in Berlin, and Dohrn in

Naples. In 1913 he was named an assistant in the psychiatric-neurological clinic of the Free University in Amsterdam and here Buytendijk also received training in clinical neurology and psychiatry. In 1914 he was given the position of lecturer in General Biology at the Free University at the age of 28. In 1917 he became head of the new physiological laboratory at the Free University, and in 1919 he received the chair in General Physiology at that same university. He published widely on basic physiological processes but from 1918 to 1920 became interested in animal psychology. In 1918 he wrote a thesis on “*experiments on habit formation in animals*” and took an interest in learning, instinct, perception, and attention in animals. He wrote two books on animals, one entitled simply *The Psychology of Animals* and the other *The Wisdom of Ants* that were widely read but also criticized by his scientific colleagues for their obvious theological overtones. In 1925 Buytendijk was appointed in Groningen to the chair of General Physiology. His inaugural lecture marked the beginning of a new interest in philosophical questions in biology and psychology. His general interest in questions of a philosophy of living things led him to animal psychology and away from basic physiology. By the end of the 1930s he had ceased doing experimental work of any sort and was writing widely on animal topics. Four different books on animals and animal psychology appeared during the 1930s, but while he was writing these books he was busy laying the foundations of an entirely different career. He maintained an extensive correspondence with, among others, the philosophers Max Scheler and Helmuth Plessner, biologists such as Johann von Uexkull, and physicians such as Ludwig Binswanger (1941). His contact with a number of key catholic thinkers such as Jacques Maritain, Gabriel Marcel, and Romano Guardini led to his conversion to Catholicism in 1937, an event that was widely reported in the Netherlands and abroad.

During the war he was a strident anti-Nazi and had published articles prior to the war already in newspapers criticizing Nazi anthropology. From July to the end of October in 1942 he was held hostage by the German occupation troops in a special hostage camp whose purpose was to prevent acts of sabotage. It was here that he wrote one of his better-known works, *On Pain*. In 1943 he was once again sought by the Germans

to be held hostage. This time, however, he went into hiding in Utrecht until the end of the war. In his very first lecture after the war, which he gave upon returning to Groningen, he began with a critique of the racial theories of the Nazis and plea for the importance of values in education.

Martinus Langeveld, who was phenomenologically oriented and had been appointed as chair of pedagogy in Utrecht ensured that Buytendijk was appointed to the chair of psychology in 1946. Its previous occupant, Frans Roels, had been removed from the chair for his collaboration with the Germans. Buytendijk's appointment was a surprise given that Buytendijk had no formal training in psychology and was self-taught in matters psychological. Furthermore, he added to this – a year later – an extraordinary chair in psychology at the University of Nijmegen, a part-time position. In Utrecht he set up a laboratory, but this was mainly a device for student instruction. His most well-known student, Johannes Linschoten, would make good use of the lab. Buytendijk himself, however, did not do any research there. The 1950s were marked by a number of varied books and publications, including a book on “woman,” which appears as a response to Simone de Beauvoir's *Le Deuxieme Sexe* that was published in 1949. Working through an existential-phenomenological position he ultimately assigns to women the role of care and men the position of labor. It would be widely critiqued by women scholars in the 1960s but would be reprinted at least 18 times and would be translated into six languages. In addition to his academic publications, Buytendijk managed to stay in touch with a broader public by writing for newspapers, magazines, and other specialty publications.

In 1957, at age 70, Buytendijk retired from Utrecht University and in 1961 from Nijmegen University. However, he maintained an office in his former psychology lab, much to the chagrin of Linschoten, by continuing to teach a course on the foundations of physiology for psychology students, allowing him to come to the lab regularly after Linschoten had already taken over the chair in psychology. After Linschoten's early death at the age of 38, Buytendijk temporarily resumed his work as the chair of psychology, finally retiring for good in 1966. He died in 1974 at the age of 87.

Buytendijk's early exposure to the work of, and his relationship with, the philosophers Max Scheler and

Helmuth Plessner would prove to be important as was his eventual relationship with Merleau-Ponty. Scheler was a German Jew who had converted to Catholicism but would eventually break with the Catholic Church before his death in 1928. He studied with Wilhelm Dilthey, among others, and was deeply influenced by Husserl. After the First World War until his death he was professor of ethics and metaphysics in Cologne. Scheler routinely invited Buytendijk to Cologne between 1920 and 1923 and Buytendijk in turn invited Scheler to the Netherlands for lectures. It was through Scheler that Buytendijk was first introduced to phenomenology as well as various aspects of Catholicism, and Scheler's vision of phenomenology was uniquely influential for Buytendijk. Scheler distanced himself from Husserl's transcendental phenomenology, as would Buytendijk. Instead phenomenology is more of an orientation, a way to view the world, and it is applicable to many disciplines. Phenomenology for Scheler is a practice and a “holding in consciousness” that can approach a pure phenomenology only by describing being as something separate from the factual-empirical givenness of experience.

Helmuth Plessner (1892–1985) was also crucial for Buytendijk's development. Plessner was a privatdocent in Cologne and from 1926 to 1933 he was an “extraordinary professor.” He fled to Groningen in 1933 where Buytendijk gave him a position as his assistant and eventually Plessner was given first a teaching position and eventually a chair in philosophy in 1946. In 1951 he returned to Germany to take a position at Göttingen. Buytendijk coauthored a paper with Plessner in 1935 that consisted of a critical study of Pavlov's work. Plessner's influence on Buytendijk was especially obvious in the latter's work on animal psychology. At the same time the importance of the body, an emphasis that Buytendijk would see confirmed and developed in the writings of Merleau-Ponty, was already clearly developed by Plessner.

Most important, however, for Buytendijk's development as a psychologist and philosophical anthropologist is the work of Maurice Merleau-Ponty (Kwant 1963). Like Scheler and Plessner, Buytendijk had a personal relationship as well as a limited correspondence with the younger scholar, but it was a much more one-sided relationship. The existential-phenomenological vocabulary that Buytendijk would

employ after World War II would come almost entirely from Merleau-Ponty. The subjective body wherein the body is both subject and the subject a body is derived from Merleau-Ponty. Suffice it to say, Merleau-Ponty's emphasis on the body as subject, as being in the world, as a pre-reflexive existence, all find their way into the phenomenology of Buytendijk and, more important, become a feature of the phenomenological psychology that is taught in Utrecht after 1946. This is not to say that Buytendijk becomes a mere adherent to a phenomenology of Merleau-Ponty but rather that the particular expression of phenomenological psychology finds its vocabulary and fundamental orientation in the writings of Merleau-Ponty.

Buytendijk's specific contribution to phenomenology consists in, among other things, a tiered expression of these questions of the body and meaning. He argues that beings have a nature that is available to the specific sciences and is objectively knowable. In addition, beings also have a body that makes an appearance that is expressive and meaningful, not just objective. Finally beings have an existence, which includes for human beings a pre-reflexive as well as conscious existence that is the foundation of our action.

Buytendijk became well known for his notion of the "encounter." Although present in the work of Sartre, Buytendijk explained its origins as essentially arising from the writings of Merleau-Ponty and Gabriel Marcel. Buytendijk argues that there are two forms of encounter, one through which we can understand the way a person can interact with others and with the things or artifacts of this world. This provides us with psychological insight but is to be distinguished from the way in which the encounter also gives us insight into the ontology of being. Every encounter provides us with some exposure to the nature of another's being, their *Dasein*. Hence the psychological and ontological are not separate but tied together; psychological knowledge is possible only on the basis of being.

Johannes Linschoten

Johannes Linschoten (1925–1964) was Buytendijk's most important student and the person appointed to his chair at the University of Utrecht when Buytendijk retired in 1957. Linschoten's reputation in the Netherlands is largely the outcome of the posthumous publication of a book he wrote just prior to his early

death on March 17, 1964, *Idols of the Psychologist* (Linschoten 1964). Having died suddenly at the age of 38, Linschoten developed into a kind of mythical figure who was originally known for his work in phenomenology but whose shift to a hard-nosed, scientific and experimental psychology was compared to a conversion experience. His last book, *Idols of the Psychologist*, was considered an important turning point that signaled the end of the phenomenological movement in the Netherlands.

Although this was overstated, one could argue that Linschoten's possible conversion away from phenomenology does mark a clear end to a particular articulation of phenomenological psychology in the Netherlands. Outside the Netherlands, however, it was his earlier interest in phenomenology that helped ensure an interest in the Dutch school and its spread beyond the Netherlands (see Giorgi 1965, 1966, 1968, 1970a, 1983; Kockelmans 1987; Luijpen 1960; Misiak and Sexton 1973). In 1961 Linschoten had written a book on William James and phenomenology that was translated and published in English in 1968 (Linschoten 1968). Prior to this, that book had also been translated into German in 1961. Because *Idols of the Psychologist* was never published outside the Netherlands, his radical conversion was neither understood nor acknowledged by those outside the Netherlands.

Like his previous books, *Idols of the Psychologist* too had been based on a series of lectures that he gave to undergraduates between 1959 and 1964. This was a time of expansion and curricular change in higher education in the Netherlands. The influx of students into the universities, their attempts to accommodate and manage the influx while growing on older curricular models, the increase in chairs of psychology and the student interest in the new discipline all led to a realization that the old curriculum must give way to forms of training that could be adapted to large numbers of students.

Phenomenological psychology, however, was idiosyncratic, required a great deal of broad, general reading, and could not be counted on to provide a coherent and uniform education in psychology. Furthermore, the new applied subdisciplines of organizational and clinical psychology showed themselves to be more amenable to Anglo and in particular American models. Technical aspects of psychology required education in

statistics and experimental methods and these were readily taught to large numbers of students in large classes. Unlike the idiosyncrasies of phenomenology which did not fit within a standardized curriculum, the new psychology could be adapted to the new realities of the education system.

The originators of the Dutch school came from many different fields. When Linschoten succeeded Buytendijk to the chair in Utrecht in 1957, it meant that phenomenological psychology rested on his shoulders, yet he had no interest in being the standard bearer for a movement. Hence, the beginning of the end of phenomenological psychology in the Netherlands was already on the horizon in 1957, and its demise was quick and sure after 1964.

In the early and mid-1950s Linschoten, like his colleagues and mentors, was quite critical of a positivistic, experimental psychology. The phenomenologists were proud of their attention to “the person” and his or her world while eschewing the objectifying tendencies found elsewhere in the discipline. Their work, however, was eclectic and never cohered into a program or even “school” despite the widespread application of that term to the group of phenomenological oriented scholars in the Netherlands.

As a footnote to this movement, it is important to note that the phenomenological psychology of the Netherlands was widely influential in certain universities and academic circles in the USA in the late 1950s and early 1960s (MacLeod 1951; McGill 1947; Smith 1983; Strasser 1963, 1977; Straus 1965; Van den Berg 1952; Van Kaam 1966). It was clearly an inspiration among others for what became known as the “Third Force” or Humanistic Psychology and a version of phenomenological psychology largely fostered by psychologists such as Amedeo Giorgi at Duquesne University would remain important in American psychology for the remainder of the twentieth century.

Piaget, Jean

JOHN D. HOGAN, MARY-JANE E. OJIE
St. John's University, Jamaica, NY, USA

Basic Biographical Information

Jean Piaget was a Swiss-born, French-speaking social scientist whose theory of cognitive development revolutionized the understanding of children's development. Trained as a natural scientist, with a strong emphasis on philosophy, Piaget employed an approach to development that was fresh and often controversial. Eventually, his research and writing came to dominate the specialty. Although his influence has waned, his work continues to have a substantial impact today.

Piaget was born on August 9, 1896, in Neuchâtel, Switzerland, the son of Arthur Piaget, a university professor, and a mother who is often described as troubled. A precocious child, Piaget published his first scientific paper at the age of 10, and became an authority on mollusks before he was out of his teens. After completing his doctoral degree in natural science at the University of Neuchâtel at the age of 22, he began an informal study of psychology, first studying at the University of Zurich and later working with Théophile Simon, a former associate of Alfred Binet, in Paris. It was through his work with Simon that he had what was perhaps his most formative insight (Piaget 1952; Vidal 1994).

Piaget was assigned the task of standardizing an intelligence test on Parisian children that had been constructed by the English psychologist, Cyril Burt. Piaget found himself fascinated not by the correct answers but rather by the children's thinking and the systematic way in which children made errors. He thought that an understanding of their errors would throw light on the entire thinking process of children. His goal in these years was to understand how knowledge was acquired; he was less interested in child development as such. Nonetheless, his writings on child development brought him to the attention of Edouard Claparède, the director of the Institut J. J. Rousseau in Geneva – the institute later became affiliated with the University of Geneva – who offered him a position as Director of Studies. Piaget continued his affiliation with the University of Geneva for the rest of his life (Elkind 1981).

In 1923, Piaget married one of his students at the Institute, Valentine Châtenay. She was of enormous assistance to him as he developed his theory of cognitive development, much of it based on observations of their three children, Jacqueline, Lucienne, and Laurent. Later, Piaget would be unfairly criticized because of his limited sample. Although he derived many of his ideas from observations of his own children, he and his coworkers and students would later include tens of thousands of children in their research. Piaget was also criticized for his “clinical approach” to research that lacked the highly controlled method of other research approaches. Using this method, Piaget was more open to the spontaneous utterances of children and let their behavior guide the direction of the encounter.

Piaget's ideas were slow to be accepted in the USA, largely because his approach was not compatible with behaviorism, the dominant approach in the USA at the time. In the 1950s, articles began to appear referencing his work, notably by David Elkind. The book on Piaget's theory by John Flavell (1963) is thought to have been particularly important in bringing Piaget's work to the attention of a US audience. Despite his international success, Piaget was modest about his research and writing. He was not interested in gaining disciples, but rather in finding the truth. He once said that to the extent there were Piagetians, to that extent he had failed. Piaget died on September 16, 1980.

Major Accomplishments/ Contributions

Piaget is properly called a constructivist. He viewed the behavior of the developing child as parallel to that of a scientist. In his view, children shape their thinking as they interact with the environment, developing hypotheses about the world, and changing them as they gain additional information. He proposed a four-part stage theory that outlined the progression of cognitive development from infancy to cognitive maturity. In doing so, he argued persuasively that children at different stages literally think differently. Through a series of clever tasks presented to children, he was able to demonstrate the quality, form, and limitations of thinking at various levels of development.

At the most basic level, Piaget illustrated how children learn sequencing and object permanence in the earliest part of life. As they mature, they tend to be very perceptually bound, frequently animistic and egocentric in their conceptions, and limited in their capacity for genuine thinking. It is only when they reach a stage he called concrete operations and achieve “reversibility” that they begin to engage in genuine thinking. Until then, their reliance on perception often yields surprising solutions to problems. However, their thinking is still not fully mature. The final stage of cognitive development occurs when children begin to develop qualities of abstract thinking, typically in their early teens.

Piaget’s beliefs about a stage theory of cognitive development touch on many aspects of child development, and have enormous implications for parenting, education, and the law. For instance, rather than interacting with children from an adult perspective, parents and educators are encouraged to determine the level of thinking the child is currently capable of and to address their comments to that level.

During his lifetime, Piaget published approximately 60 books and hundreds of articles. His work dominated developmental psychology until the late 1970s, at which point its influence began to fade. He was criticized on many fronts, which included questions about the timing of the stages and the generalizability of his concepts. Despite its reduced contemporary role, many parts of the theory remain useful today and continue to merit study (Beilin 1992).

Pillsbury, Walter B.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: July 21, 1872; Died: June 8, 1960.

Pillsbury was born in Burlington, Iowa, and got his college education at the small Quaker school William Penn College in Oskaloosa and at the University of Nebraska (B.A. 1892) with Harry Kirke Wolfe. He then went to Cornell and gained the Ph.D. in 1896, one of the first generation trained by ► [Titchener, Edward Bradford](#). For 2 years, he continued as an instructor at Cornell and then began a lifelong academic career at the University of Michigan.

Major Accomplishments/ Contributions

With Titchener, he translated into English Külpe’s “Introduction to Psychology” in 1897. Pillsbury’s most important theoretical contribution was also his earliest – his book on attention, published in French as “L’Attention” (1906) and then as “Attention” in English in 1908. Pillsbury, experienced in the laboratory study of attentive processes (Galloway and Pillsbury 1904), summarized theory and research in the methods of measuring attention and connected it across the gamut of psychological categories, including the self, emotion, consciousness, and the brain. He asserted an inverse relation between attention and emotional

arousal, noted the convergence of several studies' results on 5 as the number of items could be attended and recognized in a brief presentation, and advanced a holistic and unitary conception of the brain based on the multiple interconnections of its association areas. He did not neglect abnormal psychology, and referred to studies such as those of Kraepelin that suggested that mental disorder was distinguished chiefly by distractability. His general conclusion was that attention was an intermingling of internal and external determinants: He was aware of what now is termed the "binding problem" and spent a good deal of time as well examining the relation between self and attention, which devolved for him on the mind-body question. Several parts of the English version of Pillsbury's text, in fact, appeared first in the *Journal of Philosophy* in 1907. However, it was not a propitious time to be a specialist in an irreducibly cognitive and internal psychological process, and it was only much later that attention came back into prominence as a specific area of study. By that time, during the 1920s and 1930s, Pillsbury had settled down to producing general introductory texts which tended to look backward to the psychology of the turn of the twentieth century rather than toward the newer departures of Gestalt theory and behaviorism. His attempts at a reconciliation between Gestalt and his own views (e.g., Pillsbury 1926) were, compared to other contemporary approaches, less accessible and did not gain wide acceptance. Pillsbury tried his hand at several other aspects of psychology and wrote, at the time of the First World War, a psychology of internationalism. He also was one of three American psychologists who produced a history of psychology in 1929, but while those of the other two, ▶ [Boring, E. G.](#) and ▶ [Murphy, Gardner](#), became classics, Pillsbury's was largely forgotten. Pillsbury was politically conservative and emphatic in his support of the First World War: It is however noteworthy that he was one of the psychologists not to join the armed services during that conflict, probably because of his age but also because of his theoretical stance which echoed Titchener's distrust of psychotechnology. Pillsbury continued to work at Michigan up to his retirement and beyond. Late in his career, he made a plea for knowledge as a complement of behavior in psychological study, but by this time cognition was in the wings: The times had caught up

to him (Pillsbury 1950), but it is likely that his effect on this shift in psychological thinking was incremental at best.

Pintner, Rudolf

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: November 16, 1884; Died: November 7, 1942.

Pintner was born in England and received the M.A. from Edinburgh in 1906. He studied next at Leipzig between 1909 and 1911, receiving the Ph.D. in 1913. He moved to America and, after a short stay at the University of Toledo, taught at The Ohio State University between 1913 and 1921, and went from there to Columbia University where he remained for the rest of his career. Like Cattell and Münsterberg, Pintner easily transitioned between German academic psychology and applied psychology in the United States.

Major Accomplishments/Contributions

He began his career as a translator of German psychological works, including Wundt's *Introduction to*

Psychology (the 1912 distillation of the *Outline*), Kerschensteiner's *The Idea of the Industrial School*, Schulze's *Experimental Psychology and Pedagogy*, and, with the philosopher Emil Wilm, Otto Klemm's *History of Psychology*. He also conducted work on attention and silent versus oral reading before settling into two fields to which he contributed steadily for the next 30 years: mental testing and the education of disabled individuals, especially the deaf. In 1914, he began a collaboration with his student ► [Paterson, Donald G.](#) later to become eminent himself as a pioneer in applied vocational psychology. Within 4 years, this partnership resulted in several papers on testing practice and standardization in both normal and deaf environments as well as their nonverbal test battery *A Scale of Performance Tests* (Pintner and Paterson 1917), which established them both in their careers. Working in the context of the refinement and standardization of the Binet and other intelligence scales, they drew on existing work by, among others, H. H. Goddard, F. Kuhlmann, H. A. Knox, and William Healy to assemble a set of 15 tests, mostly variations on existing tests including the Seguin formboard, the Healy Picture Completion Test, Knox and Kempf's Feature Profile Test, Woodworth and Wells's Substitution Test, and Glueck's Ship Test. Pintner and Paterson also added some original tests of their own. This compendium filled a void in testing in situations where impaired language or other disability made testing difficult, and because of its consistent and meticulous standardization and its lucid presentation, it became a standard reference for many years and was used in many experimental studies. It also served as a springboard for the future development of the performance component of intelligence tests such as Wechsler's.

After this and after his move to Columbia, Pintner continued his dual interests in intelligence testing and in developing tests for disabled individuals, often in collaboration with students. For example, in 1923, with Bess V. Cunningham, he published the *Pintner–Cunningham Primary Mental Test* (Pintner and Cunningham 1923), a picture intelligence test which, like the Pintner–Paterson scale, had a long run as an educational measuring instrument. Cunningham later went on to become a Professor of Education at the University of Toledo and wrote a psychology textbook

for student nurses (Cunningham 1946) which was influential in the growth of a psychologically oriented nursing curriculum. Also in 1923, Pintner authored *Intelligence Testing: Methods and Results* (Pintner 1923) which was one of the authoritative sources in the field during the height of the intelligence testing controversies in the 1920s, from which Pintner kept apart. Pintner, now a member of Teachers' College, came more and more to identify with educational psychology and wrote an introductory text in that field (Pintner 1929). In 1932, he published the *Pintner Intelligence Tests* for the middle grades (Pintner 1932), but by this time he was just one of many voices in the burgeoning testing field. He compiled regular yearly surveys of advances in intelligence testing during the 1920s and 1930s which were precursors of the large compendia of test reviews such as the Buros *Mental Measurements Yearbook* that appeared at the end of the 1930s. He contributed less to theory than to practice in testing, and had his most important effect in promoting accurate and comprehensive standardization. He was honored during his lifetime for his work with deaf individuals by Gallaudet College and, after his death, the college published a memorial volume with a complete annotated bibliography (Arsenian 1951).

Poffenberger, A. T.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information/Major Accomplishments

Born: October 23, 1885; Died: December 24, 1977.

Albert Poffenberger, heir to a family tradition of becoming physicians, became intrigued by physiological psychology during his undergraduate studies at Bucknell, and after graduating in 1909 went to Columbia for graduate study in psychology. His career arc spanned the old laboratory psychology based on sensation and reaction and the new applied psychology, and he made significant and lasting contributions to each. His 1912 doctoral work was a study of the difference in reaction times between visual stimuli presented at various eccentricities (Poffenberger 1912). He estimated the difference between responding to uncrossed (same visual field as responding hand) and crossed (opposite visual field to responding hand) to be between 5 and 6 ms, a result which corresponds well with modern estimates and which he interpreted as the time for information to cross the corpus callosum. Current studies of intrahemispheric transmission time in various neurocognitive paradigms frequently reference this finding as the “Poffenberger Effect” (Saron et al. 2002). He was also involved in studies typical for the time on the effect of drugs on performance, publishing on the effects of strychnine on mental and motor efficiency in 1914. In 1917, he coauthored, with Harry Hollingworth, a comprehensive study of the sense of taste which considered, among other things, the evolution and aesthetics of taste (Hollingworth and Poffenberger 1917b). In the same year, and also with Hollingworth, who along with others at Columbia had already made significant contributions to various areas of applied psychology, he coauthored *Applied Psychology* (Hollingworth and Poffenberger 1917a) which described applied psychology as a field with good prospects for a “dignified and prosperous existence.” Written in the same lucid and accessible nonspecialist style that marked other contemporary Columbia products in applied psychology,

it covered principles and findings in the psychologies of management, business, law, social work, medicine, and education. This was followed, in the 1920s, by books by Poffenberger as sole author on advertising and on general applied psychology: His 1927 *Applied Psychology: Its Principles and Methods* was in its day a recognized standard text (Poffenberger 1927). Poffenberger saw applied psychology’s role as an agent in increasing the efficiency and economy of human effort. While as president of the American Association of Applied Psychology in 1943–1944 he played a central role in convincing the organization to become incorporated in the newly expanded and federated APA, he urged caution and recommended that programs in applied and professional psychology “above all promote in every way the pure science of psychology, for without that as an ever widening foundation our profession will wither and die” (Poffenberger 1945). Poffenberger was also a close associate of R. S. Woodworth and contributed to the development of both Woodworth’s 1921 generalist textbook and his 1938 *Experimental Psychology*. Additionally, Poffenberger worked on the problem of categorizing psychology, proposing in 1917 a revision of the Dewey Decimal System to accommodate the range of books produced by developing psychological subspecialties (Poffenberger 1917). He was also influential through his work in several organizations including the American Psychological Association, whose President he was in 1934, and through his students, who ranged from the Pavlovian Gregory Razran to the philosopher Mortimer Adler. In his insistence that beneath academic and applied psychology there is only one psychology, a scientifically grounded and experimentally validated one, he shaped psychology’s modern hybrid scientific-professional character.

Pogson, N. R.

DAVID L. SEIM

University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

Norman Robert Pogson was born on March 23, 1829, at Nottingham, England, and was raised to work in the family business in hosiery manufacture. Pogson received an ordinary education appropriate to his expected occupation. Yet along the way he showed an interest in science. His family helped him obtain employment with an optical instrument maker in the family's hometown, and after that, Pogson obtained instruction in trigonometry and other branches of mathematics. In time Pogson was introduced to a family friend, John Russell Hind, who was a respected London astronomer. Hind invited Pogson to study astronomy under his instruction, and the broader community of astronomers first heard about Pogson in 1847, when at age 18, he published highly accurate calculations of two comet orbits. For the next 44 years, Pogson would be an important British astronomer. Pogson's primary positions were at South Villa Observatory at Regent's Park (London), Radcliffe Observatory (Oxford), Hartwell Observatory (London), and (from 1861 to 1891) Madras Observatory (Madras, India). For most of these years, Pogson was a government employee of Great Britain. Pogson died in Madras on June 23, 1891, at age 63.

Major Accomplishments/ Contributions

Pogson is recognized in the history of science for his highly accurate and precise recording of variable

stars, eclipses, longitude measures, and even pendulum arcs on earth (for the purpose of remeasuring the earth's gravitational constant). But although Pogson performed many lines of important research, he is especially known for some detailed analysis he provided in one minor article, which is his description of a scale of the human visual ability to distinguish differing levels of brightness (Chapman 1998).

In November 1856 – while based at Oxford's Radcliffe Observatory – Pogson published a paper focusing on a research problem that required commitment to a “stellar magnitude scale” prior to performing any data collection and calculations (Pogson 1856). The problem was to chart expected positions of “minor planets” (i.e., asteroids) over an upcoming year. Because this work required a powerful telescope, Pogson preferred to use a magnitude scale with some kind of constant ratio between consecutive magnitude classes. Any table he might publish to predict monthly positions for asteroids needed to include an expected brightness value for the first day of each month, and Pogson decided to calculate such values “on the assumed ratio of light of 2.512, i.e., that a star of any magnitude, as for instance the eighth, contains 2.512 times the light of the next less, or ninth magnitude.” Each decrease in magnitude would thus represent a decrease in brightness equal to the fifth root of 100.

Pogson – who published his visual perception scale 4 years prior to Gustav Fechner's famous book of 1860 – recognized that other scientists might question where his scale came from (Pliskoff 1977). He therefore cited leading authorities who had already raised the issue. In particular, he noted his original plan to use one available option, which was German-Russian astronomer Friedrich Struve's constant ratio of 2.00, as suggested in 1827. Pogson explained how he changed his mind when a friend empirically approximated a ratio of 2.43 over the full range of stars, a value different enough from Struve's ratio to “throw uncertainty” upon the whole matter. Pogson then performed his own measurements, with data collection that rendered his conclusion that any constant light ratio seemed close to 2.5. Finally he made a sweeping review of others' results, which resulted in

a calculated mean of 2.40 for all magnitude ratios obtained by reliable methods. Pogson concluded that an idea of a constant ratio for the marginal change in distinguishable brightness was firmly in place. He noted the “high authority” of Prussian astronomer F.W.A. Argeländer who had recently endorsed a constant ratio of 2.519 for the specific purpose of measuring brightness levels of asteroids. While ultimately unconcerned about “which of these ratios is adopted in dealing with the ranges of ordinary telescopes,” Pogson wanted a ratio suited to powerful telescopic studies. He selected his own ratio, 2.512, for logical reasons: Argeländer had endorsed a value close to it; logarithm ratios are mathematical constants “continually occurring in photometric formulae”; the particular value of 2.512 worked “for convenience of calculation”; and Pogson’s ratio allowed that Edmund Halley’s (of the comet fame) long-established brightness range of 1–100 from the very dimmest to the very brightest of naked-eye stars be divided into six equal increments. Also a virtue was that calculations done with “Pogson’s rule” are fairly easy procedures (Jones 1968).

Although it took about 20 years after 1856, when astronomers finally adopted a standardized scale, the scale was Pogson’s ratio (Hearnshaw 1996). During those intervening years, Pogson’s empirical magnitude scale was recognized by a number of astronomers and psychophysicists, most notably Gustav Fechner.

Politzer, Georges

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/Major Accomplishments

Politzer was one of the first professional psychologists who dealt seriously with Marx’s ideas in psychology. He was born in Hungary in 1903, and was executed by the Nazis in 1942 for his communist political activities. He was an active member of the French Communist Party. Politzer founded with Paul Nizan, Henri Lefebvre, Georges Friedman, Norbert Guterman, and Pierre Morhange a series of left reviews such as: *Philosophies* (1923), *L’Esprit* (1926), *Revue Marxiste* (1929), and *La Pensée* (1939). In 1929 he founded *Revue de Psychologie Concrète* to provide a forum for dialectical materialist psychology and an outlet for concrete psychological research from around the world. In the 1930s he was the co-founder of the International Workers’ University in Paris. He published over 100 articles, monographs, and books. Politzer’s psychological and philosophical ideas were grounded within the dialectical materialist standpoint. He published a master piece on *Critique of the Foundations of Psychology* (1929, translated into English in 1994). He published a series of papers in the French left journals. Politzer wanted to see a “concrete psychology” with all of its fields and approaches. His own efforts were mainly in and for the creation of a dialectical materialist psychology based on the philosophical and epistemological principles of Marxism. Psychology, according to Politzer, is in need of a fresh start with altogether new categories, concepts, and methods. No real progress is possible as long as a psychological explanation is not integrated into the

methodological explanation offered by economics and other social and the real concrete human life. He stated that, "Psychology by no means holds the 'secret' of human affairs, simply because this 'secret' is not of a psychological order" (1929, p. 170). He conceptualized the theoretical foundations of concrete or positive psychology. He outlined three conditions that lead to establish a concrete or positive psychology:

1. Psychology must be a posteriori science, that is, the adequate study of a group of facts.
2. It must be original, that is, it must study facts which cannot be reduced to the objects of other sciences.
3. It must be objective; it defines psychological facts and methods in a manner that is universally accessible and verifiable (1967, p. 242).

In this sense, concrete psychology is the study of the singular individual, conceptualized as a conscious actor within social reality. It is also the study of the drama of human actual life, drama in the sense of doing and acting. Within the concept of drama, Politzer sought to capture both the biological existence and social interaction, and excluded abstractions by focusing on the events of human existence, both in singular individual and collective social activities.

Politzer was very critical of his present day psychology; he pointed out that, "We need to understand that psychologists are scientists like evangelized wild tribes are Christians" (1928, p. 5). He equated his concrete psychology with materialist psychology. Materialist psychology explains realities with realities.

Post-Soviet Psychology

SAMVEL JESHMARIDIAN

Borough of Manhattan Community College, The City University of New York, New York, NY, USA

Introduction

In the Soviet period, Russian psychological thought has been full of delights and disappointments. Though keeping a citizen in jail for philosophical and psychological worldview was a normal case in Soviet reality, traditions of psychological thought in the Soviet Union occurred to be pluralistically rich: Physiological Behaviorism of *Ivan P. Pavlov* (1849–1936), Cultural-historical Theory of *Lev S. Vygotsky* (1896–1934), Psychoanalytical Neuropsychology of *Alexander R. Luria* (1902–1977), Existential Psychology based on *Mikhail M. Bakhtin's* (1895–1975) philological traditions, *Alexsei N. Leontiev's* (1903–1979) Activity Theory based on the principles of the Communist Party of the Soviet Union.

It was the Christmas Day of 1991, that the USSR, born in the Bolshevik Revolution of 1917, split into 15 independent republics. Russian Federation was the most influential and important one among the successors of the Soviet Union as well as the one that inherited the right to own the Soviet socio-culture.

Soviet ideological legacy was traumatic for the culture of New Russia. Since then, three psychological factors have been shaping Russian character. Russians started to think that:

1. One person, Josef Stalin by name, was to blame for the incredible number of losses in Russian population. The tragic phenomenon has the name Stalin purges. Such feelings lead to anger and anxiety for the past.
2. The international community has the crucial, even fatal responsibility for the poor state of the Russian economy, diplomacy, and mentality. This leads to the feeling of handed helplessness.
3. The nature of Russian mind has always been so unique that no one in this world was and is able to understand it. Such approach leads to the feeling of inferiority, existential fear for the future, and rigidity in Russian Character.

Soviet Versus Post-Soviet Psychology

The collapse of the Soviet Union was a progressive event for the development of Russian psychological and sociological thought, for the development of the humanities and social science in Russia and in the newly born Republics bordering Russian Federation. Russian Psychologists are trying to reevaluate their traumatic legacy and understand the hidden and latent directions likely to result from the new academic and political environments. Translations of Western authors are viewed something decisive for today's Russian Psychology.

Though the Soviets were claiming that they have solved all the earthly and heavenly problems referring to the social, political, religious, and national life of their country, it occurred to be that a bunch of deadly problems – that tend to grow into turmoil – are hanging over the head of the newly born post-Soviet Republics. All these problems are thought to be *Psychological*, never *Political*, and post-Soviet Psychologists are expected to solve them with their magic wand:

1. Ethnic hatred, tensions, and struggle that has been a historical tradition for all Russias – Czarist, Communist, and post-Communist.
2. Alcoholism, which also has a long history in Russia, plus drug addiction. Consuming a lot of alcohol is a typical part of Russian culture, and also a major problem. Since 1990, alcohol yearly consumption among males has doubled.
3. Ugly interactions in Russian families as well as high rate of divorce. A deeper tragedy is that many divorced couples in Russia and bordering Republics continue to live together because there is no other place to live – it is too expensive.
4. Unemployment and poverty – about one-third of Russian population live below the poverty line.
5. Gangs and school dropouts. Because of poverty and little chance of finding jobs, many youngsters in Russia choose gang life over education.

The field of psychology that exists for the uses of the state, for dealing with citizens, for organizational, industrial, and labor purposes has become of utmost importance. Because of the fact that *Pavlovian*, *Marxist*, and *Communist Theories* could never solve a single social, political, and/or psychological problem in the Soviet Union, *post-Pavlovian*, *post-Marxist*, and

post-Communist theories are being developed today. They are coming into existence like mushrooms appear after rain. They tend to be exercised over the whole Russian society as well as over the societies of the bordering countries, i.e., the post-Soviet countries.

Ivan P. Pavlov's Physiological Behaviorism

Ivan P. Pavlov's physiological experiments started long before the Bolshevik Revolution of 1917. Pavlov performed and directed experiments on digestion that earned him the 1904 Nobel Prize in Physiology and Medicine. The Russian Bolshevik Revolution was more than a regime change; every area of social and intellectual life in Russia was subject to protracted, traumatic, and repeated transformation. It also transformed Pavlov's life. The new Bolshevik Government started generously supporting Pavlovian Experimental Laboratory in St. Petersburg as something important for military purposes. Pavlov's physiological theory has had two distinct sides. One of them reveals the Physiological and biomedical truth that had to coincide with Marxist Dialectical Materialism while the other ought to explain the historical truth of Marxist Teaching – “the only true one in human history” – the name of which was Historical Materialism. In fact, Pavlovian Psychophysiology has been the Russian interpretation of Wundtian Physiological Psychology, with the concept of “reflex” instead of “consciousness” plus schizophrenic citations from the classics of Marxism–Leninism. All of them had to prove the Soviet teaching of *nervism* (one should read, functions of neurons). *Psychophysiology* and *higher nervous activity* for most Russian Psychologists were and are synonymous that has been challenging to the Western understanding. Pavlovian ontology and methodology gained an official and commanding position to Soviet biomedical and psychosocial sciences in 1950 with the Resolution of the June 28–July 4 Joint Pavlovian Session of the Soviet Academy of Sciences and Academy of Medical Sciences. A large portion of Soviet psychological thought has been primarily a textual and exegetic collation and conciliation of the views of Pavlov with those of classics of Marxism–Leninism. There has been the longstanding drastic ban on intelligence testing, psychoanalysis, Gestalt psychology.

Pavlov has contributed to a few areas of physiology and neurology. These experiments included surgically extracting portions of the digestive system from animals, severing nerve bundles to determine the effects, and implanting fistulas between digestive organs and an external pouch to examine the organ's contents. This research served as a base for broad research on the digestive system.

As related to Psychology, Pavlov's work involved research in temperament, conditioning, and involuntary reflex actions. Pavlov's work on reflex actions involved involuntary reactions to stress and pain. Pavlov extended the definitions of the four temperament types under study at the time: *phlegmatic*, *choleric*, *sanguine*, and *melancholic*, updating the names to "the strong and impetuous type, the strong equilibrated and quiet type, the strong equilibrated and lively type, and the weak type."

Pavlov and his colleagues *Piotr K. Anokhin* (1898–1974) (Anokhin has elaborated a theory of *Functional Systems*) and *Levon A. Orbeli* (1882–1958) (Orbeli has played an important role in the development of *Evolutionary Physiology*) began the study of trans-marginal inhibition (TMI), the body's natural response of shutting down when exposed to overwhelming stress or pain by electric shock. This research showed how all temperament types responded to the stimuli the same way, but different temperaments move through the responses at different times. Ivan Pavlov commented, "...that the most basic inherited difference was how soon they reached this shutdown point and that the quick-to-shut-down had a fundamentally different type of nervous system."

Lev S. Vygotsky's Sociocultural Theory

Since the 1950s, Lev S. Vygotsky has been widely considered a key figure in twentieth-century Russian psychology, an influential thinker and a prolific writer, who with his cultural-historical theory explored socio-cognitive development. Lev Vygotsky started his career with using the language of Ivan P. Pavlov's and *Vladimir M. Bekhterev's* (1857–1927) *Reflexology* (in Reflexology, everything was a reflex), but called for *consciousness* to be given its place as the key concept of psychology (Vygotsky 1997a, b). In fact, it was *Wilhelm M. Wundt's* (1832–1920) psychophysiological

principle. Vygotsky expressed the idea that consciousness was not a reflex but the *organization of reflexes*, a process with a social origin. He continued with another concept – *Unit of analysis*. As *Karl Marx* (1818–1883) points out in the preface to the first edition of "*Capital*," the commodity relation is "cell" of economics. All the phenomena of capitalism can be unfolded from this simplest and most primitive of relations, just like the cell in biology and the molecule in chemistry. The idea of *Unit of analysis* originated with German poet and naturalist *Johann Wolfgang von Goethe*, and was a key methodological principle for *Georg Wilhelm Friedrich Hegel* (1770–1831), the German philosopher and *Karl Marx*, the founder of Marxism. Deriving from the Unit of analysis, Lev Vygotsky differentiated between *elementary and higher mental functions*. The three critical aspects of Vygotsky's approach are the role of *mediational* means in higher psychological functioning, the contributions of social and cultural experience in providing and supporting the development and use of these mediational means, and the privacy of the development. Developmental thought and ontological thought are tied up with material objects (tools, symbols, or other people) and the practical activities through which people use them and give meaning to them.

Lev Vygotsky has introduced *sociocultural theory* which emphasizes the contributions of the social and cultural world to cognitive development. According to the main idea of this basic psychological theory, the development of all higher cognitive processes and functions is by nature social and all social development has a cognitive basis. Social and cognitive processes are intertwined due to the processes and mechanisms of internalization and externalization. The social basis of higher cognitive processes, in turn, is intertwined with the economic conditions prevailing in a given society. Using Marxism as a starting point Vygotsky developed a threefold vision focusing respectively on *phylogenetic*, *sociohistorical*, and *ontogenetic development* (Vygotsky and Luria 1930/1993). The three processes of development could be brought together by a common Marxist vision based on the concepts of general and societal evolution, *dialectical materialism*, *determinism*, and the central importance of labor and of physical and psychological tools. Within this Marxist vision, Vygotsky's special focus was on children's development and

education within their historically and culturally constituted environments. Vygotsky would criticize Swiss Psychologist *Jean W.F. Piaget's* (1896–1980) interpretation of infants' egocentric speech. Piaget thought that the child "talking to him-/herself" was a kind of autism which eventually died away. But as Vygotsky saw it: First the child used speech to gain the help of adults, and then to control his/her own actions, and then vocalization gradually faded away as the vital function of controlling their own behavior through speech turned inward. According to Lev Vygotsky, the human organism is born with a number of functional capacities each depending on various biological structures. When developing, the basic functions – that are identical with animals – are subsumed into higher psychological functions. Mental or psychological functions develop through the social use of cultural products. The result is that new, specifically human, psychological functions successively differentiate themselves, each of which mobilize the entire range of biological formations in a new Gestalt. This allows human beings to voluntarily use different functions, such as memory, speech, visual perception, and so on, which is unavailable to animals. Such approach explains the contradictory results of investigations in brain localization of psychological functions: Every human psychological function utilizes a multiplicity of regions of the brain, as well as the whole body.

Alexander R. Luria's Psychoanalytical Neurology

Together with Lev Vygotsky and Alexander N. Leontiev, *Alexander R. Luria* put forward a theory of the socio-historical genesis of higher, specifically human, mental functions. In today's Russian perception, Alexander Luria could have been counted as the founder of modern neuropsychology, if not the Soviet regime. Luria was being forced to conform his public comments on psychology to materialistic and reflexological principles in which, e.g., speech was the speech reflex as if language use could be merely understood in terms of stimulus and response.

Alexander Luria was and is one of the most outstanding Soviet psychologists. He played a great role in the development of Soviet psychology and in the formulation of psychological problems on the basis of *Dialectical Materialism*. Luria carried out numerous

investigations into the ontogenetic and historical development of these functions, as well as their disturbance with local brain lesions. As the founder, in the Soviet Union, of the new discipline of neuropsychology, he made a very significant contribution to the study of the cerebral mechanisms of mental activity. In his comments on Psychology, Luria developed the idea that idiographic method (similar to Gordon Allport's understanding) can be more effective in neurological medicine than nomothetic method. This meant that following a single individual or a group through their life and studying the entire personality and its development can be more effective and scientifically more comprehensive than generalizing observations to formulate general principles, as is done in nomothetic science. Luria's study of an eidetic individual, S, reported in "The Mind of a Mnemonist," (English translation 1987) demonstrated that the cognitive functions were comprehensible only as part of an integrated Gestalt. The Communist trends in Soviet Psychology are precisely articulated in Alexander Luria's following description, "My entire generation was infused with the energy of revolutionary change – the liberating energy people feel when they are part of a society that is able to make tremendous progress in a very short period of time."

The Theory of Activity of Aleksei N. Leontiev

Alexsei Leontiev is the founder of Activity Theory – an extension of Vygotsky's tradition in search of an organizer of all mental processes. The concept of *activity* has played as important and ambiguous a role in Soviet psychology as did the concept of *behavior* in American studies in the first half of the twentieth century. The concept of activity is deeply ingrained in Soviet general psychological theory as something deeply communistic. It was first suggested by Lev Vygotsky as a theoretical remedy for psychological systems. Alexei Leontiev departed from Vygotsky's original concept. The demarcation line separating Vygotsky's understanding from that of Leontiev's occurred in the evaluation of the relative importance of *semiotic mediation* and practical actions for the development of intelligence. Leontiev defined Activity in terms of a three-level conceptual structure. *Activity* is a collective system of *actions*, driven by a socially determined

object and motive. Activity is realized through individual actions which are oriented to goals. The individual's goals are not the same as the social motives of the *activity*, and the formation of a goal is necessarily a complex function of the social system, if individuals are to be mobilized in the reproduction of the society. Actions in turn are realized by means of routine *operations*, which depend on the conditions of the action. As a rule, individuals are not conscious of their operations, unless something goes awry. The task of Activity Theory was to connect up the subject matter of psychology with the subject matter of sociology to lay the basis for an integrated human science.

Mikhail M. Bakhtin's Humanistic and Existential Traditions

Existential and humanistic methods of research in the humanities and social sciences successfully take the roots in the social environment of Russia, joining with traditions of psychological and philosophic ideas. Humanistic tradition in Russian psychology is understood as a tradition that derives its theoretical models from the Humanities, i.e., philology and literary scholarship. Humanistic approach in Russian psychological thought is based on the philosophy of language, literary theory, and psychological ethics of *Mikhail M. Bakhtin*, a Russian philosopher and scholar. Mikhail Bakhtin views *life as authoring* and *language as tool for cognition*. The application of these ideas refers to mental cognition, psychological situations of coping and adaptation, defensive behavior and defense mechanisms, undergoing life crises and living a life of struggle.

Mikhail Bakhtin shared with Marxist theorists an interest in the historical and social world, an interest in how human beings act and think, i.e., an interest in the formation of the subject, and an interest in language as the means in which ideologies get articulated. Unlike the Swiss linguist *Ferdinand de Saussure* (1857–1913), Bakhtin views language, as something material and ideological. Although Bakhtin was active in the debates on aesthetics and literature that took place in Soviet Russia in the 1920s, his distinctive position did not become well known until he was rediscovered by Russian scholars in the 1960s. Bakhtin was an ethical theorist. He was very much aware of Marxist theories and doctrines, and how they were being implemented.

Though Bakhtin had to be a Marxist, he was not a Marxist. He was exiled because of his political conflicts with the Soviet Union and because he got in trouble with the Soviet regime. In exile, Bakhtin did a lot of his best works which were not published until the 1970s. Bakhtin is known for a series of concepts that have been used and adapted in Russian psychological thought: *Dialogism*, *carnavalesque*, *chronotope*, *heteroglossia*. Together these concepts outline a distinctive philosophy of language and culture that has at its center the claims that all discourse is in essence a dialogical exchange and that this endows all language with a particular ethical–political force. Bakhtin has theorized that language – any form of oral speech or writing – is always a *Dialogue*. This notion of dialogue is not the same as the Marxist notion of *Dialectic*, though it is similar in focusing on the idea of the social nature of dialogue, and the idea of *struggle* inherent in it. Dialogue consists of three elements: a speaker, a listener/respondent, and a relation between two or more persons. Language, ideas, characters, and forms of truth are always the product of the interactions between two or more persons. Bakhtin contrasts that notion of dialogue to the idea of *Monologue*, or the *monologic*, which are utterances by a single person or entity. Bakhtin's writings, on a variety of subjects, inspired scholars working in a number of different traditions and in disciplines as diverse as literary criticism, history, philosophy, anthropology, and psychology. The work of the *Bakhtin circle* is multifaceted and extremely pertinent to contemporary philosophical concerns. Yet their work moves beyond philosophy narrowly defined to encompass anthropology, psychology, and historiography. The vicissitudes of intellectual life in the Soviet Union have complicated assessment of the work of the circle. The writings of the group have been read into a theoretical position framed by present-day concerns over *post-structuralism* in philosophy and psychology.

New Trends in Russian Psychology of Post-Soviet Period

Creating a *Marxist cultural psychology* in the post-Stalin (after the mid-1950s) period, USSR faced an almost insurmountable difficulty. The Soviet Union was supposed to be free of any negative phenomenon. Even those who were wise enough to know that the

Communist ideology was nonsense had no opportunity to theorize the pathology of the Soviet life, being quite unable to talk or write about such things with other people. Science cannot be built without dialogue and discussion. This meant that there was a firm line beyond which Soviet psychology and social sciences could not go without descending into hypocrisy.

Boris G. Ananiev (1907–1972) was the only Soviet Psychologist who was able to use the Communist cheap and false propaganda in a scientific way. Ananiev's scientific work has been devoted to the interdisciplinary study of personality in the area of Developmental and Educational Psychology. Boris Ananiev has introduced the notion of *personality sensory perceptible organization*. He has revealed the functional peculiarities of hemispheres and their role in mental activity.

In contemporary Russian understanding, Pavlovian Theories are no more Psychology, but are Physiology, and future research should be conducted in physiological direction. Pavlovian and the like theories belong to history, just like Marxist Teaching and Theories do. The milestones for new trends are provided by Mikhail Bakhtin's concept of *life as authoring*, by the analysis of the psychological relevance of literary form. It is argued that with the "life as authoring" approach, Soviet psychology is expected to gain a new perspective, transcending Marxist social science and Pavlovian reflexological limitations.

A new generation appeared in the 1960s, whose work and ideas became an ideological source for the psychologists of the twenty-first century. *Alexander Meshcheryakov's* (1923–1974) work created a basis for a renewal of Vygotsky's legacy. Alexander Meshcheryakov, a student of Luria, took over the work of *Ivan Sokolyansky* (1889–1960), a pioneer in the education of deaf and blind children. Meshcheryakov developed methods of education of deaf and blind children and opened a school for the deaf-blind in Zagorsk in 1962. He did groundbreaking work, superior to anything to be found in the West in this field. The education of children born without sight or hearing involved the practical construction of human consciousness where it did not previously exist. In Alexander Meshcheryakov's system, *phenomenological humanistic position* consists of the special instructions about courtesy and caring attention to the patient. The paradigmatic lesson for deaf and blind

children is learning to eat from a spoon, at first with a teacher operating the spoon, and little by little the children take the initiative. Behind the spoon is the entire history of society, the *human* way of eating. Learning how to use a spoon is the first step in becoming human and through human consciousness one becomes part of a community and society. Many of Meshcheryakov's students completed higher degrees in mainstream universities and most went on to productive careers in the general community.

Crucial to making Russian Psychological thought advanced was a group of philosophers who recognized the significance of Meshcheryakov's work. First among them was *Evald V. Ilyenkov* (1924–1979) taking up Vygotsky's ideas at a new level, based on a comprehensive critique of European philosophy including the writings of *Karl Marx*. In his work "The Abstract and Concrete in Marx's Capital," Evald Ilyenkov revives the Russian Marxist philosophy after the dark days of Stalinism. Ilyenkov's main contribution is his study of the *ideal*, of how *ideals* come into being as perfectly material cultural products, the archetype of which is money. Ilyenkov gained a formidable reputation as an interpreter of *Georg Wilhelm Friedrich Hegel* (1770–1831), the German philosopher and one of the creators of German Idealism. Ilyenkov's analysis was beyond the framework of Marxism.

Another great philosophical psychologist of the Soviet generation was *Feliks Mikhailov* (1930–2006) who tackled the seemingly insurmountable philosophical problems that arise as soon as the orthodox Marxist begins to look beyond the simple slogans of philosophical materialism.

The religious-philosophical heritage with its huge experience of comprehension of spiritual problems positively developed Russian culture and psychological thought. Russian religious existentialism is represented by *Nikolai A. Berdyayev* (1874–1948) and *Lev I. Shestov* (1866–1938). Nikolai Berdyayev was a religious thinker, philosopher, Marxist, and a leading representative of Christian existentialism. He became a critic of Russian implementation of Karl Marx's views. Berdyayev's school of philosophy stressed the examination of the human condition within a Christian framework. Lev Shestov was a Russian-writing Ukrainian existentialist philosopher. Shestov's existentialism appears earlier than European. Shestov's powerful

school of historic–philosophical analysis of existentialism kept functioning even in the Soviet period.

The soil for the Russian existential and humanistic psychology was prepared by a number of outstanding scholars. The greatest and the most typical among them was *Sergei L. Rubinshtein* (1889–1960). In his unfinished work “The Human-being and the World” (“Chelovek i mir”) Sergei Rubinstein has raised the problems of *human beings*, their internal world, the relationship of ethics and ontology, *the sense of life* (with reference to the meaning of life and the perception of life as one entity and one Gestalt).

In June of 1941, Sergei Rubinstein displayed great civic courage by voluntarily staying in besieged Leningrad as a Vice-rector of the Educational Institution in to organize work in the Pedagogical Institute in severe conditions of hostile blockade. Despite that, in 1950, Sergei Rubinstein was blamed for underestimating Ivan Pavlov’s Physiological Teaching as a natural scientific basis for Psychology. Sergei Rubinstein was rehabilitated among many others (*Piotr Anokhon*, *Nicholai A. Bernstein* (1896–1966), *Pavel P. Blonskiy* (1884–1941), *Lev Vygotsky*, *Dmitry N. Uznadze* (1886–1950), *Levon Orbeli*, *Gurgen Edilian*) living or deceased expellees of science after *Stalin’s death* (March 5, 1953) who at different times were under the press of *ideological terrorism*.

Epilogue

The move into the twenty-first century coincided for Russian psychology as well as for Russian society at large with truly revolutionary reforms in the mind of the Russian people leading to greater openness in the academic sphere. Russian psychology was able to connect in a more free and fundamental way with its own heritage and with various developments around the world. These factors affected continuity and innovation with regard to the three dominant theoretical perspectives in Russian psychology: *Vygotsky’s* Developmental Theories with Cultural methodology, *Bakhtin’s* Philosophical Theories with Psychological approach, and *Luria’s* Neurophysiological Theories with Psycho-physiological approach in materialistic tradition. Meanwhile, there have been new paradigms which got the names *Organic Psychology* and *Non-classical Psychology*.

Psychology in Russia is viewed as a “magic wand” to solve all the problems and turmoil of the past Communist period. A critical analysis of the impact of different communist regimes on the research and teaching of psychology in the Soviet Union should be understood properly. The dream of influencing others is not just the ideology of Russian Psychological thought, but the political principle of Russian culture, in general. Psychology is viewed as a magic tool to influence others. The history of Psychology in the USSR gives the key to the perspective of Russian mentality.

Those who were true Marxist-Leninists (read false scholars) had a safe, even luxurious life. But those scientists and scholars who were in search of the truth would be exiled to new territories to find out the truth (read to perish) there. In such situations, Russian character was growing into Russian personality.

At the dawn of the Soviet Psychology, three trends appeared as a result of Lev Vygotsky’s Group’s Scholars scientific activities toward a Soviet Cultural Psychology. Among them, only Vygotsky had the prior understanding of Marxism (Cole 1996; Cole and Scribner 1974). Vygotsky’s Marxism was much more sophisticated than that of the people around him. Vygotsky was developing an unequalled insight into Marx’s critical methodology. Vygotsky began a new Russian Psychology by asking, “What is the subject matter of Psychology?” The same dilemma is being discussed in contemporary Russian culture.

Psychoanalysis

JAAP BOS

Utrecht University, Utrecht, The Netherlands

Introduction

Psychoanalysis, Sigmund Freud's (1856–1939) life work, was one the last and also one of the greatest systematic attempts to construct a general theory in social sciences, encompassing what is now called clinical and cognitive psychology, aspects of anthropology and sociology, as well as psychiatry and even unrelated fields of literature and art. As such, as a general theory of man and culture, it is a thoroughly modernistic endeavor, firmly embedded in late-nineteenth-century Romantic world view while it also has roots that go back to Enlightenment philosophy.

The term “psychoanalysis” was used for the first time in print in two papers that appeared almost simultaneously in 1896, where it has a limited connotation only, namely referring to a clinical method to treat patients suffering from hysteria. However, at the time of Freud's death, a good 4 decades later, the word “psychoanalysis” referred to what W.H. Auden aptly called “a climate of opinion” – not just a scientific method nor a particular world view but a “cultural orientation.”

Psychoanalysis started as a scientific enterprise in the margins of medicine in the first decade of the new century, brought about by the publication of a series of books covering a wide range of psychological subjects. At first it was little more than a small discussion group at Freud's home address, but it gradually developed into what eventually became known as the International Psychoanalytic Society. From its popularization during the years in between the wars, to the founding of the first specialized journals and the establishment of specific training practices, all outside academia, to the great exodus of European analysts just prior to the Second World War, the growth and partial transformation of psychoanalysis and the gradual decline of the “talking cure” due to, among other factors, long judicial battles over whether laymen should be able to get access to the profession as well as the growing influence of medicine in psychiatry. In short, the twentieth

century has seen the rise and fall of psychoanalysis as a “paradigm.”

Overviewing psychoanalysis as a “grand discipline,” a common distinction is followed, differentiating between (a) psychoanalysis as a “movement,” implying processes of institutionalization and popularization; (b) psychoanalysis as a scientific theory, characterized by different phases and developments; (c) psychoanalysis as a therapeutic endeavor, which includes not only a systematic method of treating patients but also aspects of training and schooling, and (d) psychoanalysis as a cultural factor or influence upon society at large (see Moscovici 1961 for an early and still very interesting analysis of psychoanalysis as a sociological phenomenon).

The amount of literature on all four aspects is, however, so immense that it would be impossible to even begin to summarize the most important sources, let alone present a complete picture. Instead a general historical account of the development of psychoanalysis is presented, from its beginning to the death of Freud, with brief references to the years thereafter. The reader is referred to the most important sources that allow further study in all four domains. No original perspective or new interpretation of psychoanalysis is offered. Also, this entry does not cover Freud's biography or any of his followers in any detail (but see elsewhere in this Encyclopedia), nor does it deal extensively with all the later developments in psychoanalysis or the many theoretical hairsplitting that were to follow later. Finally, it does not offer technical explanations of psychoanalytic terms (but see Laplanche and Pontalis' excellent work *The Language of Psychoanalysis* (1988) for brief encyclopedic entries on all the various terms), nor does it offer philosophical or other detailed discussions or critiques. References to Freud's works are to the *Standard Edition* (SE), in English, edited by Strachey et al.

Preparatory Years 1873–1897

Evidently, the early history of the psychoanalytic movement coincides with Freud's own biography. Of the at least two dozen biographies or so that have appeared on Freud, Jones' three volume *The Life and Work of Sigmund Freud* (1953–1957) remains authoritative, despite all the criticism that has been leveled against it. Ronald Clark's (1980) more popular volume and

Peter Gay's (1988) impressive more recent account offer additional insightful studies; the latter is especially mentioned for its rich bibliographical essay that very briefly discusses a huge amount of biographical literature.

Freud was a Jew, born in the second half of the nineteenth century, in a very distinctive cultural and political climate and raised in a very distinctive city (Vienna) of a very distinctive empire. A bourgeois, anti-Semitic culture, parred with a positivistic scientific climate defined the parameters of psychoanalysis (see Schorske 1981, for a very detailed picture of political and cultural fin-de-siècle Vienna).

At the age of 17, Freud entered the University of Vienna in 1873 and joined the medical faculty. He was supervised by physiologist Ernst Wilhelm von Brücke and studied with Prof. Karl Claus, a Darwinist, which both left a lasting impression of Freud (see Ritvo 1990). In his *Lectures on Physiology*, Brücke proposed the radical view that the living organism is a dynamic system to which the laws of chemistry and physics apply: This is often considered the starting point for Freud's dynamic psychology of the mind and its relation to the unconscious (see Bernfeld 1944).

Indeed, the influence of Brücke upon his development was considered "significant" by Freud himself, who thought of him as one of the two first teachers in his field (the other being Brücke's assistant, Ernest Fleischl-Marxow, but in the background there were others such as Helmholtz and de Bois Reymond). It was also Brücke who advised Freud to abandon laboratory work as there would be no assistant's post for him (whether this was due to Freud being a Jew or not is subject of discussion), even though he aspired to continue working in this discipline. Freud followed Brücke's advice and entered Vienna's principal hospital, the *Allgemeine Krankenhaus* as an "aspirant" or interne. There he met psychiatrist Theodor Meynert, who would become the next great influence upon his intellectual development.

Under Meynert, Freud proceeded to study the central nervous system of the human and published several works on organic diseases of the nervous system. Interests in the neurological effects of cocaine resulted in a number of experimental studies, published in the years 1884–1887, in which Freud himself served as his own test subject (none of these studies are included in

the *Standard Edition* or the *Gesammelte Werke*). Allegedly also, as a result of his experimentations, Freud developed a cocaine addiction, which according to E.M. Thornton (1984) would explain his excessive interest in sexuality (being a symptom of this substance abuse). This somewhat preposterous thesis is mentioned only as one of the many examples to "explain away" psychoanalysis using details from Freud's biography.

By October 1885 Freud went to Paris on a traveling fellowship to study with Europe's most renowned neurologist and researcher of hypnosis, Jean Martin Charcot. He would later remember the experience of his stay with Charcot as "catalytic" in turning him toward the practice of medical psychopathology and away from a less financially promising career in neurological research. Upon return, in 1886, Freud married his fiancée Martha Bernays and settled as a private practitioner specialized in nervous diseases. At this time, presumably as a result of his work at the Children's Hospital, where he noticed that many aphasic children had no organic cause for their symptoms, Freud became aware of the existence of mental processes that were not conscious. He wrote a monograph about this subject (also not included in the *Standard Edition*).

Contact and subsequent friendship with physician Joseph Breuer (1842–1925) dating back to the late 1870s and a shared interest in hypnosis, resulted in collaboration on the problem of hysteria which led to a first joint publication in 1893, followed by *Studies in Hysteria* in 1895 (*SE 2*), now often considered the first psychoanalytic publication, even though it contained only the germs of some psychoanalytic ideas. In *Studies in Hysteria*, Breuer and Freud claim that what hysterics suffer from are their reminiscences – their unconscious memories.

By the mid-1880s, the term unconscious, which was previously associated with unawareness, took on a new meaning – it referred to a part of the mind beyond conscious awareness. The unconscious was a Pandora's box of traumatic memories, taboos, sexual desires, and shameful feelings that the individual refused to reveal because of fear of humiliation or condemnation. Freud, while collaborating with Breuer, turned his attention to his patients' sexual history and fantasies, with a view to understanding how childhood traumas, buried in the

unconscious, could lead to neurosis in adulthood. Tragically, Freud believed, was inherent in the human condition, the consequence of an irresolvable conflict between man's instinctual sexual nature and demands of civilization.

Cure, or at least relief from symptoms, seemed to be brought about when patients began to speak about their illness, as Breuer had discovered when he treated a hysterical patient named "Anna O" (real name Bertha Pappenheim) in 1880. Treatment thus depended upon the ability of patients to reveal their unconscious thoughts and feelings, hence the name "talking cure." The cure required some method of discharge or "abreaction" of build up psychological tension (Breuer used the term catharsis).

It was Freud who had convinced Breuer to publish the case. Thus, Anna O became the first psychoanalytic patient. She was never treated by Freud and it was not before long that Freud became increasingly critical of Breuer's treatment of Anna O, arguing that he had disregarded the affectionate feelings of his patients toward him.

The history of Anna O has given rise to a remarkable amount of debate among historians. There seems to be much uncertainty about the Anna O's actual condition as well as about the extent of her clinical improvement following Breuer's treatment. It was conformed that despite Breuer's "cure," she was admitted to a sanatorium shortly thereafter (see Borsch-Jacobsen 1986, for literature on Anna O).

And so, by the time *Studies* came out, the collaboration between Freud and Breuer has already begun to deteriorate. Freud now also put much more emphasis on sexuality as one of more fundamental contributing factors in the etiology of hysteria than Breuer, which was another cause of dissent (see Sulloway 1979, for an excellent discussion of Freud's early work and thinking).

Still heavily vested in biological thinking, Freud undertook at this point in his career an attempt to conceptualize theoretically a radical new approach within psychology, which resulted in the abandoned *Project for a Scientific Psychology* (SE 1), in which Freud had wanted to create a science of the mind on an epistemological par with medicine, with the same useful applications as medicine (Flanagan 1987). The *Project* was not to be published for a long time and in fact addressed to one reader only, the Berlin nose and throat

specialist Wilhelm Fliess (1858–1928) whom Freud had encountered in 1887 and began corresponding with that same year. Freud's relationship with Fliess is one of the most significant early influences on Freud at this point in his life. He was, says Gay (1988), the necessary friend and enemy Freud needed to develop his own ideas ("my alter," Freud wrote to Fliess). For several years, they would have regular meetings which Freud jokingly called their "private congresses," during which they would discuss scientific issues (see Farrell 2001, for an interesting analysis of the creative dynamic in the relation between Freud and Fliess).

The *Project*, retrieved from their correspondence and first published in 1950, already contains in rudimentary form a number of important psychoanalytic distinctions, notably between a perceptual system of neurons, an unconscious system, in which most of our mental life takes place, and a consciousness inducing system. The *Project* was not meant to be published however, and was left unfinished. Clearly, Freud was struggling with a fairly mechanical and still very biological conception of psychological mechanisms. Thus, in the introduction to the *Project*, the editors wrote "internal forces are scarcely more than secondary reactions to external ones. The id, in fact, is still to be discovered." The *Project* marks the end of the first phase in Freud's development.

Early Beginning and Self-Analysis 1895–1902

Midway the 1890s Freud's conception of hysteria began to change. In a now famous letter to Fliess dated September 21, 1897, Freud sums up his reasons for abandoning the "seduction thesis," his earliest theory to explain hysterical symptoms. That letter also contains his main arguments for postulating a much more psychological theory. To a certain extent, this marks the birth of psychoanalysis as it is commonly known.

When Freud, following Breuer, first began to use the "talking cure," his patients would "remember" incidents of having been sexually seduced in childhood. Until this point, Freud believed that they had actually been abused, only to later repress those memories. However, as Freud now wrote to Fliess, he believed this first theory had become untenable. As a result of his work with his patients, Freud learned that a majority of his patients complained of sexual

disturbances, many having to do with coitus interruptus as a form of birth control. He suspected their problems stemmed from cultural restrictions on sexual expression and that their sexual wishes and fantasies had been repressed. So rather than actual experiences, internal or psychological processes seemed to be at play.

Between this “discovery” of the unexpressed sexual desires and the relief of the symptoms by abreaction, Freud began to theorize that the unconscious mind had determining effects on hysterical symptoms. This then marks the birth of “modern psychoanalysis.” This introduction of a qualitative factor (as opposed to a quantitative or purely neurological factor) would alter the theory of neurosis and consequently also the therapeutic procedure involved, as well as the method of research (see Ellenberger 1970, for an extensive discussion of the roots of psychoanalysis).

It is still in the late 1890s when Freud began to work on his Magnum Opus, his book on dreams, while at the same time his relationship with Fliess began to deteriorate, due to scientific disagreements and issues of priority. Just as with Breuer, this break too upset Freud, and although it is difficult to estimate exactly how traumatic this break was to him, it has been argued that after the loss of Fliess, Freud did not dare to fully trust another person again (with the possible exception of Jung). His years of “splendid isolation” now began: a creative period of relative seclusion (Freud did have a small teaching position as a *Dozent* at the Vienna university but was otherwise cut off from Academia) during which his most important works were written (see Ellenberger 1970, who argued that this period represented a “creative crisis” in Freud’s life).

The beginning of the end of Freud “splendid isolation” is marked with the publication, in 1900, of *The Interpretation of Dreams* (SE 4/5), a work with tremendous scientific pretensions. This book can be (and often is) considered the first “real” psychoanalytic publication since it capitalizes on (a) the relation between manifest and latent content (of dreams), (b) the use of free associations to explore unconscious mechanisms, and (c) the symbolic nature of innocent representations.

Indeed, to this day, this book remains a key publication in Freud’s oeuvre. It has been updated by Freud several times with each new edition. Interestingly, the

author opens *The Interpretation of Dreams* with a statement about his theoretical accomplishment:

- ▶ In the following pages I shall provide proof that there is a psychological technique which allows us to interpret dreams, and that when this procedure is applied, every dream turns out to be a meaningful, psychical formation which can be given an identifiable place in what goes on within our waking life.

He maintains as one of his key findings that dreams are never meaningless but always the fulfillment of a wish. He provides ample examples of this principle, many of which are autobiographical. Thus in the famous dream of “Irma’s injection,” Freud explains that each element in the dream is meaningful and that the main instigating force for it was a wish to absolve himself from any blame for the lack of complete success in the treatment of Irma’s condition. Later reinterpretations have traced this dream back to Freud’s traumatic break with Fliess (see especially Masson 1984, who proposed the controversial thesis that Freud’s rejection of the “seduction theory” actually meant a conscious subversion of the truth).

The main claim in *The Interpretation of Dreams* is that dreams, far from being meaningless, are in fact “constructed by a highly elaborate intellectual activity.” What appears to be trivial nonsense in a dream, can, through the process of analysis, be shown to express a coherent set of ideas. This goes for anxiety dreams, absurd dreams, and nightmares as well as ordinary dreams, which all are believed to be expressions of unconscious desires. Freud explains that the process of “censorship” in dreams causes a distortion of the dream content while the forgetting of dreams serves the purpose of resistance. These examples of “dream work” illustrate that the mind condenses, distorts, and translates (latent) “dream thoughts” into (manifest) dream content. Freud therefore proposes that the ultimate value of dream analysis may be in revealing the hidden workings of the unconscious mind.

Since so much of the material in *The Interpretation of Dreams* is in fact autobiographical, this book is considered Freud’s self-analysis. Thus Freud was not only the inventor of psychoanalysis, he was also his own therapist. The consequence of which was that in order to become a psychoanalysis, one had to appropriate Freud – his language as well as his history.

The first edition of *The Interpretation of Dreams* did not sell well: It took some 10 years before a second edition would be needed, a fact that Freud took as a sign of neglect by the scientific community, which he both resented and took pride in. Indeed, Freud's approach was deliberately "marginal," in terms of both scientific objects (dreams) and its interpretative methodology. He complains in the second edition that colleagues in psychiatry did not take the trouble to read his book because his ideas were so "new." This ambiguous, equivocal stance toward mainstream sciences characterizes its discourse, which in several ways is unique, both stylistically (see Mahony 1987) and rhetorically (see Jaffe 1990).

Interestingly, one of the great myths surrounding Freud is that he was forced to move outside academia because he was ignored by academic psychiatry. However, historic research shows that the reverse is true. Freud was already largely outside the scientific world when he wrote this book, which in fact was received quite constructively, although also somewhat critically (see Decker 1977 and especially Sulloway 1979). Thus right from the start, psychoanalysis would be characterized by a constant dynamic of inclusion and exclusion, defense and offense, attempts to persuade and at the same time fend off outsiders (see Bos et al. 2005). Consequently, long after Freud's death, debates on psychoanalysis were still caught in the extremely polemical "if you're not for it, you're against it" mode (see Frosh 1997, for a refreshing attempt to escape this dichotomy).

Formative Years 1902–1910

With the foundations of his new approach published in 1900, Freud began to produce a series of volumes that applied his method to other domain. Of these *The Psychopathology of Everyday Life*, published in 1901 (SE 6) and his book on jokes from 1905 (SE 8) stand out. The first is an attempt to explain common (everyday life) unintentional occurrences, such as slips, errors, mistakes, the forgetting of names or words, etc., by applying the same psychological processes that determine the unconscious which are also to be found in dream life. This book is one of the most accessible and frequently translated of his volumes, and indeed, since it is so easily readable it would fulfill the purpose of bringing the gospel to both the laymen and to the

professional. Freud wrote "this book has an entirely popular character; it merely aims, by an accumulation of examples, at paving the way for the necessary assumptions of unconscious yet operative mental processes, and it avoids all theoretical considerations on the nature of this unconscious."

His psychopathology book is something of a cross-over between psychiatry and cultural studies, making it difficult to situate it in the scholarly academic structure which was still, generally speaking, a conventional structure. Consequently, it attracted little attention during the first few years of its existence. When Freud expanded its text and published it as a book 3 years later, Theodor Ziehen, a leading expert in the field, said it deserved "many but critical readers" (quoted in Decker 1977, p. 143).

Central in the book is the analysis of a case of forgetting of the "aliquis" in a poem by Virgil. The case has been analyzed and reanalyzed endlessly (see Timpanaro 1976, for a detailed discussion). It presents the reader with two elements: an autobiographical story presented in the form of a riddle (What is the next word in Virgil's *Aeneid* and why can't I remember?), as well as an explanation/resolution presented in the form of a confession (a psychological complex, a certain wish, resistance to something). It is important to note that at his point in history, none of his ideas were taken for granted, yet Freud was already certain that in 5–10 years' time, his "Psychopathology" would be considered *doxa*; such was his confidence in his own discoveries.

The book on *Jokes and the Relation to the Unconscious* sets out to investigate the underlying psychological meaning of jokes, which is, Freud claims, by and large almost always aggressive in nature. Again several unconscious psychological mechanisms are at work here, such as condensation, displacement, and representation, that allow the speaker as well as the listener to enjoy the joke without transgressing the cultural demands (and hence feeling guilty or embarrassed). The psychogenesis of jokes reveals that the pleasure in a joke is derived from a play with words or from the liberation of "nonsense" to protect that pleasure from being done away with criticism.

These two ground laying works, as well as his university lectures, attracted the interest of a small group of students who began to hold weekly informal

gatherings at Freud's office to discuss this "new psychology." These were Freud's first followers, who within a few years would form the Vienna Psychoanalytic Society (see Grosskurth 1991). Records of their meetings have been kept from 1906 on and were later published (Nunberg and Federn 1962–1975). Although many members were medical doctors, most were much more interested in cultural applications of psychoanalysis than in therapeutic possibilities, with which few had firsthand experiences. Not surprisingly, the very first psychoanalytic periodical to be published under Freud's editorship, the "Series on applied mental science" (*Schriften zur angewandten Seelenkunde*), ran exclusively literary and biographical studies, such as Freud's own study on *Delusions and dreams in Jensen's Gradiva* from 1907 (SE 9). Also, Freud, wary that psychoanalysis be absorbed by medicine, not only encouraged nonmedical applications of psychoanalysis, he strongly suggested that the practice of psychoanalytic therapy not be restricted to medical doctors only.

In the first decade of the twentieth century, psychoanalysis thus slowly emerged as a "scientific school." Among the most important early followers were Paul Federn, Eduard Hirschmann, Otto Rank, Wilhelm Stekel, and Alfred Adler, all from Vienna. Many would soon start to practice psychoanalytic therapy. The latter two furthermore edited from 1910 to 1914 a monthly journal (the *Zentralblatt für Psychoanalyse*) whose main function it seems was to disseminate psychoanalytic knowledge among a broader educated public. However, as the ideas and practices of many early followers differed from Freud's in a number of essential respects, significant friction would occur before long (see Bos and Groenendijk 2007 for a discussion of the friction between Freud and Stekel).

While the first expansion of psychoanalysis rested on the theory of dream interpretation and above all on literary and cultural applications, what was missing was a model of the development of the human mind. Freud made up for this lack with the publication of a theoretical exposition on the etiology of anxiety neurosis, neurasthenia, and psychoneurosis, published as *Three essays on the theory of sexuality* (SE 7).

Apart from *The Interpretation of Dreams*, the "three essays" are considered Freud's most important contribution to the human sciences. It too was revised and updated by its author several times. His aim was to

explain the origin of sexual "aberrations," such as "inversion" of sexual objects (homosexuality), fixations (including sadism and masochism), and other neurotic sexual preferences.

Freud proposed a model of psychosexual development that he theorized to be universally valid. He derived his model from ancient mythology and contemporary ethnography, although it appears to bear autobiographical observations as well. He wrote: "I found in myself a constant love for my mother, and jealousy of my father. I now consider this to be a universal event in childhood." The event Freud refers to here is known as "the Oedipus complex," perhaps Freud's most well-known "discovery." He recognized in the development of the dynamics of the mind a distinct pattern that follows certain stages. Each stage represents a progression into adult sexual maturity, characterized by the resolution of certain conflicts.

Thus, during the "oral phase" (first year) the child struggles with the conflict between protection and neglect; during the "anal stage" (years 1–2) between retention and letting go; and during the "phallic stage" (years 3–6) with gratification and guilt. The "Oedipus conflict" typically points to a basic problem that humans need to deal with: incest desire on the one hand, and the problem of repression on the other. Two further stages (latency phase and genital phase) characterize the development of the ego toward maturity.

The theory of developmental stages proposed in the "three essays" has been considered ground laying in developmental psychology, but has also been strongly criticized. Early attempts to confirm the theory were remarkably successful, but oftentimes biased and, in one case, fraudulent (the publication in 1921 of a diary of a young girl, by psychoanalyst Hermine Hug-Hellmuth, confirmed to the detail Freud's theory but was completely fabricated). Its neglect of female development and its one-sided emphasis on males ("phallocentrism") has led female analysts to propose a specific female sexuality, characterized by its own conflicts.

Freud's own work from this period includes furthermore two case histories. The first case history is *Fragment of an analysis of a case of hysteria* (SE 7), better known as the "Dora" case study, published in 1905. Eighteen-year-old Dora diagnosed with hysteria was

analyzed only briefly by Freud in 1900. The entire analysis rests on the interpretation of only two dreams by the girl (see Decker 1991, for a historical reading of the Dora-case). Although the cure itself was incomplete, the importance of the case history lies in the recognition of two important psychological mechanisms: resistance and transference. Resistance refers to an unconscious struggle or conflict in the mind of the patient, transference to the reproduction of that conflict in terms of new symptom produced or triggered by the treatment itself. Freud realized that these principles represented the two main tools with which an analyst has to work.

Two further case histories, both published in 1909, are *Analysis of a phobia in a five-year-old boy* (SE 10) and *Notes upon a case of obsessional neurosis* (SE 10). The first is a case of a phobic boy (“little Hans”), not treated by Freud himself. It contains some of Freud’s most important ideas on psychosexual developmental, in particular his notion of the Oedipus complex (the struggle in boys to compete with the father for the affection of the mother). The second case history (that of the so-called Rat man) outlines the intricate unconscious thought processes in obsession which at first glance do not seem to make sense but reveal a hidden logic.

From 1907 onward, Freud’s followership was expanded beyond Austrian boundaries when Swiss psychiatrist Eugene Bleuler (1857–1939), director of the psychiatric clinic Burghölzli, took an interest in psychoanalysis and began to encourage his staff to study unconscious and psychotic mental phenomena. Although Bleuler’s interest faded fairly quickly, by 1907 a regular contact was established between Freud and some of Bleuler’s students, most notably Franz Riklin and Carl Jung, who used word association tests to integrate Freud’s theory of repression with empirical psychological findings. Riklin and Jung were also the editors of the voluminous “Psychoanalytic Yearbook” (*Jahrbuch für psychoanalytische und psychopathologische Forschungen*), the first journal to publish psychoanalytic research, which appeared between 1909 and 1914.

Karl Abraham, then a student of Bleuler who later moved to Berlin, and Sándor Ferenczi of Budapest joined the growing body of followers that same year (1907), soon joined by Ernest Jones from England, Brill, Putnam, and Jelliffe from the USA, as well as

others in Holland, France, and Italy (see Alexander et al. 1966, for brief biographies of most early followers). By now, psychoanalysis was beginning to assume the properties of a “movement.” Bi-annual congresses, three periodicals, and a growing body of literature, not just by Freud but by his followers also, all securely placed outside academic circles, attracted the interest of the public and at least in literary circles, psychoanalysis became “fashionable.”

In 1909, Freud reluctantly accepted an invitation by G. Stanley Hall to receive an honorary degree at Clark University. His journey to the USA, in the company of Jung and Ferenczi, won him numerous new adherers there too but did not free him from his lifelong misgivings about America (Rosenzweig 1992). Freud’s influence on American “medicine” would nevertheless steadily increase (see Burnham 1967; Hale 1971).

Institutionalization and Consolidation 1910–1925

The founding of the International Psychoanalytic Association (IPA) in March 1910 at the Salzburg conference marks the beginning of a new phase in psychoanalysis. The first generation of followers had stood in close personal contact with Freud through both correspondence and face-to-face contact (many correspondences with Freud have now been published; they give an invaluable insight in the development of psychoanalysis). As their numbers grew, this type of informal management would no longer be possible and hence formal rules had to be introduced regarding admission to the society and to training practices. Therefore, in the next decade, psychoanalysis institutionalized its practices. To become a psychoanalyst, one had to go through a whole series of initiation rituals, including an authorized analysis by a training analyst (see Wallerstein 1998; Bos 2001).

The institutionalization of a “training analysis” during this phase, in which the analyst in training himself is analyzed by a senior analyst in order to get free from unconscious constraints, proved to be a singularly important constitutive principle in psychoanalysis. It safeguards transfer of psychoanalytic knowledge and allows it to remain “pure” at the same, since there runs a straight line from Freud, who had analyzed himself, to the first generation of analysts, many of whom had not been analyzed but instead

had received some form of personal instruction from Freud, to the third, fourth, and further generations.

Two issues related to the institutionalization of psychoanalysis emerge at this point. One is that immediately after the founding of the IPA, psychoanalysis began to expurgate “dissident” followers. Among the first were Alfred Adler, Wilhelm Stekel, and Carl Jung, who for different reasons would not adhere to the strict Freudian doctrine. Especially the loss of Jung is considered important, because Freud had hoped that he would succeed him (see the Freud–Jung correspondence edited by McGuire 1974). Jung was followed by a long list of dissenters who have been expelled from the movement at one point or another (these include Otto Rank, Wilhelm Reich, Jacques Lacan, and many others). Freud’s own polemical account of these early schisms was published in 1914 (SE 14).

A second development concerned the question of whether or not nonmedical analysts were allowed to analyze patients. The Americans in particular were against all forms of so-called wild (or non-medical) analysis, but Freud himself and several European analysts were not. After the Second World War, with a large parts of the psychoanalysts (many of whom were Jewish) having fled to the USA or England, the controversy would effectively be settled in favor of what Kurt Eissler (1965) called “medical orthodoxy” (see Wallerstein 1998 for an insiders’ perspective on the problem of “lay analysis”).

By the 1920s, to the public at large, psychoanalysis had become a respectable branch of science, thanks, in part, to Freud’s *Introductory Lectures* (ES15/16) which specifically addressed a lay public. Also the works of novelists such as Thomas Mann (*The Magic Mountain*, 1924) and Italo Svevo (*Confessions of Zen*, 1923) helped popularize psychoanalysis, as well as *Secrets of a Soul* (1925), a full-length feature film by the German film director Wilhelm Pabst, which took a psychoanalytic case history as its point of departure.

In theoretical respect, a series of papers by Freud, which appeared between 1914 and 1917, Ferenczi’s paper on introjection (1909) and Abraham’s technical papers, such as the one on the female castration complex (1920) signify the growth and development of psychoanalytic vocabulary at this point in time. For sure, a mature theory began to emerge, in which various theoretical notions were now well connected.

Freud’s paper on narcissism, for example, introduces the notion of ego-ideal and discusses the problem of ego-libido and object-libido. In “instincts and their vicissitudes” (1915), “Repression” (1915), and “The Unconscious” (1915) he now presented a systematic and coherent exposition of his psychological theories. Still utilizing an energetic system as proposed in the abandoned “Project,” Freud conceptualized in his paper on the unconscious the question of energy directed at the self versus energy directed at others. And in “Mourning and Melancholia,” which appeared in 1917 (SE 14), he suggests that certain depressions were caused by turning guilt-ridden anger on the self.

A second wave of theoretical papers appeared in the early 1920s and marks the final development of psychoanalysis under Freud’s auspices. Notably his works *Beyond the Pleasure Principle* (SE 18) and *The Ego and the Id* (SE 19), from 1920 to 1923 respectively, contain important improvements or elaborations of his theoretical framework. *Beyond the Pleasure principle* introduces the notion of “pleasure principle” and “reality principle” as two vitally important mechanisms within the mental apparatus. *The Ego and the Id* distinguishes between the three main psychological dynamic systems “Id,” “Ego,” and “Super-ego” that replace the former distinction between conscious and unconscious. In this book, repression is now considered one of many defense mechanisms that occurs to reduce anxiety.

Not all of Freud’s new distinctions were immediately accepted by his followers. In particular, the notion of “death instinct” (borrowed from Swiss analyst Sabine Spielrein and introduced in *Beyond the Pleasure Principle*) was rejected by many, while the tripartite Id–Ego–Super-ego may have been widely accepted, but its use varied widely. Thus, later revisions of psychoanalytic therapy heavily emphasized the Ego-component, from which eventually “Ego-psychology” emerged, particularly strongly represented in the USA.

By the mid-1920s, psychoanalysis thus had evolved in a formal society, a full blown theory, a standardized practice with its own rules of admission and training. It had its own press (a publishing house, several journals), was recognized by the public as a serious scientific school and had now also a footing in academia, notably in medicine, in many Western European countries.

Disintegration and Regrouping of Psychoanalysis 1925–1950

Among Freud's last major contributions are his papers on religion and questions of sociology. These are also his least accepted works. *The Future of an Illusion* (SE 21) and *Civilization and its Discontents* (SE 21), both described religion as a phase in evolution of mankind, eventually to be replaced by scientific thought (even though he remains pessimistic about the capacity of man to free himself from this collective neurosis). Several psychoanalysts, among whom Oskar Pfister, a close friend of Freud who wrote a rebuttal titled the *Illusion of a Future*, objected to such a pessimistic view.

In *Inhibitions, Symptoms and Anxiety* (SE 20), published in 1926, Freud laid out how anxiety is caused by an intrapsychic conflict between drive and super-ego and how anxiety may lead to a further inhibition of mental functions. *Inhibitions, Symptoms and Anxiety* was written partly in response to Otto Rank, an early follower of Freud who had proposed in *The Trauma of Birth* that separation anxiety plays a major role in the onset of neurosis. According to Rank, separation anxiety takes place at a developmental phase even before the onset of the Oedipus complex. This was impossible according to Freud, who saw the Oedipus complex as the nucleus of neurosis and the foundational source of all art, myth, religion, philosophy, indeed of all human culture and civilization. Rank's suggestion that the Oedipus complex might not be the only factor contributing to intrapsychic development led to an estrangement from Freud, who would eventually exclude him from the inner circle.

By the early 1930s, in Germany the Nazis climbed to power, which would cause many analysts (a majority of whom were Jews) to flee the country. Many settled in England and the USA. After the occupation of Austria (the so-called Anschluss) Freud too escaped, just in time; he ended up in England where he died in 1939.

In the years leading up to the Second World War, the psychoanalytic movement slowly began to dissipate, despite attempts to safeguard it from outer influences (a group of loyal followers around Freud's youngest daughter Anna Freud took it upon themselves to fence off any and all "intruders"). Both internal critique and emerging postwar demands led to a large number of neo-analytic schools, of which only the most important ones shall be mentioned briefly here.

A first group of neo-analysts, consisting of people such as Heinz Hartmann, Ernst Kris, David Rappaport, and Alexander Lowenstein, developed in the 1950s an approach known as "Ego-psychology," which became quite influential within psychoanalysis and to this day remains a dominant school therein. This group built upon an understanding of the synthetic function of the ego as a mediator in psychic functioning. Hartmann in particular distinguished between autonomous ego functions (such as memory and intellect which could be secondarily affected by conflict) and synthetic functions which were a result of compromise formation. Ego-psychology found a better fit in US culture than tradition psychoanalysis, as it presents a more optimistic, malleable picture of man.

A second school consists of female analysts who felt dissatisfied with Freud's one-sided emphasis on male sexuality. They argued that he had regarded females basically as "castrated males." Thus Karen Horney, Helene Deutsch, Therese Benedeck, and others, many of whom were trained in Germany and had emigrated to the USA in the 1930s, began to propound "neo-analytic" schools that explored questions of female sexuality and female development, sometimes also called "feminist Freudians." More recent authors would include Nancy Chodorow and Julia Kristeva (see Judith Alpert 1988 for an overview).

A third group of analysts is represented by Melanie Klein and her followers. She represents within psychoanalysis a school called "object-relations theory." In her work, emphasis is put on the development of the subject in relation to others within the environment. The "objects" the theory refers to are both real and internalized images of others. Object relationships are initially formed during early interactions with primary care givers (especially the mother). Today, Kleinian psychoanalysis is one of the major schools within psychoanalysis.

A fourth group of analysts, whose ideas and works have gained influence in the 1950s, consist of followers who have taken psychoanalytic interpretations into the domain of medicine proper. Georg Groddeck from Germany and Smith Ely Jelliffe from the USA and later also Franz Alexander are considered forerunners of what became known as "psychosomatic medicine." These theorists sought to establish a link between somatic and unconscious psychological processes.

Groddeck, to whom Freud owed the concept “id” (*das Es* in German), for example insisted that all bodily processes have a psychological counterpart (thus nausea represents the unconscious wish to get rid of something one cannot stomach, etc.).

From a political point of view, a group of left-winged analysts were attracted by the potentially liberating capacity of psychoanalytic doctrine, which they transferred to the domain of politics when they tried to combine Marxism with Freudianism. This group was initially represented by figures such as Otto Fenichel and Wilhelm Reich (who both immigrated to the USA), later by a group of sociologists from Frankfurt, notably Erich Fromm, Herbert Marcuse, Theodor Adorno, and others, who formed the “Frankfurt School of Social Research.” Some theorists (such as Fromm) remained fairly loyal to some of Freud’s principles, others, however, digressed far from psychoanalysis (see Robinson 1969, for an interesting discussion of the “Freudian Left”).

Finally, in France a radical new approach to psychoanalysis was offered by Jacques Lacan and later also Giles Deleuze and Felix Guattari, whose works have slowly gained influence outside of France (and reached their peak in the 1990s). Lacan (1977) integrates psychoanalysis with semiotics and Hegelian philosophy. He emphasizes the unconscious workings of linguistic processes (hence his famous saying that the unconscious is structured like a language). Deleuze and Guattari (1984) on the other hand have tried to match psychoanalysis with postmodern theory. Their works draw on Freudian theories but are at same time extremely critical of it.

Taken “orthodox” approaches together with all its various, sometimes contradicting approaches, the influence of psychoanalysis in the first 2 decades after the Second World War remained fairly considerable, especially in psychiatry. The first two editions of the *Diagnostic and Statistic Manual of Mental Disorders*, the leading sourcebook in psychiatry (DSM I and II, published in 1952 and 1968), are clearly marked by psychodynamic models of the mind inspired on Freud. In the 1960s, however, psychoanalysis was beginning to lose ground, as can be evidenced from the third edition of the DSM, published in 1980 and revised several times since.

Critique and Decline, post 1950

Psychoanalysis, both as a theory and a “movement” has always been subject of severe critique, within academia and outside of it, but it succeeded to survive until well after the Second World War. In the post 1950s, however, the Freudian empire slowly but surely crumbled and by the turn of the new century it has all but been abandoned, at least in its traditional form.

There are several reasons why psychoanalysis lost its appeal. One is that in the 1960s a new generation of much more effective medication hit the market, rendering psychodynamic approaches not only much more costly but also in fact less effective. Secondly, due to a series of judicial battles, nonmedical therapists (mostly psychologists) were finally allowed access to psychoanalytic training institutes in the USA, which in consequence meant a significant lowering of the status of the professional psychoanalyst. Lastly, several waves of critique attributed to its decline. Some of these critiques shall be discussed briefly below.

One of the first important postwar critics was Karl Popper (1990), who argued that psychoanalytic explanations are “unfalsifiable.” Its claims are not testable and therefore cannot be refuted; this makes psychoanalysis a “pseudoscience.” Similarly, Hans Eysenck (1985) strongly criticized the dogmatic and sect-like attitude of psychoanalysts, who anxiously refuse outsiders entrance into their circles and are afraid to enter into debate with them. Attempts from within hermeneutics to defend its scientific claims (Spence 1987) were unconvincing or only succeeded in moving psychoanalysis away from “hard core” sciences, into the domain of “literature.”

In the 1970s and 1980s a host of critical historical literature was published, set out to damage Freud’s reputation and, by implication, the reputation of psychoanalysis as a whole. This resulted in sometimes outrageous claims, such as that Freud was a cocaine addict, or in moral reproaches (for instance that Freud may have had an affair with his sister-in-law, etc.). Some of this “Freud bashing” continues to this day (see Crews 1995, for a more recent illustration).

A more serious attack was leveled by philosopher Adolf Grünbaum (1985), who argued that psychoanalytic claims to therapeutic success are based on circular reasoning. Thus Grünbaum demonstrates that when psychoanalysts claim that a particular therapeutic

intervention (an “interpretation”) can be shown to be effective on the grounds that it does something in the patient, it presupposes that such an interpretation actually may do something in the first place. Discussions following Grünbaum’s work reveal that psychoanalysis was unable to refute this charge.

Debates about the scientific status of psychoanalysis continue to this day, but the number of patients who submit themselves to classical psychoanalytic psychotherapy has diminished dramatically in many countries, even though many forms of psychotherapy are still being practiced, based, at least in part, on Freud’s ideas. However, use of psychoanalysis as a “scientific endeavor” today is effectively restricted to the domain of “cultural studies,” that is, as a form of literary critique. It thus ended where it started.

Psycholinguistics in Historical Perspective, From Monologue to Dialogue

DANIEL C. O'CONNELL¹, SABINE KOWAL²

A Perspective on the History of Psycholinguistics

In a recent article entitled “Recapturing a context for psychology: The role of history,” Benjamin and Baker (2009, p. 97) have stated:

- ▶ *With the ever-increasing fragmentation of psychology into narrower subspecialties, the field devolves further and further into a focus on specialized knowledge, answering smaller questions and avoiding the larger and more meaningful ones.*

Their complaint pertains to psychology in general, and the authors suggest that in order to regain a broader intellectual context, “an understanding of the history of psychological science offers a way.” In the following, we wish to take Benjamin and Baker’s lead and apply it to the subdiscipline of psycholinguistics. Our aim is to show that the historical development of psycholinguistics gives hope for a gradual perspectival shift both from an emphasis on the written to an emphasis on the spoken and from monological to dialogical language use.

Accordingly, we wish to inquire as to what psycholinguistics has been up to. Suffice it to say that mainstream modern psycholinguistics began in the mid twentieth century. But already by 1980, the “Quo vadis, psycholinguistics?” question was being posed by the Romanian psychologist Tatiana Slama-Cazacu (1980, p. 93), specifically in terms of “Should and can psycholinguistics contribute to the improvement of human communication?” Her answer was an emphatic affirmative: Psycholinguistics has both “the scientific methodological possibility” and “an obligation” to make such a contribution (p. 93). But more than a quarter of a century later, the German psychologist Theo Herrmann (2006, p. 420; our translation) has been less optimistic and has accordingly expressed his dissatisfaction that a “psychology of language use” (“Sprachpsychologie”) is currently not adequately engaged by psychologists, especially in Germany. In this context, he has asked an even more fundamental question than the one asked by Slama-Cazacu: “What is it about language that makes it so intractable for psychologists?” (p. 420; our translation). He has suggested that one reason for the inordinate intractability of language is that the term *language* has multiple meanings: What *language* means in any specific instance depends upon the *status questionis* proper to a given approach to the study of language use. This in turn is dictated by many contingencies – historical, sociological, and personal/biographical. Herrmann (p. 421; our translation) has spelled out three psychological perspectives: language as “a species specific mental faculty,” as “a process of speaking under neurological/physiological control,” and as “the most important vehicle for interaction between two or more people.” He has concluded that these three perspectives have not been integrated: “Psychologists of language use have not yet succeeded in developing a standard theory of language use that is adequately empirically based” (p. 422; our translation).

The present essay accepts the problematic nature of psycholinguistics itself as the central theme of its history and current development. More specifically, it emphasizes the gradual development of modern psycholinguistics from a preoccupation with language as “a species specific mental faculty” to an engagement of language as “the most important vehicle for interaction between two or

more people.” The history of neuropsycholinguistics will not be engaged herein (but see, e.g., Altmann 2006).

Early History of the Psychology of Language Use

In fact, a great deal had already been written about language use before the mid twentieth century. On the one hand, some authors emphasized the social aspects of language use. Thus, Moritz Lazarus (1879/1986, p. 5; our translation), founder, along with Heyman Steinthal, of the *Zeitschrift für Völkerpsychologie und Sprachwissenschaft* in 1859, was already urging the psychological investigation of “everyone’s actual, everyday, ever present conversation,” and Wilhelm Wundt continued to promote a sociocultural approach to language. In fact, according to Clark and Van der Wege (2002, p. 209), “psycholinguistics was launched in 1900 with the publication of Wilhelm Wundt’s *Die Sprache (Language)* as the first two volumes of his monumental *Völkerpsychologie*.” It is interesting to note that Blumenthal (1970, p. 7) considered Lazarus and Steinthal’s *Journal of Social Psychology and Linguistics* (his translation of *Zeitschrift für Völkerpsychologie und Sprachwissenschaft*) “the first journal largely devoted to the psychology of language” (for a thorough discussion of the German contributions from 1850 to 1920, see Knobloch [1988] and the English-language review of his book by Murray [1990]).

On the other hand, the general psychology or *Allgemeine Psychologie* of the second half of the nineteenth century was also rich in language studies. By way of contrast, Cattell (1886) was studying individual words in experimental reading settings, and Ebbinghaus (1885/1964) was investigating memory by means of consonant–vowel–consonant trigrams. A wide diversity of research topics seems to have been characteristic of the nineteenth century, and, according to Gaskell (2007, p. v), still survives in the twenty-first century, with notable differences consequent upon technology, methodology, and theoretical orientation.

But much of the early work was still being done outside of psychology. For example, in the first half of the twentieth century, most of the review articles were published in the *Psychological Bulletin*: Faris (1919), Esper (1921), Adams and Powers (1929), McGranahan (1936), and Pronko (1946). The first of these (Faris 1919) on “The psychology of language” cited

only three references, two of which had appeared in French philosophical journals. Two years later, Esper (1921) cited under the same title 17 references, all but two (12%) of which were from other disciplines than psychology: education (5), linguistics (3), communications (3), biology (2), philosophy (1), and anthropology (1). It was not long before the recognition dawned that research on the psychology of language “demands a type of investigator trained in both linguistics and psychology” (Weiss 1925, p. 57); in other words, the collaboration of psychologists and linguists or other language experts was not considered to be the ideal. The need for linguistic sophistication on the part of psychologists of language themselves is reflected over a number of decades in the three following review articles (Adams and Powers 1929; McGranahan 1936; and Pronko 1946). Therein, a successive decline from a high of 82% in cited references that clearly belong to the psychological literature – a huge and sudden increase over Esper’s (1921) low of 12–64% and then to 56% – was paralleled by an increment in references to linguistics from 11% to 18% and again 18%. This increment also set the stage for a major historical incursion from linguistics in the form of transformational grammar that would notably contribute to modern mainstream psycholinguistics.

Historical Beginnings of Modern Psycholinguistics

At mid twentieth century, World War II was over, behaviorism wasn’t going anywhere, and researchers were regrouping. To expedite the process of transition on the part of both psychology and linguistics, the Social Science Research Council established in the United States a Committee on Linguistics and Psychology in October, 1952 (in association with summer seminars at Cornell University in 1951 and at Indiana University in 1953). Thus, 1952 came to be considered in the course of time as the moment of conception for modern psycholinguistics. Knobloch (2003, p. 19; our translation), in his German-language history of psycholinguistics, has referred to these events as the “founding myth” of the discipline and to the publication resulting therefrom (Osgood and Sebeok 1954; 1965) as the “acknowledged ‘founding document’ of the new psycholinguistics.” But Knobloch himself was of the opinion that the history of psycholinguistics had

begun long before, and Altmann (2006), in his recent history of psycholinguistics, has mentioned neither the committee and seminars nor the Osgood and Sebeok publication.

The task proposed by the Social Science Research Council's committee in their initial seminar is worthy of our attention:

- ▶ The seminar first set itself to the task of examining three differing approaches to the language process: (1) the linguist's conception of language as a structure of systematically interrelated units, (2) the learning theorist's conception of language as a system of habits relating signs to behavior, and (3) the information theorist's conception of language as a means of transmitting information. (Gardner 1965, p. x [originally dated May 12, 1954])

In retrospect, this listing may not appear to be the most promising with which to launch a new scientific discipline, but it reflected both the zeitgeist and the cross-disciplinary constitution of the committee quite accurately: (1) structural linguistics; (2) behaviorist and neo-behaviorist psychology; and (3) information theory. The first author of this chapter personally recalls some of the denunciations of behaviorism (for its naivety, reductionism, and/or oversimplifications) heard from the lips of J. S. Bruner, G. A. Miller, and C. E. Osgood a decade later as they moved on into the new psycholinguistics. During the early formative period, a review article by G. A. Miller (1954) entitled "Communication" reflects his own orientation toward communication and information theory at that time. It is of historical interest to note that Miller criticized therein a variety of theoreticians, including Jakobson, Osgood, and Shannon, for their "attempts to optimize something" (p. 418). And he added that such a normative approach "makes many psychologists uncomfortable" (p. 418). However, he was soon to become the leading psychologist proponent of the new transformationalism with its emphasis on yet another normative approach to language use, namely the ideal speaker and listener. And this new orientation on his part was in its own turn to make many psychologists uncomfortable.

Diebold's (1965, pp. 205–291) "A Survey of Psycholinguistic Research, 1954–1964" pinpointed with multiple (>6) citations who the leaders in early psycholinguistic research were: Roger Brown (10),

John B. Carroll (12), Noam Chomsky (10), Eric Lenneberg (12), George A. Miller (18), and Charles E. Osgood (10) – one from the Midwest of the United States (Osgood from the University of Illinois, Champaign-Urbana) and the rest from East Coast institutions, Harvard University and Massachusetts Institute of Technology; all of them psychologists, except for Chomsky; none from outside the United States. Miller (1965, p. 306) also acknowledged: "My own opinions have been strongly influenced by Noam Chomsky." More specifically, Miller adopted a psychological generative or transformational hypothesis to the effect that generative structures of language are paralleled by psychological processes. The German psycholinguist Hans Hörmann (1986, p. 63) expressed this hypothesis as follows:

- ▶ At a certain period of its development psycholinguistics considered it to be its task to prove, by means of research into performance (only this can be examined by empirical research), the "psychological reality" of processes and concepts which had been postulated by linguistic competence theory.

The hypothesis itself came in the first instance not from empirical psychological evidence, but from a theoretical claim of one school of linguistics. Although it then elicited a great deal of empirical research, eventually it had to be abandoned for lack of empirical evidence, but seems to be still very much alive in mainstream psycholinguistics even in the twenty-first century (see below the section on [A Return to Dialogue in the Twenty-First Century](#)).

Meanwhile, an emphasis on the use of grammatically well-formed sentences in written experimental materials continued to grow unabated on the part of psycholinguists. And Chomsky (1968, p. 84) was arguing that linguistics is a subdiscipline of cognitive psychology. Chomsky (1965, p. 3) had actually proclaimed the subdiscipline several years earlier:

- ▶ Linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogeneous speech-community, who knows its language perfectly and is unaffected by such grammatically irrelevant conditions as memory limitations, distractions, shifts of attention and interest, and errors (random or characteristic) in applying his knowledge of the language in actual performance.

But from the very beginning, this linguistic concept of the ideal speaker was totally unrealistic from a psychological point of view insofar as it explicitly excluded precisely the *psychologically* relevant conditions of all language use. In historical perspective, then, it is no less than astounding that it became the model for the psycholinguistic concept of the ideal delivery in what was to be the most successful textbook in the psycholinguistics of that time: Clark and Clark's (1977) *Psychology and language: An introduction to psycholinguistics*. According to Clark and Clark, the "ideal delivery" (p. 261) was executed by someone who read a revised written text aloud – without speech error, without hesitation, and without turn-taking. Or to put it in other words: The ideal which determined what was to be considered defective speech included a written text, its fluent performance by reading it aloud, and monologue. Small wonder that Hörmann (1981, p. viii) was led to exclaim that generative linguistics "has nothing (or practically nothing) to tell us about the actual processes of meaning and understanding." It should be added that, in their preface, Clark and Clark (1977, p. vii) had acknowledged that "the primary use of language is for communication. Curiously, this fact has played practically no role in previous treatments of the field." Unfortunately, their own treatment did not succeed in engaging "people's aims in communicating with one another" and hence was unable to "correct this imbalance."

Historical beginnings and indeed the further development of psycholinguistics have been recorded in a notably disparate manner from publication to publication. As noted above, Knobloch's (2003) and Altmann's (2006) histories of psycholinguistics strikingly exemplify this phenomenon. A similar historical anomaly has occurred in psycholinguistic textbooks, wherein overlap of archival references has been quite minimal. For example, O'Connell (1988b, p. 347) reported that, across five textbooks of the 1980s, only six references were common to all: "Bever (1970), Chomsky (1957, 1965), Fromkin (1971, 1973), and Sachs (1967)." O'Connell and Kowal (1997, p. 851) found an additional discrepancy: Whereas Clark and Clark (1977), in the first major textbook in psycholinguistics, had referenced all six of these common sources, H. H. Clark (1996b) referenced none of them. Perhaps even more important in this regard is the title given by

Clark to his more recent book: *Using language*. Therein, he no longer used the term *psycholinguistics*, but instead *language use*. The theoretical and methodological implications thereof will be discussed below in the section on Clark.

Growth of Modern Psycholinguistics

The origin of the term itself – *psycholinguistics* – is dated by Miller (1965, p. 293) as about 1954, but it had already been used without further explanation almost two decades earlier by Kantor (1936, p. 55), who included in his book a section heading "The Psycholinguistic Situation Analyzed," and later by Pronko (1946), himself a student of Kantor, as part of the title of his (Pronko's) review. It is of historical interest that both these scholars were dedicated behaviorists.

Despite or perhaps partly because of its pretentiousness, the designation psycholinguistics stuck. Journals incorporated it (e.g., *Journal of Psycholinguistic Research* from 1972 on, *International Journal of Psycholinguistics* from 1974 on, and *Applied Psycholinguistics* from 1980 on), and the Max Planck Institute for Psycholinguistics was founded in Nijmegen in 1980.

In a certain sense, the term *psycholinguistics* itself contains an important lesson: *Linguistics* is the substantive portion of the term, and the *psychological* component is adjectival to it. It is not surprising that such an approach found its empirical hypotheses about language in linguistic rather than psychological theories. There are actually three common terms currently in use: psychology of language, psycholinguistics, and psychology of language use. Whereas psychology of language and psycholinguistics are typically used synonymously (e.g., Harley 2008), some authors distinguish between terms. For example, Herrmann (2006, p. 419) has considered psycholinguistics ("*Psycholinguistik*") to be a subdiscipline of linguistics, whereas he has thought of the psychology of language use ("*Sprachpsychologie*") as a subdiscipline of psychology.

During the first half of the twentieth century, periodical articles (listed above) entitled "The Psychology of language" were published in the *Psychological Bulletin*: Faris (1919), Esper (1921), Adams and Powers (1929), and McGranahan (1936). A fifth review by Pronko (1946) was entitled instead "Language and psycholinguistics: A review." It included the most numerous reviews in this set of five articles and

presented a thoroughly behaviorist approach to the topic of language use.

In the second half of the century, periodical articles entitled “Psycholinguistics” or some more specific expansion thereof were published in the *Annual Review of Psychology*: Rubenstein and Aborn (1960), Ervin-Tripp and Slobin (1966), Fillenbaum (1971), Johnson-Laird (1974), Danks and Glucksberg (1980), Foss (1988), and Bates et al. (2001). They span a period from 1960 to 2001 – the last year in which psycholinguistics appeared as a separate topic in the *Annual Review*. An analysis of the publication dates of the references in the reviews yielded a clear indication of the heyday of psycholinguistics: The 1960s were the decade of most productive research. The emphasis in the respective reviews, as indicated by their titles, has shifted over the years from “Psycholinguistics” (Rubenstein and Aborn, Ervin-Tripp and Slobin, and Fillenbaum), to “Experimental psycholinguistics” (Johnson-Laird, Danks and Glucksberg, and Foss), and, finally, to “Psycholinguistics: A cross-language perspective” (Bates et al.).

The three reviews written in the 1960s and at the beginning of the 1970s have in common the title “Psycholinguistics.” But their conceptualizations of the discipline are quite different from one another, in keeping with the shifting zeitgeist. Rubenstein and Aborn (1960, p. 291) were clearly influenced by behaviorism:

- ▶ Psycholinguistics is not a well-integrated field of study, and one can hardly speak of anything like a general trend in the field as a whole. Nevertheless, a number of studies concerned with the probability of language segments and with word association have brought forth a point of view which stresses the significance of the concept of response hierarchy in interpreting the subject’s performance in various verbal tasks.

A dramatic shift in emphasis is to be noted 6 years later in Ervin-Tripp and Slobin’s (1966) review. Although they still contended, as had Rubenstein and Aborn (1960) before them, that psycholinguistics seems to be “a field in search of a definition” (p. 435), their own definition of the field clearly reflects the influence of transformational linguistics: “the study of the acquisition and use of structured language” (p. 435). Accordingly, their review began with a section on Language Acquisition, followed by sections on Grammar and Verbal Behavior, Linguistic Perception, Internal Language

Functions, and Biological Bases of Language. In addition, they included sections on Extralinguistic Phenomena and Sociolinguistics, topics that were not taken up again in the later reviews. This exclusion parallels the gradual introduction of the topic of “Experimental psycholinguistics” as a narrowing movement in the discipline. The Ervin-Tripp and Slobin review can therefore be looked upon as a bridging moment in the history of modern psycholinguistics – retrospective with regard to behaviorism (e.g., Verbal Behavior), while also prospective with regard to the inclusion of extralinguistic and sociocultural topics.

Only 5 years later, Fillenbaum (1971) became the first of these reviewers to take a rather critical stance toward the development of psycholinguistics. He pointed out the difficulties faced by a psychologist who attempts to use a linguistic model: “Shall it be a phrase structure model of the sort presented by Yngve. . . , a stratificational model in the spirit of Lamb. . . , a transformational model after Chomsky. . . , or what, and what difference will a particular choice make?” (p. 253). And he added with respect to the revisions of models developed by Chomsky: “To the extent that psycholinguistic work is based on some linguistic formulation, it may be embarrassing or likely much worse, to find that linguists have now rejected that formulation, making very difficult indeed the interpretation of any result” (p. 254). In view of later reviews, it is of interest that Fillenbaum included a rather long section entitled Experimental Psycholinguistics. Therein, he clearly expressed his concerns about the perspective taken by the experimentalists with respect to language:

- ▶ The view of language which has been focal in recent research, perhaps just because contemporary psycholinguistics has been so strongly influenced by work in generative grammar, is one of language as idea, knowledge, or mental structure, largely or entirely abstracted from its setting, from problems of communication particularly in, say, the context of dialogue, and without much serious worry about normal temporal constraints. Obviously such a view of language concerned principally with the perception of and memory for short stretches of monologue excised from any setting and without continuity, to caricature a little (but only a little) is far from being the whole story, and there have been protests, perhaps most vigorously by Rommetveit. (p. 276)

In a similarly critical vein, he warned researchers about unwanted side effects of experimentation:

- ▶ We should be alert to the possibility that the results of some (perhaps much) experimental work may be as much a consequence of special ad hoc strategies adopted for coping with particular laboratory tasks as of anything else, and that often subjects may not at all be dealing with what we want them to deal with, and what we think they are dealing with. (p. 277)

With the 1974 review of Johnson-Laird, there occurred a shift in title from “Psycholinguistics” to “Experimental Psycholinguistics.” Accordingly, a focal limitation to “comprehension and its cognate problems” (p. 1345) was established, and this limitation persisted through the following review by Danks and Glucksberg (1980). According to Carroll (1985, p. 839), “it was Miller’s work on the psychology of grammar, inspired by Chomskyan theory and reported in his 1962 paper in the *American Psychologist*, that established the new subspecialty, called *experimental psycholinguistics*.” Foss (1988) further widened the scope of his review of Experimental Psycholinguistics so as to include both comprehension and production. He also made explicit what Johnson-Laird as well as Danks and Glucksberg had done implicitly: He limited his review to “work done with adults” (p. 302).

The last review of Psycholinguistics to appear in the *Annual Review* up to 2010 was published 13 years after the one authored by Foss (1988) – the longest interval between any of these reviews. Bates et al. (2001, p. 369) entitled their review “Psycholinguistics: A cross-language perspective” and thereby emphasized the need for cross-linguistic research in an attempt to identify “universal processes in language development, language use, and language breakdown.” Their contention shows that developmental psycholinguistics, neglected in the reviews on experimental psycholinguistics since 1974, was again being considered a legitimate part of psycholinguistics. Moreover, the inclusion of language breakdown in aphasia as a topic marked another shift toward inclusiveness. Many years earlier, Rubenstein and Aborn’s (1960, p. 308) review had explicitly pointed to methodological difficulties involved in such research:

- ▶ The research in the area of language disturbance has been quite unsatisfying from a psycholinguistic point

of view. This is not to make light of the difficulties of working with abnormals – where the experimental method has limited application and where the psycholinguist is, for the most part, faced with the time-consuming and laborious task of minute analysis of utterances.

Their warning was well taken: The topic did not occur again in the reviews for the next 40 years. Bates et al. (2001, p. 390) concluded their review with a note critical of the past, but hopeful for the future of psycholinguistics:

- ▶ The dominance of English in twentieth-century psycholinguistics was a historical accident, more socio-political than scientific. However, it has had particularly unfortunate consequences for those fields that try to study the universal psychological and neural underpinnings of language. Psycholinguistics has finally broken away from the hegemony of English, and the field is better for it.

Paradoxically, Bates et al. cited not a single non-English reference, although research regarding languages such as Russian, Kiswahili, Chinese, Italian, and Dutch was indeed referenced in English-language reports. In other words, Bates et al. indulged a second type of Anglophilia: They actually included many references to research on languages other than English, but they failed to include among their references research published in languages other than English.

A Brief Recapitulation from Central Europe

There exists also a review of “German Psycholinguistics: 1967–1977” by Hörmann (1978) that concluded with a warning about linguistics that should have been important also for American psycholinguists during those years:

- ▶ In Germany psycholinguistics has become a general psychology of language. Amid all the minute subtleties to which linguistics has directed our attention, we must not lose sight of what Bühler [1934] showed us more than 40 years ago: that man is a creature who acts purposively in his world and uses language as a tool to achieve his aims. (p. 148)

Hörmann’s movement toward a general psychology of language use was far in advance of the American

scene and was, in fact, redolent of the inclusive coverage of the general psychology or *Allgemeine Psychologie* of the nineteenth century. Meanwhile, his emphasis on the goal-oriented, purposive nature of language use was still being thoroughly neglected in most Anglo-American psycholinguistics of the era. The processing of the linguistic structure of isolated, asocial, monological sentences (e.g., the trivial *John hit Mary* and the pseudo-ambiguous *They are flying planes*) was the focus of research; at the same time, ordinary conversation was being categorized as essentially defective.

Cognitive Psychology as Umbrella for Psycholinguistics

But there was, from the very beginnings of psycholinguistics, still another general formulation, adverted to above in connection with Chomsky's (1968, p. 84) argument that linguistics is a subdiscipline of *cognitive* psychology. J. S. Bruner and G. A. Miller incorporated the formulation into the Harvard Center for Cognitive Studies when they founded it in 1960, and Blumenthal (1970, p. 241) adopted the concept of "psycholinguistics, an area within the broader scope of cognitive psychology." This conviction has accompanied psychology through the second half of the twentieth century in various guises and still serves as a banner for psycholinguistics in the twenty-first century (e.g., Cutler 2005; Trueswell and Tanenhaus 2005a; Altmann 2006; Caron 2008).

However, cognitive psychology has a history of its own that must be taken into account. Moore's (1939) original textbook *Cognitive psychology* used the concept in contrast to his *Dynamic psychology* (Moore 1924); it was clear to Moore that cognitive and affective considerations were equally important in psychology, a conviction that was soon to be forgotten. Neisser's (1967) classical textbook *Cognitive psychology* then failed even to advert to Moore. This omission was the beginning of much obfuscation as to the definition of cognition. What Neisser succeeded in doing was to chronicle the zeitgeist. From the very beginning, his use of the term cognition was open-ended, as his own developing conceptualizations of cognition through the years eloquently show: the cognitive to the exclusion of the dynamic (Neisser 1967), processes and activities of acquiring and using information (Neisser 1975), inclusive of consciousness (Neisser 1976), and inclusive of ecological validity (Neisser 1985). Many others (see

O'Connell 1988a, p. 42 f., for further details) joined the "cognitivism" (Sampson 1981, p. 730) charade to the point where everything is now cognitive, and cognition has become a shibboleth with no meaning of its own.

The cognitive revolution in psychology (Baars 1986), it was alleged, changed everything. But the concept of cognition had already become so vague as to refer accurately only to "a system of processes for the manipulation of information" (Hunt 1982, p. 33). And in the meantime, it has been erected into the all-embracing edifice of cognitivism:

- ▶ Cognitivism is both more and less than the study of cognition. It is *more* in that it covers not only topics such as knowledge, reasoning, and memory, but extends to most of the rest of psychology and cultural life, including social relationships and child development, and topics such as psychopathology and the emotions. That extension, beyond the more straightforwardly 'cognitive', is accomplished by treating knowledge-based processes (or even a particular, information processing version of them) as primary, the foundation of all the rest. (Edwards 1997, p. 27)

Further relevance of cognitivism in psycholinguistics is to be found in the subsumption of psycholinguistics under the umbrella of cognition. Textbooks in cognitive psychology published in the second half of the twentieth century always contained a number of mandatory chapters on language. This is still the case in the twenty-first century:

- ▶ It is quite clear that psycholinguistics is still being considered a part of cognitive psychology in the most recent textbooks (e.g., Anderson 2001; Best 1999; Reed 2000; Reisberg 2001). In none of these texts is there any mention of conversation or dialogue. (O'Connell and Kowal 2003, p. 196)

A European Psychology of Language Use

The preceding depictions are good examples of a notable neglect, not only of psychologists, but of an entire continent of psychologists – European psychologists of language use. Given the fact that virtually *all* of the nineteenth century pioneers in the psychology of language use were European, this is nothing short of astounding. And it certainly is not

in accord with the facts, i.e., with the existence of European psycholinguists' contributions written in the English language. Hörmann's (1978) review of "German Psycholinguistics: 1967–1977" alone, despite his very narrow definition of psycholinguistics, listed 109 references, most of which were contributions to German psycholinguistics within a single decade.

One of the first European critics of modern psycholinguistics to emerge was the Norwegian social psychologist Ragnar Rommetveit. As early as the mid-1960s, mimeographed copies of his criticisms of American psycholinguists were circulating in the Harvard Center for Cognitive Studies. His early publications in English (Rommetveit 1972, 1974, and 1979) all challenged the psychological relevance of deep structure of sentences and proposed message structure in its stead. Later, he referred to "the fragile empirical foundation of mainstream psycholinguistic models of language use" (Rommetveit 1988, p. xi). As social psychologist, his principal emphasis has been on "intersubjectivity, in which there exists a partial complementarity, temporary reciprocity, and above all a shared consciousness among interlocutors" (O'Connell and Kowal 2003, p. 203). This emphasis echoes the words of Lazarus (1879/1986, p. 42; our translation) that conversation is "a joint action of minds. . . : The thought does not originate in me or you alone, but in both of us" (see also Clark 1996b, p. 3). Obviously, Rommetveit's emphasis was at odds with mainstream psycholinguistics from the beginning, and Fillenbaum (1971, p. 276), in his critique of "the view of language. . . focal in recent research," had already referred to some of Rommetveit's early objections.

Rommetveit's more recent insistence that morality must be factored into any adequate theory of language use is even more at odds with mainstream psycholinguistics:

- ▶ Morality is an intrinsic feature of any dialogue. It is in and through dialogue that man constitutes himself as a moral agent, . . . morality is a multidimensional and multilayered phenomenon. It ranges from premoral and proto-moral forms to explicit moralization, from authentic expression to tactful respect for integrity, from embodied feeling of a social-interactional origin to socioculturally sedimented norms and values oriented to in human dialogue and interaction. Morality remains

both a prerequisite and a product of the engagement in dialogue. (Linell and Rommetveit 1998, p. 472)

This statement was the conclusion of a special issue of *Research on Language and Social Interaction* on "the relation of social interaction and morality" (Bergmann 1998, p. 279).

Hörmann (e.g., Hörmann 1978, p. 136) also began to write in English during the 1970s, referring to the theory of "Generative Linguistics" as "in itself rather a-psychological" and moving to higher ground in the following summary:

- ▶ One of the main tenets of orthodox generative-transformational grammar – that semantics is only a secondary, 'interpretative' determinant – has never been accepted in German psycholinguistics. Accordingly, language has been viewed. . . as continuation of (non-verbal) human action by a different and highly specific means, rather than as a self-contained system. One of the topics of a comprehensive psychology of language is therefore the investigation of the goal-directed dynamics of a verbal utterance. These dynamics depend heavily on the situative context of the utterance. (p. 143)

Such a statement, made as early as 1978, was extraordinarily bold and deliberately agonistic. Although Hörmann had spent a number of months as a visiting scholar at Massachusetts Institute of Technology in 1968, it seems clear that he had not been heard. Many years later, his final statements were published posthumously (Hörmann 1986, p. 268):

- ▶ Under the influence of information theory and of what was appearing with great acclaim as semiotics. . . , the process of understanding was for a long time viewed as one of decoding. It was viewed as a kind of retranslation of the language signs into the thoughts which contain this same information. Then understanding would indeed be a linguistically determined process, because it would move exclusively in the area of the language code. Now we see that understanding is a creative, constructive act that always goes beyond the information coded in the utterance itself.

In addition to intersubjectivity, morality, and creativity, at least two more elements of a psychology of language use – *dialogism* and *perspective* – have been thoroughly neglected in mainstream psycholinguistics

and are to be credited to European psychologists of language use. Both these concepts have been presented not as adjuncts or supplements to mainstream psycholinguistics, but as radical departures from its basic stance. Our own engagement of them has been of more recent date (for a summary, see O'Connell and Kowal 2008).

Linell's (1982) early insistence on the primacy of the spoken was evident in his title *The written language bias in linguistics*. Much of his research from that point on had to do with *dialogism*. In 1988, the Bad Homburg Study Group on "The Dynamics of Dialogue" was formed; the group sponsored as many as 12 seminars between 1988 and 1993. Linell (1998, p. xvi) has expressed his dependence upon and gratitude to its members: "Jörg Bergmann, Rob Farr, Klaus Foppa, Carl Graumann, Thomas Luckmann, Ivana Marková, and Ragnar Rommetveit." It was from these meetings that his clearest expression of dialogism evolved (p. xii f.):

- ▶ Thus, the paradigm of dialogism must be understood in contrast to something else, namely 'monologism'. The latter is the dominant theoretical framework in the language sciences. The term alludes to the tendency to identify the speaker alone as the origin of the utterance. Basically, such a framework adopts some version or other of the following theories; cognition as individually-based information processing, communication as information transfer, and language as a code. This is coupled with a long-standing tradition in the language sciences in general, and in linguistics in particular, to give priority to theories and methods that suit written language and text better than they do spoken interaction.

Graumann (1990, p. 14) started from the importance of taking another person's *perspective*: "The capacity to take another person's perspectives may be considered the elementary communicative competence." But behind the ability to *take* someone else's perspective is the even more fundamental necessity to *have* one's own perspective:

- ▶ Each thought or utterance views aspects of the world from some particular vantage-point, thus telling us (as recipients or analysts) something not only about the things talked about but also about the actor's background. (Linell 1998, p. 48)

As we have noted already above, one's personal perspective dictates what one means and what one's interlocutors understand, and extends to one's values and ideals: "Morality is an intrinsic feature of any dialogue" (Linell and Rommetveit 1998, p. 472).

More than any other group – especially after the untimely death of Hörmann in 1983 – the Bad Homburg Study Group symbolizes opposition to mainstream psycholinguistics and an engagement of spontaneous spoken discourse on the part of European psycholinguists. Not least in importance is the Bad Homburg Study Group's rejection of cognitivism as the theoretical umbrella for psycholinguistics and the relocation thereof to social psychology.

Another European psychologist who over the years has devoted a good part of his research to language use from the viewpoint of *Allgemeine Psychologie* has been Theo Herrmann. In our introduction to this chapter, we have referred to his (Herrmann 2006) discussion of the various perspectives taken by psychologists on the study of language use. Herrmann (2005) has repeatedly expressed his discontent with the state of the art in the psychology of language use and, more specifically, with its reductionistic approach to methodology:

- ▶ The psychology of language use as well as psycholinguistics are currently incapable, by reason of their methodology, of engaging research on many important and central aspects of basic problems of language use.
- ▶ Under these circumstances, the psychology regarding language use and psycholinguistics must necessarily neglect the problems for the time being, unless their canon of methodologies be broadened, tolerance with regard to other methods be expanded, and the requisite interdisciplinary cooperation be intensified or set in motion altogether from scratch. (p. 15; our translation)

He has found a broader approach to language use within some subdisciplines of psychology (e.g., social psychology), but also in ethnology and cultural anthropology. Nonetheless, he has concluded:

- ▶ *Mainstream psychology of language use* only seldom gets beyond research on the mental or neural processes involved in the production and reception of individual sentences. (p. 78; our translation)

Among those who have broken away from these limitations, Herrmann mentions Clark (1996b) and Hörmann (1976).

A Comparison: Modern Psycholinguistics in Field (2003) Versus Bates (1989)

Perhaps the question may arise as to whether our characterizations of mainstream psycholinguistics are sufficiently current. In fact, we have relied on the most recent summary presentations of psycholinguistics at our disposal (e.g., Cutler 2005; Trueswell and Tanenhaus 2005a; Brown 2006; Traxler and Gernsbacher 2006; Gaskell 2007; Harley 2008). We wish to add a brief analysis of one of the more recent textbooks in the tradition of mainstream psycholinguistics. Field's (2003, p. 2) *Psycholinguistics: A source book for students* was clearly intended as a handbook of the discipline for the beginner. By all criteria, it is mainstream:

- ▶ Psycholinguistics explores the relationship between the human mind and language. It treats the language user as an individual rather than a representative of a society – but an individual whose linguistic performance is determined by the strengths and limitations of the mental apparatus which we all share.

In other words, the asocial, monologistic, rule-governed behavior of the individual is to be studied. There is no mention of conversation or dialogue throughout the book. Of the references, 98% (191/195) were published since 1960, and none of the many precursors of a modern psychology of language use, none of the Bad Homburg Study Group, and none of the other prominent European contributors mentioned above are included therein. His examples are characteristically either artificial settings or at best monologistic (see, e.g., p. 208 ff.).

Contemporarily with the publication of Field's (2003) book, Elizabeth Bates, a psycholinguist of great renown, died at the early age of 56. Almost two decades ago, she had sized up mainstream psycholinguistics, but not unlike Hans Hörmann before her, did not live to reap the fruit of her research. Bates (1989) published her review of the state of the art in psycholinguistics in Italian and for the Italian journal *Sistemi Intelligenti*. In stark contrast to Field, she pointed out already at that early date the basic flaws of mainstream psycholinguistics.

First of all, she thought of herself as a psycholinguist with specialties in child language development and aphasiology. But she was convinced that, by 1989, psycholinguistics had already disappeared as a coherent and identifiable discipline. It is to her credit that she recognized the importance of Fodor et al.'s (1974) formulation: "The goal of generative linguistics was an account of linguistic competence," whereas "the goal of psycholinguistics ought to be a characterization of performance, i.e., the linguistic behavior (overt and covert) by real human beings" (Bates 1989, p. 308; her own translation). As for Fillmore's (1968) generative semantics, Bates (1989, p. 310; her own translation) described "an embarrassing year or so in which his case grammar had followers in psycholinguistics (especially child language), but no followers at all within linguistics proper (including Fillmore himself)." By then, the separation between psychology and linguistics "seemed to be complete." In their more recent review, Bates et al. (2001, p. 390) have pinpointed an important historical footnote on the Anglo-centrism of modern psycholinguistics:

- ▶ The dominance of English in twentieth-century psycholinguistics was a historical accident, more socio-political than scientific. However, it has had particularly unfortunate consequences for those fields that try to study the universal psychological and neural underpinnings of language. Psycholinguistics has finally broken away from the hegemony of English, and the field is better for it.

H. H. Clark's Shift from Monologism to Dialogism

We have repeatedly described mainstream psycholinguistics as monologically oriented from the very beginning. But nature does indeed abhor a vacuum. Within psycholinguistics, the research of H. H. Clark gradually shifted from monologism to dialogism. More than a decade ago, Garrod (1999) reviewed this tradition of research. Historically, Clark and Clark's (1977) very popular textbook was thoroughly embedded within mainstream psycholinguistics. Evidence of this has already been adverted to: Of the canon of six references characteristic of psycholinguistic textbooks (see O'Connell 1988b, p. 347), all six were cited in Clark and Clark. By way of contrast, in H. H. Clark's (1996b)

Using language, none of them were cited, and the very concept of psycholinguistics was deliberately played down (see O'Connell and Kowal 1997, p. 854 f.). However, citations of ethnomethodologists, sociolinguists, conversation analysts, and other *non-psychologist* researchers with a generally sociological background, "including Goffman, Goodwin, Greatbatch, Heritage, Hymes, Jefferson, Levinson, Pomerantz, Sacks, and Schegloff" (O'Connell and Kowal 2003, p. 205) were abundant in Clark (1996b). None of these had been cited in the Clark and Clark (1977) book, although works of at least Goffman, Hymes, Jefferson, Sacks, and Schegloff were already available. A comparison of all of the references in Clark (1996b) showed that 95% (356/376) of them do not overlap with the references in a psycholinguistics textbook by Forrester (1996) published the same year. Already by 1985, Clark had pointed out, in his contribution to the *Handbook of social psychology*, psycholinguists' "lack of interest in social processes" and had emphasized his own conviction that "language is a social process" (Clark 1985, p. 179). By the time of Clark (1996b, p. 3), his conviction had become quite explicit: "Language use is really a form of *joint action*." Accordingly, *Using language* contains many transcripts of conversations: "A book about language use wouldn't be comprehensible without examples of spontaneous speech, so I have appealed to authentic examples wherever I could" (p. x). But his engagement of spontaneous spoken dialogue was accomplished only at the cost of isolating himself – both theoretically and methodologically – from mainstream psycholinguistics as traditionally understood. Even so, he still clung to the vestigial notions of lawlessness in conversation; it remained for him "purposive, but unplanned" (Clark 1996a, p. 294).

Back to the Future

In the motion picture *Back to the future* (Zemeckis 1985), a mad scientist takes a young man back in time in order to influence his future. In recent years, an analogous phenomenon has been developing in the history of psycholinguistics and more generally in the history of a psychology of language use. What might have been becomes abundantly clear from a revisionist version of history based on an array of mostly German-language sources from the late nineteenth and early twentieth centuries. The reason for this late emergence

of sources is no mystery. In the late nineteenth century, the German language was the premier language of science. Through the influence of the First and Second World Wars and the emergence of English as the *lingua franca* of the scientific world at large, German sources have become increasingly difficult to access. The vast majority of American psychologists are unable to deal with the German language. And translations of German-language materials emerged either very late or not at all. For example, Moritz Lazarus's (1879/1986) *Über Gespräche* and Mauthner's *Beiträge zu einer Kritik der Sprache dritter Band: Zur Grammatik und Logik* (1923/1999) have still not been translated; Philip Wegener's (1885) *Untersuchungen über die Grundfragen des Sprachlebens* appeared only 86 years later in English translation (Trans. Abse 1971) as *The life of speech*; and Bühler's (1934/1982) *Sprachtheorie* was translated into English only 56 years later (Trans. Goodwin, 1990) as *Theory of language: The representational function of language*.

The overall thrust of these and other neglected sources can be summed up as radically antithetic to modern mainstream psycholinguistics as it evolved in the second half of the twentieth century. The emphasis across the board in all these early, pre-psycholinguistic sources was neither *written* language use nor the *grammatical structure* thereof. Their interest was instead extended to everyday oral language use, dialogue, and field observation. It is no exaggeration to say that, had their wisdom been heeded historically, mainstream psycholinguistics could not have seen the light of day.

More specifically, to Lazarus (1879/1986, p. 5; our translation) goes the credit of being one of the earliest to insist on the investigation of "actual, everyday, hour-by-hour conversations of ordinary people." Not long afterward, Wegener (1885) moved radically away from classical philology toward a genuinely psychological approach to language use, a method that engaged naturalistic observation of spoken dialogical usage of the mother tongue. He also insisted on the temporal and logical priority of a form of occasional speech that was later to be designated *empractical speech* by Bühler (1934/1982). Wegener's insistence upon the relevance of the situation was also taken up by his successors, not least of all by Malinowski (1923, p. 465 ff.), with his emphasis on the "*context of situation*." Knobloch (1991, p. xxxviii*) has well delineated the entire movement in

characterizing the mentalist stance of Wegener himself: “For Wegener language is situated within a world of purposeful social action.”

A Return to Dialogue in the Twenty-First Century

In 2001, MacWhinney published an overview on psycholinguistics in which he stated its purpose as follows:

- ▶ This article will examine research in six core areas of psycholinguistics: spoken word recognition, sentence comprehension, sentence production, message construction, memory limitations, and cross-linguistic comparisons. In addition to these core areas, psycholinguists are involved in the study of reading, conversational interaction, figurative language, text comprehension, aphasia, child language disorders, gesture, prosody, neurolinguistic imaging, animal communication, and language evolution. However, our analysis here will focus on these six core areas. (MacWhinney 2001, p. 12344)

MacWhinney’s selection of “core issues” (p. 12348) is relevant in the present context for two reasons: It makes explicit how strongly modern psycholinguistics is still bound to its historical beginnings in the mid-1950s, and, at the same time, it makes room for “conversational interaction,” although not as a core issue. MacWhinney’s own justification for the selection of the core areas is as follows: “These areas are central to the study of psycholinguistics, because they allow us to evaluate the psychological reality of linguistic formalisms” (p. 12348). This argument is surprisingly similar to a division of labor between linguistics and psychology expressed by Ervin-Tripp and Slobin (1966, p. 436) in their review of psycholinguistics from 1959 to 1965:

- ▶ To psychologists remains the challenge of finding the processes by which the competence described by linguists is acquired by children and is reflected in performance under a variety of conditions.

And Hörmann (1967) had entitled one of the chapters in his book *Psychologie der Sprache (Psychology of language)* more than 40 years ago “The psychological reality of grammar” (p. 246; our translation).

It should be duly noted that MacWhinney concluded his review as follows: “A satisfactory resolution of the core issue of the psychological reality of linguistic structures has not yet been obtained” (p. 12348 f.).

It should also be noted, however, that some time ago, Kurcz (1996, p. 18) had already acknowledged that an approach such as MacWhinney has portrayed was already passé:

- ▶ The idea of studying the psychological reality of any theory has come into question (Chomsky himself has rejected the validity of the conception of psychological reality, as it was used by experimental psycholinguists, cf. Rieber, 1983)

In any event, MacWhinney’s core issues have been presented by him as viable for the twenty-first century. The several review articles (Clifton and Duffy 2001; Gernsbacher and Kaschak 2003; and Diehl et al. 2004), which have appeared in the *Annual Review of Psychology* pertaining to these core issues, confirm such an interest throughout the first decade of the century. It would appear that some American and British psycholinguists are still very much committed to these core issues, insofar as they fail to engage genuine dialogical spoken language use and still substitute controlled experimentation for field observational studies.

In the following, we wish to summarize some recent developments in psycholinguistics all of which emphasize the importance of dialogue as both a significant as well as neglected topic in psycholinguistic research – developments which at the same time rely on the work of H. H. Clark and his colleagues.

Pickering and Garrod (2004), two of the leading psycholinguistic researchers on dialogue, have introduced their account of “a mechanistic psychology of dialogue” as follows:

- ▶ The most natural and basic form of language use is dialogue: Every language user, including young children and illiterate adults, can hold a conversation, whereas reading, writing, preparing speeches and even listening to speeches are far from universal skills. Therefore, a central goal of psycholinguistics should be to provide an account of the basic processing mechanisms that are employed during natural dialogue. (p. 169)

In view of the fact that currently “there is no such account” (p. 169), they have added:

- ▶ So far as most psycholinguists have thought about dialogue, they have tended to assume that the results of experiments on monologue can be applied to the

understanding of dialogue, and that it is more profitable to study monologue because it is “cleaner” and less complex than dialogue. Indeed, they have commonly assumed that dialogue simply involves chunks of monologue stuck together. (p. 170)

Pickering and Garrod’s mechanistic account is based on the assumption that “in dialogue, production and comprehension become tightly coupled in a way that leads to the automatic alignment of linguistic representations at many levels” (p. 170), and they have carefully distinguished automatic alignment through basic cognitive processes from the strategic alignment that they interpret to be Clark’s (1996b) approach. However, by 2007, Garrod and Pickering (Garrod and Pickering 2007) had added strategic to automatic mechanisms in their account of alignment: “Just like other complex cognitive processes, alignment in dialogue involves both automatic and strategic components” (p. 443). They have also insisted that research on the relative impact of both components is “a major goal for future research in dialogue” (p. 449). More generally, they contended that language is used by interlocutors to “align their mental states, so that they come to have the same ideas about the topic under discussion.” Finally, Costa et al. (2008) have pointed out the need for dialogical research in view of their speculation that “our cognitive machinery is better designed for dialogue than for processing language in an isolated context” (p. 528). But unlike Costa et al. (p. 529), who concentrated on “successful” dialogue, Clark (2004, p. 365) emphasized “the SPONTANEOUS, INTERACTIVE LANGUAGE of cafés, classrooms, and offices.”

The research of Garrod and Pickering and their colleagues has elicited a lively discussion about dialogue within psycholinguistics and beyond. However, whether or not their concepts of “mechanistic account” and “successful” dialogue will remain theoretically viable is still an open question. Moreover, it would seem that the finality of any dialogical engagement is precisely whatever interlocutors decide for it to be; otherwise, it ceases to be informed by the interlocutors’ intentions. In addition, ascertaining “the same ideas about the topic under discussion” on the part of interlocutors seems to be empirically impossible. In the face of the truly radical dialogism of Linell (2009, p. 35), such latter-day traditions within psycholinguistics itself

still appear to be too closely related to a monological system wherein “the situated meanings of utterances are determined by the individual speakers.”

Another ambitious proposal to bridge the polarities within modern psycholinguistics has been made by Trueswell and Tanenhaus (2005b, p. xv):

- ▶ A confluence of methodological and theoretical developments in psycholinguistics, linguistics, and computational linguistics, all related to the goal of providing mechanistic accounts of language use within rich referential environments, suggest[s] that the time is ripe to bridge the product and action traditions.

Trueswell and Tanenhaus (p. xi) refer the traditions of “language-as-product” and “language-as-action” back to Clark’s (1992) *Arenas of language use*:

- ▶ The product tradition, which has dominated psycholinguistics, has its roots in George Miller’s (1962) synthesis of the then-emerging information-processing approach to cognition with Chomsky’s (1957, 1959) revolutionary approach to linguistic knowledge as a cognitive system of rules and representations. Clark labeled this the language-as-product tradition because it focuses on the cognitive processes by which listeners recover, and speakers create, linguistic representations – the “product” of comprehension.
- ▶ The second tradition sketched by Clark, the language-as-action tradition, has its roots in work by the Oxford philosophers of language use (e.g., Austin 1962, Grice 1957, and Searle 1969), and work on conversational analysis (e.g., Schegloff and Sachs 1973)... This approach focuses on how people use language to perform acts in conversation, arguably the most basic form of language use.

How can one reconcile these “mechanistic accounts of language use” after all these years of conflict between “the product and action traditions” (p. xv)? The title of their first chapter (Tanenhaus and Trueswell 2005, p. 3) has specified the remedy: “Eye Movements as a Tool for Bridging the Language-as-Product and Language-as-Action Traditions,” and Tanenhaus and Trueswell have further specified that it is this single available response measure that is presently to be the key to reconciliation of the two traditions: “A response measure bridging the

action and product traditions” (p. 8); and they have added that “other methods will emerge” (p. 31).

The logical difficulty with this is that the conflicts between the two traditions are only superficially conceptualized as *product* and *action*. It seems difficult to conceptualize the differences between the two traditions as only – or even primarily – methodological. In fact, some representatives of the action tradition (e.g., H. H. Clark himself) would balk at the requirement of “mechanistic accounts” of language use. Nonetheless, Tanenhaus and Trueswell’s prediction is gratifying in the following respect:

- ▶ The most ground-breaking work will come from those using increasingly rich (and complex) data arrays to understand the dynamics of comprehension and production in conversation. (p. 31)

We have already found implausible the claim that a bridge is readily available. More important, however, is the historical picture painted by these brief excerpts. They are without doubt oversimplifications, but, nonetheless, they throw light on the development of psycholinguistics over the years. The sketch provided for language-as-product seems quite adequate (but see Bates 1989 on the foundational importance of Osgood’s mediation theory); George A. Miller was undoubtedly the most important researcher within the discipline of psychology to engage the new psycholinguistics, and Noam Chomsky’s influence was nothing less than charismatic, even though the distance between himself and Skinner was not as great as he made it out to be: “Chomskyan mentalism is not incompatible with a behaviorism that builds upon internal mediating variables” (Linell 1998, p. 58). The sketch provided for language-as-action, however, seems less straightforward. The salient thing one may note in it is that there is no mention of psychologists, but only of philosophers and sociologists, a description quite in accord with Clark’s (1992, p. xii f.) own depiction.

In a somewhat different way, a (re)turn to dialogue is to be noted in Harley’s (2008) third edition of his textbook *The psychology of language: From data to theory*. He has added an entirely new chapter entitled “How Do We Use Language” (p. 453), wherein he recommends Clark’s (1996b) book as “a classic work on using language” (p. 453). However, a noteworthy distinction is presented in some introductory remarks,

wherein he sets the understanding of a comprehender and the production of a speaker *apart from* language use:

- ▶ Much of what we have been concerned with so far is either how a comprehender understands language, or how a speaker produces language. But usually we use language in a social setting: we engage in dialog. . .
- ▶ This chapter is about how we use language. (p. 453)

Evidently, *language use* in the production and understanding of language is understood by Harley as other than *language use* in dialogical interaction – quite in accord with the monological tradition of mainstream psycholinguistics.

The recent emphasis on dialogue has also been paralleled by a plea on the part of some researchers for recognition of the importance of affective as well as cognitive processes in language use. Accordingly, Schober (2006, p. 569) has pleaded:

- ▶ Note that studies of affective processes involved in dialogue have largely been left to social psychologists. . . But cognitive and affective processes no doubt interact in important ways, and ought to be part of a full psychological theory of language use.

A radically dialogistic contribution to the literature on dialogue from outside psycholinguistics is clearly to be found in a major work published recently by Linell (2009) under the title *Rethinking language, mind, and world dialogically: Interactional and contextual theories of human sense-making*. Dialogism for Linell (p. 400) is

- ▶ a family of somewhat loosely linked theories and traditions across many disciplines. In some ways, we would claim that dialogism, by its very nature, is interdisciplinary, because most, if not all, established disciplines have been dominated by non-dialogist (‘monologist’) traditions.

Among these monologistic traditions, mainstream modern psycholinguistics surely holds the first place for Linell, and, accordingly, he has disavowed any affiliation with it. Linell (p. 3) has also pointed out that the limitation of dialogue to “one-on-one language use with a partner” (Schober 2006, p. 564) relies on a false etymology and does not accurately reflect the new dialogism.

Linell’s book is primarily dedicated to the historical and philosophical – both ontological and epistemological –

background of dialogism. There is considerable discussion of methodology, though primarily in an abstract rather than an empirical mode. And whereas his previous work might be characterized as negative in the sense that it was a critique of *The written language bias in linguistics* (2005), the more recent book is a quite positive engagement of dialogism, including even an application of dialogism to the written. The import of dialogism is then that

- ▶ a human being, a person, is interdependent with others' experiences, actions, thoughts and utterances; a person is not an autonomous individual who can decide everything for him- or herself, as monologism tends to assume. (Linell 2009, p. 11)

Hence, for Linell, “dialogism’ is a countertheory to dominant theories in psychology, social science, linguistics and elsewhere” (p. xxviii). It “requires interdisciplinary work, rather than mono-disciplinary compartmentalization” (p. 433). Whether there is currently present within the social sciences a strong enough impetus to carry forward such a radically uncompromising dialogism remains to be seen. Note, however, that Linell makes numerous references to the work of Clark and his colleagues, refers to their approach as “interactionist social psychology,” and counts it among the research traditions which “have provided important empirical evidence for the fruitfulness of a dialogical approach” (p. 399).

It would surely be a mistake to neglect Bakhtin’s (e.g., Bakhtin 1981) influence on Linell and others. For example, Morson (2006, p. 561) has emphasized Bakhtin’s insistence on the fact that language use is dialogical and that the utterance rather than the sentence is the unit of language use:

- ▶ Language is a matter of people speaking to each other on specific occasions for specific purposes, and many features of language will be overlooked if one focuses on the sentence.

Future Directions

After all the vagaries of mainstream modern psycholinguistics throughout the first six decades have been duly recorded and pondered, we wish to formulate for our readers some basic principles for future research: (1) The designation *psycholinguistics* should be restricted to “linguistic performance as a component of human

cognition” (Dietrich 2002, p. 7; our translation); by contrast, a legitimate *psychology of language use* should take into account intersubjectivity, morality, creativity, dialogism, and perspective as essential components of human discourse (Linell 2009, *passim*). (2) Such a psychology of language use, as a subdiscipline of social psychology, should be open to other social-scientific disciplines (e.g., sociolinguistics and conversation analysis, anthropological linguistics, and ethnolinguistics) and to their emphases on social role and culture (Graumann 2006, p. 62). (3) The *written language bias* (Linell 1982; 2005) must be avoided, and spoken discourse must be given consideration in proportion to its salient use. (4) In addition to the use of controlled experimentation and inferential statistics, the importance of field observation, description, and qualitative methods should be acknowledged, much as the Conversation Analytic tradition has insisted all along. (5) The Anglophilic bias must go; corpora from other languages and researchers from other cultures and languages must be taken into account (see Bates et al. 2001, p. 390; Anderson 2006, p. 274).

What did happen historically to psycholinguistics? In short, a tiny corner of formal language structure was emphasized to the exclusion of a vast universe of language use. The vehicle for this dynamic was a mechanistic cognitive view – frighteningly like behaviorism, despite all the protests and breast thumping contrition of the new mentalists to the contrary. Paradoxically, psycholinguistics mimicked the natural sciences in its meticulously quantitative and reductionistic approach to the processing of language structure, even while at the same time following the largely nonempirical epistemology and nativistic speculations of the generativist linguists down the primrose path to triviality. Small wonder that meaning still remains “a core unsolved problem of cognitive science” (Fitch 2005, p. 395). There are ways of getting at the problem of meaning, and a legitimate psychology of language use must now embrace them.

In its original format, this presentation was to have served as a complement to the historical views of Blumenthal (1970, 1985). And his reflections do encourage our own:

- ▶ Whatever the future course of relations between psychology and linguistics it should be a more intelligent

one if we pay attention to what has happened in the past. (Blumenthal 1985, p. 111)

And we may now return to Slama-Cazacu's (1980, p. 93) question, "Should and can psycholinguistics contribute to the improvement of human communication?" The answer must be: Only if there is a radical movement in the direction of dialogue. Such a change in direction is in fact the fulfillment of Lazarus's (1879/1986, p. 19; our translation) plea 130 years ago for the integration into psychology of "a future study of the lawfulness of conversation." Such a vision, however, demands a genuine psychology of language use, not mainstream psycholinguistics.

Our penultimate citation is from a linguist rather than from a psychologist, Otto Jespersen. He anticipated a great deal of the conflict between those who would engage only the abstract system of language and those who would engage the actual use of language on the part of interlocutors. The battle has endured from the very beginnings of psycholinguistics to the present day and bids well to continue on through the twenty-first century unabated. Indeed, it could be discerned in the opposition experienced by Lazarus as early as 1879, when he argued that conversation was the primary linguistic activity of mankind and should accordingly be salient in any psychological consideration of human language:

- ▶ The essence of language is human activity – activity on the part of one individual to make himself understood by another, and activity on the part of that other to understand what was in the mind of the first. . . . But in former times this was often overlooked, and words and forms were often treated as if they were things or natural objects with an existence of their own. (Jespersen 1917, p. 17)

In the light of history, it is small wonder that Theo Herrmann (2006, p. 420; our translation) exclaimed: "The current situation of the psychology of language use – at least in the domain of the German-speaking scientific community – must be judged to be thoroughly unsatisfactory." Yes, and elsewhere too! But we must never forget that the writing of history is an act of hope: Understanding the "thoroughly unsatisfactory" is the very best spur to remediation.

Psychological Theory of John Bulwer

JEFFREY WOLLOCK

Solidarity Foundation, New York, NY, USA

John Bulwer (1606–1656) was a London physician best known for his writings on gesture, the semiotics of the body, and speech for the deaf. However, his psychological theory has received almost no attention from historians, and the fact that Bulwer was the most important British contributor to the psychology of motor action, physical expression, and nonverbal communication in the period between [William Harvey \(ca. 1627\)](#) and [Thomas Willis \(1664\)](#) has gone largely unrecognized.

John Bulwer was the first surviving child and only son of Thomas Bulwer, a London physician. As an apprentice apothecary, the elder Bulwer worked under a leading light of London's medical profession – Roger Gwyn, apothecary to both St. Bartholomew's and St. Thomas's Hospitals from 1587 to 1614. Since the great majority of topographical references connected with the life of John Bulwer, including the parish of his birth, are located close to St. Bartholomew's in the northwest corner of the City of London, it may be conjectured that his father had worked with Gwyn there. Thomas Bulwer became a full member of the Grocers Company, which then still included the apothecaries, in 1599.

On July 1, 1600, Thomas Bulwer married Mary Collet, and on March 27, 1603, they christened a son, Peter; but both mother and son died that year, probably

from the plague that killed an estimated 30,000 Londoners. On May 26, 1604, Thomas married Marie Evans of St. Albans, daughter of George Evans of that city, probably an apothecary, and on May 16, 1606, John Bulwer was christened in the church of St. Michael Wood Street, a parish situated on the north side of The Cheape, a major thoroughfare and center of goldsmiths and apothecaries in northwest London. Three younger sisters, Mary, Dorothy, and Alice, followed.

Thomas Bulwer was one of the 19 men who left the Grocers Company to form the Worshipful Society of Apothecaries in December 1617. The new guild was opposed by both the Grocers and the City of London, but it was under King James's protection and received his charter in 1618. Though in some respects still beholden to the College of Physicians, the apothecaries now could practice as physicians themselves. Thomas Bulwer was one of the more prominent of the London apothecaries, and he certainly treated patients. John Bulwer, in the dedication of *Pathomyotomia* (1649) to his father, refers to “Physick, wherein your experience hath crowned your Profession, having ever been *Fortunatus in Praxi*.”

John Bulwer's parents moved to St. Albans in 1631 or 1632. By this time John was a physician himself, presumably having taken over his father's medical practice. It is noted in the 1634 Visitations of Hertfordshire (St. George 1886:35) that Thomas's son “John Buller” was by then married to “the widowe of – Middleton” (a woman who has not been further identified). Evidence suggests that by the mid-1630s, Bulwer had a prosperous and well-connected practice in the London liberties around Holborn, for many of his intellectual circle were law students at the Inns of Court during that decade, while others, also lawyers, were their fathers and uncles.

Bulwer's mother was buried August 23, 1638, in St. Albans Abbey.

Because of the disturbed conditions during the English Civil War, the Inns of Court were practically deserted from the summer of 1642 through the summer of 1646. This seems to fit with the fact that from the 1640s to 1653, Bulwer was not practicing medicine. From this decade (1644–1653) date all his publications, but in the colophon to his last, the second edition of *Anthropometamorphosis*, he bids farewell to the making

of books (unless he shall be fortunate enough to receive financial support), for he must, he says, return to the practice of medicine. Thomas Bulwer, in his will (1649), had noted that his son was not then in practice.

The genesis of Bulwer's main research project must fall somewhere within the years 1632–early 1640s. In his dedication to *Chirologia* (1644) he says that when he jotted down the basic idea of the project, the first person he shared it with was his “Intellectual Friende” Edward Goldsmith, of Gray's Inn; and that Goldsmith had strongly encouraged him and had recommended the project to his friends. Francis Goldsmith, Edward's nephew, who is known to have resided at Gray's Inn between 1635 and 1642, himself wrote a laudatory poem for *Chirologia*, and in the same dedication, Bulwer tells Edward Goldsmith that “This book by *prescription* and *signiority* of acquaintance as by a *Prerogative*, and by a reciprocation of *love* for your affection to it, falls to your *Tuition*. I confesse some other of my digested thoughts struggled for precedencie . . . and the head would have had the priviledge of primogeniture. But it fell out. . . . *This is come out first.*” (This playful figure of speech hints that Bulwer was already studying the gestures of the face and head, part of which research would later emerge as *Pathomyotomia*.)

Most likely, it was around 1641 that Bulwer showed his prospectus to Goldsmith. Bulwer's project is very likely his response to three factors: ongoing discussions of universal language stimulated by the visit to London (Sept. 1641–June 1642) of the great Moravian reformer Jan Amos Comenius; the publication in 1641 of John Wilkins' *Mercury*, which touches on some related themes in its fourteenth chapter (Wilkins 1984:158–162); and the religious political crisis of the time. Although 1641 is suggested here as a starting point for Bulwer's project, the exact date is less important than the ongoing historical context in which it was certainly embedded (Wollock 2011).

In 1648, John Bulwer published his next book *Philocophus*, dedicated to two deaf brothers, Sir Edward (b. 1620) and Mr. William (b. 1630) Gostwicke of Willington, Bedfordshire. As Bulwer explained in the dedication, he had been solicited on their behalf “by a worthy Friend of yours (who had observed you not onely to be affected but seemingly edified upon the sight of the Alphabets of my *Chirologia*

or naturall language of the hand which hee had presented you with) . . .” (Bulwer 1644a: unnumbered p.; Wollock 1996:4–5). From this it is clear that Bulwer's *Philocophus*, and his idea for an academy of the deaf, originated only after he met the Gostwicks. *Chirologia* was published in 1644; *Philocophus* was in print by July 1648, at the latest.

The first month of 1649 ended with the parliamentary execution of King Charles I. In the spring of that fateful year, Bulwer published his *Pathomyotomia* with a dedication to his father. *Pathomyotomia* complements *Philocophus* by discussing the whole topic of animate motion and the connections between sensation, mental imaging, and bodily movement. This was the same year in which Descartes issued his last published work, on a related subject, *Les passions de l'ame* (Amsterdam 1649).

Pathomyotomia, subtitled “A dissection of the significative muscles of the affections of the minde,” was based on actual anatomies conducted by Bulwer. The only place this could have been done was what he had referred to in *Chironomia* (1644b:85) as “the new Ovall Theater, lately erected for the dissecting Anatomists in Barber-Surgeons Hall in London.” Located in the northwest corner of the city of London, a very short walk north and slightly west of Bulwer's home parish of St. Michael Wood Street, it had been built in 1636 by Inigo Jones on the model of the anatomical theatre at Padua.

Thomas Bulwer died in 1649 and was buried on June 4 in St. Albans Abbey next to his wife. He left to his son his apothecary shop in St. Albans, which Bulwer later leased to the apothecary Charles Tirrell. At this time, Bulwer also inherited two tenements in St. Albans from his mother.

His father's will had stipulated that in order to inherit the St. Albans properties, John must resume the practice of medicine. In the new London of the Commonwealth, it would have been difficult to pick up where he had left off without acquiring an M.D., and it is certain that he had obtained one by 1653, and certainly not in Great Britain. Around this time, Bulwer adopted a young girl (born probably c.1649) he identifies in his will as “Chirothea Johnson alias Bulwer.” Circumstantial evidence suggests that she may have been deaf (Wollock 1996:34–35).

For some time up to 1649, Bulwer had been searching for a copy of Juan Pablo Bonet's book, *Summary of the Letters and the Art of Teaching Speech to the Deaf* (Madrid 1620), and for the teacher whom Digby, in the excerpt from his *On Bodies* (1645), quoted and commented upon by Bulwer in his *Philocophus*, had referred to (Wollock 1996:23–27). It is clear from the manuscript *The Dumbe Mans Academy* (unpublished, probably written in 1649, see Wollock 1996:16–18, 21–23), a fair copy almost ready to be set in type, that Bulwer had by then obtained a copy of Bonet's book, for it contains a paste-in of a plate from Bonet and translations from the text.

The year 1650 saw the first edition of *Anthropometamorphosis*, dedicated to Thomas Diconson. This includes a colophon listing the author's unpublished works. Two additional titles, *Glossiatrus: Tractatus de removendis loquelaе impedimentis* and *Otiatrus: Tractatus de removendis auditionis impedimentis*, are included in the updated list of "Works to Be Accomplished" printed with the second (1653) and subsequent editions of *Anthropometamorphosis* (Wollock 1996:31–32). This corresponds to the period in which Bulwer got his M.D. Their titles seem to form a pair, they are in Latin, and the subtitles sound exactly like typical titles of academic theses. Unfortunately both are lost. *Glossiatrus* was as far as is known, the first monograph on speech disorder ever written (Wollock 1996:18–19). Bulwer summarized his research on this topic in a paragraph in *The Dumbe Mans Academie* (Wollock 1996:19).

Anthropometamorphosis is a compendium of alterations to the human body, sanctioned by custom and fashion, in all parts of the globe including England. Man's corrupt ingenuity had invented myriad modes of disfiguring what William Blake would later term "the human form divine," by way of dress, cosmetics, and mutilation. Like the other works this one is about the semiotics of the human body. It has been frequently described as a work about "monsters," but this extends the word *monster* in a way that Bulwer could not have intended. True, he speaks in the dedication of "National Monstrosities" (1653: unnumbered p.), but this should be understood in a figurative sense. Bulwer was a Baconian, and Bacon clearly differentiates *monsters* (in which nature "is forced out of her proper state by the perverseness and insubordination of matter and

violence of impediments"), from "things artificial," where nature is "constrained and molded by art and human ministry." (*Novum Organum*, book II, "Aphorisms on the Composition of the Primary History.") The subject of *Anthropometamorphosis* is man's *artificial self-deformation*. Here, as in all his books, the true source of the theme is Bacon's *De Augmentis* (specifically Book IV, Chap. 2, which immediately follows the one on expression as a link between soul and body), where Bacon writes censoriously on "cosmetica," or artificial adornment).

Bulwer glossed his topic medically as *de abusu partium*, a play on the title of a classic work of Galen (*De Usu Partium*) which discusses every part of the body in terms of its purpose or final cause. Since in his previous books, above all *Pathomyotomia*, Bulwer had examined the natural expressiveness of the parts, one may assume that his concern here is the *artificial interference* with that natural expressive intentionality or finality, brought about by mankind's false ideas of beauty. On April 17, 1654, Bulwer presented a signed copy of *Anthropometamorphosis* to the Bodleian Library, Oxford.

On July 15, 1656, Bulwer made his last will and testament at Westminster. He died in October 1656 and was buried at St. Giles-in-the Fields, Westminster on October 14. The church has been rebuilt since then and there is no longer any trace of his grave or record of an inscription.

Bulwer's Theories and Their Sources

Bulwer's books tend to be treated separately by different investigators in various specific disciplines; his thought has rarely been surveyed as a unified whole. Here the attempt will be made. Though somewhat differently conceived, the *Anthropometamorphosis* also belongs to this unity. For reasons of space it cannot be treated here, but the present discussion will supply a suitable groundwork for such a treatment.

Chirologia is a treatise on natural gesture; its companion work, *Chironomia*, presents a systematic application of gesture to rhetorical delivery. The material for both is drawn from classical, biblical, and other Christian literature. The introduction to *Chirologia* presents a "General Projection" of a grand design for the study of expression and gesture, of which these books are but the first two offerings. The whole idea had been

inspired by two discussions in Francis Bacon's *De Augmentis Scientiarum*, the 1623 expanded Latin version of *The Advancement of Learning* of 1605 – Book IV, Chap. 1, and Book VI, Chap. 1.

In IV.1, Bacon calls for a new investigation of the common bond of body and soul; how they are aware of each other and how they interact. Bulwer takes his hint from Bacon's observation that although Aristotle has written on personality traits as signified by the physical features in a state of rest (physiognomics), he has ignored the whole topic of expressions and gestures.

Delving further, Bacon asks about the influence of "the humours and the temperament of the body" on the soul, and of the passions of the soul on the body. He notes that medical writers have dealt with this to some extent. As a physician, Bulwer would have been well aware of the topic, as it was important to medical practice and was discussed in the literature going all the way back to Hippocrates. Under the influence of Aristotelian and Stoic dialectic, symptomatology and medical semiotics had been systematized, the most comprehensive system surviving from Antiquity being that of Galen.

The classic definition of a sign is found in Augustine, *De Doctrina Christiana* II.1: "anything which, beyond the appearance it engenders in the sense faculty, makes something else come to our knowledge (Maclean 2002:148–149)." Augustine understood that verbal language is not the only species of sign. While spoken language and its alphabetic representation became the main focus of the medieval study of signs, it was recognized that this does not cover the whole range of signs (cf, Augustine, *Doctr. Chr.* II.2–8). Things may also be signs, whether by arbitrary imposition, by customary association, or by necessary natural connection. Modern semiotics uses the terms of Charles S. Peirce, *icon* (a sign that bears a natural resemblance to what it signifies) and *index* (a sign that has a necessary connection with what it signifies).

Medical signs are both nonverbal and natural. An observable physical sign points to an underlying condition not by custom but by natural connection. In Peirce's terms, it is an *index*. In Galenic medicine, "disordered motions" or "injured actions" are recognized as a distinct class of symptoms (Wollock 1997:109–112). However, a physician must be able to recognize not only disease but also health and all

degrees in between. Thus, just as disordered motion is a class of symptom, so all motions of the body provide clues as to what Bulwer calls (borrowing a phrase from King James I's *Basilikon Doron*, 1599, also quoted by Bacon) "the present humour and state of the minde and will." This is virtually equivalent to the study of expression as suggested by Bacon, who himself reviewed the natural signs of fear, grief and pain, joy, anger, light displeasure, shame, pity, wonder, laughing, and lust in his *Sylva Sylvarum* (published posthumously in 1627), "Experiments in consort touching the impressions which the passions of the mind make upon the body" (Cent. VIII, experiments 713–722).

From this starting point, Bulwer advanced to an insight of his own. Implicitly linking the first chapter of Book VI of *De Augmentis* (on nonverbal signs, natural and artificial) with the physical expression of IV.1, he envisioned a theory blending natural action-signs with physical expression, unmediated by the arbitrary conventions of spoken language and supported by psychology, physiology, and rhetoric.

In VI.1, Bacon describes gesture and hieroglyphic as "emblems" conveying their meaning by resemblance to what they signify. He likens gesture to a transitory hieroglyphic, hieroglyphic to a permanent gesture. Natural resemblance or connection, as well as spontaneous production, become for Bulwer the key to the relationship between gesture and cognition.

But it is also possible to construct artificial nonverbal signs, which Bacon calls "real characters." These are as arbitrary as alphabetical symbols, and may be adopted by convention. Being abstract, and capable of systematization, they are more rational than the "primitive" hieroglyph and gesture, and thus an improvement and advancement.

Significantly, Bulwer scarcely alludes to the real character, except in one place where he refers to the gestures of the hand as the "universall character of Reason" (1644a:3), and another where he describes the correspondence between particular speech sounds (from whatever language) and the motions of the mouth necessary to produce them, as "very neere to the nature of an universall character" (1648:156, cf. 38–41). This lack of interest in the artificial real character can be explained by the fact that Bulwer, as a physician, privileged the natural over the artificial. This also had ethical implications – the natural is

morally superior to the arbitrary, misleading character of verbal language – an outlook he shared with Bacon (Wollock 2002:230–240). The real character, though intended to provide an accurate reflection of the structure of reality and all its interrelationships, was still an artificial construct; Bulwer preferred a ready-made, universal mode of expression emanating straight from the roots of human nature and the structure of the human body (cf. Wollock, [forthcoming](#)).

Bulwer is aware that natural signs are not free of an element of conventionality, but he does not see this as a contradiction. In being adopted by society they become conventional by definition. Augustine (*Dpctr. Chr.* II.25) writes that “All desire a certain resemblance in signifying, in order that the signs themselves should, as much as possible, resemble the things they signify. But because there are many ways in which something may resemble something else, such things do not qualify as signs among men unless agreement occurs.”

No less than words, gestures also have an intellectual or universal level of meaning, as Bulwer explains for the sign of blessing (1644a:144). Aristotle taught that even on the intellectual level, the mind cannot think without mental images: *Nihil in intellectu quod non fuit prius in sensu* (a medieval catchphrase derived from *De Anima* III.7 [431a14–17]). Thus, imitative signs do not signify concrete particulars alone: that “imitation is natural to man from childhood” (*Poetics* [1448b6]) is related to what Aristotle says in section 9 of the *Poetics* (1451a36–b11), arguing that the imitative arts are related to philosophy because every imitation is the representation of a universal idea.

Gesture is impossible without the ability of the body to move itself. *Pathomyotomia* (1649) begins by affirming that self-motion is the highest perfection of the animate creature, the Creator’s last and noblest end in the fabric of the body; that it belongs to the very substance of the animal; and that the chiefest and nearest instruments of animate motion are the muscles. “For were the abilities that proceed from motion and its instruments separated from the Body . . . [man] could neither follow that which is wholesome, nor avoid what is noysome” (1649:2).

- ▶ He would be left destitute of the grace of elocution, and his mind would be forced to dwell in perpetual silence, as in a wooden extasie or congelation: nay his

Soul, which is onely known by Action, being otherwise very obscure, would utterly lose the benefit of explaining itself, by the innumerable almost motions of the Affections and passions which outwardly appear by the operations of the Muscles. (1649:3)

Similarly in *Chironomia* (1644b:24), the mind, “by some stratagem of wit,” expresses herself by “darting her rayes into the body, as light hath its emanation from the Sun.” Expressive gestures arise “by instinct of nature,” not by “statute of art” (1644a:1). Being natural signs, these demonstrative gestures derive their meaning from the unalterable laws of nature. Bulwer explains this by an analogy adapted from Augustine (*Dpctr. Chr.* II.2): gesture is as direct a consequence of “each motion of the Minde,” as smoke is of fire, a sweet smell is of incense, or the light of dawn is of the sunrise. Augustine’s examples are all what Peirce would call indexical signs or indices, phenomena that have a necessary connection with what they represent – in this case, effects signifying their causes – just like symptoms in medical semiotics. In other words, Bulwer believes that the formation in humans of a sign for fire is as spontaneous and as natural a consequence of the thought of fire, as smoke is of the fire itself. They signify particular states of the soul, including everything involved in their production – the whole Aristotelian action-syllogism: mental imagery, motivation, the neurophysiological functioning – including sensory integration – the entire mechanism that renders the process truly spontaneous and makes sign formation as much a physical as a mental act.

In the context in which Bulwer introduces them, such examples become still more complex, for they are not only indices of their instrumental causes, but as “transient hieroglyphics” they also bear a natural resemblance to what they represent (or to something necessarily connected with what they signify) – they are icons. This hybrid sign is what Anttila and Embleton (1995) call the *iconic index*; while this is not Bulwer’s terminology, it is clear that he refers here both to the imitative sign and to the entire process of its formation, its neuropsychology and neurophysiology. From this point of view, Bulwer sees all such manual motions and habits as arising by instinct of nature and devoid of artifice – purely natural, not imposed, not remote in

their meanings from the true nature of what is signified. Their natural resemblance or congruity to what they represent is a result of “mental habits” wrought in the pliant hand by a kind of “impetuous affection.”

What are these “mental habits”? They are those that form and concatenate mental images that direct the “pliant hand.” “When the fancy hath once wrought upon the Hand, our conceptions are display’d and utter’d in the very moment of a thought.” (1644a:4).

- ▶ The Hand . . . , receiving good intelligence of the patheticall motions of the minde, proves a Summarie or Index, wherein the speaking habits thereof significantly appear, representing in their appearance the present posture of the phansie. And as we can translate a thought into discoursing signes; so the conceptions of our minde are seen to abound in severall Dialects while the articulated Fingers supply the office of a voyce. (1644b:157)

This is true whether the volition is conscious or not. Speech and gesture are co-conceived in the mind, but gesture is almost simultaneous with thought. “And if words ensue upon the gesture, their addition serves but as a comment for the fuller explication of the manuell Text of utterance; and implies nothing over and above but a generall devoyre of the minde to be perfectly understood” (1644a:4). This is the opposite of what almost everyone else believed at the time, that is, that gesture was a decoration, at best a helpful adjunct to oratory – but it seems to be corroborated by recent scientific findings.

Is Instinct Voluntary?

But if gesture occurs by “instinct of nature,” in what sense is it a *voluntary* motion? In a discussion drawing on a treatise *On the Diseases of the Higher Faculties of the Soul* (Marinellus 1615) by the Venetian physiologist Curzio Marinelli (c.1560–after 1624), Bulwer explains, near the beginning of *Pathomyotomia* (1649:3) that the word “voluntary” is used in a wider sense in physiology and psychology than in ethics. Galen simply opposed the voluntary to the “natural” motions (such as digestion or the beating of the heart, today classed under the parasympathetic autonomic system). For Galen, as long as “we can excite these voluntary motions when we please, use them often or seldome, heighten them or abate them, and leave them quite off,” they are

“voluntary.” Some say that the muscle should be defined as the instrument of *free* or *spontaneous* motion rather than voluntary, for will presupposes reason; animals lack reason, but they have muscles. In the medical and biological literature on animate motion, “will” was not defined by rational appetite, but by appetite in general, “the propertie of the very Phancie it selfe,” as Bulwer notes, and what was called “voluntary motion” was not confined to humans (1649:4–5).

The question remains, if some form of knowledge must precede, how is it that sometimes we carry out actions unawares? Are there not many motions independent of our will? Bulwer denies this, following Marinelli in distinguishing between action *kata prohaeresin* (by conscious choice) and *kath’ormén* (by impulse), for example, in those who do a thing in their sleep, “when the outward senses are notably hindred” (an allusion to Aristotle, *De Somno*, 465a25–29 [462a19–26]). But all these actions proceed from the soul, not from anything extraneous, for “the Phansie may doe its worke and move when we perceive it not.” Even motions commanded by reason and will are physiologically identical to those of animals (1649:30–31). Galen in *De Motu Musculorum* II.4 (Galen 1821–1833: vol. 4:435–436), while he does not presume to know the cause by which we do things unawares, speaks from the probability of the matter, noting that

- ▶ wee are not intent with our whole mind upon them, as many have done actions which they forget to have done in fits of anger and passion, having made but a slight and superficial impression in their mindes . . . Contemplation of something, Custome, or some affection of the mind, may prove impediments to the knowledge of the Command of the will; for if our Cogitation be very intent upon a thing, so that it slights other things which had intended it, it errs from its proper end, which often happens to men when they intend a journey to a certaine place, and many times being engaged in other thoughts, doe passe it. . . (Bulwer 1649:33–34)

Referring again (1649:34–35) to the phenomenon of somnambulism as described by Daniel Sennert (1572–1637) in his *Institutiones Medicinae* (1611), Bulwer concludes (with Galen, *De Motibus Manifestis et Obscuris*) that when actions are performed from force of habit, more or less unconsciously, the will

does operate, but obscurely and without attention (1649:33–37).

Another objection, raised by Girolamo Cardano (1501–1576) in his *De Subtilitate Rerum* (1550), is that it is not the soul and the muscles, but custom that moves the person unawares. In his famous riposte, *Exercitationes Exotericarum . . . De Subtilitate contra Cardanum* (1557), the Aristotelian philosopher J.C. Scaliger (1484–1558) replies, in Bulwer’s paraphrase (1649:36):

- ▶ . . . what is custome? if I should aske, you would spend above two days in deliberation what you were to say, & it would fall out well if you could then come off with credit (Exerc. 339, 1620:1017–1018), Custome is nothing else but a habit, but a habit is not the cause of motions but a quality added to the motion [the qualities of promptness, order, and timing, according to Scaliger’s own text], because it so adheres to the members, that [it] . . . brings forth its actions as they are to be done without any inquisition. Custome, indeed, and the aptitude of parts doe advance and helpe forwards the doing or perfecting of some motions.

Similarly, at Exerc. 307 (1620:948), Scaliger castigates Cardano for saying that there is memory in all parts of the body, for example, in the fingers, when we play on a lute. For

- ▶ the organs of memory are not in the fingers but answer to their own principles; exercise and custom cause these principles to be conjoined and present to their effects. In this way, we find our way home without any consideration or choice: because from the custom of the parts of the body, all the organs and spirits at once, are connected with the imagination and will.

Scaliger is talking about what Aristotle calls the *hexis poetiké* (operative habit), a relatively fixed quality acquired by repetition, through which a previously indeterminate agent is disposed to act in a definite way (Wollock 1997:127, note; see also Aristotle’s *Nicomachean Ethics* II.4 [1103a29–b14] and *Met.* 5.1 [1047b32–35]: “We learn an art or craft by doing the things that we shall have to do when we have learnt it: for instance, men become builders by building houses, harpers by playing the harp” [cf. Wollock 1997:128]).

There is another sense involved in all voluntary motion. Bulwer does not mention it, but Scaliger does

at Exerc. 109. Aristotle (*De Sensu et Sensatu* vi, [445b5]) lists weight (*baros*) among the sensible qualities of a body; for the medievals as well, weight is not a quantity, but a quality perceived through the sense of touch. The key point is that for Aristotle, the organ (*aestheterion*) of touch is not the skin, but “the flesh (*sarx*) or [in other animals] its counterpart.” Ignorant of the true function of the nerves, Aristotle specifies the seat of all sensation as the *mória homoiomerei*, the simple or uniform parts (i.e., tissues), designating the nonuniform parts (which the medievals called the compound, organic, or official parts) as “the means for various activities.” (*Parts of Animals* II.1, 647a20–24; Wollock 1997:99, 115–118). Now, everything that we call muscle, Aristotle referred to as a kind of flesh. If flesh is the organ of touch and movement is a common sensible perceptible through touch, then one feels a proportionate sense of tactile movement in this flesh when either pushing or resisting an object possessing weight. Since the body itself, and every part of it, possesses weight, the weight of one’s own body can be sensed in every local motion, whether of the whole body (*holon athróon*) or any part (*kata méros*). This is the same phenomenon that Bastian in the nineteenth century called *kinesthesia* and Sherrington in the twentieth, *proprioception*. Aristotle says (DA iii.1, 425a20–21), “it is clearly impossible for there to be a special sense of any of these common sensibles, e.g., motion.” As psychologist James J. Gibson (1966:238) wrote,

- ▶ The organs with their receptors set limits on the kinds of stimulus information that can be registered. The five modes of attention, listening, smelling tasting, touching, and looking are specialized in one respect and unspecialized in another. They are specialized for vibration, odor chemical contact, mechanical contact and ambient light, respectively, but they are redundant for the information in these energies whenever it overlaps.

Motion is a common sensible, perceptible by sight, hearing, and touch. This is what Scaliger means (*ibid.*) when he refers to the motive power, in the case of weight, as a power of *perception*. What is perceived, through touch, is its motion as a common sensible.

Sensory Integration in Skilled Motor Action

Speech is just such a motion, sensed not by hearing alone, but in common with sight and touch. In *Philocophus*, Bulwer therefore argues, by a fine analysis of the process of voluntary motion, that there is no reason the deaf should not be able to speak, if properly taught. For “Letters the true elements of speech [are] made of Motions, nay [are] nothing else but locall motions of the parts of the Mouth” (1648:17). He focuses on the relation of sense and voluntary motion, the relationship and community among the senses, and the manner in which complex motions are learned and become habit. Contrary to popular belief at the time (even among many physicians), their speech motor mechanism in most cases is unaffected by whatever it is that damaged their hearing. Speech for the deaf was something that, as Bulwer knew from his reading of Sir Kenelm Digby’s *Of Bodies* (1645), had actually been achieved in Spain; but in England, up to Bulwer’s time, it had not even been attempted and was generally assumed to be impossible.

It was *Chirologia/Chironomia*, particularly the illustrations, that led to Bulwer’s introduction to the deaf Gostwicke brothers and eventually inspired him to write *Philocophus*. Astonished at the brothers’ ability to communicate so well through gestures and facial expression, Bulwer confessed he had nothing to teach them on that score. But he sympathized with their desire to communicate with the hearing through speech. With this, the issue of iconicity is shifted. In the books on gesture, iconicity concerned the resemblance of sign to its object; here we return to the question of how one who does not speak can produce words similar to those of his interlocutor (cf. Bulwer 1648:156, 38–41).

Galen, in his *Commentaries to the Sixth Book of Epidemics* V.5.2 (1821–1833: vol. 17:236), notes that little children can imitate “difficult words, such as *stranx* and *sphynx*, as soon as they hear them, unaware of which muscles of the tongue have to be moved or how it is to be extended, curved, turned around, moved up toward or pressed against the palate, or the front teeth, or any other part of the mouth.” Galen confesses that he does not understand how they do this. The question preoccupied him; he raised it also in his *De Foetuum Formatione* cap.6 (1821–1833: vol. 4:689–691;

694–698:700) and *De Motibus Manifestis et Obscuris* (alluded to by Bulwer [1649:25–27], after Scaliger).

In *Philocophus* (1648), Bulwer gives the old question a new twist: no longer is it about infants with normal hearing, but about those, whether children or adults, who cannot hear. Emphasis now falls on the fact that the action of speech, even in normal speech development, depends not only on hearing, but also on sight and touch. It requires the integration of all these sense modalities, which Aristotle attributes to the *sensus communis* or common sense.

According to Aristotle, the common sensory is the faculty that senses the unity of the several sense modalities as adhering in a single object. Besides unity, it also senses other accidents common to the five senses, such as number, motion (change), rest, and magnitude, which are therefore called the *common senses*. In speech production, the linkage in the common sensory of auditory and tactile/proprioceptive (“muscular”) sensations according to their common rhythmic motion is clearly of central importance (Wollock 1990:19; in general, see Gregoric 2007).

The common sensory is crucial not only to perception but also to voluntary motion. Aristotle hints at this in *De Anima* III.1 (425a15–20). Motion, rest, shape, magnitude, number, and unity are the sensible objects common to the five senses, but *movement is primary*; through it we perceive the others. Indeed, he speculates (DA III.1, 425b3–11) that the very reason we have five special senses and not just one is so that we can perceive the common sensibles more clearly. Shape and size, for example, are difficult to discern by sight alone.

In *Philocophus* (1648:145–147) there ensues a disquisition on the coordination of the senses in the production and reception of speech. While possibly the most penetrating up to that time, it has the unusual feature that instead of the leading role in the coordination being taken by the sense of hearing, emphasis falls on the sense of sight, which must compensate for the lack of hearing. The happy result is that in this way Bulwer became the first systematic investigator of the role of sight in speech acquisition, an issue of great importance for hearing children as well as for the deaf.

- ...to imagine after what manner the words *seene* (or as we use to speake) *heard* with his eye were transferred to *pronunciation*, and againe to the *intellect*; is the

greatest difficulty of this businesse; we will suppose this *transmutation* was not performed without a necessary *junction* between those *words seene* and the *habit of moving the vocall Muscels*. ... (1648:145)

In this way, Bulwer is brought to the general idea of an “anagram” of the senses. Since sense perception always involves the integration of modalities, senses that are deficient can always, with special training, be compensated by those that are present. The reason the sense modalities are convertible in this way, explains Bulwer, is that they are all reducible to the common sensible of *motion*.

In *Philocophus* 145–147, Bulwer reviews the psychology of infant speech acquisition; comparing a normal child learning to read, to a deaf child learning to read lips. He notes that “by joyning the vision of wordes seen in their Horn-books, to the [teacher’s] representation of the sound” the children acquire a habit of coming into the auditory mental image of the sound through the visual mental image of the letters. (“out of the Phancie of the thing seen they may come through into the Phancie of the sound. . .”). “It being wel known unto us, that boys when they learn to reade, they bring forth a voice out of a sound (i.e., out of “the Phancie of the sound” in their imagination), and that is the reason why those who are Deafe by nature, are necessarily mute (i.e., because never having heard, their minds are devoid of auditory images)” (1648:145–146).

Bulwer goes on [1648:146] to suggest that infants learn to speak in a similar way. From hearing alone, they do not comprehend, but they “learne to know,” because “although wordes are not understood by an Infant, yet this Cognition which consists in sight and hearing is proper to them; for, man hath understanding . . . from his first Infancie. . .” (That is, they connect the sight of the object with the sound by which it is called, and this is an elementary level of understanding.) And just as understanding comes from words thus seen or heard, so may it come after the same manner from the sight of writing. “For writing is “a kind of visible speech permanent, as the motions of the mouth, are a transitory speech.” This is an adaptation of what Bacon says about hieroglyphs and gesture (*De Augm.* VI.1): “Gestures, however, are as one might say, transitory hieroglyphics. And thus the hieroglyphics

expressed by gestures are transient, while those that are painted endure.” From this, Bulwer might have glimpsed a closer parallel between gesture and speech; but there is no indication that he did, because he seems to have always considered speech to be as arbitrary and artificial as gesture was natural. His only concession to naturalness in speech comes in an idea borrowed from Lazare Rivière, that interjections expressing certain emotions are natural because even the deaf make them (*Philocophus* 1648:125–126).

Speech acquisition in infants is another example of voluntary motion that is at the same time a natural instinct. As Bulwer counsels in *Pathomyotomia* (1649:225–226),

- ▶ Neither need it to trouble any one, seeing a thing [226] that is done out of Deliberation, and which seemes to proceed from Prudence, to be done by Infants, and of us without considering of it; for, Nature (as Hippocrates saies) is Learned without a Teacher. These are done by a certaine Instinct, but not such as most men take to be Naturall, for we understand this Action to be voluntarily done, because when we please we can begin it and restraine it . . . for, our voluntary motion is done somtimes by Deliberation, and sometimes by Imagination; Imagination alwaies prevents and goes before Deliberation . . .

Bulwer returns to the question of psychophysical coordination and habit-formation in the learning of speech at the very conclusion of the book:

- ▶ The first principles indeed are but simple and naked; but it is a wonderfull thing to consider the great distance betweene them, and the strange readiness and vast extent of speech resulting in process of time out of them: whereof it is enough for us to finde a ground for the possibility of the operation, [i.e., in theory] and then *the perfecting of it and reducing of it to such a height, as at the first might seem impossible and incredible, we may leave to the energeticall power of Art*. Hee that learneth to read, write, or to play on the Lute, is in the beginning ready to lose heart at every step, when he considereth with what difficulty and slownes he joyneeth the letters, spelleth syllables, formeth characters, fitteth and braketh his Fingers (as though they were upon the Rack) to stop the right frets, and to touch the right strings; And yet you see how strange a Dexterity is

gained in all these by industry and practice; and a readinesse beyond what wee could imagine possible, if wee saw not dayly the effects. (1648:189–190)

Hearing with the Eye?

Fully two-thirds of Bulwer's *Philocophus* is a line-by-line commentary on a section of Sir Kenelm Digby's treatise *On Bodies* (Paris, 1644, London, 1645) in which he talks about the "Constable of Castile's brother" (i.e., Don Luis Velasco), a deaf man in Madrid who had been taught to speak (Wollock 1996: 7. 14–17). Referring to him in Chap. 28, Digby says: "I have seen one, who could discern sounds with his eyes. 'Tis admirable, how one sense will oftentimes supply the want of another." And again, "I mentioned one that could hear by his eyes; (if that expression may be permitted me)."

Bulwer was much taken with this idea. He writes, *Philocophus* (1648:70–72):

- ▶ Now whether the expression of hearing sounds with the Eye may be permitted, will appear, if it cannot be denied but that Hearing is nothing else but the due perception of motion, and that motion and sound are not different entities, but in themselves one and the same thing, although expressed by different names and comp[r]ized in our understanding under different notions, which is proved by the observation of sounds which follow the lawes of motion, for every effect of them is to be demonstrated by the principles and proportions of motion. . . . Aristotle [DA II.8 419b4–13] therefore defines sound by motion, and the Voice to be a kind of percussio, and therefore sound is the same with motion, and no resulting quality; which may be further convinced by the ordinarie experiment of perceiving Musique by mediation of a sticke: for, a man is capable of that sound no otherwise than as bare motion is sound. Now since articulate sound or motion may be perceived by the Eye, then it may hear as well as see, and hear by seeing. It will be no great impropriety of speech to affirme the Eye may hear, since it can perceive the adequate object of hearing, and performe the office of an ear in judging of sound as it is motion (all sound being motion as soon as it is perceived) and the thing which we call sound and makes speech audible, being purely motion. Indeed sound which is but an accident of speech, & which is as they commonly speak, the sensible quality

of Hearing, is reckoned by Philosophers to be *proprium sensile*, to wit, to be perceptible but to one sense: yet as it is figure and motion, which two always imply one another, and of the essence of speech, it may be accounted *commune sensile*, and be perceived by more outward Senses than one.

Digby's philosophy was a blend of Aristotelianism and atomism. Bulwer, in "saving" Digby's text, wound up adopting a view contradictory to his own Aristotelian perspective. It would take sophisticated experimentation to discover the relation of motion to the other senses, but that sound was caused by motion had been known since time immemorial. Aristotle did not reduce sound to motion, however, but taught that it is *caused by* motion (Pasnau 2000). For Digby, on the other hand, the "resulting quality" would be nothing but an illusion. The reduction of sound to motion threatens to destroy the distinction between proper and common sensibles.

Yet the notion of "hearing with the eye" was not entirely alien to Aristotle, for he taught (*De Anima* III.1 [435a30–425b2]) that the senses perceive each other's special objects, albeit *incidentally*, because they all form a unity. When this sensory unity perceives two different sense qualities in the same object, the unitary sense makes it seem as if one sense is perceiving another's object. The real problem in that formula comes when a particular sense is lacking, as in the case of deafness. How can a sound be said to be perceived incidentally, when it is not perceived at all?

The actual Aristotelian theory of motion as a common sensible clearly explains the function of the senses in speaking; if hearing is present, it coordinates with the other senses; if lacking, its absence can be compensated by the remaining senses. The doctrine that Bulwer borrowed from Digby, that "sound is the same with motion and no resulting quality," contradicts his otherwise Aristotelian orientation, and may be described as mechanistic. (On the Cartesian theory of hearing and Digby's relation to it, see Gouk 2004:131–144.)

Was Bulwer a Mechanist?

With Richards (1992:73), one can say that Bulwer was a mechanist only in the limited sense in which the term might also apply to Bacon. In *Novum Organum* II, aphorism 5, Bacon hints at a mechanical application

to voluntary motion and speech, within the general aims of his whole philosophy, where he suggests an investigation.

- ...on the voluntary motions of animals, from the first impression on the imagination and the continued efforts of the spirit up to the bendings and movements of the limbs; or concerning the motion of the tongue and lips and other instruments, and the changes through which it passes till it comes to the utterance of articulate sounds.

This reflects Bacon's larger goal of reorienting science toward technology. Thus, we find phrases in Bulwer like "the clockwork of the head, or the springs and inward contrivance of the instruments of all our outward motions, which give motion to and regulate the dial of the affections which nature hath placed in the face of man ..." (from the dedication of *Pathomyotomia* to his father, 1649). This mechanistic language, however, is here no more than figurative: it helps to create a *myth* of a new technology. "From its first formulation by Francis Bacon," writes historian Michael Zuckerman (1993:254), "the modern mechanistic world view was a faith that outran the empirical evidence and remade the world in its own image."

In *Philocophus*, chapter 13 (pp. 45–49), Bulwer discusses the possibility (following Bacon's suggestion in *Sylva Sylvarum*, Cent. II, exp. 200) of imitating "the motions of the parts of the mouth in speech" by "mathematicall motions." In itself this thought contains nothing beyond the biomechanics of Aristotle's *De Motu Animalium* and *De Ingressu Animalium*, except for the more Platonic suggestion that behind these motions lie mathematical regularities; but this makes them amenable to mechanical imitation, toward the construction of what Bulwer calls a speaking "engine." Even in current cognitive science, this same mechanist (now computationalist) model continues to inspire new research, even though there is little evidence that the human mind works like a computer.

On the physical cause of animate motion, however, Bulwer follows Aristotle in attributing the mechanical motion to *qualitative* change in the underlying substance of the parts of the body: "whence the sense offering what is desired, the motions are done no otherwise then as you see in machines, the pullies loos'd, one thrusting forward the other, *but in*

machines without the mutation of qualityes, but in us the formall cause of motive heate and spirits is transmitted withal to the parts ..." (1649:17–18, emphasis added). Aristotle had described the substance of the parts executing motor action as capable of becoming larger or smaller by changing from solid to liquid and liquid to solid (*De Motu Animalium*, 701b13–16, 23–24); Galen described the action of the nerves as something akin to electrochemical changes, or as he puts it, a flow of heat and light through the nerve substance.¹

As to actions performed unconsciously from force of habit, Bulwer does not adopt a purely mechanical explanation like many of the later Cartesians. Rather he holds to the old Galenic position that even in such cases the intellect does act, but obscurely and without attention. This also agrees with Aquinas (*Summa Theologica*, Part I, quest. 84, art. 8, obj. 2; and Second Part of Part II, quest. 154, art. 5). Thus, as a Baconian experimental anatomist and physiologist, and as a physician, Bulwer was certainly very interested in the *mechanisms* of the human body; but he was not philosophically a *mechanist*. (The difference is immediately apparent if one compares Bulwer with Giovanni Borelli, *De Motu Animalium* of 1680, who really was a Cartesian mechanist.)

More accurate is Rowe (2001:79), who refers to Bulwer's "biomechanical but resolutely organicist explanations." His basic assumption, uncontroversial in that age of controversy and in harmony with the Galenic heritage of *De Usu Partium* and *De symptomatibus*, as well as with Bacon's DA IV.1, was that the soul expresses itself through the motions of the body, the only way the human being can express itself. And here we see another difference from Descartes's *Traité des passions de l'âme*, published the same year (1649), wherein the mind is distanced from the body with the whole palette of human expression being attributed to the purported pneumatic mechanism of nerves transporting a fluid from the pineal gland (the alleged seat of the soul) to the muscles, making them expand and shorten.² This type of theory was already shaken as early as the 1660s when Jan Swammerdam (1637–1680) demonstrated that a contracting muscle does not change its volume, and was confirmed for human muscles by Francis Glisson (1597–1677) in 1677 (Cobb 2002).

Richards (1992:18) criticizes the inclination of writers on the history of psychology to automatically assimilate seventeenth-century discourse to modern preconceptions, attributing this to the “question-begging assumption” that if psychology is a bona fide “science,” it must be “traceable to the beginnings of ‘science’ in the Scientific Revolution (hence Bacon, Galileo, Descartes, etc., earn inclusion simply by virtue of being leading figures in that revolution.” Nevertheless, he finds Bulwer (at least in the *Pathomyotomia*) in many ways closer to modern psychology than his more famous contemporaries.

- ▶ The general tenor of *Pathomyotomia* anticipates modern psychology far more closely than that of Descartes’s work. Bulwer is not concerned with the philosophical question of the soul’s relationship with the body, being content to accept that whatever the nature of the soul, its ‘motions’ are knowable only by the outward expression, but neither is he a physiological reductionist. (1992:72)

Richards takes this further:

- ▶ All the major orthodoxies on this matter appear to be seriously flawed . . . by a retrospective ascription to the major philosophers of the period of interests, aims and attitudes analogous to those of contemporary psychologists. . . . On the contrary, it appears that their prevailing interests were either theological or political, and that their statements on psychological matters were invariably manoeuvres within the theological-cum-political arena or [sic] normative moral discourse. (1992:91)

Richards (2004:671b) is right as to the genuine scientific value of Bulwer’s writings. But there is no reason to deny that he was also “concerned with the philosophical question of the soul’s relationship with the body.” And from all indications, he had strong political and theological views (Royalist and ritualist Anglican, see Wollock 2011), but the polemics are fairly subtle and unobtrusively supported by the traditional Aristotelian psychology (as slightly colored by Bacon and Digby) to which he adhered.

Influence

Bulwer had little influence in England in his own time and for a very long time thereafter. In the unsettled

conditions of the civil war and Interregnum, alienated from the main scientific circles in London, he died 4 years before the Royal Society was founded, with no one to champion his legacy, and with a great shift in intellectual style just beginning. Immediately after his death, Cartesian and neo-Cartesian theories of mind and body would come into ascendance for many decades, casting Bulwer’s traditional Aristotelianism in the shadows. Interest shifted to corpuscularianism and other materialistic theories.

These were the same forces that stifled the influence of Bacon himself in psychology, despite the fact that British science saw itself as bearer of the Baconian legacy. The direct Baconian impact on psychological thought in Britain was delayed by over a century (Richards 1992:18), largely due to the influence of Cartesianism. Bulwer on the other hand took Bacon’s idea of a science of humanity very seriously, and we can agree with Richards (2004:671b) that “his works more nearly approach modern psychology in character than those of his illustrious philosophical contemporaries . . . only at the end of the twentieth century did his long neglect as a serious thinker begin to be rectified.”

Bulwer’s influence in the seventeenth and eighteenth centuries was extremely limited. The Cartesian system of emotional expression developed by Charles Le Brun (1619–1690), Louis XIV’s favorite painter, “Méthode pour apprendre à dessiner les passions,” originally presented as a lecture before the Académie Royale de Peinture et de Sculpture in 1668 and first published by his student Henri Testelin in 1680 as *Sentiments des plus habiles peintres sur la pratique de la peinture et de la sculpture*, seems to have been loosely associated in the public mind with Bulwer’s work, but helped only to eclipse it (Cottegnies 2002). Bulwer’s ideas on gesture may have had some influence on rhetorical handbooks such as that of Obadiah Walker (*At of Oratory*, 1659), but if so it was unacknowledged.

In the later eighteenth century, Francis Green (1742–1809) of Boston, the father of a deaf son who was a pupil at the academy of Thomas Braidwood (1715–1806) in Edinburgh, published *Vox oculis subjecta, a dissertation on the most curious art of imparting speech, and the knowledge of language, to the naturally deaf, and (consequently) dumb*. . . . London, 1783, which contains extensive quotes from Bulwer. Green, the first advocate of the oral method

in America, also adopted a version of Bulwer's pen name: "Philocophos."

Nineteenth Century

During the nineteenth century, Bulwer's name was routinely cited, but no more than that, in virtually every potted history of English deaf education. With few exceptions, no serious attention was given to his writings. Thus when, for example, surgeon Charles Bell published his *Anatomy of Expression* (1806) and *Anatomy and Philosophy of Expression* (1824), he did not mention Bulwer, despite the fact that his basic standpoint, that the muscles controlling facial expression were divinely created to express uniquely human feelings, was similar to Bulwer's. In all likelihood, Bell did not know Bulwer's writings. It is easier to understand why Bulwer's work held little interest for the evolutionists later in the century: their philosophy was diametrically opposed to his. For Darwin, in his famous work *The Expression of the Emotions in Man and Animals* (1872), expression is a sign not of the working of the soul or mind, but of the working of natural selection over time (Ekman 2006).

The great neurophysiologist Charles Scott Sherrington (1857–1952), though certainly a Darwinian, would come to realize that this view of causality was overly restrictive. In *The Integrative Action of the Nervous System* (1906), Sherrington stated that "In light of Darwinian theory every reflex must be purposive. We here trench upon a kind of teleology. . . . The purpose of a reflex seems [a] legitimate and urgent . . . object for natural enquiry. . . . And the importance to physiology is, that the reflex reaction cannot be really intelligible to the physiologist until he knows its aim" (1906:235, 236). This is the famous distinction between *adaptation* and *adaptability* in biological causality. As Ragnar Granit, Sherrington's student and a major neurophysiologist in his own right, explained, "The nervous system cannot be understood without reference to its adaptability, its actual function in the life of the individual, its performance relative to the external world" (Granit 1975:262). The expression of emotions, as a form of communication, is an essential part of the day-to-day adaptability of the organism to its environment.

It is precisely adaptability that Bulwer has in mind in considering the purpose, or function, of the muscles of expression. In the dedication to the *Philocophus*

(1648, unnumbered p.), he describes it as his "Darling study to interpret the richnesse of our discoursing gestures . . . [even] to the following of them downe to their spring-heads and original, even to the finding out of their Radicall Derivations and Muscular Etymologies by that thorough progresse of observation . . ." He surely has in mind here the Aristotelian–Galenic doctrine that it is the function (final cause) that defines the organ, not the other way around; that every organ has a principal active part and other auxiliary or helping parts; and that a power is known only through the actions by which it is manifested (Wollock 1997:23 n.49; 99). *Contra* Darwin, expressions are not simply atavistic survivals of utilitarian functions of lower animals, not arbitrary signs to which meanings have been habitually attached, but the most universal and fundamental building blocks of human social communication, and thus of social life itself.

This notwithstanding, in the posthumous second edition of Darwin's *Expression of the Emotions* (1889), in the first footnote to the reprint of the Preface to the First Edition, it is acknowledged that Bulwer's *Pathomyotomia* "gives a fairly good description of a variety of expressions, and discusses at length the muscles involved in each," and that Dr. Daniel Hack Tuke (1827–1895), in his *Illustrations of the Influence of the Mind upon the Body in Health and Disease* (a work first printed in the same year as Darwin's *Expression*, 1872), "quotes the *Chirologia* of John Bulwer as containing admirable remarks on gesture." That this note appears in brackets indicates that it was added by Darwin's son Francis, no doubt at the wish of his father (Darwin 1998:xiii–xv), who knew Hack Tuke and had read his book (see Charles Darwin's letter to Hack Tuke, Dec. 22, 1872).

Two very fine articles were published on Bulwer in mid-century, the anonymous "Bulwer's Muscles of the Mind," in *Fraser's Magazine* 32 (October 1845), pp. 341–349; and another anonymous article, perhaps written by editor Winslow L. Forbes, "A Medical Psychologist of the Seventeenth Century," in the *Journal of Psychological Medicine and Mental Pathology* 13 (1860), pp. 294–314. These remain among the very few that deal with Bulwer's work specifically from the viewpoint of psychology.

In 1885, pediatric neurologist Francis Warner (1847–1926) published *Physical Expression: Its Modes*

and *Principles* (London, Kegan Paul, Trench, 1885), which accords Bulwer a prominent position in the history of the subject and quotes him extensively. Warner was already aware of Bulwer by 1882, when he published “Visible Muscular Conditions as Expression of States of the Brain and Nerve Centres,” in the neurological journal *Brain*, in the twelfth installment of which (vol. 4, p. 204), he devotes a paragraph to the *Pathomyotomia*:

- ▶ [Bulwer] expresses his opinion that every motion of the mind is indicated by a corresponding motion of the muscles. This is the same idea that Camper expressed later, and as is now well known to the physiologists, that all postures and movements are the result of changes in nerve-centres. To study the conditions of the mind it is necessary now, as in former times, that the postures and movements of the body should be largely observed In all cases, after describing the expression of a state of mind, Bulwer endeavours to explain which muscles take part in the act.

Warner was a Darwinian and held Darwin’s *Expression of the Emotions* in high regard. He certainly did not speak, like Bulwer, in terms of the soul of Aristotle and Galen, or of the body as its instrument of expression. Yet Warner was clearly impressed with Bulwer’s *Pathomyotomia* because, as a clinician, he greatly admired his forerunner’s detailed observations on expression and gesture as visible signs of muscular actions. As he emphasized from Bulwer, all expressions of the feelings, of the mind, particularly those of the face, are produced by muscles under the brain’s command.

Mrs. Alexander Graham Bell (Mabel Gardiner Bell), a teacher of the deaf, saw Bulwer from a different perspective. Having lost her hearing as the result of a childhood disease, Mrs. Bell was a highly accomplished lip-reader and a great admirer of Bulwer. Her insights into the psychology of what she preferred to call “speech reading” are a valuable supplement to Bulwer’s own theories. She published an article on Bulwer in the Proceedings of the fourth summer meeting of the American Association to Promote the Teaching of the Deaf (Bell 1894), followed more than 20 years later by another on the same subject in the *Volta Review* (Bell 1917), which was widely distributed as a reprint.

Relevance to Modern Theories

In the late nineteenth and early twentieth century, psychologists began again to take up questions not unlike those that attracted Bulwer’s attention. In explaining infant speech acquisition, James M. Baldwin (1894) defined imitations as “circular” reactions” or “motor processes that tend to reproduce their own stimuli” (Baldwin 1894: 133, specifically referring to infant speech; cf. 367–398). To this, Josiah Royce (1895:218–219) commented that the intermediate stages – in effect, translations of, for example, auditory impressions to visual, then to muscular, and from one type of muscular action to another – are not “a spontaneous accidental association” but “the gradual and habitual outcome of all the motor processes of [the] careful attention,” which arose from the child’s “deliberate effort to reproduce what he heard.” “This intermediate stage is . . . not itself the result of a function that reproduces its own stimulus, but of a function that produces, in image form, contents which are not those of the stimulus, but which have relations similar to those presented in the regular stimulus” (219). Thus, imitation must entail interpretation.

As educator George B. Germann (1873–1958) wrote:

- ▶ . . . the instinctive character of imitation and the apparent lack of any but the most rudimentary reasoning power, would lead us to conclude that practically all of the infant’s early imitations are probably subconscious or involuntary. He reacts to a copy simply and solely because he cannot help reacting. The constitution of his being compels him to react. . . . we may hint that the educational significance of this imitative tendency of both children and adults is to be found in the fact that imitative reaction if persisted in soon become crystallized into habits. . . . (Germann 1901:56, 57)

Perhaps the most interesting and important field of imitation in the infant is language acquisition, which

- ▶ has received its preliminary impulse through the early . . . babblings of the preceding months. Power to articulate arises and increases through these babblings, and associations are established between the coordinations necessary to make a sound and the sound itself as heard. When this coordination has become

sufficiently matured, it needs but little more than to have an appropriate sound made by another, in order to produce the necessary responses, responses which become easier and smoother through practice. As Preyer³ states, “although philologists may still dispute much over the possibility of the origin of language from other sources, nevertheless sound imitation remains without doubt the first and most important factor in the learning of language by the individual.” (Germann 1901:57–58)

Aside from the narrower understanding of the word “voluntary,” in agreement with modern usage, this is the very problem that baffled Galen, but which Bulwer was beginning to solve as an instance of sensory integration and automatization. Bulwer does not specifically refer to the phenomenon of babbling, but it is briefly described by the Italian physician Luigi Settala (1552–1633) in his Commentary to the Aristotelian *Problemata* xi.27 (Wollock 1997:127–128). However, Bulwer does emphasize that the imitation of speech sounds by motions of the mouth is a totally natural phenomenon (1648:156; cf. 38–41).

As developmental psychologist George Butterworth (1947–2000) notes (1994:120), it was Sherrington who first addressed the question of neonatal imitation (especially puzzling when it involves parts of the body the infant cannot see) by way of his distinction between *proprioception* and *exteroception* (1906:130). The integration of these two processes is the root of bodily self-awareness, and thus the key to imitation (Butterworth 1995:88, 98). Neonatal imitation, for example, depends on proprioceptive aspects of visual perception. These perceptual systems provide information not only about one’s own body, but also for the equivalence between self and other. It was Sherrington (1907, p. 472–473) who first demonstrated that the proprioceptive circuit is influenced by the exteroceptors, noting that “the reactions produced by the receptor organs of the deep field (proprioceptive) are results primarily due to the stimulation of the organism by itself, but secondarily due to the stimulation of the organism by the environment,” that is, as perceived through the exteroceptors. “Imitation, therefore,” concludes Butterworth (1994:121), “seems to be based on the mechanisms of perception. Perception carries information for self and

for the external environment and can be considered as if it were a phase of action, just as action can be considered as if it were a phase of perception.”

The trained body, starting from a given set of conditions, “knows how” to move, and this very movement is perceived to correspond to the mental imagery from which it originated. In other words, the coordinative structures are controlled by vestibular/proprioceptive and external sensation coordinated by the central sense power (cf. Sherrington 1953:244–245). Is this not what Bulwer refers to as the “necessary junction between those words seene and the habit of moving the vocall Musculs...”? (1648:145)

In the late 1990s, a new type of nerve was identified – mirror neurons. These mirror neurons, first discovered as closely related to the grasping mechanism in monkeys, have been shown to be the basis of human imitation, a response that replicates prominent gestalt features of its own stimulus.” It has been suggested that this is the principle of human empathy and through that, of human society and culture, of which imitation is the foundation (Arbib 2006). In other words, imitation is a natural response, it is not based on reasoning; but perception of difference between the imitation and its object is the very foundation of reasoning.⁴

Conclusions

Bulwer was, in the style of his day, both a scientific investigator and a philosopher. The larger issues he grappled with continue to confront modern researchers, who are only now beginning to recognize him as a pioneer in their field. We realize that he was in fact the first to take a scientific approach, consciously in the spirit of Francis Bacon, to many psychophysical issues of human communication that are of great interest today, whereas his philosophical insights are drawn from the whole history of the subject, emanating particularly from Aristotle and Galen (whose psychological acumen is today recognized as timeless) and their late renaissance interpreters like Scaliger (1620 [1537]) and Marinelli (1615). If Bulwer was ignored for so long, we can say in hindsight that this is not because he is unimportant, but because it has required a long historical perspective to understand that he was “ahead of his time.”

Bulwer made a valuable contribution to the science of his day – but a contribution that was very little noticed and was immediately submerged by the great changes in intellectual style introduced in France by Cartesianism and in England by the corpuscularian science of the Royal Society. With a few exceptions, it is little more than half a century since the pioneering nature of his contributions has begun to be appreciated. Still, this is only a historical injustice. The question remains, has Bulwer a positive contribution to make today?

Bulwer's key insight – that gesture is closer to the expressive impulse, with spoken words acting as a sort of commentary on the gesture (1644a:4) – is backed up in recent scientific findings by, among others, the late William Stokoe (2001), David McNeill (2005), David Armstrong, Sherman Wilcox (Armstrong and Wilcox 2007), and Adam Kendon (2005, 2007, 2008). In addition, the whole approach to learning that Bulwer represents, with its integrative and interdisciplinary vision of psychology and language, remains of great scientific and philosophical importance. It is the “cognitive” disciplines, especially cognitive psychology, cognitive linguistics, and cognitive semiotics, today, that especially need to hear Bulwer's voice, and with his guidance, begin to recover the classical tradition of inquiry in the psychophysiology of language and semiotics of which Bulwer was one of the last exponents.

Notes

1. “Galen understood this flow of power as equal to the transmission of some quality which provokes metabolic changes in the substance of the nerve. He compared this doctrine with the concept that heat and light rays issuing from the sun merely transmit the qualities of heat and light but leave the substance of the sun unchanged” (Siegel 1968:194). See also Wollock (1990:18; 1997:115, 130).
2. Descartes further distances the mind from the body by claiming that the signs of our passions are purely arbitrary, that they are connected with certain emotions by mere habit. A consideration of the universality of many of these basic expressions would reveal this as highly dubious (Ekman 1994, 2006). In the nineteenth century this was incorporated in Darwinism, because the concordance to humans of

these responses in lower animals introduced no philosophical problems if the whole phenomenon was considered merely physical.

3. William Thierry Preyer (1841–1897), English-German physiologist whose two-volume work *The Mind of the Child (Die Seele des Kinds)*, 1882, based on observations of his own son, was the first detailed study of childhood mental development.
4. As Kempf (1918:22) already understood early in the twentieth century, the reflex discoveries of Sherrington may be the mechanism for understanding the behavior of others – that is, by miniature forms of reflex reproduction of the movements of others. The proprioceptors, by giving the appropriate kinesthetic sensations, enable the personality to become aware of the significance of the posture and movements or behavior of others. Children, spontaneously and unconsciously, learn by imitation; they imitate sounds, the movements of animals, a speaker, teacher, playmate, machinery, when they are trying to get the full significance of the thing observed. We tend to reproduce another's movements when we describe conduct, adults often imitate facial expressions to understand faces of others, our facial muscles tend to reproduce the facial expressions of our associates. The more clearly we are able to reproduce another's behavior or facial expression the more accurately we understand its significance. (Edward J. Kempf (1885–1971) was an early American contributor to psychoanalytic literature who published three books and 32 papers between 1913 and 1965.)

Psychology and Antisemitism

NOACH MILGRAM

Tel Aviv University, Kochav Yair, Israel

Introduction

Origin and Definition of the Term Antisemitism

The term was first accredited to Wilhelm Marr who, in 1879, used the term to provide a racial scientific basis for his ideological hatred of Jews. Given the direct linguistic connotation and the associated racial connotation of the term, *Semite*, some Arabs have claimed that they cannot be guilty of antisemitism, because they speak a Semitic language and are, themselves Semites (Laqueur 2006, pp. 21–22). In a cultural context, however, the term is never used to refer to Arab peoples or Muslims, and throughout the Western world and the Middle East the term refers exclusively to hatred of Jews. Accordingly, it is more appropriate to eliminate the confusion between hatred of Jews and hatred of all so-called Semitic people by using an uppercase A and combining both terms in one word, “Antisemitism.” And this spelling will be used henceforth. The original hyphenated spelling is used only when it is in accord with the usage of a particular author.

A dictionary definition of antisemitism is “prejudice and hostility toward Jews in general.” Minor exceptions are made by people who hate Jews, and may even like a few Jewish acquaintances, but regard them as atypical, and not at all like the rest of the Jews. This behavioral stereotype comprises both cognitive and behavioral components:

- (a) Antisemites judge the behaviors of most Jews by a different standard than they apply to members of other groups. Mannerisms, transgressions of social norms, and crimes committed by some Jews are judged by a more severe standard than when committed by members of other religious, ethnic, and/or nationality groups.
- (b) Antisemites make more generalizations about Jews, primarily negative, than they make of other

groups. They believe that what some Jews do is an inherent trait of Jews in general. If Jews are successful in business, it is because they are avaricious and that they accumulate their wealth at the expense of others. The classic example of this stereotype is Shylock, the Merchant of Venice, a despicable, cruel Jew, interested only in accumulating wealth by maximizing his money lending profits. This type can be found repeatedly in Western literature and persists to this day.

Other racially inspired notions based on documented sources are listed below in rough historical sequence:

- (a) Jews are dishonest and lie whenever it furthers their interests.
- (b) Jews are loyal to Jews and not to the country in which they reside.
- (c) Jews regard themselves as “the chosen people,” are clannish and exclude others, and consider themselves superior to all other people.
- (d) Jewish women are lascivious and try to corrupt the moral standards of the society in which they reside (e.g., Egyptian soldiers justified killing women tourists in Sinai because these Jewish women reportedly danced nude in their presence; a Jordanian soldier killed teenage girls for the same reason at a ceremony to celebrate peace between the two countries).
- (e) Jewish men exploit the innocence of God-fearing, racially pure young women (e.g., Nuremberg trials of Jewish men for purportedly making sexual advances to Aryan women).
- (f) Jews control the press and the government in the Western democracies or persist in efforts to achieve control.
- (g) Jews conspire as a group to overthrow the established order and to control the world.
- (h) Jews promulgate the myth of the six million Jews killed in the Holocaust to make Europeans feel shame and guilt in order to extort undeserved reparations from them.
- (i) The extent that Jews were killed during World War II was not disproportionate; they were not singled out for death any more than the millions of Polish and Russian civilians who perished.
- (j) The provocative behavior of Jews in Europe elicited in large part the frustration and rage that ultimately led to the murder of Jews during the War.
- (k) The Zionists collaborated with Hitler in killing European Jews in order to justify the establishment of a Jewish State (e.g., the doctoral dissertation in 1982 of Mahmoud Abbas, current President of the Palestinian Authority).
- (l) The destruction of the Twin Towers and the other attacks on 9/11 was engineered by the Mossad (Israel’s Secret Service) to incite the West against Islam; Jewish workers were told not to report for work that day.

Economic Disparity

Prager and Telushkin (1985) demonstrate that resentment of Jewish success and affluence relative to economic standards prevailing in the non-Jewish majority in any given society among whom Jews reside does not explain antisemitism. First, because economic disparity exists within lower and middle class Christians or Moslems in their own societies without class-related massacres. Second, the hatred of the lower or working class toward the middle class or the aristocracy has never been universal or as intense as the hatred of all of these classes toward economically successful Jews. Economic disparity or economic depressions exacerbate the latent animosity already present toward Jews and cause it to erupt, but do not explain why the targets for this animosity are the Jews to begin with.

Xenophobia

The same caveat and conclusion apply to people harboring ethnic prejudice, hatred, and even murderous intentions toward others. Xenophobia, the collective term used for this phenomenon, takes the form of fear, antipathy, contempt, and/or hatred of those who are different from the rest of us. This phenomenon has always existed between different ethnic groups (Greeks and Persians, English and French, Europeans and Asians, the list is endless). Xenophobia has declined in recent years because of the relative ease of relocation (temporary or permanent, of people who wish to tour, study, or work in other countries). Moreover, recent technological advances in mass communication have created the one world or global village in which we live today.

Mass Communication

On the other hand, these same technologies have created the means through which hatred can be communicated worldwide (Milburn and McGrail 1992). The United States Holocaust Memorial Museum in the 2009–2010 annual report stated the following:

- ▶ The Holocaust did not begin with murder, it began with hate. ...and something unique to the 20th century – the development of mass communications with the ability to exploit people’s hopes and fears. How were the Nazis able to win elections in one of the most highly educated nations in the world? In a democracy with a free press? They knew not only the power of propagandas, but also how to marry it to the most advanced technologies. In our day the Nazis would be on Web sites, Twitter, Facebook, and cell phones. And that is precisely where the haters are – no longer isolated but forming communities. (p. 3)

As a consequence, it becomes easy in democracies that have known hatred of Jews in the past for some individuals to express antipathy, if not hatred of Jews, and to boycott with loathing Israel, the Jewish State, especially if they substitute the word Zionist for the word Jewish. Hatred of the Jews may exist where no Jews ever lived in substantial numbers (e.g., Japan) or where Jews no longer live (e.g., Poland, Egypt, and other European, Asian, or African countries).

Religious Bigotry

Religious bigotry per se has been proposed as a generic cause of violence and conflict for hatred of Jews. The conflict between different religions, different religious belief systems, and different religious ways of life has existed from the dawn of the polytheistic and later of monotheistic religions. Pagans have killed Christians and Christians have killed members of other Christian sects (e.g., Roman Catholic, Lutheran, Protestant, Mormon, and Christian Scientist). Within Islam Sunni and Shiite continue to fight, but all Moslems share animosity toward other religions (e.g., Bahai, Christians, and Buddhists). However, as Tom Lehrer, the Jewish Harvard-trained mathematician and pre-Bob Dylan folk singer, asserted in one of his satirical songs, “Everybody hates the Jews.” Those who hate Jews may themselves be atheists or agnostics and they may hate Jews who have

converted to other religions or Jews who no longer profess or practice Judaism.

Source of Blame for Adverse Events

Prager and Telushkin (1985) assert that the causes for Antisemitism must be selectively universal and account for the repeated eruption of intense hatred against Jews in different countries and under different circumstances. Consider the circumstances surrounding the massacres of Jews during the Black Death (1348–1349). Local citizens were trying to cope with their fear, sense of helplessness, and grief over the loss of loved ones. They may have noted that while many Jews also died from the plague, fewer Jews succumbed to the plague. The local citizens might have asked if Jewish religious practices – kosher food preparation, personal and family hygiene, household cleanliness, and removal of all rodents from the home – provided protection against the plague. They might have noted that residing in ghettos afforded Jews limited contact with the general population and provided protection against rat infestation. Had they asked, and drew cause-and-effect conclusions, they might have adopted similar practices. Instead, they chose to believe that the Jews caused the Black Death by poisoning the wells from which only Christians drank. Why did they insist on Jewish malevolence?

Similarly the depressed economy in Germany and the smoldering sense of defeat and betrayal may have brought about the rise to power of the Nazi party. These circumstances do not explain why the Nazis (and citizens within Germany and within every country they conquered) hated Jews. Nor do they explain why they allocated enormous resources in manpower and transportation to expedite the final solution, at a time when these resources were indispensable to the conduct of the War and to the defense of Germany. It would appear that success in the War against the Jews was more important than success in the defense of the Fatherland.

Does Something About Jews Trigger Hatred of Jews?

If hatred of Jews is universal and unique, it would appear that some abiding distinctive features of the Jewish people over the past 2,500 years must be considered as relevant to Antisemitism, even if today many,

if not most Jews in Western countries do not exhibit these features. More important, historically the distinctive features discussed below were the norm for Jewish communities in Europe, Africa, and Asia, and were a basis for the climate that bred hatred of Jews then and continues to do so now.

Some Evidence-Based Selective, Universal Causes of Antisemitism

Religious Features of Jewish Monotheism

The three pillars of Judaism – moral monotheism, life style, and nationhood – have been perceived as an affront to others from time immemorial. The Jewish belief in one God insulted and infuriated those people who believed in many Gods. So-called pagans (e.g., Greeks, Romans, and all who adopted a Hellenist way of life) were tolerant in religious matters. Others would honor your Gods, your idols, and your religious practices if you would reciprocate by honoring theirs. In addition, the Greek and Roman Gods were themselves poor examples of moral behavior. They could commit incest and adultery without guilt or remorse. In effect, they were children with the magical powers of superheroes and were lacking in respect for law, order, human equality, and the consequences of their immoral behavior. By contrast, the Jewish God was a moral God. The Jewish God presumed to interfere with one's life, wishes, and behaviors. This God proclaimed a series of do's and don't's, enshrined them in the Ten Commandments, and honored the interpretations and implications prepared over time by learned Jewish scholars and leaders. God punished those who transgressed from these commandments and honored those who abided by them.

While all monotheistic religions, however – whether Jewish, Christians, or Moslem – are by their basic assumptions intolerant of the belief in many Gods, the Jews were the first to arrive on the scene and to bear the brunt of pagan antagonism. Moreover, Judaism as the first of the monotheistic religions was not only a threat to the pagan religions, but was an even more dangerous threat to the great monotheistic religions that followed. The hostility of Christianity and Islam to one another and their shared animosity toward Judaism are well known, but the theological

and historical basis for their hatred of Judaism and the Jews are not always understood and are discussed briefly below.

There were too many things common to Judaism and Christianity for the latter to ignore them. Christianity was originally a sect within Judaism and when it broke away, Christianity had to deal with these features. Jesus Christ was a Jew, a pious one at that, and a member of the branch within Judaism that generated Rabbinic law and the Rabbinic way to live an authentic Jewish life. All of Christ's original disciples who dined with him at the last supper, a traditional Passover meal, were Jews. The Church fathers achieved theological integrity and consistency by breaking these connections and by delegitimizing Judaism. First, Jesus Christ was not in essence Jewish or even human for that matter. He was the son of God. He died on the Cross and joined God the Father as part of the Holy Trinity. On the other hand, as a descendent through his earthly father, he was in the messianic line from the House of David. These were beliefs that traditional Jewish theology could never accept, and their early rejection of Christianity created still other problems.

The Chosen People

In Jewish theology, the Jews are declared to be God's chosen people. The Bible clearly states that God has chosen the Jewish people to receive the Torah (the Holy Book of Book in the well-stocked Jewish theological library). Jews were commanded to study and practice its commandments, to transmit these laws and the ethical principles upon which most are based to their children, to spread the belief in a single moral God throughout the world, and to make the world better and fit for God's kingdom. Maimonides, the greatest religious authority of the Middle Ages, confirmed this interpretation and indicated that being chosen did not mean being better than others, but rather being chosen to accept awesome responsibilities that were not incumbent on others. Maimonides stated that if non-Jews observe the seven laws of Noah, they are righteous and will enjoy the blessings of this life and life in the world to come. The laws attributed to the biblical overlap with the Ten Commandments in Jewish scripture and include prohibitions against idol worship, murder, theft, sexual immorality, blasphemy, causing undue pain to animals killed for human consumption,

and the positive commandment to establish courts of law.

There are strong theological reasons to believe that the Jewish claim that they were chosen by God contributed to the justification of persecution of Jews thereafter.

Christian leaders declared that Israel had surrendered its status as the chosen people by committing a heinous crime, the killing of Christ. As a direct consequence, the Temple was destroyed, thousands of Jews were killed by Roman soldiers, and the survivors were expelled from the land of Israel. This series of events confirmed that God had withdrawn His Grace from the Jews and bestowed it on the new Israel, the Christian Church and its followers.

Islam had other theological problems with Jewish theology and the Jewish people. The two religions had a common progenitor, Abraham, with Ishmael as the progenitor of the Arab people and Isaac of the Jewish people. In Islamic theology, Ishmael was the favored son and not Isaac, while Abraham, Isaac, Jacob, Moses, David, and the other Jewish prophets were holy men and prophets, but Mohammed himself was the last and the greatest of the prophets. According to Islam, Allah had a special positive relationship with the Jewish people, the Jewish homeland, and their beloved Jerusalem, but when the Jews transgressed His laws, their favored relationship to Allah ended and they became a despicable and despised people. Moreover, Islam was an expanding and conquering religion that first offered Jews and Christians alike the choice of conversion to Islam or death, and then became more tolerant and designated all non-Moslems as second class citizens who were forbidden from flaunting their own religion or community and were required to pay special taxes and suffer forms of social humiliation. Many of these discriminatory practices were operating and sporadic massacres of Jews took place well into the twentieth century until Jews emigrated from Moslem countries after the establishment of the State of Israel.

The Distinctive Features of Jewish Life Style

The Jewish life style has rules about what can be eaten and what cannot be eaten and under what circumstances can kosher animals be slaughtered. The rules effectively prevent Jews from accepting the invitation to

dine with others. It prohibits intermarriage unless the non-Jew converts to Judaism and observes Jewish law scrupulously, including circumcision for male converts. Praying three times a day and observing the Sabbath and the other holy days are mandatory and require the presence of ten religiously observant men; consequently, even when orthodox Jews are free to reside wherever they want, they prefer to live in Jewish communities and walking distance from a synagogue. Jewish law places special emphasis on the Sabbath as a day of rest, religious study, and spiritual assessment. Moreover, the Jewish way of life, while clearly patriarchal, placed limits on the man's authority in the home, in matters of marriage and divorce, and in custodial authority over minors following divorce that the other monotheistic religions did not accept until recent times if at all. Biblical law protected slaves against the baser appetites and behaviors of their masters and it prohibited rape during war. The many strange aspects of this way of life were not conducive to friendly relations with their non-Jewish neighbors and were open to hostile interpretation.

Distinctive Features of Jewish National Identity

The third issue, Jewish nationhood, raises the use of dual loyalty and placing loyalty to Judaism and the Jewish homeland above their loyalty to the country in which they are residing. Jewish theology regards the Holy Land, Jerusalem, Hebron, and other sites as part of the Jewish heritage. When Jews pray, they turn in the direction of Jerusalem and recite prayers in which references to Jerusalem are a dominant motif. The problem of dual loyalty only arose when the nation states of Europe expanded the rights of citizens residing within their borders and had to decide what to do with the Jews.

In the United States, some aspects of the separation of Church and State permitted Jewish and latter Catholic immigrants to enjoy the rights of the Protestant founders. In France, Jews were offered an interesting choice: To receive emancipation as Frenchmen and to enjoy the rights and privileges of other Frenchmen. Jews in 1789 were required to abandon the national aspect of their Jewish identity; as a nation, they would receive nothing. The logic was simple: There cannot be one nation within another nation. Many Jews in France and Germany accepted this challenge. They modified

Judaism by downplaying or eliminating altogether the categorical implications of Jewish nationalism from Jewish prayer and ritual. They became, for example, Germans of Mosaic persuasion, and adapted their religious services to the style of their Christian neighbors.

Proliferation of Racial Theories and the Jewish Race

The sources for the racist theories that dominated Western thought were many. To cite a few, Spain found it necessary to create social status based on race, with pure blooded Spanish people at the top; Jews, Moslems (Moors), and mixed breeds at the bottom; and in some instances conversos were in the middle. These were Jews who had converted to Catholicism, and were now in the upper ranks of the clergy, the merchants, and other members of the educated classes. Spain passed the statute of (*pureza de sangre* or purity of the blood) in the sixteenth century. The logic was that even when Jews became devout Catholics, there was something morally inferior in the Jewish racial character (Laqueur 2006, p. 92).

When racial theory emerged in the late nineteenth century in Western Europe, it was speculative at best and self-serving at worst. Its proponents came from the fields of economics, biblical and oriental languages, historian and philosophers and their camp followers. The inferior traits of Jews were the preferred target because they lived and even prospered in Western society and identifying their racial character was more consequential than that of the black, brown, and yellow races that were regarded by all Europeans and also by North Americans as inferior races. Racial theory became a convenient, effective way to incite the passions of voters and members of growing political, ethnic, or cultural movements. Once it became established in people's mind that Jews were a race, it was not difficult to generalize from a few Jews to all Jews and to place in the same camp capitalists in the West, communists in the East, and radicals of any persuasion who challenged the existing order if they were carriers of Jewish blood and its consequent racial impurity. There was now fertile ground to promulgate ZOG (Zionist Occupation Government), the conspiracy theory that Jews throughout the world, regardless of their diverse religious identity from atheist to devout, wish to control the world by establishing puppet

governments in their respective countries and are becoming successful in doing so.

Disproportionate Representation of Jews in Selected Occupations

The number of Jews or people of mostly Jewish ancestry who were recipient of the Nobel Prize was 181 accounting for 22% of all individual recipients worldwide between 1901 and 2010; in sheer numbers Jews constitute a mere 0.2% of the world's population. Higher percentages were noted in recipients who were citizens of the United States. It is not difficult to show that in the United States, the number of politicians in Washington, physicians in the hospitals, lawyers in the courts, students in the prestigious universities all exceed 2, the percentage of Jews in the country. What is the explanation?

- (a) The first is the extent of literacy among Jews for over 2,000 years. Simon ben Shetach, who was active in public affairs during the rule of the Maccabean kings in the century before the Common Era, founded public schools or yeshivot in the larger cities of Judea to be funded by the respective communities and to be entrusted with instructing young boys in the Holy Scriptures as well as in the traditional Oral Law; some 80 years later Joshua ben Gemala formalized community responsibility and educational regulations to ensure that all Jewish males were literate in Hebrew (Greenberg 1966). As a consequence, Jews literate in Hebrew found it easier to read and write other languages long before literacy became common in Europe, Africa, or Asia. Jews had an enormous advantage when they were permitted to enter the fields of international commerce, regional financial affairs and businesses, or served in positions of authority under the King. The view that Jews engaged in banking out of avarice ignores several realities: There were successful Christian and Moslem men with the requisite abilities to serve as bankers and many did so, despite the prohibition against usury. Similarly there was a large supply of qualified Jewish bankers and where permitted to serve in this capacity could be expected to be loyal to their employer whose protection was essential for their livelihood and their very lives.

- (b) Jewish success in recent times was due in part to their international residence. Jews resided in many different countries, and were exposed to the scientific, literary, academic, and occupational opportunities available to them. Had they resided in a single country, especially one lacking the intellectual and cultural substratum necessary for achieving success in fields recognized by the Nobel Prize Committees, there could have been few, if any, Noble Prize recipients of Jewish ancestry.
- (c) A relatively stable family structure existed among Jews until recent times. The relatively low rates of alcoholism, divorce or desertion, and family violence were favorable for offspring acquiring the abilities to enter the universities and the free professions.
- (d) A special aspect of the phenomenon of assortative mating was a contributing factor. It was common practice in Europe, Africa, and Asia for the upper class to marry with families of similar status. It is common practice today for people of similar social status and education to travel in the same circles, to meet and to marry (Argyle 1992, pp. 194–223). This was common practice among Jews as well, but social class was based not only on wealth or renowned ancestry, but also on literacy of a particular kind, the ability to read, comprehend, and acquire the intricate reasoning associated with the study of Talmud, the vast compendium of what has been called the Jewish Oral Law. This cognitive talent became a basis for assessing the status of a potential bridegroom, regardless of his humble origins. A young Jew, with special gifts in his Jewish studies would be matched with the daughter of a great Jewish scholar or the daughter of a successful businessman. This phenomenon meant that wherever this talent was found anywhere in Jewish society, it was identified, honored, and matched in matrimony. This phenomenon over centuries is calculated to produce extremely talented animals or humans, depending on the trait that is rewarded. It is not surprising that many secular Jews came from a lineage of Jewish scholars that stretches back over centuries. One optimistic, democratic implication of these explanations is that making opportunity in all fields available to the youth in democratic countries

permits outstanding individuals to come from any ethnic (or so-called racial) group and to achieve outstanding success. Asian students, for example, born and educated in the United States as well as Asian students who immigrated are accumulating an impressive record and constitute a large percentage of students in the most prestigious universities.

Disproportionate Representation of Revolutionaries of Jewish Ancestry in Attacks on the Established Order

Alienation is a worldwide phenomenon. Some people become alienated from their families, ethnic groups, religious identification, and nation-states. Some of the more prominent radical Jews who challenged the established order by word, pen, demonstration, or military action include Karl Marx, Leon Trotsky, and the majority of the original Soviet politburo (Russia); Bela Kun (Hungary); Rosa Luxemburg (Germany); Emma Goldman, Jerry Rubin, Abbie Hoffman, Herbert Marcuse, and Noam Chomsky (the United States), and countless others. Other Jews whose egregious actions threatened existing institutions would include Michael Milkin, Bernard Madoff, and other financiers. While very few Jews are radicals and threaten the established order in any society, the number of Jews among the radicals is disproportionately high (Praeger and Telushkin 1883).

The prominent and visible role played by Jews who wished to abolish all religions and all nation-states provided evidence for the radical right and the radical left alike of a worldwide Jewish conspiracy to control the world. The non-Jewish radical right wished to sustain the existing order and its institutions and they perceived the Jews as threatening their cherished beliefs and traditions. The radical left wished to destroy the established order and targeted Jews as an immediate, vulnerable threat to their plans (Jewish capitalists, Jews who defended and were loyal to their country, moderate Jews who advocated changing existing society, but not destroying it). The non-Jewish Jews, who espoused the goals of the radical left and were admitted to its rank and file and even to its leadership, abhorred their own Jewish stain and wished to expunge it everywhere. They hated all religions, but especially Judaism, and all nation-states, but especially the Jewish nation-state.

The prominence of Jews in revolutionary movements provided the match for igniting the devastating forest fires of hatred of Jews in times of severe drought.

The Proposed Psychological Causes of Antisemitism

One of the earliest books on Antisemitism in the twentieth century came from James Parkes (1946). In chapter, *The Psychology and Sociology of Antisemitism*, he highlights the worldwide antipathy of majorities to discriminate against the minorities that dwell within their borders (e.g., the Roma in Europe, the Chinese in Thailand, Beduins and Christians in Arab countries, Hindus in Sri Lanka, the Nisei on the West Coast of the United States, the aborigines people of Japan, Australia and elsewhere). He strongly identified with Jewish suffering and supported Jewish claims for a national homeland in Palestine over Palestinian counter claims as answering the greater need of the Jews and inflicting the lesser hardship on the Palestinians. He indicted antisemitism as an enemy of the people and gave this title to his classic book on the topic (Parkes 1946). He suggested that this enemy could be fought, not by making antisemitic propaganda illegal, but by pressuring the Christian churches to rectify their biased presentation of Judaism to their congregants, and by bringing together representatives of the Jewish and the Christian communities.

The most widely read book on the psychological causes of antisemitism was written by an existentialist philosopher (Sartre 1960) in the aftermath of World War II. He argues that the Antisemite is the epitome of the frightened man who fears reason, consciousness, freedom, responsibility, and any change in society and the world. Jews become the epitome of evil against whom he vents his frustrations, instinctive passions, and his conviction that, at long last, he has found somebody whom he regards as somehow inferior to him. The choice of the Jew as the scapegoat is an incidental, historical accident.

- ▶ The Jew is the Antisemite's invention. . .the Jew is one whom other men consider a Jew. . .It is the Antisemite that makes the Jew. . .It is neither their (Jewish) past, their religion nor their soil (Israel) that unites them. The sole tie that binds them is the hostility and disdain of the societies which surround them. (pp. 13, 67. 91)

Presumably Antisemitism and the Jews themselves would disappear when Jews and non-Jews chose to espouse an existential mode of being. The reader might well argue both with Sartre's depiction of the Antisemite and of Judaism and the Jews.

A classic text by Hannah Arendt (1973) argued that Antisemitism in the late nineteenth century and in the half century that followed was due to the loss of essential economic opportunities due to Jews who were wealthy without working. In effect, she, like Sartre, ignored 2,000 years of the historical roots and offshoots of Antisemitism and focused solely on economic injustice, specifically as practiced by some Jews. This was a major concern for a doctrinaire socialist who considered religion and nationalism as irrelevant anachronisms. One wonders what she would say today (a) about the outstanding contributions by Jews to society, and (b) about the rise of militant fundamentalism in Islam, widespread attack on the legitimacy of the Jewish State to exist, and the resurgence of Antisemitism in many parts of the world.

There is a voluminous important literature on Antisemitism by sociologists, anthropologists, and other disciplines, such as biologists and social scientists. This section examines primarily the theories and research of psychologists.

Psychology Prior to World War II

One theory that focuses specifically on Antisemitism is that of Freudian psychoanalysis. The book entitled *Moses and Monotheism* was published in England after the rise of Hitler's Third Reich and the explicit threat it posed to the Jewish people (1939). In his last publication, Freud applies the classic concepts of levels of consciousness, the desire to kill the father, and collective neurotic manifestations of the defense mechanisms (e.g., repression, repetition-compulsion, projection) to assert that religion in general is a collective neurosis and that hatred of Jews stems from their preeminent role in originating monotheism. He argues that the promulgation of monotheism by Jews elicited two phenomena: (a) divinely imposed instinctual renunciation and with it the experiences of intrapsychic sin, guilt, remorse, confession of sin, and the projection of these experiences on the Jews; (b) the Jewish belief that the Jews were "the chosen people" and with it the rejection of this claim, the insistence that God cursed the Jews

and mandated their permanent suffering, their racial inferiority, and under some circumstances, their extermination. Freud's psychoanalytic theories are engrained in our culture, but the proposal that Antisemitism is a universal phenomenon has received less acceptance, and the mythological underpinning of Antisemitism has received even less.

Racial generalizations by psychologists about intellectual and personal-social traits were common and fairly unchallenged in the latter half of the nineteenth century and the first half of the twentieth century. These phenomena were prominent in Germany well before Hitler's rise to power and became policy in German universities and professional psychological organizations from which Jews were subsequently expelled. Some German psychologists, such as Koffka and especially Kohler, who shared the racial prejudices of the upper middle class toward Jews, made consistent efforts to help Jewish colleagues throughout this period, and wholly rejected legally enforced discrimination and the final solution that followed (Mandler 2002).

Quotas designed to reduce the number of Jewish students admitted to American universities and schools were common and gradually disappeared by 1950 following the temporal juxtaposition of Antisemitism and the Holocaust. During this period, men of the stature of Saul Rosensweig, Seymour Sarason, and David Shakow had to make their early important contributions to psychology when employed in non-university positions. Jewish émigrés who fled Nazi Germany, like David Rapaport and Heinz Werner, found themselves in the same situation when they arrived in the United States (Harris 2009).

The Antisemitic scandal that erupted in 1944 put an official end to this practice in Clinical Psychology even as the new profession became professionally consolidated after World War II. When Frederick Thorne, the founding editor of the *Journal of Clinical Psychology*, announced that public acceptance of the new profession would be jeopardized if Jews were overrepresented in its ranks (Thorne 1945), he stated:

- ▶ While disclaiming racial intolerance, it nevertheless seems unwise to allow any one group (the code name in this scandal for the Jews) to dominate or take over any clinical specialty, as has occurred in several instances. The importance of Clinical Psychology is

so great for the total population that the profession should not be *exploited* in the interest of any one group. (p. 13, italics added)

Psychology After World War II

American psychology adopted a strong position in advocacy, practice, and research in the years that followed. It rejected the use of quota for any minority and it made vigorous efforts to ensure that racial discrimination was not practiced. It also initiated a large-scale program of theoretical and empirical research on ethnic discrimination and conflict in the national and international arenas. The earliest theories of Antisemitism were proposed by Allport (1954) and Adorno et al. (1950). Both wrote classic texts that made no distinction between prejudice against Jews and prejudice against other targets, and both asserted that prejudiced people were abnormal. Allport was optimistic that human nature would ultimately reject violence and war in favor of living in peace with others, and proposed a contact hypothesis that under certain conditions (equal status between the groups in conflict, common goals, intergroup cooperation, and the support of authorities, law, and/or custom) reduces prejudice (Pettigrew and Tropp 2006).

Adorno and his colleagues labeled this abnormality "the authoritarian personality." This kind of person is characterized as rigid and close-minded, obeying authority figures without question and showing contempt toward groups they consider inferior to them. More recent research indicates the authoritarian personality prefers simplified explanations for complex phenomena, is more dogmatic, intolerant of ambiguity, has a strong need for order, structure, and cognitive closure, and is lacking in integrative complexity (Jost 2006; Kruglanski 2004). By implication, these overlapping concepts – conservative, authoritarian, and right-wing – characterize an entire segment of the population that is potentially fascist and Antisemitic.

Numerous theories about the nuances of interethnic conflict have been confirmed: Conflict appears intractable when a given group feels threatened by another (Pettigrew 2003); or when a group has little intergroup contact, but high pre-existing prejudice and high intergroup anxiety (Blair et al. 2003). These theories tend to ignore two relevant factors in ethnic hatred in general and in hatred of the Jews in particular: the

historical and current contexts during exacerbation of conflict, and the role of malevolent political and religious leadership that incite pre-existing prejudice in otherwise normal people against convenient scapegoats and ultimately escalate prejudice into violence, war, and mass murder. An educational approach proposed by Parkes (1946) is that hatred of the Jews may satisfy aggressive instinctual gratifications and reassuring convictions of one's self-esteem and the esteem bestowed by others (compared with a despised race).

Conclusions

Psychologists are of their own time and possess their own unique personality traits. They are students of the nature of human nature, and essentially optimistic that the world is improvable. They are also theorists who base their theories on fashionable and wisely accepted assumptions and scientists who select topics for research, use research designs, and make recommendations about peace-promoting policies.

Some regard hatred of the Jews as one instance among many of prejudice due to differences in religion, socioeconomic status, skin color, and presumed racial differences. Many psychologists wish to downplay the extent of Antisemitism over the centuries because it implies continued hostility and war. Others, chiefly Jews, are concerned about their personal security. Finally, still others regard hatred of Jews as an archetype, in Jung's terminology. It is a ubiquitous, complex phenomenon that will not disappear on its own.

The violent manifestations of Antisemitism may be reduced by social engineering and creative education. Its more subtle manifestations require the concerted effort of politicians, social scientists, and psychologists to acknowledge that we are dealing with a destructive phenomenon within society.

Psychology and Religion

GRAHAM RICHARDS

Staffordshire University, College Road,
Stoke on Trent, UK

Introduction

Appraising the relationships between Psychology and religion is a complex task, and we need first to identify

the various kinds of problems giving rise to this. Most fundamentally, the very phrase “Psychology and religion” is a misleading oversimplification, these clearly not referring to two unitary, mutually independent, camps, let alone camps of the same logical status. On the Psychology side, its sheer internal diversity in subject matters, methods, and goals renders any general statement about its relationship to religion impossible. On the religion side, not only is its internal diversity in some respects even greater than Psychology’s, but it is a logically different kind of phenomenon. While the status of Psychology is not unproblematic, at least it is unambiguously an academic discipline engaged in knowledge creation and application, and most academic experimental psychologists accept and assert that it is some kind of natural science. Religion, by contrast, is vastly broader, knowledge creation being, ironically, one of the few things with which it is not centrally concerned. Religions supply broad frameworks of meaning within which followers can live their lives. They are cosmic in range, a view of humanity’s relationship to the cosmos being vital if they are to provide such a framework. In a nutshell, being a psychologist is a profession or career, being a religious believer is a way of life. It is necessary to stress that religions are not simply comprised of sets of empirical beliefs, but encompass major rituals which structure social life, provide sources of solace, and facilitate artistic creativity, among much else. What religion *does* share with Psychology is that both propose views, theories, or images of human nature in general and human individuality, or “personality,” in particular. From this it would appear that perhaps all one can address are relationships between specific religions, religious denominations, or religious thinkers and some equally specific fields of Psychology, or individual psychologists.

A second problem is that the kinds of relationship between the two can also be of several different varieties. To list briefly, (a) psychologists may be interested in religion as a part of their own subject matter, human behavior, and attempt to “explain” it (hence the subdiscipline “Psychology of Religion”); (b) individual psychologists’ attitudes to religion may, if sufficiently strong (as either believers or opponents), affect both their modes of theorizing, their fields of specialization, and to some extent even their methods; (c) some in each camp see themselves engaged in a conflict or contest with

the other, their work will thus reflect this; (d) the role and character of religion in its host societies can also determine the kind of Psychology practised therein, indeed this is inevitable at a deeper cultural level.

A third difficulty is that, in the light of their overlapping concerns with human nature and personality, the boundary between Psychological and religious texts can become blurred. This is especially evident in some theological works (e.g., Paul Tillich’s), while in the case of psychotherapy and counselling, the two occasionally verge on outright fusion.

Fourthly, Psychology being a western cultural product, “religion” is, for our purposes, effectively synonymous with Christianity, along with a sometimes discernible Judaist strand. And even within Christianity, we are primarily concerned with the mainstream west European Protestant and Roman Catholic traditions, its other branches being variously hostile or indifferent to Psychology. This, we will see, raises some problems regarding how Psychology can relate to non-European religions, particularly Islam, Hinduism, and Buddhism.

A final issue is that in addressing the topic we are somewhat hampered by its longstanding neglect by historians from both directions. Only relatively recently has this begun to be rectified. The most notable current workers in the field are US historian of Psychology and psychotherapist Hendrika Vande Kemp and the Catholic psychologist Robert Kugelmann ([in press](#)), plus historians of Psychology of Religion David M. Wulff (1997), Netherlands-based scholar Jakob Belzen (2000), and US historian Robert C. Fuller (2006). J.M. Nelson (2009) is a further very recent addition. Even so, the focus of these writers has often primarily been on the subdiscipline Psychology of Religion rather than the broader topic concerning us here. There are, however, a number of works on individual psychologists in which the part played by religion in their professional work and careers has been explored. The cause of this relative neglect is, to oversimplify, a combination of two factors. Prior to c.1980 historians of Psychology were primarily concerned with chronicling the discipline’s emergence as a natural science, often in a somewhat celebratory fashion. This reflected the perennial anxiety of academic and experimental psychologists to locate themselves within modern natural science, or at the very least as a branch of secular scholarship. Any religious dimension thus

tended to be air-brushed out, or at best seen as of only incidental interest, irrelevant to the main story. Post-1980 more critically oriented historians, although concerned with contextualizing events (as had happened earlier in History of Science), also largely ignored religion. Quite why appears to be a mixture of personal animosity toward, or lack of interest in, religion and the fact that more immediate issues related to, e.g., Psychology's roles in social governance, its treatment of women and minorities, and its "individualist" bias in orientation were higher on their agendas. Beneath these lay a fairly uncritical acceptance of what may be termed the "secularization" plot of twentieth century history. In this image, Psychology was a proactive secular project which simply rolled back the social significance of religion as an authority on psychological matters. The cliché of the psychologist replacing the minister or priest tended to be accepted without much demur. Given religion's resurgence from the early 1990s, this already sounds somewhat dated.

With these preliminary observations out of the way, we may turn to a number of specific aspects of the topic which illuminate how profound the part played by religion in the history of Psychology has actually been. But from what has been said, a perspicuous general answer to the question "what is and has been the relationship between Psychology and Religion?" is clearly impossible.

Psychology's Origins

The "heroic" image of Psychology's origins as a "natural science" in the late nineteenth century is of it emerging first in Germany in the work of Gustav Fechner (in his 1860 *Psychophysics* wherein he described three basic experimental designs) and Wilhelm Wundt, credited with establishing the first Psychology laboratory at Leipzig in 1879. Hot on the Germans' heels the post-1859 rise of Darwinian evolutionary theory, fervently backed by Herbert Spencer and Francis Galton, then provided an integrating theoretical framework in which a variety of separate disciplines concerned with aspects of human and animal behavior could be seen as strands within the overarching project of creating a scientific Psychology. By the late 1880s, the canonical US pioneers were getting into their stride, and forging what came to be termed the "New Psychology" (a term subsequently used at

various times in rather different contexts). Meanwhile, other European national traditions of Psychology were rapidly becoming established. Religion, as already mentioned, barely figures in this received story.

Had Psychology represented only a further advance in the irresistible progress of the natural sciences, as this account rather implies, we may then wonder why it was not greeted with fervent religious opposition, especially as it was apparently concerned with issues so centrally shared with religion. It is still often claimed that the two camps are antagonistic. Yet while some in each camp have undoubtedly seen the other as an enemy, any "warfare" literature has been surprisingly sparse until very recently. There is clearly then something missing from the "heroic" "celebratory" version.

Closer investigation soon brings to light some important reasons for the lack of confrontation during Psychology's pre-1914 founding phases. As Hendrika Vande Kemp has been especially prominent in bring to light, the religious had no major grounds for serious apprehension that Psychology would pose the kind of threat which, say, Geology, Astronomy, and then evolutionary biology, had done to the Biblical physical cosmology. They had good reasons for assuming that their own "Psychological" expertise would be able to withstand, and indeed contribute to, the new discipline. Whereas there were no "Biblical Geology" or "Biblical Astronomy" in place when these disciplines emerged, there were three major, longstanding, strands of Christian "Religious Psychology."

Within Roman Catholicism, the complex and sophisticated account of human nature elaborated by Thomas Aquinas had created a tradition of Scholastic "Thomist" Psychology-cum-Philosophy. The longstanding "Rationalist" strand in European philosophy had in many respects developed from this from the seventeenth century onward, while theologically orthodox Thomism continued to reign in Catholic universities, even if largely intellectually moribund by the nineteenth century. Concerned with the marginalization of Catholicism within the sciences, in 1879 (coincidentally with Wundt's Leipzig laboratory being founded), Pope Leo XII issued the encyclical *Aerterni Patris* reasserting the authority of Thomist Scholasticism as the church's official philosophy and the need to reinvigorate this tradition. This remained the Vatican's position until the Second Vatican Council (1962–1965).

His challenge was most effectively taken up by the Belgian, Father (later Cardinal) Desiré Mercier, who now sought to create a “Neoscholasticism” in which the legitimacy of natural science could be maintained without challenging core religious doctrine. One key feature of this was a differentiation between a “Rational” and an “Empirical” Psychology. The former adhered to Aquinas’s model of the structure of the human mind and soul, arrived at by purely logical rational analysis. The latter however was free to investigate the empirical facts of human behavior and experience in a natural scientific fashion. Hence it was that Mercier founded the first Belgian Psychology laboratory at the University of Louvain in 1891, beating the British by 6 years. The substantial contribution of Catholic psychologists, particularly a US-based Neoscholastic School, into the mid-twentieth century (but dissipating after the Second Vatican Council) was thoroughly reviewed in Misiak and Staudt (1954). Ironically, this invaluable work played into the conventional story by being pitched (as I read it) toward reassuring US psychologists that they had nothing to worry about since only the “Rational” Psychology aspect had a religious character, Catholic psychologists being able to undertake “empirical” Psychology in a way indistinguishable from that of anybody else, religious or not. In fact, the book’s contents rather subvert this claim since it is clear that their religious faith had fairly profound effects on the kinds of Psychology Catholic psychologists produced, while the very distinction itself was a Thomist one. More recently, Robert Kugelmann (*op. cit.*) has been exploring the broader picture of Catholicism’s engagements with Psychology and psychotherapy, clarifying the complex internal politics in which Catholic psychologists became engaged in order to maintain their position against the more fiercely antimodernist factions within the church itself, particularly after Pope Pius X’s 1907 encyclical *Pascendi Dominici Gregis* “on the Doctrine of the Modernists” and Pope Benedict XV’s issuing of the *Code of Canon Law* (1917) in both of which modernism was wholeheartedly condemned.

A second, less prominent but nonetheless covertly influential strand was “Biblical Psychology.” This sought to identify the “Psychological” model or image of human nature and its composition implicit in the Biblical text. The origins of this project are somewhat

hazy, Franz Delitsch (1867), one of its leading exponents, tracing it as far back as some theological writings of the Renaissance anatomist and theologian Bartholinus. In the early nineteenth century, the method used centrally involved Hebrew linguistic scholarship, the American George Bush, author of *Scriptural Psychology* (1845) being a Professor of Hebrew at New York University. What emerged was a “tripartite” model in which the three components were the Soul, the Spirit, and (in Delitsch) the “I” or “Ego.” The first two were in essence, respectively, external and internal aspects of the same thing, while the I/Ego was the most profound center of our being (clearly a different usage of the term Ego to that which became common in the twentieth century). This may be read as in some respects preparing the ground for later Psychological divisions of levels of consciousness. It was additionally significant just for the simple reason that it helped put the term “Psychology” into popular circulation.

Third, and ultimately most influential in anglophone cultures, was the Protestant tradition known in the United States as “Mental and Moral Philosophy.” Rooted in the pious Scottish “realist” or “common sense” philosophical tradition of Thomas Reid and Dugald Stewart, this had been eagerly adopted in many US universities and colleges, particularly after the Scottish emigrant minister John Witherspoon’s appointment as President of Princeton University (then the College of New Jersey) in 1768. This served as a counterweight against student revolutionary radicalism during and after the French revolution, and also against the reductionist and materialist tendencies of British associationist philosophy (exemplified in David Hume). It quickly became routine for university and college presidents to teach mandatory courses in Mental and Moral Philosophy in which they sought to demonstrate that philosophical and, increasingly, scientific study of human nature was consistent with and could only strengthen or rationally authenticate Protestant religious belief (usually, if not always, of a Presbyterian Calvinist hue). Of the very numerous authors of textbooks and treatises of this kind, we should note Thomas Upham, Noah Porter, and, another Scottish Princeton President, James McCosh. Porter’s *Human Intellect* (1868) was a remarkably thorough textbook, citing numerous contemporary

European developments (including Wundt's early work), but explicitly aimed at legitimating the need for religious faith, even while purporting to promote the development of "mental science." McCosh's work became increasingly transitional in character, if no less devout, through the 1870s and 1880s, including books on both *The Emotions* (McCosh 1880) and *Psychology: the Cognitive Powers* (1886, rev. 1894).

Almost all the first generation of US psychologists had studied Mental and Moral Philosophy as undergraduates, several being in effect protégés of Mental and Moral Philosophers (e.g., J.M. Baldwin, G.S.Hall and G.T.Ladd in relation to McCosh, the University of Wisconsin's John Bascom and Porter, respectively). What is clear is that these pioneers took much of the Mental and Moral Philosophy agenda and attitudes with them and were, institutionally, able to take over its academic niche when the tradition itself faded in the 1880s and 1890s. To give just one example of continuity, the claim that religious belief was the natural outcome of healthy child development, spelled out quite explicitly in Porter's *Human Intellect*, was endorsed by all three of those just cited. Even as they affected secular scientific modes of theorizing and research, many of the first two generations of American psychologists remained personally devout. William James, though not conventionally religious, was always respectful of religious belief and of course authored *The Varieties of Religious Experience* (1902), while his mature Pragmatist philosophy held the door firmly ajar for the acceptability of religious belief. The topic of the "authenticity" of religious experience has remained a contentious leitmotif ever since, often seen as the central issue, and is currently under renewed attention as a cognitivist and evolutionary Psychology approaches have entered the fray (see below). It is though too convoluted an issue, philosophically, conceptually, and empirically, to do justice here.

A covert, largely unconscious, plot may perhaps be discerned here in which, pre-1914, American liberal Protestantism saw in Psychology a route for scientific self-legitimation and "naturalization," holding out the further promise that as scientific culture globalized so might their version of Christianity as it piggy-backed, so to speak, on that culture's scientific Psychology strand. In northern mainland Europe, where liberal Protestantism was also flourishing in league with

movements for social and political reform, there was also widespread sympathy for, and interest in, Psychology. Martin Kusch (1999) has also argued that the split in German Psychology between the Wundtian "Leipzig School" and the "Würzburg School" in part reflected a difference between their respective Protestant and Catholic cultural settings.

In short then, not only did the major Christian religious denominations fail to oppose Psychology, they were actively involved in its origins and development. Only in Britain were the canonical early pioneers, Alexander Bain, Herbert Spencer, and Francis Galton, all adamant unbelievers (Fechner's own motivations were, indeed, centrally religious, if idiosyncratic). Even in Britain, however, the religious were not entirely absent; the Unitarians W.B. Carpenter (author of the highly successful textbook *Principles of Mental Physiology*, 1874, 6th ed. 1888) and his friend the theologian James Martineau (e.g., J. Martineau 1885) were of more significance than is often acknowledged, and the Society for Psychical Research signified a widespread concern with what was really a religious issue as well as pioneering research methods (as its sister American society also did), one prominent member being F.W.H. Myers, first to cite Freud in English (F.W.H. Myers 1893), co-organizer and secretary of the 1892 International Congress of Psychology in London, and author of *Human Personality and Its Survival of Bodily Death* (1903).

Aside from their existing religious beliefs, attitudes, and assumptions, a further factor mitigated against psychologists opposing religion. Every scientific discipline needs an applied market if it is to thrive. For the early psychologists, this lay in the contributions they could make to managing the psychological problems facing urbanized industrial societies. More specifically, there was, by the 1890s, a widespread demand in northern Europe, Britain, and north America for professional expertise in the fields of (a) education and child rearing, (b) mental distress, (c) crime, (d) industrial productivity and relations. Religion had long been involved in the first three of these. Schools were widely run and managed by various religious charities and organizations, while pastoral care of the mentally distressed and "feeble minded" was one of religion's longstanding charitable tasks, as was rehabilitation of the criminal. Taking the first, as demonstrating the

point most effectively, we may briefly consider the British situation.

The British Child Study Association (B.C.S.A.) was founded in 1894, supported by James Sully (Professor of Psychology at University College, London) who became its first President. Two years later, a Childhood Society (CS) followed, originating in a Committee on the Mental and Physical Condition of Children which had begun work in 1888 and in 1895 published its *Report on the Scientific Study of the Mental and Physical Conditions of Childhood* (F. Warner 1895) claiming to have studied 100,000 children between 1888 and 1894. In both of these we find representatives of the Christian churches playing very prominent roles. In the case of the B.C.S.A. (London Branch), a particularly prominent figure was the Methodist minister, the Rev. John Scott Lidgett, who has been described as “the greatest Methodist since John Wesley.” His involvement stemmed directly from his leading role in the Bermondsey Settlement, in London’s impoverished East End, a religious project aimed at helping children who had additional connections with Oxford Anglican Evangelicals. Other ministers identifiable as active members include Rev. T.W. Sharpe, also active in the CS, and Senior Chief Inspector in the Education Department at this time, Rev. J.C. Bevan (occasionally Chair of meetings), and Rev. W.J. Adams (who became President in 1902). As well as Sharpe, the CS founding Committee included Rev. George Bell (Headmaster of Marlborough College), Rev. J.C. Weldon (Headmaster of Harrow), and the Catholic Cardinal Vaughan (Archbishop of Westminster). The religious beliefs or sympathies of other members of these societies cannot be so easily ascertained, but inferences might be made. Even Sully himself had begun training as a nonconformist minister in his early years.

As this indicates, religion was central to the cultural ambience in which British Psychology was first attempting to market its expertise beyond academia. A good case could be made that education and child rearing provided the singlemost important route by which it initially achieved this. Regarding crime, “idiocy,” and mental distress, religious figures were ubiquitous in the official and philanthropic bodies variously responsible for managing, monitoring, providing resources, and overseeing treatment as any list of witnesses before Royal Commissions and Parliamentary Committees on such matters from this period

would demonstrate. One might actually speculate how far this religious constituency acted as a brake on the “scientific” eugenicist and degenerationist lobby, but that is beyond present concerns.

So, if Psychology was to create a place for itself in the world at large, it had carefully to negotiate its relationship with religious constituencies. Conversely, to the extent that it succeeded, the religious would in turn endorse the value of Psychological perspectives on such matters. And although this is a British example, the same analysis would apply, perhaps with even greater force, to the United States and much of mainland Europe. Educational Psychology itself was substantially an earlier European creation in which religion had played a major role, being central for pious pioneers such as both the German protestant Friedrich Froebel and the Italian Antonio Rosmini Serbati (a Catholic priest) (on Froebel, see G. Richards 1992, Chap. 4). Concern with the child and education should be viewed not only as something which Psychology could use for its self-promotion, but as a very significant factor driving the actual emergence of the discipline. It was in the literature related to this, both secular and religious, that proto-Psychological ideas had been being promulgated ever since the late eighteenth century and arguably as far back as the sixteenth. Insofar as these were religious in character, they therefore played a role in Psychology’s origins.

To conclude, the rise of modern Psychology was promoted and facilitated rather than opposed or hampered by a combination of religious factors: (a) a preexisting variety of religious “Psychologies,” (b) the religious motivations behind their choice of vocation of many of its pioneers, and (c) the need to elicit the sympathy and support of religious denominations, institutions, and charities in order to market its expertise and establish a cultural niche, particularly in relation to child rearing and education, but also (d) to a lesser extent in relation to other issues such as mental distress, “idiocy” and crime which were assuming ever greater importance in northern European and north American societies.

Psychology of Religion

The most overt engagement between Psychology and religion has been the subdiscipline Psychology of Religion. The fullest review of this is D.M. Wulff’s

monumental *Psychology of Religion: Classic and Contemporary* (2nd ed. 1997). Although never a major strand, it has maintained a presence almost from the outset, albeit with very varied fortunes and sometimes on the brink of disappearing. It should be noted however that while national differences in theoretical and research styles are evident in most fields of Psychology, this is especially so in the present case. To consider the anglophone first, this originated in the United States in the 1890s with the Edwin D. Starbuck's *The Psychology of Religion* (1899) and then, having been dramatically boosted by William James's classic *Varieties of Religious Experience* (1902), rapidly expanded in a succession of works by E.S. Ames, J.B. Pratt, G.A. Coe, G.M. Stratton, and the Swiss emigré James Leuba, of which Pratt's and Leuba's (on Leuba see D.M. Wulff, 2000) have proved the most enduring. Institutionally and organizationally, its major promoter at this time was G. Stanley Hall, founder of the *American Journal of Religious Psychology and Education* (1904) which, with a slight title alteration in 1912, lasted until 1915. It was under Hall's aegis at Clark University that both Starbuck and Leuba undertook their first research, and a little later he published his two-volume *Jesus the Christ in the Light of Modern Psychology* (1917). Religion also figured in his two-volume *Adolescence* (1904). After 1920, however, this early American school began to run out of steam, and by 1933, A. Cronbach's *Psychological Bulletin* review was, in effect, announcing its demise. In truth, its agenda had never been entirely clear, and its research methods had failed to develop in the more "scientific" direction which the times were demanding of Psychology at large. In the light of the previous section, we may read the motivation of many, but not all, of its exponents as utilizing Psychology to legitimate the authenticity and value of some variety of Protestant Christianity (Leuba was a major exception, his 1922 *The Psychology of Religious Mysticism* being particularly skeptical regarding the "authenticity of religious experience" question). Even so, as well as the "authenticity of religious experience" question, they addressed a variety of issues such as the origins of religion (often from an evolutionary perspective and drawing on anthropological and comparative religion evidence), conversion phenomena, the social psychology of religious practises such as revival meetings, and the child's religious development. A few, such as Leuba,

were explicitly critical of religion in its present forms. Interestingly, in the UK Psychology of Religion never really took off, the only significant early works being R.H. Thouless's *An Introduction to the Psychology of Religion* (1923) and B.H. Streeter's strongly pro-religion *Reality. A New Correlation of Science and Religion* (1927). As we will see later, the British relationship between the two camps during this period took rather different forms.

If at a low ebb, US Psychology of Religion nonetheless continued on a rather narrower front. It now tended to concentrate on using the new attitude questionnaire techniques being developed in Social Psychology and personality research to explore religious attitudes plus both the roles and types of religious belief in the context of individual personality. One of the very first pieces of psychometric attitude research was indeed L.L. Thurstone & E.J. Chave's *The Measurement of Attitude: a Psychophysical Method and Some Experiments with a Scale for Measuring Attitudes toward the Church* (1929). In personality research, I.A.M. Nicholson (2002) has shown how the affirmation of the central importance of religion was the primary goals of G.W. Allport's co-foundation of the "Personality Theory" field in the 1930s (Allport 1937). While generally covert, this was explicitly spelled out in *The individual and his religion* (1950). Throughout the 1950s–1980s period, Psychology of Religion primarily assumed the form of a fusion of social psychological and personality research centered on psychometric techniques, with several scales being devised specifically for this purpose, most successfully the Allport-Ross Religious Orientation Scale (1967). Michael Argyle's *Religious Behaviour* (1958) was a somewhat isolated British example. We will return to the "personality" issue below. From the 1980s onward, there was a slow revival of the field as a broader project, accelerating in the late 1990s and post-2000 period. Why this was so will be considered later.

Psychology of Religion's fortunes in mainland European countries followed rather different trajectories, while the subdiscipline itself often differed somewhat in character (partly due to the more clear-cut division between Catholic and Protestant regions). One major figure was the Würzburg School-trained Estonian Karl Girgensohn, who, with the school's leader Oswald Külpe, cofounded a society for Psychology of Religion and a journal (which still survives)

Archiv für Religionspsychologie in 1914. From 1927, his follower Werner Gruehn took over directorship of the society. Girgensohn adopted a rigorous “experimental introspection” methodology in his research. This soon came to be challenged by the Zurich-based pastor Oscar Pfister’s psychoanalytic approach and the two were often at loggerheads, although common concerns eventually led to a rapprochement. Neither of these Protestant schools declined after 1930, one of Pfister’s major works appearing in 1944 (1948 in English). Religion also figured centrally in the German personality theorist Eduard Spranger’s work (see E. Spranger 1928). In the Netherlands, as J. Belzen (2000) has recently detailed, Psychology of Religion did not even manage to get off the ground until the 1950s due to religious opposition. When Carl Jung’s ideas on the nature and importance of religion rapidly acquired an ever-widening circulation during the 1930s, the nature of the issue underwent a major transformation, *Modern Man in Search of a Soul* (1933) being especially influential in this respect. (Though Jung himself was not of course an orthodox religious believer in any sense.) In Catholic countries, the presence of the strong Catholic tradition in Psychology initiated by Mercier inhibited the emergence of anything directly resembling Protestant Psychology of Religion. This did not mean religion was never addressed – one might note Henri Joly’s *The Psychology of the Saints* (1898) in France as an early example. Rather, its presence in Psychology texts would typically take the form of expounding the doctrinally orthodox neo-Thomist position. One important exception was the Italian agnostic S. De Sanctis’s *Religious Conversion: A Biopsychological Study* (1927, 1st Italian 1924).

As indicated earlier, only in the last two decades has anglophone Psychology of Religion succeeded in achieving the revival it long hankered after during the mid-twentieth century. This revival has owed no small debt to the extensive journal papers of Hendrika Vande Kemp and David M. Wulff’s magisterial work cited earlier. D. Fontana (2003) and J.M. Nelson (2009) are more recent major contributions. What might, though, be queried is whether this new Psychology of Religion is really a revival or a new project with the same name. This is for two reasons. Firstly, evolutionary psychologists and cognitive scientists have, since the late 1990s, begun turning their attention to the topic. This

generally involves applying their general theoretical frameworks to the topic as one among many others on their agendas, and, these being quite recent developments, the character of the Psychology of Religion they yield is fundamentally different from that it originally possessed. Secondly, on a different front, it has now become closely interwoven with psychotherapy and counselling, whereas initially the Psychology of Religion and religious involvement with psychotherapy represented rather distinct genres. It is to the latter we next need to turn.

Psychology, Religion, and Mental Distress

One area of common interest between Psychology and the mainstream churches has, since the outset, been the nature and management of mental distress, with Psychiatry of course being a third party in this. With “pastoral counselling” always being one of the tasks of church ministers and priests, the growth of secular ideas regarding mental illness and neurosis offered new resources for undertaking this. The earliest formal example of this in the anglophone world was probably the Boston-based Emmanuel Movement. The history of the Boston-based Emmanuel Movement, which lasted from 1906 to 1929, though was most prominent up to c.1914, has been tackled by Sanford Gifford (1998) to which I refer readers seeking a more detailed account. Three figures are primarily associated with it: the founder, medically qualified Rev. Elwood Worcester (1862–1940), psychiatrist Dr Isador H. Coriat (1875–1943), who had moved to psychoanalysis by 1914, and Dr. Samuel McComb (1864–1938) “a witty, talkative, Anglicised Irishman” (Gifford, p.60). The major account of their fairly eclectic approach, in which “suggestion” and hypnotism prominently figured, is R. Worcester, S. McComb, and I.H. Coriat (1908, 1920). It was, however, an eminent physician, Joseph H. Pratt (1872–1956), who had actually set the ball rolling in 1905 by conducting what was in effect group psychotherapy (which he termed “the class method”) with tuberculosis sufferers at the Emmanuel Church. The long-term influence of the Emmanuel Movement was to introduce the notion of medical psychotherapy to the country, including the first psychiatric outpatient clinic, and pioneering small group psychotherapy method. The extensive

development of US pastoral counselling after 1920 has been summarized down to 1970 by Vande Kemp (1984, 1986, 1996). For other overviews of the field, see W.R. Clebsch & C.R. Jaekle (1964) and H.J. Clinebell (1966). A major mid-century figure in promoting this was Seward Hiltner, author of two books and numerous journal articles, most importantly S. Hiltner (1949).

Turning to the UK, after 1918, there was a surge of religious interest in using the new psychotherapeutic approaches for pastoral counselling, especially psychoanalysis (and related schools) and various “suggestion,” “autosuggestion,” and hypnotic techniques (notably those of Emil Coué and the “New Nancy School” of hypnosis associated with Charles Baudouin, both French). (See Richards (2000a, b, 2011) for more on this and the interwar British situation in general). Young ministers who had, as padres, experienced the horrors of the Western Front and other theatres of the Great War were especially receptive to the “New Psychology,” as were many Christian doctors. In addition to selectively adopting the new psychological and psychotherapeutic concepts in their pastoral work, they also became closely involved with institutional innovation. To summarize a complex story, three figures emerged as particularly prominent in this. Hugh Crichton-Miller, whose wartime service had been in Alexandria, who founded the Tavistock Clinic in 1920; Leslie D. Weatherhead (a padre in the grim Mesopotamian campaign), a popular Methodist minister and writer who founded the City Temple Psychological Clinic in London (1936); and the academic psychologist and psychotherapist William Brown who keenly supported these projects. A number of Christian psychologists such as J.A. Hadfield and R.H. Thouless, along with psychiatrists like David Yellowlees were also involved in various capacities. The psychotherapeutic methods employed were typically, as indicated above, an eclectic blend of “suggestion,” hypnosis, and critical but sympathetic use of psychoanalytic techniques. As awareness of the differences between Jung and Freud grew, by the 1930s, Christian therapists were increasingly using a Jungian rather than Freudian theoretical framework. In the background however often lay the more traditional religious notion of “spiritual healing,” especially in Weatherhead’s case.

Other clinics established in the 1930s included the Whitefield Clinic of Pastoral Psychology and the

London Clinic for Religious Psychology. At a different level were the foundings of the Jung-oriented Guild of Pastoral Psychology (which Jung addressed at least once) in 1936 and the Marriage Guidance Council (by the Rev. Herbert Grey) in 1938, and a number of other religious societies and committees concerned with the issue. The much older Guild of Health (originally set up in 1904) also seems to have been greatly revitalized at this time.

After 1945, momentum was resumed during the late 1950s with the reopening of Weatherhead’s City Temple Clinic and Frank Lake’s foundation of the Clinical Theology Association (now the Bridge Foundation). This culminated in the 1970 opening of the Westminster Pastoral Foundation (WPF) by Methodist minister Bill Kyle, which assumed and expanded the role of Weatherhead’s clinic, which had by then closed. In 1971, Fr. Louis Mateau founded the Catholic Dymyna Institute. What is most significant is that these, and other uncited, religious psychotherapy projects provided the institutional basis for the subsequent expansion and development of professional counselling and non-Freudian psychotherapy during the 1970s and thereafter. The WPF was central in the creation of the British Association of Counselling and formally accredited training courses. While, after 1980, the field rapidly became secularized (and the Tavistock had effectively disengaged from religion during the 1930s), it is clear that the religious involvements with psychotherapy and counselling sketched here were crucial in both their institutionalization and popularization beyond metropolitan intellectual circles. This implies some adjustment to the widespread image of their current popularity being simply an after-effect of 1960s alternative culture fascination with the various “Growth Movement” therapies which mushroomed during that decade. But where did these come from? We now need to return to the US situation during the later 1940s and 1950s.

Among the leading figures in the post World War 2 “Growth Movement” were Abraham Maslow, Carl Rogers, and Rollo May. What is especially significant for our purposes is that there is a clear linkage between each of these and the New York-based Union Theological Seminary (UTS). In particular, there is a lineage from the Hassidic German philosopher Martin Buber (whose 1923 *I and Thou* was enormously influential)

into the thought of his fellow ex-Frankfurt School friend Paul Tillich and the American Reinhold Niebuhr, both eminent UTS professors at this time. All three of those just mentioned were in various ways associated with UTS at some point in their careers and were familiar with the ideas expounded by Buber, Niebuhr, and Tillich. These centered on (a) the prime importance of treating others compassionately and empathetically as fellow human beings rather than (in the therapeutic situation) simply medical “cases” and (b) on the authenticity and, indeed, necessity of what might be called “spiritual striving” for self-fulfilment, as opposed to simply the “cure” of neuroses. It may be noted that Rollo May subsequently authored a biography of Tillich (R. May 1973), while Rogers did a filmed interview with Tillich (now available on-line). An additional figure in this was Harvard-based Gordon W. Allport, a devout Episcopalian. He is, as mentioned earlier, best remembered as cofounder of the Personality Theory subdiscipline during the 1930s, but as emerges from his *The Individual and His Religion* and Nicholson’s biography (both cited earlier), he saw the achievement of mature religious belief as the culminating stage of personality development. He also regularly gave sermons in the Harvard Chapel. Since Tillich moved to Harvard in 1955 (and similarly preached there), a further linkage may be discerned. In short, while it cannot be fully elaborated here, the central “Growth Movement” founders may be seen as emerging from a specific intellectual milieu, centered on New York and Harvard, in which the underlying values of their ostensibly secular therapies were being forcefully articulated by Protestant UTS theologians. The association between the UTS and Psychology was further reinforced by its close physical proximity to Columbia University, with considerable academic traffic between them.

Contemporary psychotherapy and counselling are primarily secular in character, at least on the surface, but what is noticeable is the extent to which religious concepts of spirituality, sin, and the like have become common currency. Religious-type concerns perhaps inevitably arise in dealing with mental distress, especially when, as has happened over the last half-century, their professional treatment has become normalized beyond the traditionally conceived psychiatric mental illnesses.

Finally, one might remark that taking the religious input into account challenges the simplistic but widespread image of a historical secularization trajectory in which psychotherapists straightforwardly assumed the mantle of ministers and priests in tackling mental problems. On the contrary, their established pastoral-care role rendered them particularly sensitive to the insights offered by early twentieth century psychological ideas. Moreover, this mythical “secularization” story overlooks the extent to which psychologists themselves have often been devoutly religious and keen to collaborate with religious professionals. This point is given added force when we turn to other issues.

Religion, Education, and Child Development

The involvement of religion in educational and child-related matters did not fade out at the end of the founding phase. Given the widespread engagement of religious bodies in running and managing schools, it was to be expected that they should continue to endorse the view that belief was a normal outcome of healthy child development, and also that they would monitor and selectively adopt the new ideas on teaching methods and assessment that Educational Psychology had to offer. One area of immediate concern was, unsurprisingly, how religion should be taught. Books on this appeared, if not frequently, at least regularly, into the 1970s, while it had often figured – as its title suggests – in the *American Journal of Religious Psychology and Education*. Over 30 book titles specifically related to religious education are listed in Vande Kemp and Maloney’s 1984 bibliography for the years 1909–1964, over half being published in the United States. The British Psychological Society’s cofounder, Sophie Bryant’s 1924 *Moral and Religious Education* should be added to this list. This is undoubtedly deceptive since it does not include journal papers or pamphlets and many relevant works fell outside Vande Kemp and Maloney’s remit. Books on child care and parenting also sometimes carried Introductions or Forewords by religious figures (E.G. Braham 1936 and T.F. Metcalf 1939, being two British examples, opened, respectively, by Leslie Weatherhead and Rev. E.S. Waterhouse). One should also note that in the United States, The Religious Education Association (REA) had been founded in 1903 by William Raney Draper (and

remains active) and had launched the journal *Religious Education* (still published) in 1906 while, interestingly, the philosopher John Dewey was at one time associated with it. The REA was, more directly, involved with promoting the famous H. Hartshorne & Mark A. May “Character Education Inquiry” which produced the *Studies in the Nature of Character* (1930), still famous for its first volume *Studies in Deceit*. The affiliations of the authors of these religious educational works were variously Protestant (including evangelical Baptist), Catholic, Ecumenical (as was the REA), and, occasionally, Jewish. Mainland European religious educationists, especially in France and Germany, also published numerous works (often Catholic in commitment) during this period. One point to be remembered about the entire genre is the frequent blurring of the line between “religious” and “moral” education. The latter of course was of concern to educational psychologists generally. This topic is, however, so broad in scope and complex in detail that it cannot be further developed here.

Religious Influences in Psychological Theory

Leaving aside the explicitly Neoscholastic approaches of Catholic psychologists, such as R.E. Brennan (see R.E. Brennan 1941), religious influences on Psychological theory, as opposed to psychologists’ personal career motivations, are usually not obvious on the surface. Dig deeper however and interesting religious dimensions can emerge. J. Piaget, S. Freud, and G.W. Allport are three cases in point. These cannot be explored in depth here, but, taking them in turn: the embeddedness of Piaget’s Psychology in Swiss liberal Protestantism has been shown by F. Vidal (1988); the precise role of Judaism in framing Freud’s thought remains a matter for debate in detail, but, ever since D. Bakan’s classic and provocative study (D. Bakan 1958), it has generally been acknowledged that it *did* play a part; I.A.M. Nicholson’s biography of G.W. Allport has, as mentioned earlier, revealed the extent to which his concept of “personality” and his own personality theory were underpinned and motivated by his High Church Episcopalian (or Anglican) religious convictions (as emerges most clearly in G.W. Allport, 1950). In C.G. Jung’s thought, Psychological and religious concerns were inextricably interwoven from the outset. Although never an orthodox believer, his fascination

with symbolism and mythology, which he believed to be the profoundest products of the human “psyche,” drove him ever more deeply into engaging with religious issues at both a personal and theoretical level.

There is though a deeper level of “influence” perhaps pervading the discipline as a whole and hinted at at the outset, which is that as a product of western culture, imbued with Judæo-Christian values and attitudes, even the most secular psychologist’s thought is likely to be in some way affected by these in ways of which they are unaware. This is likely to be especially true of the United States, where secularization has never been as thorough-going as in most European countries where Psychology has flourished and where, even if church attendance saw a decline over the twentieth century, what is now being called “unchurched spirituality” remained commonplace. This “unchurched spirituality” continues to accept most of the organized Protestant churches’ moral and social values. In many respects, US Psychology has, in the main, never ceased to be guided by what the present writer has elsewhere called the “moral project” of its Mental & Moral Philosophy progenitors (G. Richards 1995). In the final analysis, it is perhaps impossible to disentangle specifically “religious” influences on psychologists’ theories or research choices from the broader role of general social, cultural, and historical factors.

Religion and Personality

One enduring component of the Psychology of Religion agenda has, as we saw, been the study and theorizing of religion’s role at the level of individual personality. Is there a “religious” personality type (or perhaps several)? What underlies peoples’ commitment, or not, to a religious belief? Is there a universal “spiritual” or “religious” striving which deeply motivates all of us whether or not it is consciously recognized? What are the correlates of religious belief with regard to social attitudes (e.g., political leanings) in general? What roles do their religious beliefs play in believers’ lives? Such questions have long attracted psychologists’ attention.

Regarding religious typology, one of the earliest distinctions was that made by William James, in *The Varieties of Religious Experience*, between “once-born” and “twice-born” believers. The former devoutly retained the religious beliefs in which they were raised

throughout their lives, undisturbed by crises of faith, the latter, whether previously believers or not, had acquired their religious convictions as a result of a profound personal experience, typically conversion or as the resolution of a crisis of faith. In 1914, the German psychologist Edouard Spranger proposed six “ideal types” of personality differing according to which was their dominating “value”: theoretic, economic, aesthetic, social, political, or religious. However, the “religious” value had a somewhat different logical status than the rest, since, although strictly referring to two types of “mystical” value orientation (immanent and transcendent), it could also combine with the others to yield distinct modes of religious expression or idealized attitudes. So the “theoretic” attitude for example might focus on theology and rational justification of belief, the aesthetic attitude on artistic expressions of faith such as painting or music. Wulff has described Spranger’s position as “existential-interpretive,” and G.W. Allport was much taken with Spranger’s approach at one point. In his theory, however, as explained in *The Individual and His Religion*, religion is conceived as an overarching integrating system of values, the ideal end product of individual psychological development. Even so, Allport was also interested in developing more psychometric approaches to the study of religion’s place in the individual’s personality, collaborating in devising the Ross-Allport Religious Orientation Scale cited earlier (ROS). This sought to differentiate “intrinsic” from “extrinsic” motivation in religious belief. For those in the former category, religion is the “master motive” and determines their whole way of life, for the latter religious belief is ultimately subordinated to practical, instrumental ends. Another popular instrument was E.L. Shostrom’s *Personal Orientation Inventory: An Inventory for the Measurement of Self-Actualization* (Shostrom 1966) (POI). The British social psychologist Michael Argyle also attempted to correlate personality variables and social attitudes with religious belief in his *Religious Behaviour* (Argyle 1958).

These moves initiated what became an ongoing research tradition amongst psychologists seeking to pin-down the varieties of religious belief at the personality level. More recently, a differentiation has been made between “religiosity” and “spirituality” to take into account the fact that nonbelievers may nevertheless

appear to have strong “spiritual” values, while practising religious believers are not always particularly “spiritual” in character. This has yielded a 2×2 matrix of High/Low Religiosity versus High/Low Spirituality, hence four types “Traditional Integrated” (High/High), the majority in the United States, “Spiritual Seeker Individualistic” (Low relig./High spirit.), Cultural Dogmatic (High relig./Low spirit), and “Uninterested or antagonistic” (Low/Low) (see J.M. Nelson 2009, p.11).

The psychometric approach as such, it is fair to say, was nonetheless bedevilled with difficulties. It was extremely hard to devise questionnaires which did not implicitly assume that those taking them were (whether believers or not!) operating in relation to one specific religion (usually Protestant Christianity). Wulff has a very useful discussion of the shortcomings of both the ROS and POI. While it seems intuitively obvious that some people are temperamentally inclined toward religious belief and/or practise, while others are not, efforts at identifying a psychometrically clear-cut and universalisable “religiosity” dimension have so far proved unsuccessful. In attempting to do so, researchers have had to confront the sheer variety of functions which religious belief can serve for different people, suggesting perhaps that Spranger’s approach was abandoned a little prematurely. Turning to social and political attitudes, it is no surprise that strong correlations can be found between specific religious allegiances and positions taken on contemporary sociopolitical issues. What is also clear though is that these are highly variable over time, and that whether religious belief “causes” the attitudes or the attitudes determine which religious allegiance is most congenial is undecidable in any general way.

The universality of “spiritual striving” also remains contentious. In some form or other, it is itself an article of faith for many in the psychotherapy field, but as an empirical proposition rather than a moral injunction, it is difficult to see how it could be confirmed. Surely the high level of sheer cynical wickedness in the world rather suggests otherwise? For a recent optimistic however see J. Bering (2010).

Psychology and Non-western Religions

Psychologists concerned with religion have, for the most part, always displayed a certain interest in non-
